The preoccupation of the European general staffs with ground warfare left little time for building air strength or planning its use. Germany, with a first-line airplane strength of more than 200, had almost twice as many planes as either France or England. The Germans had a marked superiority in airships, or lighter-than-air craft. These large airships, called Zeppelins after their creator, Count Ferdinand von Zeppelin (*q.v.*), carried out most of the German bombing attacks against England during the early years of the war.

The contending air forces had been trained and equipped primarily for observation, but it quickly became apparent that the airplane had other military uses. As the primitive aircraft on hand at the beginning of the war demonstrated their ability to perform also as fighters and bombers, the demand for specialized types of aircraft stimulated great progress in aeronautics. Airplanes grew steadily larger and heavier. Their performance characteristics—speed, altitude, fire power, range—improved greatly. Indeed, the changing fortunes of the air war between 1914 and 1918 were largely the result of aeronautical developments, with first one side and then the other gaining a temporary advantage because of some new and advanced type of plane or item of equipment.

Air Support.—During World War I air power was used primarily to support ground and naval operations. The air arm was a subordinate element of the army and navy in each country and therefore was responsive to the demands of those services. Since the greatest concentration of effort was on land warfare, the armies developed much larger air arms than did the navies, and their requirements became paramount.

Army commanders logically regarded the flying machine as the "eyes" of the ground forces. Its prime mission was to observe the disposition of enemy forces and spot the emplacement of his artillery. Whichever side could do this more effectively would have a great advantage over the other. It became apparent, even before the end of 1914, that measures would have to be taken to prevent enemy planes from carrying out their observation missions. For this purpose, planes with greater speed, fire power and maneuverability were necessary, and both sides set to work to develop them. This was the genesis of the fighter plane, whose mission was to destroy other planes and gain control of the air over the battlefield.

The Germans secured the initial advantage in 1915 when they succeeded in mounting in a Fokker monoplane a fixed machine gun which could be fired forward through the propeller. This revolutionary flying gun quickly gave the Germans a superiority in the air which spurred the Allied powers in their search for a still better plane. Until they could match the Fokker, the British and French resorted to formation flying and sought safety in numbers. At one time in 1916 the British used no less than 12 fighters to escort one observation plane.

But the proper answer to the Fokker had to be a superior airplane, and the British and French found their efforts rewarded when the de Havilland 2 and the Nieuport, with a 110-h.p. engine, proved a match for the Fokker. In preparation for the Somme offensive in 1916, the Allies also improved the strategic use of their airplanes, concentrating them in larger formations and carrying the offensive to the enemy. The Germans, in turn, were forced to increase the size of their formations and to concentrate their forces for offensive operations.

The Allies improved their techniques of employing airplanes in conjunction with the ground armies during the Verdun and Somme campaigns in 1916. They extended their bombing raids to railroad stations and aerodromes behind the front lines on a larger scale than ever before. As the role of the fighter plane grew in importance, fighting in the air became more intense and involved a greater number of airplanes.

Determined to regain their superiority in the air, the Germans

brought improved planes—the Albatross and the Halberstadt—into action during the summer and fall of 1916 and organized picked formations of fighters known as flying circuses which developed mobile tactics of fighting. The British and French countered by bringing improved planes into the battle and continuing to increase the size of their fighter units.

During 1917 the air war grew steadily more intense. individual air battles sometimes involving as many as 100 planes. Operations against enemy air units, either in the air or on the ground, came to be the dominant feature of the air war as both sides strove to achieve aerial superiority. Fighter aces became popular heroes in the warring countries as their exploits were reported colourfully by the press. Outstanding among these aces were Georges Guynemer, René Fonck and Charles Nungesser of France; Baron Manfred von Richthofen, Oswald Boelcke, Max Immelmann, Werner Voss and Hermann Goring of Germany; Edward Mannock and Albert Ball of Great Britain; William A. Bishop of Canada; and Edward (“Eddie”) Rickenbacker and Frank Luke of the United States.

Although the fighter plane continued to dominate the air war, and the fighter aces captured the imagination of the public, great progress also was made in bombardment, especially during the last years of the war. Army commanders began to see the tactical advantages to be gained by bombarding enemy rail centres and supply depots behind the lines, but it was more difficult for them to appreciate the strategic advantages to be gained from bombardment of transportation and industrial centres farther removed from the battle areas. The Allies, in particular, steadily expanded their bombing operations, organizing special bombardment units and developing larger bombs. In large measure, of course, this was made possible by the air superiority enjoyed by the Allied air forces during the last year of the war.

In the spring offensive of 1918 the Germans made a supreme effort in the air, concentrating about 900 aircraft for attack on the Allied forces. But although they achieved some impressive bombing successes against supply depots and other tactical targets, they could not wrest control of the air from the French and British, now reinforced by the Americans. Indeed, the numerical superiority of the Allies increased greatly in spite of heavy losses during the spring of 1918.

When the Allies launched their great offensive in the Somme area in Aug. 1918, their air strength of almost 2,000 planes for the operation was in a position to overwhelm the 365 German planes pitted against them. In September the Allies concentrated almost 1,500 planes in support of the successful campaign to flatten the German salient at St. Mihiel. The German air force remained in being until the end of the war, and although greatly outnumbered, it managed on occasion to gain local control of an area by concentrating its forces. But the steady offensive of the Allied air forces, sustained day after day, prevailed at all key junctures of the fighting.

Long-Range Bombardment.—World War I also saw the beginning of long-range air bombardment against civilian centres of population. Although such operations were small in scale and unsystematic, they pointed the way to organized strategic air warfare on a huge scale during World War II. The British bombed targets in Germany during 1914, but the raids were carried out by only a few planes and were directed against military targets, particularly factories producing Zeppelins. The Germans had a number of these airships on hand at the beginning of the war. Their range made them a logical choice to carry out bombing raids against Great Britain.

In Jan. 1915 Kaiser William II gave permission to attack London and other British targets. A few attacks on England had been made by German airplanes in Dec. 1914 and there were a few more during 1915, but most of the raids during 1915–16 were made by Zeppelins. On Jan. 19, 1915, naval Zeppelins dropped bombs on villages in Norfolk, Eng., and killed five people. In the first raid on London, May 26, 1915, a single airship dropped a ton of bombs, killing 7 people and injuring 35. During the latter months of 1915, London was bombed four more times.

To meet these attacks the British adopted a variety of measures.

Guns and searchlights were installed around vital centres, and airplanes were stationed near the coast to intercept raiders and to guard cities. The blackout was adopted in the East Anglia area and a mobile anti-aircraft force was established. But these defenses had little success against the Zeppelins during most of 1916. On Jan. 31, 1916, nine naval Zeppelins attacked targets in the Midlands, killing 39 people at Shrewsbury, Eng. Four more attacks on Scotland and England during April caused 84 deaths. The first suggestion of effective defense against these airships came in Sept. 1916 when the newest super-zeppelins attacked London. On Sept. 3 the first airship was shot down on English soil by an airplane. On Sept. 23 anti-aircraft guns and planes combined to bring down two more Zeppelins.

Eleven airships which attacked London on Oct. 1 caused only one death in the city. The defenders of London had now mastered the lighter-than-air attacks, and no German airships thereafter flew intentionally over the metropolis. British planes shot down additional German airships before the end of 1916, clearly indicating that the Zeppelins were highly vulnerable to air attack. Thereafter, the Germans sharply reduced the number of Zeppelin attacks—from 22 in 1916 to 7 in 1917 and 4 in 1918.

Early in 1917 the Germans began to equip a squadron with Gotha G.IV airplanes for the systematic bombing of England. The squadron began its operations on May 25, 1917, and although the 23 airplanes dispatched did not reach London, they dropped bombs in Kent and demonstrated that the British defense against airplanes was not adequate. Raids by Gothas against London were made in daylight during June–Aug. 1917, causing hundreds of casualties and necessitating diversion of royal flying corps (R.F.C.) squadrons from France to England to cope with the raiders. In September the Germans switched to night attacks and carried out 21 of these moonlight raids before the end of the war.

The raids by Zeppelins and airplanes led to demands by the British public for reprisals against Germany proper, and plans were made to carry out such raids with Handley Page bombers and DH-4s flying from bases in France. But the needs of the armies in the field were too pressing to permit much use of bomber squadrons for this purpose until 1918, and throughout the remainder of the war the ground battle took precedence over long-range bombing objectives. The commander of the royal flying corps in France, Maj. Gen. Sir Hugh Trenchard, had been urging the creation of a long-range air force for some time, and the Italian aircraft manufacturer Giovanni Caproni had proposed bombing German targets in 1916 and 1917.

But while the British made plans and preparations to bomb Germany, the Germans continued their raids on England. They dispatched their newest aircraft, the Giant, against London on Dec. 18, 1917, and followed with additional raids during 1918, using bombs weighing up to 660 lb. Both the Gothas and the Giants had relatively good speed and climbing characteristics and were difficult to intercept, especially at higher altitudes.

The Zeppelins began their last series of raids on England on the night of March 12, 1918, but because of the high altitudes from which they bombed, they did little damage. They made their last raid on the night of Aug. 5–6 but did not succeed in dropping any bombs on land.

The last airplane raid, on the night of May 19–20, 1918, was made by 43 Gothas and Giants against London. Thirteen of the planes reached the city and caused considerable damage. The British defense was alert and effective. Anti-aircraft batteries shot down three German planes, and interceptor planes brought down three more. This defensive success was final, and the German air force made no further attempt to bomb London.

In these raids on England the Germans employed 435 aircraft and 208 airships which dropped less than 300 tons of bombs, killing over 1,300 people and injuring more than 3,000. Most of the casualties were caused by the airplane raids. The material damage was considerable, and the disruption of factory work slowed down production.

Shortly before the Germans ceased their attacks on England, the Royal Air Force (R.A.F.) was established on April 1, 1918, as a separate military service, combining the army and navy aviation

elements. This event was in large measure the result of demands for an effective, integrated air arm to meet the German air threat against England and to carry the air war to Germany. The 8th brigade, a bomber force organized on Oct. 17, 1917, mounted 57 raids against military targets in Germany prior to June 6, 1918, when it was absorbed by the independent bombing force. These attacks did little damage by World War II standards, but they produced effects similar to those caused by the German attacks on England.

The attacks increased after Trenchard took command of the British independent bombing force in June 1918. Day or night raids were made by small numbers of bombers, rarely more than a dozen, against such targets as Frankfurt am Main, Coblenz, Cologne, Mainz, Stuttgart, Kaiserslautern, Karlsruhe and Mannheim. In Oct. 1918 the Handley Page bombers dropped the largest bomb—1,650 lb.—used by the Allies during the war. Trenchard and his bomber crews intended to attack Berlin, but the Armistice was signed only a few days before the attacks were to have taken place.

The independent bombing force was actually subordinated to the Allied commander in chief, Marshal Foch, and often its bombers were diverted from their strategic targets to targets closer to the battle lines, in order to assist the ground armies. The plan for a sustained strategic campaign to paralyze the enemy's munitions production eventually gained some support in high places, and on Oct. 26, 1918, after many political obstacles had been overcome, Trenchard was appointed commander in chief of the inter-Allied independent bombing force. The new command came too late to have any effect on the outcome of the war, which was already won. But it pointed the way to the future of air warfare, and there were those, among whom Trenchard, Giulio Douhet and William ("Billy") Mitchell were best known, who learned the lessons of this experience and became proponents of the doctrine of strategic warfare.

TACTICS AND TECHNIQUES

Types of Planes.—The expansion of air warfare during World War I led to the development of specialized planes to carry out the various types of missions. Three basic types had emerged at the end of the war, replacing the all-purpose plane with which most countries had entered the war.

Fighter.—The fighter was a small, sturdy, compact plane propelled by the most powerful engines that could be installed in it. It was fast, maneuverable and climbed rapidly. These remained the basic performance characteristics desired in the fighter throughout its history.

Observation.—The army commanders looked on observation as the primary mission of the airplane, and most of the planes in service in the earlier years of the war were used for observation work. Aerial observers could tell ground commanders the disposition of the enemy forces, the nature of fieldworks and terrain and the movements of the enemy.

The observation plane took photographs which gave the commander information in the most exact form possible. In time, photographic reconnaissance came to be a major function of the observation plane. Another major job was to spot enemy artillery and direct the fire of its own artillery.

The observation plane went through many changes during the war. It appeared as both a two-seated and a three-seated plane. In the early years of the war it was fitted with bomb racks and became a general-purpose plane, used for observation, bombing and even fighting. Usually it flew unescorted, although there were periods during the war when it had to be heavily escorted.

Bomber.—The bomber was the largest of the military airplane types. It had to be able to fly long distances and carry heavy loads. In the earlier stages of the war, all types of planes were used to drop bombs, but this practice was neither economical nor effective. It became apparent that planes especially designed for the purpose would have to be built if bombing was to be effective. The Germans led the way with their *Gothas* and *Giants*. Although these planes had a speed of only about 90 m.p.h. compared with the fighter's 120 m.p.h., they could carry loads of about 1,000 lbs. of bombs for several hundred miles.

The British produced the twin-engined Handley Page bomber, which gave a good account of itself. By the end of the war the British had produced three Super-Handley Page bombers, four-engined planes carrying a crew of six and a bomb load of thirty 250-lb. bombs. The Italians produced the three-engined Caproni bomber, which could carry up to 3,000 kg., depending on the distance to be traveled. (See AIRPLANE.)

Bombing.—Aside from the plane to carry the bombs, the chief requirements for effective bombing were bombs of the proper size and a method of releasing them accurately on the target. At first, bombs were simply thrown over the side of the plane by the pilot or observer, but this did not prove satisfactory. The next steps were to put fins on artillery shells and finally to design special types of bombs for release from aircraft. The earliest bombs used were small—10 and 20 lb.—but eventually standard bombs ranged upward from 100 lb.

The first bombsights were simple affairs mounted on the side of the fuselage. The bombardier bent his head over the side of the cockpit, made his adjustments and pulled the trigger. The bomb release apparatus was created to eliminate the inaccurate method of dropping bombs by hand and to avoid complicating the aircraft structure. Bomb release gear became standardized and could be attached to any type of plane.

Armament.—The requirement for fire power grew as aerial combat became a distinctive feature of the air war. The machine gun replaced the rifle, but it was difficult to use effectively, especially since the most desirable way of firing was to the front, where the propeller was a constant hazard. The use of a machine gun mounted on top of the upper wing of a biplane and firing over the top of the propeller did not prove to be satisfactory. The problem finally was solved in 1915 by Anthony H. G. Fokker, a Dutch airplane designer working for the Germans, who perfected a synchronizing gear which permitted the gun to be fired through the propeller without hitting it. The tendency from this time on was to mount more guns on the airplanes, and most fighters had at least two guns firing forward.

Organization of Combat Units.—The evolution of aerial tactics and the great increase in numbers of airplanes deployed for combat required the organization of the planes into units which met both administrative and tactical requirements.

Squadron.—The smallest administrative and tactical fighting unit, the squadron, varied greatly in size, ranging from 20 to 50 planes, depending on whether it was a fighter, bomber or observation unit. Within the squadron, there were usually several smaller tactical formations known as flights. The squadron provided living facilities for the men and repaired and maintained the aircraft.

Group.—As more squadrons came into action, it was necessary to organize a higher echelon to control their operations. The group, composed of two to four squadrons, met the tactical needs of bomber, fighter and observation aviation. As fighter formations grew in size, the squadron was no longer adequate to control the larger numbers of planes. The French and the U.S. organized squadrons into groups. The British equivalent was the wing.

Wing.—As the lesson of concentration of forces was brought home to the Allies in 1918, a still higher echelon of organization was added. The British had organized a bombing brigade in 1917 to control their long-range bomber units. In the last stage of the war, the United States used the wing, which consisted of two or more groups. The wings were used at the time of the St. Mihiel offensive in Sept. 1918, when the Allies concentrated about 1,500 airplanes under a single command. This was the largest fleet of airplanes assembled for a single operation up to that time. The normal practice had been to parcel out the air units, usually squadrons, to the ground forces, so that air strength was generally dispersed.

MILITARY AVIATION, 1918–1939

The period following World War I saw significant developments in the theory and use of air power (*q.v.*). Also there occurred great technical advances in the design and construction of airplanes, advances which constantly improved performance and promised

still more for the future. And perhaps most important of all was the development of the long-range bomber, capable of attacking cities in the interior of any enemy country.

Theory of Strategic Air Power.—In the years immediately following the Armistice, Brig. Gen. William Mitchell (*q.v.*) of the U.S. army air corps became the most colourful and vigorous exponent of using air power to bomb an enemy country into submission. Mitchell had been influenced by Trenchard of the R.A.F. and Gen. Giulio Douhet (*q.v.*) of the Italian air force. Douhet's book, *The Command of the Air* (1921), was the first thoroughgoing exposition of the theory of strategic air power. The bombing tests against naval vessels that Mitchell conducted in 1921 and again in 1923 were on the whole successful in demonstrating the potentialities of the bomber. But Mitchell's campaign for an independent air force was unsuccessful in the face of opposition from the army, the navy and the political authorities.

After Mitchell's resignation from the U.S. army in 1926, his ideas were carried on by his followers! who by the early 1930s had come into positions of authority within the air corps. Not until 1934 did they get permission to develop a bomber which would have the range and bomb load needed to test their ideas. Even then the plane was considered by the general staff as having value primarily for defense of the coasts and reinforcement of overseas possessions, particularly Alaska and Hawaii.

The adoption of the strategic bombing doctrine by the U.S. air corps was probably much influenced by the remoteness of the United States from the other great powers of the world. This gave rise to the thought that the most economical and effective way of repelling attack and carrying the war to the enemy would be via air power.

The Heavy Bomber.—Although the theory of strategic bombardment was well developed within a few years of the Armistice, the weapon on which it was based was still lacking. After the end of the war, the British did not pursue their earlier efforts to develop a large bomber. The U.S. air corps built the large six-motor Barling bomber in 1922, but it was a failure and further work was deferred for 12 years, although valuable lessons were learned from experience with the Barling. In 1932 the air corps brought out its first all-metal bomber, the Martin B-10, but this plane did not have sufficient range to be considered a long-range bomber. By 1935 aeronautical progress had reached a point that permitted the development of the Boeing B-17 four-engined bomber, which performed impressively on its first flights. In 1937 a much larger bomber, the XB-15, was flown, but it was too big for the available engines, as was the XB-19, a still larger plane designed several years later. In 1939 the air corps ordered the B-24, which became the running mate of the B-17. At the beginning of World War II, in Sept. 1939, the U.S. had only a few B-17s in service, and 3 of these were experimental models.

In Great Britain the air ministry began the development of long-range bombers in 1936. By 1941 the Stirlings and Halifaxes were coming into use. The Germans, preoccupied as always with the demands of warfare on the ground, gave little attention to the development of long-range bombers, and the German air force's only four-engined plane, the FW-200, was used primarily for anti-shiping patrol once the war began.

Technical Developments.—The major technical advances during the period between wars were in the power of the propulsion units, the design of the airframes and the materials used in the airframes. Between the 200-h.p. engines of World War I and the engines of more than 2,000 h.p. in use during World War II there lay 20 years of intensive effort by the world's propulsion engineers. Only a few days before the onset of the war in 1939, the Germans flew the first airplane propelled by a jet engine. Development of advanced types of planes—especially bombers—had usually awaited the availability of more powerful engines. As these became available, especially after 1930, it became possible to design larger planes with improved speed, range and other characteristics.

Metal construction of airframes was an especially important advance for military aviation because it permitted far better performance than had the old wood-and-fabric construction. The first all-metal plane was built in Germany by Hugo Junkers in

1915. By 1926 the Russian designer A. N. Tupolev had built an all-metal monoplane, and most of the other major air powers had turned to metal planes. After 1930 the trend was entirely toward all-metal combat planes, and by 1939 the major air forces of the world were equipped chiefly with all-metal monoplanes.

Use of Air Power.—In the years between the wars, the British used air power to enforce the *Pax Britannica* in the middle east and on the Indian frontier. In Iraq, Yemen, Somaliland and Afghanistan the R.A.F. proved itself an economical device for discouraging marauding tribesmen.

The Italian air force (*Regia Aeronautica*) had two opportunities before World War II for combat tests of its men and matériel. In the war against Ethiopia, 1935–36, there was no opportunity to test Douhet's theory of strategic warfare because of the primitive nature of the country. The air force provided close support for the Italian ground forces and gained experience in dropping supplies.

In the Spanish Civil War the Italians were joined by the German air force (*Luftwaffe*) in giving the world a preview of World War II air activities. Against slight opposition, the German and Italian air units gained control of the air and had a relatively free hand in carrying out their bombing attacks. Most of this bombing was in support of ground operations, but raids also were carried out against such major cities as Madrid and Barcelona. Italian bomber units operated against Spanish cities and harbours from the Balearic Islands, Sardinia and even the mainland of Italy. The German *Legion Kondor*, under Gen. Hugo Sperrle, provided Gen. Francisco Franco Bahamonde, leader of the Spanish insurgents, with his most effective air support, especially after it began using the Junkers 87 Stuka dive bomber and the Henschel 123. The Germans gained valuable experience and developed the techniques of close air support of ground troops which served them so well in the early campaigns of World War II.

The other major battlegrounds of the 1930s were in the far east, where Japan began waging an undeclared war against China in 1931. The Japanese air force proved to be more than adequate to control the skies over China because of the weakness of the Chinese air force. Japanese bombers attacked Nanking and other Chinese cities in daylight after 1937. But in their test of air strength against the Russians in 1939, the Japanese came off second best. The Soviet air force soundly defeated the Japanese army air force on the Russo-Manchurian border, destroying about 500 Japanese planes. The Japanese reorganized their units and changed their tactics as a result of this experience.

WORLD WAR II

Air power played an important part in the events leading up to World War II. Adolf Hitler used the threat of the *Luftwaffe*, brought into the open in 1935 after years of secret preparations, to help force British and French agreement to his terms at Munich in 1938. There can be little doubt that their lack of air strength influenced the British and French prime ministers. Neville Chamberlain and Edouard Daladier, in their decision to give in. The awesome potentialities of air power, demonstrated on a small scale in Spain, had impressed the European public greatly. In the year between Munich and the German attack on Poland, the French and British worked feverishly to expand their air forces to meet the onslaught from the *Luftwaffe* which would come some day. In turn, the *Luftwaffe* also expanded its strength substantially by Sept. 1, 1939.

Strength of Air Forces.—At the beginning of the war the *Luftwaffe* and the R.A.F. were probably the best equipped and most effective air forces in the world. The German air force had a strength of 500,000 men and about 5,000 first-line aircraft, supported by a 10% to 25% reserve of first-line planes. The R.A.F. had over 100,000 officers and men and at least 1,900 first-line planes. However, France had permitted its once powerful air force to deteriorate badly after World War I. It attempted to remedy its aircraft production deficiency by purchasing airplanes from the United States in 1938–39, but at the outbreak of war its first-line air strength was little more than 600 airplanes, and these were not effectively organized. The Polish air force had less than

500 aircraft of all types, many of them obsolete at the beginning of the war.

Of the other nations which eventually entered the war, the Italians had attained probably the best façade of strength, without any real substance. Their first-line strength of about 1,500 planes in the summer of 1940 proved incapable of coping with the British in Libya later that year, and the *Regia Aeronautica* played a minor role during the remainder of Italy's participation in the war. It is estimated that the Soviet air force had a first-line strength of between 4,000 and 5,000 aircraft in 1939, but these planes were distinctly inferior to German and British equipment.

Japan and the United States were the last of the great powers to enter the war. At the time of Pearl Harbor, the Japanese had 2,700 aircraft assigned to fully trained units which were of a high order of effectiveness. In Aug. 1939 the U.S. army air corps had a strength of 26,000 officers and men and about 1,500 tactical aircraft, only 800 of which were classified as first line. By Dec. 7, 1941, the strength of the United States had increased to almost 2,900 first-line aircraft, but many of these were really obsolete.

The Continental Campaign, 1939-40.—On the morning of Sept. 1, 1939, the German air force led the attack on Poland which set off World War II. In less than three days the *Luftwaffe* destroyed the Polish air force, largely on the ground, switching immediately afterward to the vital lines of communication of the Polish armies—railway bridges and railroad rolling stock.

This was followed by attacks on moving columns of men and vehicles on the roads, and finally by heavy bombing of Warsaw, the last seat of resistance. With the capture of Warsaw on Sept. 27, 1939, the first of Hitler's blitzkriegs had been completed in less than four weeks. In future blitzkriegs, as in the Polish campaign, the Stuka dive bomber and the tank led the German armies to quick victories.

But there was no further attack until the spring of 1940. The absence of any serious fighting in the west during the winter of 1939-40 gave rise to the term "phony war," but the Germans were simply biding their time, building their strength for the spring campaign. In April 1940 came the conquest of Norway, another triumph for the *Luftwaffe*, which flew parachute and air-borne troops to Oslo and Stavanger and supplied the invading forces from the air during the early part of the campaign.

The *Luftwaffe* played a major role in the attack on France and the Low Countries, and at times its psychological impact appeared to be almost as devastating as its military effect. It co-operated closely with the ground armies, and its transport of parachute troops and air-borne infantry was especially successful. Perhaps the most savage attack of this stage of the war was the three-hour bombing of Rotterdam just as the Netherlands capitulated. The heart of the city was wrecked. The *Luftwaffe* secured effective control of the air above the advancing German columns, and the screaming Stukas and fighters protected the flanks of the racing armour which made the great break-throughs of the campaign. Intensive bombing of the French and Belgian fortresses prepared the way for these break-throughs.

Under the shield of the *Luftwaffe* the German armies drove relentlessly forward to trap the British expeditionary force at Dunkerque, France. But the R.A.F. fighters desperately turned back or deflected most of the German air attacks on the terribly vulnerable Allied forces at Dunkerque, permitting the successful evacuation of the bulk of the British forces and some French troops—about 340,000 in all—between May 27 and June 3, 1940. Two weeks later the battle of France was virtually ended, and on June 22 the French surrendered.

Battle of Britain.—The Germans waited for six weeks after the fall of France before launching a heavy air offensive against England as a preliminary to a projected invasion—Operation "Sealion." The famous battle of Britain began on Aug. 8, 1940, with German attacks on convoys off Bournemouth and the Isle of Wight, and was followed by the start of an all-out effort against the R.A.F. on Aug. 12.

Initially, the *Luftwaffe* concentrated its efforts against aerodromes, aircraft factories and radar stations in an effort to destroy the R.A.F. fighter command as an effective force. Although these

attacks caused great damage, the Germans lost heavily (76 aircraft on Aug. 15 alone) and by the end of the month decided to shift their attacks from the R.A.F. to London in an attempt to destroy British morale.

The second phase of the battle of Britain began Sept. 7 with an attack by about 400 aircraft against London, but the Spitfires and Hurricanes shot down 40 of the attackers—a loss rate which the *Luftwaffe's* chief, Field Marshal Hermann Goring, could not afford to accept for very long. Attacks against London continued by day and night, but the Germans had difficulty in breaking through to London, and their losses mounted. On Sept. 15 the R.A.F. fighters shot down 56 German planes, with a loss of 26 of their own. By the time of the last daylight raid on London—Sept. 30—any hope of invasion of Great Britain during 1940 had been abandoned. Not only had the R.A.F. maintained superiority in the air over England; it also had destroyed much of the invasion shipping which the Germans had gathered in continental ports.

The final phase of the battle, lasting into the early summer of 1941, was known as the blitz. From Oct. 1940 the Germans made heavy, sustained night attacks against London and other British cities. They inflicted heavy damage and casualties, but they failed to break the spirit of the people or to put munitions plants out of action for long. The night bombing was erratic, and Goring failed to follow through with any consistent strategic pattern of attack. Although some of the longest and most savage attacks occurred as late as April and May 1941, there was no longer any question of Great Britain's ability to carry on the war. The campaigns in the U.S.S.R. and the Mediterranean forced the *Luftwaffe* to switch most of its strength to those areas in the spring and summer of 1941, giving Great Britain a welcome relief from the strain of the blitz.

The Germans failed for several reasons to conquer Great Britain from the air in the summer of 1940. Although they had plenty of aircraft, their bombers were not strategic bombers; they lacked the bomb-carrying capacity and defensive fire power to carry out that mission. Nor were the Germans able to sustain the necessary logistical support—to provide the bombs, fuel, repair facilities and replacement combat crews needed for such an ambitious and costly air offensive.

Furthermore, they failed to follow their original strategic plan, changing their objectives at mid-point. Finally, the R.A.F. fighter command, aided by the most advanced radar then available, waged a magnificent defensive battle, under the leadership of Air Chief Marshal Sir Hugh C. T. Dowding, which denied to the *Luftwaffe* the control of the air, which is so essential to a successful strategic air offensive.

The Mediterranean.—In Africa the numerically inferior British smashed the Italian advance into Egypt and threw the invaders far back into Cyrenaica in a brilliant two-month campaign ending in Feb. 1941. With an average of only 200 aircraft available during the period, many of them obsolete biplanes, the R.A.F. out-fought the Italian air force and played a key role in the victory. But this victory was shortly undone by the diversion of substantial air and ground forces to assist the Greeks in the defense of their homeland against the Italians and later the Germans. These forces were overwhelmed when the Germans struck at Greece in April; subsequently, they were evacuated to Crete and Egypt. Using greatly superior air strength, the Germans conquered Crete in their only major air-borne operation of the war. The heavy cost in men and aircraft, including gliders, and the narrowness by which the victory was achieved apparently dissuaded the Germans from undertaking any further large-scale air-borne operations.

Meanwhile Cyrenaica, so recently won by the British, was wrenched from them in a campaign as swift and deadly as had been their own victory over the Italians. In Feb. 1941, German troops under Field Marshal Erwin Rommel arrived in the middle east and with the help of *Luftwaffe* units drove the outnumbered British all the way back to the Egyptian frontier. As part of their effort to dominate the Mediterranean, the Germans also undertook a major air offensive against Malta from Sicily in Jan. 1941.

This key island base was a threat to Italian and German communication lines to Libya, and it also provided protection for im-

portant British convoys passing through the most perilous part of the Mediterranean. Malta suffered heavily from the attacks of the German bomber force of Junkers 87s and 88s, as did many important convoys, but the attacks were never sufficiently sustained to knock the island out entirely, and by the middle of 1942 the threat was pretty well ended.

Meanwhile the tide of battle in the western desert had flowed back and forth until in June 1942 Rommel stood once more at the approaches to Alexandria, Egy. Air Chief Marshal Sir Arthur Tedder, commanding the R.A.F. in the middle east, used superior air power to prevent Rommel from receiving the supplies and reinforcements he needed to resume his offensive. When Gen. Sir Bernard Montgomery launched his attack at El Alamein on Oct. 23, 1942, his great superiority on the ground and in the air swept the Germans back and kept them on the run, with no real hope of a counteroffensive. In Nov. 1942 an Anglo-American force under Gen. Dwight D. Eisenhower landed in northwest Africa, and Montgomery and Eisenhower subsequently destroyed or captured the German armies.

The R.A.F. desert air force and the U.S. 9th and 12th air forces secured complete control of the air over North Africa in the early spring of 1943, and early in May the Germans were defeated in Tunisia.

The War in the U.S.S.R.—Although the Soviet air force had more aircraft than the German air force pitted against it, the Germans had superior planes, equipment and crews. The surprise German attack on June 22, 1941, permitted the Luftwaffe to seize the initiative and maintain it during the early months of the war. The Soviets suffered grievous losses, probably as many as 5,000 aircraft during the first two months. Throughout its duration, the air war in the U.S.S.R. was almost entirely a tactical one, with no real strategic air offensive by either side. The Germans bombed Moscow in July and Aug. 1941, but the raids were neither sustained nor effective, and in none of them did the Luftwaffe use as many as 200 aircraft.

After 1941 the enormous length of the battle lines did not permit the Luftwaffe to play the formidable role that it had played in previous German campaigns. The demands of other battle areas, particularly the Mediterranean and Germany itself, deprived the forces in the U.S.S.R. of units, replacement aircraft and crews, and services which they needed to maintain the advantage they had gained in 1941. During 1942 the Soviet air force gradually attained parity with the Germans on most of the battle fronts, although the Germans were generally superior in any given area where they concentrated their strength. In the Stalingrad campaign in 1942-43 the Soviet air force played a powerful offensive role which resulted in the destruction of a large portion of the Luftwaffe's transport fleet and gravely affected the conduct of the remainder of the air war on the eastern front. From this time onward, the Russians held the initiative in the air from Murmansk to the Black sea, and their superiority in the air grew as the war progressed.

During 1943-45 the Luftwaffe declined in numbers and quality in the east while the Soviet air force became larger and better equipped. During this period the Russians were able to concentrate single-mindedly on the task of driving the Germans back. The Luftwaffe fought a losing war in retreat, relieved only by an occasional local victory. The U.S.S.R. established a long-range bomber force in 1942 to carry the war to the enemy, but it was never capable of a sustained strategic air offensive. It could never muster more than about 100 four-engined bombers for a single mission, and in its operations; entirely at night, it generally dispatched about 100 to 150 bombers—twin- and four-engined types — against such targets as Berlin, Ger.; Warsaw, Pol.; Königsberg, Ger. (incorporated into the Soviet Union after World War II and known as Kaliningrad); Bucharest, Rum.; and Budapest, Hung. On an average raid, they would drop less than 50 tons of bombs in the target area. By comparison with the Anglo-American bombing offensive from the west, this could hardly be called a strategic offensive. Indeed, the bombers were used as much against tactical targets in the battle areas as against long-range targets, so that they were never in a position to wage a persistent offensive.

BOMBING OF GERMANY

In the years between the fall of France in June 1940 and the invasion of Normandy in June 1944, the air was the only medium through which Germany itself could be attacked. Prime Minister Winston Churchill and the head of the R.A.F., Air Marshal Sir Charles F. A. Portal: were determined in 1940 that the war should be brought home to the Germans as it had been to the British people. The R.A.F. bomber command was given a high priority, and under a succession of able leaders, especially Air Chief Marshal Sir Arthur T. ("Bomber") Harris from 1942 on, became a powerful offensive force which proceeded systematically to attack Germany in order to destroy the German will and capacity to wage war.

Night Bombing. — It became apparent early to the British that they would have to bomb at night, because the German defenses were too strong to permit daylight bombing. The bomber command, therefore, became a force specialized in the techniques of night bombing.

At first the problems of bombing at night without radar were difficult to solve and the bombing results were poor. Between May 1940 and May 1941, for instance, no less than 40% of the bombs dropped on southwest Germany fell in open country. But in 1942-43 the necessary navigation and bombing devices came into use, and the effectiveness of bombing from 1942 on was conceded by the Germans themselves. The bombers of 1940-42—Wellingtons, Whitleys, Hampdens — were twin-engined planes, either already obsolete or on the verge of obsolescence. In 1941 the new heavy bombers — Stirlings and Halifaxes — began to come into service. The size and weight of the attacks grew steadily thereafter until the first 1,000-plane raid was flown against Cologne, Ger., on the night of May 30-31, 1942.

Daylight Bombing. — Meanwhile, the U.S. army air forces had been building the planes and organizing the air units which would test the theory of daylight strategic air bombardment. The U.S. heavy bombers destined for service against Germany — the B-17 Flying Fortress and the B-24 Liberator — were faster than the large British bombers and had a greater ability to defend themselves against air attack. They could not carry as great a bomb load as the newer British planes, but U.S. commanders, such as Generals Henry H. Arnold, Carl Spaatz and Ira C. Eaker, believed that the greater precision which could be obtained during daylight would offset the smaller bomb loads.

Beginning in July 1942, the U.S. strategic bombers were concentrated in England under the U.S. 8th air force. On Aug. 17, 12 B-17s made the first U.S. daylight attack, without loss, against the railway marshaling yards at Rouen, in occupied France. The day-and-night partnership of the U.S. and British bomber forces had begun.

The 8th air force did not begin operations against Germany proper until Jan. 27, 1943, when it attacked Wilhelmshaven. By that time it had lost a substantial portion of its strength to the 12th air force in north Africa. Accordingly, the efforts of the 8th air force were on a small scale until its build-up was resumed in the spring of 1943.

The R.A.F. bomber command and the 8th air force had attained a certain degree of co-ordination of effort from the beginning, but an over-all directive from the top authorities of both Great Britain and the U.S. was not forthcoming until 1943. At the Casablanca conference in Jan. 1943, Pres. Franklin D. Roosevelt and Churchill agreed to an intensification of the bomber offensive for the purpose of bringing about "the destruction and dislocation of the German military, industrial and economic system and the undermining of the morale of the German people to the point where their capacity for armed resistance is fatally weakened." The final go-ahead for this combined bomber offensive, as it became known, did not come until June 10, 1943. The Anglo-American machinery to direct the offensive was established and the British and U.S. bombers followed a comprehensive plan thereafter.

The Combined Bomber Offensive. — The plan for the combined bomber offensive called for the destruction or neutralization of German fighter strength as an immediate and overriding objective because control of the air over Germany was indispensable

to success. German fighter aircraft factories would be the first target system to be attacked, along with submarine yards and bases, ball-bearing plants and oil refineries. Secondary objectives were production centres for synthetic rubber and military motor vehicles.

As the Anglo-American bombing forces increased their strength, the weight of the offensive against German targets grew. Through 1943 the R.A.F. bomber command carried most of the burden of the offensive, dropping heavy tonnages of bombs at night in attacks on major targets, such as Berlin, Hamburg, Bremen, Essen, Düsseldorf, Cologne, Frankfurt am Main, Munich and Nurnberg. The daylight bombing offensive during 1943 did not reach the scale of the R.A.F.'s night effort, and the 8th air force encountered problems which threatened the whole conduct of its campaign. As early as the spring of 1943 the 8th air force began to find that the B-17s and B-24s, however heavily armed, could not defend themselves adequately against determined fighter attacks, such as were encountered over Germany. To meet the threat of the U.S. daylight precision bombing attacks, the Germans greatly expanded both their anti-aircraft artillery and their fighter forces during 1943 and gained a temporary advantage over unescorted bomber formations. In major attacks against targets deep in Germany, the 8th air force suffered heavy losses. The rate of loss was so excessive that the 8th had to curtail its attacks against Germany after it lost 60 bombers on the second Schweinfurt mission on Oct. 14, 1943.

The continued expansion of the German interceptor force made it appear that the daylight offensive against Germany proper would have to be abandoned unless the United States could find an escort fighter to accompany the bombers deep into Germany. Great efforts were made during 1943 to extend the range of the P-47 Thunderbolt, with some success, but it remained for the P-51 Mustang to give the positive answer to the German fighter attacks. The P-51s began accompanying bombers to German targets in Dec. 1943, and as the Mustangs grew in numbers, the bombers, also greatly reinforced, flew against German targets with unprecedented strength and confidence.

When American fighters appeared over targets deep in Germany in Feb. 1944, Goring refused at first to believe it, but the *Luftwaffe* fighter chiefs, Lieut. Gen. Adolf Galland and Col. Hannes Trautloft, who took to the air to observe their fighters in action, were chased all the way back to Berlin by four Mustangs.

Between Feb. 20 and 25, a period referred to as the "Big Week" by the Americans, 8th and 15th air force bombers, accompanied by fighters all the way to the targets, delivered a smashing series of blows against the German aircraft industry. They bombed plants at Regensburg, Oschersleben, Brunswick, Augsburg, Leipzig and other places, causing an immediate loss of fighter production to the Germans and inflicting prohibitive losses of 10% to 15% on the German fighter forces. In order to conserve his fighters for use against the prime threat, Goring directed that they avoid combat with the U.S. fighters and confine their attacks to the bombers. As a result of this situation, one German air commander made the rueful comment that "the safest flying that was ever possible was that of an American fighter over Germany." In March the Americans deliberately began flying routes into Germany designed to bring the maximum number of German fighters to battle, and the Mustang and Thunderbolt fighters, instead of flying close escort, ranged far afield to find and destroy German fighters in the air and on the ground.

The *Luftwaffe* never recovered from the shock of the massive onslaught in Feb. 1944, and its efforts to regain control of the air over Germany were further nullified by the build-up of United States strategic air strength in Italy as well as in the United Kingdom. The U.S. 15th air force began flying against southern Germany, Austria and the Balkans before the end of 1943. At their peak strength, the two U.S. strategic air forces, co-ordinated by a headquarters under Gen. Carl Spaatz, had available for combat in operational units more than 3,000 heavy bombers and 1,600 long-range fighters. The R.A.F. bomber command added another 1,400 operational bombers to this mighty array.

Although German fighter production increased steadily after recovering from the attacks of the "Big Week," and the *Luftwaffe*

found itself with large numbers of fighters on hand, it could not make fully effective use of them. The quality of German fighter pilots declined greatly thereafter, and lack of fuel made it impossible to give proper training or to maintain operations on an all-out basis for an extended period. Accordingly, although as many as 850 fighters might be put up against the daylight bombers on a single day, the results were usually far less than the effort should have achieved.

The day and night bomber offensive had forced the Germans to weaken their air strength in the U.S.S.R. and the Mediterranean area in order to provide for the defense of the Reich. The night war, especially, became a race between the Germans and British for the development of electronic devices, with first the offensive and then the defensive gaining the advantage.

During 1943 the British techniques of using pathfinder planes to light the targets with flares, sending the planes over the targets in a steady bomber stream in a short period of time and dropping metallic strips, known as "window," to confuse the German radar system, gave bombers the advantage. The Germans countered eventually with a new radar reporting service and stronger night fighter units equipped with better aircraft which more than redressed the balance during the first half of 1944. On two nights in March 1944 the British lost 72 out of 810 aircraft attacking Berlin and 94 out of 795 aircraft raiding Nurnberg, loss rates of 8.8% and 11.8%, respectively.

The British did not find a means of matching this German advance, largely because strategic considerations dictated by the impending invasion of Normandy required that the bomber command attack targets in France, the Low Countries and western Germany, where the night fighter system was not especially effective. The problem eventually was solved by the Allied conquest of France and Belgium, which deprived the Germans of their whole early warning system and put them at a disadvantage from which they never recovered. After the summer of 1944 the German night defense deteriorated steadily, and the R.A.F. bomber command was able to press home its attacks, although deep penetration missions were still costly on occasion.

The Final Assault.— After the attacks on the aircraft industry, which prevented the Germans from attaining their planned production peaks, the Allied bombers opened what proved to be the most significant of their campaigns—the one against oil. Germany was dependent on limited sources for both natural and synthetic oil, and these sources, although scattered, were highly vulnerable. The importance of oil as a target had been recognized for a long time by air leaders, but not until 1944 did they have the forces to undertake a large-scale campaign against oil. The attacks by the 8th air force, under Gen. James Doolittle, and the R.A.F. bomber command were delayed because their help was required in the campaign to isolate the Normandy battle area by destroying transportation facilities on the continent in the months preceding D-Day, June 6, 1944. The campaign against oil, therefore, had to be initiated by Gen. Nathan F. Twining's 15th air force, which struck the great oil fields at Ploesti, Rumania, on April 5, 1944, and followed with regular attacks until what was left of the oil installations fell to the Russians in August. The 8th air force found time from its other duties to launch its first great attack on May 12, 1944, when it bombed synthetic oil plants at Merseburg, Ger.; Leuna, Ger.; Zwickau, Ger.; Brüx (now Most), Czech.; and other places, inflicting substantial damage. Although the U.S. bombers dropped little more than 5,000 tons of bombs on oil targets during May, German oil production for June fell to half of the March output. Albert Speer, the over-all czar of German production, later said that the attacks on oil during May 1944 decided the outcome of the war.

During the summer of 1944, in addition to bombing oil and other transportation targets in Germany and German-occupied territory, the Anglo-American bombers supported the ground forces in France, helping to pave the way for the great advance to the German frontier. They participated also in the attacks on the German V-weapon launching sites in France and Belgium.

From the fall of 1944 until April 1945 the bombers ranged over Germany, inflicting great destruction on German industries, cities

and transportation. The decline in oil production as a result of these attacks affected the whole German war machine, forcing the hoarding of stocks for large-scale use on special occasions. The growing effectiveness of transportation bombing during the fall of 1914 and the following winter caused German industry to slow down and eventually grind to a virtual halt, because the whole pattern of moving raw materials and finished products had been upset. Finally, the dislocation of people on an enormous scale by the British attacks on urban areas helped to disrupt the German economy. As the Allied armies smashed into Germany from the west and Russian armies forced their way in from the east, the number of strategic targets available for bombing dwindled rapidly. On April 7, 1945, the R.A.F. bomber command discontinued area bombings, and on April 16 Gen. Spaatz declared the strategic air war at an end for the U.S. bombers. Both forces turned to assist the ground forces in the closing days of the war. Paradoxically, and fittingly also, their final missions of the war were errands of mercy during which they dropped food to the starving people of the Netherlands and evacuated liberated prisoners of war from the defeated *Reich*.

During the course of the war against Germany, the Anglo-American air forces dropped almost 2,700,000 tons of bombs.

INVASION OF FORTRESS EUROPE

For the liberation of western Europe and the conquest of Germany the Allies gathered their most powerful forces. Two tactical air forces—the R.A.F. 2nd tactical air force and the U.S. 9th air force—were organized to provide support for the ground armies during the grand assault—known to history by the code name, "Overlord." In the months preceding D-day the tactical air forces used their thousands of medium bombers and fighter bombers against airfields, radar and V-weapon sites, locomotives and rolling stock, and gun emplacements in German-occupied France and the Low Countries. The strategic bombers joined in the assault against railroads and other targets. Before D-day, German access to the Normandy area by rail had been blocked as far back as the Seine river. Incessant attacks by the Allied air forces drove the German air units back from their bases in the west to the interior of France and even into Germany itself. Many fighter units were withdrawn to defend the *Reich* against the devastating attacks of the Anglo-American bombers. Lieut. Gen. Werner Junck, commander of German fighter defenses in the invasion area, later testified that on D-day he had a total of 160 fighters, of which only 80 were operational.

On D-day the Allied air forces flew almost 15,000 sorties during a 24-hour period. The massive assault was begun during the night by thousands of transports and gliders which dropped whole airborne divisions in the hedgerows of Normandy. Allied fighters ruled the air over the landing zone and deep inland for many miles. Allied heavy and medium bombers struck at every manner of target which might have a bearing on the battle—coastal batteries, beach defenses, railroad centres, bridges, airfields, depots. The weak German air units were able to dispatch only 250 planes against the landings, of which barely a dozen were fighter bombers. The complete success of the landings was made possible by the overwhelming air superiority of the Allies.

The pattern of air domination established on D-day continued for the remainder of the campaign. Anglo-American fighter bombers spearheaded the break-throughs which collapsed the German lines and sent their armies into headlong retreat. Allied heavy bombers helped prepare the way for the break-through at St. Lô, France, in July with a tremendous bombardment of the battle area. At Mortain, France, early in August, the fighter bombers of the U.S. 9th air force and the British 2nd tactical air force administered the *coup de grâce* to German hopes of launching a counter-attack which would sweep the Allied armies into the ocean. The *Luftwaffe* was unable to offer any effective opposition in the air because of the pressure maintained by the superior Allied air forces. In one of the most remarkable events of the war, a large body of German troops trapped south of the Loire river in Aug. 1944 insisted on surrendering to a representative of the U.S. 19th tactical air command which had so harried them from the air that

they had lost all hope of escape even though they had not encountered any Allied ground forces.

On Aug. 15, 1944, G.S. and French forces landed in southern France and fought their way northward to a junction in eastern France with the Allied armies which had surged across France from the Channel coast. United States and French air units, organized as the 1st tactical air force (provisional), provided the air cover for this swift advance from the Mediterranean to the Swiss border near Belfort, France.

In the rapid sweep across France, the Allied tactical air forces kept on the heels of the advancing armies. By the end of September, the British and Americans had airfields in operation in central France and in Belgium, while the *Luftwaffe* had been flung back into Germany proper. Until Dec. 1944 there existed a comparative lull in the ground battle while the two exhausted armies girded themselves for the next round. The German attack in the Ardennes in December—the battle of the Bulge—after an initial success was blunted and turned back once Allied air power came into full play after a period of bad weather.

The Allies resumed their offensive in Feb. 1945. German resistance in the air was at an absolute minimum except for an occasional fierce attack on Allied heavy bombers, and the German armies were at the mercy of the Allied planes. The heavy bombers joined increasingly in the assault on tactical targets in the months immediately preceding Germany's surrender. On V-E day—May 8, 1945—the *Luftwaffe*, which only a few years before had been the world's most powerful air force, ceased to exist.

The Italian Campaign.—Although eventually overshadowed by the main arena of war in western Europe, the campaign in Italy contributed greatly to the Allied victory. After the conquest of Tunisia in May 1943, the Allied bombers forced the surrender of the key islands of Pantelleria and Lampedusa, making it unnecessary to fight what was expected to be a difficult ground campaign for their possession. In July and August the veteran British and U.S. air units drove the *Luftwaffe* and the *Regia Aeronautica* out of the skies over Sicily and helped hammer the German and Italian forces in Sicily into submission.

The invasion of the Italian mainland in September met strong resistance at Salerno and might have failed but for the prompt and effective use of Allied bombers and fighters against the German efforts to destroy the beachhead. The Allied air forces—the R.A.F. desert air force and the U.S. 12th air force—paced the armies in their advance up the peninsula, via Naples and Foggia on opposite coasts, until the Germans, aided by bad weather and rugged terrain, succeeded in halting the Allies at the Gustav line. The amphibious landing at Anzio in Jan. 1944, which was protected by Allied air power, pinned down a large portion of the German forces and helped make possible the resumption of the Allied advance in the spring. The retreating *Luftwaffe*, outnumbered as much as ten to one, could not interfere effectively with Allied air or ground operations except by an occasional major effort. In the campaign which led to the capture of Rome in June and a sweep beyond to the north, the Allied air forces hammered systematically at German communication lines and supplies. The campaign lived up to its code name "Strangle," literally strangling the German armies by cutting off their supplies and forcing them into what often became disorganized retreats.

After reaching the northern Apennines, the Allies bogged down in Oct. 1944, partly as a result of having transferred a substantial portion of their strength to France. During the winter of 1944–45 the Allied air forces had the chief responsibility for maintaining constant pressure on the German forces and did so with little opposition from the *Luftwaffe*. So complete was Allied air control that medium bombers usually flew without escort. Once again the Anglo-American fighters and bombers blocked German supply lines so thoroughly, especially at the Po river and the Brenner pass, that when the Allied armies resumed their advance in April 1945, they met little effective opposition from the disorganized German forces, which surrendered on May 2.

THE PILOTLESS AIRCRAFT AND ROCKET CAMPAIGN

One of the most significant features of the air war in Europe

was the use of pilotless aircraft and rockets by the Germans. Rumours of the impending use of new weapons against England had been current for some time before the British became convinced of the existence of such weapons and took measures to counteract them in 1943. In Aug. 1943 the R.X.F. bomber command attacked and heavily damaged the Peenemiinde experimental station on the Baltic, where the V-weapons, as they became known, were being developed and tested.

German preparations for launching the weapons from sites in France were discovered during the summer of 1943, and the Anglo-American air forces quickly began a systematic campaign—known as "Crossbow"—against these sites. The campaign was extended to the factories producing the weapons and the plants manufacturing the hydrogen and liquid oxygen fuels which powered them. This bombing campaign lasted 13 months, during which Allied planes dropped 100,000 tons of bombs on "Crossbow" targets, 9% of the total tonnage dropped during the period. It was estimated by the Allies that the bomber attacks delayed the beginning of the German V-weapon campaign by some three to six months.

The German programs for development and production of the V-1 and the V-2 did not keep pace with established goals. Inter-service rivalries, interference by Hitler and Allied bombings delayed the beginning of the V-1 campaign until June 13, 1944, when the first V-1 fell in southern England. This weapon, which came to be known as the "flying bomb" and the "doodle-bug," was a pulse-jet pilotless aircraft with 2,000 lb. of explosives in its nose and a speed of nearly 400 m.p.h. In all, about 8,000 V-1s were launched against England, most of them directed at the London area. After the loss of the continental coast to the Allied armies in the summer of 1944, the Germans switched to continental targets held by the Allies, chiefly Antwerp, Belg., which received most of the additional V-1s launched. The attacks against England killed 6,139 people and seriously injured 17,239, while causing extensive damage in urban areas. Allied airplanes and anti-aircraft guns proved extremely successful in countering the V-1 threat during the height of the attacks against London in July and Aug. 1944.

By early September the V-1 threat had been greatly reduced because of the loss of the launching sites in France. But on Sept. 8 the first V-2 fell in the London area; and before the end of the war about 1,100 exploded in England and 1,675 on the continent, again chiefly in Antwerp. The V-2 was a true missile rocket. It was 46 ft. long and more than 5 ft. in diameter, carried a ton of explosives in its warhead, had a range of about 200 mi. and a speed of more than 3,000 m.p.h. and was propelled by a liquid oxygen fuel. The Germans launched most of the V-2s from sites in the Netherlands. The rockets killed 2,855 and severely injured 6,268 people in England.

The V-weapon campaign did not significantly affect the conduct of the air war in Europe. To be sure, in order to counter the weapons, the Allies had to divert a substantial portion of their bombing effort from German targets and to use large numbers of troops and guns against the V-1s. But in producing and operating these weapons the Germans expended enormous resources which might have been used more effectively for other military purposes. Nevertheless, the development and use of the V-2 rocket by the Germans ushered in the age of guided missile warfare and went far toward establishing the pattern of future warfare. (See ROCKETS.)

AIR WAR IN THE PACIFIC

In the Pacific phase of World War II the Japanese, like the Germans in Europe, gained an early advantage by advance preparations and surprise attacks. At Pearl Harbor, on Dec. 7, 1941, Japanese naval aircraft temporarily crippled U.S. naval power in the Pacific. On Dec. 10, Japanese bombers sank two major British naval vessels off Malaya, thereby eliminating British naval power from the far east for some time to come.

Freed of serious naval opposition during this crucial early phase of the war, the Japanese army and navy, operating under an air umbrella, conquered the Philippines, Malaya, Burma, the Dutch East Indies (now Indonesia) and other islands in the Pacific. In

its speed and effectiveness, the Japanese advance rivaled the German blitzkriegs in Europe.

Stiffening Allied resistance eventually brought the Japanese advance to a halt in the Pacific—first at the Midway Islands and then at Guadalcanal in the Solomon Islands and in the Owen Stanley mountains of New Guinea. In Burma, the situation became stabilized at the Indian frontier, and the Japanese were destined never to attain their dream of conquering India. The headlong Japanese advance carved out an enormous empire rich in resources, but with a fatal defect which soon became apparent. The conquering forces at the far ends of this empire had to be supplied and reinforced from the homeland—many thousands of miles away over sea lanes which became the hunting grounds of avenging U.S. and British aircraft and submarines. The subsequent strain on Japanese shipping proved too great to be endured, and the perimeter of Japanese dominion in the Pacific shrank steadily after 1942.

Although the tide of Japanese conquest surged mightily during the first eight months of the war, the U.S. army air forces and the U.S. navy joined forces to bring the war home to Japan itself in a grim warning of the future. On April 18, 1942, Lieut. Col. James H. Doolittle led 16 army air force B-25 bombers from the U.S. navy aircraft carrier "Hornet" in a spectacular low-level attack against Tokyo and other Japanese cities. Although all of the planes were lost in bad weather over China, most of the crews were saved. In addition to the heartening psychological effect in the United States and in other Allied countries, the raid probably caused the Japanese to retain four army fighter groups in Japan during 1942 and 1943, when they were badly needed in the South Pacific. It appears also that the Doolittle raid impelled the Japanese to push beyond their originally planned defensive perimeter, thereby increasing the vulnerability of their supply lines.

Burma and China.—In Burma, the monsoon rains brought the Japanese advance to an end at the beginning of the summer of 1942 on the Indian frontier. The fighters and tactical bombers of the R.A.F. and the U.S. 10th air force played a dominant role in turning back Japanese attacks during 1943 and 1934. One of the most remarkable aspects of the war in Burma—indeed of World War II as a whole—was the supply of whole British armies by air for extended periods of time. During the Imphal campaign in the spring of 1944, an army of 150,000 men in contact with the enemy was maintained solely from the air by R.A.F. and U.S. army air force transport planes.

The great offensive of 1944–45 which reconquered Burma from the Japanese was also made possible by Anglo-American air power. Long-range bombers—chiefly B-24 Liberators—struck Japanese depots and installations throughout southeast Asia. The Japanese air units could muster barely 50 planes to face more than ten times as many Allied planes. The Japanese on the ground were constantly harried and slaughtered by the veteran fighter and bomber groups. Once more the air transports supplied the British 14th army—this time numbering 300,000 men and advancing in victory. The end of the war in Burma found the Japanese reduced to impotence on the ground and in the air.

In China, the U.S. established the China air task force, composed at first of the "Flying Tigers"—members of the civilian U.S. volunteer group which had been recruited before the war to fight for China against the Japanese. In March 1943 U.S. air units in China were organized into the 14th air force under the command of Maj. Gen. Claire L. Chennault, an officer with long experience in China. The 14th air force provided the Chinese armies with most of their air support during the remainder of the war and, although usually outnumbered, consistently carried the war to the Japanese, attacking targets as far away as Shanghai and preying on Japanese shipping off the coast of China.

For the greater part of the war the 14th air force was supplied by air from India. The U.S. army air forces air transport command carried out this remarkable long-range operation over the "hump" of the Himalayas, the highest mountains in the world. In spite of the great handicaps under which they laboured, Chennault's "Flying Tigers" compiled a brilliant record and made outstanding contributions to the development of tactics and tech-

niques of aerial warfare.

Guadalcanal to the Philippines.—After the fall of the Philippines in April and May 1942, Allied forces concentrated in Australia under the command of Gen Douglas MacArthur. The strategic victory of the U.S. navy over the Japanese in the battle of the Coral sea in May 1942 prevented the Japanese from taking Port Moresby in New Guinea, which could have served as a springboard for invasion of Australia itself. The respite afforded by this victory permitted a build-up of U.S. air strength in Australia, New Guinea and the Solomon Islands. In Aug 1942 U.S. marines began at Guadalcanal the long, drann-out reconquest of the Solomons, which was not completed until 1944. U.S. navy, marine, and army air forces units provided the air support which nas essential to the operation. Meanwhile, U.S. and Australian ground forces, under the constant protection of the U.S. 5th air force and the Royal Australian air force, won back New Guinea and New Britain in 1943–44. In March 1943 the Allied air forces performed one of the most striking aerial feats of the war in wiping out the greater part of a large Japanese convoy in the Bismarck sea.

Allied strategy in the Pacific called for an island hopping advance toward Japan itself, an advance which would always be under the protective cover of shore-based or carrier-based air poner. By the middle of 1944, U.S. air, ground and naval forces in the southwest Pacific had attained the strength and strategic position to undertake long-range advances. In October came the landing on Leyte in the Philippines, and in Jan. 1945 the landing on Luzon. The U.S. 5th and 13th air forces and naval air units smashed Japanese air and naval power in the Philippines and ruled the air over the battle areas and far behind the Japanese lines.

North and Central Pacific.—In June 1942 the Japanese occupied Attu and Kiska in the Aleutian Islands, but any hopes they had of exploiting their position were frustrated by the harassing bombardments of the U.S. 11th air force. In 1943 U.S. army forces reconquered Attu, and the Japanese abandoned Kiska. The 11th air force also had the distinction of carrying the air war to the Japanese home islands nith attacks against the Kurile Islands in 1943 and 1944.

In the central Pacific an island hopping strategy was also followed—always under the cover of air power. Heavy bombers of the U.S. 7th air force and carrier task forces softened up the islands before they nere assaulted by U.S. marine and army forces. Tarana and Makin mere taken in the fall of 1943, and in Feb. 1944 the Marshall Islands, far to the west of Pearl Harbor, were also taken. The Marianas, which could provide air bases from which the new heavy bombers could strike at the heart of Japan, were the next to fall. By Aug. 1944, the main islands, Guam, Saipan and Tinian, had been taken. After the war, Japanese military leaders stated that the loss of the Marianas was the turning point of the war, for it meant the penetration of the interior defenses of the empire and laid the homeland open to devastating attacks by the B-29 bombers.

The last great tactical air campaign in the Pacific was at Okinawa, in the spring of 1945. U.S. army and marine forces, supported by overwhelming air power, fought a bloody battle against fanatical Japanese resistance. It was at Okinawa that the Japanese kamikazes—suicide bomber pilots—caused great damage to U.S. naval vessels. Their technique of deliberately crashing explosive-laden aircraft into target objectives, especially ships, was a clear indication of the desperate position in which the Japanese army and navy air forces found themselves. In all, the Japanese flew 2,500 suicide sorties, of which 475 scored direct hits, sinking about 40 ships and seriously damaging many others. Many of these attacks were made during the Okinawa campaign, but the Japanese could not contest control of the air over Okinawa itself, and after the island mas conquered in June 1945, it became the main base for the planned invasion of Japan. Fighters and bombers of the 5th air force attacked southern Japan from Okinawa, and bases were built on the island for B-29s to carry the war to Japanese industrial centres.

The B-29 Campaign.—The U.S. developed the B-29 for the specific purpose of using it against the Japanese homeland. The

first B-29 units operated from bases in India and China because there were no others available for bombing Japan. B-29s first attacked Japan on June 15, 1944, striking steel mills at Yahata, and followed up with attacks on other Japanese targets from Chinese bases. But once the huge air bases in the Marianas had been completed, the total B-29 force was concentrated there under the U.S. 20th air force. This force numbered almost a thousand B-29s by the end of the war.

On Nov. 24, 1944, the first B-29 mission from the Marianas—100 strong—left Saipan and bombed Tokyo for the first time since the Doolittle raid in 1942. The attacks on Japanese targets grew in size and intensity as the 20th air force received more B-29 units. In March 1945, Maj. Gen. Curtis LeMay, commanding the bombers, made one of the most important decisions of the war. He decided to use the B-29s in low-level night attacks with incendiaries against the highly vulnerable Japanese cities. On the night of March 9, 279 B-29s, bombing from altitudes ranging between 4,000 and 9,000 ft., burned out 15.8 sq.mi. of the heart of Tokyo. The pattern established by this attack was folloned with other Japanese cities, and Nagoya, Osaka and Kōbe sustained tremendous damage also. The climax of the bombing campaign came on Aug. 6, 1945, when the B-29 "Enola Gay" dropped the first atomic bomb on Hiroshima with devastating results. A second atomic bomb dropped on Nagasaki on Aug 9 helped persuade the Japanese of the utter hopelessness of further resistance, and surrender followed soon thereafter.

In an exhaustive on-the-spot study after the war, the U.S. strategic bombing survey found that the aerial bombardment, to which aircraft carrier strike forces had also contributed during 1945, had taken a terrible toll of Japanese industry, urban areas and people. The incendiary bomb campaign had already produced a decisive result by the time the atomic bomb brought the war to a dramatic end.

Also of decisive effect on the outcome of the war was the blockade of the Japanese home islands. The Japanese merchant fleet, under attack from Allied sea and air forces, had been reduced to little more than 20% of its original strength by the end of the war. For this achievement, most of the credit belongs to the submarines of the U.S. navy, but aircraft alone sank 1,000,000 tons of Japanese shipping in 1944. B-29s helped greatly in this campaign by mining the waters around Japan, dropping 1,000 tons of mines in the Shimonoseki straits during the four days preceding the landings on Okinawa.

THE KOREAN WAR

In the decade after World War II, air power emerged clearly as the dominant mode of warfare. The strategic bomber carrying the atomic bomb became the symbol of military power. The strategic thinking of the great nations of the world became increasingly centred around the concept of destroying an enemy's capacity to wage war by attacking his centres of production with atomic and thermonuclear weapons. The remarkable technological advances of the postwar period in jet propulsion, thermonuclear power and guided missiles lent still greater emphasis to this concept of narfare. But in spite of the intense competition between the United States and the U.S.S.R., neither atomic bombs nor guided missiles were used in the Korean war.

Although it served as a testing ground for U.S. and Soviet aeronautical equipment between 1950 and 1953, the Korean mar did not prove to be a preview of the air warfare of the future. It was a limited war, requiring no all-out air effort by the United States, which carried the chief burden for the United Nations forces. The U.S.S.R. gathered valuable data from the experience of the North Koreans and Chinese with the aircraft sent them by the U.S.S.R.

The U.S. 5th air force moved with most of its units from Japan to South Korea after the North Korean invasion of June 25, 1950. The 5th was still equipped chiefly with World War II planes—F-51 Mustangs and B-26 Invaders—and its only jet airplane was the F-80 Shooting Star—already on the verge of obsolescence. Reinforced by additional combat wings from the United States and a few squadrons from other United Nations countries—espe-

cially the United Kingdom and Australia—the 5th air force quickly won mastery of the air. During the first phase of the campaign, July to Oct. 1950, the UN air forces supported the ground armies and bombed enemy supply lines and production centres. Their attacks on the North Korean armies resulted in the deaths of an estimated 39,000 soldiers and destruction of approximately 76% of the total tanks destroyed by the UN forces.

During the retreat from the Yalu river in Nov. and Dec. 1950, after the large-scale intervention of the Chinese Communist forces, the UN air forces slowed the Chinese advance, thereby permitting an organized withdrawal of the UN ground forces. The US air forces, which operated in close support of the ground troops and harassed the Chinese supply lines by day, played a large part in frustrating the Chinese effort to destroy the UN forces. The pressure of the UN bombers and fighters forced the Chinese to fight and move supplies chiefly by night.

B-29 bombers from the United States flew to bases in Japan and Okinawa shortly after the outbreak of the conflict and carried on a steady campaign against North Korean targets. But the North Koreans, and later the Chinese, received their supplies and equipment from far beyond the Yalu river boundary, and North Korea offered no such strategic target systems as had Germany and Japan in World War II. The decision of the UN to localize the war and not to attack targets in China denied the B-29s what would have been their most profitable targets.

The greater part of UN air power continued to concentrate on support of the ground armies. Bombers and fighters—including the modern jet F-84s and F-86s—took a heavy toll of the Chinese between Nov. 1950 and June 1951, a period of heavy fighting. Still unable to move troops and supplies by day because of the constant air attacks, the Chinese could not mass sufficient supplies at the front to support a sustained offensive. Until the end of the war in 1953, UN air power played a major part in frustrating all major Chinese attacks.

The CN control of the air, which helped to nullify the numerical superiority of the Chinese on the ground, could be broken only by superior air power. The Chinese Communist air force, supplied by the U.S.S.R. with the MIG-15 jet fighter, made the effort beginning late in 1950. Although safe from UN attacks on their bases beyond the Yalu, the Chinese found it difficult to dispute control of the air over the battlefield because of the short range of the MIGs. In late 1951 they began to build a chain of airfields in North Korea which would have permitted them to make much more effective use of their MIGs. But UN planes attacked these bases as they neared completion and repeated the attacks again and again as the Chinese attempted to repair the damage. The attacks provoked the largest air battles of the war—almost exclusively between the U.S. F-86 Sabrejets and the MIGs. This first large-scale combat between jet fighters in the history of warfare ended strongly in favour of the F-86s, which claimed the destruction of 800 MIGs as against a loss of only 58 Sabrejets. Much of the fighting took place in the vicinity of the Yalu, with the MIGs availing themselves of sanctuary on the Chinese side of the boundary when hard pressed by the F-86s.

GUIDED MISSILES

The launching of the first true guided missile, the German V-2, against England on Sept. 8, 1944, and the dropping of the first atomic bomb on Hiroshima on Aug. 6, 1945, heralded the beginning of a new era of warfare. These two remarkable technological advances, occurring within 11 months of each other in the last year of World War II, provided the basic elements for the most destructive mode of warfare yet devised by man.

Although strategic bombing was only one of the means employed to defeat the Germans and Japanese during World War II, its feasibility had been established, and its potential; with atomic bombs at its disposal, was truly awe-inspiring. But there was still another step—the use of atomic warheads on long-range guided missiles—which promised even quicker and more decisive results than bomb-carrying aircraft. Such missiles would travel many times faster than the fastest bomber, and defense against them would be extremely difficult.

The U.S. had begun guided missile research before 1944, but knowledge of the successful use of the V-1 and V-2 by the Germans led to an expansion and acceleration of such work by all three military services. During the first five years after the war, progress was slow; not until 1953 did the first air force missile, the Martin B-61 Matador, come into operational service. But the Matador was little more than an improved V-1 designed chiefly for short-range tactical use. Although the greatest emphasis continued to be placed on the long-range intercontinental ballistic missile (ICBM), a whole series of additional missiles of lesser range was also under development by the U.S. army, navy and air force. In 1956 the U.S. department of defense placed a high priority on development of a missile of intermediate range—about 1,500 mi. In the field of interceptor missiles, the army's Nike came into use in the early 1950s and became the chief ground antiaircraft weapon for defense of U.S. cities. In 1955 the air force put into operation the Falcon—an electronically controlled missile, launched from fighter airplanes against other aircraft at distances measured in miles.

In the decade after World War II the U.S.S.R. made rapid progress in guided missile development with the aid of German scientists and engineers who had worked on the V-1 and V-2. The problem of designing warheads of sufficient power to make the missiles effective was solved by the successful military application of atomic and thermonuclear energy. The Russians also worked toward an intercontinental missile. In 1956 the Communist party leader, Nikita Khrushchev, was able to state that the U.S.S.R. would soon be able to use missiles with thermonuclear warheads against any part of the world.

The intensive race between the U.S. and the U.S.S.R. for acquisition of guided missiles portended a capacity for destruction approaching total annihilation. The awesome power of the new weapons unquestionably acted as a deterrent to their use and tended to lend substance to the hope that war would become impossible because it invited mutual destruction. See MISSILES; BOMBING AND BOMBARDMENT; see also Index references under "Air Warfare" in the Index volume.

AIRWAYS. An airway may be roughly defined as any pathway through navigable airspace. More specifically, in its modern form, it is such a pathway equipped with aids to navigation which guide pilots in the same way that highway signs guide motorists.

Since the end of World War II and the great increase in the volume of aerial traffic, especially in the neighbourhood of all large centres of population, most countries have established systems of airways, ordinarily 10 mi. wide and extending from 700 to 24,000 ft. above sea level.

In the United States alone there are over 125,000 mi. of airways connecting about 600 communities in an air transport network known as the Federal Airways system, maintained by the Federal Aviation agency. Similar systems exist in Europe and elsewhere, wherever traffic density makes them necessary, and they are usually established and maintained by the appropriate national civil aviation authority.

Prior to World War II navigational aids on the airways consisted as a rule of radio ranges and a system of airway beacons extending across country from one airport to another. However,

the beacon virtually disappeared and the radio range was replaced by more exact navigational systems.

The two in general use in the early 1960s were VOR (very high-frequency omnidirectional radio ranges) and the Decca system, named after the British company which developed it. VOR, based on the wartime Consol system, transmits to the pilot the bearing and distance from his aircraft of an omnidirectional ground station and thus, by means of an instrument in his cockpit, shows him his geographical position. The Decca system, by means of fixes of the aircraft's position made by a master and two slave radio stations on the ground, registers and transmits to the pilot his position and progress from moment to moment. Both systems are of reasonable accuracy up to medium distances.

The system of control of aircraft on the airways varies somewhat between different countries and regions but is similar in its general principles in all areas having a considerable flow of air traffic. Since the United States is a large, homogeneous aviation area with a highly developed airways network, it is convenient to use its system as a fair illustration of the methods in operation.

The whole territory has been divided into air traffic control segments. In each segment a centre has been established known as the Air Route Traffic Control centre (ARTCC) from which traffic operating in poor visibility, under what are known as instrument flight rules (IFR), is controlled. Pilots flying by IFR report to and receive instructions from these centres at specific times from a series of geographical positions listed on their flight plans filed at the airports from which they began their flights. In these reports they state their positions and the weather conditions they are experiencing. In this connection it may be noted that in good weather flights may take place under visual flight rules (VFR) which, simply stated, specify that pilots use the ground for reference and keep an alert watch for other aircraft in the air.

When traffic reaches an approximate 30-mi. radius of a terminal area the Air Route Traffic Control centre transfers control to the airport traffic control tower.

At strategic points along the airways are situated Flight Service stations that form a link between air traffic controllers and pilots in flight. The stations provide traffic, weather and airport information, by telephone, radio or personal contact, and also relay traffic control information when requested to do so.

These three types of facilities—centres, towers and stations—are joined by thousands of miles of teletype and interphone lines and work closely with one another to maintain a safe and orderly flow of traffic on the airways.

Where the density of air traffic is low and the areas covered are large, as for instance over the open sea or wide deserts, the airspaces traversed are organized on an area basis.

For instance, at New York International airport, the ARTCC operates an oceanic sector. One area of its control extends northward to Gander, Nfd., where the Canadian government takes over and controls traffic to a point approximately 1,200 mi. across the Atlantic. From there until it reaches Europe, traffic is under control of the Shannon and Prestwick stations operated by Ireland and Great Britain, respectively. Directly east of New York, at a point about 1,000 mi. out, the Santa Maria station in the Azores, operated by Portugal, takes responsibility for oceanic traffic until it reaches the European mainland, where it is transferred to local control.

Locations of control areas are determined by the flow of traffic, and their sizes by the effective range of the communications and navigational facilities serving them. Away from the coast lines there are no visual aids and control is maintained and information transmitted by two-way radio/telephone.

AIRY, SIR GEORGE BIDDELL (1801–1892), British astronomer, the seventh astronomer royal, who discovered an inequality in the motions of Venus and Earth and reorganized Greenwich observatory, was born at Alnwick, Northumberland, on July 27, 1801. He was educated at Colchester grammar school and at Trinity college, Cambridge, where he graduated as senior wrangler

in 1823. He became a fellow of his college (1824), Lucasian professor of mathematics (1826) and then (1828) Plumian professor of astronomy and director of the new Cambridge observatory. Before long a mural circle was installed, and regular observations were instituted with it in 1833.

In the same year the duke of Northumberland presented the Cambridge observatory with a fine object glass of 12-in. aperture, which was mounted according to Airy's designs. Airy's writings during this time were divided between mathematical physics and astronomy. The former were for the most part concerned with questions relating to the theory of light, arising out of his professional lectures. Of his astronomical writings during this period the most important are his investigation of the mass of Jupiter and his memoir *On an Inequality of Long Period in the Motions of the Earth and Venus*.

Airy's discovery of a new inequality in the motions of Venus and Earth was a remarkable achievement. In correcting the elements of J. Delambre's solar tables he discovered an inequality overlooked by their constructor. Eight times the mean motion of Venus is so nearly equal to 13 times that of Earth that the difference amounts to only $\frac{1}{240}$ of Earth's mean motion, and from the fact that the term depending on this difference, although very small in itself, receives in the integration of the differential equations a multiplier of about 2,200,000, Airy was led to infer the existence of a sensible inequality extending over 240 years. The investigation leading to this result was probably the most laborious that had been made up to Airy's time in planetary theory, and represented the first specific improvement in the solar tables effected in England since the establishment of the theory of gravitation.

In June 1835 Airy was appointed astronomer royal in succession to John Pond. Under Airy's administration modern apparatus was installed, and the whole organization was placed on a scientific footing. No fewer than 8,000 lunar observations were rescued from oblivion and were, in 1836, placed at the disposal of astronomers in such a form that they could be used directly for comparison with the theory and for the improvement of the tables of the moon's motion. (See HANSEN, PETER ANDREAS.)

One of the most remarkable of Airy's researches was his determination of the mean density of the earth by means of pendulum experiments at the top and bottom of a deep mine. After some failures, successful experiments were made at the Harton pit, near South Shields, Durham, in 1854. Their immediate result was to show that gravity at the bottom of the mine exceeded that at the top by $\frac{1}{238}$ of its amount, the depth being 1,256 ft. From this Airy was led to the final value of 6.566 for the mean density of the earth as compared with that of water. At the age of 71 Airy embarked on a new method of treating lunar theory. It consisted essentially in the adoption of C. Delaunay's final numerical expressions for longitude, latitude and parallax, with a symbolic term attached to each number, the value of which was to be determined by substitution in the equations of motion. The work was published in 1886, when its author was 85 years of age. In 1881 Sir George Airy resigned the office of astronomer royal. He died at Greenwich on Jan. 2, 1892. The learned societies of his own and other countries conferred many honours on him.

See W. Airy (ed), *Autobiography of G. B. Airy* (1896).

'A'ISHA (AYSHAH, AYESHA, BIXT ABI BAKR) (c. 614–678), wife of Mohammed, the founder of Islam, who after his death became an authority on his life and sayings and those of some of his companions, was born in Mecca, Arabia, about 614. Her father, Abu Bakr (q.v.), supported Mohammed. 'A'isha became Mohammed's child wife and favourite, whom he usually defended against political critics and harem rivals. She was a childless widow at 18, and Mohammed's widows, called "mothers of the believers" were not permitted to remarry. 'A'isha used her energies in family and social activities during the strong caliphates of her father and of Omar I. When reformers demanded the abdication of the weak and aged caliph Othman, 'A'isha intrigued, hoping to regain the caliphate for her family. However, the extremists in Medina demanded Othman's death, and 'A'isha withdrew to Mecca and into a

questionable neutrality. Othman was assassinated and Ali ('Ali ibn Abi Talib), Mohammed's cousin and husband of his daughter Fatima (*q.v.*), won the succession. 'A'isha held Ali responsible for Othman's death, which she proposed to avenge. In the civil war that followed, 'A'isha's army was defeated near Basra in 656 in the battle of the Camel, so called after her mount. 'A'isha herself was captured but was released by Ali after promising to refrain from politics. She kept her promise, though her influence continued to be sought. Her oral statements and public speeches were later put into writing. She died on 17 Ramadan. A.H. 58 (July 13. 678). She is venerated by all Muslims, though her opposition to Ali is still resented by his followers, the Shi'ahs.

See Nabia Abbott, *Aishah, the Beloved of Mohammed* (1942).

(N. A.)

AISLE, in architecture, a term originally meaning the wing of a house, but more commonly used to indicate any long, narrow space separated from the remainder of the building by a line of piers: columns or arches. It is specially used to designate the side portions of a church or other large room in which interior supports occur. The term also has come to mean a passageway, especially a passageway between groups of seats, as in a church or theatre.

From the time of the early Christian basilica, the use of one or more side aisles flanking a central nave has been almost universal in church building, and church aisles are known as nave aisles, transept aisles or choir aisles from their position in relation to the nave, transept or choir. The choir aisle around the east end of a church is known as an ambulatory. In the normal Romanesque or Gothic church the roof of the aisles is lower than the central nave; but in certain examples in southern France (*e.g.*, St. Nazaire, Carcassonne), in Spain (*e.g.*, Barcelona) and especially in Germany, where for the smaller churches it is almost normal, the nave and aisles are of the same height. A church with nave flanked by one aisle on each side is known as a three-aisle church; one with two side aisles on each side as a five-aisle church, and so on.

AISNE, a *département* of northern France. Pop. (1954) 487,068. Area 2,868 sq.mi. It touches the western end of the Ardennes (930 ft.) in the northeast, but its surface is all of younger sedimentary rocks. Outlying masses of rock, often with steep flanks, form important sites such as that of Laon, the capital, and the famous Chemin des Dames. The Aisne river enters the *département* from the east just as it leaves the chalk scarp and flows west to the Oise (*q.v.*), the other river of the *département* which has been canalized to include the deep Château-Thierry portion of the Marne valley, too far west to focus on Épernay or Reims and allied to the hill country farther north rather than to Paris on the west.

The *département* had a number of forests before World War I, when it was the scene of much fighting, but it lacks metallic ores, though quarries yield building stone, gypsum and clay. Mostly in the belt of rainfall 20–30 in. and well watered and sheltered, it contains rich cornlands in the south and west, with specialization in dairying toward the northeast in Thiérache.

Of the towns, Guise in the north is an agricultural and industrial centre and St. Quentin and numerous villages are well known for weaving of cotton, wool and silk. St. Gobain has made mirrors since the 17th century. Beet sugar has been an important crop and industry. There are good communications by rail and by navigable rivers (Aisne, Oise, Marne). Laon, Soissons (*qq.v.*), St. Quentin and Vervins give their names to *arrondissements* and are, with Château-Thierry (*q.v.*) and Hirson, the chief towns. This *département* and that of Oise were rich in architectural monuments; several of which were ruined in World War I, but the churches at Laon, Braine and Urcel (mainly 12th century) survived and the splendid *basilique* of St. Quentin was largely repaired, while the castle ruin (1400) of La Ferté-Milon did not suffer.

Soissons was made the seat of a bishop in the province of Reims. The *département* was placed in the educational province (*académie*) of Douai (*q.v.*).

The German offensive launched on May 27, 1918, against the Chemin des Dames ridge is sometimes referred to as the battle of

the Aisne (*see* CHEMIN-DES-DAMES, BATTLE OF THE). Historical aspects may also be found in ÎLE-DE-FRANCE, PICARDY and CHAMPAGNE, the old provinces of France, parts of which comprise Aisne.

(AR. E. S.)

AÏSSÉ (Turkish AISHA; also called HAÏDÉE), MADEMOISELLE (*c.* 1694–1733), a Circassian girl distinguished in French literary history. Purchased as a slave in Istanbul by Charles de Ferriol, ambassador to Turkey, she was sent by him to France in 1698 to be educated by his brother's wife, a sister of Mme de Tencin (*q.v.*). Returning to France in 1711, Ferriol kept her as his mistress until his death in 1722. Meanwhile, however, she had made the acquaintance not only of literary people, including Voltaire, Fontenelle, Montesquieu, Mme du Deffand and, especially, Lord Bolingbroke, but also of the chevalier Blaise Marie d'Aydie, with whom she fell in love. She bore him a daughter secretly in 1721, but in 1727 refused his proposal of marriage. She died in Paris on March 13, 1733.

Aïssé's letters to Mme Calandrin (née Julie de Pellissary, an aunt of Bolingbroke's wife) provide valuable insights on the society in which she moved and give a moving analysis of her love and her anguish of conscience at its illicit nature. First printed in 1787, they were reprinted many times; *e.g.*, by E. Asse. *Lettres du XVIIIe et du XVIIIe siècle* (1873).

BIBLIOGRAPHY.—Mrs. Campbell Praed. *The Romance of Mademoiselle Aïssé* (1910); H. Courteault, *Mlle Aïssé . . .* (1908); J. d'Ivray, *L'Étrange Destin de Mademoiselle Aïssé* (1935).

AISTULF (d. A.D. 756), king of the Lombards from 749 to 756, whose revival of the expansionist policy of King Liutprand led to the first important Frankish interventions in Italian and papal affairs (*see* ITALY: *History*; LOMBARDS; PAPACY). Having conquered the exarchate of Ravenna by 751, Aistulf turned against the duchy of Rome and in 753 was threatening Rome itself. As the Byzantine emperor gave no effective help, Pope Stephen II appealed to Pepin, king of the Franks. In 754, having failed to defeat the Frankish army at its entry into Italy near Mt. Cenis, Aistulf was besieged in Pavia. He promised to restore the conquered territories. After the Franks had left the country, however, he resumed his aggressive policy, and in Jan.–April 756 laid siege to Rome. A fresh appeal by the pope led to a second Frankish intervention. Again besieged in Pavia, Aistulf promised to pay an annual tribute to the Frankish king and did surrender his conquests, which Pepin, in accordance with promises made in 754, handed over to the pope. Aistulf died shortly after, in Dec. 756.

(N. R.)

AITKEN, ROBERT GRANT (1864–1951), C.S. astronomer, who was an authority on double stars, was born in Jackson, Calif., on Dec. 31, 1864. Aitken was educated at Williams college, Williamstown, Mass., from which he graduated in 1887, and received his M.A. in 1892. From 1888 to 1891 he was instructor of mathematics in Livermore college, and 1891–95 was professor of mathematics and astronomy in the College of the Pacific, Stockton, Calif. In 1895 he was appointed astronomer at Lick observatory, Mt. Hamilton, California, of which he was director 1930–35. There he specialized in the study of double stars, of which he discovered more than 3,000. For these discoveries, he was awarded in 1906 the Lalande prize by the Academy of Sciences of France and, in 1932, the gold medal of the Royal Astronomical society. He published *Binary Stars* (1918) and *New General Catalogue of Double Stars* (1932). He died Oct. 29, 1951.

AIX-EN-PROVENCE, a city of southeast France, in the Bouches-du-Rhône *département*, 19 mi. N. of Marseilles by road. Pop. (1954), 38,985. It is situated in a plain overlooking the Arc river about a mile from the right bank. The roads from the north of France to Italy and from Marseilles to the Alps cross there. It is the seat of an archbishop.

The Cours Mirabeau, a tree-lined avenue, divides the newer southern part of the town from the older northern part. Among the many ancient buildings are the 11th–13th century cathedral of St. Saviour with its triptych, the "Burning Bush," by Nicolas

Froment; the 13th-century church of St. John of Malta containing the tombs of the counts of Provence; and the 17th-century church of St. Mary Magdalene. The *hôtel de ville* (17th century) contains fine woodwork and a large library with valuable old manuscripts. There are many fountains and fine old houses. The Granet is the best known of several museums. Aix-en-Provence is one of the largest university centres in France and is the seat of Aix-Marseilles university.

Aix, which is served by the Marseilles-Grenoble railway, is a tourist centre and has hot mineral springs, which are recommended for diseases of blood circulation. The springs contain lime and carbonic acid. The best known is the Sextius spring.

The town is an important agricultural centre and has a market for olive oil and almonds. Its industries are the manufacture of jams, preserved fruits, sugared almonds, burnt almonds and some local cake specialities, calissons and *biscotins*.

When Gaul was conquered by the Romans, the proconsul Sextus Calvinus, built a vast entrenched camp called Aquae Sextiae in the valley of the Arc about 123 B.C. There was fought the battle of Aix in 102 B.C. in which Marius routed the Teutones. Augustus Caesar made Aix a Roman colony, and in the 4th century it was the metropolis of Narbonensis Secunda. Occupied by the Visigoths in 477, and repeatedly plundered by Franks and Lombards, it was taken by the Saracens in 731. During the middle ages it was the capital of Provence (*q.v.*), governed by the counts and dukes of Anjou, of whom the most famous was René (1409–80), and reached its zenith after the 12th century when the houses of Aragon and Anjou made it a centre of art and learning. It became a university city in 1409 and passed with Provence to the crown in 1486, becoming the seat of *parlement*. It suffered from the wars of Charles V, the religious wars and the plague, yet remained a centre of political and intellectual activity in Provence until the 19th century. (P. Y. B.)

AIX-LA-CHAPELLE: see AACHEN.

AIX-LA-CHAPELLE. CONGRESSES OF. Three congresses or peace conferences have met at Aix-la-Chapelle (Aachen, Ger.)—in 1668, in 1748 and in 1818.

1. The treaty of May 2, 1668, which ended the War of Devolution, was the outcome of that of St. Germain signed on April 11 by France and the representatives of the triple alliance. The treaty of Aix-la-Chapelle left to France all the conquests made in Flanders during 1667, with all their appurtenances, *dépendances* et annexes, a vague provision of which, after the peace of Nijmegen (1680), Louis XIV took advantage to occupy villages and towns adjudged by him by his *Chambres de réunion* as dependencies of the cities and territories acquired in 1668. On the other hand, France restored to Spain Cambrai, Aire and St. Omer, as well as Franche Comté. The treaty of Aix-la-Chapelle was placed under the guarantee of England, Sweden and Holland, by a convention signed at The Hague on May 7, 1669, to which Spain acceded.

2. On April 24, 1748, a congress assembled at Aix-la-Chapelle to end the War of the Austrian Succession. The definitive treaty was signed on Oct. 18. Its most important provisions were those stipulating (a) a general restitution of conquests, including Cape Breton to France, Madras to England and the barrier towns to the Dutch; (b) the assignment to Don Philip of the duchies of Parma, Piacenza and Guastalla; (c) the restoration of the duke of Modena and the republic of Genoa to their former positions; (d) the renewal in favour of Great Britain of the Asiento contract of March 16, 1713, and of the right to send an annual vessel to the Spanish colonies; (e) the renewal of the article of the treaty of 1718 recognizing the Protestant succession in the English throne; (f) the recognition of the emperor Francis and the confirmation of the pragmatic sanction, *i.e.*, of the right of Maria Theresa to the Habsburg succession; (g) the guarantee to Prussia of the duchy of Silesia and the county of Glatz (Kłodzko).

The treaty was supplemented by that of Madrid (Oct. 5, 1750), by which Great Britain surrendered the Asiento right for a sum of £100,000. It left the main colonial disputes between Britain and France unsettled and Habsburg counterpoise to French power in Europe as effective as before the war.

3. The congress of Aix-la-Chapelle in 1818 was primarily a

meeting of the four allied powers—Great Britain, Austria, Prussia and Russia—to decide the question of the withdrawal of the army of occupation from France and the consequent international relationships of the powers. The congress, which opened on Oct. 1, was attended by Alexander I of Russia, Francis I of Austria and Frederick William III of Prussia. Great Britain was represented by Lord Castlereagh and the duke of Wellington, Austria by Prince Metternich, Russia by Counts G. A. Capo d'Istria and Karl Vasilievich Nesselrode, Prussia by Prince Karl August von Hardenberg and Count Christian Günther Bernstorff. The duc Armand Emmanuel de Richelieu was present on behalf of France.

The evacuation of France was agreed to in principle at the first session, the consequent treaty being signed on Oct. 9. The rest of the time of the congress was mainly occupied in discussing the form to be taken by the European alliance against a fresh outburst on the part of France. The proposal of Alexander I, to establish a "universal union of guarantee" on the broad basis of the Holy alliance, broke down on the opposition of Great Britain; and the main outcome of the congress was the signature, on Nov. 11, of two instruments: (a) a secret protocol confirming and renewing the quadruple alliance established by the treaties of Chaumont and Paris (Nov. 20, 1814) against France; (b) a public "declaration" of the intention of the powers to maintain their intimate union, of which the object was to preserve peace on the basis of respect for treaties.

The congress also concerned itself with the questions of the suppression of the slave trade and the Barbary pirates. In neither case was any decision arrived at, because the other powers refused to agree with the British proposal for a reciprocal right of search on the high seas, and Great Britain objected to international action, which would have involved the presence of a Russian squadron in the Mediterranean. A great variety of lesser questions was considered. The congress represents the restoration of France to the status of a great power, and the highest point reached in the attempt to govern Europe by an international committee of the powers.

AIX-LES-BAINS, a thermal spa and fashionable resort in eastern France, in the *département* of Savoie, lies 9 mi. N. of Chambéry along the Lac du Bourget at the mouth of a gap in the Préalpes used by the Mt. Cenis route to Italy. Pop. (1954) 12,799. The sulfur and alkaline springs have been used since Roman times, and there are the remains of Roman baths. The local museum lies within the site of a Roman temple. The tourist station on Mt. Revard at 4,578 ft., reached by aerial cableway, offers a fine panorama, and the lake and beach add to the amenities that attract many summer visitors; situated at the entry to the Alps, Aix also serves as a base for winter sports. (AR. E. S.)

AJACCIO, the capital of Corsica (*q.v.*), lies on the west coast of the island. Behind the sandy beaches of Ajaccio bay the land rises up to the snow-covered Monte d'Oro (7,844 ft.) Pop. (1954) 28,732. It is the seat of a bishopric. The harbour to the east is protected on the south by a peninsula, where the citadel (1551) is situated. On the base of the peninsula is the old part of the town. Ajaccio is the birthplace of Napoleon and the association is emphasized by street names and statues. The *Maison Bonaparte*, where he was born, has been turned into a museum with many personal relics. The town hall has another Napoleon museum. The cathedral was completed in 1593 and its magnificent high altar came from Lucca, the gift of a sister of Napoleon. The Fesch palace contains a library and an art gallery. Apart from a few boulevards, Ajaccio has narrow streets. It is linked with the mainland of France by sea and from Campo del Oro (5 mi.) air services connect it with France, north Africa and London, while railways and highways run to other parts of the island. It is a tourist centre, having a mild winter and a hot summer climate.

There are fetes, carnivals, horse racing and a regatta.

Macaroni, sails and a liqueur of citron and myrtle are manufactured in the town and there is shipbuilding. Timber, pit props, briar pipes, planks, dried fruit and almonds are exported.

The original Roman settlement of Ajax lay about 2 mi. N. of the present site, to which the town was transferred by the Genoese in 1492. Occupied in 1553 by the French, it again fell to the Genoese after the treaty of Cateau Cambresis in 1559. The town finally passed to the French in 1768. In 1793 Corsica was divided into two *départements*, Golo and Liamone, Ajaccio becoming the capital of Liamone. In 1811 Corsica became a single *département* with Ajaccio as its capital. (F. P.E.)

AJANTA, a village in Aurangabad district, Maharashtra state, India, celebrated for its Buddhist caves and wall paintings. The site is reached by road, either from Jalgaon on the Delhi-Bombay main railway line (58 mi.) or from Aurangabad on the Manmad-Secunderabad metre-gauge line (66 mi.). The caves lie in a wooded and rugged ravine about 3½ mi. from the village. The ravine is that of the Wagura river, a tributary of the Tapti, which falls from the east over a bluff forming several waterfalls. There are about 30 caves excavated in the precipitous south side of the ravine. They are of two types, viharas (monasteries) and chaityas (meeting halls). The viharas reflect the plan of structural monasteries throughout India and essentially consist of a square hall surrounded by cells on three sides. The front has a broad veranda. In the back wall was placed a shrine which gradually came to dominate the structure. The chaityas are oblong with apsidal ends and pillared aisles. A stupa or dome-shaped memorial shrine was set in the centre of the apse. The oldest caves probably date from the 1st century B.C.—A.D. to the 3rd century. A second important group dates from the 6th–7th centuries. These contain inscriptions of the Vakataka dynasty of Berar (*q.v.*), the contemporaries of the Gupta dynasty of north India. The caves are unique in India for the quantity and quality of their fresco paintings. The earliest are thought to belong to the 1st or 2nd century A.D. but the majority are of the 6th–7th centuries. Strictly they are not frescoes, in that the surface was prepared with a cow-dung plaster and finished with white gypsum on which the paintings were done. Although many of them were in decay when discovered they have now been carefully conserved and form an important record of the wall-painting techniques and life of medieval India. See INDIAN ART; see also Index references under "Ajanta" in the Index volume.

AJAX, the name of two figures in Greek legend.

1. **AJAX THE GREATER**, son of Telamon, king of Salamis, is described in the *Iliad* as being of great stature and colossal frame, second only to Achilles in strength and bravery. He engaged Hector in single combat and, with the aid of Athena, rescued the body of Achilles from the hands of the Trojans. In the competition between him and Odysseus for the armour of Achilles, Agamemnon, at the instigation of Athena, awarded the prize to Odysseus. This so enraged Ajax that it caused his death. According to a later story, accepted by Sophocles as the basis of his drama, Ajax' disappointment drove him mad. He rushed out of his tent and fell upon the flocks of sheep in the camp under the impression that they were the Greeks; on coming to his senses he slew himself with the sword that he had received as a present from Hector. From his blood sprang a red flower (see *HYACINTHUS*), which bore on its leaves the initial letters of his name, AI, also expressive of lament. He was the tutelary hero of the island of Salamis, where he had a temple and an image and where a festival called Aiantea was celebrated in his honour (described by Pausanias).

2. **AJAX THE LESSER**, son of Oileus, king of Locris, was called the Lesser or Locrian Ajax to distinguish him from the son of Telamon. In spite of his small stature, he held his own among the other heroes before Troy; he was brave, next to Achilles in swiftness of foot and famous for throwing the spear. But he was boastful, arrogant and quarrelsome. Voyaging homeward, his ship was wrecked, but Ajax was saved by a rock. Boasting of his escape he

was cast by Poseidon into the sea and drowned. For his crime (not definitely mentioned by Homer) of dragging Cassandra from the statue of the goddess Athena, during the sack of Troy, and violating her, he barely escaped being stoned to death by his Greek allies. In addition, a plague fell upon the Locrians. Following an oracle they undertook 1,000 years' penance (which was still being observed in early Christian times) by which they sent yearly two girls chosen by lot to serve in the temple of Athena at Troy.

Ajax was worshiped as a national hero by the Opuntian Locrians (on whose coins he appeared), who always left a vacant place for him in their battle line.

'AJLUN, a town and district of the Hashemite Kingdom of Jordan. The town is situated on the mountains overlooking the Jordan valley a few miles west of Jarash. The district has an area of 1,313 sq.mi. and includes the subdistricts of Irbid, Jarash, Kura and Mafrag. Pop. (1959 est.) town 3,098; district 270,446. The town has an interesting early mosque with a square minaret, and on the mountain top to the west is the Arab castle called Qalat al-Rabadh, built by Aus al-Dyn Ausama, cousin of Saladin, in 1184 and enlarged in the 13th century. (G. W. L. H.)

AJMER (AJMERE; AJMIR), a large city in Rajasthan state, India, and the administrative headquarters of the district of the same name, is 275 mi. S.W. of Delhi on the Western railway. The population of Ajmer in 1901 was 73,839 and by 1951 it had risen to 196,633, making it the second largest city of Rajasthan (second only to Jaipur). It is on the lower slopes of Taragarh hill (3,000 ft.) in the Aravalli range. To the north of the city is a large artificial lake called the Ana Sagar constructed in the 11th century, and farther up the valley is a new lake, the Foy Sagar, from which the water supply of the city is derived.

The chief object of interest is the dargah, or tomb, of the famous Muslim saint Muin-ud-din Chishti (d. 1235). It consists of a group of white marble buildings without much pretension to architectural beauty. An ancient Jain temple, converted about A.D. 1200 into a mosque, is also on the lower slope of the hill. Although, with the exception of that part used as a mosque, it is largely in ruins, the architectural and sculptural remains are of considerable beauty. The summit of the hill is crowned by a fort, two miles in circumference, which can be approached only by steep, roughly paved paths.

The modern city is an administrative and railway centre. It is well laid out with wide streets and handsome houses, and does an active trade in salt, which is imported in large quantities from the Sambar lake (45 mi. N.E.) and Ramsur. The extraction of vegetable oil is also a profitable trade. Cotton cloths are manufactured to some extent, for the dyeing of which the city has attained a high reputation. The educational institutions include the Mayo Rajkumar college, opened in 1875 for training the sons of the nobles of Rajputana on the lines of an English public school, and five of the colleges of Rajasthan university, of which two are for women.

Seven miles west of Ajmer lies the lake of Pushkar, one of the most sacred pieces of water in India, where a pilgrim fair is held every autumn and where is found almost the only temple dedicated to Brahma in India.

AJMER STATE (called AJMER-MERWARA before 1950) was formerly administered by the government of India through a chief commissioner. It was divided into two isolated tracts, the larger comprising the subdivisions of Ajmer and Merwara; the smaller, to the southeast, being the Kekri subdivision. Of the Hindus, the Rajputs are largely landholders and the Jats and Gujars cultivators. The Jains are traders and moneylenders. The aboriginal Mers are partly Hindu, partly Muslim. The state became the Ajmer district of Rajasthan in 1956. Area 3,283 sq.mi.; pop. (1961) 976,375.

The distinguishing feature of the district is the Aravalli range (*q.v.*), running northeast-southwest between Ajmer and Nasirabad and marking the watershed of northern India. The district is on the border of the arid zone and the soil is generally sandy. The

main crops are maize, millet, barley, cotton, oilseeds, wheat, chillies and onions; but Ajmer is not self-supporting in foodstuffs. There are cotton, textile and hosiery mills and factories for ginning and pressing cotton. Beawar and Kekri are the chief trading centres. Mica, steatite, beryl and asbestos quarries are worked. Ajmer city is connected by rail with Ahmedabad and Delhi.

Ajmer was founded by a Chauhan ruler, Ajayadeva, about the end of the 11th century A.D. It became an appanage of the crown of Delhi in 1193. Its internal government, however, was handed over to its ancient rulers upon the payment of a heavy tribute to the conquerors. It acknowledged the suzerainty of Delhi till 1365, when it was captured by the ruler of Mewar. Akbar took it back in 1556; and it continued in the hands of the Moguls, with occasional revolts, till 1770 when it was ceded to the Marathas, from which time up to 1818 the unhappy country was the scene of a continual struggle, being seized at different times by the Mewar and Marwar rajas, from whom it was so often retaken by the Marathas. In 1818 the latter ceded it to the British in return for a payment of Rs. 50,000. (C. C. D.; S. G. L.; S. M. T. R.)

AKAN. The Akan are peoples who speak languages of the Twi branch of the Kwa subfamily of the Western Sudanic linguistic stock. These languages include Ahanta, Akwapim, Akyem, Agni, Asante, Asen, Bono, Brusa, Chakosi, Fante, Guan, Kmahu, Nzima and Wasa. The Akan inhabit the eastern part of Ivory Coast, the southern half of Ghana and parts of Togo. Only the Chakosi live in north Ghana, in the Dagomba district. The majority are in Ghana, where they settled in successive waves between the 11th and 18th centuries. The most powerful Akan states were Bono, Denkeria, Akwamu, Akim and the Ashanti (*q.v.*) and Fanti (*q.v.*) confederacies which developed in the 17th and 18th centuries.

The Akans have certain common institutions. The basis of their social and political organization is the lineage of maternal kinsmen, in which inheritance and succession are based on matrilineal descent. A tribe consists of several lineages which form a political unit under the chief, elected from one of the lineages, and a council of elders, each of whom is the elected head of a constituent lineage. Besides public offices, land tenure is also vested in the lineage.

The tribes are grouped into clans. Most accounts give seven: Aduana, Agona, Asenee, Asona, Bretuo, Ekona and Oyoko; but some count localized matrilineages and give more than these. Clans were exogamous and matrilineal, the members being united by belief in a common descent from a remote ancestress.

Though succession to property and public office is based on matrilineal descent, the Akan peoples recognized paternal descent also. Everyone belonged to one of a dozen Ntoro groups: Bosomafi, Bosomafam, Bosomafan, Bosomayesu, Bosomdwerebe, Bosomkansi, Bosomkrete, Bosommuru, Bosompo (or Nketia), Bosompri, Bosomsika, Bosomtwe—membership of which derived from one's father. Common taboos, surnames, forms of etiquette and ritual lustrations linked members of the same Ntoro. Among some Akan peoples, such as the Fanti, there were also quasi-military groupings based on paternal descent.

The Akan have common religious beliefs and practices based on belief in a supreme deity who created the universe, in lesser deities who derive their power from the supreme deity and in spirits who have their abode in shrines, trees, rivers or rocks. But the most prominent aspect of Akan religion is the worship of ancestors. Periodical rites in which ancestors are commemorated are the most powerful sanctions of tribal unity and morality. The Akan are thus linked by bonds of language, social institutions and religion.

(K. A. Bu.)

AKBAR (JALAL-UD-DIN MOHAMMED) (1542–1605), the greatest of the Mogul emperors in India, was born in Oct. or Nov. 1542 at Umarkot in Sind when his father, Humayun, driven from the throne of Delhi by the Afghan usurper Sher Shah, was escaping to Iran. It was not until 1555 that Humayun undertook to reconquer

Hindustan and when he died in 1556 the Mogul empire was still only an idea. On succeeding his father, Akbar first overthrew all rivals, the chief of them being the Hindu minister Hemu, defeated at Panipat on Nov. 5, 1556. Akbar then embarked upon a career of conquest. By 1562 his kingdom embraced the Punjab and Multan, the basin of the Ganges and Jumna rivers from Panipat to Allahabad, Gwalior in central India, Ajmer and, in Afghanistan, the province of Kabul. Another 14 years of warfare resulted in the conquest of Malwa, Chitor, Ranthambhor, Kalinjar, Gujarat and Bengal. Between 1586 and 1595 he added Kashmir, Sind, Baluchistan, Kandahar and parts of Orissa to his dominions. With his power firmly established in the north he then crossed the Narbada river into the Deccan and annexed Khandesh, Berar and parts of Ahmednagar. By 1605 his empire comprised 15 subahs (provinces) and stretched from the Hindu Kush to the Godavari river and from Bengal to Gujarat.

Akbar did more than achieve Mogul political hegemony in northern India; he stabilized and prolonged it by giving it a framework of administrative and military institutions and a foundation of political and social principle. Moreover, he provided the inspiration as well as the opportunity for the burgeoning of a remarkable synthetic Mogul culture extending over art, architecture, literature, history, gastronomy, dress and pastimes, which dominated the imagination and engaged the sympathies of Indians of diverse communities until the 19th century. His system of provincial administration, still discernible in modern India and Pakistan, and drawn in its details from the experience of nearly 400 years of Muslim rule was based on the subah, sarkar (district), pargana and mahal (revenue division), the principal executive officers (whether financial or military) being appointed and transferred frequently from the centre.

Under vigorous management, such as Akbar himself provided, the military system of recruiting cavalry by *mansabdars* (imperial officers) provided an army loyal, effective and large enough for Indian conditions before the 18th century. The reform of the traditional method of land revenue collection, by which the state's demand for one-third of the gross produce was commuted into a cash payment scientifically assessed by reference to average local prices and yields, provided Akbar with the resources that his schemes of conquest required, without oppressing the cultivator.

Akbar deliberately founded his empire on an understanding with the Hindu Rajputs and on respect for Hindu religion and culture. In 1562 and 1570 he married Rajput princesses. He conferred important *mansabs* upon Rajput chiefs and appointed some to high positions in revenue departments. He set his face against a militant orthodox Islam by formally abolishing, in 1564, the *jizya* or poll tax on non-Muslims and by rescinding the taxes previously levied on Hindu pilgrims. He discouraged cow slaughter, participated in Hindu festivals and encouraged the study of Sanskrit classics, ordering their translation into Persian.

In his own personal religious life, too often regarded as purely opportunistic politically, Akbar stood at the confluence of many contemporary streams of thought, all militating against a strict Sunni orthodoxy and in favour of toleration. The famous *mahzar* or "declaration" of 1579, to which a group of religious scholars at his court subscribed, allowed Akbar certain powers of religious interpretation as a mujtahid of Islam in matters not already explicitly covered by a clear scriptural text or by agreement among the religious scholars (only ignorance of the character of religious authority in Islam or of the text itself, however, could suggest that the *mahzar* conferred "papal" powers on Akbar). In 1575 Akbar built an *ibadat-khana* (house of worship) at Fatehpur-Sikri in which Muslims of many hues, Jesuit fathers from Goa, Zoroastrians, Hindu pandits and yogis, discussed religion aith Akbar himself. After 1582 he and his mentors at court formulated the *tauhid-i-ilahi* or divine monotheism compounded of ideas from Sufism and observances from Zoroastrianism, with Akbar himself as the adherents' *pir* or spiritual leader. Akbar did not compel adherence to his beliefs in the empire at large. As a sincere seeker after God and as a ruler, he would not have been true to himself had he acted otherwise. Akbar died at Agra on Oct. 16, 1605. See INDIA: *History*; see also Index references under "Akbar" in the

Index volume.

AKEE, the West African name of a small tree (*Blighia sapida*) of the soapberry family (Sapindaceae), native to Guinea, and also of its important food fruit. Introduced in 1778 into Jamaica, which exports the fruit, its cultivation has spread throughout most of tropical America. The shrublike, stiff-branched tree, sometimes 20 ft. to 30 ft. high, bears handsome red or orange coloured fruits, about 3 in. long, in small clusters at the tips of slender branches. The fruit, which is a soft-walled capsule, splits when ripe into three sections, from apex to base, displaying round, shining, black seeds, attached to the base by large whitish or yellowish fleshy arils. When cooked the arils bear a resemblance to a fine omelette both in taste and in appearance. Ripe fruit may be eaten fresh by most persons without producing any untoward effects; unripe and overripe akees, however, may be decidedly unwholesome and even poisonous.

AKELEY, CARL ETHAN (1864-1926), U.S. naturalist, was noted for his taxidermy and sculpture of African big game, and for advances in museum methods helping to usher in a new era in exhibition—that of big habitat groups showing animals in natural surroundings. Born May 19, 1864, in Orleans county, N.Y., he served an apprenticeship in Ward's Natural Science establishment, Rochester, N.Y. During his productive years he was associated with the Chicago Natural History museum (1895-1909) and the American Museum of Natural History, New York city (1909-26). He wrote *In Brightest Africa* (1923).

The big game of Africa fascinated him, and he made five trips there to study and to collect living animals. He once killed barehanded an attacking leopard and another time was badly mauled by an elephant. He died Nov. 17, 1926, and was buried on Mt. Mikeno in Parc National Albert in central Africa, a sanctuary especially for gorillas, the establishment of which was one of the goals of the conservation-minded Akeley.

He devised a method of mounting big mammals by applying the skin to a finely modeled manikin, giving realistic results never before approached, which helped gain support for his vision: a panorama of Africa and its big game in U.S. museums.

His modeling led to sculpturing, with notable pieces showing elephants, lions and Nandi lion-spearers. Inventions that grew out of his work include the Akeley cement gun, from modeling, and the Xkeley camera, from field photography.

See Akeley Memorial Number, *Nat. Hist.*, N.Y., vol. 27, no. 2, pp. 115-179 (1927). (A. L. RD.)

AKENSIDE, MARK (1721-1770), English poet and physician best known for his philosophical poem *The Pleasures of Imagination*, was born at Newcastle-upon-Tyne on Nov. 9, 1721. He went to Edinburgh university, intending to become a minister, but began to read medicine. His training was completed by a brief stay in Leyden in April and May 1744. His first poem, "The Virtuoso," a Spenserian imitation, appeared in the *Gentleman's Magazine* in 1737, and in 1738 he published *A British Philippic . . . Occasioned by the Insults of the Spaniards and the Preparation for War*. In 1744 his most celebrated work, *The Pleasures of Imagination*, appeared in three books. Akenside subsequently added a fourth book and extensively revised the poem, and his final version appeared in his collected *Poems* (1772) with the title *The Pleasures of the Imagination*. The work is an eclectic philosophical essay which takes as its starting point Joseph Addison's papers on the same subject in the *Spectator*. It is in Miltonic blank verse, and according to Akenside's preface he used Virgil's *Georgics* and Horace's *Epistles* as models. The influence of the *Georgics* is clear in the studied elevation of the language and the skill with which Akenside evolves a poetic style suitable for a subject not in itself poetical. There is, *mutatis mutandis*, something of the pleasure which Addison distinguishes as characteristic of the Georgic in Akenside's work, namely watching the poet "toss the dung about with an air of gracefulness," perceiving in this case how he endows the abstractions of philosophic thought with

poetic form. The Horatian influence is clear in the skillfulness of the transitions and the tact with which Akenside handles his subject.

Later in 1744 Akenside turned to satire in *An Epistle to Curio*, a poem occasioned by the change of political attitude which had enabled William Pulteney, leader of the opposition to Walpole, to accept the earldom of Bath in Henry Pelham's ministry. In 1745 he published *Odes on Several Subjects*, and thereafter the ode was his favourite form.

Akenside's willingness to consider himself as the English Pindar is satirized with other aspects of his character in Tobias Smollett's *Peregrine Pickle* (1751), where he appears as the physician in the continental scenes.

Meanwhile Akenside was making slow progress as a doctor. On his return from Leyden he had attempted unsuccessfully to establish practices first in Northampton and then in Hampstead. In 1747, however, his financial worries ended when his friend Jeremiah Dyson established him in a house in Bloomsbury square, London, and settled upon him a generous allowance. Here his medical reputation increased and he was eventually appointed physician to the queen. He delivered the Gulstonian lectures in 1755; the Croonian lectures in 1756 and the Harveian oration in 1759. In 1746 he had published his "Hymn to the Naiads" and "To the Evening Star" and he also contributed essays to Robert Dodsley's periodical the *Museum*.

Akenside died in London on June 23, 1770.
See C. T. Houpt, *Akenside: a Biographical and Critical Study* (1944); Samuel Johnson's *Lives of the Poets*, iv (1781). (J. N. C.)

AKERSHUS, a fylke (county) of southeast Norway, surrounds Oslo and extends northward to Lake Mjøsa. Pop. (1959 est.) 221,878. Area 1,895 sq.mi. Forested hills of Pre-Cambrian bedrock in the east and south, and of plutonic granite in the west surround undulating lowland covered by submarine clay. Two big rivers, Vorm and Glomma, meet in Akershus and flow into Lake Øyeren to the south. Akershus was well populated even in prehistoric times. Eidsvoll in the north was an early religious and administrative centre; the constitution of Norway was drafted and sanctioned there in 1814. Lillestrøm at the head of Øyeren and Sandvika in the southwest are small industrial communities in the outskirts of the capital. The lowland is among the best agricultural regions of the country, producing milk, grain, potatoes, vegetables and fruits. (L. H. HG.)

AKHENATEN: see IKHNATON.

AKHISAR (anc. THYATEIRA), a town in the Manisa il of Turkey, lies in a fertile plain on the Gurduk Chai (*Lycus*), 58 mi. N.E. of Izmir with which it is connected by railway. Pop. (1960) 40,013. The area around is extensively cultivated; tobacco and grapes are the chief crops, and a cotton of excellent quality is grown. The town exports tobacco, cotton, wool, opium, cocoons and cereals, and is celebrated for its scarlet dyes. Thyateira was an ancient town repopulated with Macedonians by Seleucus about 290 B.C. It became an important station on the Roman road from Pergamum to Laodicea, and one of the "Seven Churches" of Asia (Rev. ii, 18), but was never a metropolis, though made the centre of a *conventus* by Caracalla. (N. TU.; S. ER.; E. TU.)

AKHMATOVA, ANNA (real name ANNA ANDREYEVNA GORENKO) (1888-), one of the finest Russian poets of the early 20th century. She was born in Kiev. In 1910 she joined the "Acmeist" writers (who rejected symbolism, aiming at a neoclassic purity of expression), wrote for their magazine *Apollon* (1909-17) and married the Acmeist poet Nikolai Gumilev, whom she divorced in 1918. The lyrics in her collections *Vecher* ("Evening," 1912), *Chetki* ("The Rosary," 1914), *Belaya Staya* ("The White Flock," 1917), *Podorozhnik* ("The Buckthorn," 1921) and *Anno Domini MCMXXI* (1922) are remarkable for their simplicity and intensity: many are love poems, all are profoundly personal, like her only long poem *U samogo morya* ("At the Edge of the Sea," 1921). She published no original verse from 1922 to 1940, when *Iz shesti knig* ("From Six Books") and *Iva* ("The Willow Tree") appeared. During World War II she published poems in magazines and in 1945 gave a popular series of readings from her own work; however, in Aug. 1946 her poetry was attacked by the central committee of the

Communist party as "empty" and "bourgeois" and in Sept. 1936 she was expelled from the Soviet writers' union. Poems signed by her here published as *Iz tsikla "Slava Miru"* ("From the Cycle, Glory to Peace") in 1950.

BIBLIOGRAPHY.—Much of her verse was translated into English by N. S. Duddington as *Forty-Seven Love Poems* (1927). See also Gerald Shelley, *Modern Poems from Russia* (1942); L. I. Strakhovsky, *Craftsmen of the Word: Three Poets of Modern Russia* (1919).

AKHMIM (ΕΚΗΜΙΜ), a market town of Sawhaj province in upper Egypt, on the east bank of the Nile 66 mi. S. of Asyut by river and 4 mi. above Sawhaj on the west bank. Pop. (1957) 39,392. The town has several mosques and two Coptic churches. It maintains a weekly market and manufactures textiles from cotton and flax, particularly the pale blue galabia and check shawls favoured by the Egyptian peasantry.

Outside the walls are the scanty ruins of two ancient temples. In the time of Abulfeda (*q.v.*; 13th century A.D.) a very imposing temple still stood there. Akhmim was the Egyptian Apu or Khenmin. in Coptic Shmin. known to the Greeks as Chemmis (Khemmis) or Panopolis, capital of the 9th or Chemmite nome of upper Egypt. Herodotus mentions the temple dedicated to "Perseus" and asserts that Chemmis was remarkable for the celebration of games in honour of that hero, after the manner of the Greeks. at which prizes were given; but it is possible that he confused Coptos with Chemmis. Strabo mentions linen weaving as an ancient industry of Panopolis, and it is not altogether a coincidence that the cemetery of Akhmim is one of the chief sources of the beautiful textiles of Roman and Coptic age that are brought from Egypt. Monasteries abounded in this neighbourhood from a very early date. Nonnus, the Greek poet, was born at Panopolis.

AKHTAL, AL- (GHİYATH IBN HARITH) (c. 640–710), Arab poet of the Omayyad period, highly esteemed for his perfection of form, was born about 630 either at Hira, not far from Rusafa in Mesopotamia, or in the Syrian desert, and belonged to the Mesopotamian tribe of Taghlib. Like his fellow tribesmen he was a Christian, enjoying the freedom of his religion but nor taking its duties very seriously. Al-Akhtal, Jarir and al-Farazdaq form a famous trio among the Arabs, but there is dispute as to their relative superiority. The celebrated philologist Xbu 'Ubaida placed al-Akhtal highest of the three on the grounds that among his poems there were ten flawless qasidas ("odes") and ten more that were nearly so, and that this could not be said of the other two poets.

Griffini, *Le Diwan d'al-Ahtal reproduit par la photolithographie d'après un manuscrit trouvé au Yemen, avec préface, glossaires . . .* (1907). For a full account of the poet and his times see H. Lamens, *Le chantre des Omiades* (1895), a reprint from the *Journal Asiatique* for 1895.

AKIBA (AQIBA) **BEN JOSEPH** (c. 40–135), Palestinian teacher and rabbi, was one of the group known as tannaim whose teachings comprise the body of the Mishnah. An illiterate shepherd until 40, Akiba, after mastering the necessary rudiments, joined the great academy of scholars at Yabneh and rose to prominence there. Later he established his own academy at Bene Berak. Among his many students were those, like Rabbi Simeon ben Yohai and Rabbi Meir, who became the leading teachers of the following generation and through whom Akiba exerted a formative influence on the development of later talmudic thought. Akiba's genius was both legal and humanitarian. He was apparently the first to organize into a code, divided logically by subject matter, all the legal and ethical norms constituting the traditions of the various sages. He developed principles of biblical exegesis which formed the basis for all subsequent talmudic speculation. Maintaining that no letter or word in Scripture was superfluous but that each had its special meaning! he was able to find a scriptural basis for norms he felt to be vital to the needs of Jewish life in his time. Opposing the priestly interpretation of biblical law, Akiba tended to recognize the problems and views of the disadvantaged groups, the artisans and labourers. He tried to limit the prerogatives of the priests; to raise the status of women; and to foster the doctrine of peace as a fundamental political and religious ideal. Although Akiba recognized Bar-Cochba as a possible messiah, the usual view that he

played an important part in Bar-Cochba's revolution seems erroneous. Nonetheless, Akiba was imprisoned by the Romans for continuing to teach Torah after that had been forbidden. According to tradition he was flayed alive in 135, after three years' imprisonment, and met his death with steadfastness and composure.

See Louis Finkelstein, *Akiba—Scholar, Saint and Martyr* (1936); and the biography of Akiba by Louis Ginzberg in *The Jewish Encyclopedia*. (L. F.)

AKITA, Japanese prefecture on the Sea of Japan coast of northwestern Honshu. Area 4,333 sq.mi. Pop. (1960) 1,335,511. Most of the population is located on lowlands along the courses of the Yoneshiro (north) and Omono (south) rivers. Essentially agricultural. Akita produces large rice surpluses even though cultivation is restricted to the summer months; the winters are long, cold and snowy. Lumbering, based on large timber stands in the mountainous interior, ranks second in importance. Akita is Japan's leading petroleum producer and has small exploitable deposits of copper, sulfur, lead and manganese. Petroleum products and chemicals from Akita city and wood products from Noshiro are the principal manufactured items.

AKITA is the capital and largest city (203,643 in 1960) of Akita prefecture. It is located at the mouth of the Omono river. Formerly a castle town of the Satake clan, it is the prefecture's administrative, commercial, industrial, transportation and cultural hub. It is served by an outport, Tsuchizaki. (J. D. E.E.)

AKKAD, the ancient name designating the northern part of the country in middle Iraq, which was the home of the Babylonian civilization (see BABYLONIA AND ASSYRIA). Geographically its boundaries are not clearly defined, even as against Sumer, the southern part of the country. From about 2000 B.C. rulers of the whole land called themselves "kings of Sumer and Akkad." Roughly, the location of Akkad was in that region where the Tigris and Euphrates rivers approach closest to each other, and its northern limit may be placed above the line of the modern Fallujah and Baghdad. The boundary on the Tigris between Akkad and its northern neighbour Assyria lay at about latitude 34° N., where the tributary Adhem joins the Tigris. The name of Akkad was taken from the city of Agade (*q.v.*), founded by the Semitic conqueror Sargon I, about 2300 B.C. At least from that time onward the inhabitants of this northern region were predominantly Semitic, and it is their speech (the oldest Semitic dialect to be preserved, in the cuneiform script) which was called by them, as by modern scholars, Akkadian (see AKKADIAN LANGUAGE). Within the area of Akkad lay some of the principal centres of Babylonian civilization, Babylon itself, Kish, Borsippa, Cuthah, Eshunna, Sippar and Akshak. (C. J. G.)

AKKADIAN LANGUAGE, one of the Semitic languages (*q.v.*), was the language of Mesopotamia (present-day Iraq) in the three thousand years before the Christian era. Assyrian is a dialect of Akkadian, but the entire language was once referred to as "Assyrian" because explorations of Mesopotamia in the early part of the 19th century brought to light inscriptions materials from Assyria long before the discovery of comparable materials in Babylonia. (See BABYLONIA AND ASSYRIA.)

Akkadian is often assigned to the eastern group of Semitic languages, in contrast to Hebrew, Phoenician, Amorite, Ugaritic, Aramaic (including Syriac), Arabic and Ethiopic, in the western Semitic group.

The oldest sources of Akkadian appear at the beginning of the third millennium B.C. in personal names and loan words occurring sporadically in inscriptions written in the Sumerian language (*q.v.*), the commonly used language of the period in southern Mesopotamia. With the rise of the Akkad dynasty under its great Sumerian ruler Sargon, the Akkadian language spread widely over the whole expanse of the Sargonic empire, extending from the shores of the Mediterranean sea to the Persian gulf. After a short setback during the period of the Sumerian revival under the 3rd dynasty of Ur, at the beginning of the Old Babylonian period (c. 2000 B.C.), Akkadian became the only spoken language of Mesopotamia, while Sumerian continued in partial use as the written language of sacred literature.

The three earliest stages of Akkadian, attested in the pre-

Sargonic, Sargonic and Ur III periods, are generally included under the term Old Akkadian. After the fall of the 3rd dynasty of Ur, the Old Akkadian language broke into two dialects: Assyrian, spoken in Assyria, in the northern part of Mesopotamia; and Babylonian, spoken in Babylonia, in the southern part of Mesopotamia. Each of the two dialects is considered in three chronological subdivisions, Old, Middle and New.

Assyrian and Babylonian. — The Assyrian dialect was used extensively in the Old Assyrian period in correspondence and commercial records between the Assyrians and the natives of Asia Minor, and in historical inscriptions. In the Middle Assyrian period the code of laws, contracts and letters were written in the Assyrian dialect, but the historical inscriptions began to be written in the Babylonian dialect.

In the New Assyrian period, at the time when the Assyrians held sway over the whole near east, the Babylonian dialect took over almost entirely. In that period the official and historical inscriptions, belles-lettres and the religious literature were all written in Babylonian. However, the Assyrian dialect continued to be used in legal contracts and in letters.

The expansion of the Babylonian dialect outside Babylonia proper reached its height in the middle period, when Babylonian became the lingua franca of the near east. The correspondence archive of the Egyptian kings discovered at Tell-el-Amarna in upper Egypt testifies to the use of Babylonian in international relations between Egypt, Syria, Palestine, Asia Minor and Assyria. Babylonian was also used extensively in Elam, in the southern regions of what is now Iran. In the New Babylonian period, another Semitic language, Aramaic, gradually replaced Babylonian as the spoken and written language of the country, limiting the latter to learned literature of mathematics and astronomy. By the time of Christ, Babylonian had died out entirely, and all knowledge of it was lost until its recovery by decipherment in the first half of the 19th century.

Akkadian Writing. — In contrast to all other Semitic languages, which used writings consisting of a limited number of from 22 to 30 signs, all developed ultimately from a form of writing originating in Syria, the Akkadian language used a type of writing, called cuneiform (*q.v.*), which utilized about 600 word and syllable signs, developed from Sumerian.

Phonology. — The classical Akkadian has 20 consonantal phonemes. They are ' , b, d, g, *h*, j, k, l, m, n, p, q, r, s, š, S. There are eight vowel phonemes, a, i, e, u, both short and long.

Morphology. — The noun has two genders, masculine and feminine; three numbers, singular, plural and dual; and three cases, nominative, genitive and accusative. The feminine is distinguished from the masculine by the addition of a morpheme -at- or -f- to the stem. The plural is usually formed by the prolongation of the gender vowel of the singular, as in *kalbū* (originally **kalbūm*), "dogs," beside *kalbu(m)*, "dog," or *kalbātu(m)*, "bitches," beside *kalbatu(m)*, "bitch." Later on the masculine plural was formed with the endings -ē and -ānu/i. The use of the old dual is limited in classical Akkadian to words denoting parts of the body. The case endings in the singular are -um in the nominative, -im in the genitive, and -am in the accusative; mimation had no function and disappeared in the later language. Characteristic of Old Akkadian only is the use of the case endings -iš for the dative and -ūm for the locative.

The verb has two tenses, preterit, as in *iḫrus*, "he decided," "he has decided," and present-future, as in *iparras*, "he decides," "he will decide." A tenseless stative (or permissive) has, in this verb, the form *paris*, which can be translated as "it is (was, will be) being decided." Of the four main stems, the first, the one in the above quoted examples, is called basic; the second stem, marked by the doubling of the second root consonant, denotes plurality or intensity of action or gives a causative meaning to intransitive verbs; the third stem, marked by an infix š, denotes a causative, as in *ušaḫris*, "he caused to decide"; the fourth stem, marked by an infix n, denotes the mediopassive, as in *ipparis* (from *inparis*), "it was decided." Each of the stems can appear with further infixes, t, tn (and even tt, *ttn*), to denote various shades of reciprocal, reflexive, iterative and other aspects. The

forms with *t* evolved into a new tense called perfect. The verb distinguishes also a subjunctive, an allative, an imperative, used with the second person only, an infinitive and participles.

See W. von Soden, *Grundriss der akkadischen Grammatik* (1952); R. Labat, *Manuel d'épigraphie akkadienne* (1948). (I. J. G.)

AKLAN, a province in the Republic of the Philippines, occupying the northwestern portion of Panay Island. The province was created in 1955 from the western portion of Capiz province. Pop. (1960) 226,516. Most of the population reside in the valley of the Aklan river and along the north-facing coastal lowland, both rice-producing centres.

Kalibo, the provincial capital, had a population of 21,320 (1960) within the municipality. It is the province's main trading centre and transportation junction. The port of New Washington, 7 mi. E. of Kalibo, provides interisland shipping connections; Ibajay, 18 mi. W. of Kalibo, is the province's second trading centre.

(R. E. HE.)

AKOLA, a town in Maharashtra state, India, the headquarters of Akola district. It is on the Murna tributary of the Purna river 140 mi. W.S.W. of Nagpur (158 mi. by rail). Akola proper is on the west bank and Tajnapeth, containing the administrative buildings and most of the population, is on the east bank. Pop. (1951) 89,606. The town has walls built mainly by a Mogul feudatory about 1700 and a citadel built under Hyderabad rule in the early 19th century. It is on the national highway and main rail route from Calcutta to Bombay and at the junction of the Central railway broad-gauge route from Nagpur to Bombay via Bhusaval, and the metre-gauge route linking Khandma with towns in the Godavari basin to the south. Akola is one of the cotton towns of Berar (*q.v.*) and has ginning factories and cotton presses. There is a government college affiliated to Nagpur university and an industrial school supported by a Protestant mission.

AKOLA DISTRICT is in general flat, the greater part being in the central valley of Berar. Pop. (1951) 950,994. Area 4,095 sq.mi. It is bounded on the north by the Melghat hills; and on the south by eastern outliers of the Ajanta hills, with summits rising to 2,000 ft., and by the fertile Washim (Basim) tableland, which slopes from 1,000 ft. southwestward into the valley of the eastward-flowing Penganga. North of the Ajantas the land is drained westward by the Purna (an affluent of the Tapti, *q.v.*) and its tributaries. The heat from April to mid-June is great (May maximum 107° F., mean 94° F.), but the nights are cool. Annual average rainfall is 34 in. In the north the Purna valley, where the elevation falls below 1,000 ft., has rich black loamy soil particularly suited to cotton. Almost all the district is cultivated, secondary crops after cotton being jowar and some wheat and oilseeds. The district's largest towns after Akola, Akot (24,255), Karanja (22,098) and Washim (18,763), are: unlike Akola, predominantly centres of agricultural population. Washim, 37 mi. S. of Akola, was the capital of a feudatory kingdom of the Hindu Vakataka dynasty in the 4th century A.D.

(S. M. A.)

AKRON, a city of Ohio, U.S., and seat of Summit county, is situated on the watershed which separates the tributaries of the Ohio river from the waters flowing north to Lake Erie. It is approximately 1,200 ft. above sea level and one of the highest points in the state. The name Akron was taken from a Greek word meaning "high." Akron was established in 1825, incorporated as a village in 1836, became the county seat in 1842 and was chartered as a city in 1865. It is about 35 mi. S.E. of Cleveland and has an area of 53.7 sq.mi. The population in 1960 was 290,351. The population of the standard metropolitan statistical area (Summit county) in 1960 was 513,569. The city of Barberton adjoins Akron on the southwest. On the north is the city of Cuyahoga Falls (*q.v.*). North of Cuyahoga Falls are the residential communities of Stow and Silver Lake. Other villages near Akron in Summit county are Tallmadge, Hudson, Munroe Falls and Mogadore.

The Ohio and Erie canal linking Lake Erie with the Ohio river was opened in 1827; and the Pennsylvania and Ohio canal linking Akron with Pittsburgh and Beaver, Pa., was opened in 1840. These canals afforded Akron its most important means of transportation for 25 years, until the advent of the railroads. Water

power supplied by the canals led to Akron's early development as an industrial centre. By 1840 there were flour and cereal mills, iron furnaces and plants making tile, brick and sewer pipe among other items. After the American Civil War, the manufacture of mowers and reapers was started, as well as plants producing matches and fishing tackle.

The ample water supply, the transportation afforded by two railroads and the financial assistance of a persuasive board of trade led B. F. Goodrich to move a small rubber factory to Akron in 1870. Other rubber companies were established during the next two decades. These companies first manufactured rubber hose, bicycle tires and solid rubber tires for buggies. The introduction of the automobile created a demand for pneumatic tires, and the existing companies expanded and several new ones were organized. The expansion of the rubber industry fostered Akron's rapid growth. Between 1910 and 1920 the population of the city tripled to 208,435. Thereafter Akron was known as the "rubber capital of the world."

Other products made in Akron include steam boilers, steel rims for trucks and tractors, metal stampings and military aircraft. Wood, plastic and synthetic rubber products number in the thousands. Chemical companies make ingredients for paints: sulfur is refined; salt, silica sand and clay are mined in the area. The many machine shops located in Akron, Barberton and Cuyahoga Falls, make machinery, molds, tools and other equipment used by rubber manufacturers and by the government. Synthetic rubber plants built during World War II and operated for the government were later purchased by private companies and expanded for increased production. Several large trucking companies have their headquarters in or near Akron.

Because of the dominating industries, Akron's population tended to have a preponderance of men, a large proportion of skilled and semiskilled labour, relatively high wages and a high percentage of men engaged in gainful occupations. The population was not congested, even after the period of rapid growth. Small detached or semidetached dwellings are most common. After mid-20th century approximately 70% of the homes were owner-occupied.

Metropolitan parks occupying more than 4,300 ac., about 12 lakes and reservoirs and several golf courses afford recreation areas. The University of Akron was created in 1913 when the city council accepted as a nucleus the plant and endowment of Buchtel college, founded in 1870 and named after its chief benefactor John R. Buchtel (1822-92), an Akron businessman. After mid-20th century, the university enrolled more than 5,000 students.

The old Portage trail, used by the Indians in carrying their canoes from the Cuyahoga river to the Tuscarawas in the journey from Lake Erie to the Ohio, runs through the city for about 7 mi. The Summit County Historical society has placed historical markers along the Portage trail and operates a house once occupied by John Brown, the abolitionist, as a historic house museum. (W. D. Ov.)

AKSAKOV, the name of a family of Russian writers.

SERGEI TIMOFEEVICH AKSAKOV (1791-1859) was born Sept. 20, 1791, at Ufa, on the Russian steppelands, and brought up in patriarchal conditions on the estates purchased from the Bashkirs by his pioneering grandfather. He was educated in the 18th-century French pseudoclassical tradition at home, at school and at the newly founded university in Kazan (1804-07). He became a translator in the legislative commission of the civil service, resigning in 1811; served in the militia in the war of 1812; married in 1815; and in 1816 retired to the family estate. After a decade as a sporting country squire, with little talent for estate management, he returned to the civil service in Moscow and became literary censor (1826), inspector (1834) and, later, director of the college of land surveying. Inheriting money, he retired in 1839 and lived in and near Moscow, entertaining his friends, mainly writers and Slavophiles. He died at Abramtsevo, April 30, 1859.

Before 1834, when his successful *Blizzard* was published, Aksakov's writings reflected outmoded literary tastes: translations of Boileau and Molière, undistinguished verse and articles on the theatre—the latter valuable source material. But he was in-

spired by his love for rural Russia in the days of serfdom, by his Slavophil sons and by Gogol, whose genius—though poles apart from his own—he admired, to set down the story of his grandfather, his parents and his own childhood recollected in tranquillity and transposed into realistic fiction in three books which have become classics: *Semeynaya Khronika* and *Vospominaniya* (both 1856), and *Detskie gody Bagrova vnuka* (1858). Though necessarily introspective, Aksakov unfolds his epic chronicle objectively in an unaffected style and simple language. Its interest lies in the Proustian illusion of reality and intimacy created by his vivid remembrance of the continuous past. These works, a cross between memoirs and the novel—a new genre in Russian literature—brought Aksakov fame. He is also one of the few Russian writers on shooting, fishing and butterfly collecting, and his reminiscences of Gogol are firsthand material on his friend's complex personality.

BIBLIOGRAPHY.—His collected works were ed. by I. S. Aksakov (1886); other editions 1909, 1911 and 1916. For full bibliography see I. V. Vladislavlev, *Russkie Pisateli* (1924). There are English translations of *Semeynaya Khronika* by M. C. Beverley as *Chronicles of a Russian Family* (1924) and by J. D. Duff as *A Russian Gentleman*, in the "World's Classics Series" (1923); and of *Vospominaniya* as *The Autobiography of a Russian Schoolboy* (1917), and *Detskie gody Bagrova vnuka* as *Years of Childhood* (1916), both by J. D. Duff. (E. H.L.)

Aksakov's sons were also well-known writers and Slavophiles.

KONSTANTIN SERGEEVICH AKSAKOV (1817-1860), the Slavophil movement's principal theorist, was born April 10 (new style: March 29, old style), 1817, in Aksakovo, Orenburg. A keen student of Hegel, he became a literary critic, a grammarian, a historian and a political philosopher. In his interpretation of history a mystical conception of ancient "land" (*Zemlya*) was contrasted with the "state"—an alien idea imposed by Peter the Great, whose Europeanizing influence he deplored: he praised the traditional spiritual "conscience" of Russia and decried European legal values. For him "Holy Russia" literally was sacred. He died on the Greek island of Zante, Dec. 19 (N.S. 7, O.S.), 1860.

His brother IVAN SERGEEVICH AKSAKOV (1823-1886) was born at Nadezhdin, near Yekaterinburg (Sverdlovsk), Oct. 8 (N.S.; Sept. 26, O.S.), 1823. He founded and edited the newspapers *Den* (1861-65) and *Moskva* (1867-69)—often suppressed and censored; and wrote the first Russian narrative poem on peasant life, *Biodyaga* ("The Tramp," 1852). Leader of the Pan Slavists during the Russo-Turkish War (1877-'78), he was exiled for denouncing the treaty of Berlin (1878) but returned to found the influential journal *Rus* in 1880, editing it until his death in Moscow, Feb. 8 (N.S.; Jan. 27, O.S.), 1886.

AKSHAK, a powerful city of ancient Mesopotamia, on the northern boundary of Akkad, identified by some authorities with Babylonian Upi (Opis). About 2500 B.C. it was conquered by Eannatum, king of Lagash, who had previously worsted its ally Kish. About a century later, according to the king lists, Akshak established its hegemony over Sumer and Akkad, following on the 4th dynasty of Kish. The proposed location of this important city on the site of the later Seleucia (mod. Tall Umar on the west bank of the Tigris, south of Baghdad) is uncertain. The Mari documents (c. 1770 B.C.) indicate that it lay near Eshnunna in the Diyala valley. See further BABYLONIA AND ASSYRIA. (M. E. L. M.)

AKSUM (AXUM), the ancient capital of Ethiopia and the spiritual home of Abyssinian religion and civilization to the present day. Aksum is situated in the Tigre province of northern Ethiopia, a few miles west of Adwa, at an altitude of 7,000 ft. (For the history of the Aksumite kingdom see ETHIOPIA OR ABYSSINIA: *History*.)

Aksum had been known to classical and early Christian writers. In the *Periplus Maris Erythraei*, an anonymous 1st-century account of travel and trade in the Indian ocean, we encounter probably the first reference to "the city of the people called Auxumites"; i.e., Aksum. A far more detailed story is told by Cosmas Indicopleustes in his *Christian Topography*. Cosmas had visited Aksum about the year A.D. 525 and had marveled at its churches and antiquities. Aksum is also mentioned in south Arabian and early Ethiopic inscriptions, and the city's ancient monuments have been meticulously studied by the German Aksum expedition

(1906). by U. Monneret de Villard (1937) and others. Earlier European travelers already had brought back descriptions of the Xksumite monuments which varied considerably in value and accuracy. The significance of the holy city of Aksum forms the centrepiece of the greatest work of Ethiopian literature (*q.v.*), the Kebra Nagast ("Glory of the Kings"), which describes the transference of the Ark of the Covenant from Jerusalem to Aksum, the new Zion, by Menelik, the son of the queen of Sheba and King Solomon.

The Ark (tabot—replicas are in every Ethiopian church) is alleged to be kept in the holy of holies of the most famous rectangular sanctuary in Ethiopia, the church of St. Mary of Zion at Aksum, which was known already in the 6th century. At the top of the flight of stairs leading to this church there is a throne and footstool, a characteristic feature of the Aksumite remains. The most notable achievements of indigenous art are the deservedly famous Aksumite obelisks which embody delicately executed ornamental designs of the story or window type. They are pre-Christian and served as gravestones and memorials. The perfection reached by the largest of these monoliths is expressed not only in the immense technical skill required in working, moving, and erecting these colossal single blocks of granite but especially in their beautiful sculpturing and rich decoration as well-proportioned multi-story towers. The largest obelisk still standing at Aksum is nearly 70 ft. high: while the biggest of all, though broken through the force of its fall, measures about 110 ft. in height and is thus the largest (at one time upright) monolith in the world (exceeding the height of the Lateran obelisk by just over four feet).

BIBLIOGRAPHY.—For a detailed topographical, architectural and epigraphic account of the Aksumite monuments see the four volumes by E. Littmann, T. von Lüpke, D. Krencker, *Deutsche Aksum-Expedition* (1913); J. T. Bent, *The Sacred City of the Ethiopians* (1893); A. Dillmann, "Zur Geschichte der Axumitischen Reichs," *Abhandlungen der königlichen Akademie des Wissenschaften* (1880); E. Glaser, *Die Abessinier in Arabien und Afrika* (1895); *Guida dell' Africa Orientale* (1938); U. Monneret de Villard, *Aksum* (1938); E. Ullendorff, *The Ethiopians* (1960). (E. U.)

AKTYUBINSK, an oblast (province) and town in the northwest of the Kazakh Soviet Socialist Republic: U.S.S.R. The oblast is bounded on the west by the Guryev and West-Kazakhstan oblasts of the Kazakh S.S.R., on the north by the Orenburg oblast of the Russian Soviet Federated Socialist Republic, on the northeast by the Kustanai oblast of the Kazakh S.S.R., on the east and southeast by the Karaganda and Kzyl-Orda oblasts of the Kazakh S.S.R., and on the south by the Kara-Kalpak Autonomous S.S.R. Area, 115,753 sq.mi. The population in 1959 was 404,000, of which 44% was urban and 56% rural. The three largest towns are Aktyubinsk (the capital), Temir and Chelkar. There are 13 rayons (districts).

The oblast includes brown soil steppe in the north and desert in the south. The Caspian lowland (west) is separated from the Turgai tableland (east) by the Mugodzhzar hills. The precipitation is low, varying from 10 in. in the south to 16 in. in the north, and the river network is therefore scanty. The main rivers are the Emba (*q.v.*), which flows southwest toward the Caspian sea, and the Irgiz, which waters the eastern section and flows into the inland lake Chelkar-Tengiz.

Most of the oblast is devoted to livestock breeding (sheep, goats, camels), and agriculture is restricted to the north. There are rich nickel deposits near Batamshinski and chrome at Donskoye and Khrom-Tau, east of the town of Aktyubinsk. Coal is mined at Berchogur. Large phosphorite deposits round Kandagach south of Aktyubinsk are processed into fertilizers at the Alga Chemical works. Another chemical plant at Chelkar exploits the salt deposits from the Aral sea. The eastern section of the Emba oil deposits has its chief field at Shubar-Kuduk. The Transcaspian railway intersects the oblast northwest by southeast, crossing the Orsk-Guryev line at Kandagach. In the early 1960s there were more than 600 schools in the oblast.

The town of AKTYUBINSK (pop. 97,000 in 1959) is situated on the Iek river, a tributary of the Ural. It began its existence in 1869 as Ak-Tyube ("white hill" in Kazakh), a small fort. In

1878 the first Russian settlers arrived there and in 1891 it was established as the capital of an *uyezd* (district). It is one of the most important industrial centres of Kazakhstan and has electro-technical engineering works, stockyards and flour mills. During World War II a ferroalloys plant was established near the town for working the nickel and chrome of the Mugodzhzar hills. Educational establishments include a woman teachers' training college. (G. E. WR.)

AKUTAGAWA RYUNOSUKE (1892–1927), a Japanese writer of stories, plays and poetry, was born in Tokyo on March 1, 1892. As a boy he was sickly and hypersensitive, but excelled at school and was an omnivorous reader. He began his literary career while attending Tokyo university, where he studied English literature from 1913 to 1916. The publication in 1915 of his short story "Rashomon" led to his introduction to Natsume Soseki, the outstanding novelist of the day. Under Natsume's encouragement he began to write a remarkable series of stories, derived largely from 12th- and 13th-century collections of Japanese tales but retold with modern psychology in a highly individual style. Akutagawa's stories have a feverish, unhealthy intensity well suited to their often macabre themes and revealing much of his own highly strung sensibilities. It is easy to see resemblances between the artist described in his *Jigokuhen* (Hell Screen, 1917) who must witness with his own eyes scenes of horror before he can paint his gruesome masterpiece, and Akutagawa himself, who underwent constant mental agonies as a writer. In 1922 he turned away from medieval themes to devote himself mainly to thinly disguised autobiographical fiction. Akutagawa's modern stories lack the exotic if sometimes lurid glow of the older tales, a fact that may account for their comparative unpopularity. His last important work, *Kappa* (1926–27), a satirical fable about elflike creatures, is written, despite the subject, in the mirthless vein of his last period and reflects his depressed state at the time. Akutagawa committed suicide on July 24, 1927, leaving behind many works that were published posthumously.

English translations of Akutagawa's works include *Rashomon and Other Stories*, translated by Takashi Kojima (1952); *Hell Screen and Other Stories*, translated by W. H. H. Norman (1948); and *Kappa*, translated by Seiichi Shiojiri (1951). (D. K.)

AKYAB, a municipality and district in the Arakan division of the Union of Burma. The district includes the confluence of the Mayu, Kaladan and Lemro rivers. The Arakan coast on the Bay of Bengal receives the full force of the southwest monsoon and Akyab has been built in a relatively sheltered site on the eastern side of a hilly ridge. In addition to the usual public buildings it has several rice mills and the chief export is rice. After the cession of Arakan to the British by the treaty of Yandabu in 1826, the old capital Arakan (on a small branch of the Kaladan river) now known as Myohaung ("old city") was abandoned as the seat of government, and Akyab on the sea coast selected instead. Trade restrictions were removed and Akyab rapidly grew from a small fishing village into a leading port of Burma. The population has varied but slightly since the census of 1881, and in 1931 it was 38,094 (28,724 males and 9,370 females). Of these, 4,049 were then classed as "adventitious" Muslim and Hindu labourers—Indians who came temporarily as labourers, leaving their womenfolk behind. These figures illustrate the reliance of Akyab as a port on Indian workers and the effect of isolation from the rest of Burma, then reached only by sea. Since the independence of Burma in 1948, the Indian population has greatly decreased. The 1953 census showed a population of 42,329.

AKYAB DISTRICT, with an area of 5,176 sq.mi and a population in 1941 of 760,705, forms the natural geographical hinterland of the port. Rice is grown on extensive alluvial plains and there is little settlement on the wet, forested hill ridges. See also ARAKAN. (L. D. S.)

ALA, in architecture, one of the side recesses which usually opened off the atrium (*q.v.*) of a Roman house. One was placed on each side in the corners off the back of and entirely open to the atrium. The term applies also to the wings, open their entire width in front, at each side of the cella in one of the Tuscan temple plans.

ALABAMA is called the "Yellowhammer state" because of its state bird, the "Cotton state" because of its chief agricultural product and the "Heart of Dixie" because of its location. The state is situated between 84° 51' and 88° 28' 03" W. and 30° 13' and 35° N., and is bounded north by Tennessee, east by Georgia, south by Florida and the Gulf of Mexico and west by Mississippi. The total area of Alabama is 51,609 sq. mi., of which 549 sq. mi. are inland water surface. It is the 29th state of the union in size. The state capital is Montgomery and the state entered the union on Dec. 14, 1819, as the 22nd state.

The southern pine has been adopted as the state's official tree and the camellia as the official flower. The state flag is a red cross of St. Andrew on a white field; square in shape, the flag is modeled upon the battle flag of the Confederacy. The name "Alabama" is of Choctaw origin and means "thicket-clearers" or "vegetation gatherers" and not "here we rest" as it is sometimes erroneously rendered.

PHYSICAL GEOGRAPHY

Physical Features.—North Alabama is a diversified region, invaded by the Appalachian highlands. In the northeast, Lookout, Sand and Raccoon mountains are important physical features. The rugged Cumberland plateau, extending deeply into the state from Tennessee, is crossed from east to west by the fertile Tennessee valley. The highest point in Alabama is Cheaha mountain (2,407 ft.) in the northeastern corner of the state. The great Appalachian valley and the Piedmont plateau invade the state for a considerable distance from the Georgia line. The Coosa and the Tennessee rivers drain the highlands and provide an important source of hydroelectric power. The "black belt" is prairie country which crosses the central portion of Alabama generally from east to west. Farther south lies the Gulf coastal plain, which slopes gradually down to sea level in the south, where it touches the Gulf of Mexico.

The principal rivers of Alabama are the Tombigbee and Black Warrior in the west, the Alabama and the Coosa in the central portion, the Tennessee in the north and the Chattahoochee, which forms much of the Georgia boundary, in the east. The Alabama river flows to the southwest where it joins the Tombigbee; their waters then part to flow into Mobile bay as the Mobile and Tensaw rivers. Mobile bay averages about 12 ft. in depth, although there is a ship channel through the bay with a controlling depth of 36 ft. and a width of 400 ft.

Climate and Soil.—Alabama has a temperate climate. The average mean temperature for the state in winter is 46° F. and in summer 79° F. Snow falls only once or twice a year in the northern part. Alabama has abundant rainfall with a yearly average of 53 in. Heaviest rainfall is along the Gulf coast with about 65 in. per year, and the lightest is near the center of the state with about 50 in.

Rainfall and temperature account for the state's long growing season—298 days in south Alabama and 198 days in north Alabama.

There are four principal belts of soil. In the timber belt along the coast the soil is sandy. North of this lies the "black belt" ("black prairie" or "cotton belt"), approximately 13,000 sq. mi. in extent, which has black soil that is rich in limestone and marl formations, without sand or loam and is especially adapted to the production of cotton and grasses. Between the cotton belt and the Tennessee valley lies the mineral belt, the soils of which are of varied fertility. North of the mineral belt is the cereal belt in the Tennessee valley, containing red clays and dark loams.

Vegetation and Animal Life.—Plants and animals are both numerous and varied in the semitropical climate of Alabama. There are about 4,500 kinds of native plants. The approximately 125 varieties of trees include soft pines such as loblolly, shortleaf, longleaf and slash. In addition there are 22 kinds of oak trees, cedar (red and white), walnut, sweet gum, other gum trees, magnolia, tulip trees, dogwood, haw (20 kinds) and others. Examples of the state's abundant plant life include shrubs (more than 150 species), native grasses (more than 200 species) and many wild flowers, ferns, vines and mosses. Honeysuckle, Virginia creeper

and smilax are common.

Spanish moss grows on the coastal plain and the carnivorous pitcher plant is found in the forests.

Ornithologists have identified 325 species of birds in the state including quail (the most abundant game bird), turkeys, pintail ducks, mallards, geese, doves, robins, cardinals, mockingbirds, warblers, eagles, ospreys and yellowhammers.

Fresh-water fish of particular interest to fishermen include bream and catfish. A common sight on Alabama farms is the private, stocked fishpond. Along the Gulf coast, the prevalence of salt-water fish such as tarpon and king mackerel promotes sport fishing, which is climaxed by an annual Deep Sea rodeo. Commercial fishermen catch red snapper, mullet, flounder, shrimp, crabs and oysters.

There are 63 kinds of snakes found in Alabama, all of them nonpoisonous except the copperhead, the cottonmouth moccasin, the coral and the rattlesnake. Alligators are found in the swamps and bayous.

Animals found in the forests include deer, bears, opossums, raccoons, wildcats, foxes (red and gray), coypu or nutria, mink, skunks, otters and beavers. The most numerous small animals are rabbits and squirrels; other common ones are gophers, moles and muskrats.

Parks and Monuments.—Alabama has 16 state parks which are administered by the state department of conservation which also has responsibility for five parkways, four historic sites, one monument and 19 public lakes. The largest is the Oak Mountain State park in Shelby county (9,940 ac.) and the smallest is Roman Beach park in Baldwin county (5 ac.). Besides Oak Mountain the most important parks are De Soto (De Kalb county), Gulf (Baldwin county), Little Mountain (Marshall county), Cheaha (Clay-Cleburne-Talladega counties), Joe Wheeler (Lawrence-Lauderdale counties), Monte Sano (Madison county), Chenacla (Lee county), Ft. Morgan (Baldwin county) and Meaher (Baldwin county).

The state government maintains a number of public lakes, the most popular of which is that in Tuscaloosa county.

Horseshoe Bend National Military park, near Dadeville and Alexander City, was created by an act of congress in 1956 to commemorate Andrew Jackson's victory over the "Red Stick" (Creek) Indians, March 27, 1814, during the War of 1812. The park is administered by the national park service which also administers the historic Natchez Trace parkway which crosses the northwestern corner of Alabama, connecting southward with Natchez, Miss., and northward with Nashville, Tenn.

Conecuh National forest is in the extreme southern part of Alabama, while Black Warrior National forest is in the northwestern part of the state.

In eastern Alabama is located the Choccolocco division of Talladega National forest; the Okmulgee division of the same forest is in central Alabama.

HISTORY

Early Indian Life.—Indians living in the area now designated as the state of Alabama left artifacts which yield a more detailed prehistoric record than other sites in North America. In 1956 the Smithsonian institution and the National Geographic society supported excavation work by Carl F. Miller who employed the radioactive carbon 14 method in excavating Russell cave in Jackson county in the northeastern corner of Alabama. The detailed record of Indian life thereby uncovered extended over a period of nearly 9,000 years.

Prehistoric Indians developed their technical skill to the point of building remarkable mounds, many of which are still to be seen at various sites along the rivers of Alabama. Artifacts of the mound builders are exhibited by the state of Alabama in the museum at Mound State monument in Moundville. Hale county.

When Europeans came to the shore of Alabama, the principal Indian groups were as follows: Chickasaws (northwest Alabama), Cherokees (northeast Alabama), Muskogees, also designated Creeks (southeast and central Alabama), and Choctaws (southwest Alabama). Each of these groups extended beyond Alabama

into the adjoining states.

In the second half of the 20th century there remained only one Indian settlement in Alabama—that of about 500 Creeks in the southern part of the state.

Exploration and Early Settlement.—Into the lands of the Alabama aborigines there penetrated each of the European powers which became a major contender for dominance in North America. The first of the known explorers were Spaniards, including Xlönzo Alvarez de Piñeda (1519), Pánfilo de Narváez (1528), Hernando De Soto (1540), Guido de las Bazaes (1558) and Tristán de Luna (1559–61). Luna's men made several temporary settlements in Alabama, particularly at Mobile, Claiborne and on the Coosa river. The exploration of Alabama areas by De Soto was extensive—from north to south, from east to west and finally from south to north.

The scene of one of the bloodiest battles between Europeans and Indians was at Mabila in Clarke county, where De Soto and his men fought the Indians under Chief Tuscaloosa, Oct. 18, 1540. The smallest figure set by the conflicting contemporary accounts of Indian casualties was 2,500.

In addition to the Spaniards, the English and the French also claimed the area which became Alabama. The English included the Alabama country in the Carolina charters of 1663 and 1665, and English traders from the Carolinas made numerous trips to the valley of the Alabama river prior to establishment of the first colony in the area by the French, who founded the first permanent European settlements in Alabama. Under the leadership of the Le Moyne brothers, Pierre Le Moyne, Sieur d'Iberville and Jean Baptiste Le hloyne, Sieur de Bienville, the French established Ft. Louis (1702, at Twenty-Seven Mile bluff), Port Dauphin (1702, Dauphin Island), Mobile (1710), Ft. Toulouse (1714, near Wetumpka) and Ft. Tombeché (1736, in Sumter county). These settlements were parts of the chain of forts which stretched from the Gulf of Mexico, through the Mississippi valley to Canada for defense against the British.

The struggle of France against Great Britain' in the Second Hundred Years' War (1689–1763) was reflected in campaigns in the Alabama country which involved the Indian allies of the European powers. The Choctaws were allies of the French while the Chickasaws were allies of the British.

Before Statehood.—The treaty of Paris (1763) removed the French and established British mastery in the Alabama country. During the American Revolution, Spanish forces under Bernardo de Gálvez seized portions of Alabama and also land farther along the fringe of the Gulf coast. This physical possession was confirmed in the treaty of Paris (1783), whereby Spain held Mobile and the coastal fringe, and the U.S. held the more northerly parts of Alabama. The dividing line between Spain and the U.S. in the Alabama country was the southern boundary of the U.S. at the time, but its exact location was not clear until Thomas Pinckney negotiated the treaty of San Lorenzo el Real (1796), establishing the boundary along the thirty-first parallel. This became known as Ellicott's line, named for Andrew Ellicott of Massachusetts who surveyed the line. Spanish control of Baldwin and Mobile counties was not removed until 1813 when the U.S. took possession of the area, claiming it to be a part of the Louisiana Purchase. Thus all of Alabama first came under the U.S. flag in 1813.

War with the Creek Indians centred in the Alabama area and was closely woven into the War of 1812. The Shawnee chief, Tecumseh, persuaded a majority of the Creek Indians to take up arms against the American settlers while at the same time the Shawnees in the Great Lakes area were also resisting the advance of the American frontiersmen. In the early stages of the Creek War there occurred one of the bloodiest Indian massacres on the American frontier—the massacre of Ft. Mims, Aug. 30, 1813, in which more than 500 persons were killed. The most important engagement in the Creek War was the battle of Horseshoe Bend, March 27, 1814. Gen. Andrew Jackson's victory in this battle was a major step in a career which led to the presidency and significant national leadership. The Creek War ended with the treaty of Ft. Jackson (1814).

With the restoration of peace, the trickle of Anglo-Americans from nearby states, especially from Georgia, the Carolinas, Virginia and Tennessee, swelled into a flood which quickly populated the Alabama country. In 1817 the Alabama territory was created, with the capital at St. Stephens and William Wyatt Bibb as the governor.

Alabama became a state in 1819, with the capital located successively at Huntsville (1819–20), Cahaba (1820–26), Tuscaloosa (1826–47) and Montgomery.

Ante-Bellum Problems.—The principal problems of ante-bellum politics centred about the state bank, Indian removal, education (see *Education*, below) and slavery.

The state bank, actually owned and operated by the state, was established in 1824 to provide money and credit which were much needed in the rapidly growing frontier state. The bank proved so profitable that all state taxation was abolished in 1836. The panic of 1837 placed too much strain on the bank, however, involved as it had become in politics, with bank officials elected annually. The bank was put out of business in 1843 after Benjamin Fitzpatrick was elected governor on the platform to abolish it.

The Indians were moved from Alabama by successive treaties of the federal government between the years 1814 and 1835.

Following the Mexican War (1846–48), political controversy stirred throughout the nation over the extension of slavery into the territories. This became a dominant theme in the history of Alabama. William L. Yancey was the author of the "Alabama platform," declaring that the federal government could not legally bar the extension of slavery to the territories. This issue was one of the prime reasons that a majority of Alabamians saw in the election of Abraham Lincoln to the presidency in 1860 adequate reason for secession.

At a specially convened state convention, Alabama seceded on Jan. 11, 1861, by a vote of 61 to 39, with most of the antisecession votes coming from north Alabama.

Civil War and Reconstruction.—Montgomery became the first capital of the Confederacy, and there, on Feb. 18, 1861, Jefferson Davis was inaugurated president of the Confederate States of America. Military operations in Alabama included raids by Union forces: John B. Turchin, 1862; A. D. Streight, 1863; Lovell H. Rousseau, 1864; and J. H. Wilson, 1865. The battle of Mobile bay (1864) was won by Adm. David G. Farragut.

Estimates of the Alabamians in Confederate military service vary from 65,000 to 100,000. Thirty-nine generals in the Confederate army came from Alabama. Approximately 3,000 Alabamians served in the Union army.

The postwar reconstruction in Alabama had three distinct phases: (1) The presidential period of reconstruction (1865–67) which was marked by a constitution adopted in 1865 that ratified the 13th amendment abolishing slavery, nullified the ordinance of secession and provided for the election of state officers. Opposition to certain state laws by the radical Republicans in the national congress resulted in the denial of seats to Alabama's representatives and senators. (For the general background of this period see UNITED STATES [OF AMERICA]; *History: From 1865 to 1910.*) (2) The second period of reconstruction (1867–68) was ushered in by the national acts of March 1867 making Alabama a part of the third military district. Maj. Gen. Wager Swayne of Ohio was appointed under presidential authority as military governor of Alabama and the radical Republicans took charge of the state's electoral processes. In Nov. 1867 another constitutional convention drafted a new constitution which, in accord with the aims of the radical Republicans, forced the adoption of the 14th amendment. (3) The "carpetbag-scalawag" era (1868–74) was the third phase of reconstruction. It was marked by corruption and extravagance on the part of numerous public officials and is generally regarded as the low ebb of the state's history.

Between the terms of radical Republican governors William H. Smith (1868–70) and David P. Lewis (1872–74), the Democrats managed to elect Robert B. Lindsay (1870–72), but it was not until the term of Democrat George S. Houston in 1874 that self-government was restored to the state.

The period from 1874 to 1896, designated the "Bourbon era," was characterized by economy, retrenchment, conservatism and dominance of the Democratic party. Paradoxically this period was marked by progress in education and industry, as the state struggled to recover from the costly losses of 14 years of war and reconstruction. The general level of economic life was low, however, by comparison with the 20th century and also with antebellum times.

Widespread poverty and depressed agricultural prices sparked the Populist revolt of the 1890s. This political group, using the designation "Jeffersonian party," nearly captured the governorship in 1890 and again in 1892, but never quite succeeded in taking over the reins of Alabama's government.

The farm revolt gradually subsided, but left a legacy of demands which were for the most part enacted into law during the 20th century.

The 20th Century.—Alabama started the 20th century with a new constitution—that of 1901—under which the state has since been governed. (See Government, below.) The Democratic party remained dominant, but some counties of the hill area consistently voted Republican. Many Negroes in Alabama also voted Republican, particularly in the period prior to 1936. In 1928 the Republicans came within approximately 7,000 votes of carrying the state.

In 1948, when Pres. Harry S. Truman ran as the regular Democratic nominee against Thomas E. Dewey, Republican, Alabama's electoral votes were cast for J. Strom Thurmond, States' Rights Democrat. In 1952 Dwight D. Eisenhower proved popular in Alabama, but failed to carry the state against Adlai Stevenson who had as his running mate Alabama's senator, John J. Sparkman. In 1956 Stevenson again carried Alabama over the nationally successful Republican candidate, Eisenhower. The slate of Democratic electors won in 1960 but six unpledged electors cast their electoral college votes for Sen. Harry F. Byrd of Virginia while five supported the successful national party candidate, John F. Kennedy. The number of electors dropped to ten as a result of the 1960 census.

During World War II, Alabama supplied personnel in the armed forces totaling 288,003, or approximately 2% of the total for the nation. Military installations in the state included Maxwell field, Camp Rucker, Ft. McClellan and Brookley field. There were increases in agricultural production, manufactures and commerce. One shipbuilding company of Alabama pioneered in the construction of ships with welded hulls, a major innovation promoting speed in wartime shipbuilding. Jan. 31, 1958, was a date of particular significance in Alabama's history, since it marked the orbiting of the first U.S. satellite, Explorer I, which was developed at Huntsville in the U.S. army's ballistic missile centre, Redstone arsenal.

GOVERNMENT

The constitution of the state dates from 1901, earlier constitutions being those of 1819, 1865, 1868 and 1875. The constitution of 1901 is a long document comprising 18 articles and 139 amendments. It contained a suffrage clause that restricted the right to vote to those who could read and write any article of the constitution of the United States and who had been regularly engaged in some lawful employment, business or occupation, trade or calling, for the greater part of the 12 months preceding the time they offered to register, or who had paid taxes on property assessed at \$300.

However, by what was called the "grandfather clause" those who had served in the army or navy of the United States or of the Confederate states in time of war, their lawful descendants in every degree, and persons of good character who understood "the duties and obligations of citizenship under a republican form of government" were relieved from the operation of this law, provided they registered prior to Dec. 20, 1902. Moreover, the new constitution stated that no person under 45 years of age might vote who had not paid, by the Feb. 1 preceding an election, all poll taxes due from him to the state.

Constitutional amendments of 1923, 1924 and 1944 exempted

veterans of World Wars I and II from the latter provision. Such restrictive clauses in the constitution prevented most Negroes from voting in Alabama.

The legislature meets biennially in regular session, and in special session when summoned by the governor. Members of the house and senate serve four-year terms, being elected in alternate, even-numbered years. The house of representatives comprises 106 members, each county having at least one member. The senate has 35 members, representing 67 counties, and the members are elected from districts comprising from one to three counties. Much of the business of the legislature is transacted by standing committees, of which there are 15 in the house and 30 in the senate.

Revenue bills originate in the house of representatives and must have senate approval. The state's revenue in the second half of the 20th century derived from nontax money (13%), federal funds (21%) and state taxes (66%).

The governor also serves a four-year term, and is chosen in the same election as the legislators, but unlike legislators is not eligible to succeed himself. The governor, however, is eligible for re-election to nonconsecutive terms. Since the ratification of the constitution, only two governors have actually served two terms: Bibb Graves (1927-31 and 1935-39) and James E. Folsom (1947-51 and 1955-59). The administrative organization of Alabama was streamlined under the leadership of Gov. Frank M. Dixon (1939-43), the culmination of efforts to this end dating back to the administration of Gov. Benjamin M. Miller (1931-35). Judges are chosen by popular election, and the larger burden of litigation falls upon the state circuit courts. The probate judge in each county has administrative and legislative duties as well as judicial functions. The probate judge is often considered the most influential official of an Alabama county.

Since the county is a subdivision of the state, the distinction between state and county government is not always clear either in law or in administrative procedure. The following are usually regarded as holding important county positions: the various county judges, the county engineer, county board of education and superintendent of education, also the sheriff, tax assessor and public health officer.

Alabama cities afford examples of all three of the principal types of city government found in the United States. The mayor-council plan, oldest of the three, is the one most widely used. Only three cities utilize the city-manager plan. Six of the seven largest cities in Alabama employ the commission plan.

Finance and Taxation.—The state's annual receipts from all sources amount to more than \$500,000,000. Of this sum, about one-fifth is derived from the federal government and about three-fifths from state tax sources. Sales taxes, income taxes (both individual and corporate) and general property taxes are the chief taxes. The state's annual expenditures total slightly more than \$400,000,000. In 1960 the state's gross debt stood at about \$131,000,000. Approximately 32% of the state's revenues are spent on education, about 25% on highways, nearly 13% on public welfare and slightly more than 6% on health and hospitals. The state's income, after World War II, increased about five times over the prewar figure, but the state's per capita income remained among the lowest in the union, 45th among the states.

POPULATION

The population of Alabama in 1820, a year after it obtained statehood, was 127,901. Its population ranked 20th among the 27 states and territories that then comprised the union, and was classified at 100% rural. The next decade was the period of the most rapid growth in the state's history—the population increased by 142% between 1820 and 1830.

Immediately before the Civil War, in 1860, the state had a population of 964,201. Of this total 435,080 (nearly half) were Negro slaves. It had advanced to the 13th most populous state, and was about 95% rural in character. The next ten years had the slowest population growth in the state's history. In 1870 the population was only 3.4% greater than it had been in 1860.

At the beginning of the 20th century, the state had slipped to

18th in rank of population with a total of 1,828,697 persons by the 1900 census. It was still largely rural in character; 88% of the people were classified as nonurban dwellers. From 1900, the nonwhite population began a slow, but steady decline which continued through the 1950 census. In 1880 the nonwhite population was 47.5% of the total, but by 1950 had declined to 32.0%. The 1950 population showed a total of 3,061,743 persons. The rural population had declined to 60% of the total at that time. The six standard metropolitan statistical areas existing in 1960 (Birmingham, Mobile, Gadsden, Montgomery, Huntsville and Tuscaloosa) contained, in 1950, 39% of the total population.

*Populations are reported as constituted at date of each census.

Note: Dash indicates place did not exist during reported census, or data not available.

By 1960 these metropolitan areas housed 44% of the total population. In 1960 Alabama had a population of 3,266,740, an increase of 204,997 or 6.7% over 1950 compared with an increase for the U.S. of 18.6% during the same period, even though Alabama's birth rate is higher, and its death rate lower, than the nation as a whole. These figures point to migration from the state that is only in part countered by migration into the state. Twenty-one counties increased in population during the ten-year period and 46 counties sustained net losses of population, primarily the result of migration of agricultural workers into urban areas in addition to the migration of population from the state. In 1960, for the first time in the history of Alabama, more than half of the population of the state was concentrated in ten counties.

The population per square mile in 1960 was 63.3, as compared with 49.6 for the United States as a whole. The 1960 urban population was 1,791,721 or 54.8% of the total, continuing the trend toward increasing urban residence—the direct result of the

increasing industrialization of the state.

EDUCATION

Among the earliest schools in Alabama were the John Pierce school at the boat yard on Lake Tensaw (1799), Washington academy at St. Stephens (1811) and Green academy at Huntsville (1812), all private schools. One of the most celebrated of the ante-bellum schools was the Greene Springs School for Boys (1847-82), founded and operated by Henry Tutwiler.

Altogether Alabama had an extensive, if inadequate, system of private schools before any of its counties had a public-school system.

When Alabama became a state in 1819 the legislature provided that funds derived from the sale of the 16th section (610 ac.) of land in each township be allotted for public education. but a number of years passed before public schools actually operated. The first public education was at the college level, when the University of Alabama commenced operating in 1831. The Mobile public-school system was created in 1852, and two years later, through the efforts of A. B. Meek, chairman of the legislature's committee on education, a Public School act was passed which authorized public schools throughout the state. This system grew rapidly between 1854 and 1861 until about one-half of school-age white children were enrolled in schools.

After the Civil War and reconstruction, the constitution of 1875 made provision for public education, despite the state's unfavourable financial condition. Illiteracy decreased from 50.9% in 1880 to 34% in 1900, and by the second half of the 20th century the population was almost entirely literate.

The 1901 constitution made detailed provisions concerning public education. Most important was the provision that school money should be apportioned among the counties according to school population in order to provide school terms in the various counties of equal or nearly equal length. This provision was important because the distribution of children and of taxable wealth was not closely correlated. Equalization was not substantially achieved, however, until the equalization program of 1929, while Bibb Graves was governor.

Other outstanding acts of the 20th century affecting public education were the three mill tax, authorizing counties and school districts to increase local school taxes from one mill to three, the School Budget act, and acts for minimum school program, teachers' tenure and teachers' retirement. There was a general shortage of teachers in the state during the 1950s. At that time, Alabama spent \$188 annually per pupil or a little more than \$100 less per pupil than the U.S. average. In 1938 the state appropriated about 8% of its income for educational purposes, but after World War II, four times as much was being spent.

In the second half of the 20th century Alabama had 14 senior colleges and 7 junior colleges for white students and 8 colleges for Negroes. State-supported senior colleges for white students were: the University of Alabama (1831, Tuscaloosa); the Medical College of Alabama (1859, Birmingham); Auburn university (1872, Auburn); Alabama college (1895, Montevallo); and State Teachers' colleges at Florence (1872), Jacksonville (1883), Livingston (1883) and Troy (1887).

The state had the following state-supported colleges for Negroes: Alabama Agricultural and Mechanical college (1873, near Huntsville); Alabama State Teachers' College for Negroes (1884, Montgomery); and Tuskegee institute (1881, Tuskegee). Tuskegee, supported only in part by state funds, has been well known since the days when Booker T. Washington and George W. Carver worked there for pragmatism in education.

Private senior colleges for white students were: Athens college (1822, Athens, Methodist); Spring Hill (1830, near Mobile, Catholic); Judson (1839, Marion, Baptist); Howard (1842, Birmingham, Baptist); Huntington (1854, Montgomery, Methodist); and Birmingham-Southern (1856, Birmingham, Methodist). Junior colleges for white students included the following: Alabama Christian college (1942, Montgomery); St. Bernard college (1892, Cullman, Catholic); Marion Military institute (1887, Marion); Snead college (1892, Boaz, Methodist); and Walker college (1938,

Jasper).

Privately owned colleges for Negroes in Alabama were: Talladega college (1867, Talladega); Stillman college (1876, Tuscaloosa, Presbyterian); Selma university (1878, Selma, Baptist); Daniel Payne college (1889, Birmingham); and Miles college (1905, Birmingham, Methodist).

HEALTH, WELFARE AND CORRECTION

Alabama's various philanthropic institutions include an institution for white deaf and blind and a school for Negro deaf and blind at Talladega; a hospital for insane whites and Negroes at Tuscaloosa and one for Negroes at Mount Vernon; and a school for mental defectives at Tuscaloosa. All these institutions are under the management of trustees appointed by the governor.

Penal institutions maintained by the state government included 5 prisons, 30 road camps and 3 training schools for youthful offenders.

THE ECONOMY

Agriculture.— Nearly one-fourth of the employed population in Alabama work in agriculture, forestry or fisheries with most of them in agriculture. The comparable figure for the United States as a whole is approximately one-eighth in agriculture, forestry or fisheries. During and after World War II, there were trends in Alabama toward fewer farmers, fewer and larger farms, less total farm acreage, more mechanization, more rural electrification, fewer tenant farmers, less farm debt and more farm income. Cotton remained the chief money crop, as it had been through most of the years since colonial times. Alabama ranked as the fourth state in the nation's total cotton production. Yet, for various causes, particularly the system of federal government allotments, the state's cotton acreage declined rapidly; especially between the years 1925 and 1947, when cotton acreage in Alabama was cut in half.

While cotton acreage was reduced from year to year, the acreage of forestry increased, as did diversification of farm production of row crops and livestock. Conversion of former cotton fields into permanent pasture for dairy and beef cattle was marked, particularly in some of the counties located in the Tennessee valley and in the "black belt."

The shift from cotton to cattle represented a full turn in the cycle of history, for cattle raising was the chief agricultural pursuit in Alabama prior to statehood and the growth of the cotton kingdom.

Manufactures.— The growth of manufactures was notable after World War II, although the history of manufactures actually extends into colonial days. In the 18th century manufacturing in Alabama consisted of hand processing of such products as indigo, naval stores and skins and furs. During the first half of the 19th century Alabama manufactures were usually produced on the farm and in small shops with extremely limited facilities of tools and power although some water power was used. Iron manufacturing, as noted previously, began in 1818. Sawmills, gristmills and boat yards were found in the state even earlier.

Before 1850 Alabama had a dozen cotton mills employing more than 700 persons and processing more than 5,000 bales of cotton yearly. In the same year the state had a total of 16 foundries, forges and furnaces. Crude as their methods were, ante-bellum ironmakers more than doubled the value of their raw materials through manufacturing. Owners of all manufacturing plants of Alabama in 1849 numbered 1,026 with a capital investment of \$3,450,606; 4,938 persons were employed. The average factory employed five workers and represented an investment of \$3,500. By 1860 the U.S. census showed that 56 items were being manufactured in the state.

Average annual pay, however, was low. For example, in 1860 the coal miner averaged \$344 and the cotton textile worker only \$151 yearly.

As late as 1880, flour and gristmills led all factories in the value of their products, but iron products moved into first place during the 1880s. In 1880 and again in 1890 manufactures of lumber and timber ranked in second place in value of products. By 1900

Alabama had about 5,000 factories employing nearly 53,000 persons. The period after 1910 witnessed enormous strides in manufactures as the state succeeded in balancing agriculture with industry.

Of all employed persons, 21.8% worked in factories—a figure which nearly equaled the average for the United States (25.9%). This trend was gradual throughout the period, but accelerated after 1940 when Alabama experienced a faster relative growth of industry than the south as a whole and a faster rate than the nation.

The largest industry in the state by mid-20th century was the manufacture of primary metals. Rated according to value added by manufacture, the 12 leading industries in Alabama were: primary metals; textiles; food; lumber and wood; chemicals; pulp and paper; fabricated metals; petroleum and coal products; apparel; transportation equipment; stone, clay and glass; and printing and publishing. At that time the total value added by manufacture was more than \$1,000,000,000 annually, an increase of 50% over the immediate post-World War II figure. With adjustments made for monetary inflation, the increase was nearly 28%.

Minerals.— Iron and coal have played starring roles in the drama of industry in Alabama. During the decade 1880-90 industries based upon iron and coal became dominant, but iron manufacturing began in 1818 when the Cedar Creek furnace started operating in Franklin county. Alabama coal received wide attention for the first time when in 1849, the British geologist Sir Charles Lyell, often called "the father of geology," published his *A Second Visit to the United States of North America*, in which he gave an account of his visit to the Warrior coal field. In addition to the Warrior, largest of the Alabama coal fields, there are the Coosa field and the Cahaba field. In ante-bellum times coal production was measured by the bushel, but by 1870 Alabama coal production was 13,200 tons.

Alabama's first blast furnace began operating in 1880 and the first steel mill in 1888 and by 1891 the state had 53 blast furnaces and 9 rolling mills. Rapid expansion of the coal, iron and steel business depended upon close proximity in the state of large deposits of iron ore, coal and limestone—the three basic materials for steelmaking. Pig iron reached a record volume of production in Alabama in 1957, with 4,442,000 gross tons. Coal production in Alabama reached a peak during 1926 of 21,001,000 net tons.

Measured by value of production, coal and iron account for a considerable part of the mineral wealth of Alabama. Yet the extent and variety of all minerals is noteworthy—coal, iron, clays, stone, limestone, sand, gravel, bauxite, greensand, gold, graphite, copper, barite, asphaltic sandstone, asphaltic limestone, salt, kaolin, fuller's earth, ocher, fluorite, silica (glass sand), lead, arsenic, manganese, lignite, dolomite, corundum, asbestos, marble, natural gas and petroleum. Some of the Alabama deposits of these minerals are small, inaccessible or for some other reason have failed of commercial exploitation. Others have accounted for much of the wealth of Alabama.

Manufacturing primary metals is Alabama's leading industry, whether measured by payroll or value added by manufacture. The world's largest known deposit of white marble is found in the vicinity of Sylacauga. Natural gas has been produced in Fayette, Marion and Walker counties. Since 1944, when the first oil well in Alabama commenced producing, over 1,000 wells have been drilled. Of these only four have yielded gas in commercial quantities, but about 400 have yielded petroleum.

The oil fields of Alabama are Citronelle (Mobile county); East Gilbertown (Choctaw county); West Gilbertown (Choctaw county); Pollard (Escambia county); and South Carlton (Baldwin and Clarke counties). Mining is the occupation of 2.7% of all employed people in the state.

Transportation.— Alabama has 1,237 mi. of navigable rivers, as follows: Black Warrior-Tombigbee waterway (465 mi.); Tombigbee from Demopolis to the Mississippi boundary (107 mi.); Chattahoochee river (135 mi.); Alabama river (315 mi.); and that portion of the Tennessee river which is in Alabama (200 mi.). The U.S. government spent millions of dollars on the elimination of obstructions in the rivers and on the improvement of Mobile

harbour. Federal, state and city funds were used to improve the facilities of the port of Mobile. During 1920 the first vessel of a fleet of government-owned-and-operated self-propelled barges made its way down the Mississippi river to New Orleans and through the Mississippi sound to Mobile and then up the rivers to Birmingham and Cordova, in the heart of the Warrior coal fields, a system of locks and dams having canalized the Tombigbee and Black Warrior, making the latter navigable deep into the mineral region of the Cumberland plateau.

An act of the legislature at the session of 1923-24 provided for an issue of \$10,000,000 of bonds for the Alabama state docks, which have played a dominant role in the increase in foreign commerce through the port of Mobile. After 1958 the port had excellent facilities for docking and loading.

All the large railroad systems of the southern states enter Alabama. The lines are: the Louisville and Nashville; the Gulf Mobile & Ohio; the Southern; the Seaboard Air Line; the Illinois Central; the Atlantic Coast Line; and the Central of Georgia. The total mainline railway mileage in the state is 4,917.

There are about 65,000 mi. of highway, of which more than 39,000 are paved. In 1930, 277,146 motor vehicles were registered; 30 years later the number exceeded 1,200,000 of which over 200,000 were trucks.

At the same time, Alabama had more than 100 public and private airports. The cities of Birmingham, Mobile, Montgomery, Selma, Dothan, Gadsden, Tuscaloosa, Florence, Sheffield, Tuscumbia and Huntsville are served by one or more airlines.

"ALABAMA" ARBITRATION, a notable example of peaceful settlement of a dispute between the United States and Great Britain, according to the treaty of Washington (1871). The dispute centred on the cruiser "Alabama," built in England and used by the Confederacy as a commerce destroyer during the American Civil War.

With the outbreak of the Civil War in 1861 it became necessary

for the leading maritime powers of Europe to define their relations to the conflict. The blockade of the ports and coasts of the Confederacy by the Federal government under its declaration of April 19, 1861, automatically extended belligerent status to the Confederate government, yet the United States protested any foreign action having the same effect. The British government, in protection of its own interests, accorded the same status to the Confederacy through its proclamation of neutrality on May 14. Similar action on the part of other countries followed.

The Confederacy immediately set about building a navy to defeat the Union naval power and to destroy the mercantile marine of the United States. The principal instrument for destroying Union commerce on the high seas was the Confederate cruiser "Alabama," built by the Laird company of Birkenhead under contract with Capt. James D. Bullock of the Confederate navy. Acting on evidence provided by the U.S. consul at Liverpool, Charles Francis Adams, U.S. minister to Great Britain, requested Earl Russell, the British foreign secretary, either to detain the vessel or to certify to its friendly character in respect of the United States. Subsequent representations to the foreign office: and reference of the question to lesser authorities, such as the commissioners of customs, had no immediate effect, but later, upon receipt of more convincing evidence, the British government issued an order of detention. However, before the order was received by the enforcement officers the "Alabama" set out to sea without clearance and did not return. She proceeded to the Azores, where she received armament and additional seamen from two British ships. Aboard commanded by Capt. Raphael Semmes (*q.v.*) of the Confederate navy and superbly equipped, the "Alabama" virtually drove Union ships from the high seas for a period of almost two years until her destruction by the "Kearsarge" off Cherbourg, France, on June 19, 1864.

Angry feeling developed in the United States over the destruction and immobilization of the nation's merchant marine and over the maritime economic advantage which accrued to Britain as a result. As early as Oct. 23, 1863, Adams protested to Earl Russell that the "Alabama" had been built, armed and equipped with "one single criminal intent," with the main portions of the crime planned and executed within the lawful jurisdiction of Great Britain. He asserted that the British government must assume responsibility for damages to U.S. citizens sustained by depredations of the "Alabama" but stated that the United States would submit to any fair and equitable form of conventional arbitration. Earl Russell replied on Oct. 26, disclaiming responsibility for the acts of parties fitting out "a seeming merchant ship" and converting it into a vessel of war after leaving the jurisdiction of British courts. Expressing surprise that the U.S. navy had not captured the "Alabama," he observed that the object of Her Majesty's government was to perform the duties of neutrality fairly and impartially, and at the same time to maintain the spirit of British law and protect the shipbuilding industry. On Aug. 30, 1865, Earl Russell added further fuel to the flames of American feeling by declaring that the two questions involved—(1) the due diligence or good faith and honesty of the British government in maintaining their neutrality and (2) the proper understanding of the law officers of the Foreign Enlistment act in declining to advise detention of the "Alabama" and other ships—could not be put to a foreign government with any regard to the dignity and character of the British crown and nation. He finally agreed to refer to a commission all Civil War claims on which the parties could agree.

After prolonged negotiation between Reverdy Johnson, the new U.S. minister to Britain, and Lord Clarendon, the new British foreign secretary, the Johnson-Clarendon convention was signed, under which four commissioners would settle all outstanding claims where possible, and on irreconcilable questions would utilize an umpire. Sen. Charles Sumner attacked the treaty in a senate speech, charging the absence of any expression of regret by Great Britain, undue haste in negotiations and responsibility to Britain for a prolongation of the war. The treaty was rejected by a vote of 44 to 1.

A negotiating state of mind soon prevailed in both countries.

It was realized that something must be done to settle the disputes growing out of the Civil War, regarding the northeast fisheries and the San Juan water boundary. On Jan. 26, 1871, Sir Edward Thornton, British minister at Washington, suggested to Secretary of State Hamilton Fish that a joint high commission be set up to settle these and any other outstanding controversies between the two nations. The commission began its work in Washington, D. C., on Feb. 27, 1871. The United States was represented by Hamilton Fish and four others. Great Britain was represented by Earl de Grey and Ripon, together with four additional colleagues. On May 8, 1871, the treaty of Washington was signed. It provided for four separate and distinct arbitrations and was the most ambitious arbitral undertaking the world had experienced up to that time.

The principal arbitration, that of the "Alabama Claims," was to be held at Geneva, Switz. Following an unusual procedure, the United States named Charles Francis Adams and Britain named Sir Alexander Cockburn as their arbitrators. At the invitation of the parties, Italy named Count Frederic Sclopis, Switzerland named Jacques Staempfli and Brazil named Viscount D'Itajuba as additional arbitrators. The U.S. agent was J. C. Bancroft Davis and the British agent was Lord Tenterden. Both were supported by an imposing array of counsel.

Upon the insistence of the U.S. commissioners, the negotiators had agreed, in article 6 of the treaty, on three rules which would be the test of neutral duty that would apply to the case. By these rules a neutral government was bound:

First, to use due diligence to prevent the fitting out, arming or equipping, within its jurisdiction, of any vessel which it has reasonable ground to believe is intended to cruise or to carry on war against a power with which it is at peace; and also to use like diligence to prevent the departure from its jurisdiction of any vessel intended to cruise or carry on war as above, such vessel having been specially adapted, in whole or in part, within such jurisdiction to warlike use. (With substitution of "means at its disposal" for "due diligence," this rule was adopted in article 8 of the Hague convention, 1907.)

Second, not to permit or suffer either belligerent to make use of its ports or waters as the base of naval operations against the other, or for the purpose of the renewal or augmentation of military supplies or arms, or the recruitment of men.

Third, to exercise due diligence in its own ports and waters, and, as to all persons within its jurisdiction, to prevent any violation of the foregoing obligations and duties.

The United States, in asking the tribunal to award compensation for damages caused by the acts of the "Alabama" and other Confederate cruisers of British origin, set forth the following categories of claims:

1. The claims for direct losses growing out of the destruction of vessels and their cargoes by the insurgent cruisers.
2. The national expenditures in the pursuit of those cruisers.
3. The loss in the transfer of the American commercial marine to the British flag.
4. The enhanced payments of insurance.
5. The prolongation of the war and the addition of a large sum to the cost of the war and the suppression of the rebellion.

The tribunal rendered its award on Sept. 14, 1872. In regard to the first item, the "direct" losses, the tribunal, voting unanimously in the case of the "Alabama" and with some dissenting votes in the cases of other ships, found Britain legally liable for the direct losses caused by these ships, and awarded the United States \$15,500,000, including interest. As to the second category of claims, *i.e.*, that of the national expenditures in pursuit of cruisers, the tribunal decided that they could not properly be distinguished from general expenses of the war conducted by the United States, and by a majority of 3 to 2, denied any compensation to the United States. With respect to the third, fourth and fifth classes of losses, embracing "indirect" claims, Great Britain stoutly denied the jurisdiction of the tribunal on the ground that such claims were barred by the treaty. The United States insisted that the treaty embraced them. This difference, which threatened the success of the tribunal, was resolved by a pre-

liminary declaration by the tribunal that these claims, despite any view of the two governments regarding the competence of that body, did not, under international law, afford a good basis for compensation and should be excluded from consideration. Thus the "Alabama" arbitration was brought to an end.

This case has had a profound effect on the history, practice and procedure of arbitration, and on the progressive development of international law. It gave to the process of arbitration, latent for many years, a new impetus, both in practice and in theoretical discussion. Differences at first regarded as inviolate questions of national honour were eventually submitted to arbitration as ones of international interest and concern. The unusual procedure of including three arbitrators chosen by as many neutral governments contributed to a growing flexibility of arbitration as a process. The rather novel nature of the claims, from a legal standpoint, indicated the wide reach of arbitration to classes of disputes then scarcely deemed justiciable in their nature. The acceptance of the three rules of the treaty of Washington disclosed a readiness to supply the defects of unsettled rules of international law by means of a device legislative in character. The number and variety of private interests affecting a great number of American nationals gave the arbitration a genuine national character. The consummate diplomacy of the members of the joint high commission in planning the labours of a future board of arbitration demonstrated in a striking manner the importance of prior negotiation as an aid to arbitration. The arbitration was a triumph for diplomacy as well as for international law and arbitration.

ALABAMA RIVER, in Alabama, U.S., is formed by the Coosa and Tallapoosa rivers about 7 mi. N.E. of the city of Montgomery; its name is derived from a Creek Indian tribe, the Alabama. The Coosa is navigable for about 200 mi. southward from Rome, Ga., largely within Alabama. Full navigation of the Tallapoosa (268 mi. long and originating in Paulding county, Ga.) is prevented by a 60-ft. fall at Tallassee, northeast of Montgomery.

The Alabama winds westward from Montgomery to the town of Selma and then flows southward. Its width varies from 600 to 900 ft. and its depth from 3 to 7 ft. Its length by steamboat measurement is 420 mi. and by U.S. survey, 315 mi. It drains about 22,600 sq.mi. of the state and is navigable through most of the year. Its chief tributary, the Cahaba (185 mi. long), rises near Birmingham and enters the Alabama at Cahaba, about 17 mi. below Selma; it is joined 44 mi. above Mobile by the Tombigbee river (about 450 mi. long, with a drainage of about 19,500 sq.mi. in Mississippi and Alabama) to form the Mobile and Tensaw rivers which flow into the Gulf of Mexico.

Until about 1900 the Alabama and its related waterways exerted a dominant influence upon economic developments in the state. Mobile and Montgomery became major cities largely because they were on the river. The Alabama is still an important carrier of cotton, cottonseed, fertilizer, cereals, lumber, naval stores, textile goods, iron products and automobiles. (W. T. Jo.)

ALABASTER (ARBLASTIER), **WILLIAM** (1567–1640), English poet, mystic and scholar in Latin and Hebrew, is the author of the Latin tragedy *Roxana* (1597, published 1632), which Dr. Johnson thought the finest Latin writing in England before Milton's *Elegies*. He was born in 1567 at Hadleigh, Suffolk, and matriculated at Trinity college, Cambridge, in 1584. As chaplain to the earl of Essex he accompanied him on the Cadiz expedition of 1596, and in 1597 was converted to Roman Catholicism. He suffered several terms of imprisonment in England on this account, but when visiting Rome in 1609 was denounced to the Inquisition because of his mystical writings. For the next eight years he wavered between Catholicism and Protestantism, finally becoming

Anglican and hence king's chaplain in 1618. In 1627 Alabaster was appointed rector of Little Shelford, Cambridgeshire. He died in April 1640.

Alabaster's unfinished Latin epic, *Elisaesis*, glorifying Elizabeth I. was praised by Spenser in 1591. His many spiritual sonnets and occasional poems in Latin, Greek and Hebrew, only a few of which have been printed, reveal his study of the Kabbala. His mysticism is apparent in the prose works *Apparatus in revelationem Jesu Christi* (1607) and *Ecce Sponsus venit* (1633), as well as in his commentaries on Revelation and the Pentateuch.

See L. J. Guiney and G. Bliss (eds.), *Recusant Poets* (1939); G. M. Story and Helen Gardner (eds.), *Alabaster Sonnets* (1959).

(M. H. D.)

ALABASTER. The alabaster of the ancients was really a marble; the alabaster of modern times is a granular form of the mineral gypsum. On the European continent the centre of the alabaster trade is Florence, where it is extensively used for statuary work and carving of ornamental objects. The best kind is pure white and translucent, but by careful heating in nearly boiling water it can be made nearly opaque, resembling marble. For discussion of the occurrence, composition and uses of alabaster see GYPSUM; MARBLE.

ALACA HUYUK, an archaeological site about 20 mi. N.E. of Bogazkoy, the old Hittite capital city of Hattushash, a few miles northwest of the Turkish market town of Alaca. The name "Eyuk," current in older sources, represents a haphazard transliteration of the old Ottoman spelling of *huyuk*, "mound."

The low but extensive mound near Alaca attracted the sporadic attention of archaeologists from the 19th century onward. Part of it was occupied by a modern village, and the only visible monuments were two colossal stone sphinxes forming part of a one-time city gate. After preliminary diggings by Georges Perrot (1861), Ernest Chantre (1863) and Hugo Winckler (1906), the excavations of Makridi Bey in 1907 revealed sections of buildings inside the gateway and a number of sculptures dating from the period of the Hittite empire. Yet the truly significant discoveries were reserved for the systematic explorations begun by the Turkish Historical Society in 1935 under the direction of H. Z. Kosay and R. O. Arik. Inside the sphinx gate traces of a large building were discovered, reminiscent of the Hittite temples at Bogazkoy. In soundings undertaken between the houses of the modern village Kosay penetrated beyond the Hittite level to a layer of ashes and debris pointing to the catastrophic end of an earlier settlement.

At and below this level the excavators uncovered between 1935 and 1939 a royal necropolis of 13 tombs dating from the Central Anatolian "Copper Age" shortly after the middle of the 3rd millennium B.C. (cf. ASIA MINOR: *Archaeology*). Previously the same period was known from the earlier levels at Alishar Huyuk (*q.v.*), which pointed to a relatively primitive community of farmers and traders. The tombs of Alaca Huyuk, however, provide evidence of uniaue cultural accomplishment and refinement in their particular topographical and chronological setting.

The small intramural cemetery was located near the centre of the city, wedged in among the town buildings. The interments reflect a succession of occupation levels spanning a number of generations. Several tombs contained the remains of both a man and a woman. The standard type is a shallow rectangular shaft lined with stones, in which the individual body was placed on its side in a contracted position. Weapons, or ornaments and toilet articles, accompanied the man or the woman respectively. Facing the dead were found vessels and household goods, numerous objects, probably used for religious purposes, notably so-called solar disks, and various statuettes and figurines. The tomb pits were covered with wooden ceilings, clay and earth; the location was marked with another stone lining, next to which lay the skeletal remains of animals sacrificed as part of the funeral proceedings.

While the pottery is comparatively primitive in style, the tomb finds (now in the Ankara museum) offer eloquent evidence of the advanced accomplishments of Copper Age metallurgy. Filigree diadems: bracelets, anklets, buckles, pins, handles, bowls, jugs and chalices of gold were found, and sheet gold or gold wire was freely used in ornamentation. Vessels and bands of silver and bowls and

statuettes of copper or bronze are freely represented. Alloys were used in mixing metals and incrustation with jade, electrum and diverse precious stones was common. A unique find was a dagger with an iron blade: iron was by far the rarest and most expensive metal of the time and still a rarity a whole millennium later.

The metal "solar disks" and animal statuettes (stag, ox) are frequently fitted to a narrow base obviously designed to be attached to the top of a staff and are hence referred to as "standards." The figurines are generally female "idols" with grotesquely accentuated sexual characteristics, probably early cult images of the typical Anatolian Mother Goddess.

There is nothing to indicate Mesopotamian inspiration or influence in the Alaca culture. While the ethnic identity of its pre-literate bearers must remain obscure, it seems most plausible to assign them to the autochthonous pre-Indo-European "Hattic" population. From an archaeological point of view approximately contemporary parallels are available among Heinrich Schliemann's Trojan treasures from Troy II, from the Early Bronze Age at Cyprus and in a find of similar gold, silver and copper objects near Amasya, northeast of Alaca, in 1950.

See H. Z. Kosay, *Les Fouilles d'Alaca Hüyük* (1951); S. H. F. Lloyd, *Early Anatolia* (1956). (J. Pl.)

ALACALUF, an Indian tribe, almost extinct, living in the west Patagonian channels, chiefly in the vicinity of Ración sound. Formerly they were much more numerous; and their canoes might be seen southward from the Gulf of Peñas to Brecknock peninsula in Tierra del Fuego, including the Strait of Magellan. Their culture in general closely resembles that of the other canoe-using tribe of Tierra del Fuego, the Yahgan (*q.v.*). The use of planked canoes by the Alacaluf has suggested the possibility of culture transference from Polynesia, but the Alacaluf planked canoe is demonstrably a local development.

See J. M. Cooper, "Analytical and Critical Bibliography . . . of Tierra del Fuego," in *Bureau of American Ethnology Bulletin* 63 (1917). (S. K. L.)

ALACOQUE, SAINT MARGARET MARY (1647–1690), French Visitandine nun and initiator of the modern practices of devotion to the Sacred Heart of Jesus, was born at L'Hautecour, Burgundy, on July 22, 1647. Having been cured of paralysis, as she believed by the Blessed Virgin, she entered the Visitation convent at Paray-le-Monial in 1671 and made her profession of vows in 1672. Leading a life of severe austerity and strict observance of rule, she testified that Christ had revealed to her his heart burning with love for mankind and bade her establish the practices of Holy Hour, communion on the first Friday of the month, and the feast of the Sacred Heart, to be observed on the Friday after the octave of Corpus Christi.

Devotion to the Sacred Heart spread rapidly in the Catholic Church, and Margaret Mary, who died on Oct. 17, 1690, was pronounced blessed in 1864 and canonized in 1920. Her feast day is Oct. 17.

BIBLIOGRAPHY.—St. Marguerite Marie Alacoque's writings and autobiography are contained in *Vie et oeuvres par les contemporaines*, 2 vol. (1901); the autobiography was published again at Paray-le-Monial in 1918 and translated into English in 1930. See also E. Bougaud, *Life of St. Margaret Mary Alacoque* (1920); *The Letters of Saint Margaret Mary Alacoque* (1954). (L. Cs.)

ALAGÔAS, a small state in northeastern Brazil, bounded on the east by the Atlantic ocean, north and west by the state of Pernambuco and south and west by the states of Sergipe and Bahia, from which it is separated by the São Francisco river. It has an area of 10,731 sq.mi. The terrain in Alagôas slopes downward from a semibarren plateau through wooded ridges and fertile valleys to a narrow coastal plain. The climate is hot and dry in the interior and humid along the coast. The name of the state is derived from the many lakes (*lagôas*) formed near the coast by beach sands blocking the river outlets. The valleys and slopes are cultivated and produce sugar, cotton, tobacco, Indian corn, rice, manioc, fruit and castor beans. Hides and skins, mangabeira rubber, cabinet woods and rum are exported in moderate amounts. Cattle raising was formerly a prominent industry but has steadily declined in recent years. Manufacturing, which has been insignificant, was expected to expand as a result of the abundant electric power avail-

able from the Paulo Afonso hydroelectric project on the São Francisco river between Alagôas and Bahia. The capital, Maceió (pop. [1956 est.] 144,663), is the chief commercial city of the state, and a modest foreign and coastwise trade is carried on through its port (Jaragub).

Alagôas was a district of Pernambuco until 1817 when it became a captaincy. It became a province of the Portuguese empire in 1823 and a state of the republic in 1889. Transportation and communication links between Alagôas and the rest of Brazil have not expanded greatly under the republic, with the result that the state has not fully kept pace with political and social developments and the material progress achieved in other areas of the northeast. State politics are marked by periodic violence, and the literacy rate (14.7%) is the lowest in Brazil. Pop. (est. 1956) 1,900,000.

(R. E. P.)

ALAIN (real name ÉMILE AUGUSTE CHARTIER) (1868–1951), French philosopher whose work profoundly influenced several generations of readers: was born on March 3, 1868, at Mortagne. Orne, and went to school there before proceeding to Alençon and Paris. Graduating in philosophy, he taught at *lycées* in a number of towns, including Rouen, where he became involved in politics and began contributing his daily *propos*, a short article of 600 words, to a Radical newspaper. The high literary quality of these *propos* soon attracted attention and they were collected and published (1908) in a book which came to be regarded as a classic. Appointed to teach philosophy at the Lycée Henri Quatre in Paris, Alain became the mentor of most of the teachers of philosophy of the next generation in France. In defiance of public opinion he foretold and denounced World War I; on its outbreak, however, he enlisted in the artillery. Refusing promotion, he spent the whole war in the ranks; and it was in the front line or in battery telephonists' dug-outs that he wrote *Mars, ou la guerre jugée* (pub. 1921; Eng. trans. by D. Mudie and E. Hill, 1930) *Quatre-vingt-un Chapitres sur l'esprit et les passions* (1917) and *Système des beaux-arts* (pub. 1920). Subsequently he resumed his post at the Lycée Henri Quatre. His most important publications over the ensuing years were *Les Idées et les âges* (1927), *Entreviens au bord de la mer* (1931), *Idees* (1932), *Les Dieux* (1934), *Histoire de mes pensées* (1936) and *Les Aventures du coeur* (1945). When age and painful disease made it impossible for him to teach any longer, he retired to a little house in the neighbourhood of Paris, where his disciples could visit him. In 1951 he was awarded the Grand Prix National de Littérature, of which he was the first recipient; this was the only honour that he accepted. He died at Le Vésinet, near Paris. June 2, 1951.

Most contemporary French critics recognize Alain as a great writer, comparing him with his friend Paul Valéry. Like Socrates Alain tried to provoke thought by stimulating and shocking men's minds, not to impose a predigested system. At the same time he was like Descartes in wanting men to be capable both of doubt and of making a choice; and he was like Spinoza in regarding happiness not as the reward of virtue but as virtue itself. We must promise ourselves to be happy, he maintained: it is man, not the physical universe, who is to blame for the sufferings of humanity. Error is human and cannot be eliminated; it can however be transcended, and it is the source of all truth. In *Les Dieux* Alain presents the religions of the world as being not milestones in a horizontal progress (*étapes*) but complementary levels in a vertical construction (*étages*); and he reverently examines each one for the measure of truth that it contains. Similarly, his attitude to individual philosophers is that it is more important to understand their meaning than to refute their arguments. Practising always what he professed, he was indeed a true lover of wisdom, in the classic sense.

See A. Maurois, *Alain* (1949); H. Mondor, *Alain* (1953). (A.E.M.)

ALAIN DE LILLE (ALANUS DE INSULIS) (c. 1128–1202), French theologian and poet, so celebrated for his varied learning that he was known as "the universal doctor." probably was born at Lille in about 1128 and studied and taught at Paris. He lived for some time at Montpellier and later joined the Cistercians, withdrawing to Cîteaux where he died in 1202.

Alain's eclectic scholasticism is both rational and mystical; his

allegorical poetry is didactic and moral. In his apologetic works Alain endeavours to prove by reason the tenets of the faith in opposition to the opinions of unbelievers. His main theological treatise, *The Art of the Catholic Faith*, purports to present a rational demonstration of the faith in a mathematical manner; his *Treatise Against Hevetics* essays to refute heterodoxy on rational grounds; and his *Maxims of Theology* assume that the principles of the faith are self-evident propositions. Alain is noted in the history of medieval Latin literature for two poems: his *Plaint of Nature*, a clever satire on human vices; and his *Anticlaudianus*, a lengthy allegory on the creation and perfection of the human soul by God and nature, theology and philosophy, the virtues and arts.

BIBLIOGRAPHY.—Alain de Lille's published works are in J. P. Migne, *Patrologia latina*, vol. 210; see also M. B. Hauréau, "Mémoire sur la vie et quelques oeuvres d'Alain de Lille," *Mémoires de l'Institut National de France, Académie des Inscriptions et Belles-Lettres*, vol. xxxii, pp. 1–27 (1886); M. Baumgartner, *Die Philosophie des Alanus de Insulis* (1896). (D. D. McG.)

ALAIN-FOURNIER (real name HENRI ALBAN FOURNIER) (1886–1914), French writer whose one novel, *Le Grand Meaulnes*, has become a classic: was born on Oct. 3, 1886. He was brought up in La Chapelle-d'Angillon (Cher), a quiet country village where his parents were schoolteachers, and completed his education at the Lycée Lakanal in Paris; after two years' military training he became first a reporter and then private secretary to a businessman. He was posted missing, presumed killed, after being ambushed on Sept. 22, 1914, during the first battle of the Marne.

Most of his writings were published posthumously; they include his early verse and prose, *Miracles* (1924), and his correspondence with his close friend Jacques Rivière. His fame, however, rests on his one completed novel, *Le Grand Meaulnes* (1913; Eng. trans. *The Lost Domain*, 1959) which was inspired by his own experiences and aspirations. The hero, an idealistic but forceful schoolboy, runs away from his village school and wanders into a children's party in a decrepit country house, where he meets a beautiful girl; the story of his search to rediscover the girl, the house and the mood of wonderment he had known there completes the novel, the outstanding quality of which is its atmosphere of other-worldly nostalgia, evoked against a realistically observed rural background.

See R. Gibson, *The Quest of Alain-Fournier* (1953). (R. D. D. G.)

ALAJUELA, a town in Costa Rica, located on the central plateau at an altitude of 3,141 ft. Its population in 1960 was 18,453. It is on the Inter-American highway and the Costa Rican railway. Alajuela, also known in Spanish colonial times as La Lajuela and Villahermosa, by the late 18th century had a population of only a few hundred people. The town was active in support of independence from Spain in 1821 and five years later suffered from a plot to restore Spanish control over Costa Rica. Alajuela was the capital of Costa Rica for a brief period in the 1830s. It was the home of Juan Santamaria, a Costa Rican soldier and hero of the defense against the invasion by William Walker (*q.v.*) in 1856. Costa Rica's coast-to-coast railway was begun in the 1870s with Alajuela the starting point and centre of much of the construction activity.

Alajuela is the capital of ALAJUELA PROVINCE, which has an area of 3,668 sq.mi. and in 1960 a population of 218,219. Next to San José it is the leading province in Costa Rica in livestock and in industrial and commercial activity. Alajuela produces about one-half of the nation's sugar cane and is a significant producer of coffee and fruits. (T. L. K.)

ALALAKH, an ancient city in the Orontes valley on an old trade route connecting Aleppo with the Mediterranean. This site, in southeastern Turkey northeast of Antioch, is marked by a mound named Atshana, which was excavated by Sir Leonard Woolley between 1936 and 1949. Eighteen main levels of occupation were defined, each accompanied by a distinctive architecture. The place was certainly occupied before 3200 B.C., but there are no buildings that need be dated before c. 2100 B.C. Remains of a massive palace with a mud-brick colonnade prove that the township was already rich in the 19th century B.C., and this preceded an even greater structure in level VII known as the palace of Yarim-Lim, a contemporary of Hammurabi of Babylon, of c. 1780 B.C. At this time Alalakh was the chief city of the district known as

Mukish and was incorporated within the kingdom of Yamkhad, of which Aleppo was the capital. The layout of the palace has something in common with Cretan architecture, but is in fact Syrian, and anticipates a type of building known as *bit hilani* more than 1,000 years later. Later levels included an important series of temples, houses and military buildings within powerful fortifications.

Even more grandiose was a towered palace in level IV occupied by several successive rulers, one of whom, Idrimi, ruled for 30 years and probably died about 1450 B.C. His magnesite statue with a long inscription records his seven-year exile and his return after coming to terms with the king of Mitanni. Extensive evidence of destruction by fire provides vivid proof of the dangers that beset this township, situated as it was in border country, on the fringes of the Egyptian, Hittite and Mitannian empires. The dominant element in a mixed population was Hurrian; in spite of many murderous raids the town was frequently rebuilt and remained a rich centre until its final destruction by the "Sea peoples" shortly after 1200 B.C. Luxury goods were common; pottery proves close contact with Cyprus and the Aegean. There was a squirearchy known as *Marianmu* who probably provided chariots in time of war, and an educated class of scribes. Inscribed tablets refer to a bazaar in which many different trades were plied. Husbandry was one of the chief sources of wealth. Silver and gold were abundant.

ALAMANNI (ALEMANNI), a Germanic people first mentioned by Dio Cassius in connection with the Roman attack on them in A.D. 213 under Caracalla. In the following decades their pressure on the Roman provinces became severe, Italy itself being more than once threatened. They occupied the Agri Decumates (*q.v.*) c. 260 and maintained pressure on the Romans in eastern Gaul as long as the Western empire existed. Late in the 5th century they expanded into Alsace and northern Switzerland, thus making those regions German speaking. In 495 they were conquered by Clovis and incorporated in the Frankish dominions.

They were originally composed of fragments of several Germanic peoples and remained throughout a loosely knit confederation of tribes (*pagi*)—the Juthungi, the Lentienses, the Bucinobantes and others. These tribes found it difficult to combine, though several of them might put their military forces under the joint command of two leaders for the duration of a campaign; *e.g.*, in 357 when the Romans under Julian defeated them in the battle of Strasbourg. But they had nothing that could be called a central government; a tribe could undertake a campaign on its own initiative, and war between tribes may not have been unknown. The Alamanni remained pagan until the first half of the 8th century. See also Index references under "Alamanni" in the Index volume. (E. A. T.)

ALAMEDA, a city of Alameda county, Calif., U.S., located in San Francisco bay on an island 1 mi. wide and 4 mi. long with an elevation of 15 ft. It is separated from Oakland to the east by an estuary crossed by four bridges and an underwater tube. The population in 1960 totaled 61,316. (For comparative population figures see table in CALIFORNIA: Population.)

The city is widely known as the site of one of the largest naval air stations in the United States. Established in 1940, the base became a home for the navy's fleet and aircraft squadrons supporting the action in the Pacific ocean during World War II and the Korean war. These defense installations cover about 2,500 ac., with buildings, grounds and repair shops valued at more than \$100,000,000. The naval air station employs a staff of approximately 15,000 military and civilian personnel.

During the early Spanish rancho era Alameda was a cattle-grazing region. Following the gold-rush days it became a residential district noted for its favourable climate, vegetable gardens, flowers and long stretches of sandy beach. The town was incorporated in 1854.

After 1900 the business and social life of Alameda was closely related to the entire east-bay metropolitan area which includes

Albany, Berkeley, Emeryville, Piedmont, Oakland, San Leandro and Hayward. The city residential districts stand in contrast to the docks, warehouse terminals, shipbuilding ways and industrial plants scattered along the 14 mi. of water front. Manufacturing includes steel fabrication, lumber mills, paper products and food processing. Alameda adopted a council-manager form of government in 1917. (R. M. W.)

ALAMEIN, BATTLE OF: see EL ALAMEIN, BATTLE OF.

ALAMGIR I: see AURANGZEB.

ALAMGIR II (1699-1759), Mogul emperor from 1754 to 1759, was born in Multan on June 6, 1699, a younger son of the emperor Jahandar Shah (reigned 1712-13). He was placed on the throne by Imad ul-Mulk, the wazir who had deposed Ahmad Shah (*q.v.*). Since his father's murder, Alamgir had been secluded in the fort of Delhi, devoting himself to study and piety. Though he adopted Alamgir I (Aurangzeb, *q.v.*) as his exemplar in the public conduct of business, Alamgir II remained always the puppet of more powerful men. Provoked by Imad ul-Mulk's attempt to reassert control over the Punjab, Ahmad Shah Durrani (*q.v.*) occupied Delhi in Jan. 1757 and confirmed Alamgir as emperor of Hindustan. His withdrawal opened a struggle for the plundered capital between his agent Najib Khan and the Marathas (in alliance with Imad ul-Mulk). The Marathas seized Lahore from Ahmad Shah Durrani's son in April 1758, leading to another Durrani invasion in Oct. 1759. Fearing that Alamgir II would again be captured by the invaders and turned into a tool against him, Imad ul-Mulk on Nov. 29, 1759, had the emperor murdered.

See Sir Jadunath Sarkar, *Fall of the Mughal Empire*, vol. ii, 2nd ed. (1950). (P. H.)

ALAMO, a historic building in San Antonio, Tex., noted as the scene of a heroic defense by a small body of Texas volunteers against a Mexican army in Feb.-March 1836. The building was originally the chapel of the Mission San Antonio de Valero, founded between 1716 and 1718 by Franciscans. Before the end of the century the mission was abandoned and the buildings had fallen into partial ruin. After 1801 the chapel was occupied sporadically by Spanish troops. Apparently it was during this period that the old chapel became popularly known as "the Alamo" from the grove of cottonwood (*Sp. alamo*) in which it stood.

In Dec. 1835, at the opening of the Texas war for independence (see TEXAS: History), a detachment of Texas volunteers drove a Mexican force from San Antonio and occupied the Alamo. Some Texan leaders, including Sam Houston, counseled the abandonment of San Antonio as impossible to defend with the small body of troops available, but the volunteers at the Alamo refused to retire from their exposed position. On Feb. 23, 1836, a Mexican army, numbering about 4,000 and commanded by Gen. Antonio López de Santa Anna, arrived from south of the Rio Grande and immediately began a siege of the Alamo. The defending force was a small body of about 180 men commanded by Cols. James Bowie and William B. Travis and including the renowned Davy Crockett. For 12 days they held out, but on the morning of March 6 the invaders stormed through a breach in the outer wall of the courtyard and overwhelmed the Texans. Santa Anna had ordered that no prisoners be taken, and the defenders were all slain. The invaders suffered heavy casualties, with the number killed reliably estimated at from 1,000 to 1,600. These casualties and the time lost in reducing the Alamo dislocated Santa Anna's campaign long enough to permit Houston to perfect plans for the defense of Texas. The Alamo became for Texans a symbol of heroic resistance in the cause of freedom.

For many years after 1845 the Alamo was used by the U.S. army for the quartering of troops and the storage of supplies. In 1883 it was purchased by the state of Texas. In 1903 Texas acquired title to the remainder of the old mission grounds. The Alamo and adjacent buildings have been restored and are maintained as a historic site and as a memorial to the heroes of the 1836 siege.

BIBLIOGRAPHY.—Amelia Williams, "A Critical Study of the Siege of the Alamo," *Southwestern Historical Quarterly*, xxxvi-xxxvii (1933-34); J. M. Myers, *The Alanzo* (1948); F. C. Chabot, *The Alanzo: Altar of Texas Liberty* (1931). (H. W. By.)

ALAMOGORDO, a city in southern New Mexico's Tularosa

basin, U.S., 80 mi. N.N.E. of El Paso, Tex., seat of Otero county. (For comparative population figures see table in *NEW MEXICO: Population.*) The name is from the Spanish and means "the big cottonwood tree." Founded in 1898 by the Southern Pacific railroad, Alamogordo until World War II was economically dependent upon the railroad and ranching, and upon the timber, recreational areas, and orchards and farms of the Sacramento mountains. The New Mexico School for the Visually Handicapped is located there. White Sands National monument, Lincoln National forest, Mesquero Indian reservation and Sacramento Peak observatory are nearby.

The first atomic bomb was exploded July 16, 1945, at the Alamogordo air force base. This base subsequently was converted to the Holloman Air Development centre for testing guided missiles and pilotless aircraft, and for aeromedical and space-biology research. (I. G. C.)

ALANBROOKE, ALAN FRANCIS BROOKE, 1ST VIS-COUNT (1883–), of Brookeborough, British field marshal, one of the leading figures of World War II. was born at Bagnères de Bigorre, France, of north Irish stock, on July 23, 1883, and educated abroad. After serving in the royal artillery in World War I he became director of military training at the war office (1936–37) and held the antiaircraft and southern commands at home. In World War II, as commander of the 2nd army corps, he rendered outstanding service during the retreat to Dunkerque (Dunkirk) and commanded the reconstituted expeditionary force until the French armistice. In July 1940 Brooke became commander in chief of the home forces, and in Dec. 1941 he succeeded Sir John Dill as chief of the imperial general staff, a post he held until 1946. As chairman of the chiefs of staff committee he represented their views ably and firmly to the prime minister and to the United States and played an important part in the direction of Allied strategy. Highly respected as a staff officer, Brooke was also recognized as a brilliant commander in the field: it was his ill-fortune that none of the great overseas commands fell to him. Alanbrooke was made a baron in 1945 and created a viscount in 1946.

ÅLAND ISLANDS: see *AHVENANMAA*.

ALANI, a nomadic pastoral people who occupied the steppe region northeast of the Black sea. Their name first appears in Roman literature in the 1st century A.D. Later they frequently raided the Parthian empire and the Caucasian provinces of the Roman empire. Overwhelmed by the Huns c. 370, many fled westward and crossed into Gaul in 406 in company with the Vandals and Suebi. Some of these settled near Orléans and others near Valence, but most crossed to Africa with the Vandals. The official title of the Vandal kings in Africa was "king of the Vandals and Alans." Those Alans who remained under the rule of the Huns are said to be the ancestors of the modern Ossetians in the Caucasus, whose speech belongs to the Iranian group of Indo-European languages.

The Alans are described by Ammianus Marcellinus in the 4th century as a people to whom agriculture and slavery were unknown; they lived in wagons and moved from pasture to pasture with their herds, devoting particular attention to horse breeding. Warfare was their great delight. They had no temples or shrines but worshiped a naked sword stuck in the ground. (E. A. T.)

ALAPAYEVSK, a town of Sverdlovsk *oblnst* of the Russian Soviet Federated Socialist Republic, U.S.S.R., is situated on the eastern flank of the Grals, on the Neyva river and on the north-south lateral railway, with a branch westward to Nizhni Tagil. A centre of iron and copper mining, it is one of the oldest metallurgical towns in the Urals, dating from 1703. There is an integrated iron and steel works, and copper smelting and machine building are carried on. There is a hydroelectric plant on the Neyva river., Pop. (1959) 42,000. (R. A. F.)

ALARCON, PEDRO ANTONIO DE (1833–1891), Spanish writer famous for his novel *El sombrero de tres picos* (*The Three-Cornered Hat*), was born at Guadix, March 10, 1833. He had achieved a considerable reputation as a journalist and poet when his play *El hijo pródigo* was hissed off the stage in 1837. The

failure exasperated Alarcón so much that he enlisted as a volunteer in the Moroccan campaign of 1859–60. The expedition provided the material for his brilliant *Diario de un testigo de la guerra de África* (1859), a masterpiece in its way as a description of campaigning life. On his return Alarcón served the liberal cause as editor of the periodical *El Ldtigo*. But in the years 1868–74 he ruined his political reputation by rapid changes of front. His literary reputation steadily increased, however. *El sombrero de tres picos* (1874; Eng. trans. 1918, 1935), a short novel inspired by a popular *cancidn*, lives for its skilful construction and pointed observation. It is a masterpiece of the *costumbrista* ("regional") manner and a pointer to later things. Manuel de Falla based his ballet of the same title on the story. His major novels are: *El final de Norma* (1855), *El escándalo* (1875), *El niño de la bola* (1880) and *La prddiga* (1882). These all show a picturesque, vivid style, often marred by high-flown rhetoric, characteristic of Spanish romantic writing. Alarcón died at Valdemoro, near Madrid, July 10, 1891. (I. M. G.–LL.)

ALARIC (c. 370–410), chief of the Visigoths from 395 to his death, conqueror of Rome, was born on the island of Peuce at the mouth of the Danube. A nobleman by birth, he entered the Roman empire in 376 with the rest of his people from their former homes in the region now known as Rumania and settled with them in Moesia between the Danube and the Balkan mountains in 382. On the death of the emperor Theodosius I in 395: Alaric, chosen as chief of his people, complaining that the Visigoths had not been paid the agreed subsidies, marched on Constantinople. Diverted by the prefect Rufinus, he turned on Macedonia and Thrace. He was met by Stilicho (*q.v.*) and a Western Roman army who, however, were rendered powerless by the machinations of Rufinus and the Eastern emperor Arcadius. Alaric and his men turned southward and devastated southern Greece. Thebes was saved but the Piraeus was plundered, and Corinth, Megara, Argos and Sparta were ravaged. In the spring of 397 Stilicho again brought a force to Greece and surrounded the Visigoths in Elis, but for unknown reasons did not force them to surrender. Alaric then plundered Epirus until Arcadius placated him, probably by appointing him *magister militum* (master of the soldiers) in Illyricum. In 401 Alaric appeared west of the Julian Alps and advanced to Aquileia. Stilicho withdrew his troops from the Rhine and from Britain and inflicted a reverse on the Visigoths at Pollentia (Pollenzo) on Easter Sunday, April 6, 402; but he allowed Alaric to leave Italy. In 403 Alaric again crossed the Julian Alps and threatened Verona, where he was defeated by Stilicho but was allowed once again to escape from Italy.

Little is known of him in the years that immediately followed. He intrigued with Stilicho against the Eastern empire, but in 407 obliged the Roman senate to pay him 4,000 lb. of gold. On the murder of Stilicho (Aug. 403) an antibarbarian party took power in Rome and incited the Roman troops to massacre the wives and children of the barbarian soldiers who were serving in the Roman army. These troops thereupon went over to Alaric and substantially increased his military strength. Although he was anxious to keep peace with Rome, his negotiations broke down; he invaded Italy, reached the walls of Rome and cut off the city's food supply. When the senate promised him a large sum of money and assistance in his negotiations with the emperor Honorius, Alaric raised the siege of the city, which had suffered severely from famine. Honorius remaining intransigent, however, Alaric in 409 marched again upon Rome, and again the city suffered from hunger as a result of his blockade. A rival emperor, Priscus Attalus, was set up and gave Alaric an important official position in the Roman service, that of *magister utriusque militiae* (master of both services), but refused to allow Alaric to occupy Africa. Alaric subsequently deposed him but again failed to reach agreement with Honorius. In 410 he laid siege to Rome for the third time. The city gates mere treacherously opened to him on Aug. 24 and for three days his men occupied the capital, which had not been captured by a foreign enemy for nearly 800 years. Much wealth was plundered and some buildings were burned. But several stories were afterward told to illustrate the humanity of the Christian Visigoths while inside Rome, and there is no reason to attribute any extensive

destruction of the buildings in the city to Alaric's men. When he withdrew from Rome, taking with him as a prisoner the emperor's sister Placidia, he planned to occupy Africa, the granary of Italy. He marched southward to Rhegium (now Reggio di Calabria), but the ships he assembled were wrecked in a storm and the enterprise had to be abandoned. The Visigoths turned northward again, but Alaric died at Consentia (Cosenza) and was buried with many treasures in the bed of the Busentus (Busento) river, where his body might never be found and desecrated. He was succeeded as leader of the Visigoths by his brother-in-law Ataulphus.

The chief event with which Alaric's name is associated, the capture of Rome in 410, was a symbol of one of the great processes of history, the fall of the Western Roman empire; yet few would refer to him as one of the "great men" of history, for in fact his career was a failure. Throughout his time as leader of the Visigoths his aim was to find land within the Roman empire on which his people could settle in security and peace and where he himself would be recognized as an important Roman dignitary. But he never achieved this aim, and all his marches and countermarches in Greece and Italy were ultimately futile. It is impossible to estimate in detail his qualities as a military leader, for no description exists of any of his battles. None of his major battles was a complete success, and his losses were often severe. He penetrated to Rome only when the Roman government had been disorganized by the murder of Stilicho and his followers. Yet in spite of his consistent lack of success his influence over the Visigoths appears to have been immense, for mention is rarely made of dissensions in his camp or of his men deserting to the Romans (though cases are not wholly unknown).

It is also impossible to form a picture of his personality, for the sources of information about him are very meagre and disjointed. But he does not appear to have been a mere rude barbarian. Throughout his career he moved on terms of some familiarity with members of the official aristocracy of the empire, and these Roman officials were able to exercise considerable influence over him in such important matters as the raising of the siege of Ravenna during the campaign of 409 and the deposition of his puppet emperor Attalus. In the opinion of the Gothic historian Jordanes, it was his farsighted policy to bring it about that Romans and Goths should live on such amicable terms that both might be considered to be a single people; and this policy was subsequently taken up by his successor Ataulphus, though it was never fully achieved.

Two anecdotes told about Alaric are perhaps revealing. When advised to withdraw from Italy in 402 he told his warriors that a clear voice had come to him from a grove, saying "Thou shalt penetrate to the city." And when a monk urged him to abandon his designs on Rome in 408, he is said to have replied that he was not acting of his own free will but was forced by some power which incessantly urged him to occupy Rome. He apparently believed that it was his destiny to capture the city. He was an Arian Christian, like the majority of his followers.

See J. B. Bury, *History of the Later Roman Empire*, vol. i (1923); E. Demogeot, *De l'Unité à la division de l'empire romain*, 395-410 (1951). (E. A. T.)

ALARIC II (d. 507), king of the Visigoths, succeeded his father Euric on Dec. 28, 484. His dominions comprised Spain (except Galicia), Aquitaine, Languedoc and western Provence. Alaric, like his father, was an Arian Christian, but he mitigated the persecution of Catholics and authorized the Catholic council at Agde in 506. To provide a law code for his Roman subjects he appointed a commission to prepare an abstract of Roman laws and imperial decrees. This code, issued in 506, is generally known as the *Lex Romana Visigothorum* or Breviary of Alaric (*q.v.*).

Alaric tried to maintain his father's treaty with the Franks, but Clovis, the Frankish king, made the Visigoths' Arianism a pretext for war. In 507 the Visigoths were defeated in the battle of the Campus Vogladensis (Vouillé or Vouglé, in Poitou). Alaric is said to have been overtaken in flight and killed by Clovis himself.

ALAS, LEOPOLDO (pseudonym, CLARÍN) (1852-1901), Spanish novelist, an Asturian but born at Zamora, April 25, 1852, became by his periodical articles, sometimes called *paliques* ("chit-

chat"), the most feared and influential literary critic of Spain in the period 1887-1900. Among his friends were Menéndez y Pelayo, Armando Palacio Valdés and Miguel de Unamuno. His enemies were numberless. In two of the greatest novels of the century, *La Regenta* (1884-85) and *Su único hijo* ("An Only Son"; 1890), he transfixed with biting irony and brilliant characterization the intriguing, selfish bourgeois society of a provincial city, especially that of Vetusta (Oviedo), in which he spent his life as a professor of law. In his delightful and often humorous short stories are revealed his love for Asturias, the breadth of his reading and the richness of his personality. His early advocacy of anticlericalism, naturalism and Krausism considerably obscured his fame in Spain. He died at Oviedo on June 13, 1901. (R. F. B.)

ALAS, a Malayo-Polynesian agricultural and village people of north central Sumatra. See GAJO.

ALASEHIR (anc. PHILADELPHIA), a town in the Manisa il, Turkey, lies in the valley of the Kuzu Chai (Cogamus) at the foot of the Boz Dag (Tmolus), 83 mi. E. of Izmir (105 mi. by railway). Pop. (1960) 13,923 (urban), 34,695 including villages administered by the town. It is connected by railway with Afyon Karahisar and Izmir. Alasehir is poorly built but, as it stands above the wide fertile Hermus plain, the distant view is imposing. There are small industries and a fair trade. A mineral spring yields a heavily charged water, eau de vols, in great demand in Izmir. Tobacco, grapes and fruit are the main agricultural products; the town exports these and imports cereals: especially wheat to meet local demand. Philadelphia was founded by Attalus II of Pergamum about 150 B.C., became one of the "seven churches" of Asia and was called "Little Athens" because of its festivals and temples. It was subject to frequent earthquakes. Philadelphia was an independent neutral city, under the Latin knights of Rhodes, when taken in 1390 by Sultan Bayezid I after a long resistance, when all other cities of Asia Minor had surrendered. Twelve years later it was captured by Timur, who built a wall with the corpses of his prisoners. (N. TU.; S. ER.; E. TU.)

ALASKA, largest state of the United States of America, occupying the extreme northwestern part of North America and including the adjacent islands. The name "Alaska" is an adaptation of the Eskimo Alakshak, meaning "mainland," though much popular belief, going back to the voyages of Captain Cook, gives it the meaning "the great country." The state of Alaska comprises first, all that part of the continent west of the 141st meridian; second, the eastern Diomed Island in Bering strait (the western island, little more than a mile away, is in C.S.S.R. territory), all islands in the Bering sea and the Aleutian chain lying east of a line drawn from the Diomedes to pass midway between Copper Island, off Kamchatka, and Attu Island of the Aleutians; third, a narrow strip of coast and adjacent islands north of a line drawn from Cape Muzon, in latitude 54° 40' N., up Portland canal to its head and thence, following the summit of the mountains situated parallel to the coast, to the 141st meridian, provided that when the line runs more than ten marine leagues from the ocean the limit shall be formed by a line parallel to the windings of the coast which shall never exceed the distance of ten marine leagues therefrom. This strip is sometimes called the Panhandle. Alaska is bounded on the north by the Arctic ocean; on the west by the Arctic ocean, Bering sea and Bering strait; on the south and southwest by the Gulf of Alaska and the Pacific ocean; and on the east by British Columbia and Yukon Territory. Alaska covers 586,400 sq.mi., an area equal to nearly one-fifth that of the rest of the United States. Admitted to the union as the 49th state in 1959, it is sometimes known as "the Last Frontier."

The state capital is Juneau (*q.v.*); the state flower is the forget-me-not and the state bird is the Alaska willow ptarmigan. Gold stars representing the Big Dipper and Polaris on a field of blue form the state flag.

I. PHYSICAL GEOGRAPHY

Alaska may be divided into three great regions on the basis of topography, drainage and climate: (1) mountainous southern Alaska; (2) the Interior, a broad area of low relief drained by the Yukon and Kuskokwim rivers; and (3) arctic Alaska, which is separated from the Interior by the Brooks range.

1. Southern Alaska.—This is a mountainous strip often a hundred miles wide comprising a number of exceedingly rugged ranges, crowned by Mt. McKinley, the highest of North American mountains. The sea-borne visitor approaches southeastern Alaska along the sheltered Inside passage through the evergreen-clad islands of the Alexander archipelago. Proceeding through Icy strait to the Gulf of Alaska, he may glimpse the most heavily glaciated area of Alaska, including the piedmont-type Malaspina and Bering glaciers, each as large as the state of Rhode Island. Along much of the coast, however, the ranges rise to great heights directly from the ocean. Toward the west, the mountains of the Alaska peninsula and the Aleutian Islands are lower and younger, having shown volcanic activity at least 47 times since 1760.

This region is an extension of the Coast range, a section of the great arc of mountains surrounding the Pacific basin. Tilted sedimentary deposits of great depth are intermingled with volcanic rocks to form an exceedingly complex geological story. To the effect of repeated folding and uplifting has been added glacial action. Large areas were probably at one time under a continental sheet, and native legend suggests that glaciers may have been much larger within the past 1,000 to 2,000 years.

In consequence of its geological history, southern Alaska has short river valleys and limited amounts of level land. Hence agriculture is at present largely confined to limited areas around Palmer in the Matanuska valley and around Homer on the Kenai peninsula. A second consequence is the presence of minerals. Gold has been found at a number of places. An extremely rich copper mine was operated at Kennicott. Coal is known in a number of places. Oil has been produced commercially at Katalla. But because of the great amount of faulting, rich mineral prospects have not always demonstrated sufficient reserves to sustain commercial operation.

2. The Interior.—The Interior of Alaska is a broad area between the Alaska range to the south and the Brooks range to the north. It is a land of broad valleys and comparatively low ranges.

Its dominant feature is the Yukon river, which rises in Canada and flows northwesterly to join the Porcupine at Fort Yukon (*see also* YUKON RIVER). It then flows southwesterly to the Yukon delta, where, near Russian Mission, it again swings northwest to the Bering sea. At the Canadian boundary a wedge-shaped projection of hills separates the Yukon from its southern tributary, the Tanana. The city of Fairbanks is located in the Tanana valley, the principal agricultural area of the Interior.

The wedge of hills converges near Livengood, broadening out only to be cut by the Yukon river as it tumbles through its narrow confines at Rampart. There the Ray mountains blend with the foothills of the eastern Brooks range, which are drained by the Koyukuk, the Chandalar and other streams whose names have become half forgotten since the gold rush of 1898.

In the southwest, the many-branched Kuskokwim river drains the foothills of the Alaska range, then flows through the Kuskokwim mountains to empty its waters in the great delta areas of the Yukon. Southwest of its upland plateau are a number of smaller rivers draining into Bristol bay.

To the northwest lies the mountainous Seward peninsula, terminating in Cape Prince of Wales at Bering strait. Gold, tin and platinum are among the minerals which have been recovered in commercial quantities from this area.

3. Arctic Slope.—The Brooks range separates the Yukon valley from the arctic slope. It is an extension of the Rocky mountain system. At the Canadian border it approaches the Arctic ocean. Its peaks reaching an elevation of 9,239 ft.; toward Bering strait their elevation decreases to around 3,000 ft. The average width of the range is about 50 mi. The mountains are for the most part rugged and barren. A number of mountain groups compose the range. Anaktuvuk pass in longitude 151° W. is the principal means of access from the Yukon.

North of the Brooks range lies a foothills province which is about 20 mi. wide at the Canadian border and reaches its greatest width, 80 mi., near the Colville river, which flows easterly some distance through the foothills before turning north to the ocean. While the foothills break sharply from the mountains at an elevation of about 4,000 ft., their transition to the coastal plain is at times very gradual.

The arctic coastal plain forms a crescent, the tips of whose horns touch the Canadian border on the east and Cape Beaufort on the west. Its greatest breadth, about 90 mi., is south of Point Barrow. The plain is remarkable for the number of shallow lakes covering its northern portion. During the summer much of the area becomes so swampy as to be impassable. The plain is so flat that hummocks a dozen feet high may be seen at great distances. The coastal waters are shallow, with frequent sand bars and islands paralleling the coast. Occasionally the shore line consists of bluffs, seldom exceeding 25 ft. in height.

About 37,000 sq.mi. of the 76,000 sq.mi. north of the divide constitute the United States naval petroleum reserve number 4. From 1923 to 1926 the U.S. geological survey conducted reconnaissance surveys of the geology and topography of the region. A wartime effort to locate fuel resources was begun in 1944 and continued until 1953. At Umiat an oil field was located. Gas struck near Barrow was piped to that village for fuel. The principal gas discovery was the Gubic field.

4. Climate.—Alaska presents wide variations in climate. no error being greater than to assume that all areas are arctic, or that the heaviest glaciation is in the arctic areas.

Southern Alaska has an oceanic climate with no great extremes of temperature, the Japan current bringing both warmth and moisture. The southeast coast has a heavy rainfall?the amount varying sharply within a few miles, due to local factors. Juneau (*q.v.*), with an annual rainfall of about 90 in., is fairly typical. This rainfall is no greater than at Tillamook, Ore., although a greater proportion falls during the summer at Juneau. Juneau airport receives 25 in. less than the city. Ketchikan receives about twice

the rainfall of Juneau. The south central coast tends to have less rain and more snow. Anchorage's annual precipitation is 18.6 in.

The great glaciers of Alaska lie principally between Glacier bay and Prince William sound, where the heights of the St. Elias, Wrangell and Chugach mountains, a number of which are 10,000 to 15,000 ft. high, intercept the moisture-laden winds from the Pacific. Other glaciers lie along the Alaska-Canada boundary of southeastern Alaska. Glaciers are reported to cover only 3% of the area of Alaska.

The Aleutian Islands are cool in summer, cold in winter and rainy at all times. Temperatures seldom exceed the range 0° to 70° F. The annual rainfall at Unalaska Island approximates 80 in., with 250 rainy days out of the year. The main plague of the navigator is fog.

The Interior has a continental climate, with an annual rainfall of about 20 in. The mean temperature for January at Fairbanks is comparable to that of Nebraska. Winter temperatures occasionally fall below -70° F., while the long hours of summer sunlight may send the temperature above 90° F. Along the Bering sea the tempering influence of the ocean currents practically disappears north of the Pribilof Islands, which are often within the edge of the midwinter ice fields.

The arctic slope is wind swept; the midsummer and early autumn temperatures are relatively mild.

Ice bars shipping from Point Barrow from October to August. On land, however, the spring and late autumn are the best seasons for movement of supplies by aircraft or motor vehicles.

5. Soils.—Two characteristic conditions of Alaskan soils are glacial gravels and permafrost. This is the condition in which the soil is frozen several feet below the surface throughout the year. Permafrost exists throughout the arctic slope and in roughly half the Yukon valley. It exists in isolated spots in southern Alaska. During the summer the surface will thaw, the depth depending on latitude, vegetable cover, orientation to the sun and other factors. Where small bodies of ice have formed, removal of the vegetable cover will cause pits to form, requiring repeated leveling for farm use or for construction purposes. Special engineering techniques have been devised to protect buildings and airfield runways from sinking as the thaw progresses. Other problems created are sewage disposal, protection of ground-water supplies from contamination, piping of domestic water and soil fertilization.

6. Vegetation.—The Alaskan flora is varied. Wild flowers are alpine in size, colour and profusion. The timber of the Tongass National forest in southeastern Alaska is primarily hemlock. Other common varieties are Sitka spruce (see SPRUCE) and cedar. While that area has been described as "northern jungle," the timber of the Chugach National forest around Prince William sound is stunted and of little immediate commercial value. The western timber limit is on Kodiak Island. The Aleutian Islands are almost destitute of trees, although shrubs and berries grow, and grass is often lush and rank.

The woods of the Interior consist largely of spruce, with birch and balsam poplar intermixed. Thickets of alder and willows grow in wet places and on new-made land, while west of the spruce area aspens and large cottonwoods are common. Northward, the timber line follows the southern slope of the mountains from Kotzebue sound to a point eastward of Anaktuvuk pass, where the timber line crosses to the northern slopes.

On the arctic slope the willows shrink to shrubs. Several varieties of grasses are found. Most distinctive is the ubiquitous carpeting of mosses and lichens, varying in colour from the pure white and cream of the reindeer moss, a species of lichen, to the deep green and brown peat moss, all conspicuously spangled in the brief summer with bright flowers, heavy blossoms on stunted stalks.

7. Animal Life.—Alaska's rich and surprisingly varied animal life has not only been the economic base of Eskimo, Aleut and Tlingit cultures, but has proved the principal economic base of its development under Russia and the United States.

Most universally exploited of its fish have been the salmon, on which all its peoples have depended. Halibut remains a staple.

The cod have almost disappeared. King and Dungeness crabs and smaller shellfish are marketed. The sea otter, whose fine pelt became the staple of the Russian-American company, was found all along the southern coast from the Aleutians eastward. After becoming almost extinct, the sea otter is again increasing in numbers. The sea lion, walrus and fur seal are found, the latter breeding on the Pribilof Islands. Big game along the south coast and in the Interior included bear, moose and elk. Great herds of caribou range the arctic slope and are occasionally seen in the Interior. Whale continue to provide food to the Eskimo, as well as commercial fats and proteins to modern whalers. Animals hunted for their fur include several varieties of fox, the sable, ermine, wolverine, mink, land otter, beaver and muskrat.

8. National Parks and Monuments.—Glacier Bay National monument (*q.v.*) is about 100 mi. N.W. of Juneau. Brought to public notice by the writings of John Muir, it is now accessible by air as well as by sea. It has been the site of many glaciological studies. Mt. McKinley National park is accessible from the Alaska railway and from the Alaska highway system via the Denali highway. Mt. McKinley rises to a height of 20,320 ft. (see MCKINLEY, MOUNT). The park is also a wildlife preserve. Katmai National monument on the Alaska peninsula was established after the eruption of Mt. Katmai in 1912 was found to have created a host of fumaroles in the Valley of Ten Thousand Smokes (*q.v.*) similar to those of Yellowstone. Although this volcanic activity has decreased sharply, the monument has become a Mecca for sports fishermen. Sitka National monument is a 54-ac. park on the site of the Indian fort destroyed by the Russians in 1802. Its notable totem pole collection came from old Haida (*q.v.*) villages in southern Alaska.

9. Transportation Routes.—The principal sea routes to Alaska have been from Seattle through the Inside passage to southeastern Alaska ports, or from San Francisco directly to Cook inlet, Prince William sound or the Bering sea. Until 1898 the few bulk commodities that went to the Interior were usually shipped by river steamer up the Yukon. The White Pass and Yukon railroad, following a miners' trail, opened an alternate route through Canadian territory. Two routes to the Interior were opened through Alaskan territory, one from Prince William sound where a trail was developed into the Richardson highway, the other being the Alaska railroad's route from Cook inlet. The Alaska highway begins at Dawson Creek, B.C. It follows the course of the Tanana river. One may cross the mountains north of the Tanana to the Yukon by either the Taylor highway to Eagle, Alaska, or to Dawson, Yukon Territory, or travel the Steese highway to Circle, Alaska. Point Barrow was formerly accessible only by ship during late summer, or by dog sled. Regular air flights have been established to Point Barrow, as well as to Kotzebue.

II. HISTORY

1. Russian Period.—At approximately the same time that French fur traders and trappers were paddling up the Great Lakes, Russian traders and trappers were following the rivers of Siberia to the Pacific. Further exploration awaited Peter the Great's commissioning Vitus Jonassen Bering (*q.v.*) to determine whether Siberia and North America were linked. In Aug. 1728 Bering sighted St. Lawrence Island and entered the Arctic ocean, returning without having sighted the American mainland or having definitely proved it to be separated from Siberia.

Though probably sighted in 1732, effective discovery of Alaska, which came to be known as Russian America, and exploration of its southern coast awaited Bering's second voyage in 1741. On July 15 Alexei Chirikov, commanding Bering's second vessel, made a landfall, and on the next day Bering sighted magnificent Mt. St. Elias (18,008 ft.) on the southern coast. Bering's vessel was wrecked on Bering Island (one of the Commander group), where he died. The survivors brought pelts of the sea otter to Petropavlovsk, stimulating a demand which lured fur traders to the new coasts.

During the next six decades a host of traders and hunters purchased or stole peltries from the Aleuts, seized their women, massacred and enslaved them. (See also ALEUT; ALEUTIAN ISLANDS.)

Bottom right: Hunter's cabin on the Pelly river in the Yukon

Until 1773 no ensign other than the imperial Russian eagle had been seen along the Alaskan coast. However, in that year a tiny Spanish schooner commanded by Juan Francisco Quadra reached the site of Sitka. The British ensign was borne into the Gulf of Alaska by Capt. James Cook in 1778. Cook's landfall at Mt. Edgumbe approximated Quadra's farthest penetration. Cook continued westward, explored the inlet given his name, sailed through Bering sea and into the Arctic ocean in search of the north-west passage. On his return he made a three-week stay at Unalaska, where he shared geographical data with the Russian explorer Gerasim Grigorievich Ismailov. The following year Cook's vessels again attempted the northwest passage. Failing, the vessels put into Canton, China, where the sailors received high prices for the furs they had bartered for trinkets. This casual trading is credited with having established the triangular trade, to the northwest coast for furs then to Canton for tea and Chinese luxuries, in which both British and American shipmasters engaged. While Cook's vessels retraced their path through Bering strait, a second Spanish expedition, commanded by Lieut. Ignacio Arteaga, explored the southeast coast from Prince of Wales Island to Cook inlet.

The fleur-de-lis was seen in 1786 when a French scientific expedition under Jean François de Galaup la Perouse spent six weeks exploring the vicinity of Lituya bay. This expedition and reported Russian advances alarmed Spain, which renewed its explorations. An expedition under Estevan José Martinez and Lopez de Haro visited the Russian settlements on Kodiak and Unalaska in 1788. Intimations that the Russians were planning to occupy a site on Vancouver Island led the viceroy of Mexico to order establishment of a Spanish settlement at Nootka sound in 1789.

Meanwhile, in 1785 and 1786, Capt. James Hanna had brought a British brig from Canton to trade along the northwest coast. In 1787 eight British vessels appeared, the "Nootka" under Capt. John Meares penetrating Cook inlet and Prince William sound. Although ordered away for infringing on a British company's monopoly, Meares was back at Xootka sound (Vancouver Island) in 1788 with two vessels under Portuguese registry. He put ashore 50 Chinese labourers with instructions to build living quarters and a vessel. On May 6, 1789, Martinez' Spanish squadron reached Nootka sound, expecting to find the Russians established. Instead, Martinez found the Meares settlement. He seized four of Meares's vessels as prizes of war, then released two provisionally and sent two to Mexico as prizes.

Great Britain considered this seizure a cause for war and hastily endeavoured to fit out its fleet. Spain sought and failed to obtain military support from France. After extended negotiations, Spain paid an indemnity, and each nation acknowledged the other's right to navigation of the North Pacific and use of Nootka sound. Of historical significance is the fact that by this act Spain relinquished its previous exclusive claims to the northwest coast. The first United States vessels reached the northwest coast in 1788. They were the "Columbia" under Capt. John Kendrick and the "Lady Washington" under Capt. Robert Gray. They wintered at Nootka (King George's) sound, Vancouver Island, and were not molested by Martinez. Gray reached China with a cargo of furs in the "Columbia," formerly under Kendrick. These were forerunners of Yankee vessels that traded along the Alaskan coast.

To close the Sootka sound controversy, the British government sent Capt. George Vancouver with two vessels to Xootka sound. He spent the summers of 1792, 1793 and 1794 in surveys along the coast, including the Alexander archipelago. Meanwhile, the settlement established at Kodiak in 1784 was the main centre of Russian activity until the headquarters of the Russian-American company were transferred to New Archangel (Sitka) in 1804. The bitter competition between rival fur interests and the appearance of the British and Spanish vessels along the coast led Grigori Shelekhov, one of the leading Siberian merchants, to recommend the formation of a trading monopoly. In 1799 Shelekhov's heirs obtained imperial consent to the creation of the Russian-American company, in which they held about one-third of the shares.

2. The Russian-American Company.—Before the imperial government had chartered the company, Aleksandr Baranov,

Shelekhov's manager at Kodiak, had already moved to secure new fur country by establishing a post at Takutat. He moved south in 1799, building a fort on Baranof Island. This the Tlingit attacked and burned in 1802. In 1804 Baranov retaliated by bombarding the Sitkan Indians' fortress and rebuilding his post, New Archangel, beside its ruins. There he ruled until 1818.

Under a succession of governors, of whom Baron Ferdinand von Wrangell, Adolph Etolin and Prince Matsoutov deserve mention, New Archangel developed a shipbuilding industry which launched about 23 vessels up to 1860. Its foundry cast not only steam engine parts, but church bells, some of which went to the Spanish California missions. A sawmill and machine shop were established. Nautical charts were engraved and printed. A magnetic observatory was established, which has operated since 1842. An Orthodox seminary existed for a short time.

Attempts to grow cereals in Russian America failed. After Count Nikolai Rezanov made a much-romanticized trip to San Francisco seeking famine relief in 1806, a fort with outlying farms was established in 1811-12 north of San Francisco. In 1841 this unprofitable operation was abandoned. Ft. Ross in California and the ill-starred efforts of Baranov's agent, Yegor Schefier, to establish Russian influence in the Hawaiian Islands mark the extreme advance of the Russian-American company.

Russian exploration of the Interior dates from 1833, when the mouth of the Yukon was explored and St. Michael's redoubt was founded. In the succeeding decade the lower reaches of the Yukon and Kuskokwim rivers were traced and several posts were founded. From 1842 to 1844 Lieut. Lavrenti Alekseev Zagoskin made extensive explorations on the Koyokuk, Yukon and Kuskokwim. The Hudson's Bay company meanwhile was pressing westward from the Mackenzie watershed. In 1847 Alexander Murray descended the Porcupine to its junction with the Yukon and established Ft. Yukon in Russian territory. While the Interior thus became known, decades elapsed before the Indians opened the passes from the south coast to the whites.

3. International Conflicts, 1821-67.—Russia's policy was unsuited to its economic means. By a ukase of 1821, other nations were forbidden "the pursuit of commerce, whaling and fishery, and all other industry: within an area extending from Bering Strait south to 51° of north latitude on the American coast." Unfortunately for Russian interests, the colony repeatedly had to depend on the purchase of foreign cargoes for trade goods, and Russian naval forces were seldom present to enforce the order.

Both the U.S. and Great Britain protested against the ukase. After negotiations, Russia and the U.S. signed a treaty in 1824 which defined the southeastern boundary of Russian America as latitude 54° 40' N., and granted the U.S. trading rights for ten years. The Russo-British treaty of 1825 defined more exactly the common boundary with British North America. Russia also abandoned its claims to sovereignty over the high seas north of 51°.

In 1834 Peter Skene Ogden of the Hudson's Bay company sought to pass up the Stikine river to establish a post in British territory, but was barred by the Russians. The British government presented a bill of damages at St. Petersburg, claiming infraction of the treaty. As a result, an agreement was reached by which Russia leased the mainland strip from Portland canal to Cape Spencer to the Hudson's Bay company. The agreement was in effect from 1839 to 1859.

American whaling vessels had appeared off Russian America about 1820. In 1842 and afterward Governor Etolin urged his government to drive American vessels from the Bering sea, which Russia considered to be enclosed territorial waters. Eventually more than 300 vessels were whaling in the area, of which the majority were American.

The outbreak of the Crimean War in 1854 placed Russia's Pacific colonies in a vulnerable position. A fictitious sale of the Russian-American company to a San Francisco firm was planned. Rumours of the negotiations with U.S. interests led to a pact between the two fur companies protecting the properties of both. This the British and Russian governments unofficially endorsed. The exposed position of Russian America led the imperial government to consider the possibility of a sale to the C.S. Further,

a gold rush to British Columbia showed how word of any gold discovery in the Russian possessions would attract hosts of American prospectors. In 1857 the Russian minister to Washington was instructed to hint that Russia might sell its colony. Negotiations were undertaken in 1859, but the American Civil War delayed further consideration of the matter.

In Feb. 1867 the Russian minister to Washington returned to his post with instructions to enter into negotiations. One consideration was the possibility of embroiling Britain with the United States and diverting its attention from the straits at Constantinople. The treaty was completed in haste on March 30, the agreed sale price being \$7,200,000. The treaty passed the senate on April 9, but the appropriation did not pass congress until July 1868. (See also SEWARD, WILLIAM HENRY.)

4. Alaskan Government, 1867–1912.—Transfer of control to the United States took place at Sitka on Oct. 18, 1867, and most of the full-blooded Russians departed. Administration of Alaska was placed under the department of war, and a collector of customs was appointed by the department of the treasury. The new American residents of Sitka organized a town council and opened a school. After five years of struggle, both expired.

In 1877 the last soldiers were withdrawn from Alaska to help suppress an Indian uprising in Idaho and administration was transferred to the department of the treasury. The collector of customs remained the sole official, until he, too, departed in 1878. Meanwhile the Indians were constantly becoming more threatening. When repeated appeals for a U.S. warship went unanswered, an appeal was made to the British government at Vancouver, and a ship was dispatched to Sitka. A short time afterward it was relieved by the U.S.S. "Jamestown." Until 1884 Alaska was under the treasury department, with a vessel of the revenue cutter service, a precursor of the coast guard, representing law and order.

With the discovery of gold in Juneau in 1880, a renewed demand came for a genuine government. To the voices of the miners was added that of the Rev. Sheldon Jackson, a pioneer of Protestant missions and later of public schools in Alaska. The Organic act of 1884 provided for a governor, a district court, a marshal and four commissioners who were to be mining registrars as well as perform functions of justices of the peace. Alaska was proclaimed a land district, and \$25,000 a year was provided for education.

Between 1897 and 1901 several acts were passed concerning Alaska. Its homestead act was less generous than the act of 1862 applying to the surveyed public domain in the western United States. Civil and criminal codes were provided, judicial districts were created and provision was made for incorporation of towns and establishment of municipal schools. In 1906 Alaska was granted a nonvoting delegate to congress.

With the growth of the conservation movement during Theodore Roosevelt's presidential administration, it was natural that reservations of resources should be made in Alaska. However, by the way in which land laws were applied, economic development was retarded. A scandal arose when it appeared that certain coal-mining claims! supposedly granted to private individuals, were actually held by the Guggenheim-Morgan copper-mining syndicate. This resulted in a notable controversy between Richard A. Ballinger, secretary of the interior, and Gifford Pinchot, chief forester.

In 1911 bills were introduced into congress to create a territorial legislature. After 16 months of argument, the Organic act of 1912 was passed. This created a legislature that was more restricted than earlier U.S. territorial legislatures, especially in taxing and licensing powers.

5. Economic Development, 1867–95.—Speculators flocked from the United States to Sitka with the transfer of sovereignty. A San Francisco firm bought the warehouses and much of the trading stock at Sitka. A New London whaling firm bought the salt-houses and buildings on the Pribilof Islands, but found the San Franciscans and another firm already entrenched on the islands. These three drove off all other interests until, in 1870, congress authorized leasing of the sealing concession. The San Francisco interests, now called the Alaska Commercial company, obtained a no-year lease. This company built a number of trading posts, had

lobbyists in Washington and long dominated the economic and political life of the territory. However, when the lease came up for renewal in 1890, it was granted to the North American Commercial company. Upon expiration of the second lease the U.S. government undertook direct management of the seal islands.

The first known prospectors on the Alaskan Yukon were Arthur Harper and Leroy McQuesten, who entered the territory in 1873. All gold discoveries, however, were in Canadian territory up to 1886 when a strike on Fortymile creek just within U.S. territory led to a small stampede. Meanwhile, the U.S. army detailed Lieut. Frederick Schwatka for an exploration of the Yukon in 1883. Reaching the Yukon from Lynn canal, he descended the river to its mouth. In 1885 Lieut. H. T. Allen reached the Yukon from Prince William sound via the Copper river.

6. Economic Development, 1896–1940.—By 1896 gold production in the Alaskan Yukon had reached about \$700,000 a year. Then in Aug. 1896 gold was discovered on the Klondike in Yukon Territory. It was not until 1898 that miners reached the area in substantial numbers or that the richness of the mines was fully demonstrated. The record known pan of gold contained \$212. Mining camps sprang up in the territory, notably at Dawson, while impatient miners filled Skagway and St. Michael, Alaska, on their way to the Interior. Northwest mounted police estimates indicate that no more than 4,000 miners were on the Klondike at any one time, although popular estimates of the numbers in the camps have run as high as 40,000. From 1897 to 1900 over \$50,000,000 in gold was mined in the Klondike. The White Pass and Yukon railway was begun in midsummer 1898 and completed in 1900, eliminating the principal hazards of the trail.

The Nome gold rush followed hard on the heels of the Klondike excitement. Prospectors discovered gold on Anvil creek in 1898. In 1899 "claim jumpers," a ruthless element that sought to drive off many of the original prospectors, caused mounting tension at Nome. Discovery of gold in the beach sands, which none could claim but all could work, relieved the tension.

In 1900, when 18,000 people were estimated to be in the Nome (*q.v.*) area, Arthur H. Noyes arrived with an appointment as U.S. district judge, accompanied by his friend and accomplice, Alexander McKenzie. The conflicting mining claims provided Noyes with the opportunity to appoint McKenzie receiver and operator of the disputed properties. The two men defied a circuit court order to make restitution of all properties. Only in 1901 was Noyes finally removed from office. About \$5,000,000 was mined annually from 1900 to 1906; in 1907 production reached \$7,500,000. Thereafter large investments in dredges became increasingly necessary. Mining activity in the Nome area continued on a reduced scale for over half a century.

The year of gold, 1898, likewise saw the discovery of rich copper ore on the Copper river. Four mines were worked over a period of four decades, the last one closing in 1938. In order to remove the ore, the Kennecott Copper company built the port of Cordova (*q.v.*), constructed a railway and acquired control of the Alaska Steamship company.

Several railway lines were begun in Alaska around the turn of the century. None succeeded in joining the southern coast to the Interior until in 1914 the congress authorized the construction of such a railroad. The rights and properties of the Alaska Central from Seward (*q.v.*) northward and the Tanana Valley railway were acquired. The port of Anchorage was built as a construction base. In 1923 the line was completed to Nenana. It was extended to Fairbanks a year later.

The 1920s were marked by the development of aviation in Alaska. With the most rudimentary aids, Alaska's "bush pilots" carried men and materials throughout the territory. Where roads were lacking, air transport opened a new era in communications. Radio likewise broke down the isolation of remote communities and reduced dependence on the mail carrier and his boat or dog sled.

The decade of the 1930s saw a new generation seeking the Alaskan frontier. Men who had lost jobs or businesses at home through the economic depression decided to try their luck in the fisheries and the mines. In 1935 the Federal Emergency Relief

administration colonized 200 families in the Matanuska valley, a project which received much publicity but which failed to start a northwestward migration. Branches of various federal welfare agencies were established in Alaska during the decade. On the brink of World War II, Alaska had a population of 73,000, half of whom were natives. It was a frontier area showing steady but unspectacular growth.

7. *Diplomacy Involving Alaska.*—The Russo-British treaty of 1825 had provided that the boundary between Russian America and British North America should be the crest of the mountains, except where the crest lay more than ten marine leagues from the coast, in which case the line should run at that distance. In 1898, as miners were rushing through Skagway (*q.v.*) to the Klondike, Canada claimed that the boundary should be measured from the tips of the promontories rather than from the windings of the coast. In 1903 a convention was signed providing for arbitration by a board of six impartial jurists. After several months, a line was drawn recognizing the principle of the U.S. contention. The line followed the crest of the mountains for the most part, but the ports on Lynn canal were retained by the U.S.

Fur seals caused extended controversy between Canada and the U.S. These marine animals range widely over the North Pacific, but annually return to breed on the Pribilofs, the Russian Commander Islands and a Japanese island. On land it is possible to select the young males for their skins without reducing the breeding stock. On the sea, pelagic sealers must kill indiscriminately, losing up to half those killed, and also losing a pup and an unborn seal each time a female is destroyed. In 1886 the U.S. government ordered a revenue cutter to seize all vessels found sealing in the Bering sea. Three Canadian ships were seized and condemned. In 1887 six U.S. and six Canadian sealers were seized. To Canadian protests, the U.S. replied that the Bering sea had been a *mare clausum*, that is, a closed sea under the dominion of the state, under the Russians, and the U.S. had succeeded to the Russian rights.

An arbitration tribunal in 1893 sustained the Canadian claims and assessed \$473,151 damages against the U.S. Only in 1911, when the seal herd had been reduced to about 125,000 from perhaps 3,000,000, did the U.S., Canada and Japan give effective protection to the seals under the North Pacific sealing convention. In 1941 Japan withdrew from the agreement, claiming that the seals were damaging its fisheries. A temporary agreement was arranged between the U.S. and Canada. In 1956 representatives of Canada, the U.S., Japan and the Soviet Union worked out a new convention.

The U.S. and Canada likewise found their interests in conflict over fisheries. A landmark was the establishment of a closed season under the North Pacific halibut treaty of 1923. During the 1930s Japanese boats fishing offshore produced several instances of violence. In 1954 the three nations organized the International North Pacific Fisheries commission as a permanent body sponsoring fisheries research and regulation. A sharp increase in the Japanese salmon catch along the Aleutians in 1957, with a decrease in the Alaskan salmon catch, created a serious problem of redefining fisheries rights and regulating fishing methods.

8. *Impact of World War II.*—From the turn of the century to 1940 mining and fisheries contributed about equally to Alaska's wealth. A new and potent force in its development entered in 1941 when the U.S. government began to make Alaska the northwestern bastion of North America's defenses. Kodiak Island became the site of Alaska's principal naval base. A major air base and fort were established outside Anchorage. Ladd field was established at Fairbanks on the air supply route to Siberia. Many secondary airfields were built and the communications network was strengthened. Construction of the Alaska highway provided an inland supply route, should control of the sea routes be lost to the enemy. The outbreak of war in Korea in 1950 produced a second military construction boom which stimulated Alaska's industries. This time many military personnel brought their families, thus increasing the civilian population.

9. *The Statehood Movement.*—Although Alaska was an organized territory from 1912 to 1958, it at no time received the full

measure of powers that had been granted to older continental territories. Amendments to the Organic act were proposed at every session of congress for 42 years, but only six were adopted.

The first bill for Alaskan statehood was introduced in 1916, when it had already appeared that territorial development was hampered by congressional unwillingness to give adequate consideration to Alaska's problems. Efforts to strengthen the territorial government took precedence, however, until 1943, when a statehood bill was again introduced in congress.

The statehood issue was debated extensively in congress during 1950. It was not allowed to die until statehood had been granted in 1958. Meanwhile, in 1956, a constitutional convention met on call of the territorial legislature. The draft constitution was approved by popular vote on April 24, 1956 (see *Government*, below). Following Tennessee's precedent, two senators and a representative were elected and appeared at Washington, but congress did not act in time for them to be seated. Proponents of statehood claimed that the development of Alaska had too long awaited local control of its resources. Arguments against statehood centred on possible increases in Alaska's taxes and loss of federal subsidies. Pres. Dwight D. Eisenhower signed the Alaska Statehood act on July 7, 1958. The required referendum approved the constitution and terms of admission j to i. On Jan. 3, 1959, the president formally announced the admission of Alaska as the 49th state.

III. THE PEOPLE

Alaska's native races have been a constant and colourful element in its population. Approximately half have been Tlingit, Haidn (*q.v.*) and Tinneh (see *ATHAPASKAN*) Indians, the balance being Eskimos and Aleuts. The Aleuts declined sharply in numbers during the Russian occupation. Prior to World War II the Scandinavian element was conspicuous among the whites. A sprinkling of Russian names occurred. During and after World War II a Negro element was added to the population.

1. *The Indians.*—The *Tlingit*.—This tribe predominates along the southeastern coast. Their territory extends from Portland canal to Controller bay. A few Haidas dwell on Prince of Wales Island. A group of Tsimshians migrated to Metlakatla from British Columbia in 1887 with the Rev. William Duncan.

The Tlingit are the tallest of the coastal Indians. They are broadheaded, and may exhibit the Mongolian eye fold. Four clans and fourteen geographical divisions of the tribe are recognized.

All three tribes belong to the northwest coast cultural complex, based economically on fisheries. The relative abundance and seasonal appearance of the catch left time for cultivation of the arts. Wood carving is the predominant artistic medium of the culture. Basketry also plays an important role. Best known of the art objects are the totem poles. Stylized representations of the bear, wolf, beaver, killer whale, sea otter, salmon, raven and eagle form much of the art.

The Tinneh.—These Indians of the Yukon, also known as Dene, speak an Athapaskan language. Their territory extends from the Mackenzie watershed to the Yukon delta, with a branch at Cook inlet and Copper river.

The Alaskan branch of the family has assimilated many of the elements of Eskimo culture. The tribes are without clans and have little cohesiveness.

Small birchbark canoes were used for transportation in summer, while dogs were depended on in winter. Dried salmon constituted the staple food, except for one group that depended on hunting. Roman Catholic missions were in contact with most of the Tinneh before the close of the 19th century. The modern Tinneh divide their time between the fishing and hunting of their fathers and the construction gangs and other pursuits of the whites. (See also *INDIANS, NORTHWEST COAST.*)

2. *Eskimos and Aleuts.*—The Eskimos inhabit the coasts of the Arctic ocean, Bering sea and the Gulf of Alaska, villages having existed as far east as Prince William sound. The Aleutian Islands and the south side of the Alaska peninsula are the home of the Aleuts, the first of the native peoples to come under Russian domination.

The similarities in language, physical type and culture between

the Aleuts and Eskimos are more striking than their differences. The Eskimo and Aleut tongues are related. Both groups are light yellowish-brown in colour; the hair is straight and black, the face broad, cheekbones high, the nose flat, eyes black and beards scanty, resembling north Asians. Blood-type tests indicate kinship between the Eskimos and Aleuts, although the parent stocks probably diverged centuries ago.

Archaeologists distinguish several layers of culture, both on the Aleutian Islands and around Bering sea. Radiocarbon dating indicates that the oldest known Aleutian culture existed around 1000 B.C. The Old Bering Sea Eskimo culture has been dated around 300 B.C. Archaeological and ethnological evidence relates these peoples to a Mesolithic, or Middle Stone Age, Lake Baikal culture of Siberia.

The Eskimo igloo and Aleut barabara were crude sod houses with driftwood timbers supporting the roof. By mid-20th century these had been almost entirely replaced by small frame houses. The summer tupek of skins had given way to the canvas tent. Fishing and hunting of sea mammals—the seal, walrus, sea lion and whale—formed the basis of Eskimo and Aleut economy. A few inland Eskimos relied on the caribou. Berries and roots formed a supplement to the flesh diet. Kayaks were used for the hunt. Umiaks, large open boats made of skins, were used for transport. Both have largely given way to the motorboat.

The Eskimos are noted for their manual dexterity. Their ivory carving is justly famous. Basketry is the most distinctive of the Aleut native crafts, Attu baskets being particularly prized. Aleuts and Eskimos have long been employed in commercial fisheries. Petroleum prospecting and military construction in the Alaskan arctic during the 1940s and later brought unaccustomed wealth to many Eskimo communities.

Reindeer, introduced into northwestern Alaska during the 1890s, once numbered 250,000 head. Eskimo herders were trained and a commercial outlet developed. A federal policy decision forced the commercial outlet to close in 1939, destroying the industry. By 1950 the herds numbered less than 30,000 head. (*See also ALEUT; ESKIMO.*)

3. Social Welfare.—The Alaska native service of the bureau of Indian affairs, a branch of the C.S. department of the interior, for long was responsible for the education, health and welfare of the natives. Despite schools in many of the villages, the educational level of the natives is about the fourth grade. Natives attend municipal high schools when available; for those from the villages there are boarding facilities at the federal Mt. Edgecumbe vocational boarding school and the Presbyterian-supported Sheldon Jackson high school and junior college, both at Sitka. In the 1950s the territorial government began taking over operation of the native service schools.

The hospitals were transferred to the U.S. public health service in 1955.

IV. POPULATION

The federal census of 1960 showed a total population of 226,167 persons. At the time Alaska was admitted to statehood, it was estimated that there were about 211,000 persons, of whom 171,000 were whites. Natives numbered about 35,000, while the remaining 5,000 were mainly Negro and Filipino. Over half the total were in the age bracket 20–44, as against one-third in the U.S. as a whole.

When ceded to the U.S. in 1867, Alaska's population was estimated at 30,000, of whom no more than 1,000 were whites. The census of 1880 (unreliable) reported 33,426. Gold strikes on the Yukon and Klondike brought the total to 63,592 in 1900. During the next decade the peak was passed. By 1920 the total had fallen to 55,036.

In 1939, 72,524 were reported. Nonwhites numbered 33,354; native-born whites, 30,384; foreign-born whites, 8,786. Of these, 42% were born in Norway and Sweden.

The wartime peak of 1943 consisted of 75,000 civilians and 150,000 military personnel.

As a frontier area, Alaska has had a surplus of males. In 1910 there were five white men to every white woman. In 1950 the ratio

TABLE I.—Alaska: Places of 5,000 or More Population (1960 Census)*

	Population				
	1960	1950	1939	1920	1900
Total state	226,167	128,613	72,524	55,036	63,592
Anchorage	44,237	11,254	3,495	1,856	—
Fairbanks	13,311	5,771	3,455	1,155	—
Juneau	6,797	5,956	5,729	3,058	1,864
Ketchikan	6,483	5,305	4,695	2,458	459
Spennard	9,074	2,108	—	—	—

*Populations are reported as constituted at date of each census.

Note: Dash indicates place did not exist during reported census, or data not available.

was still two to one.

Although only two Alaskan cities have a population (1960 census) of over 10,000, most communities serve a considerable trading area and their commercial facilities and social activities make them more cosmopolitan than their size suggests.

See also separate articles on principal cities, as ANCHORAGE; JUNEAU; etc.

V. GOVERNMENT

1. Constitution.—The constitution of Alaska was drawn up by a convention which completed its work on Feb. 5, 1956. It was subsequently approved by a vote of the people and submitted to the U.S. congress for its approval. The document which sets the minimum voting age at 19 years, is a model for brevity, for a modern restatement of the Bill of Rights and for its creation of strong legislative, executive and judicial branches.

The senate consists of 20 members elected for four-year terms. The house of representatives consists of 40 members elected for two-year terms. There are, however, only 24 election districts from which the latter are chosen. Thus the Anchorage district initially was apportioned eight representatives, the Fairbanks district five, Ketchikan, Sitka, Juneau, Kodiak and Nome two each and the remaining 17 districts one each. Two election districts are combined to form 12 senate districts entitled to one senator apiece; these are combined once more to form 4 large districts each entitled to two senators. Legislative sessions are annual, with a legislative council functioning in the interim.

The governor and secretary of state are the two constitutional executive officers, all others being created by statute. A single vote cast for the two assures their being of the same party. The governor has broad powers of appointment and assignment of functions among the executive departments. He may veto any bill, and strike out or reduce any item in an appropriation bill.

The constitution vests details of administration in not more than 20 departments, with minor boards and regulatory bodies in addition. When the constitution became effective 16 major departments were in existence. Fiscal control rested with the department of finance. It prepared the budget; maintained central accounts, purchased all supplies, examined all claims, administered much state property, could reduce appropriations if revenues were insufficient to meet the budget, filed records of all corporations authorized to do business in Alaska and certified declarations of candidacy for state office.

The court system under the territorial government had consisted of a U.S. district court of four divisions which heard cases arising under both federal and territorial law. Appeals lay with the U.S. circuit court in San Francisco, and thence with the U.S. supreme court. The district court for the territory of Alaska, with its four divisions, was abolished and a single federal district court for the state of Alaska was created with provision for holding court at Anchorage, Fairbanks, Juneau and Nome. The Alaska constitution created a supreme court with a minimum of three justices. A superior court bench of five judges, increased by the first legislature to eight judges in four districts, was established as the trial court of general jurisdiction. Power to create lower courts was given to the legislature. A judicial council with the chief justice as chairman was provided to lay down rules for all courts and to study the improvement of court administration.

2. Public Finance.—The fiscal system of Alaska underwent a pronounced change at the 1949 legislative session. Repeal by congress of the licence statutes of 1899 and 1900, under which the federal government pre-empted the licensing of certain occupations

and industries. enabled the legislature to establish a new revenue structure. This included an income tax on persons and corporations, a business licence tax and taxes on the value of canned salmon, raw fish, fish traps, motor fuel, tobacco, fishermen's licences, automobile and drivers' licences and a general property tax. The former liquor taxes and head tax for schools were retained.

Biennial territorial revenues in the mid-1950s totaled about \$40,000,000, income tax being the largest single source. Expenditures were budgeted at approximately \$37,000,000 exclusive of highway and harbour construction. Elementary and secondary education represented half the above figure, while \$3,900,000 in addition was appropriated for the University of Alaska.

Revenues conferred upon the state of Alaska by the federal government under the admitting act included: 70% of the net proceeds of the sale of sealskins and sea otter skins; 5% of the net proceeds of the sale of federal public lands in Alaska; monies allocated to the territory for wildlife restoration. A substantial increase in federal funds for highway construction was also anticipated with achievement of statehood.

3. Principal Federal Agencies.—From the days when a collector of customs, a small army force and, later, a warship represented U.S. authority, federal agencies have profoundly influenced Alaskan life. The geological survey has carried out detailed explorations and furnished technical advice to miners. The bureau of mines has been particularly interested in Alaska's coal resources. The Alaska native service, a branch of the bureau of Indian affairs, has provided for the education, health and welfare of a substantial share of the population. The department of agriculture has had control over two huge national forests, and has furnished funds for agricultural research. The bureau of fisheries and the fish and wildlife service have studied and regulated one of Alaska's greatest resources. After 1940 policy affecting all phases of Alaskan life was made by the war, navy and defense departments.

4. Economic Research.—In 1945 the Alaska Resource Development board was created. The board was composed of the governor, the president of the University of Alaska and the heads of the departments of fish and game, mines, highways and public works, aviation, agriculture, and lands. Its publications furnish the basic economic and statistical data needed by settlers and investors.

VI. EDUCATION AND WELFARE

When Alaska became a state, approximately 21,000 pupils attended 28 district schools; 5,800 pupils were in attendance at federally financed and territorially administered military base schools; 3,000 were in 68 rural territorial schools. Alaska native service day schools enrolled about 3,700, while about 750 were at Mt. Edgecumbe secondary and vocational boarding school at Sitka. About 1,200 were in other public and private schools.

The University of Alaska, near Fairbanks, was founded in 1917 as a land-grant college and began instruction in 1922. Under the Community College Enabling act of 1953 the university cooperates with qualified high school districts in organizing community colleges of junior college level, which offer credits for transfer to the university as well as terminal and semiprofessional courses. Public community colleges organized under this act include Anchorage, 1954; Juneau-Douglas at Juneau, 1956; Ketchikan, 1954; and Palmer, 1958. Sheldon Jackson junior college at Sitka is a Presbyterian institution; Alaska Methodist university at Anchorage was chartered in 1957 and began instruction in 1960.

The department of public welfare administered old-age assistance to approximately 1,600 persons annually during the mid-1950s. The program of aid to dependent children had a load of somewhat under 1,500 family cases, approximately two-thirds the cost of both programs being borne by the federal government (see also *SOCIAL SECURITY*). A licence system for foster boarding homes was established in 1956-57. The Alaska Pioneers home for aged residents of the state, located at Sitka, had accommodations for 250 persons, entrance requirements being five years' residence in Alaska immediately preceding application; and age 65. Welfare needs of fishermen were met from a special fishermen's fund.

The health needs of the native population have been cared for in a measure by a system of federally supported hospitals. Tuberculosis treatment is carried out at a sanatorium at Sitka.

VII. THE ECONOMY

The economy of Alaska has been founded on extractive industries. Fisheries have been its most constant source of revenue. Mining has rivaled fisheries in total value of product. Furs were Alaska's original commercial mainstay, and remain important. In the decade following 1945, increased attention was given to lumbering and wood pulp production, while military construction and service industries based on military personnel and their families gave an additional stimulus to the economy.

1. Living Conditions.—In towns of even a few thousand population most personal services and all essential household needs are available. Despite a wide variety of occupations the comparatively small numbers employed in any one area makes job placement difficult at times. There are three mass employers of labour: fisheries and canneries, mines and dredges, and construction companies. As these industries often bring in seasonal labour from Seattle and

TABLE II.—Cost of Living, Compared With Seattle as 100 (Aug.-Sept. 1956)

Principal items	Ketchikan	Sitka	Juneau	Anchorage	Fairbanks
All items	122.2	121.7	123.5	140.8	153.5
Selected items:

Personal care	120.8	124.4	117.3	127.1	134.6

San Francisco, opportunity is often furnished for employment while looking for a permanent position.

2. Mining.—Between 1880 and the mid-1950s approximately \$1,000,000,000 in minerals were mined in Alaska. Gold and copper led in value.

As early as 1861 gold discoveries were made on the Stikine river; colourings along the Yukon were reported in 1866-67 and

TABLE III.—Minerals Extracted, 1880-1957

Product	Value	Amount
Gold	\$722,122,186	28,859,718 fine ounces
Copper	226,889,964	685,910 short tons
Silver	14,483,547	20,217,441 fine ounces

systematic prospecting of the upper river began about 1873. Juneau was founded in 1880 following placer gold discoveries; its famous quartz mines were opened later. Coarse gold was discovered on Fortymile creek in 1886, the first significant discovery in the Alaskan section of the Yukon valley. The excitement following these discoveries, however, was as nothing to the feverish rushes that followed the location of the first Klondike claims in Canadian territory and the discovery of gold at Nome. (See *Economic Development, 1896-1940*, above.)

In the closing years of Alaska's territorial period, its mining industry experienced a shift to production of construction materials, explorations for a variety of minerals and growing excitement over the possibility of substantial petroleum discoveries. During the 1950s military and highway construction shifted mining interest to gravels and clays. Thus while gold production averaged \$8,400,000 annually in the 1950s, sand and gravel production rose to \$8,800,000 by 1957. The total annual value of minerals produced in the decade 1948-57 rose, with minor fluctuations, from a low in 1948 of \$13,000,000 to a high in 1957 of just under \$29,000,000.

Mineral explorations in the second half of the 20th century included surveys of iron deposits in southeastern Alaska, chromite in the Kenai-Moose range, tungsten and copper on Kodiak. Deposits of other metals which have been exploited commercially at some time include tin and platinum on the Seward peninsula, chromite on the Kenai peninsula and mercury at several points.

Alaska's fuels include coal, petroleum and gas. Known coal reserves amount to over 100,000,000,000 short tons, of which over 70,000,000,000 tons are subbituminous and lignite. They occur at many locations throughout Alaska. Bituminous and anthracite coals occur in the Bering river and Matanuska fields. The Anchor-

age and Fairbanks areas have made use of domestic coals over a number of years. Petroleum was produced and refined at Katalla, southeast of Cordova, until the refinery burned in 1933. Oil seepages on the arctic slope were reported in the 1880s. A naval oil reserve near Point Barrow was created in 1923, but exploratory drilling was not undertaken until 1944-53. A producing well was brought in at Umiat, while gas was struck near Point Barrow, and a find of substantial gas reserves at Gubic aroused the hope of supplying gas to the Yukon valley. During the late 1950s several major oil companies undertook petroleum explorations and had brought in two wells in south central Alaska by the close of 1958. Petroleum was also sought on the Alaska peninsula.

3. Fisheries. — Alaska's fishing industry has been equal to mining in importance to its economy. Two salmon canneries were established at Sitka (*q.v.*) and Klawak in 1878, their first season's pack being valued at \$16,000. In the second half of the 20th century there were about 170 wholesaling and manufacturing establishments which had a total annual production of 226,000,000 lb., valued at approximately \$92,900,000 wholesale. Salmon accounted for 161,000,000 lb., valued at approximately \$82,000,000. There were about 23,600 persons employed of whom about 12,500 were fishermen.

Alaska's fish products are handled in a variety of ways. King salmon command a premium price as fresh fish. Sockeye or red salmon supply the choice canning grades. Halibut are marketed fresh or frozen. Among the shellfish are shrimp, razor clams, Dungeness and king crabs, much of the shellfish being canned.

Resident fishermen ordinarily operate trawlers or other small craft. Cannery corporations have invested substantial sums in fish traps: box nets supported on pilings with funnel nets inside to trap the fish. If the traps are set too close to the mouth of a stream, or operated continuously through a season, so few salmon escape to return to their spawning grounds that the catch is cut materially in future years of that particular cycle. In 1957 there were 11,253 fishermen registered, of whom 8,171 were residents and 3,082 were nonresidents.

4. Fur Industry. — Alaska had produced over \$200,000,000 worth of furs between 1867 and the late 1950s. Sealskins from the Pribilof Islands (*q.v.*) contributed half this total. Throughout Alaska trap lines have furnished a source of cash income to native peoples and whites alike.

By the 1920s fur farms were being established, particularly on the coastal islands which were well adapted to control and protection of the animals. About 300 farms were in operation prior to World War II; at the end of the war a quarter of them were still in operation. During the 1950s the annual value of the fur seal harvest was ordinarily between \$4,000,000 and \$5,000,000. The value of other furs exceeded \$4,000,000 in 1948, but averaged around \$1,500,000 annually during the next decade.

5. Agriculture. — Alaska's long hours of summer sunlight are adapted to the growing of many varieties of vegetables and cereals. Cabbage, lettuce, cauliflower, potatoes, beets and carrots grow well in certain areas, sometimes reaching enormous size. Grasses, clover, vetch and peas help to support the dairy industry. Wheat, oats, rye and barley may be grown in the Interior. Blueberries, raspberries and strawberries thrive. The dairy industry has been one of the most successful, being carried on in southern Alaska as far west as Kodiak and on the upper reaches of the Yukon.

Farming areas in southeastern Alaska are small and scattered, usually being located on the deltas of creeks or rivers. A large proportion are dairies or poultry ranches. In the Matanuska valley about 8,000 ac. are under cultivation, producing dairy products, meat, poultry, eggs and vegetables. Small grains grow well in the Interior. Hardy wheats have been introduced from Siberia, and much experimental work has been carried out. The Fairbanks area has been considered the best farming region of the Interior.

The annual value of Alaska's agricultural production was around \$3,000,000 in the mid-1950s, rising to \$4,500,000 in 1957. Farming development has been encouraged by an agricultural extension service, a farm loan program and several agricultural research stations. By the second half of the 20th century soil surveys and classification had covered 1,900,000 ac.

6. Timber Production. — Most of Alaska's commercial timber is contained in the two great national forests, the Tongass in southeastern Alaska and the Chugach on Prince William sound. In the Interior valleys are about 25,000,000 ac. of spruce and birch.

Estimates of the marketable timber in the Tongass forest run about 78,000,000,000 bd.ft., primarily western hemlock, with marketable quantities of Sitka spruce, western red cedar and Alaska cedar. Potential productivity has been estimated as high as 1,000,000,000 bd.ft. a year. However, much of the timber is overripe, and yield estimates are uncertain.

In the mid-1950s the Tongass National forest was blanketed by timber leases for the production of pulpwood and saw timber. Mills had been established at Wrangell, Ketchikan and Sitka, while a small mill was operating at Juneau. Value of timber products ran about \$4,300,000 annually from 1950 to 1953. In 1956 it shot up to \$34,400,000, with 1955 and 1957 production just under \$30,000,000.

7. Power. — Electric power has been derived from a variety of sources: small hydroelectric plants, diesel and steam engines. The potential hydroelectric power production in several areas of Alaska is vast. The Juneau area is estimated to have a potential annual firm production of 9,800,000,000 kw.hr., with 8,800,000,000 in the Yukon flats area and a total for Alaska of 46,900,000,000 kw.hr. annually of firm power.

8. Communications. — For 60 years after 1867 mail steamers were the principal means of communication, supplemented by dog teams for winter mail in the arctic. Airmail was established in 1924, and by 1940 much of the mail was moving by air. The Alaska Communications system was established under the army signal corps in 1900 to carry governmental and commercial messages. It has developed cable, telegraph, telephone and radio links. Radiotelephone stations in remote areas were established by the territory and the Alaska native service. By the late 1950s "White Alice," an integrated microwave communications system, was providing high-quality service for all government agencies in Alaska.

9. Transportation. — High transportation costs have been a continuous factor in retarding Alaska's economic development. These costs have been justified to some extent by high insurance rates and a limited amount of cargo for back haul from Alaska. In other instances, charges have been clearly discriminatory. With statehood, Alaskans hoped to remedy the situation.

Coastal transportation has been built around the schooner, coastal steamer and smaller craft. The Inside passage provides sheltered communication along the southeast coast, but elsewhere navigation is hazardous. In part because of airline competition, the last American flag shipboard passenger service to Alaska was discontinued in 1954. Canadian steamers, however, continued the tourist run.

Commercial aviation developed rapidly in Alaska during the 1920s, proving invaluable in a region of few roads. Even before World War II, Alaskans flew 23 times as often and shipped 1,034 times as much air freight per person as other U.S. citizens. By the late 1950s Alaska had 7,915 mi. of civil airways and Anchorage was rated third among U.S. cities in volume of air traffic.

Alaska's principal highway prior to World War II linked Valdez (*q.v.*) on the coast with Fairbanks. During World War II the Alaska highway was opened from Dawson Creek, B.C., to Fairbanks. The principal routes from the United States run from Great Falls, Mont., through Edmonton, Alta., to Dawson Creek, and from Seattle to Vancouver and up the Fraser river to Dawson Creek. Normal driving time from Great Falls or Seattle to Fairbanks is six to eight days. Most of the road is macadam and is open at all seasons. Current information should be obtained from provincial authorities at Edmonton before planning a trip. Branch highways run to Haines (closed in winter), Anchorage, Palmer and neighbouring towns.

The federally owned Alaska railroad runs from Seward through Anchorage to Fairbanks, a distance of 470 mi. A branch runs to the port of Whittier. Passenger and freight service are provided. The White Pass and Yukon railway, running for 91 of its 111 mi. within Canada, connects the port of Skagway with Whitehorse,

Yukon Territory. See also Index references under "Alaska" in the Index volume.

BIBLIOGRAPHY—For a guide to the period up to 1924, see James Wickersham, *A Bibliography of Alaskan Literature* (1927). *Arctic Bibliography* (7 vol. to 1957) is exhaustive on scientific topics and covers many basic studies in other fields.

For general descriptions of Alaska, see U.S. Department of the Interior, *Mid-century Alaska* (1957); Herbert Hilscher, *Alaska Now* (1948); B. W. Denison *et al.*, *Alaska Today* (1950); Merle Colby, *Alaska* (1940).

Outstanding on political and economic problems is Ernest Gruening, *The State of Alaska* (1954). See also the Governor of Alaska, *Annual Reports* (1910–58). See also Jeannette Paddock Nichols, *Alaska: a History of Its Administration, . . . During Its First Half Century Under the Rule of the United States* (1924).

For explorations, see John Muir, *Travels in Alaska* (1915); B. R. Hubbard, *Cradle of the Storm* (1935); A. H. Brooks, *Blazing Alaska's Trails* (1953). Reports of official explorations from 1867 to about 1900 are available in the congressional document series.

For Alaskan history, see C. C. Hulley, *Alaska, 1741–1953* (1953), which sheds new light on the gold rush while providing a competent summary of older materials; S. R. Tompkins, *Alaska, Pronzyshennik and Sourdough* (1945); H. H. Bancroft, *History of Alaska* (1886); W. H. Dall, *Alaska and Its Resources* (1870).

The U.S. Department of the Interior, *Alaska: Reconnaissance Report on the Potential Development of Water Resources in the Territory of Alaska*, House Document 197, 82nd Congress, 1st Session (Jan. 1952), goes far beyond water resources in describing the economy and physical geography of the region.

Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments; the principal figures together with the current history are summarized annually in the *Britannica Book of the Year*, American edition. (J. E. CL.)

ALASTOR, in Greek mythology, the name of a person and also of an idea.

1. Alastor in early mythology is the spirit of revenge that prompts the members of a family to commit fresh crimes to obtain satisfaction. Further acts of vengeance transmit the curse from generation to generation (cf., e.g., the repeated murders in the house of Atreus [*q.v.*]).

The word is also used for a man's evil genius that drives him to sin; a man so driven is sometimes called Alastor. The epithet is applied to the Erinyes as the deities of revenge, and to Zeus when he is invoked as the "Avenger."

2. Alastor, a son of Neleus, whose wife, Harpalyce, was seized from him by her incestuous father, was killed by Heracles at the siege of Pylos. (T. V. B.)

ALA-TAU (variegated mountains) is the name given to the following ranges in Asiatic Russia: (1) Terskei; (2) Kungei; and (3) Trans-ili (Zailiyski). All three link the Tien Shan (*q.v.*) and the Kirgiz ranges. (1) Lies south and (2) and (3) north of and parallel to Lake Issyk-Kul (*q.v.*). The average height is 6,000–7,000 ft. (Pik Talgar 16,243 ft.) and the snow line 11,000–11,700 ft. (4) Talasski Ala-Tau, also called Talastau, is west by south from the Kirgiz range. (5) Dzungarian or Dzhungarski Ala-Tau is a range bordering the Dzungarian gate, north of the Tien Shan, with an average height of 6,250 ft., max. 14,645 ft. (6) Kuznet or Kuznetski Ala-Tau, between the upper Ob and the upper Yenisei, west of the Abakani mountains, has an average height of 6,000–7,000 ft. (G. E. WR.)

ALATRI, a town in Lazio, central Italy, in the province of Frosinone, lies in the valley of the Cosa river, 1,706 ft. above sea level. Pop. (1957 est.) 20,636 (commune). It is said to have been founded in 1830 B.C. as Aletrium, mentioned by Strabo and Pliny; it belonged to the confederation of the Hernici (*q.v.*) of which it was the chief bastion in the struggle against Rome. Archaeologically it is most important. Its ancient origin is attested by traces of a great belt of Cyclopean walls (6th century B.C.), within which is the superb trapezoid "Pelagian acropolis," the most beautiful and complete that has been preserved, whose walls are almost intact.

In the outer circle of walls, which extend about 4 km. (2½ mi.) and at intervals in which are fine medieval towers, are the Porta Civita with its monolithic architrave, the Porta Minore and the Nuova Porta, recently discovered. Other important monuments and buildings are the churches of Sta. Maria Maggiore, S. Francesco and S. Silvestro, all rich in frescoes; the palace of Cardinal Gottifredi "Casegrandi," now the civic museum, the

bishop's palace, the episcopal seminary and the Conti Gentili college.

Alatri is a holiday resort 17 km. (10½ mi.) from Fuggi, with quick, convenient and frequent connections with Rome (90 km. [56 mi.]) and Naples (235 km. [146 mi.]). It is a pleasant place because of its healthful air, the good quality of its agricultural products (cereals, wine, oil and vegetables) and the excellence of the water (there are two mineral water springs). A business centre, the city is expanding westward where the modern part of the town lies, augmented after World War II with imposing public and private buildings.

ÁLAVA, MIGUEL RICARDO DE (1771–1843), Spanish soldier and statesman, was Spanish commissary at the duke of Wellington's headquarters during the Peninsular War and was active in political life thereafter until 1837. Born at Vitoria in 1771, he was a member of the Bayonne assembly which in 1808 accepted Joseph Bonaparte as king of Spain. Shortly afterward, however, he joined the patriotic party fighting the French and was made an aide-de-camp to Wellington, being promoted brigadier general. Out of favour because of his liberal ideas on the restoration of Ferdinand VII, he was appointed ambassador to the Netherlands in 1815 and so came to be present at the battle of Waterloo. (Having previously been on board his uncle's flagship in the battle of Trafalgar, he is said to have been the only man present at both Trafalgar and Waterloo.) He became president of the *Cortes* in 1822, but the absolutist reaction of 1823 forced him into exile in London. Returning to Spain after Ferdinand VII's death (1833), he supported Maria Cristina against Don Carlos. He was ambassador to Great Britain in 1834 and to France in 1835. Having refused to take the oath to the constitution of 1837, he went into exile from Spain again and died at Barèges, France, in 1843.

(R. S. LL.)
ÁLAVA, one of the Basque provinces of northern Spain, flanks part of the upper Ebro valley and the southern Basque mountains. Pop. (1960 est.) 123,108; area 1,177 sq.mi.; density per square mile 104.6. Formerly a lordship, Alava was incorporated in Castile in 1332. In the southern part of the province is the Trevifio enclave (190 sq.mi.) which belongs to the province of Burgos.

As the Basque name of Álava (araiar, "set among the mountains") implies, its core area is an intramontane basin (about 1,500 ft.). This basin is called the Llanada de Vitoria and is a continuation of the tectonic corridor in which Pamplona is situated. From the north the valleys of the Urquiola, Bayas and Omecillo rivers enter it and carry roads between the mountains of Aitzgorri, Peiia de Gorbea and Pefia Igaña, all of which rise above 4,500 ft. The Montes de Vitoria separate the Llanada de Vitoria from the enclave of Trevifio, partly an ancient lake drained by the Ayuda river. To the south the mountain ranges of Cantabria and Toloiio overlook the third and lowest plain, the Alavese Rioja, which goes down to the Ebro.

In many respects the province is transitional between the Basque lands to the north and Castile to the southwest. It shares the continental cold and summer drought of the Meseta. Its landscapes are much more open than those of the northern provinces, with bare or scrub slopes, fewer forests and extensive fields of cereals on the plains. Maize is grown only in the northern valleys with higher rainfall; wheat, barley and oats are grown elsewhere. The Alavese Rioja is famous for its vineyards. Few Spanish provinces have more mechanized farming, and sugar-beet production is very important in the Vitoria district.

The population is less scattered than farther north, and the hamlet is an ancient feature. Vitoria (*q.v.*) the capital (pop. [1960 est.] 54,659) remained the only town with more than 3,500 inhabitants. Built in 1256 near the site of an ancient hamlet, its oval plan showed little growth and it was still a small market town of 15,569 in the mid-19th century. It grew rapidly thereafter, first with the advent of the railway and later with the establishment of new factories for agricultural machinery, sugar refining, furniture making, truck construction, etc. These industries are supplied with hydroelectric power from dams constructed on the upper courses of the Bayas, Urrunaga and Zadorra, and also from the Ebro dam near Reinosa in Santander. (J. M. Ho.)

ALB, a liturgical vestment, reaching from neck to ankles, worn by the officiants at Mass. Both the alb and its name are derived from the *tunica alba*, the white under-tunic that formed part of the ordinary dress in the Roman and Greek world. The date of its definite adoption as a liturgical vestment is uncertain; as late as the 9th and 10th centuries the *alba* was still an everyday as well as a liturgical garment. See **VESTMENTS, ECCLESIASTICAL**.

ALBA (ALVA), FERNANDO ALVAREZ DE TOLEDO, DUQUE DE (1507–1582), Spanish soldier and statesman, famous for his conquest of Portugal and notorious for his tyranny as governor general of the Netherlands, was born at Piedrahita (Ávila) on Oct. 29, 1507, of a rich family with a long record of service to the kings of Castile. In 1524 he joined the Spanish forces fighting the French at Fuenterrabia and so distinguished himself that he was appointed governor of the town after its capture. Subsequent campaigns made him the most thoroughly professional military commander of his age. He insisted on rigorous training and discipline for his troops and developed the tactical use of firearms. He was a master of logistics, and his greatest asset was unshakable self-confidence which enabled him to resist the rash counsels of his more impetuous officers.

In 1546–47 Alba commanded the imperial armies against the German Protestant princes of the League of Schmalkalden. By his victory at Muhlberg (April 24, 1547), Alba placed the emperor Charles V at the pinnacle of his power. Alba was made commander in chief of the imperial forces in Italy in 1552 and, after the succession of Philip II of Spain, viceroy of Naples (1556). In the last phase of the Franco-Spanish war in Italy, he outmaneuvered the duc de Guise and forced Pope Paul IV to come to terms with Spain (1557).

After the peace of Câteau-Cambrésis (1559), Alba became one of Philip II's two leading ministers. In opposition to the other, Ruy Gómez de Silva, he pressed for a vigorous foreign policy. Following the popular movements of 1566, Philip sent Alba to the Netherlands with a large army to punish the rebels, root out heresy and re-establish the king's shaken authority (Aug. 1567). Alba arrested the comte d'Egmont and Philippe de Montmorency, comte de Horn, the rather halfhearted leaders of the opposition, and set up a new court, the Council of Troubles (soon to be known as the Council of Blood). This court set aside all local laws and tried and condemned thousands who had taken part in the religious and political opposition to the king. It was a deliberate policy of terror, and it worked in the short run. Not a single town rose to support William the Silent, prince of Orange, in his invasion of the Netherlands in 1568. Egmont and Horn were executed.

Alba was, however, unsuccessful in placing his government on a stable financial basis, independent of the estates. He proposed a 10% sales tax but this proved inoperable and he had to modify it. The opposition of the lower classes and the clergy was so strong that even this modified tax was never collected. In 1572 the Gueux (*q.v.*) captured most of Holland and Zealand, and the prince of Orange and his brother Louis of Nassau invaded the Netherlands from Germany and France respectively. Alba defeated the land invasions and recaptured part of Holland, where his troops committed terrible atrocities. Short of money and lacking adequate sea power to oppose the fleet of the Gueux, he failed to recapture the remainder of Holland and Zealand. (See also **NETHERLANDS**.)

Alba's failure and the intrigues of the Gómez party at the court induced Philip II to recall him (1573). In 1579 Alba was placed under house arrest on his estates after his son had defied the king in marrying against the royal wishes. In 1580 Cardinal Granvelle persuaded Philip to let Alba command the invasion of Portugal. Within a few weeks, in one of his most brilliant campaigns, Alba took Lisbon. Yet he never regained Philip's favour. He died at Lisbon on Dec. 11, 1582.

In Protestant countries Alba's name became a byword for cruelty and religious tyranny. Outside Spain he has never been forgiven for his disregard of legality, for his policy of terror and for the outrages committed by his troops in the Netherlands and in Portugal. Of the responsibility for these acts he cannot be exonerated nor were they universally accepted even by Catholic opinion in the 16th century. In Spanish history Alba is important

as a representative of the old nobility, independent and proud of its rights and privileges yet willing to serve as the champion and defender of an absolute monarchy.

See Duke of Berwick and Alba, *The Great Duke of Alba as a Public Servant (1947)* and *Epistolario del III Duque de Alba, 3 vol. (1952)*. (H. G. Ko.)

ALBACETE, a town of Spain and capital of the province of Albacete, lies on the Balazote river where it unites with the Canal of Maria Cristina, 134 mi. S.E. of Madrid. Pop. (1960 est.) 79,875 (mun.). The upper town, to the south, is the old quarter, while the lower town is modern. The principal church is dedicated to San Juan Bautista and there is a provincial museum containing pictures, sculpture and archaeological finds. Canalejas park is the chief open space. The aerodrome is at Los Llanos where there is an aviation school. Albacete has an annual fair with bullfighting. Flour and cutlery are made, and knives and daggers from Albacete are well-known throughout Spain. It is a market town for saffron, fruit and other agricultural produce. First mentioned in the 12th century when the district was being freed from Moorish domination, Albacete was founded in 1365 and became separate from neighbouring Chinchilla. It played an important part in the War of the Spanish Succession, the battle of Almansa being won near there by Philip V in 1707. During the civil war of 1936–39 Albacete remained in Republican hands.

ALBACETE PROVINCE covers an inland area of 5,737 sq.mi. Pop. (1960 est.) 419,862. It is somewhat featureless except for the Sierra de Alcaraz in the west. The drainage is almost entirely to the Mediterranean by the Júcar and Segura rivers, but the rainfall is low and the province contributes little to these rivers except from the western sierras, where the snow lies for several months; elsewhere the climate is mild and healthful. The chief towns are the capital Albacete and Almansa and Hellín. Other towns are Alcaraz, Casas Ibañez, Chinchilla, La Roda and Yeste. The province is crossed by the main routes from Madrid to the plain of Valencia and the southeast. The railway from Madrid passes through Albacete southwest to Chinchilla where it divides, one branch going to Alicante and one to Murcia. A large part of the province is accessible only by road. Manufactures include the making of flour, coarse cloth, porcelain, earthenware and cutlery; hemp is spun and brandy is distilled. Albacete is a stock-raising province, but wheat-growing is increasing steadily with a corresponding decline in livestock. Of these, sheep of the large Manchigan breed are the most important. Cheese is sent to all parts of Spain; vines, which have suffered much from phyloxera, and olives are cultivated; the peaches of Cabriel and Jucar valleys supply canning factories in Valencia. Saffron, esparto grass and wood from the pine forests are traded.

ALBACORE (*Thunnus alalunga*), a large, edible oceanic fish allied to the tunas and mackerels (*qq.v.*) and placed with them in the family Scombridae.

ALBA FUCENS (mod. ALBE), an ancient town on a lofty site (3,347 ft.) at the foot of Monte Velino, 4 mi. N. of Avezzano in the modern Italian regione of Abruzzi e Molise. Originally a town of the Marsi, it was occupied by a Latin colony c. 303 B.C. It lay at the junction of the Via Valeria (the road from Rome to the Adriatic) with a road coming up the Liris valley from the south. It was situated just south of the Via Valeria on a hill with three distinct summits, all of which were enclosed within the walls. Its strong position made it important in the Social War (when it was perhaps captured; it was widely replanned thereafter) and in the civil wars; state prisoners of the Romans were often held there. The main circuit of walls, much of which survives, dates from c. 303 B.C. and is about two miles in circumference; the walls are of polygonal masonry, carefully jointed, with faces smoothed. Three gateways remain; they are so placed as to expose the right side of an attacking force. A stretch on the northwest side was later doubled by a second wall of similar construction but with smaller blocks. Early in the 1st century B.C. this part and the southeastern section also were strengthened. The acropolis in the northern corner (where the ruins of the village of Albe and the Orsini castle lie) had in addition a separate line of walls and thus formed an independent stronghold. Extensive excavations (from 1948) have

revealed *terra cottas* which indicate the existence of a temple on the site by c. 500 B.C., while the town plan and streets of the later settlement have been recovered, together with buildings in the central area: a basilica, market place, baths, temples, theatre, shops and houses. The amphitheatre was built by the praetorian prefect Naevius Sertorius Macro (c. A.D. 40). Finds of marble statuary are numerous.

See the excavation reports in *L'Antiquité classique* (1954, 1955), *Fasti Archaeologici*, vol. iv (1951-); *Archaeology*, vol. xii (1959). (H. H. SD.)

ALBA IULIA (Ger. KARLSBURG; Hung. GYULA-FEHÉRVÁR), a town of former Transylvania, in the region of Hunedoara, Rumania, lies on the Mures, 117 km. (73 mi.) S. of Cluj by rail. Pop. (1956) 14,543. It consists of an upper town or citadel and a lower town, and was the seat of a Roman Catholic bishop. Its fine 13th-century cathedral, rebuilt in Gothic style (1443) by the Hungarian national hero John Hunyadi, contains his tomb.

Near the cathedral are the episcopal palace and Batthyaneum, founded by Count Batthyány in 1794, containing a valuable library with many incunabula and old manuscripts (including one of the *Nibelungenlied* and the 9th-century *Codex aureus*), an observatory and a museum of antiquities and minerals. The citadel was built in 1716-35 by the emperor Charles VI. Alba Iulia occupies the site of the 2nd-century Roman colony of Apulum and many Roman relics are in the museum. In the 16th century the town became the residence of the independent Transylvanian princes. From that period date the castle (now in ruins) and the buildings of the former university founded by Gabriel Bethlen, now used as barracks. Alba Iulia with Cluj was the Transylvanian centre of the Rumanian national movement. It was there in 1600 that Michael the Brave proclaimed himself prince of Transylvania, Walachia and Moldavia. In 1918 the union of Transylvania with Rumania was proclaimed at Alba Iulia and King Ferdinand of Rumania was crowned there in 1922.

ALBA LONGA, an ancient city of Latium, on the western edge of Lake Albano, probably situated where the modern Italian town of Castel Gandolfo stands, about 12 mi. S.E. of Rome. Founded traditionally by Ascanius, the son of the legendary Aeneas, c. 1152 B.C., it was said to be the oldest Latin city and to have founded others including Rome. It headed a Latin league of uncertain extent, until destroyed c. 600 B.C. by its daughter city Rome, whither some of its inhabitants were transported; others survived at Bovillae (q.v.). The name Albanum, from about 150 B.C. until the time of the emperor Constantine the Great, meant the imperial villa in the Alban territory. The emperors formed a single estate out of a considerable part of this district, including apparently the whole of the lake, and Domitian was especially fond of it. The imperial villa occupied the site of the present Villa Barberini at Castel Gandolfo, and considerable remains still exist. To the south a camp, with baths, an amphitheatre and a large water reservoir, was constructed by Septimius Severus for the Second Parthian legion, his bodyguard. The camp was given up in the time of Constantine, when the *Civitas Albanensis* (Albano) arose.

Of the pre-Roman Alba only the necropolis has been revealed. The earliest of its tombs are Villanovan (Early Iron Age). Later ones belong to the 7th century B.C.

The *lapis Albanus* is a green-gray volcanic stone with black and white grains in it (peperino), much used for building material in Rome and its neighbourhood.

See R. MacIver, *Italy in the Iron Age* (1927); B. Tilly, *Vergil's Latium* (1947).

ALBAN, SAINT (3rd century A.D. ?), the first British martyr, traditionally of Verulamium (St. Albans). According to Bede he served in the Roman army and was converted to Christianity by a fugitive priest whom he sheltered and exchanged clothes with, so that he was martyred in the priest's place. Gildas surmised, and Bede stated, that he suffered during the persecution of Diocletian (c. 286-303), but there is no certainty that this persecution extended to Britain. His feast day, properly June 22, is commemorated on June 17 in the Church of England because of a confusion between Roman numerals. The tomb of St. Alban was venerated by St. Germanus of Auxerre as early as 429, when a church had

also been built. Later a monastery was founded, around which grew the town of St. Albans (q.v.).

See H. Thurston and D. Attwater (eds), *Butler's Lives of the Saints*, 2:612-614 (1956); W. Levison, "Saint Alban and St. Albans" in *Antiquity*, 15:337-359 (1941). (PL. GN.)

ALBAN HILLS (MONTI ALBANI or COLLI ALBANI), a district of extinct volcanoes southeast of Rome, Italy, consists of an outer circle, approximately 6-8 mi. in diameter, and an inner crater rim, approximately 1½ mi. across. The highest point of the outer rim is Monte Peschio (3,081 ft.) and of the inner rim, Monte Faete (3,136 ft.). Lakes Albano (q.v.) and Nemi occupy two of the ancient craters. Even before the emergence of Rome as a great power the Alban hills were a place sacred to the people of the Latium (Lazio) region, and Roman roads, temples, villas and theatres are still partially preserved there. Because of their coolness in summer and the absence of malaria the Alban hills have for centuries been a favourite summer residence of Romans, where they built such magnificent summer residences as the Villa Falconieri and Villa Mondragone. The Alban vineyards produce the wines known as those of the *castelli Romani*, the most popular of the Roman region. An electric suburban railway connects Rome with Frascati, Grottaferrata, Albano, Velletri, Genzano and Castel Gandolfo. (G. KH.)

ALBANI (ALBANO), **FRANCESCO** (1578-1660), Italian painter, whose exquisite compositions are distinctive among the works of the followers of the Carracci, was born at Bologna. His first master was Denis Calvart, with whom Guido Reni was at the same time a pupil. He was soon left by Calvart entirely to the care of Guido whom he followed to the school of the Carracci. Albani opened an academy in Rome, where he resided for many years. There he painted, after the designs of Annibale Carracci, the whole of the frescoes in the chapel of San Diego in the church of San Giacomo degli Spagnuoli. His best frescoes are those on mythological subjects.

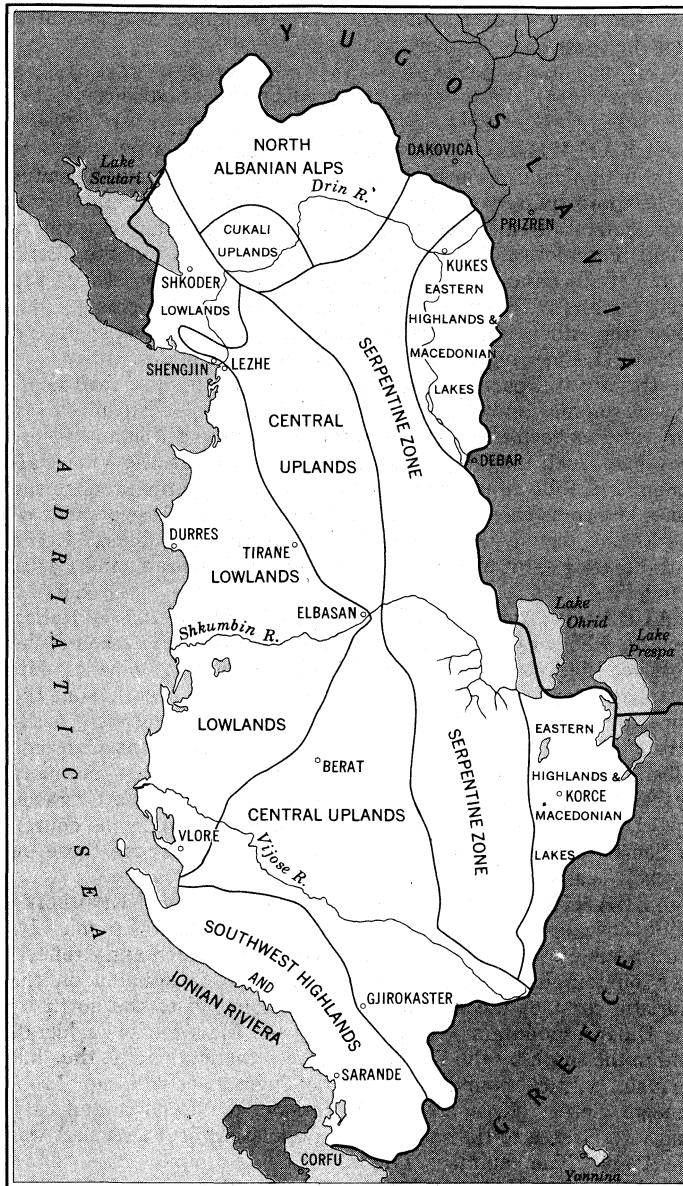

ALBANIA, a People's Republic, officially styled **REPUBLIKA POPULLORE E SHQIPERISE**, is a small state of 11,100 sq.mi. Its local name *Shqiperi* means "eagles' country," which aptly reflects its mountainous nature and remoteness. It is situated on the Adriatic coast of the Balkan peninsula bounded to the north by the Dinaric mountains, to the east by the Macedonian highlands and to the south by the Pindus (Pindhos) mountains. It thus has common political boundaries with the Yugoslav republics of Montenegro, Serbia (Kosmet) and Macedonia to the north and east, and with Greece to the south. The population (1955 census) was 1,391,499. The capital is Tirane.

- V. Administration and Social Conditions
- VI. The Economy

I. PHYSICAL GEOGRAPHY

Structure and Relief.—Albania forms part of the Dinaric folded mountain system largely uplifted during the Tertiary era. Some movement continued into the Quaternary, and minor earthquakes which still affect the region are a reminder of its inherent tectonic instability. The Dinaric system is characterized by northwest-southeast trend lines and these are strongly reflected in the relief of the country as a whole. Anticlinal and synclinal axes are as aligned as are lines of tectonic weakness to which most of the main rivers have succeeded in adjusting themselves. The axial plane of a massive overthrusting associated with the Serpentine complex of rocks in eastern Albania is also roughly Dinaric

PHYSIOGRAPHIC REGIONS OF ALBANIA

in alignment; but the structural grain of the country is not everywhere so simple. It is complicated in the east by a north-south trend reflected in the rift valley of the Drin i Zi (Black Drin) and Lake Ohrid and in the western boundary fault of the Mal' i Thate. In central Albania there are traces of a southwest-northeast faulting diametrically opposed in direction to the Dinaric trend, and in the north overthrusting on an east-west axis combined with fracturing and imbrication, or shinglelike overlapping, complicate the structure still further. Block faulting is a feature in the extreme southwest of the country.

The solid geology of Albania ranges from the Upper Paleozoic, through Mesozoic and Tertiary to the deposits of the Quaternary era. The resultant varied surface lithology is a factor in the multiplicity and diversity of land forms which owe their origin in part to differential weathering. In general the relief of Albania may be likened to an amphitheatre with lofty mountains and dissected plateaus fringing a coastal lowland. A series of long rivers traverse the country and debouch on a low marshy coastal plain. The drainage pattern has distinctly angular characteristics; the principal rivers have pronounced L-shaped bends; there are recurring deep gorges and rapids and the long profiles of the rivers are interrupted by a series of knickpoints or abrupt changes in gradient. A trellis pattern of drainage has developed characterized by the recurring theme of basin and gorge so widely

prevalent in the country. Where local lithology has allowed slope wastage the river valleys are broader and shallower but otherwise they are deeply incised in narrow valleys. In consequence the rivers do not provide easy access to the interior, nor are their valleys easily crossed. The main water parting, or divide, between rivers flowing into the Adriatic on the one side and into the Black sea and Aegean on the other is farther removed from the Adriatic in Albania than is the case in either Yugoslavia or Greece. The fast-flowing perennial rivers have brought down considerable quantities of detritus and have built out an extensive coastal plain into the Adriatic. Finally, during Quaternary times oscillations in sea level combined with periglacial action have resulted in the alternate deepening and aggregation of river courses, while in the North Albanian Alps features resulting from glacial erosion are found.

Geographic Regions. — *The North Albanian Alps* is a convenient name to describe an extensive series of high mountain ranges and plateaus varying between 5,000 to 8,000 ft. in the extreme north of the country adjoining similar territory in Montenegro (Crna Gora). Maje Jezerce, the highest peak, attains 8,838 ft. Sandstones, limestones, conglomerates and shales outcrop at the surface. The whole area has been uplifted and dissected by radial drainage. Glaciation has resulted in a deepening and widening of the valleys, and in fretted slopes and in arêtes. The slopes are heavily wooded and the high plateaus are clothed in alpine meadow. The whole area is isolated and sparsely populated.

The Cukali Uplands immediately to the north of the Drin river consist of a number of anticlines formed of Mesozoic shales, cherts and limestones. The surface forms are more rounded and dome-like than those found in the Alps, the valleys shallower and the elevation, from 3,000–5,000 ft., is lower.

The Serpentine Zone of east-central Albania includes most of the extensive high plateau of Albania south of the Drin river. Rocks outcropping at the surface include various limestones, for example the *krasta* (karst) of the Golloborde plateau (see KARST), as well as Tertiary marls, loams and clays, but the prevalent and most distinctive rocks are the Serpentine, the largest complex of such metamorphic rocks in Europe. They give rise to bold rounded upland features; for the most part the rock is pervious and dry and once the original forest vegetation has been removed it is usually replaced by a poor scrub or heath. The Serpentine rocks are rich in chrome and copper ores and these are of some importance in the economy.

The Eastern Highlands and Macedonian Lakes include the deeply trenched valleys of the White and Black Drin, lakes Ohrid, Prespa and Maliq (now drained), the Kenete depression, the basins of Korce and Bilisht together with the associated highlands. All the lakes act as local collecting centres of inland drainage. Lake Prespa, which is shallow, drains underground into the deep Lake Ohrid which occupies a tectonic depression, and this lake in its turn is drained by the Black Drin northward. In this eastern area the mountain ranges are roughly aligned north-south and are formed for the most part of metamorphosed rocks of Permocar-boniferous and Triassic Age or of tabular limestone. The dazzling white peaks of the Korab range composed of gypsum and marble and which attain a height of over 8,000 ft. are especially conspicuous. To the south extend the high mountains of the Mal' i Thate, the Morava and Gramos, for the most part composed of limestone. This eastern borderland of Albania is somewhat isolated by reason of its physical structure and drainage from the rest of Albania.

The Central Uplands comprise a very large area of central Albania stretching from the coast ranges in the north right through to the Greek boundary in the southeast. It is a zone with a relatively simple Dinaric structure where a series of parallel folds have given rise to successive anticlinal ridges and synclinal valleys aligned along a northwest-southeast axis. The physiography consists of an overburden of Lower Tertiary rocks (flysch) through which Serpentine and Cretaceous rocks outcrop. These outcrops often form lofty plateaus capped with limestone with well marked karst features. The most extensive surface rocks however constitute the so-called flysch (*q.v.*) which consists of friable beds of shale and marl with occasional sandy limestones and coarse con-

glomerates. These rocks are much softer than the Serpentine and Mesozoic tabular limestones and have been much eroded. Gullying is a feature on the upper slopes, and landslips are common in wet weather. The north coast mountain ranges with a characteristic Dinaric northwest-southeast trend are typical of the ranges of the central upland. They form an extension of the Dalmatian coastal ranges into Albania. South from Shengjin these mountains continue as the Kruje ridge inland in the direction of Elbasan.

The Coastal Lowlands consist for the most part of relatively broad stretches of Tertiary sands, clays and marls, separated by low ranges of rain-washed sandstone and pitted, limestone hills. Included in the lowlands are the diversified plains of Shkoder (Scutari), Tirane (Tirana) and Elbasan, all with fertile pockets of soil and well populated in comparison with other parts of the country. The coast itself is fringed with dunes and recurring spits enclose reedy, marshy lagoons. In parts there are great spreads of gravel into which the rivers have incised their beds. Near the coast the rivers frequently change their courses; the Drin itself has so changed in historical times. Only small areas of the marshy plains, once plagued by malaria: had been reclaimed by 1960. Paradoxically the coast has been a barrier against rather than a link with the outside world.

The Southwest Highlands consist of a series of dissected block-faulted anticlines with a northwest-southeast axis. Limestone dominates but Triassic sandstones and soft Tertiary rocks are present as well. The most distinctive feature of this region is its sheltered coast where limestone cliffs and clear water justify the description of the Albanian or Ionian riviera, strongly contrasting with the low coast so characteristic of Albania north of Vlore (Valona).

Climate.— In general Albania has a climate characterized by mild winters: hot summers and moderately heavy rainfall. Marked regional contrasts in climate do occur however and only sheltered, lowland coastal districts enjoy typically Mediterranean weather. Inland diurnal and seasonal temperatures become progressively more extreme according to aspect, altitude and distance from the coast. Since Albania experiences the passage of depressions, or low-pressure centres, not only from the Atlantic but also from the Mediterranean, and is additionally subject to cyclones originating locally in the Adriatic, weather tends to be wetter and more changeable than elsewhere in the Mediterranean. In the North Albanian Alps and other high mountains snowfall is frequent in winter and the summers are subject to rainstorms. High thermal and barometric gradients between the interior and the sea in winter give rise to the bora, strong dry winds, in all but sheltered coastal districts.

Vegetation.— The natural vegetation of Albania has been much influenced by man and his grazing animals and in part has been reduced to brushwood and rock-strewn, herbaceous communities. Except for lacustrine and coastal marshes, which have an interesting flora of their own, for a few skeletal soils and for the alpine mat flora of the high mountains, the climax vegetation is predominantly forest. Oak-hornbeam, beech or pine dominate according to local climatic and soil conditions. Near the coast maquis (tough scrub) is prevalent, consisting for the most part of evergreen brushwood ascending to about 3,000 ft. on the coastal ranges, typical species being the strawberry tree, juniper, holm oak, myrtle, wild rose, bramble and thorny smilax. Inland, oak forest is widely prevalent in varying stages of degradation. Hairy, Turkey and Macedonian oak form the chief varieties.

Apart from wild swine the oak forest has few animals but has been intensively used for grazing and for fuel. Where it has been cleared it is replaced by a secondary growth of deciduous shrubs with such plants as broom, dwarf juniper, hazel and locally *çiblak*. The latter forms an impenetrable mass of thorny scrub with Christ's-thorn dominating. On the higher slopes a great deal of beech forest still survives; usually in the cloud belt 3,000–5,000 ft. above sea level. Because of its inaccessibility the beech wood has been put to little economic use. Above the beech zone, and also at lower altitudes in areas of dry soils, pine forest is dominant. Black pine and peuke pine occur in Serpentine rocks, for example, and the white-barked pine on deep limestones. Above 5,000 to 6,000

ft. occurs the alpine mat plant community, rich in grass and flowering plants and affording pasture in summer. The area of alpine vegetation has been much extended downhill by grazing.

II. THE PEOPLE

Tribal Organization.— The character, manner and outlook of the people of Albania cannot be understood without reference to their tribal organization, of paramount importance in the past and still influential. Even communism is unlikely to modify for some time the core of traditional behaviour which sprang originally from the strict observations of the customary ordinances collectively known as the Canon of Lek. Single tribes or clans (*fis*), usually grouped for the convenience of administration and intermarriage into bajrak (literally, *'standard'), claimed male descent from a single male progenitor. Life was entirely prescribed by customary enactments and the more severe intertribal crimes were resolved by blood feud. Land and grazing rights were jealously guarded and kept within the tribe, and business was conducted by a council of elders. Tribal organization survived in its purest form in Albania north of the Shkumbin river and embraced both the Roman Catholic and Muslim population.

Language.— A common language has provided the unifying force in the development of the Albanian nation. For centuries after the destruction of the Roman frontier on the Danube, hordes of alien invaders pressed south from eastern Europe and Asia. Classical and contemporary languages in Illyria and Thrace survived only in remote places and Albanian is one such survival (see ALBANIAN LANGUAGE). It has a widespread distribution in the western Balkan peninsula partly because of the outward migration of Albanians during the Turkish period. Thus there are more than 500,000 Albanian speakers in Yugoslav Kosmet. 100,000 in Macedonia, perhaps as many as 200,000 in modern Greece and a substantial element in southwest Italy and Sicily.

Religion.— Both the Church of Rome and the Orthodox Church were instrumental in bringing Christianity to Albania. In general the north came under the influence of the former and the south of the latter. The Turks brought the Muslim faith into the country and the majority of people in central Albania accepted, or were forced to accept, Islam. The Turks proved more tolerant of the Orthodox Church but Roman Catholicism survived in the high mountains of the north. Today Roman Catholics constitute about 12% of the population and Orthodox Christians about 20%. The Orthodox Church became self-governing in 1937. The Muslims are mainly Sunnites but there is a strong element of the Bektashi sect (see BALKAN PENINSULA: Ethnology: Turks) of which the world headquarters is at Tirane. (H. R. Wt.)

III. HISTORY

For the early history of Albania to the Slavonic invasions of the Balkan peninsula, see ILLYRIA. When, at the beginning of the 8th century, the wave of Slavonic invasions subsided, the ethnological structure of the Balkans had been greatly modified. The lands of the Albanian-speaking people had been reduced to present-day Albania, Kosovo (in Yugoslavia), parts of western Macedonia and northern Greece. Until the overthrow of the West Bulgarian empire by the Byzantines in the 11th century Slavs were occupying even the Drin and Devoll valleys in present-day Albania. The first recorded use of the name Albanians instead of Illyrians occurs in Anna Comnena's account of the resistance by her father, the Byzantine emperor Alexius I Comnenus, to the attack by the Normans from southern Italy under Robert Guiscard, who took Durazzo (Durrës) in 1082.

1. The Despotate of Epirus.—After the capture of Constantinople by the Latins of the fourth crusade and the substitution of the Latin empire for the empire of the Comnenii (see BYZANTINE EMPIRE; CRUSADES), Michael Angelus Comnenus founded the despotate of Epirus (*q.v.*), which he ruled until 1214, maintaining himself against the Greek emperor of Nicaea. This despotate extended beyond the limits of present-day Albania. Michael's successor Theodore Angelus, however, proclaimed himself the only legitimate heir to the imperial throne, in opposition to the Latins, as well as to Nicaea. Having overthrown the elected Latin em-

peror Peter of Courtenay (who had landed at Durazzo on his way from the west to Constantinople) in 1216, Theodore had himself crowned emperor at Salonika in 1224 but was defeated on his way to Constantinople by the Bulgarian king Ivan Asen II. Ivan Asen could then claim to have extended his empire over Albania, Greece and Serbia. After Ivan's death Michael II Angelus restored the despotate of Epirus, but was defeated by the emperor Michael VIII Palaeologus in 1264. Albania then became once more a dependency of the Byzantine empire. After establishing his Angevin dynasty in southern Italy, Charles I of Naples resumed the quarrel that his Norman predecessors had had with Byzantium and took the title of "king of Albania," but was never able to consolidate his authority over the country.

2. The Serbian Occupation.—At the end of the 13th century the Serbs were already occupying parts of Albania, and in the first half of the 14th century the country was annexed to Stephen Dushan's short-lived empire. This disintegrated, however, after Stephen's death in 1355. Many Albanians meanwhile had fled south and founded colonies as far away as the Morea (Peloponnesus).

3. The Ottoman Invasion and **Skanderbeg**.—In the second half of the 14th century, when the Ottoman Turks were overrunning the Balkans, Albania was in the throes of feudal quarrels between a number of small principalities virtually independent of Byzantium. The chief dynasties were, from north to south: Balsha, Dukagjin, Thopia, Kastrioti, Muzaki, Xrianit-Komneni and Shpata. All were staunchly Catholic, strongly attached to the papacy—a tradition maintained since the early days of the Christian Church when Albanian bishops took a prominent part in ecumenical councils. Taking advantage of the rivalry between these princes, the Venetians had occupied Alessio (Lesh), Scutari and Durazzo, and the Turks were able to make deep inroads into Albanian territory. The Albanian princes were forced one by one to capitulate and to pay the sultan tribute. Turkish garrisons were established in the main cities and in the fortified citadels such as Kruje, Kanine and Sfetigrad.

In 1443 George Kastrioti, surnamed Skanderbeg (q.v.), rallied the Albanians and proclaimed holy war against the Turks. In 1449 the sultan Murad II sent an army under his best general to crush Skanderbeg, but it was defeated at the frontier. This Albanian victory won for Skanderbeg the felicitations of Christian rulers, but the war that it inaugurated was to last a quarter of a century. Invading Turkish armies appeared almost every year and were as regularly destroyed. Unable to continue the struggle singlehandedly, Skanderbeg in 1451 made an alliance with King Alfonso I of Naples (Alfonso V of Aragon), whose vassal he became, and a permanent Neapolitan garrison was installed in his fortress of Kruje. The misgivings of the other Albanian princes about this treaty were allayed by papal representations.

The popes did what they could to help the Albanians, but the other European princes were too deeply engaged in their own quarrels to support Skanderbeg. Pope Pius II's appeal fell on deaf ears. The climax came in 1466 with the siege of Kruje by 200,000 Turks led by the sultan Mohammed II, who had to return home unsuccessful. A second siege of Kruje by Mohammed in 1467 was likewise raised, but this was Skanderbeg's last triumph. A year later he died from fever, mourned by a whole nation. Kruje fell to the Turks in 1478 and the conquest of Albania was completed with the evacuation of Durazzo by the Venetians in 1501.

4. Under Turkish Rule.—As a result of the Turkish conquest Albania was devastated, and the destruction of the monuments of Latin and Christian civilization, begun during previous invasions, was intensified. Thousands of Albanians fled to Italy; many others, especially among the landowning class, embraced Islam. Turkish administration was established in the cities and the lowlands but the communities of the mountainous interior continued to enjoy their ancient autonomy, subject to the payment of tribute. For more than four centuries Albania suffered cultural stagnation and economic decadence. The land could not feed even a depleted population, and many Albanians left to seek fortune in other parts of the Ottoman empire. Muslim Albanians, educated in Turkish schools, reached high positions in the army and in the administra-

tion, and hardy mountaineers joined the Turkish army as professional soldiers. But national sentiment never died, and whenever Turkey went to war with European powers the Albanians seized the opportunity to revolt.

When the crisis of the Ottoman empire began in the 19th century (see EASTERN QUESTION) administrative chaos and economic stagnation in Albania were at their worst. Two-thirds of the population had become Muslims, the remainder being Roman Catholics and Greek Orthodox. Muslim and Christian lived side by side without acute religious strife. Some of the Muslim landlords who had acquired their titles of bey or pasha by military service with the sultan acted as his local representatives, while the virtually independent highland communities of northern and eastern Albania were ruled by their *bajraktar* (standard-bearer) assisted by a council of elders.

The weakness of the central power encouraged ambitious local leaders. In the south, Ali (q.v.), son of a minor bey, rose to be pasha of Janina and made himself an independent ruler from the Shkumbin river to the Pindus mountains. After a ruthless and efficient career, however, he was overthrown and killed at Janina in 1822.

In northern Albania three generations of the Bushati family strove to make themselves independent of Constantinople. The lands of Mehmet Bushati, in the 18th century, stretched from Scutari to Tirane, but his grandson Mustafa was captured by the Turks in 1831 in the Rosafat fortress at Scutari. Once their nominal authority had been re-established over Albania, the Turks introduced the administrative and social reforms of the *tanzimat* (see ABDUL MEJID I) but their success was sporadic and limited.

5. The Independence Movement, 1878–1914.—At the congress of Berlin (q.v.) in 1878, the European powers confirmed the cession to Montenegro of the Albanian districts of Gusinje and Plave and the ports of Antivari (Bar) and Dulcigno (Ulqinj), which Russia had snatched from Turkey by the treaty of San Stefano (q.v.). With the support of the Turkish authorities, the Albanians formed a national league at Prizren to resist this cession. The powers sent warships into the Adriatic to secure the ports at least for Montenegro. Then the Turks, aware that the Albanians were fighting for their own independence, turned against them and assisted the naval squadron. The loss of the two ports, however, greatly stimulated the Albanian independence movement.

The Albanians had to struggle against both the repression by the Turks and encroachments by their neighbours. Publications in Albanian were forbidden by the Turks since the national language and alphabet served as a unifying factor to counteract religious diversity. The League of Prizren was disbanded, but patriotic societies were formed in Constantinople and in the Balkan capitals and published the works of poets and writers which were secretly distributed in Albania. The national movement was intensified after the revolution of the Young Turks. A national congress at Monastir (Bitolj) in 1909 (which also adopted the unified Albanian alphabet) appointed a committee of national union, envisaging, as a first step toward complete independence, an autonomous Albania within the Ottoman empire, including the four vilayets (provinces) of Scutari, Kosovo, Monastir and Janina. The Young Turks however, though they owed much of their success to the Albanians, refused to acknowledge their right to self-government until a national uprising in 1912 culminated in the occupation of Shkup (Skopje) by Albanian mountaineers under the command of Isa Boletin. Thereupon the Young Turks yielded. The puppet chamber of deputies was dissolved and a Turkish delegation went to Pristina (Prishtina) to negotiate.

The neighbouring Balkan states resented the Albanians' success, since an independent Albania within its ethnical frontiers would deprive them of the best part of the spoils of the Ottoman empire which they coveted. With a view to partition of these areas they had signed a military alliance early in 1912, and they now had to go to war earlier than they had intended (see BALKAN WARS). The sudden collapse of the Turkish army left the Albanians exposed to the onslaught of the Greek, Serbian and Montenegrin armies. Nevertheless their national leaders gathered in Vlore (Valona) to proclaim the independence of Albania on

Nov. 28, 1912, and Ismail Qemal Vlora became the head of the first Albanian government.

The Serbs' advance toward Durazzo alarmed Austria-Hungary, just as the Greeks' declared aim of annexing southern Albania including Vlore alarmed Italy. To prevent the war's leading to a general European conflagration, Sir Edward Grey called a conference of the powers in London. Russia took the Slav side, Austria-Hungary and Italy the other, but finally the principle of an independent Albania was accepted (Dec. 1912). When it came to drawing frontiers, however, self-determination gave way to the balance of power, and Serbia was allowed to keep Kosovo, a province with more than 800,000 Albanians in it. The Greek frontier was left to be established on the spot by an international commission, which eventually drew it in the protocol of Florence (1913).

The great powers decided to appoint Prince William (*q.v.*) of Wied as ruler of the new state, assisted by an international control commission. After his long-delayed arrival in Durazzo a new government under Turkhan Pasha tried to establish its authority over the territory that was to become Albania. But Greece had turned southern Albania into the so-called autonomous Northern Epirus, Montenegro had occupied Scutari thanks to the treachery of Essad Pasha (*q.v.*), and a peasant revolt had spread in central Albania. Confusion and disorder were at their highest when World War I broke out. Albania was then occupied by the belligerents and became a battleground in spite of its declared neutrality.

6. The Settlement of 1921.—At the conference of Paris after World War I, Italy joined Albania's Balkan neighbours in contending for the partition of the country, but Woodrow Wilson saved it from being sacrificed to diplomatic expediency. The Paris deliberations closed without solving the Albanian problem, which was passed to the so-called Conference of Ambassadors (*q.v.*). The Albanians, tired of waiting, held a national congress (1920) in the small town of Lushnje, despite the presence of Italian troops. A regency council was elected, a government formed under Sulejman Delvina and Tirane chosen as the temporary capital. The Allied troops occupying Shkoder and Korce handed these places over to the national government. An Albanian rising in Vlore then forced the Italians to withdraw, the troubled state of affairs in Italy itself adding to their difficulties. In Dec. 1920 Albania entered the League of Nations, and in Nov. 1921 the Conference of Ambassadors at last reaffirmed the frontiers of 1913. The League intervened to induce the Yugoslavs to evacuate the Albanian territory that they had occupied.

7. The Kingdom of Albania.—From 1921 to 1924 the liberal intelligentsia of the new state tried in vain to set up a democratic regime. Ahmed Bey Zogu, prime minister from Dec. 1922 to Feb. 1924, was driven from the country in June 1924 by a national uprising, which led to the formation of a revolutionary government under Bishop Fan Noli. Six months later Ahmed Zogu, who was to rule dictatorially until the Italian invasion of 1939, came back to power with the backing of the conservative landlords and the highland chieftains and with help from the Yugoslavs.

Despite his obligation to the Yugoslavs, Ahmed Zogu aligned Albania with Italy by two treaties (1926 and 1927). Next, in 1928, he proclaimed himself king of the Albanians as Zog I (*q.v.*). The political and military alliance with Italy however was accompanied by concessions to Italian companies. Albania received a loan of 50,000,000 gold francs at a heavy rate of interest and, unable to pay the interest even for the first year, was to lose its freedom of action in the economic and eventually in the political field. Practically nothing was done to organize agriculture, the mainspring of the country's life, on a sound basis, and the great landlords were left to exploit their estates for their personal benefit. Grain had to be imported, and the balance of trade showed a constant deficit. Finally Italy had to subsidize the monarchy for purely political reasons.

Behind a constitutional façade Zog ruled as a dictator, buying support with patronage. Poverty was widespread and discontent acute among the peasants and the liberal intelligentsia. The lower strata of the educated class were already looking to communism as a solution of the country's social problems. Several attempts at armed revolt proved to be costly failures and led to further

repression. Yet the 11 years of Zog's monarchy formed the only period in modern times when Albania enjoyed political stability under a national government. Public administration and all the machinery of a modern state had to be created. The gendarmery organized by British officers was a model. Hundreds of boys and girls received scholarships to western universities and on their return many were appointed to administrative posts. In spite of Italian pressure fascism was never introduced, so that public education and literary creation remained free from ideological regimentation. The main towns were linked by good roads, and for the first time in history the central government's authority was exercised in the remote mountain districts, so that national unity became at last a reality. Albania in the long run would have been able to free itself from Italian tutelage if the course of international affairs had been different.

Zog's marriage to the Hungarian countess Geraldine Apponyi in 1938 amid genuine popular rejoicing was the swan song of the Albanian monarchy. Hardly a year had passed before Mussolini, prompted by Germany's annexation of Bohemia and Moravia, decided to turn Albania into an Italian military outpost. His ultimatum to Zog, demanding a monetary and customs union and the installation of an Italian garrison on Albanian territory, was rejected, and Mussolini chose Good Friday, 1939, to invade Albania with 100,000 troops backed by his navy and air force. The Albanian government was unprepared, and such sporadic resistance as the invaders encountered came from local units fighting against overwhelming odds. Military occupation was followed by the transformation of the country into an Italian province with a puppet Albanian government. Victor Emmanuel III of Italy was proclaimed king of Albania, and supreme power was exercised by his lieutenant general, Francesco Jacomoni. Preparations for World War II were hastened, and the exploitation of Albania's natural resources began in earnest to increase Italy's supplies of essential raw materials (oil, iron, copper, etc.).

8. World War II.—Italy entered World War II in June 1940 and, on Oct. 28, invaded Greece from Albania, but instead of the triumphant advance on Athens that had been expected the adventure ended in military disaster. The Greeks occupied the Albanian districts of Korce and Gjirokaster (Argyrokastron) and furthermore took the opportunity to revive their claim to Northern Epirus. Finally, Hitler rescued the Italians by sending his troops through Yugoslavia to Greece.

When the storm of invasion had died down Albanian nationalists began to organize secret resistance against the occupier. The Balli Kombetar (National Front), with members from all classes of society, was formed to restore independence under a democratic regime of equality, social justice and personal freedom. Its armed bands, under army officers or civilian leaders, did much to hinder the Italian war effort, as did the Zogists of the Legality party.

When the Germans invaded the U.S.S.R. in 1941 the Communists aligned themselves with the resistance. They numbered only a few scattered groups, mainly of petty-bourgeois intellectuals, but with the help of two emissaries sent by Tito from Yugoslavia they organized themselves into a party which was eventually recognized by the Comintern. To win popular support the party adopted the camouflage of the National Liberation movement (L.N.C.), which at first issued an impeccably democratic program with only hints of future plans. The general course of the war after June 1941, moreover, led to the Communists' receiving more support and material help from the western Allies than was given to any other group in Albania. This, added to their ruthless methods and propaganda, ensured that they would remain the only organized political force in the country. Only after Mussolini's downfall did the Balli Kombetar and the nationalist Communists try to form a united front, but this agreement was denounced by the pro-Tito and the pro-Russian Communists, who then plunged the country into civil war. The nationalist movement was reduced to powerlessness.

9. Communist Supremacy.—Totalitarian communism was set up in Nov. 1944 with the formation of a government led by Enver Hoxha (Hodja). A wave of terror swept the country. Thousands were summarily executed for alleged collaboration with the enemy and various crimes were invented by the new rulers to destroy their

Administrative Subdivisions

Districts	Area in sq. mi.	Population (1955 census)	Districts	Area, in sq. mi.	Population (1955 census)

opponents. The Roman Catholic clergy suffered most heavily. The Communists then carried out their social revolution with ruthless efficiency. All properties belonging to the Italian government or to private citizens were nationalized. The landowning class was virtually wiped out and the large estates were distributed to the peasants who worked on them. Next the bourgeoisie was deprived of its assets through overwhelming taxation. Many of its prominent members, moreover, were put to death on political charges. Elections to a national assembly took place in 1945.

From the end of World War II to 1948 Albania was a satellite of Yugoslavia with a customs and monetary union, and a series of mixed companies were formed to carry out economic development with Yugoslav help. This co-operation, however, had hardly begun when Yugoslavia was expelled from the Cominform, and the Albanian Communists were faced with a crucial choice. Koci Xoxe (Dzodze), a former tinker who had become organizing secretary of the Communist party and head of the secret police, led a small pro-Yugoslav clique, but this was overpowered by the Stalinist faction, which had Hoxha as its political expert and Mehmet Shehu as its military strategist. Xoxe and his chief supporters were put to death as traitors.

Thenceforward, from 1948, Albania was a satellite of the U.S.S.R. In the elections for the national assembly in 1950, when the Democratic front, led by the Party of Labour (Communist), was modeled on the Communist and nonparty bloc in the U.S.S.R., official candidates won 99% of the votes. Though geographically isolated from the territory of the Soviet bloc, Albania was included in the Warsaw Treaty organization in 1955. Thousands of experts and all kinds of industrial equipment were sent to exploit the country's raw mineral resources, and preparations were made to turn Vlore into a Soviet naval base. Russia's long-standing desire for an outpost on the Adriatic was fulfilled—ironically not in a Slav country but in one against whose creation the Russians had fought implacably. In 1957 an Albanian delegation led by Hoxha and Shehu paid an official visit to the U.S.S.R.

The Albanian Communists maintained a Stalinist system of government while paying lip service to N. S. Khrushchev's new policies, and no relaxation of the police regime was felt in any quarter. The U.S.S.R., however, found it expedient to continue to support the Tirane regime. The cancellation by the U.S.S.R. of an accumulated debt of 422,000,000 rubles was announced in 1957, together with the opening of a large new credit. An extended visit to Albania paid by Khrushchev in May–June 1959 was interpreted as signaling Albania's status as a fully integrated member of the Soviet bloc. But from 1960 Albanian-Soviet relations deteriorated. Soviet economic aid dried up and Albania signed economic agreements with Communist China. Albanian hostility toward Yugoslavia was intensified, and propaganda attacks against Yugoslav revisionism followed the same line as those of China. Following Khrushchev's denunciation of Albania's pro-Stalinism at the 22nd congress of the Soviet Communist party, the Soviet government severed diplomatic relations in Dec. 1961. (T. Z.)

IV. POPULATION

The total population at the census of 1955 was 1,391,499. The principal towns in order of size are: Tirane (Tirana), the capital, 108,183; Shkoder (Scutari) 38,564; Korce (Koritsa) 31,833; Durres (Durazzo) 25,579; Vlore (Vlone or Valona) 28,212; Elbasan 23,616; Berat 14,374; Kavaje 12,757; Gjirokaster (Argyrokastro) 12,322. In 1955, 67.8% of the population was engaged in farming or stock raising; 15.9% was manual workers; 11.8% state employees; the rest craftsmen, traders or professional. At that time much of the farming community still had individual holdings, but by 1960 the majority of farm land was under collective farming.

V. ADMINISTRATION AND SOCIAL CONDITIONS

In 1946 the Communist government, promulgated a soviet-type constitution, which was revised in 1950. The people's assembly, elected by universal adult suffrage, with its presidium, is nominally the sovereign body, but executive power lies with the council of ministers. In practice all decisions are taken jointly by the cabinet

and the central committee of the Communist party and simultaneously communicated to the qark (region) executive committees and the parallel party committees. There are 26 districts (rretheve) and the city of Tirane.

Taxation and Wages.—The main sources of revenue are the compulsory deliveries of farm produce at fixed prices; a turnover tax; the profits of state enterprises; and direct taxes on incomes of workers and employees. Wage rates are weighted in favour of manual as against office workers. Real wages are low by most standards. Rationing was removed in the late 1950s and official price reductions were necessitated to correct increased prices.

Housing.—Housing in the towns is controlled; in the villages individuals are still free to build. By tradition southern village houses are mainly grouped together, but in the north sturdy, stone houses often stand alone on the farmer's land, from customary motives of independence and security against attack; the grouping of new houses is now encouraged.

Social Conditions.—In the past Albania was almost entirely an agricultural and pastoral country. Land was owned largely by families in the north, where the clan system persisted, and in parts of the south where many men bought land with savings accumulated during emigration, principally in the United States. In central Albania (Tirane, Elbasan, Berat and Vlore) land was chiefly owned by the beys and farmed by peasants on a partnership basis. Produce was brought into markets and freely sold. Large flocks of sheep and goats were grazed everywhere on communal pastures, often, especially by the Vlach shepherds of the south, on the mountains in summer and on the plains in winter. Sheep are milked and dairy products form the staple items of diet apart from bread. Meat was a luxury, chiefly for festive occasions, though more was eaten in the towns. The proportion of wheat to maize (corn) bread has been increasing, but since the 1913 frontier deprived Albania of substantial plains now in Yugoslavia the country has never been self-sufficient in cereals and this problem had not been solved up to the 1960s. Clothing of extreme durability, from wool and goats' hair in various local designs, was entirely handmade, as were the women's beautiful national costumes.

The Communist government has aimed at transforming the economy into an agricultural-industrial one. Planning of sowing and harvesting is centralized and compulsory deliveries of crops, as well as surpluses, are collected by the state. Emphasis is placed on industrial crops, and flocks also are state-owned. As a very large proportion of the agricultural as well as the mineral wealth is exported to other Communist countries in return for machinery, equipment, etc., the condition of the individual peasant remains poor as in the past.

The development of industry has been artificially rapid and consequently skilled workers are at a premium, foreign technicians being much employed. A constant drive has been made to recruit women into industry, though the raising of families is also encouraged by tax concessions, grants and public crèches. Many villages have electricity, and radio sets are widespread. The youth movement (*rimija*) and the pioneer organization for the very young are strongly activated by the government. Sport is encouraged, as are the theatre, ballet and music, and Tirane has its own film studio. These developments, accompanied by the general regimentation of the people, have radically changed the national life.

Justice.—The districts have tribunals of first instance, with elected magistrates, and there is a high court at Tirane. An act concerning "personal crimes" was aimed at stamping out the traditional vendetta.

Welfare Services.—Medical care is free and after 1945 there was a large increase of hospitals, sanatoriums and maternity clinics, all state-owned. There are state life, crop and stock insurance schemes.

Education.—Primary education is compulsory for four years for boys and girls from the age of seven. There are 7-year and 11-year schools, which include the primary classes, and kindergartens, evening schools, teachers' training schools and technical schools, both industrial and agricultural. The State University of Tirane, founded in 1957, incorporating six former institutes of higher learning, has faculties of law, economics, history and philology, engineering, medicine, natural sciences and pedagogy. There is a high institute of agricultural and veterinary science. Increased adult education classes are claimed to have reduced illiteracy. A reorganization plan laid down in 1960 envisaged compulsory eight-year schools in place of the previous system, with continuance into general and technical higher schools.

Defense.—Albania has an army, navy and air force, a frontier guard and internal security forces, including police. The armed forces consist mainly of conscripts, with regular officer and non-commissioned officer establishments. Albanian pilots operate aircraft supplied by the U.S.S.R. from modern military airfields. A Russian naval base has been established at Sazan Island at the mouth of Vlore bay. A paramilitary organization, SH.N.U.M. (Association for Assistance to the Army and Defense), trains volunteers of both sexes in marksmanship, communications and nursing, and encourages physical fitness. (D. R. 0.-H.)

VI. THE ECONOMY

The deeply dissected, mountainous nature of the country, two-thirds of which is over 3,000 ft. in height, the marshy, malarious coastal plain, the general difficulty of communications both internally and with the outside world have all been factors inhibiting the economic development of Albania in the past. The long period of Turkish administration when the country was largely cut off from contacts with western Europe added to its difficulties. At the beginning of the 20th century the population of Albania was largely illiterate, traditional and generally oriental in outlook, with a standard of living barely at subsistence level. Agricultural practices had remained unchanged for centuries; the resources of the country were unknown. The development of the modern economy only began after World War I largely under Italian instigation. After 1944, when the Communist government came into power, plans for development were speeded up, but lack of capital was a considerable handicap. At first help was sought from the Yugoslavs but after the break with Yugoslavia in 1948 Albania relied almost entirely upon the Soviet Union, both for technical advice and for capital loans. An interim two-year plan was put into operation in 1949–50, followed by two five-year plans, 1951–55 and 1956–60. The aim of government planning has been to transform the whole of the social and economic life by the rationalization of agriculture and industrialization. The Albanian economy is therefore in the throes of a painful transition and it will be some time before the full results of this policy can be assessed.

Agriculture.—The basis of the Albanian economy has long been agriculture. Of a total land area of 2,874,000 ha. (about 11,100 sq.mi.) in the late 1950s less than half could be said to be in some form of agricultural use including some 850,000 ha. in pasture; only about 404,000 ha. were in arable cultivation and about 8,000 ha. in fruit, 3,000 ha. in vine and 15,000 ha. in olive. Arable cultivation is limited by lack of suitable land, but it could be increased by effective drainage and reclamation. Maize is the chief crop but wheat and rice were both becoming increasingly important in the mid-20th century. Other crops of note are sugar beet, cotton and tobacco. Changes in methods of agriculture are slowly taking place; tractors drawing modern farm implements are replacing oxen and wooden plows, and combine harvesters have been imported from the Soviet Union.

As one might expect from the physical conditions, stock rearing has always been important, probably more so than crop farming both because of the cash proceeds from the sales of wool, hide and milk products and the prestige attached to the ownership of animals. The total number of animals was just about back to prewar levels by the late 1950s with about 2,500,000 sheep and goats and about 500,000 cattle. But quality is still poor; an attempt is being made to improve breeds by means of imported stock but this is a very slow process. The big exception was the improvement in both quality and number of pigs, which almost tripled after 1946, reaching about 100,000 by the late 1950s. The opposition to pig farming on the part of the Muslim population is still effective, however.

About 84% of all agricultural land in Albania has been collectivized. The freehold of the cultivated land formerly in the ownership of the family is now invested in the state. Collective farms are most profitable where physical conditions favour a large consolidation of holdings but these physical conditions are rarely found in Albania and what success ultimately attends the co-operative movement yet remains to be seen. Actual production has consistently lagged behind planned production and Albania is still dependent on imports of grain from the Soviet Union. Potentially the country should be able to feed itself and have a good surplus for export and there are great possibilities of developing irrigation in coastal districts and river basins. There are good prospects also in fruit farming and olive cultivation and it was reported that over 3,000,000 olive trees were planted between 1956 and 1960.

Forestry.—About half the total land area of Albania is under forest but not all of it is of particularly good quality. Some of the more exceptional trees, such as walnut, were exploited and devastated before the war, and some of the best timber is inaccessible in the high mountain ranges. Nevertheless, forestry is playing an important role in the economic development of the country and in the years after World War II about 17,000 ha. of forest were replanted and 57,000 ha. improved. The emphasis is on chestnut, oak and lime.

Mining.—Although not rich in mineral wealth Albania has important mineral resources. Bituminous coal is lacking but brown coal is worked near Tirane as well as in the Memaliaj-Tepelene district, the Korce basin and at Pogradec. Albania is an important producer of chrome. New deposits have been found in the north-east. The copper ores are worked both in the north and in the southeast at Vithkuq near Korce. Other minerals worked include pyrites, iron nickel ore, arsenic ore, bauxite, gypsum, and of course limestone for cement, as well as oil, asphalt and bitumen.

Even before World War II the Albanian oil fields were being exploited by foreign oil companies, mainly Italian. The chief fields are at Kucove (Qytet Stalin) and at Patos northeast of Vlore. Drilling is proceeding in many other localities. Before the war oil was piped to Vlore for export to Italy but at the end of the 1950s about half of it went to Rumanian or Caucasian refineries and the rest to Cerrik (near Elbasan), which is said to have an ultimate capacity of 300,000 tons, enough for most local needs. Natural gas is also an important source of fuel only limited in use because of distribution problems.

Industry.—Before 1940 there were few industries in Albania apart from those associated with agricultural activities such as brewing, flour milling and tobacco, together with cement, brick-making and carpentry. Heavy industry was nonexistent and the few consumer goods needed were imported. As industrialization is an important aim of the present regime, a large proportion of the national income is devoted to industrial investment. In the first instance the emphasis has been on the development of hydro-electricity as a major source of power. In this connection the advantages of the many perennial streams fed by heavy rainfall from the mountains are obvious. High evaporation rates and seepage from storage basins present difficulties. The scattered sparse population also makes distribution costly and inhibits really large capital schemes except at a few points. The two largest schemes are the Karl Marx at Ulze with a capacity in 1959 of 125,000,000 kw.hr., ultimately to be expanded, and the Lenin plant near Tirane

which supplies the capital with its electricity and water supply. About 100 small power stations have been built to supply local needs.

Some progress has been made with the introduction of consumer industry: plants established after 1945 include cotton ginning at Fier, a large cotton and wool cloth combine, brick factories, a food combine, a glass factory and a metal-working plant at Tirane. Cement works and a rice mill at Vlore and sugar-beet refineries at Korce and Maliq, in addition to numerous smaller developments particularly in food processing, canning and the production of leather, footwear, soap, chemicals and copper concentrates. plywood and timber for furniture, and rubber goods. Lack of accessory services and skilled labour, however, results in high production costs.

Transport and Communications. — Albania has long been a backwater in southeastern Europe and trade routes have tended to bypass it on either side. Italian and central European trade contacts with the eastern Mediterranean lands were easier and cheaper by sea and Venetian and Ragusan ships ignored Albanian ports. Turkish caravan routes and later railways made use of the Vardar valley routeway through Macedonia. In fact, only two highways have traversed Albania in the past. The "Egnatian way" was engineered by the Romans to link Italy directly with the Balkan provinces and to carry Roman troops and trade overland to Salonika. Upon the breakup of the Roman empire into its east and west components this route fell into disuse. The Via Zenta, the Drin valley route, was developed by Ragusan merchants to tap the resources of the old Serbian empire. The advent of the Turks, the eclipse of the medieval Slav empires and the troubles which followed put an end to this trading enterprise and Albanian caravan routes lost their importance. The Turks had no interest in maintaining roads across Albania beyond those necessary for general administration, nor did the primitive tribal economy of the country call for a system of communications more elaborate than satisfied its needs and these were met by mule and cart tracks focusing on small market towns.

Modern communications, when they did come, were constructed largely for strategic reasons, first by the Austrians and then by the Italians. As a result Albania still lacks an integrated pattern of communications and many rural areas in north and central Albania are as distant as 10–15 mi. from the nearest road. Shkoder is the best road centre but is of peripheral importance to the rest of the country. Tirane is linked by adequate roads not only with the port of Durres and with Shkoder, but south with Elbasan and Korce and east with the hinterland. Altogether there are probably not more than 3,000 mi. of modern roads and, although some of the roads have been excellently engineered through difficult country, the surfaces are poor because of the difficulty of road maintenance. New road construction is costly because it calls for many bridges and elaborate engineering to overcome steep gradients; moreover it is a heavy drain on capital in relation to the potential density of traffic. Nevertheless, full development of the country is likely to be seriously delayed if communications are not improved.

Albania has few railways; the only normal gauge lines are those which were constructed after 1945 to link Durres with Tirane and with Elbasan. Air services, however, have developed with Tirane as the centre since the 1930s, and in 1958 an air service between Moscow and Tirane was inaugurated, dictated largely by political necessity. The country has a reasonable telephonic network, the basis of which was laid by the British-organized gendarmery before World War II, and Tirane now has an automatic service. Radio transmission throughout the country has been improved with Soviet aid.

Trade and Finance. — The prospects of Albanian foreign trade can only be assessed in the light of the financial situation in which the country finds itself. As a poor, underdeveloped country before the war, Albania suffered from an adverse trading balance and a severe shortage of capital for internal investment. It had no coinage of its own before 1925 when the National Bank of Albania was founded, largely as an Italian-aided venture. The monetary unit was the Albanian franc, divided into five leks and fixed at

parity with the Swiss franc. Thereafter Albania was largely financially dependent upon Italy. In 1939 the franc was linked to the Italian lira. In 1946 Albanian financial ties with western Europe were broken and a new currency based on the lek was established linked to the Yugoslav dinar. This was at a time when the plans of the two countries were being integrated. In 1948, following the break with Yugoslavia, the currency was reorganized yet again and now the lek is linked to the Soviet ruble and Albania has become strongly dependent on subsidy and loans from the Soviet Union.

The revenue of the country is said to have increased threefold since 1938 but currency changes make any comparison difficult. In 1958 the revenue amounted to 26,700,000,000 leks, and at that time Albania had received a loan of 300,000,000 rubles from the Soviet Union. International investment is fixed according to the quinquennial plans, the target figures of which are annually drastically revised in the light of actual attainment. Industry, power projects and technical education receive priority. The revenue is largely raised by indirect taxation and by a system of levies and quotas on the production of farms.

Albania has nominal trade agreements with the various countries of the eastern bloc as well as with China and some other Asiatic countries, but geography dictates that in the long run trade can be profitably developed only with the neighbouring countries of the Mediterranean and central Europe. In recognition of this fact Albania has trade agreements with both Italy and Yugoslavia but vigorous trade exchanges are inhibited by the difficulties of financial negotiations and the political climate. Albania has a surplus of oil, chrome and other ores, timber, fruit and other specialized agricultural products and a need of capital goods and services.

ALBANIA, the ancient name of part of the Azerbaijan Soviet Socialist Republic, U.S.S.R., in the eastern Caucasus, extending along the left bank of the Kura (Cyrus) river from the hills west of the confluence of the Kura with the Alazan as far as the Caspian sea. The Albani, according to Strabo, were tall and well-built and, in character, simple and honest; they worshiped Zeus, the sun and, more especially, the moon. They lived on the produce of their fertile land but were less skilled in agriculture than their western neighbours, the Iberi. They became subject to Armenia after their defeat by Tigranes I c. 90 B.C. When in 65 B.C. the Romans under Pompeius Magnus invaded their territory, the Albani are said to have mustered 60,000 infantry and 12,000 cavalry in an unsuccessful attempt to oppose them. By the terms of Pompeius' general settlement of the near east in 62 B.C. the king of the Albani became nominally a vassal of Rome. Their king made submission to the emperor Trajan again in A.D. 114. Their territory was overrun by the Alani during the reign of Hadrian and passed under Sassanid suzerainty, at the latest, by A.D. 364. They were driven finally into Armenia by the Khazars and ceased to exist as a separate people.

ALBANIA, ORTHODOX CHURCH OF, an autocephalous Orthodox Church the members of which are a minority in a predominantly Muslim country. Its Orthodox metropolitans formerly were Greek bishops directly dependent upon the ecumenical patriarchate of Constantinople. Before World War I, however, with Albania newly become an independent state, strong separatist tendencies were revealed in ecclesiastical as well as political mat-

ters, and the Albanian government began to claim ecclesiastical independence for its Orthodox population (about 20% of the total). In 1937 this was finally granted by the ecumenical patriarch, whose honorary primacy is recognized by the Albanian Orthodox. The Albanian synod is formed by the archbishop of Tirane as president, and the bishops of Berat, Korçe (Koritsa) and Gjirokaster (Argyrokastron). A seminary was founded to provide elementary ecclesiastical education for parish priests. Many of the Albanian bishops had received their education in Greek seminaries and at the University of Athens.

Under Italian rule during World War II, the Albanian Orthodox Church suffered considerably, and some of its bishops were sent into exile. The policy of the Communist regime is not much more favourable to it, though the church theoretically enjoys complete religious liberty under the Albanian constitution. There is practically no communication with other Orthodox churches except those behind the "iron curtain." The language used in both teaching and worship is Albanian, into which all the liturgical books have been translated from the original Greek. A small number of Orthodox Albanians live abroad (some for political reasons), especially in the U.S. where a small independent Albanian Orthodox Church was founded under Fan Noli (Albanian prime minister in 1924), who became its bishop. See also **ORTHODOX EASTERN CHURCH**. (H. S. AL.)

ALBANIAN LANGUAGE, an Indo-European language, is spoken by about 2,000,000 inhabitants of the eastern Adriatic coast, within the national boundaries of Albania, and in neighbouring Serbia (Kosovo-Metohija) west of a line from Pristina to Lake Ohrid. There are perhaps an additional 500,000 speakers in isolated villages and village groups in southern Italy (Abruzzi e Molise, Basilicata, Apulia, Calabria and Sicily) and southern Greece (Boeotia, Attica, Euboea, Andros and the Peloponnesus).

Origins both of the general name Albanian (attested since Ptolemy; Calabrian Albanian Arbresh, modern Greek Arvanit-is, Turkish Arnaut), which traditionally referred to a clan area in central Albania, and of the native official name Shqiperi which may be a totem name originating in the term for "eagle," are much disputed.

Dialects.—The two principal dialects, Gheg in the north and Tosk in the south, are bounded roughly by the Shkumbi river, which bisects Albania. Gheg has more marked subvarieties, the most striking of which are the northernmost, which include those of the city of Shkoder (Scutari), the neighbouring mountains, Kosovo-Metohija, and the isolated village of Borgo Erizzo, on the Croatian coast of Dalmatia near Zadar (about 2,000 speakers; founded in the early 18th century by refugees from near Bar, formerly Antivari). All the Italian and Greek enclaves are Tosk and seem to be related in dialect most closely to the extreme south of Albania, known as Camerija; they represent incompletely understood population movements of the 13th–15th centuries. A few isolated outliers in Bulgaria, Turkey and Bessarabia are of unknown date, provenience and vitality, though an extant Tosk enclave in the Ukraine appears to be of moderately recent settlement; the enclaves of Istria and Sirmia are extinct. Gheg and Tosk have been diverging for a millennium; their less extreme forms are mutually intelligible.

History.—The official language, written in a standard Roman-based orthography adopted only in 1909 at a congress in Monastir (Bitolj), was from the beginning of the Albanian state until World War II based on the south Gheg dialect of Elbasan and after that time on Tosk. Before 1909, the little literature that was preserved, apart from material scientifically recorded by 19th-century scholars, was written in local makeshift Italianate, Hellenizing or even Turco-Arabic characters and systems.

A few brief written records are preserved from the 15th century, such as a baptismal formula from 1462. The scattering of books produced in the 16th and 17th centuries originated largely in the Gheg (often Scutarene north Gheg) area and reflect Roman Catholic missionary activities. Much of the small stream of literature in the 19th century was produced by exiles in foreign cities. The earliest purely literary work is perhaps the 18th-century poetry of the Calabrian Gjul Variboba, of the enclave at S. Giorgio, Italy;

a trickle of literary production continued through the 19th century in the Italian enclaves. No similar activity is recorded in the Greek enclaves. All these documents show the language in general little different from what is found today.

Morphology.—The grammatical categories and form classes of Albanian are much like those of other European languages. Nouns show gender, number, and case (three or four of them); a unique feature is that nouns are further inflected obligatorily to show definite or indefinite meaning. Adjectives, except numerals and certain quantifying expressions, follow the noun and are remarkable in having a prefix agreeing with the noun. Verbs have roughly the number and variety of forms found in French or Italian, and involve considerable irregularities. In general mechanics Albanian is reminiscent of Serbian, modern Greek and Romance; in sounds, of Hungarian and Rumanian.

Classification.—Albanian is of clearly Indo-European origin; this fact was recognized by Franz Bopp in 1854, and the details of its main correspondences were elaborated by Gustav Meyer in the 1880s and '90s. A few etymologies suffice to illustrate this relationship, as later refined by other scholars, particularly H. Pedersen and N. Jokl (the asterisk denotes a hypothetical form): pese "five" (from *penk^we), zjarm "fire" (*g^wlzermos), nate "night" (*nok^wt-), gjumë "sleep" (*súp^wnos), gjarpën "snake" (*sérpōn-), bjer "bring!" (*bhere), djeg "I burn" (*dheg^whō), kam "I have" (*kap^wmi), pata "I had" (*pot-), pjek "I roast" (*pek^wō), thom, thua, thote "I say, you say, he says" (*kē(n)s^wmi, *kēns . . . , *kē(ns)t . . .). The verb system includes many archaic traits: retention of distinct active and middle personal endings (as in Greek); change of a stem vowel e in the present to o (from *ē) in the past; and reflexes of Indo-European stem suffixes in the present. Because of the superficial changes in the shape of the language over two millennia, and because of its borrowing of words from diverse neighbouring cultures, the clear continuity of the Indo-European heritage in Albanian has been underrated.

Albanian shows no obvious close affinity to any other Indo-European language; it is plainly the sole modern survivor of its own subgroup. Of ancient languages, both Thracian and Illyro-Messapic have been claimed as its ancestor or next of kin, but this relationship is not yet settled. (See **ILLYRIAN LANGUAGE**.)

Vocabulary.—Among the host of interesting borrowings from its neighbours, Albanian shows exceedingly few evidences of contact with ancient Greek; one such is Gheg *mokën* (Tosk *mokërë*) "millstone." Obviously close contacts with the Romans gave many Latin loans: e.g., mik "friend," kendoj "sing, read" (for this association of senses cf. Turkish *okumak*). Furthermore, Albanian attests parallel developments in Balkan Latin to those reflected in Rumanian: Latin *paludem* "swamp" became *padulem* and then Rumanian *padure*, Albanian *pyll* "forest." Conversely, Rumanian shares some apparently native terms with Albanian: Rumanian *brad*, Albanian *bredh* "fir." Thus these two languages reflect special historical contacts of early date. Early contacts with Slavs gave *gozhde* "nail." Many Italian, Turkish, modern Greek, Serbian and Macedonian-Slav loans are easily referred to cultural contacts of the last half millennium with Venetians, Ottomans, Greeks (to the south), and Slavs (to the east). A fair number of features (e.g., the formation of the future tense) are shared with other Balkan languages, but are of obscure provenience and development; Albanian or its earlier kin could easily be the origin for at least some of these.

ALBANO, LAKE (LAGO DI ALBANO), a crater lake in the Alban hills southeast of Rome, Italy. The lake, elliptic in shape, formed by the fusion of two ancient craters, lies at 961 ft. above sea level. It is 2 mi. long with a maximum width of 1½ mi.; and its greatest depth is 558 ft. Among the towns on its banks, Castel

Gandolfo (*q.v.*), summer residence of the pope and probable site of Alba Longa (*q.u.*), is best known.

An outlet of Lake Albano was made in 398–397 B.C. because the Delphic oracle said that Veii (*q.v.*) could only be taken when the lake's waters reached the sea. This outlet, still in use, is 1 mi. long, 6 ft. high and 4 ft. broad, with vertical shafts and a sluice chamber.

(G. KH.)

ALBANY, DUKES OF. The name Albany, which formerly designated those parts of Scotland lying north of the firths of Clyde and Forth, has on several occasions been attached to a dukedom. After the four dukes of the first two creations (1398 and *c.* 1458; see below), the dukedom of Albany was next bestowed upon Henry Stuart, Lord Darnley, in 1565 and passed from him to his son James VI of Scotland and I of England, who gave it to his second son Charles (I) at birth. Charles II in 1660 gave it to his brother James, duke of York (later king as James VII and II). King George I, however, in 1716, gave the title duke of York and Albany to his youngest brother, Ernest Augustus (1674–1728), bishop of Osnabrück, who died without heirs. Next, in 1760, Edward Augustus (1739–67), second son of Frederick Louis, prince of Wales, was created duke of York and Albany by George II, but he also died without heirs. Then in 1784 the same title was given to George III's second son (see YORK AND ALBANY, FREDERICK AUGUSTUS, DUKE OF), but he likewise left no heir. For the creation of 1881 see below.

The First Creation.—ROBERT STEWART (*c.* 1340–1420), duke of Albany, regent of Scotland, was the third son of Robert II of Scotland and his first wife, Elizabeth Mure. He was made high chamberlain of Scotland in 1382 and won a military reputation in campaigns against England. Chosen guardian of Scotland by the estates in 1388, he retained the control of affairs after his brother John became king as Robert III in 1390. In April 1398 he was created duke of Albany. In 1399, however, his nephew David, duke of Rothesay, the heir to the crown, succeeded him as governor. Uncle and nephew soon differed, and in March 1402 the latter died in prison at Falkland. While Albany and the earl of Douglas were certainly responsible for the imprisonment of Rothesay, the cause of his death is unknown, though contemporary suspicion pointed to the uncle's guilt. Restored to the office of governor, the duke was chosen regent of the kingdom after the death of Robert III in 1406, because the new king, James I. was a prisoner in London. Albany continued, with vigour if with no great success, to prosecute the war with England, which had been renewed a few years before. He suppressed a formidable revolt led by Donald Macdonald, 2nd lord of the Isles, who claimed the earldom of Ross and was in alliance with Henry IV of England. Albany died at Stirling castle in Sept. 1420 and was buried in Dunfermline abbey. His son, MURDAC (or Murdoch) STEWART, succeeded him as duke of Albany and regent but was executed in 1425, when the dukedom became extinct.

The Second Creation.—ALEXANDER STEWART (*c.* 1454–1485), duke of Albany, the second son of James II of Scotland, was styled earl of March in 1455 and created duke of Albany before 1458. Both he and John, earl of Mar, quarreled with their brother James III, who imprisoned them in 1479. Mar died but Albany escaped to carry on a series of intrigues with the English, who supported his pretensions to the Scottish crown. He was lieutenant general of the realm during the winter of 1482–83, but was attainted in 1483 and defeated in another rising in 1484. Escaping to France, he died there in 1485.

JOHN STEWART (*c.* 1481–1536), duke of Albany, regent of Scotland, was the only son of Alexander Stewart by his second wife, Anne de la Tour. In 1515, at the request of the Scottish parliament, he came to Scotland from France. Inaugurated regent in July, he organized resistance to the English influence of Queen Margaret (*q.v.*) Tudor, whom he took prisoner at Stirling in August. Subsequently he suppressed the rebellion of the Home family, the earl of Angus (Margaret's second husband) and James Hamilton, earl of Arran. He was declared heir to the throne on Nov. 13, 1516. Returning to France in 1517 he concluded the treaty of Rouen, which renewed the alliance between France and Scotland and stipulated that a daughter of Francis I of France

should marry James V of Scotland. Returning to Scotland at the close of 1521 he immediately became the object of English attacks. He reconciled himself temporarily with Margaret, supported her cause against Angus and was accused by the English government of scheming to marry her himself. This was denied by the Scots, and the English demand for the regent's dismissal was refused. War with England broke out in Sept. 1522, but Albany had little success in the field and retired to France. Returning again in Sept. 1523 he failed once more and finally left Scotland on May 20, 1524. His regency was expressly terminated by the declaration of parliament later that year. From 1530 he acted as French ambassador in Rome. In 1533 he conducted Catherine de Médicis, his wife's niece, to France for her marriage to Henry (afterward Henry II of France). Thereafter much of his time was spent in protracted and fruitless negotiations for the marriage of James V. Albany died on June 2, 1536, leaving no legitimate heir.

A singularly unfortunate commander in the field, Albany was an honest, loyal and unselfish ruler and administrator. He regarded himself, however, essentially as the subject and servant of the king of France and so subordinated Scottish interests to French interests.

The Creation of 1881.—LEOPOLD GEORGE DUNCAN ALBERT (1853–1884), the youngest son of Queen Victoria, was born on April 7, 1853, and created duke of Albany in 1881. Distinguished for his interest in the arts, in science and in language and for his promotion of education, he died at Cannes on March 28, 1884. A posthumous son, LEOPOLD CHARLES EDWARD GEORGE ALBERT (1884–1954), born at Claremont in Surrey on July 19, 1884, succeeded to the dukedom of Albany and, on July 30, 1900, became duke of Saxe-Coburg and Gotha after the death of his father's brother Alfred. Deprived of his British titles in 1919 he later co-operated with the Nazis and was president of the German Red Cross. He died at Coburg on March 6, 1954. (G. S. P.)

ALBANY, LOUISE MAXIMILIENNE CAROLINE, COUNTESS OF (1752–1824), was the wife of the "Young Pretender," Prince Charles Edward, and later became the mistress of the Italian poet and dramatist Alfieri. The elder daughter of Gustavus Adolphus, prince of Stolberg-Gedern, she was born at Mons in the Austrian Netherlands on Sept. 20, 1752. She entered the convent of Ste. Waudru in Mons, where as a canoness she was able to receive a good education despite the poverty in which her father's death at the battle of Leuthen had left her family. In 1772 she was married to Prince Charles Edward, self-styled count of Albany, who was 32 years older than she.

In Rome the countess was embarrassed by her husband's attempts to have her treated as a queen. After they had moved to Florence it became plain that she would not present him with an heir, his bouts of drunkenness returned and they became estranged. In 1780 she fled from him and placed herself under the protection of his brother Henry, cardinal duke of York. Charles Edward's ill-treatment of her was the reason given for this move, but the real cause was her liaison with Count Vittorio Alfieri (*q.v.*), who soon followed her to Rome. When this liaison became known to the cardinal he withdrew his support and had Alfieri banished. After some wanderings the couple settled in Florence, Louise having obtained a legal separation from her husband in 1784 through the intervention of Gustavus III of Sweden. On a visit to London the countess was received at court and obtained a pension from George III.

After Alfieri's death (1803) Louise continued to live in Florence in the company of the French painter François Fabre, to whom she bequeathed all her property. Her house on the Lung' Arno was frequented by scientists and men of letters and she enjoyed a reputation for wit. Her letters show a spiteful and uncharitable disposition with an undue preoccupation with her position as "legitimate" queen of England. She died at Florence on Jan. 29, 1824.

ALBANY, a municipal town of Western Australia, lies on the northern shore of Princess Royal harbour in King George's sound

on the most southerly stretch of the state's coast. It possesses a fine protected and deepwater anchorage. Pop. (1954) 8,265. Area 13 sq.mi. The population of the town increased 250% between 1946 and 1960. The town hall (1888) and St. John's Anglican church (1848) are on York street; other main business streets are Stirling terrace, Middleton road and Albany highway. Albany is 340 mi. distant from Perth by rail, 254 mi. by road and 241 mi. by air and is linked by regular services. It has government and commercial radio stations. Industries include woolen mills, fish and meat canning, superphosphate and brick works, whaling, dairying and fruit growing. The climate is mild, with an average summer maximum of 74° F. and an annual rainfall of 38 in.

Albany, the oldest settlement in Western Australia, was founded by an expedition sent by the New South Wales government, which landed at the site on Christmas day 1826. Capt. Matthew Flinders (*q.v.*) had landed at the same place in 1801. The first road to Perth was opened in 1841. Albany became a municipality in 1871.

(D. J. Su.)

ALBANY, a city and seat of Dougherty county, in southwestern Georgia, U.S., 170 mi. S.E. of Atlanta at the head of navigation of the Flint river. Founded in 1836 by Nelson Tift, who laid out broad streets in checkerboard fashion, it was incorporated in 1838 and early enjoyed a lucrative wagon trade from the surrounding cotton plantations. In 1857 the Southwestern railroad connected it with Macon. Later six other lines converged on the point to make it the principal transportation hub in southwestern Georgia. Cotton growing in the area declined after the entry of the boll weevil about 1915. A wide diversification of agricultural products followed, with emphasis on papershell pecans and Spanish peanuts, the processing of which became an important industry. Other industries included textiles, meat packing, candy, farm implements and pharmaceutical chemicals. Radium Springs, four miles south of the city, is an important recreation centre. In 1903 Albany State college, a coeducational teacher-training and liberal arts college, was founded there as a school for Negroes.

A council-manager form of government was adopted in 1924. Pop. (1960) city 55,890; standard metropolitan statistical area (Dougherty county) 75,680. For comparative population figures see table in *GEORGIA: Population*.

(Js. C. B.)

ALBANY, capital city of the state of New York, U.S., on the west bank of the Hudson river, is 145 mi. N. of New York city and the junction of the water route from New York city to the Great Lakes, and to Montreal; it is the seat of Albany county and a port of entry. Albany has claims to being the oldest existing town in the 13 original American colonies, and is the second permanent settlement operating continuously under the original city charter. A rail, highway, waterway and air crossroads, it established the first municipal airport in the U.S. (1919). Ocean-going freighters using the 32-ft.-deep Hudson channel dock at the port of Albany.

Albany was first reached in 1540 by Frenchmen who, according to later Indian reports, constructed a small fort on Westerlo Island in the Hudson. It was rediscovered and claimed for the Dutch by Henry Hudson in 1609. In 1614 a new fort was constructed on Westerlo (then Castle) Island, and was used by agents of the United Netherlands company for three years as a trading post. In 1618 a new trading post was established on the mainland, but permanent colonization did not begin until 1624, when a group of Dutch Walloon families arrived and built Fort Orange near the site of the present capitol. The settlement around it was known as Beverwyck. In 1629 the Dutch West India company granted a large tract of land on both sides of the river to Kiliaen Van Rensselaer, a diamond merchant of Amsterdam. His grant, which included the area of Beverwyck, was named Rensselaerwyck, and attracted a sizable body of colonists. In 1652 Peter Stuyvesant, after a lengthy controversy with the director of Rensselaerwyck, established Beverwyck as an independent village. When Fort Orange surrendered to the English (Sept. 24, 1664), Beverwyck was renamed Albany, one of the titles of the duke of York (later James II). The Van Rensselaer family in the Netherlands attempted to obtain a patent from the duke of York which would restore their control of Beverwyck, but Thomas Dongan, one of

the first English governors, declined to grant it because he "did not think it convenient that the second town in the government should be in the hands of private men."

On July 22, 1686, Governor Dongan granted a city charter to Albany by which all vacant and unappropriated lands within its limits were vested in the mayor, aldermen and commonality of the city. Peter Schuyler (1657-1724) was appointed the first mayor.

At that time, Albany had about 200 families, according to the report of the Rev. John Miller, who described the city a few years later (1695). This represented a substantial increase over the 25 or 30 families reported by Father Isaac Jogues in 1643. The first federal census (1790) counted a population of 3,498; by 1850 it had reached 50,763; and by 1960, 129,726. In 1960 the population of the Albany-Schenectady-Troy standard metropolitan statistical area (Albany, Rensselaer, Saratoga and Schenectady counties) was 657,503. (For comparative population figures see table in *NEW YORK: Population*.)

As late as 1750, a Swedish naturalist, Peter Kahn, who wrote a vivid description of the city, found, although the dress was English style, the language and manners were Dutch. Early Dutch origins are reflected in street and park names and in the importance placed upon Dutch ancestry by many of the city's families.

Albany's strategic location made it a place of importance throughout the colonial period. Not only did it attract settlers, but it also developed as a meeting place for representatives from the other colonies. In 1689, in one of the first intercolonial conventions, delegates from Massachusetts Bay, Plymouth, Connecticut and New York met with Indian representatives of the five nations (the Iroquois confederation) to plan a system of defense. A more significant historical gathering took place in 1754 when the famous Albany congress met in anticipation of hostilities with the French. Among the delegates was Benjamin Franklin, who proposed a plan for "one general government" of the English colonies for purposes of common defense. Adopted by the congress, the "Albany plan," although disapproved by the English rulers and by the colonial governments, paved the way for the congress of 1765 and the continental congress of 1774. Migrating pioneers journeying west began to appear in the city as early as 1783, and by 1795, 500 oxcarts a day were making their way through the town. By 1825 the opening of the Erie canal had linked Albany to the Great Lakes; canal traffic increased the flow of migrants through the city and doubled its population. There were six-day lines to Michigan, and passage to the Northwest territory and the Mississippi could be booked on the pier at Albany. Many wagon trains made Albany their point of departure, forming and supplying themselves with provisions, before taking to the western road.

Albany, primarily known as a seat of government, became the permanent state capital in 1797. Industries include papermaking and the manufacture of felts and blankets, meat products, printing, stationery and paper products, dye stuffs, pharmaceuticals, chemicals and cleansers, industrial fabrics, machine tools, steel, foundry products and castings, brushes, baked goods and brewing.

There are a number of fine specimens of colonial and later architecture in the city. These include the Schuyler mansion (1761), a state historical monument; the State Bank of Albany (1803); the original Albany academy (now the Joseph Henry memorial); the Capitol, and the State Education building, which houses the State museum. Among the colleges in Albany are the New York State College for Teachers (1844), a constituent unit of the State University of New York; the professional schools of Union university; Albany Medical college (1839), Albany Law school (1851), Albany College of Pharmacy (1881) and Dudley observatory; the Roman Catholic colleges of Saint Rose (women) and Siena (men); and Russell Sage Junior college. Albany provides an extensive public park and recreational system and is within easy travel distance of New York's upstate lakes and the Berkshires and Green mountains of New England.

A high point each year is the tulip festival. City parks and private gardens are ablaze with this flower, and descendants of the city's founders, dressed in ancient Dutch costumes, scrub down the main street of the community.

(P. F. W.)

ALBANY CONGRESS, an intercolonial conference held June 19–July 11, 1754, at Albany, N.Y., on invitation from Lieut. Gov. James DeLancey at the behest of the British board of trade. The board's chief purpose in calling the conference was to conciliate the Iroquois whose loyalty was thought to be wavering. There were, therefore, 150 Indians present as well as 25 representatives of New York, Pennsylvania, Maryland and the four New England colonies. DeLancey took the lead in parleys with the Iroquois, placated them with promises of redress of grievances and dismissed them with presents and provisions.

In accordance with the board's broader purpose, the congress, led by Thomas Hutchinson from Massachusetts, forcibly drew public attention to French encirclement. It also made suggestions that produced practical results in the form of the royal appointment of superintendents for Indian affairs and in regulation of the westward push of the pioneers.

In the spirit, if not the letter, of the board's instructions the congress also proposed a colonial union based on a plan submitted by Benjamin Franklin. This plan called for parliament to create a federation with a central government consisting of a president general appointed by the king and a representative council chosen by the colonial legislatures. Parliament was to empower this government to regulate trade with the Indians and the sale and settlement of Indian lands. It was also to have authority to build forts, raise armed forces and levy taxes on the colonists to defray the expense of these measures. This plan, acceptable neither to the colonies nor the crown, foreshadowed, in its federal aspect, the constitution of the United States drawn up in 1787.

BIBLIOGRAPHY.—L. H. Gipson, *The British Empire Before the American Revolution*, vol. v (1942); Robert Newbold, *The Albany Congress and Plan of Union of 1754* (1955); D. M. Ellis et al., *A Short History of the State of New York* (1957). (J. T. Ho.)

ALBANY REGENCY, the name given to a coterie of politicians who from about 1820 to 1854 largely controlled the machinery of the Democratic party in the state of New York. Among the members of this unofficial body, whose headquarters were at Albany, were Martin Van Buren, W. L. Marcy, Silas Wright and John A. Dix.

See also **NEW YORK: History.**

ALBANY RIVER of northern Ontario, Can., rises in Lake St. Joseph about 50° 55' N. and 91° 25' W. and flows 610 mi. eastward into James bay, descending 1,218 ft. It is navigable for nearly half its length to Martin's falls. The lower 150 mi., lined by a strip of forest, leads through flat, swampy country. Principal tributaries are the Ogoki, running parallel to the upper Albany, and the Kenogami, whose many branches rise north of Lake Superior. There are four Hudson's Bay company trading posts on its banks, including Fort Albany (established 1684) near its mouth. Hydroelectric power is generated at Rat Rapids. (An. Kr.)

ALBATEGNIUS: see **BATTANI, AL-**

ALBATROSS, a large, powerful-flying sea bird, any one of 13 species related to the petrels (*q.v.*) and constituting the family Diomedidae in the order Procellariiformes. They have large heads, stout bodies, extremely long narrow wings and short or moderately long (*Phoebastria* species) tails. The bill, very stout and hooked, is covered with distinct horny plates; a short tube-like structure on either side of the upper beak houses the nostril. The legs are short and the feet webbed, with the hind toe (*hallux*) lacking or rudimentary. Plumage may be brown, black and white or almost wholly white; the sexes are alike in coloration except in the wandering albatross (*Diomedea exulans*).

Albatrosses inhabit southern oceans from about latitude 30° to Antarctica and are in northern Pacific waters to the Bering sea. Nine species are confined to colder parts of the southern hemisphere; one is equatorial but feeds mostly in temperate waters of the Humboldt current; and three belong to the North Pacific area.

When not breeding they range the high seas for months on end, seldom coming close enough to be seen from land. Masters of gliding flight, they are capable of remaining air-borne on virtually motionless wings for many hours and can breast the strongest winds with apparently effortless ease. Albatrosses customarily

accompany ships long distances to feed on discarded refuse. But, contrary to popular belief, the same birds are rarely in attendance for more than a few days.

There is evidence that some albatrosses may circumnavigate the southern hemisphere one or more times between breeding seasons. A wandering albatross shot on the coast of Chile in 1847 bore a vial in which there was a note documenting a journey of 3,150 mi. during a period of only 12 days. Of much interest also was the capture near Cape Horn in 1916 of an albatross banded three years earlier at Kerguelen Island in the southern Indian ocean—a distance of 6,000 mi.

The phenomenal homing instinct of these oceanic birds is suggested by experiments in which 18 nesting Laysan albatrosses (*D. immutabilis*) were removed from Midway Island and sent by plane to be released at distant parts of the North Pacific. All but four returned to their nests, one having covered 4,120 mi. in 32 days and another 3,200 mi. in just over 10 days, at an average speed of 317 mi. per day.

The name albatross is a corruption of the Spanish word *alcatraz*, meaning a pelican. Various vernacular names are also applied by sailors, especially mollymawk (or mollyhawk, mollymoke, etc.) for the smaller species and goney or gooney for the larger forms, the latter designations being English dialect words for a simpleton or booby.

Seamen formerly held albatrosses in considerable awe: they believed that ill luck followed the bird's destruction—a superstition that became the theme of Coleridge's *Rime of the Ancient Mariner*. Despite this superstition generations of seafaring men amused themselves on long voyages by capturing albatrosses on baited hooks trailed in the water. The sailors fashioned albatross skins into feather rugs, feet webs into tobacco pouches and the long hollow bones into pipestems. But far more serious than the random destruction of albatrosses by seamen were the organized raids on breeding colonies by professional plume hunters. Their systematic slaughtering of the birds greatly diminished the North Pacific species and virtually exterminated the short-tailed albatross (*D. albatrus*), once the commoner of the two species to reach the offshore waters of western North America.

Although accustomed to the ceaseless movements of the sea, captive albatrosses nevertheless show the classic symptoms of seasickness when brought aboard a ship, and at all times they have the disagreeable habit of discharging musky oily fluid from the mouth and nostrils when disturbed.

Albatrosses feed on fish, squid and other marine animals. They drink sea water with impunity, the excess salt being discharged from the body by means of enlarged nasal glands. All breed in colonies on remote oceanic islands, sometimes in steep and virtually inaccessible sites. With the exception of the Galapagos or waved albatross (*D. irrorata*), which lays its eggs in May and June (late fall in the southern hemisphere), the breeding season for both the northern and far southern species is September to February. Both before and after mating some albatrosses indulge in elaborately stylized courtship performances accompanied by

grunting, croaking and braying sounds. The nest may be either a hollow in the ground or a low mound of grass, moss and earth. The single white egg is extraordinarily large (equivalent to the volume of six chicken eggs), chalky and coarse in texture and sometimes speckled with brown. Incubation, shared by the parents, may in the larger species last 70 to 80 days. The young, fed by food regurgitated by the parents, soon become excessively fat. In some species the pure-white downy chicks remain in the nest eight months or longer, leaving only when finally deserted by their parents, who apparently breed at two-year intervals.

The largest and most famous species is the wandering albatross, which ranges over southern oceans and northward occasionally to the Tropic of Capricorn. Mainly white, but with black wing tips and mottled tail and wing coverts, it measures 44–53 in., weighs 15–18 lb. and may have a wingspread of 11½ ft.—the greatest of any present-day bird. Immature birds are brown, becoming more white with each molt. Other essentially white species are the somewhat smaller royal albatross (*D. epomophora*), found off the coasts of southern South America and southward to New Zealand; and the short-tailed albatross, the only white species in the North Pacific but now almost extinct. (E. R. BE.)

ALBAY, one of the six provinces of the Bikol region of southeastern Luzon, Republic of the Philippines. Pop. (1960) 515,961, a density of 518 per square mile. The province is an area of volcanic soils derived chiefly from the debris of Mt. Mayon (7,943 ft.), the most perfect known volcanic cone. Destructive eruptions of Mayon have occurred from time to time. The most notable eruption occurred in 1815 when approximately 1,200 inhabitants were killed and much of the nearby area was buried under several feet of ashes, cinders and lava.

Albay is basically an agricultural province with a fertile soil and abundant rainfall throughout the year. Rice fields dominate the lowland landscape; abaci (Manila hemp) and coconuts are produced on the rolling uplands and lower mountain slopes. Rice is the food crop and abaci the principal money crop; the larger abaca plantations are in the Lagao-Iriga area and on the lower slopes of Mt. Mayon. Albay is noted for the manufacture of abaci rugs, place mats, slippers, bags and sinamay cloth. Coconut groves are important chiefly on the hillsides north and south of the Legaspi plain and along the shores of Tabaco, Bacacay and Libog. Minor crops are corn, sweet potatoes, cassava, fruits, vegetables and pili nuts. Minerals include coal on Batan Island and copper on Rapu-Rapu Island and at Lagao.

The principal towns are Legaspi City (pop. [1960] 60,768), the capital and chief port (formerly a chartered city); Tabaco (pop. [1960] 46,689), a copra and hemp port; Guinobatan, the site of an abaci experiment station; Lagao; and Iriga. (AN. C.)

ALBEDO (from Lat. *albus*, "white"), "whiteness," a word used principally in astronomy for the measure of reflecting power. A body shining by reflected light is said to have albedo ½ if it reflects (or scatters outward) half the light incident on it. The albedo for visual light of the cloud-covered planets (Venus, Jupiter, Saturn, Uranus, Neptune) ranges from 0.56 to 0.73; of Earth 0.43; Mars 0.15; Moon 0.07. See also METEOROLOGY: *The Insolation Heating of the Earth's Surface and of the Atmosphere*.

In nuclear physics albedo refers to the reflective coefficient defined as the fraction of neutrons reflected back to the source. See DIFFUSION: *Importance and Application of Diffusion*.

ALBEMARLE, GEORGE MONCK, 1ST DUKE OF: see MONCK (MONCK), GEORGE, 1ST DUKE OF ALBEMARLE.

ALBEMARLE SOUND, a large sea-level bay on the Atlantic coast of North Carolina, U.S., separated from the ocean by a long, narrow barrier beach known as the Outer Banks. It was explored by Ralph Lane of Sir Walter Raleigh's Roanoke Island colony in 1585. The earliest permanent North Carolina settlements were made along its shores and tributaries in the 1660s. Originally called Bay of Albemarle or Albemarle river, it was named for George Monck, duke of Albemarle, one of the original lords proprietor of Carolina.

Albemarle sound extends in an east and west direction along the 36th parallel of north latitude for a total length of about 52 mi., and varies in width from 5 to 14 mi. At no spot deeper than 25

ft., it averages between 5 and 10 ft. in depth. It receives the water flow from a large mountainous area of western North Carolina and Virginia through the Chowan and Roanoke river systems at its western end, and discharges this flow at its southeastern end through the smaller Roanoke and Croatan sounds to Pamlico sound, and thence through Oregon, Hatteras and Ocracoke inlets to the sea.

A number of smaller bays, rivers and creeks branch off from Albemarle sound, draining the Dismal swamp on the north and other swamps and lakes on the south. It is connected with Chesapeake bay by the Dismal Swamp canal and the Albemarle and Chesapeake canal, and is crossed near its eastern end by the Intra-coastal waterway. (DA. ST.)

ALBÉNIZ, ISAAC (MANUEL FRANCISCO) (1860–1909), Spanish pianist and composer, one of the leaders of the Spanish nationalist school of musicians, was born at Camprodon, Catalonia, on May 29, 1860. He appeared as a piano prodigy at the age of four in Barcelona, and at seven in Paris; but being declared too young for admittance to the Conservatoire there he went to study in Madrid, only to run away when he was nine, and again later, to give concerts in various parts of Spain.* He embarked for Costa Rica, played throughout the United States and returned via England to become a pupil at the Leipzig conservatory at the age of 14. Returning to Spain without funds, he was fortunate in obtaining a royal grant enabling him to study in Brussels. In 1878 he fulfilled a long-held ambition by going to Budapest for lessons from Liszt, whose influence on his style was considerable. He toured extensively as a virtuoso, often playing small romantic pieces of his own which he composed with great facility, among them several with a Spanish flavour such as *Cdrdoba* and his famous *Tango*. He then settled down to teach in Barcelona and Madrid.

Only in 1890 did he take up composition more seriously when, having moved to Paris, he came under the influence of Vincent d'Indy, Paul Dukas and other French musicians. In the following year the English banker Francis Burdett Money-Coutts offered him a handsome allowance on condition that Albéniz set to music various opera librettos of his. After the production in London of the comic opera *The Magic Opal*, libretto by Arthur Law (1893), Albéniz wrote the three-act *Henry Clifford* (Barcelona, 1895), but neither this nor *Merlin*, the first of a projected Arthurian trilogy, proved very congenial to him, and it was not until the one-act *Pepita Jiménez* (Barcelona, 1896) that he achieved a real stage success.

He developed Bright's disease (eventually to prove fatal), and after 1900 spent most of his time in Spain, where he worked at the Arthurian opera cycle and continued to write copiously for the piano. It is on his music for that instrument that his fame chiefly rests, particularly on *Iberia*, a collection of 12 scenes of Spanish (mainly Andalusian) life, written during 1906–09, coloured by the rhythms and harmonies of Spanish popular music, but highly virtuosic and complex in texture. He died at Cambo-les-Bains, Basses-Pyrénées, on May 18, 1909.

ALBERDI, JUAN BAUTISTA (1810–1884), perhaps the most influential of 19th-century Argentine political thinkers, was born in the province of Tucumán on Aug. 29, 1810. He joined the liberal opponents of the dictator Juan Manuel de Rosas (*q.v.*) and in 1838 went into exile in Uruguay, where he took a law degree. In Uruguay, in Chile and in Europe, Alberdi studied and wrote voluminously about the reactionary condition of his country. After the defeat of Rosas (1852), Alberdi distilled his ideas into a book entitled *Bases and Starting Points for the Political Organization of the Argentine Republic*, which emphasized the need for a central, federalized government and urged immigration and foreign investment. His ideas influenced the constituent assembly which in 1853 wrote Argentina's enduring constitution. Certainly his writings helped to guide his countrymen toward a liberal era which, before Alberdi's death and in keeping with his motto "to govern is to populate," saw a vast expansion of Argentina's econ-

omy and population.

Appointed by Pres. Justo José de Urquiza to represent Argentina in Europe in the 1850s, Alberdi was not in the favour of Pres. Bartolomé Mitre and his successors after 1861. He spent his last years in semiexile in Europe, continuing his extensive and significant writing until his lonely death in Paris, Jan. 18, 1884.

(T. F. McG.)

ALBERONI, GIULIO (1664–1752), Italian cardinal and statesman, who as *de facto* prime minister of Spain from 1716 to 1719 played a major part in bringing about the revival of Spain after the War of the Spanish Succession, was born at Piacenza on March 21, 1664, the son of a gardener. Educated by the Jesuits, he took holy orders and by 1698 had been appointed to a canonry at Parma. In 1702 he was sent on a diplomatic mission from the Parmesan government to the duc de Vendôme, the commander of the French forces in Italy during the War of the Spanish Succession. Subsequently he accompanied Vendôme to France in 1706 and to Spain in 1711, acting as his secretary but remaining an agent of the duke of Parma. After Vendôme's death in 1712, Alberoni was ordered to remain at Madrid and in April 1713 he was made official Parmesan representative there. In this position he was responsible for negotiating, through the *princesse des Ursins* (*q.v.*), the marriage of Philip V of Spain with the duke of Parma's niece and step-daughter, Elisabetta Farnese. Under the protection of the new queen, Alberoni's influence at the Spanish court increased steadily during 1715 and by the beginning of 1716 he was exercising the powers of a prime minister.

Alberoni's domestic policy was largely a continuation of the administrative centralization and fiscal reform begun by Jean Orry. He also encouraged the establishment of industry by tariff reform and by the importation of foreign craftsmen. His greatest service to Spain, however, was the destruction of the power of the royal councils (which, though originally the chief executors of royal policy, had, by this time, become the centres of aristocratic opposition to reform), which he brought about by a series of decrees issued in Jan. 1717. His foreign policy was motivated by a desire to drive the Austrians from Italy and to safeguard Spanish trade with its American colonies. This policy was accompanied by the successful rebuilding of the Spanish navy, but the credit for this properly belongs to Alberoni's principal lieutenant, José Patiño. The Spanish military expeditions to Sardinia (1717) and Sicily (1718), which led to war with the quadruple alliance of Great Britain, France, Austria and the Netherlands, were regarded by Alberoni as premature and only resulted from a policy imposed on him by the queen. Nevertheless, the failure of the Spanish forces during the Franco-British invasion of Spain led to his banishment on Dec. 5, 1719.

Alberoni, who had been made a cardinal in 1717, went from Spain to Italy, where for a time he was forced to go into hiding. But he took part in the conclave which elected Pope Innocent XIII in 1721 and was later acquitted by a papal inquiry into the charges made against him by Spain. He became legate of Ravenna in 1735 and of Bologna in 1740. He died at Piacenza on June 16, 1752.

ALBERT, SAINT (called THE GREAT): see ALBERTUS MAGNUS, SAINT.

ALBERT I (1875–1934), king of the Belgians, was born in Brussels on April 8, 1875, the younger son of Leopold II's brother Philip, count of Flanders (1837–1905), and Princess Marie of Hohenzollern. The premature death of Prince Leopold, only son of Leopold II, on Jan. 22, 1869, made Albert's brother Baudouin (born 1869) heir presumptive to the Belgian crown, but on Baudouin's death on Jan. 23, 1891, Albert became next in the line of succession. He received his training in military matters at the École Militaire and served as an officer to the grenadier regiment. On Oct. 2, 1900, he married in Munich Elisabeth (b. July 25, 1876), second daughter of Charles Theodore, duke of Bavaria. Three children were born of this marriage: Leopold, duke of Brabant (the future Leopold III), 1901; Charles, count of Flanders, 1903; and Marie José, 1906.

On Dec. 23, 1909, Albert took the oath of fidelity to the Belgian constitution and became king under the name of Albert I. He was a patron of art and literature and occupied himself actively with the improvement of conditions in his country, interesting himself in various social and legal reforms and especially in the organization of the army. In May 1913 he gave his assent to a law designed to secure for Belgium an army of 350,000 men. On July 31, 1914, when World War I was breaking out, Albert wrote to the German emperor William II, reminding him of the respect due to Belgian neutrality. Germany replied by the ultimatum of Aug. 2, which was rejected. Hostilities then began. The king took command of the troops and established his headquarters first at Louvain and afterward in Antwerp. He directed in person the first advance from Antwerp toward Louvain with a view to relieving the French and British forces engaged with the German right wing. After the fall of Antwerp, the king and queen accompanied the retreating army until it came to a halt on the Yser river. From Oct. 17 to 24 the Belgian army, under the king's command, withstood the German invasion without any assistance. During the whole of the war he remained with his troops, exposed to the risk of enemy bombardment. He made continual visits to the front-line trenches from his headquarters at La Panne and even surveyed the enemy's lines from an aircraft.

When the general Allied offensive of Oct. 1918 was undertaken, Albert was appointed commander of the northern army group, consisting of both Belgians and French, which captured the forest of Houthulst, Thourout, Ostend and Bruges and forced the passage of the Lys. After the armistice the king asked the Allies for the abolition of Belgian neutrality and of the treaties of 1839, which had left Belgium open to invasion.

Albert also interested himself in the Belgian Congo and presided in person over the colonial congresses of 1920 and 1926. On Feb. 17, 1934, while rock climbing at Marche-les-Dames, near Namur, he fell and was killed.

BIBLIOGRAPHY.—P. Nothomb, *Le Roi Albert* (1934); E. Cammaerts, *Albert of Belgium* (1935); Gen. R. van Overstraeten (ed.), *The War Diaries of Albert of Belgium* (1954). (J. E. D.)

ALBERT I (c. 1255–1308), German king from 1298 to 1308, was the eldest son of King Rudolf I, of the house of Habsburg. He was invested with the duchies of Austria and Styria in 1282. After Rudolf's death (1291), the electors, determined to prevent the German crown from becoming a hereditary possession of the powerful Habsburgs, checked Albert's aspirations by choosing Adolf (*q.v.*) of Nassau as German king. Albert, however, drew the electors into an alliance (1297), engineered the deposition of Adolf and defeated him on July 2, 1298, at Gollheim. His election, proclaimed at Mainz before the battle, was repeated at Frankfurt, on July 27, and he was crowned at Aachen on Aug. 24.

Albert, after signing an alliance with Philip IV of France in 1299, claimed possession of Holland, Zealand and Frisia as vacant fiefs. This effort to obtain control of the mouths of the Rhine was opposed by the four Rhenish electors, who agreed at Heimbach on Oct. 14, 1300, to procure the eventual deposition of Albert. Albert, aided by the cities of the Rhineland, crushed the coalition in a series of savage campaigns between 1300 and 1302. He obtained confirmation of his election from Pope Boniface VIII on April 30, 1303, swore an oath of obedience to the pope and promised that none of his sons should be elected German king without papal consent. His attempt to place his son Rudolf on the vacant throne of Bohemia in 1306 was only momentarily successful, and his claim to Thuringia and Meissen, inherited from Adolf of Nassau, was checked by a defeat near Lucka in 1307. On May 1, 1308 Albert was assassinated in Brugg on the Reuss by his nephew John of Swabia, later called the "Parricide," from whom the king had unjustly withheld his inheritance.

See A. Hessel, *Jahrbücher des deutschen Reichs unter König Albrecht I von Habsburg* (1931). (C. C. BA.)

ALBERT II (1397–1439), German king, king also of Hungary and Bohemia from 1438 to 1439 and, as Albert V, duke of Austria, was born in Aug. 1397, the son of Albert IV, duke of Austria. His father's early death was followed by a long regency (1404–11), but after this the young Albert began to show his capacities; *e.g.*,

in the economic and military organization of his lands (there were Hussite invasions until 1434) and in his acceptance, in 1418, of full authority from Pope Martin V for the reform of the Austrian monasteries. After the death of the German king Sigismund (whose daughter Elizabeth he had married), Albert was in 1438 elected king of Hungary (Jan. 1), German king (March 18) and king of Bohemia (June 29). As German king he advocated a policy of neutrality for the princes of the empire with regard to the affairs of the Council of Basel and the crisis of the papacy. His death from dysentery, on Oct. 27, 1439, in Neszmély near Esztergom in Hungary, on his way home from a campaign against the Turks; cut short his plans for reform of the empire. His posthumous son was László V of Hungary. The Czech chronicler Bartosek calls him "good though German, bold and merciful."

See Wilhelm Wostry, "König Albrecht II," *Prager Studien aus dem Gebiet der Geschichtswissenschaft*, 12 and 15 (1906-07). (A. L.H.)

ALBERT (1828-1902), king of Saxony, was born in Dresden on April 23, 1828, the eldest son of Prince John, who succeeded to the throne in 1854. Commissioned as lieutenant in the artillery in 1843, Albert was at Bonn university in 1847-48. He served as a captain in the Schleswig-Holstein campaign of 1849 against the Danes. He married Caroline, granddaughter of Gustavus IV of Sweden, in 1853. In 1857 he was made general of infantry. He became a member of the upper chamber of the Saxon parliament in 1862. In the Seven Weeks' War of 1866 he commanded the Saxon army, effecting an orderly retreat when the Prussians invaded Saxony and holding his position with tenacity in the defeat at Königgratz (Sadowa). Albert had always favoured the Prussian connection and on Saxony's entry into the North German federation he became commander of the 12th army corps, formerly the Saxon army.

In the Franco-German War of 1870-71, Albert's corps fought at Gravelotte and with the Prussian guard, carried the attack on St. Privat, the conclusive action of the battle. In the march on Paris he commanded the 4th army, consisting of Prussian and Saxon troops, and played a vital role in the operations preceding the battle of Sedan. In the battle itself he conducted the envelopment of the French on the east and north. After the armistice of Jan. 28, 1871, he commanded the army of occupation from March 18 to June 8. On his return to Saxony he was made inspector general of the German army by the emperor (June 15) and field marshal by King John of Saxony (July 11).

Succeeding to the Saxon throne on Oct. 29, 1873, Albert concerned himself mainly with military affairs, but also approved the administrative reforms of his reign. Decrees of 1873 regularized local administration and education and instituted school inspectors, and in 1878 fiscal reforms based on a progressive income tax were introduced. Throughout the reign industrialization increased rapidly and the railways were nationalized in 1876.

A Catholic ruler of a Protestant country, Albert remained popular with his subjects. He died in Schloss Sibyllenort, near Ōls (Olesnica) in Silesia, on June 19, 1902, leaving no children, and was succeeded by his brother George.

ALBERT (FRIEDRICH RUDOLF ALBRECHT), ARCHDUKE (1817-1895), Austrian field marshal, the son of the archduke Charles (Karl Friedrich), was one of the last of the colourful princeling generals who had commanded continental armies for so long but who were by his time already outmoded. Born in Vienna on Aug. 3, 1817, he was educated privately under the strict supervision of his father: before entering the Austrian army as a colonel of infantry in 1837. In 1839 he transferred to the cavalry. Six years later he became military governor of Austria. About this time he became a pupil of Radetzky in the art of war. This for the time being removed him from the ceremonial to the more practical and sterner side of soldiering. As a result of this association he fought as a volunteer under Radetzky throughout the Italian campaign of 1848 and was present at the action at Pastrengo and at the battles of Santa Lucia and Custoza. He then greatly distinguished himself as a divisional commander in the 2nd corps at Novara.

In 1850 he was promoted to the rank of general of cavalry and from 1851 to 1860 he was military governor of Hungary. Soon

after the termination of this appointment he was made commandant in Vicenza, Venetia. and in 1863 he became a field marshal. When war became imminent early in 1866 the archduke took command of the field army in Italy. Although in a secondary theatre of operations, Albert soon showed his capacity as a commander by winning a decisive victory at Custoza on June 23, 1866. The fighting lasted for only eight days, but the defeat of the Italian army in this battle brought about its disintegration and enabled Albert to send most of his troops to Bohemia where the Austrians, hard pressed by the Prussians, were falling back on Vienna. On July 10, 1866 the archduke assumed command of the forces defending the capital, but peace intervened and his plans were never tested. (See SEVEN WEEKS' WAR.)

With the end of hostilities he became what was virtually inspector general of the Austrian army. By this time the advent of railways had made it possible to support much larger field armies and Albert's main task was to reorganize the Austrian forces on a short-service national basis. By conscripting men for a short period a large reserve was created, which could be mobilized quickly in the event of war.

The archduke Albert lived at a time of transition in military affairs. Railways and the general staff system had greatly increased the size of armies and the speed and efficiency with which they could be assembled and controlled. In the tactical field fire power had been vastly increased by the introduction of new weapons. Moreover, there was now no place for the princely sort of commander who, in Prussia, was on the point of being superseded by the dedicated and highly trained general staff officer, typified by the elder Moltke. The Austrians had lagged behind the Prussians in these new developments, with the result that in the Seven Weeks' War Austria was defeated in a very short time.

In the latter years of his life Albert edited the military works of his father and also wrote a few books of his own on military subjects. He died in Arco, Tyrol, on Feb. 18, 1895.

See Carl von Duncker, F. M. *Erzherzog Albrecht* (1897).

(C. N. B.)

ALBERT OF SAXE-COBURG-GOTHA (1819-1861), the PRINCE CONSORT of Queen Victoria of Great Britain, was born in Rosenau, near Coburg, Ger., on Aug. 26, 1819, and was baptized as Francis Charles Augustus Albert Emmanuel. He was the second son of Ernest, duke of Saxe-Coburg-Gotha, by Princess Louise of Saxe-Gotha-Altenburg (d. 1831), from whom the duke was divorced in 1826. Albert's father's sister married the duke of Kent, whose daughter Victoria was born in the same year as her first cousin. He and his brother Ernest were educated privately, in Brussels, and at the University of Bonn, and in 1836 accompanied their father to England on a visit to the widowed duchess of Kent. Marriage between Victoria and Albert was the cherished plan of their uncle Leopold I of Belgium, but was opposed by William IV, who favoured Prince Alexander of Orange as Victoria's husband. Albert himself was "gloomy" of the outcome; nevertheless, after wintering in Italy with his mentor, Baron von Stockmar (*q.v.*), Leopold's former adviser, he returned to England in Oct. 1839. Betrothal swiftly followed. His future, he realized, was "high and brilliant but also plentifully strewn with thorns." Victoria and Albert were married on Feb. 10, 1840.

Politically, the role of the queen's husband was anomalous; but he received a "key to the secret boxes" during her first pregnancy (1840) and thereafter was effectively Victoria's private secretary and confidential adviser. The fall of the Melbourne government (1841) made way for Sir Robert Peel, with whom the prince had much in common: both were men of serious temper, remarkable ability and industry, happiest in their domestic circle and least at their ease with the English aristocracy. Albert thus became, in Russell's later phrase, "an informal but potent member of all cabinets." With the retirement too of the Baroness Lehzen, Victoria's former governess, who had come to rule the royal household, to Hanover in 1842 he had gained effective control of, and by 1844 had completely reorganized, the household. Further, he busied himself with the improvement of the queen's properties. He made the queen intensely happy, steadied her self-willed judgment and

made her almost as hard-working as he was himself. A handsome, accomplished and serious-minded man, he was unable, however, to persuade many of her subjects to like him. The aristocracy still looked askance at the palace, perhaps the more readily for its new and severely domesticated moral tone; the prince, although he both shot and rode well, was too intellectual, too professorial, for the English gentleman, nor might every minister welcome the degree of consultation which his vigilance enjoined. "He had not the knack," said Walter Bagehot, "of dropping seed without appearing to sow it."

His public life may hardly be separated from that of the queen herself (*see* VICTORIA). Prejudice against him was never fully dissipated in his lifetime; if his understanding love and self-sacrificing labour were a benison to the queen, the value of his counsel, based on wide knowledge, pertinacity and caution, might scarcely be known beyond a very small circle. His especial political preoccupation was to maintain (it was wrongly believed that his aim was to extend) the influence of the crown as an increasingly nonpartisan agency in domestic government; and in foreign affairs to ascertain that the private intelligence available to a ruling family with a growing body of relatives throughout Europe was made available to, and taken into consideration by, a foreign office not eager, especially in Lord Palmerston's day, for this advantage. In 1846-47 the royal pair encountered a wave of unpopularity, in the main directed at the prince; on the eve of the Crimean War there was a strong rumour that he had been imprisoned in the Tower as a Russian (some said an Austrian) agent; and in 1854 there were newspaper attacks upon "the influence of the Crown." In fact, "under his care the Crown played the part reserved for it under a constitutional monarchy and played it well" (Gavin B. Henderson, "The Influence of the Crown," *Crimean War Diplomacy* [Jackson Son & Co. (Booksellers) Ltd., Glasgow, 1947]). His was an increasingly valuable second opinion. In 1856, for example, he showed the foreign secretary that his proposed dispatch to Prussia might suggest an ultimatum and Clarendon gratefully altered it; again, in 1861 it was Albert's characteristic changes (just before he died) in the dispatch addressed by Lord Russell to the U.S. government over the seizure of the confederate envoys on the English steamer "Trent" which opened up the possibility of the peaceful settlement which eventuated. Growing daily in his lifetime, perhaps his most important political influence came after it: what she imagined would have been his judgment remained his widow's ultimate criterion.

In critical and foreign surroundings he found his greatest satisfaction, outside his family, in encouragement of the arts (he was himself an erudite and accomplished musician) and in the application of science to manufacturing industry. In the face of fierce and sustained prejudice, not unmixed with personal abuse, he was the prime mover in the Great exhibition of 1851. His detailed perseverance as president was rewarded by success, the surplus realized going to endow the South Kensington (afterward renamed Victoria and Albert) museum. Similar activities found in him ready and learned support, and provided an opportunity to deliver speeches characterized by a firm grasp of English, of information and of purpose. To the education of his family and the cause of army reform he applied the same German thoroughness. In neither was he especially successful, but the domestic felicity of the royal family became proverbial and played its part in guaranteeing the continuity of the English monarchy, a regime by no means so assured on the queen's accession. In 1856 the queen drew attention to his equivocal position; he had received special precedence by letters patent but still held no titular rank by law. Even so, it was still thought wiser to avoid parliamentary (it did not offset newspaper) controversy and when he became prince consort in 1857 it was also by letters patent.

In 1861 he was busy with the projected international exhibition when he was seized with what proved to be typhoid fever and, congestion of the lungs supervening, he died at Windsor castle on Dec. 14. He had persistently lived on "the treadmill of never-ending business" and he did not "cling to life." The queen was overwhelmed and the universal sympathy was not unmixed, perhaps, with compunction for earlier want of appreciation.

Memorials were erected throughout the country, most notably the Albert memorial (1863-72) and the Royal Albert hall (1867-71) in London. His name was also commemorated in the queen's institution of the order of Victoria and Albert (1862) and of the Albert medal (1866) for gallantry in saving life.

BIBLIOGRAPHY.—By the queen's authority, her secretary C. Grey compiled *The Early Years of the Prince Consort* (1867), and *The Life and Letters of the Prince Consort*, 5 vol. (1877-80) was similarly edited by Sir Theodore Martin. His *Principal Speeches and Addresses*, with an introduction by Sir Arthur Helps, was also published (1862). *See* also C. F. von Stöckmar, *Memoirs* (1872); *Letters of Queen Victoria*, 1st series (1907); G. B. Henderson, *Crimean War Diplomacy* (1917); Roger Fulford, *The Prince Consort* (1949). (E. T. Ws.)

ALBERT (1490-1568), last grand master of the Teutonic Order and first duke of Prussia, a-as born in Ansbach on May 16, 1490, the third son of Frederick of Hohenzollern, prince of Ansbach and Bayreuth, and Sophia, daughter of Casimir IV, king of Poland. On Jan. 3, 1511 Albert was made grand master of the Teutonic Order, which had held East Prussia under Polish suzerainty since 1466. In 1519 Albert was at war with his Polish suzerain, and though a truce was made in 1521 the dispute, which was referred to the Holy Roman emperor, remained unsettled. In addition there was the antagonism between the Teutonic knights and the local nobility. To overcome these difficulties, Albert decided in 1525 to follow Luther's advice given at Wittenberg two years earlier, to dissolve the order in Prussia and to transform the territory into a dukedom under Polish suzerainty. The agreement of Sigismund I of Poland was obtained in April 1525 at Cracow.

The new duke proceeded to further Protestantism in East Prussia. In 1530 the emperor Charles V ordered the return of Prussia to the Teutonic Order, but the knights were unable to recover the duchy. Albert was placed under the ban of the empire in 1531, but the ban was never enforced. To counteract the isolation brought about by his breaking away from the order's extensive organization, he was fairly active as a member of the leagues which German princes formed in opposition to Charles V's imperial policy; moreover, when Sweden and Denmark had become Protestant, he attempted to co-ordinate his politics with the actions of these Baltic powers. In internal affairs he secularized the centralized administration established by the order, but he had to concede to the land-owning nobility, now a uniform body, a definite influence on the government of the land. The situation of the peasants deteriorated in his territory, as it did everywhere east of the Elbe. In 1544, in spite of some opposition, he founded a university at Königsberg, where he appointed his friend Osiander to a professorship in 1549, although he lacked the formal qualification of a theological degree. In addition Osiander's divergence from the doctrine of justification by faith, current in Wittenberg, involved him in a violent quarrel with Melancthon, who had adherents in Königsberg, and these theological disputes soon led to an uproar in the town. The duke strenuously supported Osiander, and the area of the quarrel soon broadened. After Osiander's death in 1552, a preacher named Johann Funck, with an adventurer named Paul Scalich, exercised great influence over Albert. The turmoil caused by these disputes compelled Albert to consent to a condemnation of Osiander's teaching, and in 1566 the estates appealed to Sigismund II, king of Poland, who sent a commission to Königsberg. Scalich fled, and Funck was executed; the question of the regency was settled and a strict form of Lutheranism was declared binding on all teachers and preachers. A disappointed man, Albert died in Tapiau in East Prussia on March 20, 1568.

ALBERT III (ANIMOSUS OF THE COURAGEOUS), DUKE OF SAXONY (1443-1500), the founder of the Albertine branch of the house of Wettin (*q.v.*), was born in Grimma on July 31, 1443, the younger son of Frederick II, elector of Saxony. In July 1455 Albert and his brother Ernest were abducted by Kunz von Kaufungen, a member of the lesser nobility, but on the way to Bohemia were rescued by workmen and were restored to their father. This

incident, known as the *Prinzenraub*, was typical of the relations between the orders of society in 15th-century Germany and became famous in legend and literature. On their father's death (Sept. 1464) Albert and his brother became joint rulers of his territories.

Albert had married Sidonia, daughter of George of Podebrady (*see* PODEBRAD, GEORGE OF), in 1464, but his candidature for the Bohemian throne in 1471 was unsuccessful. In 1472, however, he purchased the lordship of Sagan in Silesia. Firmly loyal to the Habsburgs, Albert was marshal of the Holy Roman empire under Frederick III and imperial governor of the Netherlands from 1488 to 1493. He was made hereditary governor of Friesland in 1498.

In the Wettin lands, Albert centralized the financial administration and established a central high court at Leipzig in 1482, but it was his initiative which brought about the Leipzig partition of 1485. This ended the dual reign of Albert and Ernest and divided the Wettin lands between them. The partition, which resulted in the lasting separation of the Wettins into Ernestine and Albertine branches (*see* SAXONY), was not meant to be permanent and so was not based on geographical realities, though Albert's personal authority in his lands on the middle Elbe was strong enough. He died in Emden in lower Saxony on Sept. 2, 1500. In his will he attempted to establish primogeniture in his lands.

(HE. K.)

ALBERT I THE BEAR (c. 1100–1170), margrave of Brandenburg, was one of the main leaders of 12th-century German expansion in eastern Europe. The only son of the "Ascanian" Otto the Rich, count of Ballenstedt, and Eilika, daughter of Magnus Billung, duke of Saxony, he inherited the Saxon estates of his father between the Harz mountains and the middle reaches of the Elbe in 1123 and, on his mother's death in 1142, succeeded to possessions of the Billung dynasty in central Germany. The main inheritance, however, including the Saxon dukedom, went to the Welfs. Although Albert used every opportunity to attempt a reversal of this decision and to obtain a foothold in northern Germany near the seaboard and had for some time the support of Conrad III, the first German king of the Hohenstaufen dynasty, his Welf counterparts Henry the Proud and Henry the Lion prevailed during his lifetime. Albert's greatest achievement was in the east. After his services in Italy (1132) had been rewarded in 1134 by the investiture of the north mark, east of the junction of the Elbe and Havel rivers, he spent three years campaigning against the Wends and, by an arrangement made with Pribislav, prince of the Haveland, secured that district when the prince died in 1150.

Taking the title margrave of Brandenburg, he pressed the warfare against the Wends, extended the area of his mark and increased its population and prosperity by introducing Frisian and Saxon settlers. In this work of colonization based on forest clearance and drainage of swamps he had the help of the Premonstratensians and Cistercians; missionary work among the Slav population, which included the revival of the bishoprics of Havelberg and Brandenburg, was the other aspect of his policy.

A loyal supporter of the Italian policy of Frederick I Barbarossa, Albert may have been made archchamberlain of the empire, an office which afterward gave the margraves of Brandenburg the rights of an elector. He died on Nov. 13, 1170. His surname "the Bear" can be traced back to Helmold, the contemporary historian of the German expansion in the north.

See A. Krabbo, "Albrecht der Bar," *Forschungen zur Brandenburg-Preussischen Geschichte*, vol. 19, part 2 (1906); A. Jaster, *Geschichte der askanischen Kolonisation in Brandenburg* (1934). (H. Lz.)

ALBERT II ALCIBIADES (1522–1557), margrave of Brandenburg-Kulmbach, was born in Ansbach on March 28, 1522, a member of the Franconian branch of the Hohenzollern family. His father, Casimir of Brandenburg, died in 1527 and Albert was declared of age by the emperor Charles V in 1541. His restless nature marked him as a leader of mercenaries; and, having collected a small band of soldiers, he assisted the emperor in his war with France in 1543. Sharing in the attack on the Saxon electorate, Albert was taken prisoner at Rochlitz in March 1547 by John Frederick, elector of Saxony, but was released as a result of the emperor's victory at Mühlberg in April. He then followed the

fortunes of his friend Maurice, the new elector of Saxony, deserted Charles and joined the league which proposed to overthrow the emperor by an alliance with Henry II of France in 1552. Having extorted a large sum of money from the burghers of Nürnberg, he quarreled with Henry and offered his services to the emperor, Charles, who was attempting to reconquer Metz from France, assented to Albert's demands and ratified his possession of the lands taken from the bishops of Würzburg and Bamberg. But now Protestant and Catholic princes allied against Albert under the leadership of Maurice, whose forces defeated him at Sievershausen (July 9, 1553), though Maurice himself was killed. Outlawed by the imperial chamber at Speyer (Dec. 1, 1553), Albert had to seek asylum in France (June 1554). He returned in 1556 with plans of revenge, but died on Jan. 8, 1557, at the court of his brother-in-law, the margrave of Baden.

See O. Kneitz, "Albrecht Alcibiades . . .," *Die Plassenburg Blätter für Heimatkunde und Kulturpflege* (1951). (H. Lz.)

ALBERT III ACHILLES (1414–1486), elector of Brandenburg from 1470 to 1486, surnamed Achilles because of his relentless energy, physical strength and bravery. Combining political shrewdness and enthusiasm for tournaments and chivalrous display, he was a German representative of a type most fully developed at the Burgundian court. He was born in Tangermünde on Nov. 24, 1414, the third son of Frederick I of Hohenzollern, elector of Brandenburg. On the division of territory which followed his father's death in 1440 he received the lands around Ansbach; on the death of his brother John in 1464 he inherited Bayreuth. During this period the city of Nürnberg remained a dangerous antagonist, so that Albert was never a friend of towns and their citizens. On Dec. 20, 1470, on the abdication of his brother Frederick II, he became elector of Brandenburg.

Family aggrandizement was his main object and the development of a coherent administration his main achievement. To provide their sons with appropriate positions and income was an important motive in the policy of territorial princes of the time, but Albert saw that division of the inheritance weakened a family's power. He therefore devised the famous *Dispositio Achillea* of Feb. 24, 1473, which decreed that the mark of Brandenburg should descend intact to the eldest son; two younger sons were to receive the Franconian possessions of the Hohenzollerns which at this time yielded a larger income. By this regulation Albert wished to emphasize the duty of his descendants to preserve the dynasty's inheritance intact. He did not establish the principle of primogeniture, but his disposition started a tendency in this direction. Albert was one of a small class of German magnates of the late 15th century who began to take seriously the administrative needs of their territories. He combated the banditry of the lesser nobles with effective legislation, paid his officials and regulated their methods. Under him an accounting system for the ducal administration was instituted. The separation from Franconia resulting from the *Dispositio Achillea* narrowed down the political activities of his successors in Brandenburg, especially in imperial affairs. Albert died in Frankfurt am Main on March 11, 1486.

Kauter, *Markgraf Albrecht Achilles*, vol. i (1911). (H. Lz.)

ALBERT (1490–1545), elector and archbishop of Mainz, attacked by Martin Luther over the sale of indulgences, was born on June 28, 1490, the younger son of John Cicero, elector of Brandenburg. He became archbishop of Magdeburg and administrator of the bishopric of Halberstadt in 1513 and archbishop and elector of Mainz the next year.

This pluralistic holding of episcopal dignities was contrary to canon law and Albert had to contribute a considerable sum toward the rebuilding of St. Peter's in Rome in order to induce Pope Leo X to overlook the irregularity. The money was borrowed from the banking house of Fugger, and to repay it Albert obtained permission from the pope to conduct the sale of a special plenary indulgence in the dioceses of Magdeburg and Halberstadt, half the

proceeds of which were to go to him and half to the pope. To sell the indulgence Albert procured the services of the Dominican Johann Tetzel (*q.v.*), whose activities provoked Luther to publish his 95 theses in 1517, attacking Albert and through him the system of indulgences. In 1518 Albert was created cardinal.

During the imperial election of 1519 his vote was eagerly courted and he was well paid for the vote that he eventually cast for Charles V. At one time his well-known liberal outlook suggested he might support the Reformation; but after the peasants' war of 1525 he strenuously opposed it, though he was compelled to grant religious liberty to the inhabitants of Magdeburg in exchange for 500,000 florins, a sum he used to pay off his debts. During his later years he became less tolerant toward the Protestants, and by inviting the Jesuits to Mainz he helped to foster the Counter-Reformation in Germany.

Albert was a generous patron of art and learning and his large and liberal ideas won him the friendship of men like Ulrich von Hutten and Erasmus. He founded the Stiftskirche at Halle in 1528 and adorned it and the cathedral at Mainz in sumptuous fashion. His motto was *Domine, dilexi decorum domus tuae*, from Ps. xxvi, 8 (in the Authorized Version: "Lord, I have loved the habitation of thy house, and the place where thine honour dwelleth"). He died in Aschaffenburg on Sept. 24, 1545.

ALBERT OF AIX (fl. c. 1130), canon and *custos* ("keeper") of the church of Aix-la-Chapelle (Aachen), author of a history of the first crusade and of the early years of the Latin kingdom of Jerusalem (to 1121), in 12 books. This work, entitled *Historia Hierosolymitanae expeditionis* or *Chronicon Hierosolymitanum de bello sacro*, was used by William of Tyre for the first part of his history of the kingdom of Jerusalem and was very widely read in the middle ages. Albert was not an eyewitness, but gathered his information from diverse sources. Writing at a time when the history of the crusade was beginning to be surrounded by legends, c. 1125 or later, he accepted some of these, especially those concerning Peter the Hermit. He was also particularly interested in the crusaders from lower Lotharingia (Lorraine) and the family of Godfrey of Bouillon. His work is, nevertheless, one of the best sources for the history of the crusade. First printed in 1584, the text was reprinted in the *Recueil des historiens des croisades*, vol. iv (1879).

See S. Runciman, *History of the Crusades*, vol. ii (1952) and works there cited. (J. B. R.)

ALBERT OF SAXONY (1316?–1390?), German scholastic philosopher especially remarkable for his investigations into physics, was born at Helmstedt in lower Saxony. He studied at Prague and then at Paris university, where he was a master of arts from 1351 to 1362 and rector in 1353. Most probably he is to be identified with the Albert of Ricmestorp or Riickmersdorf who was rector of Vienna university in 1365 and bishop of Halberstadt from 1366 until his death there in 1390. Albert based his logic on William Ockham, his physical theory on Jean Buridan, his mathematics on Thomas Bradwardine and his ethics on Walter Burley (rejecting Buridan's psychological determinism) and was at first respected more for clarity and exactness in exposition than for originality. The later scholastic logicians adopted many of the terminological distinctions first found in his works (see for instance A PRIORI AND A POSTERIORI), and he examined and classified 254 *sophismata* or logical paradoxes. In physics, he wrote at length on place, space and time, on the impossibility of a plurality of worlds and, in great detail, on the movement of bodies (Leonardo da Vinci seems to have been indebted to him on this subject). Albert gave particular attention to the problem of gravity, being perhaps the first thinker to distinguish the centre of gravity from the geometrical centre, and to that of the velocity of falling bodies, appreciating that the question was whether velocity was proportional to time or to space. He can also be regarded as a precursor of aerostatics, as he maintained that a light balloon would rise and remain sus-

pending in the air if a particle of fire were enclosed in it. Finally, his search for mathematical formulas to express laws of nature foreshadowed the usage of modern physics.

ALBERT L'OUVRIER ("the Worker"; real name ALBERT ALEXANDRE MARTIN) (1815–1895), the first industrial workingman to enter a government in France, was born in Bury, Oise, on April 27, 1815. A convinced socialist and republican, he played an active part in the Revolution of 1848 and was made a member of the provisional government, his name appearing on all documents as "Albert l'Ouvrier." He was subsequently appointed vice-president of the Commission du Luxembourg (an assembly of workers' delegates) under Louis Blanc (*q.v.*). Sentenced to life imprisonment for his part in the uprising of May 15, 1848, Albert was amnestied in 1859. He died in Mello, Oise, on May 28, 1895.

ALBERT, HEINRICH (1604–1651), German composer of a famous and popular collection of songs, was born in Lobenstein, Saxony, July 8, 1604. He was a cousin of Heinrich Schütz, with whom he studied composition at Dresden before taking a course in law at Leipzig, where his musical studies were encouraged by J. H. Schein.

In 1627 Albert set out for Königsberg to pursue a musical career; after being taken prisoner by a Swedish army he arrived in 1628. He was appointed cathedral organist (1631) and there published works from 1632. He died in Königsberg, Oct. 6, 1651.

Albert composed numerous festival pieces for the Brandenburg princes but is best known for his *Arien*, published by himself between 1638 and 1651. These settings of sacred and secular texts form the most characteristically German song collection of the 17th century. He also has a place in the early history of German opera; the scores have not survived, but two pieces from *Cleomedes* occur among the *Arien*. (C. P. Co.)

ALBERT, LAKE, is situated in equatorial Africa astride the boundary between Uganda and the Republic of the (former Belgian) Congo. It was named after Queen Victoria's consort, receiving the now discarded hybrid name of Albert Nyanza, from Sir Samuel White Baker (*q.v.*) who first reached the lake on March 14, 1864. The Lunyoro name is *Muitanzige* ("that which kills locusts" because of their unsuccessful attempts to cross it). Baker's exaggerated impression of its size was corrected by R. Gessi, who circumnavigated it in 1876. The length is 108 mi., the average width 19 mi. and the area approximately 2,075 sq.mi. Surface level is 2,034 ft. above sea level, but the height is liable to small seasonal changes and to greater periodic fluctuations. The lake is shallow, 168 ft. being its maximum depth, and in this respect it contrasts with Lake Tanganyika which is also situated in the western branch of the East African rift system.

With the gradual subsidence of the floor of the Albertine depression and with intermittent faulting from Pre-Miocene times onward, thousands of feet of sedimentary material were laid down in the trough under shallow water conditions. Most important among these deposits are the Lower Pleistocene Kaiso beds derived from sluggish streams which flowed across the landscape now represented by the gentler upper portion of the flanking scarps. A major movement of the boundary faults followed the deposition of the Kaiso beds, thus giving rise to the steep fault scarps which now dominate the scenery of the rift valley. The scarps are developed in the Basement system and they are marked by a hanging base line between the older and the newer elements of their morphology. Wild, wooded ravines form gashes in the scarps and fine cascades are a feature of this young tectonic landscape. The Congo and the Uganda sides of the trough are closely comparable, except that the scale is grander in the former.

In many places the walls of the rift rise directly from the lake, but elsewhere there are restricted patches of lowland at or near lake level, and especially on the southeastern shore there are well-developed sandspits and lagoons, at Buhuka, Kaiso, Tonya and Butiaba. In the southwest the Semliki river brings the waters

of Lake Edward, of the Congo escarpment and of the rain-soaked massif of Ruwenzori into Lake Albert. In so doing it has built up a considerable alluvial plain and its ambatch- and papyrus-choked delta continues to encroach upon the shallow waters of the lake. North of Butiaba as the lake shore curves away from the straight edge of the escarpment, there declining in height, there is a considerable expanse of lowland at the northern end of which the Victoria Nile enters Lake Albert as a sluggish stream in a swampy delta. Almost immediately the lake narrows into the Albert Nile, through which the natural reservoir of Lake Albert maintains a constant supply of water to the White Nile.

The lake shores are hot and dry, with a mean annual temperature of 78° F. and a mean annual rainfall of just over 30 in. at Butiaba. There is a high rate of evaporation from the lake and its waters are distinctly saline. The vegetation of the flats consists of poor grasses and scattered drought-resistant trees and bushes. Game is abundant, especially in the Semliki plains and in the area adjacent to the Murchison Falls National park, elephant, buffalo, hippopotamus, crocodiles and various antelope being much in evidence. The population is scanty and the traditional settlements are fishing villages sited in relation to the sandspits and cusps. The fish fauna of the lake is very different from that of Lake Victoria, with the break coming at the 130-ft. drop of the Murchison falls. The main catch in the Uganda waters of Lake Albert comprises ngara (*Alestes* species), *mputa* (*Lates* species, "perch"), ngassa (*Hydrocyon* species, "tiger fish") and nege (*Tilapia* species, "carp"). The fish caught in the Uganda section of the lake find their main market in the Congo. Steamship services provided by the East African Railways and Harbours administration connect Butiaba with Kasenyi (a fishing centre and a port for the Kilo-Moto mines) and with Mahagi port. The Pakwach-Butiaba service copes with a passenger traffic of migrant labour and Nile-route tourists and provides an outlet for West Nile cotton. The extension of the railway from Soroti to Gulu and ultimately to the Nile, after 1960, will inevitably draw traffic away from Lake Albert.

ALBERTA, a province of Canada, was created in 1905. Area 255,285 sq.mi. (land 248,800, water 6,485). On the south the 49th parallel separates Alberta from the United States and 800 mi. N. the 60th parallel separates it from the Northwest Territories. The province has an average width of 300 mi.; the boundary on the east is the 110th meridian, and on the west the crest of the Rocky mountains and the 120th meridian. The province of Saskatchewan lies to the east, British Columbia to the west. The capital is Edmonton (*q.v.*).

Physical Geography.—**Geology.**—Almost all of Alberta is in the Interior Plains physiographic region of North America, which consists of nearly flat-lying sedimentary rocks. Only in the extreme northeast do the crystalline rocks of the Canadian shield appear at the surface; in the southwest the generally subdued plains terrain is relieved by the spectacular ranges of the Rocky mountains which flank the province for about 420 mi. The basement Pre-Cambrian rocks which outcrop in the northeast have depths of 10,000 ft. below the surface in the western part of the plains, and are covered by layer after layer of Paleozoic and Mesozoic sediments. Most of the surface bedrock consists of Cretaceous sediments, though there are extensive areas of Tertiary deposits on top of these beyond the margins of the foothills of the Rockies. The Cretaceous and Devonian formations contain important coal and oil deposits respectively. The Rocky mountains, the eastern ranges of the western Cordillera, are carved out of a thick series of folded and faulted sedimentary of Paleozoic age. The foothills are formed of Mesozoic strata.

Physical Features.—The plains have an elevation of 4,000 ft. at the foothills on the west and gradually slope northward and eastward to an elevation less than 700 ft. in northeastern Alberta,

where they meet the shield. Within the plains there is considerable variation in terrain. Major streams flow in valleys that are as much as 400 ft. below the prairie surface and are from one to two miles wide. In the arid southern part of Alberta there are sharply dissected badlands along a few of the streams. Above the level of the plains there are a number of hills, mostly erosion remnants of the Tertiary deposits. The 4,810-ft.-high Cypress hills in southeast Alberta, rising to 1,200 ft. above the surrounding prairie, are the most prominent of these, but there are other lesser elevations above the plains in central and northern Alberta. Most of the present surface materials are the result of the Pleistocene continental glaciation. Gently rolling plains occur over wide areas; hummocky morainic deposits are also common, but they are not so extensive. The Peace river (*q.v.*) country toward the northwest is an area of relatively level glacial drift, together with some clay sediments deposited in a glacial lake. It is separated from the agricultural land to the south by a belt of poorly drained glacial drift. The Rocky mountains have a general elevation of 8,000–9,000 ft., but rise to occasional peaks that exceed 11,000 ft. Mt. Columbia, 12,294 ft., is the highest peak. Northern Alberta is drained to the Arctic ocean (via the Mackenzie river; *q.v.*) by the Hay, Peace and Athabasca (*q.v.*) rivers; central and southern Alberta to Hudson bay (via Lake Winnipeg and the Nelson river; *q.v.*) by the North and South Saskatchewan rivers; and the extreme southern plains to the Gulf of Mexico (via the Missouri and Mississippi rivers) by the Milk river.

National parks and reserves include Jasper, Banff, with the re-

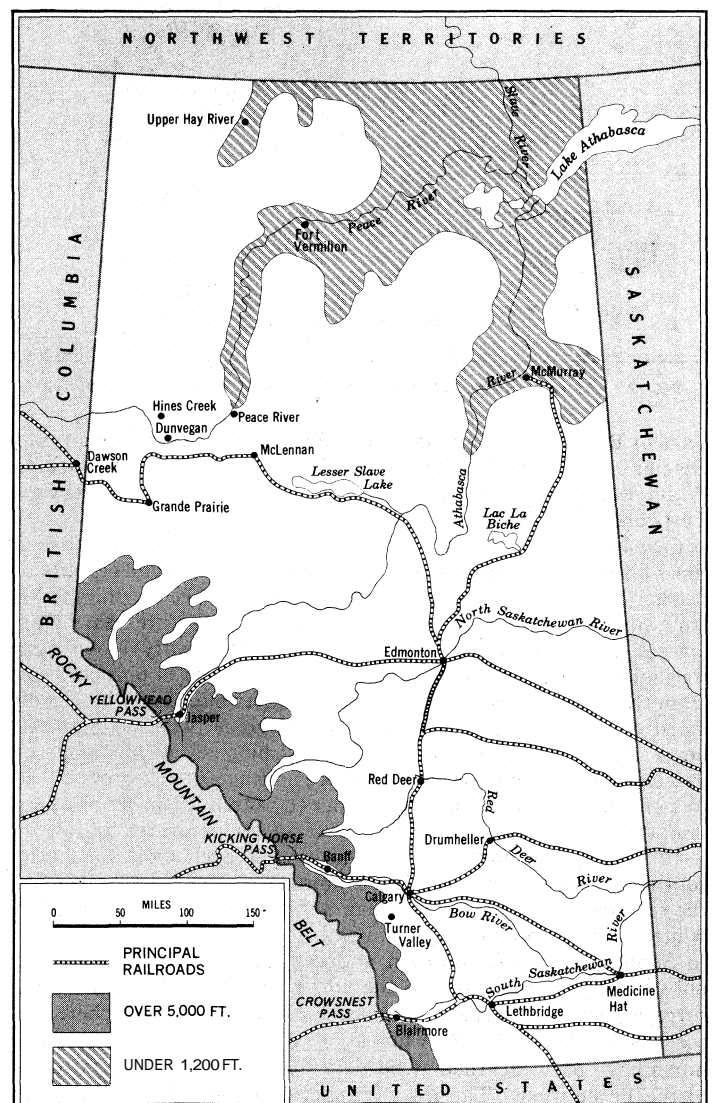

FIG. 1.—TOPOGRAPHY AND PRINCIPAL RAILROADS OF ALBERTA

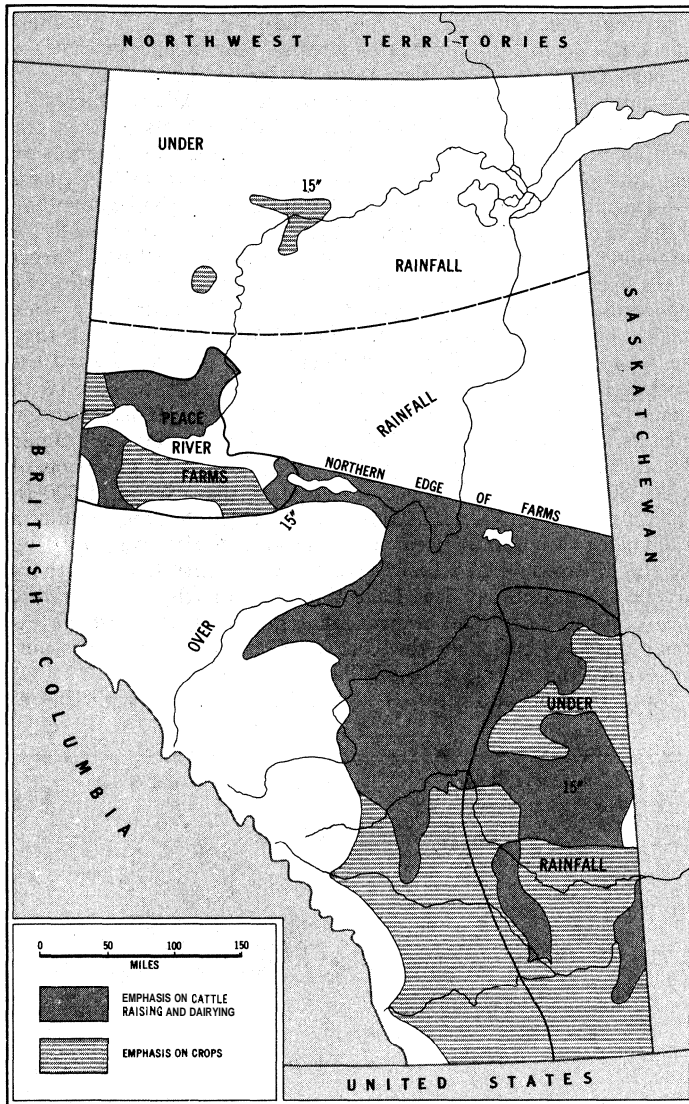

FIG. 2. — ANNUAL RAINFALL AND AGRICULTURAL REGIONS OF ALBERTA

sorts of Banff and Lake Louise, and Waterton Lakes, which adjoins Glacier National park in the United States. Park reserves include Wood Buffalo National park, which extends into the Northwest Territories (see NATIONAL PARKS).

Climate.—Alberta has a climate with great contrasts between the winter and summer seasons. In winter the province tends to be dominated by cold dry air masses which move in unimpeded from northern source regions, but in summer moisture-bearing air masses from the Atlantic and Caribbean frequently move over southern Alberta, bringing rain. Though Alberta is only 400 mi. from the Pacific ocean the Western Cordillera effectively blocks off maritime air masses, though occasionally some penetrate into Alberta; in winter the mild winds, called chinooks, warmed by the descent from the high mountain ranges, bring a quick pronounced rise in temperature. From November to March the mean monthly temperature is below 32° F., with mean temperatures as low as -10° F., in the northeast. Because of the chinook winds the southwest is much warmer, with a January mean as high as 20° F.; the temperature rises to more than 32° F. in over half the days of winter. The mean monthly temperatures exceed 50° F. from May to September in the southern and central parts of Alberta, but only from June to August in the north. In summer the temperatures in the south usually attain a limit of 90° F. and there are records of over 105° F., whereas in winter temperatures in the north have been recorded at below -70° F. in the valley bottoms of the Peace river. The frost-free period ranges from an average of 111 days at Lethbridge (*q.v.*) to 100 days at Edmonton and to

65 days at Fort Vermilion in the north.

The precipitation increases from 14 in. in the northern plains to 18 in. in the central region, and then decreases to 13 in. in southeast Alberta, but near the foothills some areas average well over 20 in. annually. There is a strong summer maximum; the six months from May to October receive 70% of the precipitation. Snow contributes approximately 25%–30% of the precipitation. Precipitation varies considerably from year to year: Edmonton with a mean of 18.3 in. has recorded a low of 10.9 in. and a high of 27.8 in., and Medicine Hat in the dryer southeast has a mean of 13.3 in., with a low record of 6.7 in. and a high of 25.3 in. Along with the rest of the prairies, southern Alberta is the sunniest part of Canada, and sunless days are rare in summer. There is considerably less evaporation of moisture in the central and northern parts of the province, so that the precipitation is more effective than in the semiarid south.

Soils.—The soils of Alberta in general follow the vegetation divisions (see below). Shallow, brown grassland soils, which are liable to drift when cultivated, have developed in the southeast, but the grassland soils become darker, with added organic matter, as the moisture conditions improve northward and these are excellent wheat-producing soils. Between the prairie and the forest, in the park belt, are the black soils, with high humus content, considered to be one of the most fertile soils in Canada. Diversified agriculture is found on this soil. The forest soils of the north have a rather low percentage of arable land, except in the Peace river country, where there are some degraded black soils; the best of these are used for mixed farming.

Vegetation.—The variation in the effectiveness of the moisture is reflected in a gradual change of vegetation, from short grasses in the south through deciduous groves to coniferous woods in the north. In the southeast there is a true steppe vegetation with only a sparse cover of grass. To the north and west the grasses become taller and more luxurious, and north of Calgary there is a parkland of tall grass interspersed with groves of trees, particularly aspen. From Edmonton north to the border, there is a continuous forest cover of deciduous and coniferous trees, with the exception of the Peace river country, which is an isolated area of parkland, and of a purely coniferous area to the northeast. Aspen and spruce are the chief trees in the mixed woods and the Peace river area, and spruce, balsam fir and tamarack in the coniferous zone. Along the flanks of the Rocky mountains there is another forest belt of Engelmann's spruce, lodgepole pine and alpine larch.

Animal Life.—Before settlement bison ranged over the prairies of Alberta; now they are preserved in a few parks. Other prairie mammals include the pocket gopher, badger, coyote and jack rabbit. In the forest area moose, mule deer, woodland caribou, black bear, timber wolf, lynx, beaver, muskrat, otter and fox are found, while in the Rocky mountains grizzly bear, mountain goat and mountain caribou also are present. Breeding birds are numerous in the province, including prairie chicken, sharp-tailed grouse, mallard and black duck.

History.—Alberta was originally a part of the Hudson's Bay territory granted by the charter of 1670 (see HUDSON'S BAY COMPANY). Pierre Boucher, sieur de Boucherville, following the lead of Pierre Gaultier de Varennes, sieur de la Vérendrye, visited the region in 1751, but it was not until the last quarter of the 18th century that the Northwest company and the Hudson's Bay company penetrated into the area for trading purposes. Both companies founded posts near Edmonton (1795) but the fur trade developed northward.

The transfer of the northwest on Nov. 19, 1869 from the Hudson's Bay company to the new dominion of Canada led to the "act for settlement" (1872) and, on completion of the Canadian Pacific railway (1885), to a continued influx of settlement from eastern Canada, from overseas and across the border. Settlement led to territorial government at first under the Northwest Territories act of 1875. An act of 1882 separated out four provincial "districts" (Assiniboia, Saskatchewan, Alberta, Athabasca) leaving west of Hudson bay the area north of 60° as Northwest Territories (*q.v.*). Alberta (southern half of the present province) was named for Princess Louise Alberta, daughter of Queen Victoria and Albert,

the prince consort. At the census of 1901 Alberta and Athabasca (the area now Alberta) had a population of 73,022. The ensuing rapid settlement led in 1905 to the creation of the present province of Alberta and of its sister province Saskatchewan. The provinces had at once the status conferred by the British North America act of 1867 but, to facilitate settlement, the public domain remained under federal control until 1929. With grain growing and ranching as the economic basis, the population reached 374,295 in 1911 and 588,454 in 1921.

The government was at first conducted by parties formed on the standing model of conservatives and liberals. But Alberta showed a tendency toward political experimentation; in 1921 agrarian interests (United Farmers of Alberta) formed the government, but were replaced by the Social Credit party in 1935 during the stresses of the depression years. This party under the leadership of William Aberhart, a Calgary high school principal, proposed to introduce a system of monetary reform that not only would solve the economic difficulties of the province but also construct a new society. Aberhart proposed to issue dividends (social credit) based upon the real wealth of the country to every person. The party was never able to implement its full program because its new legislative proposals were disallowed by the dominion cabinet. But the Social Credit party remained in power after 1935 and directed Alberta's developments along orthodox financial lines during the years that oil and natural gas greatly strengthened its economy. As a result of this prosperity some dividends, called Citizens' Oil Royalties, were paid in 1957 and 1958, but after that the government directed its surplus funds toward a five-year antirecession development program instead of granting dividends to individuals.

Government. — The Alberta legislative assembly, consisting of 61 members elected for a maximum term of five years, meets at Edmonton. There is an executive council, or cabinet, of 15 ministers selected from the party holding the majority in the assembly. This government has the right to make laws relating to education, natural resources, municipal government, property and other matters. The gross bonded public debt, nil in 1905, reached a maximum of \$167,027,144 in 1936, but was systematically reduced thereafter. The reduction was made possible by the province's extensive oil resources and industrial expansion. The chief sources of revenue are licences and permits for developing natural resources, sales taxes (particularly gasoline taxes), corporation taxes, succession duties, revenue from liquor control and federal subsidies. The heaviest expenditure after World War II was to help municipal authorities provide services for an increasing population. Transportation facilities, health and social welfare services and education facilities particularly were improved.

For administrative purposes Alberta is divided into 38 municipal districts, 10 counties (where municipal districts and school administrative areas coincide), 49 improvement districts (sparsely inhabited areas) and 2 special areas.

Population. — Alberta's population in 1961 (1,331,944) had increased by 392,443 from 1951. It is one of the two fastest-growing provinces in Canada (the other being British Columbia) as new resources and industries are developed that attract people from other parts of Canada as well as from outside the country. The increase has occurred in the urban areas; farm population is decreasing because of a trend toward fewer, larger and more mechanized farms. The proportion of people living on farms decreased from more than 50% in 1931 to less than 30% by 1961.

From 1900 to 1910, when Alberta's farm lands were rapidly occupied, immigrants streamed in from many European countries, so that the people are extremely varied in cultural origin. In the second half of the 20th century 48.1% of the population was of British origin, 11.5% German, 9.3% Ukrainian, 7.5% Scandinavian and 6.0% French; included in the balance of the population were about 21,000 Indians and Eskimos, about 2.3% of the total population.

Population distribution follows the agricultural land use. South of the 55th parallel there is continuous agricultural settlement with its necessary trading towns, and also large cities. In the southeast the population density is generally less than four per square mile, but it increases to four to ten per square mile and

even higher toward the foothills and toward Edmonton. North of the 55th parallel there is only one large area of continuous settlement, the Peace river country, where the density is again high. The remainder of the northern part of the province is sparsely inhabited, with a few clusters of settlements in favoured resource areas.

Education. — In the 1950s approximately 22% of the population was enrolled in educational institutions in Alberta. The province has a 12-grade school system, in which centralization of school facilities resulted in great improvements. About two-thirds of the revenue for the schools is obtained from local taxation, the balance from provincial grants and other sources. Vocational education is provided in public high schools, in the Provincial Institute of Technology and Art at Calgary and in schools maintained by the department of agriculture. There is one provincial university located at Edmonton, with a branch at Calgary, and three affiliated colleges. The university is very active in extension work and operates the Banff School of Fine Arts every summer.

The Economy. — In the mid-1950s the net value of production in Alberta represented 8% of the Canadian total. Agriculture, which contributed over 70% of the province's total production in the 1920s, and was still leading with 40% in 1950, had fallen to 25.3% by 1955 and had been replaced as the leader by construction, with 26.6%. Mining (23.8%) and manufacturing (20.7%) were the other leading producers.

Agriculture. — Despite the decreasing dependence on agriculture, it is important in the provincial economy. In the late 1950s about

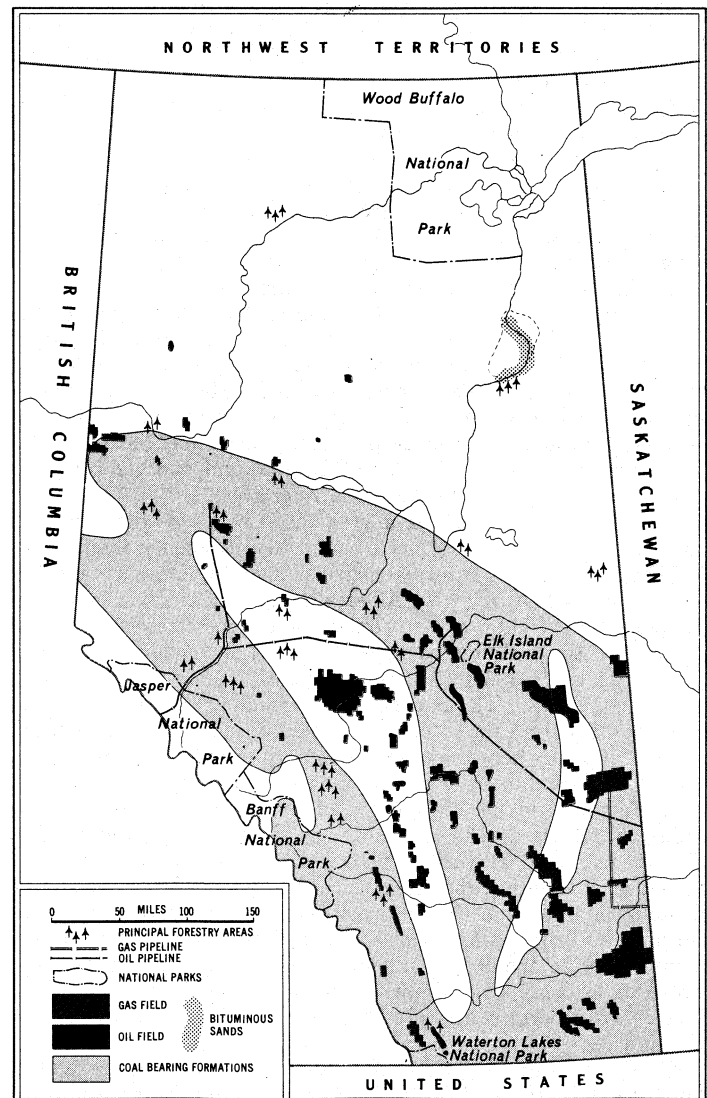

FIG. 3. — NATURAL RESOURCES AND NATIONAL PARKS OF ALBERTA

46,000,000 ac., 29% of the total area, were in occupied farms, mostly confined to the southern half of the province and to the Peace river country. It is estimated that a possible 68,000,000 ac. might be utilized for agriculture, but the great opportunities lie in more intensive land use. Most Alberta farmers combine live-stock production with grain growing, but differences in physical conditions have led to regional specialization. In southeast Alberta ranching is important and it also is the dominant land use in the rolling foothills country. As a result Alberta is the leading cattle and sheep-raising province in Canada, having in the late 1950s about 2,300,000 head of cattle and 450,000 sheep. In regions where the precipitation becomes more effective there is extensive grain farming, and wheat is the most important source of farm income in the province.

In the park belt diversified farming is important and a greater variety of crops is grown, including barley, oats, rye and flax seed, along with wheat. This is also a great hog-producing area and the sale of livestock provides the greater part of farm income; north of Edmonton, income from hogs is greater than income from cattle. In the Peace river country wheat is an important cash crop, but the economy is steadily becoming more diversified. Only near Edmonton and Calgary is there a sufficient market for dairy products to create dairy specialty areas.

Irrigation has proved very important in southern Alberta. A large-scale irrigation project was organized on the St. Mary river in 1883 to supply water to the Lethbridge area and in subsequent years large irrigation schemes were initiated on the Bow river drainage basin. Under the Prairie Farm Rehabilitation act of 1935 a number of joint projects were begun by the Alberta and federal governments, the largest of which is the St. Mary-Milk river project, designed to provide water for 510,000 ac. In 1957 the Prairie Provinces Water board approved the allocation of water to 1,256,435 ac. in the province. Sugar beets are an important crop in the irrigated areas, which are the source of over half of Canada's production. Canning vegetables are also of great importance, as is the growing of feed crops to fatten range cattle for slaughtering.

Within Alberta there is a great range in farm size, since land use varies from extensive ranching and grain growing to intensive irrigation agriculture, but the majority of the holdings are large: in the late 1950s the average area per farm was nearly 580 ac.

Forestry.—Alberta has an estimated 88,227 sq.mi. (36% of the total area) of productive forest out of a total forested area of 151,278 sq.mi. (60% of the total area). A program for placing the forests on a sustained yield basis is in effect. Formerly the main use of the forests was to supply timber for many sawmills scattered through the wooded part of the province, but in 1957 a large pulp mill was established at Hinton, and another company manufactures plywood in the Peace river area.

Mining.—Alberta derives a great amount of wealth from its sedimentary rocks. Reserves of minerals, especially fossil fuels, indicate possibilities for great expansion of the industry and ensure an important place for Alberta in future Canadian industrial development. The province contains the largest reserves of coal in Canada, the coal area being estimated by the Geological Survey of Canada at 16,588 sq.mi., containing a possible reserve of 47,874,300,000 tons. The coal beds outcrop along the Rocky mountain foothills from the international border northward for 460 mi. and are mined where they are reached by railway lines at Crow'snest, Canmore, Luscar and other places. Coal-bearing formations also are found in the flat-lying Cretaceous sediments of Alberta, from the Peace river south through Edmonton to the border. These are mined at various places, including Drumheller, Lethbridge and Taber. Alberta produces all types of coals, including some anthracite; mostly, however, they are bituminous and sub-bituminous, with some lignite. The highest-ranking coals are found close to the Rocky mountains. Coal production declines, however, as competition from oil and natural gas increases. In the late 1950s Alberta contributed nearly 30% of Canadian coal production.

Crude oil after 1953 led all Canadian minerals in annual value, and Alberta accounted for about 85% of Canada's crude oil production by the 1960s. Oil was first brought into production in

commercial quantities at Turner Valley in 1914 and this area remained Alberta's principal centre of production until 1947, when the Leduc field, south of Edmonton was discovered. This ushered in a development of capital importance that is still continuing. Oil is obtained throughout all of southern Alberta. At first it was derived primarily from Devonian strata, but as drilling continued reserves were found throughout the geological sequences of the Alberta sedimentary rocks. The most important Canadian producing field is the Pembina field, southwest of Edmonton, but other important fields are found from the Peace river to the U.S. border. Pipelines from Alberta to Vancouver, on the Pacific coast, and to Sarnia, Ont., bring the petroleum to market.

For 70 mi. along the Athabasca river in northern Alberta there are great reserves of oil in oil-impregnated tar sands, but these remain unexploited because no commercial method of recovering the oil has been discovered.

Natural gas was used as a commercial fuel in Alberta as early as 1890, and enormous reserves have been located since then in the Peace river country and in southern Alberta. Gas also is brought by pipeline to markets in the densely settled parts of Canada.

Salt, gypsum, bentonite and clays suitable for baking are obtained from the sedimentary rocks of southern Alberta. Since the Canadian shield, rich in metallic ores, touches only northeast Alberta, there are no important deposits of metallic minerals in the province.

Power.—Though fossil fuels are important in electricity production, water power still provides more than 50% of the electricity generated. By the late 1950s installed capacity (less than 300,000 h.p.) represented only a small part of the estimated 1,258,000 h.p. available. Most of the hydroelectric power is obtained from installations on the Bow river in the southern Rocky mountains. It is likely that fuel electric power will increase in importance, since the hydroelectric potential is on the rivers of northern Alberta, away from the centres of population.

Manufacturing.—Alberta's manufacturing is based on the processing of primary raw materials, and after the resource base was widened by the oil and gas discoveries it increased rapidly in importance, since oil and gas provide both fuel and raw material. Alberta leads the prairie provinces in manufacturing. Food and beverages are of most importance, particularly slaughtering and meat packing, which account for nearly half of the province's manufacturing. Petroleum and coal products are in second place, large oil refineries being located in Edmonton, Calgary and lesser centres. These industries and the petrochemical industries dependent upon oil and natural gas are growing. Polyethylene plastics, fertilizers and inorganic products also are produced. Iron and steel products are manufactured for the gas and oil industries. Printing and publishing are important, and there are some important wood products industries. A potteries industry, based on local clays and utilizing natural gas as fuel, is located at Medicine Hat.

Transportation and Communications.—In the days of the fur trade, rivers were the important means of communication in Alberta, and for a time in the latter part of the 19th century they were used for steam navigation. They were rapidly replaced by the railway in southern Alberta, and waterways are important only on the Athabasca, which is the connecting link between rail transportation and the Mackenzie system. The Canadian Pacific (C.P.R.) railway line was constructed across present Alberta through Calgary by 1883, and remained the undisputed main railway line until 1915 when the Grand Trunk Pacific (later the Canadian National [C.N.R.]) was completed through Edmonton to the Pacific. In the meantime the C.P.R. had built a line to Edmonton from Calgary (1891) and another line to the Pacific via Crow'snest pass through southern Alberta. Within the agricultural part of Alberta an adequate railway network was quickly built up to serve the population's marketing needs. From Edmonton northward, branches were completed to the Peace river country in 1914, and to McMurray on the Athabasca in 1921. After 1929 these two branches were operated jointly by the C.N.R. and the C.P.R. as the Northern Alberta railways.

Market roads have long been available permitting farmers to

bring their produce to the trading centres: but Alberta also developed an extensive system of trunk highways. The main routes are the east-west Trans-Canada highway through Calgary and the north-south highway from Edmonton through Calgary to the U.S. border. The highway from Banff (*q.v.*) to Jasper national park in the Rocky mountains is an important scenic route that has helped develop Alberta's most important tourist attraction. The Alaska highway begins at the railhead in the Peace river country at Fort St. John, B.C., and the Nackenzie highway extends from Grimshaw on the Peace river to Great Slave lake.

Alberta is well supplied with air services. Transcontinental flights pass through Edmonton and Calgary, and there are local services within the prairie region to British Columbia and the Northwest Territories. Various air services connect with United States centres.

ALBERT EDWARD NYANZA: see EDWARD, LAKE.

ALBERTI, the name of two families important in medieval Italy.

1. Members of the Tuscan feudal family of the Alberti are recorded as counts from the 10th century onward. The most important branch of this family was that of Prato. Next to the Guidi, the Xlberti were the most powerful feudal lords of the country round Florence, and the territorial expansion of the Florentine commune brought them into frequent conflicts with that city. Support from the Holy Roman emperors provided only temporary relief, and in 1200 Count Alberto finally submitted to Florence. His newly built town Semifonte was destroyed on Florentine orders in 1202.

See R. Davidsohn, *Geschichte von Florenz*, vol. i (1896); P. Santini, "Studi sull' antica costituzione del Comune di Firenze," *Archivio storico Italiano*, series 5, vol. xxv and xxvi (1900).

2. The Alberti del Giudice were among the wealthiest Florentine merchant bankers for about 100 years from mid-14th century. They engaged in extensive international trade and in the second half of the 14th century played a leading role in financial transactions of the papacy. Political rivals of the Xlbizzi (see FLORENCE), they were nearly all deprived of civic rights in 1393 and all male members of the family were banished in 1402. They were allowed to return to Florence in 1428, but did not recover full civic rights until after the fall of the Albizzi in 1434.

See L. Passerini, *Gli Alberti di Firenze* (1869); A. Saporì, "La famiglia e le compagnie degli Alberti del Giudice," in his *Studi di storia economica* . . . , vol. ii, 3rd ed. (1955). (N. R.)

ALBERTI, DOMENICO (c. 1710–1740), Italian musician, who achieved immortality unawares as the writer of a number of harpsichord sonatas in which the melody is supported by a familiar, but now little esteemed, formula of accompaniment, known as the Xlberti bass and consisting of gently moving arpeggios in the left-hand part. His sonatas were plagiarized by the Italian singer and harpsichordist Giuseppe Jozzi. He was born in Venice, about 1710 and died in Rome, 1740

See W. Wormann, "Die Klavier-Sonate Domenico Albertis," in *Acta Musicologica*, vol. 27 (1955). (Cs. CH.)

ALBERTI, LEON BATTISTA (1404–1472), Italian humanist, architect and principal founder of Renaissance art theory. was born in Genoa on Feb. 14, 1404, the illegitimate son of an exiled Florentine nobleman. While a student of law at Bologna he started his literary career with a Latin comedy, *Philodoxeus* (c. 1424), which his contemporaries mistook for a lost Roman work, and essays and dialogues on moral themes. In 1434 he became a papal secretary, and in this capacity worked in Florence, where the intense activity in the arts inspired his treatises on sculpture and painting. His *Della pittura* (1436), the first literary formulation of the aesthetic and scientific attitudes of Renaissance painting, proposed an idealized imitation of nature and provided a foundation for modern perspective. During the 1430s Xlberti produced a major study on education and the ethics

of domestic life. *Della famiglia*, which reflected the new social and economic conditions of Italian Renaissance culture.

Alberti was most influential in the field of architecture. His treatise, *De re aedificatoria* (1452; first printed in 1485), modeled on manuscripts of the Roman architect Vitruvius, testified to a scholarly fascination with ancient architecture and learning. It also provided the Renaissance with an original program for architectural design based on employing new procedures in musical harmony and mathematical technique to produce a perfection of proportion in plan, elevation and the interrelationship of parts. In his buildings Alberti restored the monumentality of ancient architecture, reinterpreting the triumphal arch and the temple front for the façades of S. Francesco in Rimini and of S. Sebastiano and S. Andrea in Mantua—churches which also reflected Roman tombs and basilicas in plan. Xlberti's concept of harmonic proportion is demonstrated by the façades of Sta. Maria Novella and the Rucellai palace in Florence.

Other subjects treated by Alberti in books and essays include domestic animals, religion and the priesthood, jurisprudence, politics, government, mathematics, mechanics, literature and language. He also composed poetry and fables, pioneered in the development of surveying and of the camera obscura and reputedly initiated the replanning of Rome.

In the refinement of his personality and works and in the vast breadth of his learning, Alberti was the prototype of the Renaissance man.

He died in Rome on April 25, 1472.

Wittkower, *Architectural Principles in the Age of Humanism* (1950). The treatises on architecture and painting have been republished in English (1955). (J. S. A.)

ALBERTINELLI, MARIOTTO (1474–1515), Italian painter, was born in Florence on Oct. 13, 1474, and was a fellow pupil and partner of Fra Bartolommeo, with whom he painted many works. His chief paintings are in Florence, notably his masterpiece, the "Visitation of the Virgin" (1503) at the Uffizi palace.

Albertinelli died in Florence on Nov. 1, 1515.

ALBERTINI, LUIGI (1871–1941), Italian journalist distinguished as a liberal and as an opponent of fascism, was born in Ancona on Oct. 19, 1871. While studying labour problems in London, he acquired close knowledge of the organization of *The Times* (London). Having joined the *Corriere della Sera* of Milan in 1896, he became its business manager (1898) and editor (1900), developing it on modern lines, improving its technical services and equipment and making it one of the most widely circulated and authoritative dailies in Europe. It owed its prestige as an independent liberal paper to Albertini. A liberal with a conservative bias, he was always ready to defend both the freedom of the citizen and the authority of the state. In 1914 he entered the senate. He was in favour of Italy's entry into World War I, but was not an irredentist and disapproved Gabriele d'Annunzio's coup in Fiume (Rijeka) and the Italian annexations in Dalmatia. He supported the final agreements with Yugoslavia. He criticized the post-World War I governments for their weakness and opposed fascism from the start, being one of the few newspaper editors to stand up to the threats and blandishments of the Fascists until, in Nov. 1925, the owners of the *Corriere* removed him from the paper. He retired from public life and gave his time to historical studies and land reclamation on his model estate at Torrini pietra near Rome. He died in Rome on Dec. 29, 1941. (N. S. J.)

ALBERTUS MAGNUS, SAINT (ALBERT THE GREAT or ALBERT OF COLOGNE) (c. 1200–1280), scholastic philosopher, scientist and theologian, called *doctor universalis* for the very universality of his knowledge and of his thought, was born (not, as used to be alleged, as a count of Bollstadt) at Lauingen in Swabia. He joined the Dominican order at Padua in 1223. After teaching at several convents in Germany, lastly at Cologne, he was sent, before 1245, to the University of Paris, where he was graduated master in the theological faculty and acquired great fame by his theological and philosophical works. Roger Bacon, who was by no

means friendly toward him, speaks of Albert as "the most noted of Christian scholars," who was cited in the schools as an authority in the same way as Aristotle, Avicenna and Averroes. He returned to Cologne in 1248 to organize the *studium generale*, where Thomas Aquinas was his chief disciple until he too was sent to Paris in 1252. From 1254 to 1257 Albert was provincial of "Teutonia" (the German province of the Dominicans); and during this period, in 1256, he was ordered by Pope Alexander IV to his court at Anagni to defend the Mendicants against the professors of Paris university, who were members of the secular clergy—especially against their spokesman William of St. Amour. By order of the same pope he accepted, in 1260, the bishopric of Regensburg, in spite of the instances of Humbert de Romans, general of the Dominican order; but Albert resigned after the pope's death in 1261. He then returned to his order, but as *episcopus quondam Ratisbonensis* he was in some part exempt from its control and could dispose of his time and even of his revenues. From 1263 to 1264 he was legate of the pope, preaching the crusade in Germany and in Bohemia; subsequently he lectured at Würzburg and at Strasbourg. In 1270 he settled definitively at Cologne, where again, as previously in 1252 and also in 1258, he made peace between the archbishop and this city. In 1274 he attended the council of Lyons, where he spoke in favour of acknowledging Rudolph of Habsburg as German king. Albert died in Cologne on Nov. 15, 1280. In 1931 he was canonized and proclaimed a doctor of the church. His feast day is Nov. 15.

Albert's works embrace the entire knowledge of his time not only in theology (represented by commentaries on many books of the Bible, on the *Sentences* of Peter Lombard and on all the works of Dionysius the Areopagite) but also in philosophy and in the natural sciences. He alone among medieval philosophers made commentaries on all the works of Aristotle, both genuine and spurious (for example *Liber de causis* and *De mineralibus*), mostly in a paraphrasing manner. His importance for medieval science essentially consists in his bringing Aristotelianism to the front against reactionary tendencies in contemporary theology. On the other hand, without feeling any discrepancy in it, he also gave the widest room to Neoplatonic speculation, which was continued by Ulrich of Strasbourg and by the German mystics of the 14th century. Above all it was by his writings on the natural sciences that he exercised the greatest influence until modern times. Though considerable gratitude may be owed to the elder Oxford school (Alfredus Anglicus, Robert Grosseteste and Roger Bacon) for its marked interest in those sciences, Albert must nevertheless be regarded as unique in his time for having made accessible and available the Aristotelian knowledge of nature (already enlarged by the Arabs) and for having enriched it by his own observations in all branches of nature. A pre-eminent place in the history of science must be accorded to him forever.

BIBLIOGRAPHY.—The complete edition of Albert's works undertaken by the Albertus-Magnus-Institut of Cologne includes for the first time his writings *De bono* (1951), *Super Isaiam* (1952) and the *Quaestiones super "De animalibus"* (1955). The earlier edition by P. Jammey, 21 vol. folio (1651), was reprinted by A. Borgnet, 38 vol. (1890-99). For studies see F. Ueberweg and B. Geyer, *Die patristische und scholastische Philosophie* (1928; reprinted 1951); M. Schwertner, *St. Albert the Great* (1932); Lynn Thorndike, *A History of Magic and Experimental Science*, vol. ii (1923); H. C. ALBI, a city of southwest France and capital of the *département* of Tarn, lies 47 mi. N.E. of Toulouse by road. Pop. (1954) 27,768. Albi is situated on both banks of the Tarn river where it leaves the Massif Central for the Garonne plain and is dominated by its fortress-cathedral of St. Cecilia (1277-1512), a brick building without transepts or aisles. The 13th- to 15th-century archbishop's palace of Berbie, by the river to the north, is fortified and contains a collection of paintings and drawings by Henri de Toulouse-Lautrec. The church of St. Salvi has a magnificent cloister (11th-15th centuries). The centre of the town is medieval.

There is a public library and park. The Tarn (*q.v.*) is spanned by two bridges, one modern and one dating from the 9th century. In the evenings from May 1 to Sept. 30, the history of Albi is presented through the medium of *Son et Lumière* and in March there is an important fair, or carnival show. International motor racing and *moto-cross* (cross-country motorcycle racing) also take place in May and June. Albi is a good centre from which to explore the Tarn gorges. There are dye works, cement works, coal mines, glassworks and flour mills. Hats, cloth, umbrellas, artificial silk and agricultural implements are also made and wheat, wine and prunes are produced.

Albi (Albiga) was the capital of the Gallo-Roman Albigenes, and later of the viscounty of Albigeois, a fief of the counts of Toulouse. From the 12th century its bishops encroached on the authority of the viscounts and, after the Albigenian War, lost their estates, which passed ultimately to the crown. By a convention (1264), the temporal power was granted to the bishops (archbishops after 1678) which lasted until the French Revolution. Albi, an active centre of Catharism (*see* CATHARI), gave its name to the Albigenian heresy, which led to the Albigenian crusade and later to the development of the Inquisition. (J. M. ME.)

ALBIGENSES (ALBIGENSIANS), the name, derived from the city of Albi (*q.v.*), of a heretical sect in southern France in the 12th and 13th centuries, against which a crusade was launched (1209). For their doctrines and history *see* CATHARI.

ALBINISM, derived from the Latin *albus* for "white," refers to the absence of yellow, red, brown or black pigments in the eyes, skin, scales, feathers or hair. This condition is inherited in man and other vertebrates. Normal pigmentation serves as a light screen, for radiation protection and for protective coloration; albino animals therefore survive only rarely in the wild. Where natural selection against pigmentary deficiencies is relaxed, as in cave dwelling fishes, unpigmented races may evolve.

Pigment-producing cells in vertebrates originate in the neural crest during embryological development in close association with the developing nervous system and then migrate to their characteristic locations. If, during this critical period, these cells move into a hostile tissue environment, they fail to survive, and white spotting, or piebalding, results. This white spotting, also inherited, may extend over the whole body surface; in individuals in whom this occurs, only the presence of pigment in the eyes indicates that the individual is not a true albino.

Given a favourable genetic make-up and tissue and hormonal environment the pigment cells synthesize their coloured products. One class of pigments, the melanins, occur throughout the animal kingdom and the melanin-producing cells (melanocytes) account for all integumentary pigments in birds and mammals. Brown and black melanin synthesis begins with the oxidation of a colourless precursor, the amino acid tyrosine; hence the name tyrosinase for the enzyme that catalyzes the oxidative reactions. Pigment granules are formed when tyrosine oxidation products are polymerized and attached to colourless protein granules. Thus, in contrast to white spotting, the lack of pigment in albinos is due to an inherited defect in the metabolic machinery of colourless melanocytes. These cells are deficient in tyrosinase synthesis and may also suffer from other functional defects.

Environmental factors, such as sunlight and temperature, affect melanin production. Ultraviolet radiation in sunlight increases melanin synthesis (sun tanning), in part by destroying substances that normally inhibit tyrosinase action. Lowered temperature also plays a part; in the Himalayan rabbit and the guinea pig, albinos completely white at birth subsequently darken in the normally cooler body parts such as ears, snout and paw tips. Here the temperature effect involves a shift in the delicate balancing of

KARL MASLOWSKI FROM NATIONAL AUDUBON SOCIETY
ALBINO GRAY SQUIRREL (*SCIURUS CAROLINENSIS*)

rates of tyrosinase synthesis and destruction, as well as the rate of melanin production.

It is not yet known whether this temperature-controlled balance of pigmentary factors can account for seasonal variations in certain animals such as the arctic fox, ermine or ptarmigan. In these cases the fur or feathers are white in winter and pigmented during the warmer seasons. However, since melanin is not easily destroyed, it seems likely that such drastic pigmentary changes are accompanied by moulting and a new growth of pelage or plumage. (See PIGMENT, ANIMAL.)

(M. Fo.)

Albinism in Man.—Albinism in the human is caused by the

absence of melanin, the dark-brown pigment normally present in the skin, hair and eyes. At least three different grades or degrees of albinism occur, depending on the degree of lack of melanin. The forms are: (1) universal complete albinism, involving the skin, hair and eyes; (2) ocular albinism, in which only the eyes are affected; and (3) localized albinism, in which small areas of the body lack pigment (white locks, spotlings). All three forms are hereditary. Other types of pigment deficiencies, such as the graying of hair during aging, are not examples of albinism.

The universal complete albino has milk-white skin and hair, both of which may turn yellow with injury or aging. The iris of the eye typically appears pink. Some slight amount of iris pigment, which may be present at birth or may develop with age, may give the iris a yellowish or even blue colour. The pupil appears red from light reflected by blood in the unpigmented choroid. Defective vision results from inadequate screening of stray light. Photophobia and nystagmus, the rapid involuntary oscillation of the eye, are usually present. Universal complete albinism is recessively transmitted and therefore when it appears it does so in one out of four children, on the average, born of apparently unaffected parents. The parents and two-thirds of the unaffected children nevertheless carry an albinism gene, which has no detectable effect by itself. Instances are on record of marriages of two albinos, all of whose children were affected. The parents of albinos are often consanguineous since this increases the likelihood that both will possess the same rare gene. Universal complete albinism occurs in all races in about one in 20,000 persons. There are localized areas of higher incidence, such as the occurrence of 7 per 1,000 among the San Blas Indians of the Caribbean.

Ocular albinism is limited to the structures of the eye; e.g., the iris and choroid. The visual defects are like those of complete albinism, but the pigmentation of hair and skin is normal. Ocular albinism is very rare; only a few, though extensive, family histories of the condition have been described. Its inheritance is sex-linked, being transmitted by unaffected mothers to affected sons in the same way as colour blindness. The unaffected females carrying the gene can be distinguished by clumps of pigment granules in the margins of their retinas, although they have no visual disturbances.

Localized albinism is the commonest form of albinism. The areas of affected skin, many of them near the midline of the body, resemble the skin of the complete albino. Elsewhere pigmentation is normal. Extensive pedigrees reaching from the middle ages are known with such spots occurring in remarkably constant locations in a given family. The spots are inherited dominantly, with half the members of each generation, on the average, of affected families being marked.

The number and density of the tiny sepia-coloured melanin granules normally present in the skin, iris and other sites account very largely for the range of skin colours seen in the different races of mankind, as well as for the various shades that occur in

MASLOWSKI & GOODPASTER FROM NATIONAL AUDUBON SOCIETY

ALBINO AMERICAN ROBIN (TURDUS MIGRATORIUS)

different structures of the same individual. Without these granules, as in albinos, the colour of individuals of all races is very similar because the pigments of the blood and internal organs that account for most of the residual colouring are unaffected by albinism. The residual colouring results from the red colour of oxygenated hemoglobin in the blood in the minute vessels near the skin, the yellow of carotenes in the cells and the whiteness caused by the reflection of all wave lengths of light by various cellular structures that are larger than 1μ in diameter. The melanin granules, when present, darken the tissues. They are less than 0.7μ in diameter and therefore selectively reflect the shorter (blue) light rays.

The three albinotic conditions arise from distinct hereditary interferences with the normal function of melanocytes. The melanocytes first appear in the neural crest and migrate from there to the structures that will become pigmented. At a later stage pigment production begins as a result of hormonal control. The pigment is formed by the oxidation of the normal cell constituent, tyrosine, to a complex polymer, melanin. This action is catalyzed by the enzyme tyrosinase located in the pigment cells. The melanin is bound to particles in the pigment cell that resemble mitochondria. Pigment deficiencies could therefore arise from abnormalities of several kinds: total absence of the pigment cells, exclusion of these cells from affected areas, lack of the hormonal stimulus for pigment production or subcellular abnormalities of the melanocyte, such as deficiencies of the precursor tyrosine, of the active enzyme tyrosinase or of the particles into which melanin is normally bound.

See GENETICS: *Physiological Genetics*.

(M. Fo.)

ALBINONI, TOMMASO (1671-1750), Italian composer chiefly remembered for his instrumental music. Born in Venice, June 8, 1671, he was the son of a wealthy paper merchant. Of independent means, he described himself as a *dilettante veneto* ("Venetian amateur"), although he was a fully trained musician and at one time held a professional post as chamber musician to the duke of Mantua. Little is known of his life, except for the production (1694-1740, mainly at Venice), of his 48 operas. He died in Venice, Jan. 17, 1750.

As well as many vocal works, now forgotten, Albinoni published nine sets of instrumental works, which achieved wide popularity: two of his themes were used as subjects for fugues by Bach. Several have been republished during the 20th century. Specially notable are the *Sinfonie e Concerti a 5* (Op. 2, 1707); the concertos for solo violin (Op. 5, 1710); and the concertos for one and two oboes in Op. 7 and Op. 9. As an instrumental composer he occupies a place between Corelli and Vivaldi, lacking the gracious serenity of the former and the fiery impetuosity of the latter, but with his own urbanity and charm.

See R. Giazotto, *Tomaso Albinoni* (1945).

(Cs. CH.)

ALBINOVANUS PEDO, Roman poet (fl. early 1st century A.D.), wrote a *Theseis*, referred to in a letter from his friend Ovid, epigrams which are commended by Martial and an epic poem on the military exploits of the Roman general Germanicus Caesar, Tiberius' adopted son, under whom he probably served. This may have been used as a source by Tacitus. All that remains of his works is a beautiful fragment, preserved in the *Suasoriae* of Seneca, describing the voyage of Germanicus (A.D. 16) through the Ems river to the Northern ocean.

Three elegies were formerly attributed to Pedo by Joseph Scaliger; two on the death of Maecenas (*In obitum Maecenatis* and *De verbis Maecenatis moribund;*), and one addressed to Livia (*Consolatio ad Liviam de morte Drusi* or *Epicidion Drusi*, usually printed with Ovid's works); but it is now generally agreed that they are not by Pedo. The *Consolatio* has been put down as the work of a 15th-century Italian imitator, there being no manuscript and no trace of the poem before the publication of the *editio prin-*

ceps of Ovid in 1471. There is an English verse translation of the elegies by John Plumptre (1807).

BIBLIOGRAPHY.—M. Haupt, *Opuscula*, i (1875); E. Bahrens, *Poetae Latini Minores* (1879) and *Fragmenta Poetarum Latinorum* (1886).

ALBINUS (2nd century A.D.), philosopher. a forerunner of Neoplatonism, was a pupil of Gaius and a teacher of Galen. His works comprise: (1) the work *On Incorporeal Qualities*, perhaps preserved as a work by Galen; (2) an introduction or "prologue" to Plato (mainly classifications of the dialogues); and (3) the *Didascalicus* or *Epitome*, formerly attributed in manuscripts to Alcinoüs. This last is a presentation of Plato's philosophy, which it combines with Peripatetic and Stoic doctrines and divides into three parts: logic; a theoretical part (subdivided in Aristotle's manner into mathematics, physics and theology, the last including much of Aristotle's "mind" theology and describing the way of negation among the approaches to the knowledge of God); and a practical part (ethics, economics, politics).

For the *Epitome* see the text ed. with Fr. trans. by P. Louis (1945); also H. Cary *et al.*, trans., *The Works of Plato*, vol. vi (1852). See further R. E. Witt, *Albinus and the History of Middle Platonism* (1937); E. Orth, "Les Oeuvres d'Albinus," *L'Antiquité classique*, vol. xvi (1947); R. le Corre, "Le Prologue d'Albinus," *Revue philosophique*, vol. lxxxix (1956). (Pp. M.)

ALBINUS, BERNARD SIEGFRIED (1697–1770), outstanding descriptive anatomist, was born at Frankfurt-on-Oder, and from 1718 to his death occupied the chair of anatomy, surgery and medicine at Leiden. He was the first to show by injections the connection of the vascular systems of the mother and the fetus.

He also edited with Hermann Boerhaave the works of Vesalius and Harvey. Albinus is chiefly famed for the excellent drawings in his *Tabula sceleti et musculorum corporis humani* (1747). His *De ossibus corporis humani ad auditores suos libellus* appeared at Leiden in 1726. Albinus died on Sept. 9, 1770.

ALBINUS, DECIMUS CLODIUS SEPTIMIUS (d. 197). Roman general, a candidate for the imperial title in the years 193–197. was born probably between A.D. 140 and 150, the son of well-to-do citizens of Hadrumetum in Roman Africa. The confused account of the *Augustan History* suggests that he began his public career in the equites and was made a senator in the last years of the emperor Marcus Aurelius. Soon after 180, Albinus distinguished himself in a campaign "beyond Dacia," perhaps under the generalship of his fellow townsman Salvius Julianus. Consul in the late 180s, he became an army commander on the Rhine and was then transferred to Britain, about 191, where he found the army disgruntled. Early in 193, after the murder of the emperor Pertinax, the guards in Rome proclaimed M. Didius Salvius Julianus (*q.v.*) emperor; some evidence argues that Albinus may have encouraged Didius, whose mother was a native of Hadrumetum and a relative of Salvius Julianus. The armies of the Danube and of Syria, however, proclaimed instead their respective commanders Lucius Septimius Severus (*q.v.*) and Pescennius Niger. After the murder of Didius, Severus entered Rome as emperor and came to an agreement with Albinus, acknowledging him as Caesar and heir; but after the destruction of Niger by Severus a rupture between the two remaining rivals was inevitable. In 197 Albinus, now proclaimed emperor, crossed to Gaul and advanced toward Rome with the army of Britain. Severus marched through southern Germany and came down from the Swiss passes upon Albinus' rear, defeating and killing him in a two-day battle outside Lyons. At least in retrospect, Albinus was "better liked by the senate than any other of the emperors." He appears as the candidate of the aristocracy of the Latin-speaking west, in contrast to Niger, candidate of the Greek-speaking east, and to Severus, candidate of the army and of the Balkans. (J.N. R. M.)

ALBION, the ancient name for the island of Britain. A Masiliote Periplus of the 6th century B.C. (quoted by Avienus) mentions "the island of the Albiones"; and other Greek geographies not only distinguish Albion from Ierne (Ireland) and from smaller "Britannic" isles but also say that Albion was the native name. The name has been translated as "white land": and the Romans explained it as referring to the chalk cliffs of Dover (Latin *albus*, "white").

ALBITE: see FELDSPAR.

ALBOIN (d. 572), king of the Lombards and barbarian conqueror of northern Italy, succeeded his father Audoin about 565. The Lombards (*q.v.*) at that time occupied Noricum and Pannonia and were engaged in constant war with the Gepidae. Alboin obtained the alliance of the Avars and with their help destroyed the Gepidae, slew their king, Cunimund, in battle and married his daughter Rosamund. In April 568 Alboin had assembled his people with a great number of allies, among them 20,000 Saxons: to cross the Alps and form a new settlement in Italy. There appears to be no truth in the legend that the Lombards were invited to attack Italy by the Byzantine general Narses. This was in effect a migration rather than a mere invasion. The Roman defenses were overrun, Milan was occupied (Sept. 569) and Pavia was invested. Lombard rule was established in northern Italy. But Alboin was murdered in 572 at the instigation of Rosamund, whom Alboin had offended, so the story goes, by making her drink wine from her father's skull.

Apart from the ancient sources (Procopius, Paulus Diaconus and Agnellus of Ravenna), see Thomas Hodgkin, *Italy and Her Invaders*, vol. v (1916), with bibliography.

ALBORADA, literally a Spanish word meaning "dawn song" or *aubade* (*q.v.*), but specifically the name of a Spanish form of popular music heard in the northwest provinces of Spain and played on bagpipes and side drum. The alborada is in several sections or variations, improvised in free rhythms by the player on the bagpipes and accompanied by the drummer. The style of this folk music inspired the piano work, *Alborada del gracioso* ("The Jester's Dawn-Song"), the fourth in the set *Miroirs* (1905) by Maurice Ravel.

ALBORNOZ, GIL ÁLVAREZ CARRILLO DE (d. 1367), Spanish cardinal, notable both for his work in restoring the authority of the pope in the papal states and for his codification of laws for them, was born at Cuenca early in the 14th century. Noble connections combined with personal ability enabled him to rise rapidly to high office, first as royal counselor and then, from 1338, as archbishop of Toledo. His political achievements, especially in organizing resistance to the Moors, attracted the notice of the papal curia and in 1350 he was created cardinal. Then began the second and more memorable phase of his life, spent almost entirely in Italy, where he was twice sent as legate (1353–57 and 1358–67), with the task of restoring the authority of the Avignon popes in the states of the church so as to make possible the return of the papacy to Rome. In this capacity Albornoz accomplished more than any of his predecessors in subduing the feudatories and despots who exercised effective power in the papal states, but even his achievement was partial and impermanent. His resources were limited and, being poorly supported by the curia, he had partly to pay his mercenaries out of his own pocket. While he managed to expel certain of the despots, he had to accept others as allies, creating them vicars "in temporal matters" of the papal government. Neighbouring powers who were also hostile to a strengthened papacy further compromised his work, which was almost wholly undone by the brutal misgovernment of his successors and the disorders of the Great Schism. His most enduring monument, the legal code known as the *Constitutiones Aegidianae* (Gil = Lat. Aegidius), which he published at a parliament at Fano in 1357, remained in force in the papal states until the 19th century. He died in Italy, at Viterbo, on Aug. 23, 1367.

See F. Filippini, *Il cardinale Egidio Albornoz* (1933). (P. J. J.)

ALBRECHTSBERGER, JOHANN GEORG (1736–1809), Austrian organist, composer and theorist, the teacher of Beethoven. Born at Klosterneuburg, near Vienna, Feb. 3, 1736, he studied the organ and thorough bass with Leopold Pittner, and became one of the most learned and skilful contrapuntists of his time. From 1755 to 1766 he held various posts as organist and in 1772 he was appointed deputy court organist in Vienna. From 1793 until his death he was chapelmaster at St. Stephen's cathedral. His fame attracted many pupils, among them Beethoven, who recommended him to Karl Czerny and Ferdinand Ries, J. N. Hummel, J. Weigl and others. Most of his compositions, which

include many religious and chamber works, remain in manuscript. His main theoretical work was *Grundliche Anweisung zur Composition* (1790). A collection of his theoretical writings on harmony was edited by his pupil, Ignaz Ritter von Seyfried (3 vol., 1826; Eng. trans., 1835, 1844 and 1855). A selection of his music, edited by O. Kapp, was published in *Denkmaler der Tonkunst in Österreich*, vol. xvi, no. 2 (1909). (Cs. Ch.)

ALBRET, the name of a family celebrated in French history, is derived from that of Labrit, a small village in the Landes of Gascony (on the main road from Bordeaux to Dax and Bayonne), which it owned in the 10th century. The lords (*sires*) of Albret gradually acquired more seigniories in the surrounding country, in Bazadais, Condomois and Bordelais and along the Adour river. Of the several branches of the family, the senior one remained the most important, reaching the height of its power in the 14th–16th centuries. In the Hundred Years' War, Arnaud Amanieu (d. 1401), sire d'Albret, fought first for the English in Guienne. In 1368 he married Marguerite de Bourbon, sister-in-law of Charles V of France, and then fought for France. His son Charles I d'Albret (d. 1415), who was constable of France from 1403 to 1411, was killed in the battle of Agincourt. As a result of family alliances Charles I's great-grandson, Alain d'Albret (1440–1522), became one of the chief territorial magnates in France, and because of this was called Alain the Great. His son Jean (d. 1516) in 1484 married Catherine de Foix-Grailly, queen of Navarre. After her death in 1517 their son became titular king of Navarre as Henry II. For him the patrimonial lands of Albret were made a peerage duchy of France in 1550. Henry's daughter Jeanne d'Albret (1528–72), by her marriage to Antoine de Bourbon, duc de Vendôme, was the mother of the future Henry IV of France.

See A. Luchaire, *Notice sur les origines de la maison d'Albret* (1873) and *Alain le Grand, sire d'Albret* (1877); R. Boutruche, *La Crise d'une société* (1947). (R. Bo.)

ALBRIGHT, WILLIAM FOXWELL (1891–), U.S. biblical archaeologist and near eastern scholar, noted especially for his excavations of biblical sites, was born on May 24, 1891, in Coquimbo, Chile, the son of U.S. Methodist missionaries. His family returned to the United States in 1903. He obtained his doctorate in Semitic languages at Johns Hopkins university, Baltimore, Md. While there he studied under Paul Haupt, whom he succeeded in 1929 as W. W. Spence professor of Semitic languages, a position he held until his retirement in 1958.

Appointed fellow of the American School of Oriental Research, Jerusalem, in 1919, Albright served as the school's director for 12 years (1920–29, 1933–36). Among his excavations are Gibeah of Saul, Tell Beit Mirsim (Kirjath-Sepher), and, in association with others, Beth-zur and Bethel in Palestine and Baluah and Petra in Jordan. In 1950–51 he was chief archaeologist of excavations made by the American Foundation for the Study of Man at Wadi Bayhan (Beihan), Hajar Bin Humaid and Timna in Arabia. In addition; he undertook important archaeological explorations in Jordan and in Sinai. He was a pioneer in stressing the value of archaeology and of topographical and linguistic studies for biblical history, and in making pottery and potsherd identification a reliable scientific tool.

Albright's scientific writings, which considerably influenced the development of biblical and related near eastern scholarship, include, among others, *The Archaeology of Palestine and the Bible* (1932–35), *The Vocalization of the Egyptian Syllabic Orthography* (1934), *The Excavation of Tell Beit Mirsim* (1932–43), *From the Stone Age to Christianity* (1940–46) and *Archaeology and the Religion of Israel* (1942–46); *The Bible and the Ancient Near East* (1961).

ALBULA PASS, in the Albula Alps in Switzerland, the principal route from northeast Graubiinden to the upper Engadine, has been used since the 13th century. A carriage road (highest point, 7,585 ft.) was made across it in 1865, but for a long time it was

not used as much as the Roman route over the Julier pass (7,493 ft.). The opening of the railway in 1903, however, greatly increased its importance. Starting from Chur the railway follows the Rhine to Reichenau (6¼ mi.), and then the Hinterrhein to Thusis (10½ mi.). It then runs through the deep Schyn gorge (cut by the Albula torrent) to Tiefencastel (7½ mi.), where it leaves the Julier route to the south and continues to follow the course of the Albula past Filisur and Bergiin (12½ mi.) to the mouth (5,879 ft.) of the first of the three spiral tunnels (each ¾ mi. in length, highest point 5,987 ft.) before entering the 3¾ mi. long tunnel at Preda which was pierced below the pass. The railway then descends through the Bevers gorge to Bevers (24 mi.) in the upper Engadine, about 5 mi. below St. Moritz, which is 56 mi. from Chur by this route. (A. F. A. M.)

ALBUMAZAR (ALBUMASAR; also ABU-MASHAR) (805–886), a celebrated Muslim astrologer, was born in Balkh, Khurasan, Persia, flourished in Baghdad and died in Wasit, central Asia. His principal works were translated into Latin: *Zntroductorium in astronomiam* (1489); *De magnis conjunctionibus* (1489), plagiarized from al-Kindi; *Flores astrologici* (1488). He maintained in the second that the world, created when the seven planets were in conjunction in the first degree of Aries, will come to an end at a like conjunction in the last degree of Pisces. Albumazar's name is used for the subject of *L'astrologo* by Giovanni Battista della Porta (1606), a play adapted in *Albumazar* by Thomas Tomkis, played before James I in 1615 and revived by John Dryden in 1668.

See G. Sarton, *Introduction to the History of Science*, vol. i (1945). (D. McK.)

ALBUMINS are a class of proteins characterized by heat coagulability and solubility in dilute salt solution. Among the best known are: ovalbumin (egg white), lactalbumin (in milk) and blood serum albumin. The last has the important function of maintaining the osmotic pressure of blood; thus human serum albumin is used medically for the treatment of shock. The molecular weight (69,000) and shape (ellipsoid, 150 Å long by 38 Å in diameter) of human serum albumin are ideally suited for osmotic regulation. (See SHOCK.)

The albumins of animal blood are similar to human albumin in gross chemical and physical properties. During World War II strenuous efforts were made to utilize albumin from bovine blood for the treatment of shock in humans, but anaphylactic reactions obtained in test subjects were adjudged too severe for safe usage. The resulting availability of highly purified bovine albumin, however, contributed to the remarkable postwar expansion of protein research.

See A. White *et al.*, *Principles of Biochemistry* (1954); H. Neurath and K. Bailey (eds.), *The Proteins: Chemistry, Biological Activity, and Methods* (1953–54). (W. F. Wh.)

ALBUMINURIA is the condition in which the urine contains abnormal amounts of the protein albumin. Other proteins and similar compounds such as albuminoses and proteoses occasionally also are found in the urine; these conditions are called proteinurias. Excessive loss of protein from the body produces serious physiologic changes, and the loss of even small amounts may profoundly affect metabolism. Therefore, the detection of albumin in the urine is of great diagnostic importance, for its presence may indicate serious pathologic changes in the body, particularly in the kidneys. The urine may contain red blood cells or hemoglobin, a protein found in red blood cells, but these conditions are not classified as albuminuria. Protein also may appear in the urine as a result of injury or disease of parts of the urinary tract other than the kidneys, being referred to as "accidental," "false" or "post-renal" albuminuria.

Although the urine normally contains minute amounts of albumin, under normal conditions the kidneys do not permit the escape of appreciable amounts of the blood proteins. However, when the kidneys are diseased, particularly in nephritis (see KIDNEY, DISEASES OF), their ability to prevent the loss of protein is seriously affected and these substances appear in readily detectable amounts in the urine. In severe albuminuria the loss of protein may be from one gram to two grams per 100 cubic centimetres of urine.

Diagnosis of albuminuria is made by means of chemical tests which result in precipitation and coagulation of the protein dissolved in the urine. Usually in these tests acids, such as nitric, sulfosalicylic or acetic, are added to the urine; protein, if present in the urine, will form a white or cream-coloured precipitate. Use of heat when the urine is acid also will cause the coagulation of protein. Determination of the amount of protein requires more elaborate chemical tests which usually depend upon chemical analysis for nitrogen in the precipitated protein.

Under certain conditions, the urine of persons apparently healthy may contain albumin (physiologic albuminuria). The commonest causes are strenuous muscular exercise, excessive protein in the diet or exposure to cold. Protein is also commonly found in the urine of infants and women in the later stages of pregnancy. The appearance of albuminuria may be intermittent (paroxysmal albuminuria) and without obvious cause. A special example of physiologic albuminuria is orthostatic or postural albuminuria, which disappears when the patient remains in bed but reappears when he gets up.

The chief significance of albuminuria is in reference to nephritis, in which albumin characteristically appears in the urine. Frequently, however, during the course of the disease protein is absent, and repeated tests usually are necessary before the signs and symptoms of the patient can be correlated with the presence or absence of albuminuria.

A proteose known as Bence Jones protein occasionally may be found in the urine, occurring in connection with certain diseases such as multiple myeloma; similar proteoses may also be found in the urine of persons ill with leukemia, osteomalacia and myxedema. The presence of Bence Jones protein in the urine can be determined because, unlike albumin, the white precipitate that forms in the presence of heat and acetic acid at 60° C. dissolves when the temperature is raised to 100° C., again to reappear when the mixture is cooled. Albumin remains in the precipitated form at the temperature of 100° C. (T. B. M.)

ALBUQUERQUE, AFFONSO DE (1453-1515), known as THE GREAT, the second viceroy of Portuguese India and the virtual founder of the Portuguese dominion in the Indian ocean, was born at Alexandria, near Lisbon, in 1453. He was already a veteran soldier when in 1503 he made his first expedition to India, where he obtained permission from the king of Cochín to build a Portuguese fort. He returned home in July 1504, and King Emmanuel gave him the command of a squadron of 5 vessels in the fleet of 14 which sailed for India under Tristão da Cunha. After a series of attacks on the Arab cities on the east coast of Africa, Albuquerque separated from Da Cunha and captured (Sept. 1507) the Island of Ormuz in the Persian gulf; he held the island, then one of the chief centres of commerce in the east, for some months. He reached the Malabar coast at the end of 1508 and produced a commission from the king empowering him to supersede the governor Francisco de Almeida. The governor imprisoned him, and he was only released on the arrival of the grand marshal of Portugal with a large fleet.

The strategic operations which Albuquerque now set in motion were designed to secure four major fortified bases, Aden, Ormuz, Goa and Malacca, from which Portuguese power could control the commerce of the Indian ocean and southeast Asia. An unsuccessful attack upon Calicut in Jan. 1510 was immediately followed by the capture of Goa. Albuquerque abandoned the town in August and returned with reinforcements in November when he obtained undisputed possession. He then directed his forces against hhalacca, which he subdued after a severe struggle. In 1512 he sailed for the coast of Malabar. On the voyage Albuquerque's vessel, the "Flor de la Mar," which carried the treasure he had amassed in his conquests, was wrecked and he himself barely escaped with his life. In September of the same year he returned to Goa where he suppressed a serious revolt.

For some time Albuquerque had been under orders from the home government to undertake an expedition to the Red sea to secure it exclusively for Portugal. Accordingly he besieged Aden in 1513 but was repulsed and his voyage into the Red sea, the first ever made by a European fleet, had no substantial result. His last

success was the recapture of Ormuz in 1513.

Albuquerque had several enemies at the Portuguese court. On his way home from Ormuz he met, at the entrance to Goa harbour, a ship from Europe bearing dispatches announcing that he was superseded by his personal enemy Lope Soarez. He died at sea on Dec. 15, 1515. Before his death he wrote a letter to the king vindicating his conduct and claiming for his son the honours and rewards due to himself. His body was buried at Goa and in 1566 was removed to Portugal; it is, perhaps, the most convincing proof of the justice of his administration that Moslems and Hindus used to go to his tomb to invoke protection against the injustice of his successors.

BIBLIOGRAPHY.—Affonso (Braz) de Albuquerque, *Commentarias do Grande Affonso d'Albuquerque* (1557), Eng trans. by W. de G. Birch, 4 vol., Hakluyt Society (1875-84); *Cartas de Affonso de Albuquerque*, 7 vol. (1884-1935); Edgar Prestage, *Afonso de Albuquerque* (1929) (R. A. SN.)

ALBUQUERQUE, the largest city of New Mexico, U.S., seat of Bernalillo county, was founded in 1706 when 36 families settled at a ford on the Rio Grande opposite a pass between the Sandia and Manzano mountains to the east. The town, named for the duke of Albuquerque, then viceroy of New Spain, became an important trading centre on the Chihuahua trail from Mexico. After 1800, growing trade on the Santa Fe trail brought settlers from the states. After U.S. occupation (1816) an army post was established there. During the American Civil War the town was captured by the Confederates (1862), but remained loyal to the Union.

The original plaza was the town's centre until 1880 when the Atlantic and Pacific railroad (later the Atchison, Topeka and Santa Fe) laid its tracks one mile east of the plaza. The town quickly closed the gap with a streetcar line and began to spread eastward. By the time the "new town" was organized as a town (1885) the first "r" had been dropped from the name. Albuquerque was incorporated as a city in 1890 and adopted the commissioner-manager form of government in 1917. The characteristically Spanish "old town" of Albuquerque and the mission church of San Felipe de Nerí (1706) still survive.

The population of the town was 11,020 in 1910. As New Mexico's climate became favourably known for the treatment of tuberculosis, new citizens came and several sanatoriums were built. Numerous federal government agencies were established there in the 1930s and by 1940 the population was 35,449, after which the establishment of nuclear research centres was responsible for substantial population increases, to 96,815 by 1950 and to 201,189 by 1960. The population of the standard metropolitan statistical area (Bernalillo county) in 1960 was 262,199. (For comparative population figures see table in NEW MEXICO: Population.)

One year after the first atomic bomb, designed and assembled at Los Alamos as the Manhattan project, was exploded near, Alamogordo on July 16, 1945, a branch laboratory was set up at Albuquerque. In 1949 the Sandia corporation was formed as a subsidiary of Western Electric company to take over the laboratory activities and, under a nonprofit contract with the Atomic Energy commission (A.E.C.), to conduct research, development and prototype production on the ordnance aspects of atomic weapons in close support of the University of California's nuclear physics laboratories at Los Alamos and at Livermore, Calif. In the same year Kirtland air force base, established on the site of a municipal airport and used for flight tests of the Manhattan project, became the U.S. air force special weapons centre; it also served for flight tests for the A.E.C. In the early 1960s control of the field was turned over to the city, the air force remaining as a tenant.

Albuquerque also has numerous light industries and distributes supplies and material of all kinds to the sheep and cattle industry, to mining and timbering operations and to smaller cities and towns throughout the state. The Santa Fe maintains large railroad shops there.

Albuquerque is the seat of the University of New Mexico. The university, founded in 1889, was remodeled and enlarged in 1903 in an adaptation of the pueblo style of architecture, suggested by the nearby pueblo of Isleta.

The bracing climate and the large proportion of sunshiny days have given Albuquerque a reputation as a health resort. The city, in co-operation with the Middle Rio Grande Conservancy district, formed to drain marshes and develop irrigation for agriculture, established a natural park along the river with swimming beach and zoo. (E. FE.)

ALBURY, a city of New South Wales, Austr., about 135 mi. S.W. of Canberra (q.v.). It lies on the north bank of the Murray river, approximately 1,470 mi. from its mouth, and on the border between New South Wales and Victoria. Pop. (1954) 16,726. The mean temperature is 60.7° F. and annual rainfall 27.65 in., of which 18.9 in. falls between April and October. The city's position on the flank of the eastern highlands and on the main connecting lines between Sydney (about 450 mi. N.E.) and Melbourne (about 200 mi. S.W.) contributes to its importance as a distributing and marketing centre. The Victoria and New South Wales railway systems join there. At the centre of the eastern Riverina (q.v.), Albury adjoins a rich agricultural and pastoral district producing sheep, wheat, fruit and dairy products, and has many light industries. The district provides fishing, boating and skiing as well as varied and beautiful scenery for tourists.

The Murray river was first crossed at this site by the explorers Hamilton Hume and William Hovell in 1824. The tributaries Mitta Mitta and Kiewa meet the Murray near Albury and the historic River Murray agreement (1914) resulted in the building of the nearby Hume reservoir to the east of the city. Albury became a municipality in 1859 and a city in 1946.

ALCAEUS (c. 620—c. 580 B.C.), Greek lyric poet born in Mytilene in Lesbos, wrote in local (Lesbian-Aeolic) dialect on diverse themes in an unprecedented variety of metres. He was a contemporary of Sappho. What remained of his work in the 2nd century B.C. was collected and edited in ten books, first by Aristophanes of Byzantium and later by Aristarchus. This edition did not survive and nothing of Alcaeus' poetry remained except a few brief quotations in other authors. In the 20th century, however, the stock was greatly increased (and the reputation of Alcaeus greatly enhanced) by the recovery of fragments of at least 21 different papyrus texts, all from the 1st to the 3rd centuries A.D.

Most of the fragments fall under four main headings, very diverse in tone, style and matter: (1) delicately phrased hymns in honour of divinities and legendary persons; (2) love poems (sparsely represented now, but attested by Cicero, Horace and others); (3) other songs for recitation at table, various in theme and mood; (4) political poems, reflecting the struggle for power in Mytilene, including vituperative attacks on enemies, especially Pittacus. Enough survives to indicate the broad outlines of Alcaeus' career. When the ancient hereditary kingship of Mytilene ended (mid-7th century B.C.), several groups of nobles competed for supremacy. Alcaeus, himself of good family, was a champion of one such group, and much of his life seems to have been spent in a vain struggle to obtain control of the state. His poems, supplemented by other scanty sources (themselves dependent on his authority) show, first, the brothers of Alcaeus together with Pittacus overthrowing a rival, Melanchrus; then Alcaeus himself fighting beside Pittacus against the Athenians at Sigeum (in this battle Alcaeus dropped his shield and ran); then the treachery of Pittacus, who broke his oath of loyalty to the group and joined the archenemy Myrsilus in control of Mytilene, leaving Alcaeus in exile; next, jubilation at the death of Myrsilus, and an appeal to the people to reject Pittacus despite which Pittacus was elected sole ruler. So far as is known, Alcaeus' party never came to power and the fragments afford no evidence about his career after the establishment of Pittacus as sole ruler (traditionally 590 B.C.).

All Alcaeus' poetry shows his natural, easy command of language and metre. He is concise, lucid and forceful in expression, using as a rule simple and apt words with very little embellishment or artifice. His poetry is straightforward and sincere, though never profound in thought, showing a keen eye for beauty, and a comprehensive range of loves and hatreds. Its political outlook is narrow and selfish.

BIBLIOGRAPHY.—Fragments ed. by E. Lobel (1927). Complete text (to date), together with Sappho, ed. by E. Lobel and D. L. Page in

Poetarum Lesbiorum Fragmenta (1955). See also the companion volume by D. L. Page, *Sappho and Alcaeus* (1955), with Eng. trans., commentaries and further bibliography. (D. L. P.)

ALCAICS, a variety of Greek lyric stanza named after and presumably invented by the Lesbian poet, Alcaeus, and employed in Latin by Horace. The first two cola ("limbs") are of the same form: anceps (a long or short syllable), cretic (—v—), anceps and —v—v—; e.g.,

Ōdī profanum || vulgus et arceo.
favete linguis: || carmina non priūs

The third colon consists of anceps, cretic, anceps, cretic, anceps:

audita musarum sacerdos

and the fourth is a prosodiac (see PROSODY, CLASSICAL):

virginibus puerisque cāto

Alcaeus sometimes permits a word to overlap from the third to the fourth colon, so that these must originally have been conceived as a single verse. Horace's alcaics are composed according to strict rules and differ in some ways from those of Alcaeus. Horace's *incipitia* are usually long. In the first two cola there is caesura after the fifth syllable (as in his lines quoted above). Word-end occurs at this point in about two-thirds of Alcaeus' lines. In the third colon, word-end after the fourth syllable is avoided by both Alcaeus and Horace (with the exception of *Odes* I, xxvi, 11). Word-end after the fifth syllable, when long, is avoided by Alcaeus, but freely allowed by Horace.

Tennyson's Milton is an example of English alcaics.

(L. P. E. P.)

ALCALÁ (Arabic AL KALA, "fortress" or "castle"), is the name of 13 towns in Spain, founded and named by the Moors.

ALCALÁ DE HENARES, lies on the Henares river in the central plateau 29.5 km. (18 mi.) N.E. of Madrid by road. Pop. (1960 est.) 21,000 (mun.). It contains the unique Magistral Church of San Justo, called La Magistral because Pope Leo X in 1519 expected all its canons to have the degree of doctor or professor. The university buildings, now used as a school, include the college of San Ildefonso (1508) with a beautiful façade. The former archbishops' palace is a seminary. There are military quarters, an airfield and a bull ring. Known under the Romans as Complutum, Alcalá was destroyed in 1000 and rebuilt in 1038 by the Moors, who called it Al Kala en Nahr. It was reconquered in 1083 by Alfonso VI. Its university was founded in 1508 by Cardinal Francisco Jiménez de Cisneros (q.v.) who there ordered the production of the Complutensian Polyglot Bible (1514–17). In 1836 the university was moved to Madrid. The town was the birthplace of Cervantes, the emperor Ferdinand I and Catherine of Aragon. Products include chemicals, cotton goods, perfumes, pottery and the famous (iced) "almonds of Alcalá." (J. GA.)

ALCALÁ LA REAL, a municipality and city in the province of Jaén, lies on the Sierra de Parapanda, 76 km. (47 mi.) S. of Madrid. Pop. (1950) 30,062 (mun.). Its title, "la Real," was granted by its conqueror, Alfonso XI of Castile, in 1341. The town has a medieval appearance with stone houses having heraldic shields and interior patios. It had great strategic importance during the conquest of Granada from the Moors; parts of the walls remain. The surrounding land is fertile and well watered, producing grain, olives and pasture.

ALCALÁ DE LOS GAZULES lies on the Barbate river in the province of Cádiz. Pop. (1950) 10,340 (mun.). It takes its name from a famous Moorish family. Sheep and goats are raised, and there are about 23 sq.mi. of cork trees. Flour milling is also carried on.

ALCALÁ DE GUADAIRA lies on the Guadaira river 14 km. (8½ mi.) S.E. of Seville in Seville province. Pop. (1950) 25,049 (mun.). It is popularly known as Alcalá de los Panaderos because of the number (64) of its bakeries and its flour mills. The other big industry is connected with olives many of which are exported; oil from them is expressed and refined in the town. (M. B. F.)

ALCALÁ ZAMORA, NICETO (1877–1949), Spanish statesman, who was president of the second republic in Spain from

1931 to 1936, was born at Priego, Córdoba, on July 6, 1877. Elected to the Cortes in 1905, he became minister of works (1917) and minister of war (1922). In 1930 he declared himself a Republican and was sent to prison for his share in a military rising at La Jara. He headed the poll in Madrid in the municipal elections of April 1931 and, as leader of the revolutionary committee, demanded Alfonso XIII's abdication. After Alfonso's departure (April 14), he became prime minister of the provisional government. He resigned on Oct. 14, 1931, because of the acceptance by the Cortes of the anticlerical articles (no. 24 and 26) in the new constitution. Nevertheless, on Dec. 11, 1931, he was elected the first president of the second republic.

Behaving in strict obedience to the new constitution, with which, as a devout Roman Catholic, he himself was not fully in agreement. Alcalá Zamora attempted to exercise a moderating influence in politics. In fact, he was increasingly attacked by both right- and left-wing parties, and after the popular front victory of Feb. 1936, a motion for his deposition was passed by the Cortes by 238 votes to 5. Subsequently, Alcalá Zamora went into exile in France and, later, in Argentina. He died at Buenos Aires on Feb. 18, 1949.

ALCALDE (from Arabic al-qadi, "judge"), the Spanish title for the mayor of a town or village. Formerly the term was applied to local government officials whose functions were various but always included a judicial element. Types of alcalde were differentiated according to the specialized nature of their judicial functions: the alcalde de *corte* was a judge of the palace court, with jurisdiction in and about the residence of the king; the alcalde mayor assisted the judges (*corregidores*) appointed by the king in the towns. From the 19th century the alcalde has had the dual character of leader of the local council (*ayuntamiento*) and representative of the central government. His duties have become mainly administrative, with scarcely any judicial attributes.

ALCAMENES, a Greek sculptor perhaps from Lemnos, but domiciled in Athens. He was a younger contemporary of Phidias and noted for the delicacy and finish of his works, among which a Hephaestus and an "Aphrodite of the Gardens" were conspicuous. Pausanias says that he was the author of one of the pediments of the temple of Zeus at Olympia, but there are great chronological and stylistic difficulties in accepting this. At Pergamum there was discovered in 1903 a copy of the head of the "Hermes Propylaeus" of Alcamenes identified by an inscription

See Gisela M. A. Richter, *Sculpture and Sculptors of the Greeks*, rev. ed., pp. 237-240 (1950).

ALCAMO, a town in the province of Trapani, Sicily, lies 51½ mi. W.S.W. of Palermo by railway. Pop. (1957 est.) 43,443 (commune). The name comes from the Saracenic fortress of Alqamuh on Monte Bonifato. The present town was founded by the emperor Frederick II in 1233. The 17th-century Assunta church contains frescoes by Guglielmo Borremans and sculptures by Antonello Gagini (1511); the church of S. Tomaso has an elaborate 14th-century doorway.

ALCÁNTARA, a small agricultural town of western Spain in the province of Cáceres, is built on a rock above the left bank of the Tagus about 45 mi. N.W. by road of Cáceres and 7 mi. E. of the Portuguese frontier. Pop. (1950) 4,150 (mun.). The walled town was named after the six-arched Roman bridge (Arab. al-kantara, "the bridge") spanning the Tagus, built in A.D. 105-106 in honour of the emperor Trajan. Destroyed by the Moors in 1214, it was restored in 1543 and has been altered many times since. There is a small Roman temple where it joins the left bank and a triumphal arch in the centre. The church of Santa Maria de Almocobar dates from the 13th century; that of San Benito (1576) belonged to the now ruined convent and contains tombs of many grand masters of the knights of Alcántara. The town is served by buses to Cáceres and Ceclavin. It is doubtful whether there was a Roman town there, but it became famous about 1215 as the stronghold of the knights of Alcántara.

ALCATHOUS, in Greek legend, was a son of Pelops, brother of Atreus (q.v.). He slew the Cithaeronian lion, which had killed Euippos, son of King Megareus, and thereby won the king's daughter and succeeded to the throne of Megara. With the help of Apollo he rebuilt the malls of the city, which had been destroyed

in the Cretan invasion (see NISUS), becoming a kind of refounder of the city. Games were celebrated in Alcathous' honour, as described in Pindar's Isthmionikai, and a heroum was dedicated to him in the city. (T. V. B.)

ALCÁZAR DE SAN JUAN, a town of central Spain in the region of New Castile and province of Ciudad Real, lies on the high Iberian plateau 2,135 ft. above sea level, 92 mi. S.S.E. of Madrid by rail. The old part of the town has many narrow streets in contrast with the wide avenues and tree-lined squares of the newer districts. The church of Santa Maria stands on the site of a pre-Christian temple of Hercules and nearby is the 14th-century tower of Don Juan of Austria and the municipal archaeological museum containing Roman mosaics of the 2nd and 3rd centuries. The main line south from Madrid divides at Alcázar de San Juan, one branch running southeast and the other southwest. There are railway works and ironworks. The town is the marketing centre of an agricultural and industrial district, its particular products being wines and cheeses, a cheese made from sheep's milk being a speciality. Pop. (1950) 25,259 (mun.).

Alcázar de San Juan was known to the Romans as Alces. The Arabs renamed it Al Kazar ("the palace"). The knights of St. John conquered it in 1186 and ruled it until 1292, when it was captured by King Sancho IV of Castile. It was the centre of the order of San Juan in the 14th, 15th and 16th centuries.

ALCAZARQUIVIR (KSAR EL KEBIR OF AL QSAR AL KBIR, "The Great Fortress"), a town of Morocco, lies on the road from Rabat to Tangier. Pop. (1960) 34,035. It is at the centre of a wide cultivated plain crossed by the Lucus (Loukkos) river, and is essentially a rural market. The old Arab village was enlarged and surrounded with walls by Yakub al-Mansur (1184-99). In 1912 the Spanish found a sleeping town which they occupied and largely rebuilt. Near the town, by the banks of the Makhazan river, is the site of the "battle of the three kings," fought in 1578 between Dom Sebastian, king of Portugal, and the Moors under Abd al-Malek, in which the Moors were victorious, though both kings perished as well as the deposed Mohammed XI, who had called in the Portuguese to his aid. (G. L. M.)

ALCHEMY. In the strict sense, alchemy is the pseudo science which concerns attempts to transform base metals such as lead or copper into silver or gold. At all times, however, such attempts have involved purely chemical procedures, and the pseudo science has, for most of its existence, been closely connected with the development of chemistry itself. In fact, for many centuries the history of alchemy is the history of chemistry.

The close connection is shown in the name, which in the opinion of most scholars is derived from the Greek word cheo, "I pour" or "cast," and which refers to the activities of the metal workers who were the originators of alchemy. An alternative theory ascribes the word to the ancient name for Egypt, Khem, "the Black Land" (referring to the black soil of the country). This would indicate the Egyptian origin of alchemy. During the Arabic period, the Arabic article, al, was added to produce the word alchemy, and when chemistry emerged as an independent science, the article was dropped.

EARLY HISTORY AND PHILOSOPHICAL BASIS

The exact date at which alchemy began is not known. The first alchemical writings, at least in the western world, date from the 3rd or 4th centuries A.D., but they already represented a flourishing science and it is thought that the earliest alchemists were active during the 1st century. There is no doubt that alchemy originated in the Hellenistic culture of Alexandria in Egypt. Alexandria at this period was the centre of the learned world, and there met and mingled the three streams from which alchemy was formed. These were Greek philosophy, Egyptian technology and the mysticism of the middle eastern religions.

Greek philosophy always attempted to explain the nature of the entire physical world, though the Greek contempt for manual labour prevented any effort to check these explanations by experiment. The theories reached their culmination in the system of Aristotle, whose ideas for nearly 2,000 years remained the basis for all attempted scientific speculations. Certain of his ideas con-

tributed directly to the theories of alchemy. Aristotle believed that there existed a prime matter which was the basis for all substances in the terrestrial world. Upon this prime matter a variety of forms could be impressed by suitable means. The interaction of matter and form gave rise to the four elements, fire, air, water and earth, which in turn through their various combinations produced all material objects. In a sense these elements represented what we today consider physical properties. A preponderance of earth in a body caused it to be solid; water tended to produce liquids, or at least substances which could be melted; air was a spirit, sometimes equated with the soul by the Stoics; and fire represented the principle of combustion. Changes in the proportions of these elements resulted in change in the form of the prime matter, and so, in theory, any substance could be changed into any other substance if the right conditions could be found.

Egypt had long had a class of skillful artisans who were especially adept in working with metals. The Hellenistic culture of Alexandria encouraged some of these artisans to speculate on the causes for the physical facts which they observed. Since they operated their own workshops, they had lost the old Greek contempt for work with the hands, but they now gained the philosophic viewpoint which had animated the Greek cosmologists. These men formed a class which in its combination of philosophy and technology approached more nearly the modern concept of a group of scientists than existed again until the Renaissance. Such men as Archimedes in his studies of hydrostatics or Hero in his mechanical inventions which used the power of steam are examples of these early scientists.

The first alchemists were typical members of this group. They were the metallurgical workers who not only prepared gold and silver objects for wealthy nobles, but also manufactured cheaper substitutes for poorer citizens. They naturally attempted to make these resemble true gold or silver as much as possible, while recognizing the inferior nature of their materials. In view of the Aristotelian theories, however, they knew of no reason why they could not make real silver or gold almost as easily as they could manufacture the obvious substitutes.

They were supported in this view by the astrological ideas which came chiefly from Mesopotamia. The astrologers believed in the coexistence of the macrocosm, the great world of stars and planets, and the microcosm, the small world of man. Events in the macrocosm were reflected in the microcosm, and vice versa. Thus, under the proper astrological influences a change of lead to gold might easily occur, and the proper way to bring this change about was to use the methods of the microcosm: growth and development. As men grew and changed, so could the metals grow and change; as the human soul perfected itself and passed through death and resurrection to the perfection of heaven, so could metals develop in the earth from the less perfect to the most perfect, gold. The artisan in his laboratory could perhaps hasten this process by careful nurture and long heating, by "killing" the metal and then reviving it in more perfect form until the ultimate perfection of gold was reached.

Thus copper could be "killed" by blackening it (converting it to the black oxide) and then revived by forming a silver-coloured alloy with mercury or arsenic, a whitening process. Other reagents produced yellow or red colours and represented the final steps in the process. This sequence of colours made a strong impression on the Alexandrian artisans, who besides their metallurgical work, were often dyers as well. They came to believe that the series of colour changes, black-white-yellow (later red), was essential to a successful transmutation, and that the stage of any such change could be determined by the colour at any given time. The sequence black-white-red became standard in all later alchemy, and many chemical discoveries resulted from attempts to produce the correct colour.

It can be seen then that the original alchemy was a practical series of chemical operations, guided by the accepted theory of the nature of matter, and in its actual operations directed by the astrological and religious ideas which circulated freely in Alexandria. This practical alchemy could be, and was, expressed symbolically in terms of the perfection of the human soul. This aspect

appealed to many who were in no way interested in actual laboratory operations. Almost from the first there occurred a split between the practical and the mystical alchemists, and this distinction existed throughout the entire history of the art.

The practical alchemists invented and used many types of laboratory apparatus which in modified form are used today. Stills, furnaces, water baths, flasks and beakers were in everyday use. Chemical reactions were their stock in trade. The alchemists were still essentially artisans, however, and did not wish to reveal their trade secrets. They therefore invented many concealing names for the materials with which they worked. Almost every piece of apparatus, every reagent, acquired a symbolic name. Astrological influences led to ascribing each metal to a heavenly body. Gold, the noblest metal, obviously belonged to the sun, and silver to the moon. There had to be five other metals, since there were five planets. In general, copper belonged to Venus, lead to Saturn, iron to Mars, tin to Jupiter, and mercury to the planet of that name. The metals were then represented in alchemical manuscripts by the astrological sign of their controlling body. Other reagents were given names such as "bile of the tortoise." Such names multiplied until the uninitiated could not understand the text at all. The writers usually ascribed their manuscripts to some god, hero, king or philosopher of olden time. Alchemical manuscripts were said to have been written by Isis, Moses, Aaron, Hermes, Solomon, Democritus and many others.

These confusing tendencies, initiated by the practical alchemists, were intensified as the mystically minded began to develop alchemical ideas. C. G. Jung has shown that the symbolism of alchemy appeals to basic psychological tendencies of the human mind, and so it is not surprising that many were attracted to alchemy by its symbolism and its search for perfection, without any knowledge of the practical chemistry upon which it was originally based. Their mystical writings tended still further to bring confusion to the subject. Even the earliest works which have come down to us, the *Physica et Mystica* by an author who wrote under the name of Democritus, but was probably a certain Bolos of Mendes, and the encyclopaedia of alchemy by Zosimus,

PHOTOGRAPH, HANFSTANGL

"THE ALCHEMIST." DETAIL FROM A PAINTING BY DAVID TENIERS THE YOUNGER (1610-90)

are very difficult to read. As Hellenistic philosophy shifted more and more from the technical scientific viewpoint to the emphasis on divine revelation of Gnosticism, Neoplatonism and Christianity, the alchemical writings became more and more mystical and allegorical. They often became mere commentaries on each other, adding nothing to what had already been said. The later Byzantine manuscripts are of this type.

Chinese Alchemy. — While these developments were occurring in the west, a similar alchemy was growing up in China. Based on the Taoist philosophy (see TAOISM) which sought to understand the "way" of nature (tao means "way" or "path"), Chinese alchemy like its western counterpart tried to perfect base metals into gold. In two respects, however, the Chinese form differed from the western. The Chinese alchemist made use of a "medicine," a substance which he added to mercury or other metals to bring about the transmutation. The gold thus prepared was valued less for its own sake than for the fact that the metal possessed the power of conferring immortality on anyone who ate it, or in less favourable cases, at least of prolonging life and curing illnesses.

As time passed, both in the west and in the east the mystical alchemists became dominant. Writings became more and more obscure; the alchemists separated themselves more and more from the laboratory. In China the art degenerated into a mass of superstitions and contributed nothing more to the intellectual life of the nation. In the west a different path was followed.

Arabian Alchemy. — The Nestorian Christians who broke away from the Orthodox Church in Byzantium in the 5th century spread their faith rapidly throughout Asia Minor. They founded schools in Edessa, Nisibis and Jundi-Shapur, and in these they taught the philosophy and science of their Hellenistic background. They translated all the available manuscripts of Greek learning into their own language, Syriac. Many alchemical works were included in these translations. In the 8th and 9th centuries the Nestorians came into close contact with the rising power of the Arabs, among whom a group centring around the court of the Caliph in Baghdad became deeply interested in Greek science. The manuscripts were again translated, this time from Syriac into Arabic.

A number of practical alchemists began to work among the Arabs, bringing the art of alchemy back to its origins in the laboratory. These included such famous physicians as Rhazes and Avicenna (*q.v.*). The most active workers were to be found among the sect of the Isma'iliya (whose modern descendants follow the Agha Khan). This group published a large body of alchemical and mystical literature, most of which was attributed to a certain Jabir ibn Hayyan (see GEBER). Jabir may have actually lived in the 8th century and written alchemical books, but the great majority of the works said to have been written by him were certainly composed by members of the sect in the 9th and 10th centuries. Nevertheless the name of Jabir became the best known of all Arabic alchemists.

Arabian alchemy drew its chief ideas from the alchemy of Alexandria, but the Arabs were also in contact with China and they took over the two most characteristic ideas of eastern adepts. The Chinese "medicine" which had to be added to base metals to produce gold became the "philosopher's stone" of later European alchemy, and the idea of the healing power of gold was expanded into a belief that this philosopher's stone could not only heal "sick" (*i.e.*, base) metals by converting them to gold, but could also act as the elixir of life, in much the same way as the Chinese gold. The Arabian alchemists also modified the Aristotelian idea of the four elements by supposing that all metals were actually composed of two immediate constituents, sulfur and mercury, though these in turn were built up from the four elements. The sulfur and mercury were not the actual substances, whose properties were perfectly well known, but represented the basic principles of combustibility and liquidity which made possible burning or melting.

Arabic alchemists discovered important new classes of chemicals such as the caustic alkalies and improved such technical methods as distillation. After the 10th century, however, the same trend

AN ALCHEMIST HOLDING A SALAMANDER IN THE FIRE. AN ILLUSTRATION FROM AN ALCHEMICAL TREATISE. "THE BOOK OF LAMBSPRINCK." THE SALAMANDER WAS BELIEVED TO BE BORN IN FIRE AND CAPABLE OF WITHSTANDING ITS FLAMES

toward domination by mystical and allegorical thinking became apparent as had appeared in the west and in China. Again a new people stepped in to reverse this trend.

DEVELOPMENTS SINCE THE 10TH CENTURY

Almost all traces of Greek philosophy and science had been lost in western Europe after the fall of Rome. Alchemy completely disappeared. In the 11th and 12th centuries, however, a reawakening of interest in science led to a recognition of the value of the Arabic accomplishments. In Spain and Sicily, where Europeans and Arabs were in close contact, new schools of translation were set up. Many scholars devoted themselves to translating the works of Arabic physicians, philosophers and scientists into Latin. Works which had come from Greek through Syriac and Arabic now reached the west and through their Latin versions eventually were translated into all the major European tongues. Among these were many of the alchemical manuscripts.

These first translations were in no sense made by alchemists. Neither was their wider dissemination due to alchemical influence. In the 12th and 13th centuries a number of scholars, such as Arnold of Villanova, Roger Bacon, and above all Albertus Magnus, devoted themselves to compiling all phases of human knowledge into encyclopaedic works. The alchemical explanation of the nature of matter was naturally an important part of such books. This portion of their work was at once seized upon by the alchemically minded, and alchemy entered upon a new phase of vigorous activity.

As was to be expected, the practical and mystical branches of alchemy developed more or less separately. The practical alchemists were the earliest European chemists. The most influential of these was an author who wrote under the name of Jabir, or Geber in the Latin form, probably in order to benefit from the prestige of the great Arabic alchemist. It is likely that he was a practising Spanish alchemist of the 14th century. He used alchemical theory to explain his results, but the practical portions of his books are clearly the work of a man familiar with experimental laboratory operations.

The works of Geber became the textbooks of the alchemists, but their own books, which appeared in increasing quantity, began to show the familiar shift toward mysticism and allegory. The alchemist became a recognized figure in his society, usually re-

garded with some awe and not a little contempt, for it was soon realized that most of the professed members of this group were actually dishonest charlatans. This aspect of public feeling is reflected in the Canon's Yeoman's Tale of Chaucer and in Ben Jonson's play *The Alchemist*.

At the same time many honest men spent their lives and fortunes in the attempt to transmute base metals into gold. Nobles and kings, such as James IV of Scotland and Rudolf II, the Holy Roman emperor, often supported alchemists in the hope of augmenting their revenues, though frequently the unfortunate alchemists who failed to supply the promised gold lost their lives as a result.

The alchemy of the 15th to the 17th centuries produced little that was new, though much that was obscure. Alchemical symbolism and allegory became more and more complex. Many beautifully illustrated manuscripts were produced, but their texts were usually mere repetitions of what had gone before. Gradually the practical alchemists began to turn their attention to more useful purposes than the attempt to make gold. One of the greatest of such alchemists was Paracelsus (*q.v.*) who took for his purpose the manufacture of metallic medicines to cure ills with which the Galenic physicians of his day could not cope. He thus founded the school of iatrochemistry, the chemistry of medicines, the forerunner of modern pharmacology. He and his followers spoke in alchemical language, but in spirit they were true chemists.

The revival of classical scholarship in the 16th century led to a rediscovery of Greek atomism and a strong shift away from Aristotelian theory. The newer schools of physicists and chemists no longer accepted the possibility of transmutation. The chemical facts which had been accumulated by the alchemists were now reinterpreted and made the basis upon which modern chemistry was erected.

This did not mean that the alchemists vanished. The hope of gaining great wealth through conversion of cheap materials into gold did not die easily. Alchemists have existed until the present day, but they have sunk to the level of astrologers, numerologists, and other practitioners of what once were respectable sciences.

The discovery of the structure of the atom at the beginning of the 20th century has, in a sense, vindicated one of the oldest of alchemical theories, since the electron and nucleus of protons and neutrons might be considered the prime material, and their structural relations the form which confers individual properties on material substances. By suitable treatment the modern scientist has indeed been able to transmute one element into another, and even to "make gold," but such transformations are a far cry, both in method and purpose, from the attempts of the ancient alchemists. See also CHEMISTRY: *Emergence of Alchemy*. For the historical development of science from ancient time through the 20th century see SCIENCE.

BIBLIOGRAPHY.—J. Read, *Prelude to Chemistry* (1937) contains excellent colour reproductions of alchemical illustrations. Other good general studies of alchemy are J. Read, *Humour and Humanism in Chemistry* (1947); F. Sherwood Taylor, *The Alchemists* (1949); E. J. Holmyard, *Alchemy* (1957). Special fields are covered by A. J. Hopkins, *Alchemy, Child of Greek Philosophy* (1934); O. S. Johnson, *A Study of Chinese Alchemy* (1928); J. Needham, *Science and Civilization in China*, vol. 1 (1954); P. Kraus, *Jabir ibn Hayyan. Contribution à l'histoire des idées scientifiques dans l'Islam*, 2 vol. (1942–43); C. G. Jung, *Psychology and Alchemy* (1953). The setting of alchemy in the history of chemistry is well discussed in J. M. Stillman, *The Story of Early Chemistry* (1924). The classic comprehensive works on alchemy are M. P. E. Berthelot, *Collection des anciens alchimistes grecs* (1888) and *La chimie au moyen âge* (1893); and E. O. von Lippmann, *Entstehung und Ausbreitung der Alchemie* (1919–31). (H. M. L.)

ALCIBIADES (c. 450–404 B.C.), Athenian general and statesman who provoked the sharp political antagonisms which were the cause of Athens' final defeat in the Peloponnesian War (*q.v.*). He belonged to the family of the Alcmaeonidae and was a near relative of Pericles. He was very handsome and possessed great wealth, which he squandered in every sort of dissipation and extravagance, including the upkeep of a fine stud of horses. He was an admirer of Socrates, who saved his life at Potidaea (432), a service which Alcibiades repaid at Delium. In 421 Alcibiades came

to the fore in politics as the opponent of Nicias and the peace party and engineered an anti-Spartan alliance between Athens and the democracies of Argos, Mantinea and Elis. Sparta was thus placed in a critical position, and the policy might have succeeded if Athens had disregarded the opposition of Nicias and given it wholehearted support. But in 418 Alcibiades was not re-elected general and Sparta broke up the confederacy by the crushing victory of Mantinea. Alcibiades' most bitter enemies were the leaders of the radical democrats who inherited the policies of Cleon (*q.v.*) and resented Alcibiades' influence with the people; this bitterness was aggravated when Alcibiades unexpectedly allied himself with Nicias to secure the ostracism of the radical democrat Hyperbolus in 417. When Nicias had failed in Thrace (418–417), Alcibiades became the chief advocate of the Sicilian expedition, partly from policy and partly from private ambition, and was appointed commander jointly with Nicias and Lamachus. But shortly before the expedition was due to leave the *hermae* (numerous small effigies in the streets throughout Athens) were found to have been mutilated, and Alcibiades was accused of being the originator of the sacrilege (and also of having profaned the Eleusinian mysteries). Alcibiades demanded an immediate inquiry but his enemies, led by Androcles, obliged him to set sail with the charge still hanging over him. When he reached Sicily he was recalled to stand trial, but on the journey home he escaped to Sparta. Learning that he had been condemned to death in his absence, he openly joined the Spartans and persuaded them to send Gylippus to assist the Syracusans and to fortify Decelea in Attica (which they did in 413 B.C.), advice which proved the ruin of Athens. He then passed over to Asia Minor, induced many of the Ionic allies of Athens to revolt and procured an alliance for Sparta with the Persian satrap Tissaphernes. But in a few months he had lost the confidence of the Spartans and made an enemy of their king Agis (whose wife he had seduced). He therefore retired to the court of Tissaphernes (412) and, hoping to secure his reconciliation with Athens, advised the satrap to withdraw his active support from Sparta. At the same time he conspired with the oligarchic party at Athens who brought about a revolution in 411, with the aim of having Alcibiades recalled to Athens as the price of Persian support; Androcles and Hyperbolus were murdered but in the end Alcibiades was not recalled. He therefore attached himself to the fleet at Samos, which remained loyal to the democracy, and was at last recalled by Thrasybulus, but he did not at once return to Athens. Being appointed commander in the neighbourhood of the Hellespont, he defeated the Spartan fleet at Abydos (411) and Cyzicus (410) and recovered Chalcedon and Byzantium (408). These successes encouraged him to return to Athens, where he was welcomed with enthusiasm (407); proceedings against him were canceled and he was appointed general with full powers. But he was attacked by Cleophon who after the defeat at Notium (406) induced the Athenians to dismiss Alcibiades from his command. He thereupon retired to the Thracian Chersonese. After the final defeat of Athens he was exiled and took refuge in Phrygia with Pharnabazus; who was induced by the Spartans to have him murdered (404).

Alcibiades possessed great charm and brilliant political and military abilities but was absolutely unscrupulous. His advice, whether to Athens or Sparta, oligarchs or democrats, was dictated by selfish motives and the Athenians could never trust him enough to take advantage of his talents. He could not practise his master's virtues, and there is no doubt that the example of Alcibiades strengthened the charges brought against Socrates in 399 of corrupting the youth.

See J. Hatzfeld, *Alcibiade* (1940).

(R. ME.)

ALCIDAMAS (fl. 4th century B.C.), a prominent Greek sophist and rhetorician who taught in Athens, was born at Elea in Aeolis. He was a pupil of Gorgias and a rival of Isocrates. His only extant work, *Peri Sophiston* ("Concerning Sophists"), stresses the superiority of extempore (though prepared) speeches over written ones. The oration attributed to him entitled *Odysseus* is spurious. Only fragments of his other works survive. Two papyrus fragments of his *Mouseion* are possibly part of an early version of the *Agon Homerou kai Hesiodou* ("competition Between Homer and Hesiod") which is extant in a 2nd-century A.D. form.

Aristotle criticized Alcidas for his improper and too frequent use of adjectives, and cited him as an example of frigidity of style.

BIBLIOGRAPHY.—For *Odysseus* and *Peri Sophiston* see F. Blass' ed. of Antiphon in the "Teubner Series" (1881). For fragments see C. Müller, *Oratores Attici*, vol. 2, pp. 316–318 (1858); T. W. Allen's ed. of Homer in the Oxford classical texts, vol. 5, p. 225 (1912); and G. S. Kirk, "The Michigan Alcidas-Papyrus," *Classical Quarterly*, 44:149–167 (1950). See also E. R. Dodds, "The Alcidas Papyrus Again," *Classical Quarterly*, 46:187–188 (1952); H. L. Hudson-Williams, "Impromptu Speaking," *Greece and Rome*, 18:28–31 (1949); M. J. Milne, *A Study in Alcidas and His Relation to Contemporary Sophistic* (1924); G. Walberer, *Isokrates und Alkidamas* (1938).

ALCINOÛS, in ancient Greek legend, king of the Phaeacians, on the fabulous island of Scheria, son of Nausithous and grandson of Poseidon. His reception and entertainment of Odysseus (*q.v.*), who when cast by a storm on the shore of the island was rescued by the king's daughter Nausicaa, is described in the *Odyssey*. Scheria was identified in very early times with Corcyra, where Alcinoos was revered as a hero; Homer relates that the ship in which Alcinoos sent Odysseus home to Ithaca was transformed by Poseidon into a rock, which can still be seen as the island Pontikonisi in the harbour of Corcyra (Corfu).

In the Argonautic legend, Alcinoos dwelt on the island of Drepane, where he received Jason and Medea in their flight from Colchis, pursued by her father's men who sought to compel her to return. Alcinoos agreed to return Medea only if she were still single, whereupon (as related by Apollonius Rhodius) she and Jason were married. (T. V. B.)

ALCIPHON (2nd century A.D.), Athenian rhetorician, was the author of a collection of fictitious letters, of which 124 (118 complete and 6 fragments) have been published; they are written in the purest Attic dialect and are considered models of style. The scene throughout is at Athens; the imaginary writers are country people, fishermen, parasites and courtesans, who express their sentiments and opinions on familiar subjects in elegant language. The "courtesan" letters are especially valuable, the information contained in them being chiefly derived from the writers of the New Comedy, especially Menander. Alciphron is believed to have been a contemporary and imitator of the sophist and satirist Lucian.

See M. A. Schepers (ed.), *Alciphronis rhetoris Epistularum libri iv*, in the "Teubner Series" (1905); *Letters From the Country and the Town, of Fishermen, Farmers, Parasites, and Courtesans*, trans. by F. A. Wright (1923).

ALCITHOE, in Greek legend, was the daughter of Minyas of Orchomenus, in Boeotia. She and her sisters alone once refused to participate in Dionysiac festivities, remaining at home spinning and weaving. Late in the day Dionysiac music clanged about them while their stuff turned to ivy; the house was filled with fire and smoke and the sisters were metamorphosed to bats (see Ovid, *Metamorphoses*).

According to Plutarch the sisters, driven mad for their impiety, cast lots to determine which should offer her child to be eaten. In retribution their descendants were pursued at the Agrionia (*q.v.*) by the priest of Dionysus, who was permitted to kill any he caught, as indeed once happened even in Plutarch's time.

(T. V. B.)

ALCMAEON, of Argos, in Greek legend, was the son of Amphiaras (*q.v.*) and Eriphyle. When his father set out with the expedition of the Seven against Thebes, which he knew would be fatal to him, he enjoined upon his sons to avenge his death by slaying Eriphyle (who had been bribed by Polyneices with the necklace of Harmonia [*q.v.*] to persuade her husband to fight) and undertaking a second expedition against Thebes. After the destruction of Thebes by the Epigoni (the sons of the Seven), Alcmaeon carried out his father's injunctions by killing his mother, as a punishment for which he was driven mad and pursued by the Erinyes from place to place.

On his arrival at Psophis in Arcadia, he was purified by its king, Phegeus, whose daughter Arsinoe (or Alphisiboea) he married, making her a present of the fatal necklace and the robe of Harmonia, which brought misfortune to all who possessed them. But the land was cursed with barrenness, and the oracle declared that Alcmaeon would never find rest until he reached a spot on which

the sun had never shone at the time he slew his mother. Such a spot he found at the mouth of the Achelous river, where an island had recently been formed by the alluvial deposit. There he settled and, forgetting his wife, married Callirrhoe, the daughter of the river-god.

His new wife longed for the necklace and robe, and Alcmaeon, returning to Psophis, obtained possession of them, on the pretense that he desired to dedicate them at Delphi. When the truth became known he was pursued and slain by Phegeus and his sons. On his death, Callirrhoe prayed that her two young sons might grow to manhood at once and avenge their father. This prayer was granted; her sons, Amphoterus and Acarnan, slew Phegeus, and, returning with the necklace and robe, dedicated them at Delphi.

After his death Alcmaeon was worshiped at Thebes; his tomb was at Psophis in a grove of cypresses. His story was the subject of an old epic and of several tragedies, none of which has been preserved, and of the modern parody, "A Fragment of a Greek Tragedy," by A. E. Housman. (T. V. B.)

ALCMAEON OF CROTONA (5th century B.C.), Greek philosopher and physiologist, may be regarded as a typical scientific researcher of the pre-Socratic period, before there was any clear division between philosophy and physiology (in which he had a special interest). He observed that "most things human are two" and made a "list of opposites" that bears a superficial resemblance to the Pythagorean list; but there is no clear evidence that he belonged to the Pythagorean community flourishing at Crotona in his time.

His doctrine was that health consisted in the "isonomy" of the components of the body (like a city whose citizens are all of equal standing); the "monarchy" of any one ingredient led to disease. A very similar theory is found in the Hippocratic treatise *On Ancient Medicine*, where health is said to lie in the equal "blend" of the bodily components or "powers." Alcmaeon is the first person known to have practised dissection (probably not vivisection) for scientific purposes; his aim was to discover the seat of the intelligence. He inferred that this was the brain from his observation that concussion of the brain resulted in injury to the intellect as well as to the senses; and his dissections showed "passages" connecting the brain with the eyes and ears. He also distinguished between sensation (in animals) and intelligence (in man only) and conducted research in embryology.

(A. L. Pk.)

ALCMAEONIDAE, a powerful Athenian family claiming descent from the legendary Alcmaeon, which played a leading part in the politics of the 6th and 5th centuries B.C. During the archonship of an Alcmaeonid Megacles (?632 B.C.) a certain Cylon unsuccessfully attempted to make himself tyrant and his followers were murdered when they had taken sanctuary. The Alcmaeonidae consequently incurred bloodguilt which was to be frequently raked up in later years for political reasons. The family was banished for the murder but returned by the time of Solon (archon in 594) and Alcmaeon, son of Megacles, led the Athenian contingent supporting Delphi in the Sacred War of c. 590. In the next generation another Megacles married Agariste, daughter of Cleisthenes, tyrant of Sicyon, and led a party in Athens which accepted the reforms of Solon. When Pisistratus (*q.v.*) became tyrant in 561–560 the Alcmaeonidae, allied with the more conservative aristocrats, drove him out, but soon preferred to help him back to power at the price of a marriage alliance. The alliance broke down and Pisistratus was again driven out (556). When he returned to power after his second exile, the Alcmaeonidae again were exiled and plotted continually to return. Cleisthenes, son of Megacles, was recalled and made archon in 525 after the death of Pisistratus, but after the murder of Pisistratus' son Hipparchus in 514 he was again exiled by Hippias. He then led the Alcmaeonidae in an abortive invasion

of Attica from their base in Boeotia. While in exile the Alcmaeonidae, whose great wealth may have been largely derived from friendly relations with the Lydian court, rebuilt Apollo's temple at Delphi more handsomely than the contract specified. They were rewarded when the Spartans, largely at the insistence of the Delphic oracle, drove out the Pisistratidae (510). When in 508 Cleisthenes (*q.v.*) adopted a radical program of constitutional reform, Sparta intervened and under the pretext of the bloodguilt expelled Cleisthenes and his supporters. The policy followed by this opportunist family during the next generation is obscure: they were suspected of Medism at the time of Marathon; the direct line was considerably less prominent after the Persian Wars, but Alcibiades and Pericles were members of the family on their mothers' side. The Spartan demand for the expulsion of the Alcmaeonidae recurred as a provocation directed at Pericles at the beginning of the Peloponnesian War. (R. ME.)

ALCMAN (active in Sparta in the second half of the 7th century B.c.), Greek poet, is traditionally held to have founded Dorian choral lyric poetry. He probably owes this reputation to the fact that earlier choral lyrics did not survive in any considerable quantity into Hellenistic times. His work is known mainly from quotations and references in later writers; but he was the first Greek lyric poet to benefit by papyrological discoveries. One papyrus fragment contains over 100 lines of a *parthenion* (song for a chorus of girls). Alcman's language, though strongly flavoured by epic and Laconian usages, is clear and simple, and so, except in one fragment, are his metrical schemes. His manner is light and gay and unlike the traditional idea of Sparta; hence it was disputed in antiquity whether he was a born Laconian or an "incomer" from Lydia. He had a sharp eye for a pretty girl and a fondness for good living, but there was more substance in his poetry than philandering and gastronomy.

(1961). (JN. A. D.)

ALCMENE, in Greek mythology, the daughter of Electryon, king of Mycenae, and wife of Amphitryon (*q.v.*). She was the mother of Heracles by Zeus, who assumed the likeness of her husband during his absence.

ALCOBAÇA, a town of Portugal, in the district of Leiria, lies at the confluence of the Alcoa and the Baça rivers in a fertile fruit-growing valley. 17 mi. S.S.W. of Leiria city. Pop (1950) 4,373. Alcobaca is chiefly interesting for its Cistercian monastery (Mosteiro de Santa Maria), now used partly for administrative offices and partly for a college. It was founded by King Afonso I about 1148 and was rebuilt in the 13th century. During the middle ages it rivaled the greatest European abbeys in size and wealth. It was supplied with water by an affluent of the Alcoa, which still flows through the kitchen. The vast abbey church is early Gothic somewhat defaced by baroque and later additions. Portions of the library are preserved in the public libraries of Lisbon and Braga. Alcobaca is the marketing centre for the fruit (pears, plums, melons) grown in the district; some of the fruits are candied, and cotton materials and pottery are made there.

ALCOCK, JOHN (c. 1430–1500), English bishop and statesman who founded Jesus college, Cambridge, was born in Beverley, Yorkshire, and educated at Cambridge. In 1461 he was made dean of Westminster and thereafter his promotion was rapid in church and state. In 1462 he became master of the rolls and in 1470 was sent as ambassador to Castile. He became successively bishop of Rochester (1472), Worcester (1476) and Ely (1486). He also held the office of chancellor and conducted negotiations with James III of Scotland, besides filling other posts under both Edward IV and Henry VII. He died at Wisbech castle on Oct. 1, 1500. Alcock was a man of learning and an architect. Besides founding a charity at Beverley and a grammar school at Kingston-upon-Hull, he restored churches and colleges and founded Jesus college, Cambridge, on the site of the convent of St. Radeunda. His published works, most of which are extremely rare, are: *Mons perfectionis, otherwise in English, the Hill of Perfection* (1497); *Galicantus*

Johannis Alcock episcopi Eliensis ad fratres suos curatos in sinodo apud Barnwell (1498), a good specimen of early English printing and quaint illustrations; *The Castle of Labour* (1536), translated from the French; and various other tracts and homilies.

See F. Brittain, *A Short History of Jesus College, Cambridge* (1946). (X.; M. D.x.)

ALCOCK, SIR JOHN WILLIAM (1892–1919), English aviator who, on June 14–15, 1919, achieved fame by flying from Newfoundland to Ireland together with Lieut. Arthur Whitten Brown in the first nonstop transatlantic flight. Alcock was born in Manchester on Nov. 6, 1892, the son of a horse dealer. Before World War I he had been in possession of the aviation certificate for two years, when he joined the royal naval air force as an instructor in 1914. In 1916 he was posted at no. 2 wing at Mudros. There he performed many famous exploits, including the bombing of Istanbul on Sept. 30, 1917.

He was forced to alight at sea near Suvla bay on his return from this expedition, and he and his companions swam ashore and were taken prisoners by the Turks. After leaving the air force in March 1919, he set the transatlantic record with Brown, flying from St. John's, Nfd., to Clifden, Ire., in 16 hr. 27 min. He was then created knight commander, order of the British empire. A week later Alcock was flying to Paris in an amphibian airplane when he crashed and sustained fatal injuries at Côte d'Évrard, Normandy, on Dec. 18, 1919.

See G. Wallace, *The Flight of Alcock and Brown* (1955).

ALCOFORADO, MARIANA (1640–1723), Portuguese pseudo authoress believed until 1926 to be the writer of the *Letters of a Portuguese Nun*, was born April 22, 1640, in Beja, where she died on July 28, 1723. The letters, originally five in number, appeared anonymously in French in Jan. 1669. In the preface the publisher, Claude Barbin, stated that they had been translated from the Portuguese, but he revealed neither his sources nor the name of the translator. The volume met with an extraordinary success, due in great part to the mystery that surrounded its appearance and to the scandalous character of the intrigue. A French officer, taking advantage of the custom of the time that allowed visits to the religious, seduced a Portuguese nun in a convent of Alentejo. Fearing the consequences, he left the country hurriedly for France. The letters describe the nun's betrayed faith and disillusionment. A Cologne edition of the same year stated that they were addressed to the marquis de Chamilly and had been translated by the comte de Guilleragues. In 1810 the French scholar J. F. Boissonade caused a sensation by claiming that he had seen the name of M. Alcoforado written by an unknown hand in a copy of the first edition. Speculation grew until F. C. Green found the royal privilege (1688) granted to Barbin, which showed that the author was Guilleragues and put an end to a literary mystification.

See F. C. Green, "Who Was the Author of the 'Lettres Portugaises'?" *Modern Language Review* (April 1926); A. Gonçalves Rodrigues, *Mariana Alcoforado — história crítica de uma fraude literária* (1935). (L. DE S. R.)

ALCOHOL, without modifying adjectives, refers to a particular class of oxygen-containing organic chemical compounds. The term denotes as well one member of this class, ethyl alcohol (*q.v.*), known also as grain alcohol or spirits of wine, which is the physiologically active principle of beverages produced by fermentation. Ethyl alcohol has the chemical formula C_2H_5OH ; it may be considered a derivative of water, HOH, in which one hydrogen atom has been replaced by the ethyl group, C_2H_5 , or it may be described as a derivative of the hydrocarbon ethane C_2H_6 , in which one hydrogen has been replaced by the hydroxyl group, OH. The class of alcohols comprises those organic compounds which, like ethyl alcohol, contain a hydroxyl group attached to a saturated carbon atom; *i.e.*, one in turn attached to three other carbon or hydrogen atoms. Since wide variation is possible in the carbon-containing portion of alcohols, a large number of compounds, including complex species such as sterols and carbohydrates, may be classed as alcohols. Compounds with a hydroxyl group attached to an unsaturated carbon atom, such as phenols, are not generally considered alcohols.

The generally accepted derivation of the word alcohol is from the Arabic *kuhl*, *kohl* or *kohol*, meaning a "very fine powder." *Alkohol*, or the "fine powder," referred usually to a finely powdered antimony sulfide used in cosmetics to darken the eyelids. For a long time the word *alkohol* or *alcool* referred only to a fine powder. For example, *ferrum alcoholisatum* was finely powdered iron. Gradually the word came to mean "essence" and Paracelsus defined it in the 16th century as "the most subtle part of anything." It was in this sense that he wrote of *alcool vini*, the most subtle part of wine, but never *alcool* alone. Gradually *vini* was dropped, but it was not until the 19th century that the term alcohol came to be used generally for wine spirits. The limiting term "ethyl" refers to the fact that this particular alcohol can be converted to ether. The "-yl" suffix is derived from the Greek work "hyle" and was employed first by Justus von Liebig and Friedrich Wöhler in the sense of "stuff" or "material."

Important alcohols of commerce include: methyl or wood alcohol, better known as methanol, which is used as a solvent, radiator antifreeze and as a chemical intermediate, chiefly in the manufacture of formaldehyde; ethyl alcohol, occurring in beverages, which is important as a solvent and for the synthesis of such compounds as acetic acid, acetic anhydride, ethyl acetate and tetraethyl lead; n-butyl alcohol, a solvent and precursor of solvents; ethylene glycol, the nonvolatile antifreeze, which is also necessary to the preparation of synthetic polyester and polyurethane fibres and resins; glycerol or glycerin, required in manufacture of alkyl resins, nitroglycerin, and in the formulation of cosmetics, tobacco products, inks and other materials. Other alcohols produced on a large scale are isopropyl alcohol, allyl alcohol, propylene glycol, pentaerythritol, sorbitol and polyvinyl alcohol. Still other alcohols are used in smaller amounts in the preparation of perfumes, synthesis of pharmaceuticals and in other branches of the chemical industry.

Members of the alcohol group occur throughout nature, often combined as esters. The lower monohydroxy alcohols are frequently so found in the volatile oil of fruits; e.g., ethyl acetate in the pineapple. Animal and vegetable waxes are mixtures of esters of long-chain monohydroxy alcohols with long-chain fat acids. Fats and oils are mixtures of esters of the trihydroxy alcohol glycerol (glycerides) with similar acids. Naturally occurring free alcohols are the sterols, high-molecular-weight alcohols with a complex hydrocarbon framework. Among these are cholesterol (*q.v.*), present in the blood and tissue of animals and related to the bile acids and steroid hormones, and ergosterol, a precursor of vitamin D obtained from yeasts. Vitamin A₁ is another complex alcohol occurring naturally. The extremely widespread and important carbohydrates, including starch, cellulose and sugars, are polyhydroxy alcohols.

(See also BUTYL ALCOHOLS; CARBOHYDRATES; ETHYL ALCOHOL; GLYCERIN; GLYCOLS; METHYL ALCOHOL.)

Nomenclature.— Many of the structurally simple and common alcohols are named by modifying the word alcohol by a term descriptive of the nonhydroxylic portion of the molecule. Compounds containing two hydroxyl groups on different carbon atoms are known as glycols and may be named similarly. This method of nomenclature becomes impractical in most cases, however, and one of three more systematic approaches is used instead: (1) In the I.U.C. (International Union of Chemistry) or Geneva system, the suffix "-ol," plus an appropriate positioning number, is added to the name of the hydrocarbon from which the alcohol is derived. (2) The alcohol is named as a derivative of methyl alcohol, called carbinol. (3) In complex cases containing certain additional functional groups, the hydroxyl group is indicated by the use of a number plus the term hydroxy.

Because the properties of alcohols vary somewhat with the position of the hydroxyl group in the carbon skeleton, alcohols are also divided into three classes, depending on the number of carbon atoms attached to the hydroxyl-bearing atom. Where this number is one, as in ethanol and dodecanol-1, the alcohol is known as a primary alcohol; in cases such as propanol-2, the alcohol is secondary; and when three carbons are attached to the hydroxyl-bearing carbon, as in 2-methylpropanol-2, the alcohol is called

Examples of Alcohol Nomenclature

Formula	Common names	Geneva system	Carbinol system
CH ₃ OH	methyl alcohol	methanol	carbinol
C ₂ H ₅ OH	ethyl alcohol	ethanol	methylcarbinol
C ₃ H ₇ OH	isopropyl alcohol	propanol-2	dimethylcarbinol
CH ₂ (CH ₂) ₁₀ CH ₂ OH	lauryl alcohol	dodecanol-1	
CH ₂ CHOHCH ₂ OH	propylene glycol	propanediol-1,2	
CH ₂ OHCH ₂ OH	glycerol	propanetriol	
CH ₃ CHOHCOOH	lactic acid	2-hydroxypropionic acid	
(CH ₃) ₃ COH	tertiary butyl alcohol	2-methylpropanol-2	trimethylcarbinol

tertiary. Methanol: although by this definition not a primary alcohol, is often considered to be one. Other divisions of alcohols are made on the basis of the hydrocarbon portion of the molecule, e.g., into aliphatic, alicyclic and araliphatic; or because of additional functional groups present in the molecule, e.g., into amino alcohols, olefinic alcohols, keto alcohols, etc.

Physical Properties.— The lower monohydroxy alcohols containing less than three carbon atoms are completely miscible with water and most organic solvents. Alcohols of up to five carbon atoms are appreciably soluble in water, while higher monohydroxy alcohols are not. The water solubility of tertiary alcohols of given molecular weight is higher than that of primary or secondary alcohols; e.g., 2-methylpropanol-2 is completely miscible with water but butanol-1 is only slightly soluble. Increasing the number of hydroxyl groups in the alcohol molecule increases the water solubility and decreases the solubility in organic solvents; glycerol, for example, is completely miscible with water but insoluble in such organic solvents as ether and carbon tetrachloride.

Alcohols boil at higher temperatures than the hydrocarbons of equivalent molecular weight; methanol, molecular weight 32, boils at 64° C. and propanol-1, molecular weight 60, boils at 97° C. although the corresponding hydrocarbons ethane (molecular weight 30) and butane (molecular weight 58) boil at -88° C. and 0° C. respectively. This phenomenon arises from the association of alcohol molecules in the liquid state through interaction of the highly polar hydroxyl groups. Boiling points for a given molecular weight range increase with the number of hydroxyl groups in the molecule: ethylene glycol, CH₂OHCH₂OH, boils at 197° C., 100° C. higher than propanol-1, the monohydroxy compound of approximately the same molecular weight.

With increasing chain lengths the liquid straight carbon chain alcohols become increasingly viscous; the first straight chain alcohol to be solid at room temperature is dodecanol-1. Chain branching, however, generally raises the melting points of alcohols, 2-methylpropanol-2 melting at 25° C., while butanol-1 melts at -80° C. Additional hydroxyl groups also raise the melting point, but polyhydroxy compounds have a marked tendency to supercool.

Chemical Properties.— The distinguishing feature of alcohols is the grouping -C-O-H, the reactions of which give rise to the characteristic chemical properties of alcohols. Many of the reactions of alcohols bear a resemblance to those of water.

Alcohols are very weak acids, about as acidic as water, but they do react with alkali metals and with amalgamated aluminum or magnesium to liberate hydrogen gas and form salts known as alkoxides, as illustrated by the reaction of ethyl alcohol and sodium,

Alkoxides are hydrolyzed by water to regenerate the alcohol and form a hydroxide,

Metal alkoxides are very strong bases and are used as condensing agents in organic synthesis. Certain of them, such as aluminum isopropoxide, are useful as reducing agents.

In addition to their acid properties, alcohols have weakly basic characteristics and in the presence of strong acids form oxonium salts,

Because of this reaction many water-immiscible primary alcohols such as butanol-1 are soluble in concentrated aqueous acid. However, under these conditions, tertiary alcohols and, to a lesser extent, secondary alcohols undergo reactions in which the hydroxyl group is lost. On treatment with concentrated hydrochloric acid, 2-methylpropanol-2 is converted to 2-chloro-2-methylpropane:

and with aqueous sulfuric acid to the olefin 2-methylpropene (isobutylene),

If conditions are properly chosen, alcohols can generally be made to form unsaturated compounds by loss of the elements of water, either by acid treatment or, more satisfactorily, by passing the alcohol vapour over a hot alumina surface.

Another reaction of alcohols brought about by anhydrous strong acid is the formation of ethers, as exemplified by the formation of ether (diethyl ether) itself by sulfuric-acid treatment, under proper conditions, of ethyl alcohol:

This reaction was reported in the 16th century.

The preparation of esters by reactions of alcohol with acids is a general and exceedingly useful reaction. Alcohols can be made to form esters with inorganic acids such as nitric, sulfuric and phosphoric, as well as with organic acids. For example, glyceryl trinitrate, formed by reaction of glycerol with nitric acid in the presence of sulfuric acid,

is the important explosive more often called nitroglycerin. Pentaerythritol tetranitrate (PETN) is another member of this class. Cellulose nitrates, although extremely inflammable, have been used in the past as a base for photographic films and molded plastic products; certain grades are used to make gun cotton.

Phosphate esters of alcohols are also of importance; triethyl phosphate, $(\text{C}_2\text{H}_5\text{O})_3\text{PO}$, is used in the synthesis of insecticides and tributyl phosphate as a plasticizer in the formulation of plastics. These are esters prepared in the reaction of phosphorous oxychloride with the corresponding alcohols. Sodium dodecyl sulfate, $\text{CH}_3(\text{CH}_2)_{10}\text{CH}_2\text{OSO}_3\text{Na}$, a salt of the half ester of dodecyl or lauryl alcohol with sulfuric acid, is an important ingredient of detergent formulations.

With carboxylic acids (*q.v.*), again under acid catalysis, alcohols form carboxylic esters. Butyl acetate, solvent, can thus be formed by reaction of *n*-butyl alcohol with acetic acid in the presence of a strong acid such as sulfuric:

Carboxylic esters may also be formed by the reaction of an alcohol with an anhydride, as illustrated by the formation of cellulose triacetate, an intermediate in the production of acetate rayon, photographic film and other plastic products:

Acyl halides may also be used to introduce the acid component. A further method of producing carboxylic esters, known as transesterification, involves the base catalyzed reaction of an alcohol with an ester to produce a new ester plus the alcohol of the first ester. By way of illustration, dimethyl terephthalate is converted to the hydroxyethyl ester of terephthalic acid, an intermediate in the production of polyethylene terephthalate fibres and films:

In general both inorganic and organic esters may be hydrolyzed to the alcohol plus the acid (or its salt) in the presence of acidic (or basic) catalysts. Soaps are the sodium or potassium salts of the long-chain fatty acids obtained, in addition to glycerol, by alkaline hydrolysis (saponification) of animal or vegetable fat:

The esterification of alcohols and the saponification of their esters increase in difficulty in the order primary, secondary, tertiary.

Alcohols may be oxidized. Primary alcohols are converted to aldehydes:

or carboxylic acids:

while secondary alcohols are oxidized to ketones:

Tertiary alcohols can be oxidized only with disruption of the carbon skeleton.

Several methods are available to bring about these reactions. In the laboratory, chromic acid is frequently used as the oxidant. The oxidations of ethanol to acetaldehyde and isopropyl alcohol to acetone are carried out on a large scale as dehydrogenation reactions in which the alcohol is passed over a copper catalyst at $250^\circ\text{--}300^\circ\text{C.}$:

Characteristic of the hydroxyl function of alcohols is its replacement by a halogen when treated with phosphorus halides, thionyl chloride or, in the case of tertiary alcohols, simply halogen acids. This reaction proceeds with increasing ease in the order primary, secondary, tertiary, and is illustrated by the reaction of 2-methylpropanol-2 with hydrochloric acid, mentioned above, and the preparation of *n*-butyl bromide by treatment of butanol-1 with phosphorous tribromide:

Preparation. — Numerous methods are available for the preparation of alcohols, some used in the laboratory for the preparation of alcohols of complex structure, others for large-scale production.

Fermentation processes are important for the industrial synthesis of ethyl alcohol and *n*-butyl alcohol, the latter being formed in a process which also produces acetone. The substrates for the microbiological action are carbohydrates from molasses or grain.

A more general technique for the preparation of higher alcohols is the hydrogenation (reduction) of more highly oxidized hydrocarbon derivatives, particularly esters; *e.g.*,

This transformation may be carried out by means of hydrogen gas under pressure in the presence of a metal or metal oxide catalyst. Other reagents used are sodium metal dissolving in a lower alcohol and metal hydrides such as lithium aluminum hydride, LiAlH_4 . The reduction of esters yields primary alcohols from the acid portion of the ester. Aldehydes, RCHO , may be similarly reduced; when applied to ketones, these reactions produce secondary alcohols:

Carbon monoxide, reduced by hydrogen over an oxide catalyst, is the source of most methanol:

Alcohols are also prepared from olefins, hydrocarbons containing a double bond, by hydration, a reaction usually carried out with an aqueous acid such as sulfuric. Ethyl alcohol and isopropyl alcohol are produced in this way from ethylene and propylene:

In this reaction, the hydroxyl group is always introduced at the carbon which bears the fewer hydrogen atoms. When sulfuric acid is used as the catalyst, an intermediate is the sulfuric acid half ester with the alcohol; this ester is hydrolyzed to the alcohol and sulfuric acid.

Mixtures of higher alcohols are produced industrially by the "oxo" reaction of olefins, carbon monoxide and hydrogen, or by the reduction of aldehydes produced in this process.

The hydrolysis of alkyl halides provides a route to alcohols; C_5 alcohols (amyl alcohols) are prepared from a mixture of chlorinated pentanes, and allyl alcohol arises from allyl chloride:

A number of alcohols are prepared by hydrolysis of their naturally occurring esters with various acids, the most noteworthy example being glycerol.

Industrially, the controlled oxidation of hydrocarbon provides a route to alcohols, as well as other organic compounds. Ethylene is oxidized over a silver catalyst to ethylene oxide, which may in turn be hydrolyzed to ethylene glycol:

Some alcohols are produced by the condensation of aldehydes or ketones with themselves or each other, usually followed by a step involving reduction. The variations on this method are manifold. An example may be noted in the synthesis of pentaerythritol from acetaldehyde and formaldehyde:

Organometallic compounds such as organolithium and organomagnesium compounds react with aldehydes to yield secondary alcohols and with ketones and esters to yield tertiary alcohols:

This reaction is used primarily in the laboratory.

See C. R. Noller, *Chemistry of Organic Compounds*, 2nd ed. (1957); R. E. Kirk and D. F. Othmer (eds.), *Encyclopedia of Chemical Technology* (1947-56). (K. D. K.)

ALCOHOLIC BEVERAGES, DISTILLED, are variously described under terms such as spirits, distilled spirits, liquors, etc.; among English-speaking peoples they include brandy, gin, rum, whisky and vodka. The excise, duty or revenue imposed upon distilled alcoholic beverages by all governments constitutes such an important part of the income of most national treasuries that distilling throughout the world is a carefully supervised and regulated industry. In most countries it is conducted under direct control and supervision of government excise or treasury agents. No still may be built or operated without a licence; and these licences are always precarious in nature, being subject to immediate cancellation if the distiller should infringe or violate a regulation. All operations and installations are subject to inspection by government agents at any time. Other regulations affect the labeling of various beverages, prohibit adulteration, etc.

Distillation and Components.—The principle of alcoholic distillation is based upon the different boiling points of alcohol (78.3° C.) and water (100° C.). If an alcohol-containing liquid is heated to a temperature above 78.3° C. but below 100° C., the alcohol will vaporize and separate from the original liquid and can be gathered and recondensed into a liquid of much greater alcoholic strength. Similar but cruder separation results can be obtained by inverting the process; *i.e.*, by freezing the alcohol-

Congener Content of Six Types of Distilled Spirits

Ingredient	American blended whisky	Canadian blended whisky	Scotch blended whisky	Straight bourbon whisky	Bonded bourbon whisky	Cognac brandy
Total congeners (wt./vol. %)	0.116	0.085	0.160	0.292	0.309	0.239

containing liquid. The water portion will freeze at 0° C. and thus may be separated from the alcohol, whose freezing point is considerably lower (-114° C.).

The major components of distilled alcoholic beverages are ethyl alcohol ($\text{C}_2\text{H}_5\text{OH}$) and water. The combination of these two substances alone does not produce an attractive beverage. It is from small quantities of other constituents having a more complex nature that alcoholic beverages obtain their individual characters.

The minor constituents, termed congeners or congeners, include higher alcohols, aldehydes, ethers, esters, volatile acids, furfural and other organic compounds, whose influence on the character, aroma and flavour of the beverage is out of all proportion to their quantities. As they are too great or too small, they invest the liquor with fuller or feebler flavour than may be desired.

The aim of the distiller has always been to produce a spirit of satisfactory strength with sufficient flavouring agents to yield a palatable product. The variance in congeneric content of several types of whiskies and Cognac brandy is illustrated in the table above.

Distilling in Antiquity.—The evaporation of the alcohol out of the various beers, wines and such liquors and its reclamation in liquid form gave rise to interesting developments in the forms of distilling apparatus. Originally a cool surface was held in the hot vapours from the boiling liquor and periodically cleared of the fluid which collected upon it. Pliny mentions the hanging of fleeces over boiling resin to collect turpentine, and Alexander of Aphrodisias records that sailors boiled sea water and collected sweet water by hanging sponges in the steam. This expedient seems to have been superseded, for the sake of more efficient collection, by the use of a bowl filled with cold water, from the outer surface of which the condensate dripped into a vessel within the still pot (Tibetan and Bhutan style) or into a tube which transferred it to an external receiver (according to Peruvian practice).

FIG. 1.— ANCIENT FORM OF STILL USED IN TIBET

By leading the vapours from the still pot through a pipe into a receiving vessel where they condensed naturally, the Kalmuck Tatars made another evolutionary step; the Sinhalese in their warmer climate augmented the effectiveness of this arrangement by immersing the receiver in cold water. The natives of Tahiti sought to chill the vapours before they reached the receiver by cooling the connecting pipe, and so invented the precursor of the Darioot or Liebig condenser, which

has in modern times been modified into many ingenious forms. The Alexandrians elaborated the primitive cold surface into a more complex still head, or alembic, with an annular gutter by which the distillate was led to an external receiver; the addition of supplementary water cooling to this head exemplifies the form of the Mysore still, which was reinvented in later years in the guise of Kodak and Sheldon condensers.

Modern Types of Still.—Simple pot stills constructed on the lines of the Tahiti model are used even now in France for brandy and in Scotland and Ireland for whisky, but the pot is usually

FIG. 2.— ANCIENT FORM OF STILL USED IN PERU

surmounted by a bulbous head or capital for the purposes of freeing the rising vapours from spray, which would contaminate the distillate, and of avoiding the risk of priming or blowing liquid over with the vapour. In some Irish installations, however, the still is connected to the condenser through a cooled lyne arm which partially condenses the less volatile components of the vapour, these being returned to the still pot while the more volatile substances pass on to the condenser. This is a primitive type of fractionator or rectifier. Some of the French brandy stills have a two-compartment bulbous vessel between the still and the condenser: one compartment contains the next charge to be transferred to the still; while in the other the less volatile substances are partially condensed, as in the lyne arm of the Irish still, but the heat lost by the vapour in becoming liquid is gained by the wine about to be run into the pot. This heat interchanger is an economizer of fuel. The pot stills used in the whisky distilleries of Scotland become more complicated, with two or more vessels between pot and condenser; they are retorts (the "eggs" of Eduard Adam's patent of 1801, inspired by the Woulfe bottle) or rectifiers, which return less volatile components to the pot and pass on the lighter fractions toward the condenser. These operate by virtue of the latent heat liberated by the steam during its condensation, evaporating spirit out of liquid which has already condensed. Wash heaters or heat interchangers are also incorporated.

The idea of the charge heater of the French brandy still is not modern, for a similar design appears in a publication by H. Braunschwick in 1512 (see fig. 6) the arrangement being shown as surmounting the boiler; it thus appears as the precursor of the modern refluxing fractionating column or still head which, in all its complicated modification, is designed to give the maximum separation of volatile components in the course of a single operation. These improvements have been so effective that fractionating columns have become quite useful instruments in an analyst's equipment.

It is by an easy progression from the fractionating column, via the designs of Louis Charles Derosne, J. H. L. Pistorius and J. J. Saint-Marc, that Aeneas Coffey's and other patent stills were developed; these offer an efficiency in industrial operations which is unattainable on the laboratory scale so far as economical operation is concerned. The subject of Coffey's patent of 1831 consists of two towers that are essentially large-scale fractionating columns and heat interchangers (see fig. 7). The first tower, called the analyzer, may or may not surmount a boiler and is a fractionating column into which steam is blown at the bottom and the alcoholic liquor or wash injected near the top. The tower is packed with perforated plates through which the steam blows, preventing the wash from passing from one plate to the next below through the perforations; when any upper plate carries sufficient liquor, the excess flows through a short pipe standing in a cup which rests on the plate below. This serves both as weir and as an obstruction to the steam, which can then rise through the tower only by bubbling through successive layers of liquid. The heat evolved in the condensation of some of this steam evaporates or strips the alcohol out of the wash; and the mixed vapours pass to the base of the second tower, or rectifier, which contains an arrangement of plates similar to that of the analyzer and a pipe lying in sinuous coils between each pair of plates. This pipe serves two purposes: it acts both as a heat interchanger, by warming the wash which passes through on its way to the top of the analyzer; and as a cooler, by causing partial condensation of the vapours passing through the column. Finally, the vapour issuing from the top of the column is condensed as high-strength spirit containing few impurities and known as plain, neutral, silent, velvet or Cologne spirit. It is used to dilute other alcoholic drinks which are too highly flavoured, to prepare compounded spirits and to fortify weak wines; the rest of it finds an outlet in industry.

Much industrial equipment has an important peculiarity: a refrigerator, which usually has the form of a simple worm condenser, is interposed between the condenser proper and the receiver; its purpose is to complete condensation and to chill the distillate, so

FIG. 3.— STILL OF ANCIENT TYPE AS USED IN TAHITI

reducing the vapour pressure of the latter that loss by evaporation, is minimized.

Origin.— The history of distilled beverages is obscure, but the following brief tabulation shows the origin of some of them:

Date	Country	Raw material	Fermented liquor	Distillate
—	China	Rice and millet	Tchoo	Sautchoo
800 B.C.	Ceylon and India	Rice and molasses or palm sap	Toddy	Arrack
—	Asiatic	Mare's milk	Kumiss	Arika
—	Tatary			
—	Caucasia	Mare's milk	Kefir	Skhou
—	Japan	Rice	Sake	Sochu
A.D. 500	Britain	Honey	Mead	Mead
1000	Italy	Grapes	Wine	Brandy
1100	Ireland	Oats and barley malt	Beer	Usquebaugh
1200	Spain	Grapes	Wine	Aqua vini
1300	France	Grapes	Wine	Cognac
1500	Scotland	Malted barley	Beer	{Aqua vitæ {Whisky

In general, the raw material is a sugar such as is to be found in honey, ripe fruit, sugar cane, beetroot, milk or a substance of an amylaceous nature which may be easily converted into a sugar. Fortunately this change is simply effected, for some of the active agent is already present in cereals containing the necessary starch or is easily developed in them; where it is absent, as in potato starch, a suitable cereal can be added.

Action of Enzymes.— The active agents which break down

starches into sugars and sugars into alcohol are known as enzymes; they are generally water-soluble nitrogenous compounds having something of the nature of albuminoids. They behave rather like catalysts in that a very little of them will cause a fundamental change in large quantities of the material being processed; they are easily poisoned by certain substances such as hydrocyanic acid, mercury salts and formalin, are sensitive to temperature variations (being rendered inactive in certain conditions), and are specific in action in that each is effective for certain classes of substance only. They convert complex insoluble material into simpler assimilable substances: the enzyme amylase, for instance, will reduce starch to dextrin and then to the sugar maltose; the enzyme maltase will reduce maltose to the simpler sugar dextrose; and, finally, the enzyme zymase will ferment the dextrose to alcohol and carbon dioxide. All of these changes take place easily in aqueous solution. The presence of amylase and maltase in cereals, particularly if germination has begun, and the presence of zymase in yeast ensure that all the necessary materials for the manufacture of spirit are readily and economically available. There are, of course, other enzymes—sucrase, present in yeast and malt, will break down cane sugar to invert sugar; lactase will hydrolyze milk sugar to simpler fermentable sugars; cytase will disintegrate cellulose; lipase will degrade fats, and so on.

Processing.— In the case of cereals, processing is begun by grinding the grain and heating it with water to gelatinize the starch and so form the mash. This is cooled to a temperature between 50° and 60° C. and saccharified by adding ground malt, a preparation obtained from a cereal such as barley which has been moistened, allowed to germinate, dried, kilned (over peat fires for Scotch whisky) and ground; in this meal there are sufficient amylase and maltase to break down not only the starch of the malted cereal but also that of the other amylaceous material. The liquid, now known as wort, is cooled to about 20° C. and pitched with yeast to initiate fermentation, a process which produces a wash ready for the stills.

Saccharine materials do not need the assistance of malt to prepare them for fermentation, and the simpler ones, such as honey and grape sugar, can be fermented without any preparation other than solution in water; but the more complex sugars, such as cane sugar (molasses), beet sugar and many fruit sugars, need to be simplified or inverted before the yeast can attack them. The enzyme effecting this change, invertase or sucrase, is fortunately present in yeast and malt, and its action can proceed simultaneously with fermentation.

Yeast, the fermenting agent, is a budding fungus or unicellular vegetable organism without chlorophyll belonging to the genus *Saccharomyces*; of its many kinds, those of interest to brewers and distillers are of the species *cerevisiae*. In this species there are many varieties that do not always contain the same enzymes and that behave differently toward various sugars. Charles Simmonds gives an interesting synopsis in his book *Alcohol*.

The whole story of yeasts and molds, their active principles and the manner of utilizing them, is a long and fascinating one that has occupied the attention of many investigators since the publication of the researches of Louis Pasteur (*q.v.*).

Maturing.— The wash or the wine is conducted to the stills where, in the case of the pot stills, two or more successive distillations are performed to produce a spirit of the desired strength; in the case of column- or patent-still distillates, the process is completed in one continuous operation. The resultant liquid is colourless and rather sharp or ram in aroma and taste, although the higher proof spirits distilled off at between 90% and 96% of alcohol are much less so. The lower the proof at which the spirit comes off the still, the higher its congeneric content will be, and for greater palatability, it must be matured.

Generally, distilled spirits mature best in barrels, casks or puncheons made of seasoned American white oak. Notable exceptions are cognac, which is aged in Limousin oak casks, and armagnac, aged in casks coopered from the black oak of Gascony. In the case of American straight whiskies, U.S. government regulations specify that the barrels must be new (unused) and charred internally. In other distilling centres the casks are not charred,

FIG. 4.— ANCIENT STILL USED IN SOUTHERN INDIA (MYSORE STILL)

FIG. 5.— DIAGRAM OF SINGLE TYPE OF IRISH POT-STILL PLANT (JOHN JAMESON'S DISTILLERY, DUBLIN)

and casks that have previously been used to hold sherry or a spirit are preferred. When the liquid is barreled its alcoholic content is reduced by the addition of water. Barreling or filling strength practices vary from region to region. In the United States, whiskies are generally barreled at 103 proof (51½% alcohol); in Scotland, filling is usually at 124 proof (62% alcohol); while in Cognac the brandy is filled at 140 proof (70% alcohol), the proof at which it came off the still.

Maturing customs vary, but generally the barrels or casks are stored in warehouses where there will be no drafts and are placed in tiered racks that permit constant inspection for leakage. During the aging period marked changes occur in the liquid. The wood of the cask is sufficiently porous to permit air to penetrate, and at the same time to allow some of the liquid to escape through evaporation. In most cases more water is lost than alcohol, and the remaining alcohol proportion will be greater, i. e., the proof will increase, as occurs in American whiskies; in other cases, such as cognac, the reverse is true. At the same time other important changes take place among the secondary constituents. The volatile acids and the alcohols combine to produce an increased ester content, while the alcohols combine with air, primarily the oxygen, to form a larger quantity of aldehydes. The liquid also extracts tannins and additional furfural (which is an aldehyde) from the wood of the cask, acquiring colour meanwhile. The length of time required for optimum maturation varies with different distilled spirits. The lighter bodied spirits require less than the fuller bodied. Spirits mature more rapidly in a new charred oak barrel than in a re-used cask, and climatic conditions are still another determining factor. The minimum aging is two years but most aged spirits are matured in wood four years or more. If a spirit is kept in wood too long, it will absorb an excess of tannin and furfural and will acquire a sharp woody taste. Cognac brandy may be kept longer in wood than other distilled spirits, but it is

FIG. 6.— DESIGN FOR DISTILLING APPARATUS FROM BRAUNSWICK'S DAS BUCH ZU DISTILLIEREN (1512)

rarely kept over 50 years, and if kept that long it is periodically refreshed through additions of younger, fresher brandies. Distilled spirits do not mature in glass. Once bottled they will never become "older" than they are on the day of bottling.

Classification of Potable Spirits.— There are a number of classes of commercially produced distilled spirits:

Whisky (or whiskey) is a distilled spirit obtained from the distillation of a fermented mash of grain, suitably aged in wood. Whiskies are produced in many countries, but the principal ones, in order of importance, are the United States, Scotland, Canada and Ireland. It is spelled "whisky" in Scotland and Canada and "whiskey" in Ireland and the United States. U.S. whiskies are defined by government regulations as straight, bourbon, rye and blended whiskey. Scotch whisky is wholly a product of Scotland. Its distinctive peaty (smoky) taste is due to the use of peat to dry the freshly sprouted barley malt in open kilns and to the quality and character of the water found in Scotland. Irish whiskey is produced in a somewhat similar fashion, except that the malt is not kilned "in contact" with peat smoke, and the whiskey therefore has no peaty or smoky flavour. Canadian whisky distilling is similar to that of the U.S.

Vodka is an unaged distilled spirit, obtained from a fermented mash of any suitable raw material, filtered through vegetable charcoal and reduced to potable strength with water. In Russia and Poland more vodka is distilled from potatoes than from grain, but in the United States (the next largest market) practically all vodka is distilled from a fermented grain mash. The distilled spirit for vodka comes off at a very high proof, over 190 in the United States; this together with charcoal filtration assures a beverage "without distinctive character, aroma or taste."

Rum (Spanish ron, French rhum) is any distilled spirit obtained from fermented sugar-cane juice or its molasses. Whenever sugar cane grows a rum is distilled, almost always as the by-product of sugar manufacture. Rums can be classified into three basic groups: the dry, light-bodied, brandylike rums best exemplified by those of Puerto Rico and Cuba (rums of this type are also produced in Mexico, Brazil, Argentina and Paraguay); the rich, full-bodied, pungent rums such as those of Jamaica, Barbados, Demerara (British Guiana), etc.; and the brandylike but very aromatic rummy Batavia Arak from Java in Indonesia. In between are the brandylike yet full-flavoured Haitian and Martinique rums.

Brandy is a potable distilled spirit obtained from wine or a fermented mash of fruit, usually suitably aged in wood. The use of the term brandy by itself is generally accepted to mean grape brandy, i. e., the distillate of wine; the universally accepted pre-eminent brandy is that of Cognac, France. Other fruit brandies are distilled from the fermented mash of apples, plums, cherries, apricots, etc. In general these brandies are marketed and better known under specific names.

Slivovitz is the generic term employed to describe the plum brandy which is the national beverage of Hungary, Rumania and Yugoslavia, but the plum brandies of Alsace derive their names from the variety of plum used; i. e., Quetsch or Mirabelle. Hungary's Barat Palinka is a brandy obtained from the fine-flavoured Hungarian apricot. All of these brandies are matured in wood, are golden-brown in colour and possess the distinctive aroma of the fruit.

The cherry brandy which is called kirsch in France and kirschwasser in Germany and Switzerland, the three principal regions of production, is obtained from a small black cherry found in the Rhine basin. It is always colourless and is not aged. It possesses a fine clean cherry aroma and flavour, together with a slight bitter-almond undertone derived from the cherry stones which are partly crushed and remain in the mash during fermentation. For the same reason the bitter-almond undertone is characteristic of slivovitz, Barat Palinka and other fruit brandies, except apple brandy.

Other Distilled Spirits.— Tequila, the national distilled spirit of Mexico, is obtained from the heart-sap of the genus *Agave* of the amaryllis family, a cactus also known as the century plant or American aloe, termed *mezcal* (mescal) in Mexico. Both unaged

and four-year-old tequila are marketed at 86 to 100 proof in Mexico and the United States.

Okolehao or "oke" is an exotic Hawaiian contribution to distilled spirits. It is a distillate obtained from the fermented mash of the proper proportion of sugar-cane molasses, Koji rice lees and the juice of baked tiroot, to which water has been added. (Tiroot is the root of the taro or kalo plant—*Colocasia antiquorum*. It is also from tiroot that Hawaiians make one of their favourite foods, poi.) Okolehao is matured for several years in charred oak barrels and marketed at 80 or 90 proof. It is dark in colour and has a smoky aroma and flavour imparted by the baked tiroot. White *okolehao* is also produced by using coconut milk in place of tiroot and aging in uncharred barrels. It is almost colourless.

Ng ka py (whisky in Chinese) is a distilled spirit obtained from a fermented mash of millet, with various aromatic herbs added. It is slightly sweetened and has an aromatic aroma and flavour. Ng ka py is aged in wood and generally marketed at 96 proof.

Flavoured Spirits.—In the family of distilled spirits the next most important group is that which embraces the flavoured spirits, notably gin, aquavit, absinthe, zubrovka, etc. They are all obtained by redistilling a spirit in the presence of the flavouring agent or agents. Gin is the most universally produced and used. The primary flavouring of gin is the juniper berry, although many other "botanicals" are also used to lend subtle nuances of aroma and flavour.

The national distilled spirit beverage of the Scandinavian countries is aquavit or akvavit, which is produced in the same manner as gin. High-proof potato spirits are redistilled in the presence of the flavouring agents, the selection of which varies from one country to the other but which always includes caraway and cumin seeds. Danish akvavit is colourless and has the most pronounced caraway flavour, while the Norwegian and Swedish versions have a straw colour and sweeter spicier taste, and the Finnish variety has a cinnamon flavour. Scandinavian aquavits are marked at 83 to 90 proof.

Liqueurs.—Finally in the family of distilled spirits there is the group of brightly coloured, fragrantly flavoured and richly sweetened liqueurs or cordials. They were developed originally during the middle ages by physicians and alchemists as medicinal remedies, love potions, aphrodisiacs and general cure-alls. Through the centuries they have been known as elixirs, oils, balms, and ratafias as well as liqueurs and cordials. The variety of colours, flavours and combinations thereof is limitless; the one factor that makes them cordials is their sugar content. Under U.S. regulations a cordial must contain more than 2½% of sugar, but all cordials contain considerably more. They are divided into two groups: those with generic names, produced in all parts of the world; and those with proprietary brand names, which are produced by the trade-mark owner, such as *Bénédictine* or *Chartreuse*, and are made only at their places of origin. The list given below indicates the name, flavour, usual colour and alcoholic content of some of the better known cordials:

GENERIC NAMES			
<i>Cordial</i>	<i>Flavour</i>	<i>Colour</i>	<i>% of Alcohol*</i>
Anisette	anise	white	27
Anis	anise	white	39-48
Apricot	apricot	brown	30
Blackberry	blackberry	dark-red	30
Cherry	cherry	bright red	30-32
Crème de Cacao	chocolate, vanilla	brown or white	25-27
Crème de Cassis	sweet currant	red	12-25
Crème de Framboises	raspberry	red	30
Crème de Menthe	mint	green, white, pink	30
Crème de Roses	roses	rose	30
Crème de Vanille	vanilla	brown	30
Crème de Violettes	violet	violet	30
Curaçao	orange	orange	30-42
Danziger Goldwasser	orange-spicy	white	38
Kümmel	caraway	white	39-46
Maraschino	cherry	white	30-32
Ojen	anise	white	42

GENERIC NAMES—Continued

<i>Cordial</i>	<i>Flavour</i>	<i>Colour</i>	<i>% of Alcohol*</i>
ouzo	anise	white	45-49
Parfait Amour	violet	violet	27-30
Peach	peach	golden-brown	35-40
Prunelle	plum	brown	40
Sloe Gin	sloeberry, tart	reddish	30
Swedish Punsch	rummy, sweet	yellow	28-30
Triple Sec	orange	white	38-40

PROPRIETARY BRANDS

<i>Liqueur</i>	<i>Country of Origin</i>	<i>Flavour</i>	<i>Colour</i>	<i>% of Alcohol</i>
<i>Bénédictine</i> ,				
D.O.M.	France	spicy	golden	43
B and B, D.O.M.	France	spicy	golden	43
Chartreuse yellow	France	spicy-anise	gold-yellow	43
Chartreuse green	France	spicy-licorice	green	55
Cherry Heering	Denmark	cherry	cherry-red	24½
<i>Cordial Medoc</i>	France	orange-cocoa	brown	44
Cointreau	France	orange	white	40
Crème Yvette	United States	violet	violet	33
<i>Drambuie</i>	Scotland	spicy-Scotch	golden	40
Falernum	Barbados	lime-almond	white	6
Forbidden Fruit	United States	orange-grapefruit	orange	35

Grand Marnier	France	orange	orange-red	40
Gilka Kümmel	Germany	caraway	white	43
Irish Mist	Ireland	spicy-honey	golden	40
Liqueur d'Or	France	spicy-lemon	light gold	43
Strega	Italy	spicy	light gold	42½
Tia Maria	Jamaica	coffee	brown	31½
Vielle Cur6	France	spicy	golden	43

*Note: In the United States, the alcoholic strength of these beverages is always expressed in degrees proof, each of which is equal to ½ of 1%; therefore, 27% of alcohol is 54 proof.

For more detailed discussions of the different classes see the articles BRANDY; GIN; LIQUEURS; RUM; VODKA; and WHISKY. There are also articles on several of the liqueurs—*BÉNÉDICTINE*, *D.O.M.*; *CHARTREUSE*; etc.

General Properties of Distilled Beverages—Apart from aroma, which is usually caused by small quantities, even traces, of strongly flavoured secondaries, essences or extracts, the general properties of distilled beverages are those of aqueous solutions of ethyl alcohol, a colourless mobile liquid with a slightly higher

FIG. 7.—DIAGRAM OF COFFEY STILL

viscosity but a lower surface tension and a much lower electrical conductivity than water. It is neutral in character, but can act either as a base, by combining with acids to form esters or ethereal salts; or as an acid, by combining with strongly basic metals to produce ethylates. It can burn in air with a blue nonluminous flame and is decomposable in the absence of air at high temperatures, particularly in the presence of catalysts such as powdered aluminum, zinc dust, reduced nickel, thoria or alumina, releasing hydrocarbons and other simple compounds. On the other hand, contact with strong oxidants will result in the formation of aldehyde, acetic acid and even of carbon dioxide and water. Absolute alcohol is hygroscopic and miscible with water in all proportions, with an accompanying evolution of heat and a contraction in total volume that is most noticeable when 52 volumes of alcohol are mixed with 48 volumes of water at 20° C., to yield 96.3 volumes when temperature is restored to 20° again. Specific heat is about $\frac{2}{3}$, and thermal expansibility $5\frac{1}{2}$ times that of water at 20° C.; these characteristics, coupled with the possession of a low freezing point (−114° C.), render the liquid a suitable filling for certain ranges of thermometers. The boiling point of alcohol is 78.3° C.; heat of vaporization is only about $\frac{2}{11}$ of that of water; vapour pressure at ordinary temperatures is about $2\frac{1}{2}$ times as great: these facts are reflected in the relatively easy separation of alcohol from water by fractional distillation—up to a certain limit—and in the lesser known data of flash points. According to von Schwartz, the following temperatures may be taken as a guide to the flash points of various alcoholic liquors:

Ethyl alcohol 100%	10.6° C.
Ethyl alcohol 95%	13.9° C.
Rum, arrack and cognac	25° C.
Whisky	27.8° C.
Hollands gin	31.7° C.
Sherry and port wine	53.9° C.

These temperatures must be regarded with a certain amount of reserve, since they are dependent upon spirit strength, which has a considerable range of variation in each type of beverage. Aqueous mixtures at any given pressure boil at various temperatures, according to the alcohol content, but the lowest boiling point is that of a solution containing 4.43% of water, the mixture of constant boiling point; *i.e.*, 79.15° C. at 760 mm. as against 78.35° C. for pure alcohol. This is an azeotropic mixture—one which distils at a constant temperature lower than the boiling points of its components, without change of composition, when the pressure is kept constant. Constitution varies with pressure, and at pressures below 70 mm. of mercury the alcohol-water azeotrope does not exist; it is therefore possible to obtain absolute alcohol by vacuum fractional distillation, although in practice the separation is not easily effected because of the small difference between the boiling points of the absolute and aqueous alcohols. The spirit produced from wash by any simple distillation process at ordinary atmospheric pressures can never be pure alcohol; but the latter may be obtained by drying out the water with powerful dehydrating agents before a final distillation, by vacuum fractional distillation or by adding to the aqueous alcohol a sufficient quantity of another liquid, such as benzene, or a chlorohydrocarbon to form a triple azeotrope boiling at a still lower temperature and fractionating. In this instance, first the triple azeotrope containing the undesired water, and then a double azeotrope containing the excess of the added substances are eliminated, leaving absolute alcohol as a residue or final distillate.

Mixtures of alcohol and water have values intermediate between those of the pure components for some of their physical characteristics, such as viscosity, heat of vaporization, specific heat, thermal expansion, vapour pressure, electrical conductivity, boiling point, refractive index and specific gravity. Although the variations may not be strictly proportional to the amount of alcohol present, they are nevertheless generally progressive for certain ranges, if not right through the scale of concentrations. This fact has provided some convenient physical means of determining spirit strength, and it is common practice to derive such information from the specific gravity. Provided that the liquid is free, or has been freed by distillation, from saccharine and other

matter which would interfere, the specific gravity is determined by immersing in it a hydrometer which may be graduated: (1) in terms of specific gravity; (2) with arbitrary scales (Great Britain, U.S.S.R.); (3) in percentages by volume of alcohol (Belgium, France, Italy, Norway, Spain, Sweden); (4) in percentages by weight of alcohol (Germany); (5) in percentages by volume of proof spirit (U.S.); and (6) with a scale based upon fractions of the volume of the instrument (Netherlands). In all cases these instruments are calibrated at standard temperatures; when the liquid to be tested is cooler or warmer (as it usually is), reference is made to tables to ascertain the true value for the spirit at the standard temperature.

Spirit strength may be designated in several ways—percentage by weight, weight per gallon, gallons per hundredweight or percentage by volume, all these having reference to absolute alcohol and water. But there are other standards in common use; *e.g.*, U.S. proof spirit, which is 50% by volume of alcohol and water, and British proof spirit, which is of such a strength that at 51° F. its weight is $\frac{1}{2}$ of an equal volume of water; this solution contains 49.28% by weight or 57.10% by volume of alcohol at 60° F. The subject of alcoholometry is comprehensively described in Simmonds' *Alcohol*. See also ALCOHOL.

ALCOHOLISM, better called chronic alcoholism, is a disease in which a person has an uncontrollable desire for alcohol. Once his craving is triggered he begins to drink steadily and excessively. A state of physiological dependence exists, and the true alcoholic may be considered to be addicted to alcohol. Not all persons who drink regularly or even excessively are alcoholics. Most drinkers, even including some who drink regularly or even to excess occasionally, are not addicted and are able to give up alcohol at will. Chronic alcoholics are of two types, the spree drinker and the steady drinker. The spree drinker alternates periods of sobriety with periods, lasting for days or weeks, of drunkenness. The steady drinker consumes too much alcohol every day.

Alcohol (see ETHYL ALCOHOL) has little medical value, but the drinking of alcoholic beverages allays anxiety and thus is a promoter of social ease. On the other hand, alcohol addiction is an important public health problem in most western countries.

Physiological Action of Alcohol.—After alcohol is ingested it is rapidly absorbed in the gastrointestinal tract (stomach, small and large intestines) and rises to high levels in the blood in a relatively short time (see fig. 1). From the blood the alcohol is distributed to all parts of the body. It is absorbed until an equilibrium is attained between the alcohol in the blood and that in the various organs. Considerably more time is required to eliminate alcohol from the blood stream. Some alcohol is still present in the blood stream 18 hours after ingestion. This discrepancy between rapid absorption and slow removal is an important factor in determining the maximal level of alcohol in the blood (blood alcohol). It assures a relatively long stay of alcohol in the body, during which time it continues to exert its characteristic actions. The degree of intoxication reflects to a certain extent the concentration of alcohol in the blood.

The presence of food in the gut slows the rate of absorption of alcohol, and it is well known that alcohol exerts a greater effect when consumed on an empty stomach. All foodstuffs, however,

FROM A. J. CLARK "APPLIED PHARMACOLOGY." J. B. CHURCHILL LTD (1938)

FIG. 1.— COMPARISON OF RAPID AND SLOW CONSUMPTION OF WHISKY AND THE RESULTANT LEVEL OF ALCOHOL IN THE BLOOD

Eight fluid ounces of whisky, containing 100 c.c. of alcohol, taken in one dose (A) produces a higher level of alcohol in the blood than $2\frac{1}{2}$ fluid ounces of whisky, containing 30 c.c. of alcohol, taken four times (B) at three-hour intervals

are not equally effective in impeding absorption. Milk (actually the fat contained) and meat (protein) are particularly potent in this regard. The diminished degree of intoxication that results when alcohol is consumed with or after food must be imputed largely to the reduction of its maximum concentration in the blood and therefore in the brain. Though the amount of alcohol finally absorbed may be the same, the peak concentration is lower and occurs later.

Slow rate of drinking also reduces the maximal level of alcohol in the blood by slowing absorption. Fig. 1 shows that the alcohol contained in eight ounces of whisky taken in one dose produced a sharp increase in the blood alcohol level, while four spaced doses of two and one-half ounces each raised the level to a much lesser extent.

Dilution also influences the blood alcohol level. When the percentage of alcohol in a beverage is small, the amount of alcohol per volume of absorbed fluid is correspondingly low. On the other hand, in high concentration the irritating effects of alcohol on the lining of the gastrointestinal tract diminish absorption. Taking into consideration all the data, the most rapid rate of removal from the gastrointestinal tract occurs when alcohol is imbibed in 10% to 30% dilutions, in wines and highballs. For equal volumes of alcohol, beer (with dilutions ranging from 1% to $7\frac{1}{2}$ %) and neat whisky (43% to 53%) are less intoxicating than wines and highballs with alcohol in 20% dilution.

Oxidation.—During the time when alcohol is being absorbed, metabolic factors are initiated that tend also to diminish its concentration; they continue to function until all alcohol is removed. A relatively small amount of alcohol, at most approximately 10%, is eliminated in the urine, in the breath and in perspiration. The remainder, at least 90%, is consumed in the body by oxidation. The rate of oxidation is slow, however, approximately one ounce of whisky per hour.

There is some doubt as to whether the rate of oxidation is constant, as indicated in fig. 1 and 2, or whether the rate is slightly faster when the concentration of blood alcohol is higher and somewhat slower as the concentration diminishes. But the central fact that the rate of combustion is slow, alcohol remaining in the body for a long period, is undisputed.

The process of oxidation yields carbon dioxide, water and heat to the extent of seven calories for each gram of alcohol oxidized. Hence it must be regarded as a food which, in this sense, can take the place of carbohydrate, fat or protein. There are three chief steps in the oxidation process: (1) the combustion of alcohol, chiefly in the liver, producing acetaldehyde, a chemical that appears in the blood only after alcohol is ingested; (2) the oxidation

of acetaldehyde to acetic acid, taking place not only in the liver but in other organs as well; and (3) oxidation of the acetic acid to carbon dioxide and water, a reaction that takes place readily throughout the body.

At least two important peculiarities of alcohol combustion make it different from most other foodstuffs. Chiefly because of its slow rate of oxidation, limited mainly by the capacity of the liver, there is a limit to the amount of alcohol that can be oxidized in 24 hours. The highest reported amount of alcohol metabolized in a single day is 300 g., yielding 2,100 calories; such a caloric yield is sufficient for a sedentary person, but activity increases the energy need, and a person performing physical work could not live on alcohol, since the amount oxidized cannot be raised above the level of approximately 300 g. per day.

A second characteristic of alcohol as a food lies in the fact that it is devoid of such dietary elements as vitamins, essential amino acids, essential fatty acids and minerals. As a matter of fact, too-exclusive reliance on alcohol for calories results in a number of deficiency diseases which may complicate the course of alcoholism (see below).

Alcoholic Intoxication.—Since there is an equilibrium between the alcohol in the blood and that in the brain, it might be expected that there would be some relationship between the blood alcohol concentration and mental changes. To gauge the degree of intoxication by the symptoms alone is unsatisfactory, and even physicians fail to agree when using such a basis. Laboratory tests to determine the alcohol content in the blood afford an objective measurement of the severity of intoxication. Blood alcohol also can be estimated indirectly by its concentrations in the urine, saliva or exhaled air in accordance with the following ratios:

$$\begin{aligned} \text{Urine : blood} &:: 1.20-1.30 : 1 \\ \text{Saliva : blood} &:: 1.3 : 1 \\ \text{Alveolar air : blood} &:: 1 : 2,100 \end{aligned}$$

The urine and saliva contain slightly higher concentrations of alcohol per given volume of fluid than does the blood, whereas air from the lungs (alveolar air) contains much less per given volume. Tests for mental impairment and muscular co-ordination show that abstainers and moderate drinkers exhibit undesirable changes when the levels of alcohol in the blood are between 0.05% and 0.1%, and even heavy drinkers habituated or accustomed to alcohol may show disabilities with values above 0.1%. Intoxication becomes obvious to the onlooker when the blood alcohol rises above 0.15%.

The American Medical Association Committee to Study Problems of Motor Accidents and the National Safety Council Committee on Tests for Intoxication made recommendations which in general indicate that persons with concentrations of less than 0.05% of alcohol in the blood should not be regarded as under the influence of alcohol. The interpretation of alcohol levels in the blood is necessarily questionable between the blood levels of 0.05% and 0.10% because the phenomena of tolerance and habituation must be taken into consideration in relation to the impairment of judgment and performance. Tolerance depends upon individual susceptibility or resistance to alcohol, and is inherent. Habituation differs from tolerance in that it is acquired by practice; there is good evidence that it is an adaptive change whereby the brain reacts to alcohol to a lesser degree as a result of previous exposure.

Blood alcohol values of 0.10% or more can be taken as legal evidence that the person is under the influence of alcohol. Fig. 2 shows the volumes of whisky or beer necessary to produce levels of 0.05% and 0.10% respectively in a person weighing 150 lb. (68 kg.). In order to attain in the blood the amount of alcohol contained in four ounces of whisky it is necessary to have imbibed slightly over five ounces of whisky, because of the various processes, described above, that act to remove alcohol from the body.

The earlier standard of 0.15% as indicating the level of alcohol in the blood at which a person is considered a definite hazard on the road was too high. Additional information, obtained by actual field tests in automobiles and by laboratory experiments, led the Committee on Alcohol and Drugs of the National Safety Council

to recommend that the standard be reduced to 0.10%, *i.e.*, a person having a blood alcohol level of 0.10% or higher should be considered under the influence of alcohol and therefore a dangerous driver. This standard, long accepted by many European countries, has now been generally adopted in many states of the U.S.

Drug Action.—The above discussion reveals that alcohol in excess has a pronounced effect on the mind in terms of altering behaviour. It exerts a depressant action on the brain; it muffles the mind. It therefore belongs to the group of depressant drugs, of which ether and the barbiturates are representative. Under the influence of alcohol the functions of the brain are depressed in a characteristic pattern. The so-called higher or more complex functions rather than the semiautomatic ones are affected first (for example, a stenographer under the influence of alcohol may type at her usual speed but the errors become more numerous). The most complex actions of the brain—judgment, self-criticism, the inhibitions learned from earliest childhood—are thus depressed first, and the loss of this control results in a feeling of excitement in the early stages. For this reason, alcohol is sometimes thought of, erroneously, as a stimulant. Under the influence of increasing amounts of alcohol the drinker gradually becomes less alert, awareness of his environment becomes dim and hazy, muscular co-ordination deteriorates and sleep is facilitated.

Finally, with increasing effects of alcohol, even the vital centres—those which control pulmonary ventilation, heart rate and blood pressure—become impaired. If medical treatment is not initiated, death due to respiratory failure and shock associated with low blood pressure is imminent.

Ether exerts a similar graded pattern of depression, observed first in the higher centres, which lose their control of the rest of the brain and result in the excitement stage of ether. In contrast with alcohol, however, ether can be used as an anesthetic because of the wide dosage margin between the depression of the higher activities of the brain and the lower vital ones. With large amounts of alcohol the depression of the vital centres occurs at doses relatively close to the lethal dose.

Causes of Alcoholism.—The stupor and forgetfulness which result from excessive doses of alcohol can become desired ends for the confirmed addict. But the earlier comforting action of alcohol which is sought by the inexperienced drinker is the depression of the higher centres and the reduction of anxiety. Occasionally an unpalatable compromise must be accepted. The discomfort accompanying such situations can be effectively allayed, temporarily, by alcohol. A drink or two before going to sleep can bring relief from useless and painful reviews of the day's events. This comforting action of alcohol is noted in the New Testament, where St. Paul advises Timothy, "No longer drink only water, but use a little wine for the sake of your stomach and your frequent ailments" (I Tim. v, 23). The great physician William Osler said, "Alcohol does not make people do things better, it makes them less ashamed of doing them badly." Self-criticism is removed, self-doubt is eliminated and inhibitions are stilled. When alcohol is used to the exclusion of other more realistic means to meet life situations, however, when the person relies on alcohol alone to relieve his anxiety and does not assay more appropriate methods of overcoming his difficulties, he starts a trend which under certain circumstances can lead to chronic alcoholism.

There must be additional contributing factors in the produc-

tion of alcoholism, however, since many persons who drink regularly never become addicts. One of these factors is a personality characteristic in which a person has less than average tolerance for the anxiety caused, for example, by frustration or criticism. This type of person has a stronger push to recourse to alcohol than have others who are less sensitive. There are also certain psychotic persons who can achieve reasonably satisfactory relations with others only through the aid of alcohol; though his difficulties may be imaginary, they are very real and compelling to the person who has them, and by blunting his mind he can effect a better rapport with those around him. With this aid, for example, a schizophrenic can make a marginal adjustment to the demands of society and even, in a small way, make a contribution to it. Such a person obviously can fall a victim to alcoholism more easily than can a person who is not psychotic.

The discussion of personality characteristics predisposing to alcoholism leads to an examination of the heredity factor. Heredity has been suggested as a predisposing factor because of such work as that of R. J. Williams, who believes that individuals may inherit metabolic patterns which result in nutritional deficiencies that in turn give rise to a craving for alcohol. Such persons have unusually large requirements for vitamins, and when these needs are not satisfied they revert to alcoholism. Other evidence does not support this viewpoint. Many alcoholics do have an alcoholic parent, and the normal expectancy of alcoholism is vastly higher among children of alcoholic parents as compared with the general population. But in a study in which 36 children of alcoholic parents were separated from the true parents and reared by non-alcoholic foster parents, none of the children became alcoholics. Such observations suggest that heredity alone cannot account for the choice of alcoholism as a way of escape from life's difficulties. Environmental influences seem much more important.

The accepted customs of the society in which a person lives have a strong influence on the attitude toward alcohol. For example, in the United States women are brought up to regard drunkenness more seriously than do males, and American male alcoholics outnumber women by five to six times. In a group that frowns on drunkenness, even though its members may frequently use alcohol in many forms, alcoholism may be practically unknown. One such group is represented by the Orthodox Jews, among whom drinking is used to draw the family together, to facilitate other interpersonal relationships and as part of the religious rituals. In this group drinking is not associated with strong emotion. There are no movements for total abstinence, and drunken parties are equally unknown. Violators of the rules followed by this group are punished in one way or another, and persons who succumb to drunkenness are scorned. In contrast, there are other groups among whom disapproval is applied irregularly and who drink together for fun, to escape from social pressures rather than as in the preceding group, in conformity with accepted standards. Drinking may then be attended by a feeling of guilt, and may be exhibitionist or carried out secretly. In such groups alcoholism is not rare. Still others (for example, the Mormons) forbid alcohol, and usually it is an outcast who yields to drunkenness, which is regarded as immoral.

It must also be realized that the immediate cause of alcoholism is not known. The use of alcohol does not necessarily induce alcohol addiction. In the United States less than 10% of drinkers become alcoholics. Similarly all persons are subject to anxiety, but only a few succumb to alcoholism. Even in groups which tolerate drunken episodes, only 3% to 7% of users become addicts. Why one person in a setting favourable to alcoholism remains untouched while a second succumbs, and why others in similar situations develop ulcers of the stomach or become schizophrenic, cannot be explained.

Nature of Addiction.—Some of the mechanisms which trap the alcoholic and maintain his addiction are known, however, as is the fact that an addicted drinker is a changed person, both psychologically and physiologically.

Physiologic.—For the alcoholic, alcohol has become a necessity; it has assumed the characteristics of a food, and he is worse off without it than with it. There has occurred a profound change

in the cells of his body, which have become adapted to alcohol and operate poorly in its absence.

This physiological change is evidenced by the fact that withdrawal of alcohol from the addict produces grave disturbances which affect not only the patient but those around him. In contrast, the nonaddicted drinker can stop drinking at any time without ill effects. The more moderate signs and symptoms seen after an addict is deprived of alcohol include an intense craving for it, weakness, tremor, perspiration and an increase in anxiety (the last caused partly by the other withdrawal symptoms). The alcoholic deprived of his potion characteristically has the "shakes," or becomes tremulous, and a few drinks usually eliminate this symptom. More grave results of withdrawal are nausea and vomiting, fever and rapid heart rate, convulsions and hallucinations. Delirium tremens combines several of these withdrawal symptoms, including loss of awareness of the environment as well as an impairment of insight or understanding of the situation. Delirium tremens can also occur during a drinking bout (see DELIRIUM).

Continued excessive drinking produces a number of disagreeable physical symptoms that add to the alcoholic's anxiety and call for additional drinking. The lining of the stomach and intestines becomes inflamed so that food is not easily digested. Furthermore, morning nausea renders any food unpalatable, and the alcoholic therefore may take two or three drinks on arising in order to overcome his nausea and anxiety. With the loss of essential dietary constituents the alcoholic begins to show signs of food deficiencies. His nerves, particularly those in his legs, may undergo degeneration, giving rise to pain and weakness. The liver suffers severe changes, grouped by physicians under the term cirrhosis. The organ is enlarged, the person's skin darkens as he becomes jaundiced, the abdominal cavity swells as it fills with fluid. Sometimes the patient dies in a coma as a result of failure of liver function. He suffers severe headaches, dizziness, nausea and vomiting, the well-known hangover symptoms. These symptoms are partly due to gastritis, or inflammation of the lining of the stomach, but they are also a direct effect of alcohol on the inner ear, the part of that organ that aids in regulating the equilibrium of the body. The characteristic thirst is ascribed to loss of fluids through perspiration, urination and vomiting.

Psychologic.—While the alcoholic is undergoing these changes in his body he passes also through a series of behavioural patterns. At first, he utilizes alcohol for its anxiety-relieving action only occasionally. Later he imposes on alcohol for more continuous relief, and drinks daily. At this time he must drink greater quantities as he becomes habituated. Then he may become subject to blackouts, exhibiting a complete loss of memory in the morning for what he said or did the previous evening. He drinks surreptitiously and avidly. He is overcome with guilt feelings in regard to his drinking and avoids reference to alcohol in his conversation. Finally there is loss of self-control, and any drinking starts a chain reaction of further drinking based on intense craving. By now he is under severe pressure from his wife, his business employer and his friends to reduce his drinking, and he seeks a series of alibis to explain it. Sometimes, in remorse, he has periods of total abstinence. Finally, he may become a confirmed alcoholic. He drops his friends, quits his job and goes on prolonged binges. He suffers ethical deterioration and impairment of thinking, and even may become psychotic (see PSYCHOSES); at this time he may lose some of his tolerance and habituation to alcohol.

The alcoholic may also suffer mental deterioration, though degeneration of the brain probably is caused by the imperfect diet and is not a primary effect of alcohol. There is a growing incapacity for sustained attention, and memory as well as other mental functions become impaired. The alcoholic becomes careless of his personal appearance and neglectful of his family. Social responsibility disappears. Usually he is in carefree good humour, but any reproof may evoke a violent outburst of irritability. He is occasionally brutal, surly and without shame.

Treatment.—Acute Alcoholic Poisoning.—Treatment of a patient suffering from acute alcoholic poisoning—that is, a drunken episode—is divided into two stages. For the earlier excitement, sedatives such as tranquilizing drugs or barbiturates (*qq.v.*) are

used. The more dangerous deeper stage of coma, or alcohol anesthesia, is a serious medical emergency caused by the excessive presence of alcohol in the body. Treatment to speed up the elimination of alcohol is therefore required. It is impossible to administer medication by mouth to a patient in coma; it must be injected into the veins. Glucose, with or without insulin, fructose, amino acids and vitamins may speed the combustion of alcohol. These substances are injected intravenously in saline fluids which the dehydrated patient sorely needs.

Delirium Tremens.—This is another acute episode in which tranquilizers and intravenous medications are necessary treatment. Most U.S. psychiatrists believe that in the treatment of delirium tremens alcohol should be withdrawn immediately and medication prescribed as for a comatose patient. Some physicians prefer a more gradual withdrawal of alcohol, a tapering-off process, logical for patients in whom the delirium tremens was brought on by abstinence.

Long-Term Treatment.—In contrast to treatment of these comparatively temporary conditions is the treatment of the alcoholic between drinking bouts, when attempts must be made to help him overcome his disease. This treatment is most difficult and meets with repeated failures. In an attempt to treat chronic alcoholism it is necessary to consider both the physical and psychological aspects of the disease.

The various physical disorders secondary to alcoholism and caused in part by an inadequate diet can be corrected by a return to better eating habits, with foods containing mostly carbohydrates and proteins and only moderate amounts of fat. The B group of vitamins, as well as A and C, should be added to the diet. These dietary measures also apply to all the other complications of alcoholism.

Psychological factors are of greatest significance in the impelling motivation for alcoholism and hence of greatest significance in its treatment. The personality structure must be investigated. In a way the treatment should be regarded as a learning process, the desired result being to make the patient another kind of man who is better able to understand his condition (and thus reduce his anxieties) and to accept more readily the unavoidable stresses of everyday living. The role played by interpersonal relationships cannot be overemphasized. A possessive mother, a domineering father, a spouse who keeps the mate in a dependent position must be informed of their contributions to the patient's condition. In these efforts not only the psychiatrist, trained to treat alcoholism, but the general physician and the clergyman should be enlisted. The international organization of Alcoholics Anonymous (AA), which emphasizes both medical and religious aspects, has a membership of alcoholics and former alcoholics who meet to discuss their common problem. In the company of other persons who suffer from the same disease, the alcoholic realizes that others share his problems and have valuable suggestions for the maintenance of sobriety. The society, numbering over 6,000 chapters throughout the world, also recognizes the worth of a spiritual awakening as an aid in combating the craving for alcohol.

The motivation of the patient is of great importance in combating the illness. He must want treatment. He may say that he has realized his situation and has decided to stop drinking and, therefore, has no problem. He will cite previous instances when he has actually stopped drinking for a shorter or longer time. Yet, without a fundamental desire to change, eventually he will relapse to his former pattern of drinking. Thus, as the first step in the treatment of alcoholism, the patient must admit that he is a problem drinker. Frequently it requires some dramatic incident with high emotional content to cause the drinker to seek treatment. He must "hit bottom." Sometimes the threat of divorce or of dismissal from employment can cause him to face his problem. His motivation for treatment is highest immediately after the hangover, and the object of treatment is to maintain this motivation. One step in that direction is to allow the patient to speak freely. Conversations with the therapist can throw light on the particular series of events which forced him into the path of alcoholism. The therapist should withhold moral condemnation. Though an old viewpoint regards alcoholism as immoral,

the current view is that it is a disease; hence the therapist's aim is to correct the causes rather than to lecture the patient.

Administration of Antabuse, or disulfiram, and Temposil, citrated calcium carbimide, can help the patient continue in the path of sobriety. These drugs increase the concentration of acetaldehyde in the body whenever alcohol is consumed, for they retard the oxidation of that substance to acetic acid. The accumulation of acetaldehyde in the body produces a series of changes which resemble those of the acute hangover. In fact, the patient feels so uncomfortable that fear of the results can strengthen any faltering determination to abstain from alcohol. After disulfiram has been taken, even the smallest amount of an alcoholic beverage can initiate almost unbearable effects. The drinker first has a feeling of warmth in his face; the face, neck and chest are suffused with scarlet and the eyes become bloodshot. At the same time he is aware of palpitation of the heart and feels choked for want of air. Nausea and vomiting follow, and the intense flushing is replaced by pallor as blood pressure falls. Formerly the patient was given a test dose of an alcoholic beverage after receiving disulfiram, to illustrate for him the effects that alcohol would produce, but today the physician generally describes the painful results of defying the alcohol prohibition. The patient's willingness to take this drug can be accepted as a sign, at least for the moment, that he is strongly motivated in his desire for relief from alcoholism. This treatment has other advantages; instead of fighting the craving for alcohol many times a day, the patient has to make his decision only once, at the time he is taking his disulfiram medication. Temposil is a weaker drug than Antabuse and therefore has less deterrent action against the drinking of alcohol, but it is correspondingly safer.

Another method is the aversion treatment, in which alcohol is administered with a drug that produces nausea and vomiting. If the patient successfully establishes an association between the physical discomfort and drinking, an aversion to alcohol is created.

Outlook.—Alcoholism cannot be regarded as a curable disease. The best that can be hoped for is arrest of its progress. The patient must be disabused of the idea that he can take an occasional drink with impunity. For success in the treatment of alcoholism there can be no compromise with the principle of complete abstinence from all alcoholic beverages.

Public Health Aspects.—The foregoing discussion points up the complexity of the alcoholism problem, concerned as it is with multiple factors directly and indirectly related to the health and welfare of man. One of the means of attacking such a complex problem is the public health approach of which there are three chief facets: (1) the biological and medical, with the conception that the inability to control one's drinking is a disease and that there is an individual susceptibility to alcoholism; (2) the psychological, concerned not only with the personality of the addict but also with the interpersonal relationships between the addict and his fellows; and (3) the social and economic, the influence of the particular social circumstances of the drinker and of the culture in which he lives as well as of his economic status. Combining these three aspects we find that the stresses of society may sometimes render life almost unbearable; alcoholism is one way out. Alcoholism may therefore be regarded as a reaction of certain individuals to abnormal circumstances.

A vital part of the public health approach is the gathering of statistics in an effort to evaluate the magnitude of the problem. Although statistics from different sources, and based on different definitions of alcoholism, do not correspond, it is safe to say that there are in the U.S. alone over 4,000 per 100,000 of the adult population admitted to hospitals (public and private) annually. Only first admissions are tallied, with male patients predominating in a rough ratio of five to each female patient.

The World Health organization estimates indicate that alcoholism is widespread in western countries. Data (approximate for 1953) of the number of all alcoholics, proportional to the population, show that the United States leads, followed, in descending order, by France, Sweden, Switzerland, Denmark, Canada, Norway, Chile, Finland, Australia, England and Wales, and finally,

Italy.

ALCOTT, AMOS BRONSON (1799-1888), U.S. teacher, reformer and philosopher, associated with the Transcendentalists, was born in Wolcott, Conn., Nov. 29, 1799. After a brief schooling and several peddling tours in the south he began teaching children in accord with a theory which owed something to Pestalozzi but more to the examples set by Socrates and Jesus. His chief aim was to "awaken the soul" and stimulate original thought. In method his teaching was conversational and in manner uniformly courteous, gentle and firm. Questions of discipline were referred to the class as a group, and punishment consisted only of requiring the pupil to strike the teacher's hand with a ruler.

These innovations were too bold for the time, and before he was 40 Alcott had to close his last school, in Boston. He continued his teaching on lecture platforms, bringing to adults as he had to children a doctrine of pure idealism. In 1842 he visited England, and there, while living at Alcott house, named in his honour, caught the contagion of reform. One result was his founding of a short-lived utopian community, called Fruitlands, in northern Massachusetts.

He was a vegetarian, an abolitionist, an advocate of women's rights and a charter member of the Transcendentalist group. His thought was vague! lofty, consistent and intensely spiritual. As a speaker he exerted a wide influence, wholly for good. His life was a deliberate imitation of Christ, whom he did not think divine. Always poor and in debt, he lived on the bounty of others. His wife and daughters adored him. Ralph Waldo Emerson said that for pure intellect he had never seen Alcott's equal. Henry Thoreau said that Alcott was the sanest man he ever knew. Most of the reforms Alcott fought for eventually triumphed. Many who had laughed at his impracticality came to admire his serene wisdom. The literary success of his daughter Louisa May Alcott, whom he had educated, brought him financial security. Even the town of Concord, Mass., which had cold-shouldered him for many years, had to respect the Summer School of Philosophy, founded by him and held on his grounds.

He died in Boston, March 4, 1888. The best of Alcott's writing is available in *The Journals of Bronson Alcott* (1938), selected and edited by Odell Shepard.

Alcott's educational theory and practice are described by Dorothy McCuskey in *Bronson Alcott, Teacher* (1940). A comprehensive biography based upon original manuscripts is Odell Shepard's *Pedlar's Progress, the Life of Bronson Alcott* (1937).

(O. Sp.)

ALCOTT, LOUISA MAY (1832-1888), U.S. author well known for her children's books, especially *Little Women*, and the daughter of Amos Bronson Alcott (q.v.), was born Nov. 29, 1832, in Germantown, Pa., where her father was teaching at the time. She spent most of her life in Concord and Boston, Mass. Ralph Waldo Emerson and Henry Thoreau were her earliest friends; Nathaniel Hawthorne was her neighbour; and from childhood she was exposed to the conversation of Margaret Fuller, Oliver Wendell Holmes, William Ellery Channing, Henry James, Sr., and other scholars.

Louisa soon realized that her father was too impractical to provide for his wife and four daughters; after the failure of Fruitlands, his experiment in "consociate" living, her lifelong concern for the welfare of her family began. As a child she earned money making dolls' clothes; then she went on to other sewing, to teaching school (which she hated), even to a brief period of domestic service! and finally to writing—at first potboilers, then books.

Her first published book was a collection of fairy stories, *Flower Fables* (1855), originally told to Emerson's daughter Ellen.

An ardent abolitionist. Louisa volunteered as a nurse when the Civil War began. She contracted typhoid from unsanitary hospital conditions and was sent home. She was never completely well again, but the publication of her letters in book form, *Hospital Sketches* (1863), brought her the first taste of fame.

Her stories began to appear in the *Atlantic Monthly*, and she was asked by Roberts Brothers to write a book for girls. At first she refused, "not liking girls, preferring boys." But, because family needs were pressing, she wrote the autobiographical *Little Women* (1868-69), an immediate success and one of the most popular books for girls ever written. In 1869 she wrote in her journal: "Paid up all the debts . . . thank the Lord! . . . Now I think I could die in peace."

Other books followed, drawn from her early experiences: *An Old-Fashioned Girl* (1870); *Aunt Jo's Scrap Bag*, 6 vol. (1872-82); *Little Men* (1871); *Jo's Boys* (1886); and others. Two serious novels, *Moods* (1865), her favourite, and *Work* (1873), were less successful, as was *A Modern Mephistopheles* (1877). They were almost all written under pressure when she was in ill-health.

The last years of her life: though free from financial worry, mere shadowed by the deaths of Elizabeth (the "Beth" of *Little Women*), her mother, and her youngest sister, May, who left a little daughter for Louisa to rear. Tired and in constant pain, she sought peace in the home of her physician, Rhoda Lawrence, where she died, March 6, 1888. She was buried in Concord's Sleepy Hollow cemetery on Author's hill, near the graves of Emerson, Thoreau and Hawthorne.

Louisa May Alcott: her Life, Letters, and Journal was edited by Ednah Cheney (1889).

BIBLIOGRAPHY.—In addition to the *Life* by Miss Cheney, there are biographies by Marjorie Worthington (1958), Madeleine Stern (1950), Katharine Anthony (1938), and Belle Moses (1909). (M. Wt.)

ALCOY, a town of southeastern Spain, in the north of the province of Alicante, is situated on the small Serpis river 25 mi. N. of Alicante city. Pop. (1950) 42,454 (mun.). Standing on the foothills of the Penibético system, it has a high and irregular terrain. There was a town there before Roman times but the Moors founded the present Alcoy, giving it the name of Alcoyll after a city in Tunis. The narrow streets and juxtaposition of old and new buildings give the town a variegated appearance. A fiesta, held on the day of San Jorge, the town's patron saint, is a great tourist attraction. Alcoy is the terminus of a branch line from the Barcelona-Valencia-Alicante railway; the line to Gandia was constructed in 1893 by the English. The town is an important centre of the textile industry and as early as 1590 it had 140 looms. A Real Fábrica de Paños ("Royal textile factory") was established there in 1800 and it was the site of the first Spanish industrial school. The industry was mechanized about 1925. The principal manufactures include paper, especially cigarette paper. There is also some metallurgical industry. (M. B. F.)

ALCUIN (c. 732-804), English scholar and ecclesiastic, born in or near York about 732, is of great importance for three reasons. First, he carried English learning to France, working as head of that Palace school established by Charlemagne at Aachen in which the king-emperor himself, his family, his friends and his friends' sons were taught in a centre of lively discussion and exchange of knowledge mingled with wit and sharp criticism. Second, as the loyal and devoted adherent of Charlemagne and his subjects, he fought heresy both by preaching and teaching and by his writings, and laid the foundation of the Roman Catholic mission. Third, he left more than 300 Latin letters, a valuable source for the history of his time.

Alcuin's life was divided into three periods. Fifty years were spent in Vorkshire, where he went as a pupil to the school of York, the most renowned of its day, under Egbert, archbishop of York, and Aelbert, master of studies. Then, after Aelbert became archbishop, Alcuin was made head of the school (778). In 781, when on a journey in Italy, he was invited by Charlemagne to become director of the Palace school of Aachen and accepted the call.

Probably shortly before he left York he wrote a long poem in hexameter verse telling of men of renown in York's history. His source here was largely Bede, but he describes much of interest from his own knowledge. In 796 he resigned his work at the court, to rule as abbot the monastery at Tours made famous by St. Martin. There he encouraged the work of his monks on the beautiful script known as Caroline minuscule which was to become ancestor of the modern Roman type. He died at Tours on May 19, 804.

His life throughout was marked by strong contrast, the result of an inner conflict of zeal with uncertainty and diffidence. He was a leader in church and state, and his leadership was to be remembered throughout the middle ages. Yet he remained but a deacon to his death, and his writings as teacher show no original mind. He loved England, but in the troubled 8th century he went to live permanently abroad. He loved Charlemagne, his king-emperor, as his letters show; but his fear was as great as his love. Medieval men looked back with gratitude to his work for the liberal arts. The church did not include him in the canon of saints, yet has ever held in reverence his labour for the liturgy.

Alcuin's position as a formative influence in the development of Roman Catholicism rests mainly on his revision of the liturgy of the Frankish Church, which was based partly on the Gregorian sacramentary received from Rome and partly on the so-called Gelasian sacramentary which combined Roman, Gallican and other practice. He was also responsible for the introduction of the sung creed; arranged votive masses for particular days of the week in an order still followed by Catholics; re-edited the Latin Vulgate; wrote works on education and encouraged study of the secular liberal arts for the better understanding of spiritual doctrine; and was the author of biblical commentaries and of studies in theology and philosophy.

Certain questions concerning Alcuin are of interest. Did Alcuin, who amid much mediocre verse wrote with charm on the nightingale and the cuckoo, herald of spring, write also those well-known poems "The Contest of Winter and Spring" and the "Farewell to My Cell"? What was his share in shaping for Charlemagne the document *De litteris colendis*, that general letter which commanded the abbots of his realm to hasten diligence in learning among their novices and pupils? Did he preside over the scholars of Charlemagne who met to compose the *Caroline Books*, sent forth in wrathful protest against action in the east and demanding a sane and sober reverence for the statues and images in churches east and west? And, finally, what part did he play in the events preceding the coronation of Charlemagne by Pope Leo III on Christmas Day, 800? Did he work to restore the Roman empire in the west? On these questions scholars differ and it seems unlikely that definite answers can soon be given.

BIBLIOGRAPHY.—For further details on Alcuin's life and writings and for bibliographies see C. J. B. Gaskoin, *Alcuin* (1904); S. J. Crawford, *Anglo-Saxon Influence on Western Christendom* (1933); C. ALCYONE (HALCYONE), in Greek mythology, daughter of Aeolus and wife of Ceyx. For their insolence in calling themselves Zeus and Hera, Alcyone was changed into a diver, Ceyx into a kingfisher. In another story, Ceyx was drowned and his body cast on the shore. His wife found the body, and the gods, out of compassion, changed both into kingfishers. The winds ceased to blow during their brooding time, hence the expression "halcyon days," used in ancient and modern times to denote a period of calm and tranquillity.

ALDABRA ISLANDS, a group of islands lying in the Indian ocean 265 mi. N.W. of the northern point of Madagascar, 630 mi. S.W. of Mahé and 70 mi. W. of the Cosmoledo group. They form part of the British colony of Seychelles. Pop. (1947) 47. The islands constitute an oval atoll about 1½ mi. broad which

is 23 mi. long and 8 mi. wide and encloses a large but shallow lagoon. Channels divide the ring into four islands which rise from 20 to 80 ft. above the sea. Grande Terre or South island forms three-fifths of the circumference; the other islands are West island or Ile Picard, Polymnie, Middle island, and several islets (*e.g.*, Ile Michel) in the lagoon. The total land area is about 60 sq.mi. Cliffs of coral and limestone are in places replaced by sandy beaches and sand hills, and there is very little soil. Dense scrub covers most of the land, but the lagoon shore is bounded by mangrove swamps.

In common with the other islands of the Seychelles (which were visited by the John Murray scientific expedition in 1934), the Aldabra group seems to have been built up on the sunken surface of the old southern continent of Gondwanaland (or Lemuria, as it is sometimes called) by a deposit of foraminiferal remains, mostly coccoliths and rhabdoliths; it has never been joined to any other land. At Aldabra the coral foundation is totally above water; the coral is generally reddish, but runs from light yellow to chocolate brown. The coral limestone of the atoll is vitrified and gives out a ringing sound when struck or simply walked on.

In 1955 the islands were leased for the commercial exploitation of mangrove timber and fishing, under stringent safeguards for the rare flora and fauna. South island has been declared a nature reserve with absolute protection for animal and bird life. Rarities include a rail (*Dryolimnas aldabranus*), an ibis (*Ibis abbottii*) and a dove (*Alectroenas sgazini*). The giant land tortoise (*Testudo elephantina*) is found and the lagoon teems with hawksbill and edible turtles including the unique "blonde" hawksbill turtle. Oysters and large crabs also occur and a small mussel is found in enormous numbers. Besides mangroves, there are some endemic plants but both flora and bird life are predominantly derived from Madagascar brought by currents and winds.

Aldabra was visited by the Portuguese in 1511 but was already known to the Arabs, who named it. In the 18th century the islets became dependencies of the French establishments at Bourbon (Réunion). In 1810, with Mauritius, Bourbon (for a time), the rest of the Seychelles and other islands, Aldabra became British.

See also SEYCHELLES.

ALDAN, a river in the U.S.S.R., the second largest tributary of the Lena (*q.v.*) by length and the largest by area of its basin, rises in the Stanovoi range and after taking a northward course, turns sharply to east-southeast and then swings in a giant curve to the north and west to join the Lena at Batamai (Ust-Aldan). It is 1,288 mi. long and drains more than 277,000 sq mi. Its width varies from 160-270 yd. in its middle course to nearly 1,000 yd. in the lower reaches, where it divides into innumerable channels. The average annual discharge is 184,000 cu.ft. per second, but there is considerable variation both seasonally and annually. The river is frozen from mid-October to mid-May. The Aldan is navigable to Tommot, while the lower reaches of its major tributaries, the Maya and Uchur, are also navigable. The chief economic importance of its basin lies in the gold fields south of Tommot. (R. A. F.)

ALDANOV, MARK ALEKSANDROVICH (real surname LANDAU) (1889-1957), Russian émigré writer bitterly critical of the Soviet system, was born Nov. 7, 1889, in Kiev, where he took a university degree in chemistry. In 1919 he emigrated to France, which he left for the United States in 1941. He wrote an essay on Lenin (1921), a work comparing the Russian and French revolutions, *Deux Révolutions* (1921), and a scientific treatise, *Actinochimie* (1936), as well as many novels, most of which were translated into English, including a trilogy on revolutionary France, *My slitel* (1923-25; *The Thinker*, 1924-28), an anti-Soviet satire, *Nachalo kontsa* (1939; *The Fifth Seal*, 1943) and *Istoki* (1947; *Before the Deluge*, 1948), a picture of Europe in the 1870s. He died in Nice, France, Feb. 25, 1957.

ALDEBARAN, officially designated as α Tauri, one of the 20

brightest stars in the sky, is in the constellation Taurus (*q.v.*). It is a reddish giant star having a diameter approximately 50 times that of the sun and is located at a distance of about 80 light-years. It is accompanied by a very faint companion star.

ALDEBURGH, a municipal borough on the coast of East Suffolk, Eng., lies 25 mi. N.E. of Ipswich by road. Pop. (1961) 2,972. Area 4.2 sq mi. Formerly the coast extended farther east—the 16th-century Moot hall is now almost on the beach—and the Alde estuary formed a harbour of some importance to the medieval town. The river is diverted sharply southward a few yards from the sea at Slaughden, 1 mi. S., by a shingle bank extending for 12 mi. to Hollesley bay. Though there is still some fishing, Aldeburgh is chiefly a residential and holiday town with golf links and a lifeboat station. The annual summer Aldeburgh Festival of Music and Arts was inaugurated in 1948, the prime mover being Benjamin Britten (*q.v.*), several of whose works received their first performance there. The festival includes exhibitions of East Anglian artists' and craftsmen's work (*e.g.*, printing, china). The manor, mentioned in Domesday Book, was bequeathed in 1155 by William Martel, together with the church, to the abbey of St. John at Colchester to endow what was soon to become an independent Austin priory at Snape. In the 16th century it came into the hands of Cardinal Wolsey and later it came into the possession of the Wentworth family. In the 16th century Aldeburgh was a place of considerable commercial importance: the earliest charter was conferred by Henry VIII in 1529 and the town was incorporated under Edward VI. The borough sent two members to parliament from 1572 until 1832 and three years after that the town was deprived of its charter, but it was newly incorporated in 1885. Elizabeth Garrett Anderson (*q.v.*), one of the first women doctors, was elected mayor of the town in 1908 and became the first woman mayor in England. In the Perpendicular parish church is a bust of the poet George Crabbe (*q.v.*) who was born in Aldeburgh and was curate there for a time.

ALDEHYDES AND KETONES, two important related classes of chemical compounds containing the carbonyl grouping, CO. Aldehydes are characterized by the general formula R—CO—H, where R is either a second hydrogen atom or an alkyl (aliphatic) or aryl (aromatic) radical; ketones, on the other hand, are characterized by the general formula R—CO—R', where R and R' may be either the same or different (see also below), but neither can be a hydrogen atom. Since aldehydes and ketones differ in several important ways, they are discussed separately.

ALDEHYDES

The group CHO which is to be found in all aldehydes contains the most active form of the carbonyl radical known to chemists, and it is to the intense reactivity of this radical that the aldehydes owe their importance as organic synthetic agents both in nature and in the chemical laboratory.

Aldehydes are generally named specifically after the acids into which they are converted by oxidation; thus formaldehyde, acetaldehyde and benzaldehyde furnish formic, acetic and benzoic acids, respectively. In more complicated cases, the termination "al" is employed to denote aldehydic functions, according to the Geneva convention of chemists, thus geranial, the aldehyde of lemon-grass oil, is the oxidation product of the alcohol geraniol, contained in geranium oil (*see TERPENES*).

Many aldehydes are known to chemistry, some being produced artificially, whereas numerous others are found in the vegetable kingdom either free (*e.g.*, cinnamaldehyde in cinnamon oil) or combined in certain glycosides (*e.g.*, benzaldehyde in amygdalin; *see GLYCOSIDES, NATURAL*).

Properties of Typical Aldehydes.—Formaldehyde, H—CHO, the simplest of the aldehydes, is a gas at the ordinary temperature (b.p. -19° C.) and is prepared by passing the vapour of methyl alcohol and air over heated copper gauze. The gaseous aldehyde is collected in water to form a 30-40% solution known commercially as Formalin. This solution on concentration yields a white amorphous solid known as paraformaldehyde, which is considered to be a complex mixture of substances of type formula $\text{HOCH}_2\text{-(OCH}_2\text{)}_n\text{OCH}_2\text{OH}$, with n possessing values up to about 100.

When, however, formaldehyde is distilled from a 60% aqueous solution containing 2% sulfuric acid, it polymerizes to a crystalline modification termed a-trioxymethylene or trioxane, $(\text{CH}_2\text{O})_3$. These polymeric forms are dissociated on heating into the gaseous monomeric formaldehyde.

Acetaldehyde, prepared by oxidation of ethyl alcohol (*q.v.*) or by hydration of acetylene (*q.v.*), is a volatile liquid boiling at 21°C . and miscible in all proportions with water. It is readily polymerized catalytically by traces of zinc chloride, hydrochloric acid, etc., at the ordinary temperature to para-acetaldehyde or paraldehyde (*q.v.*), $(\text{C}_2\text{H}_4\text{O})_3$, a liquid boiling at 124°C . and only moderately soluble in water. Paraldehyde, employed medicinally as a sedative without action on the heart, is administered intravenously as an anesthetic or hypnotic. When the foregoing polymerization of acetaldehyde takes place in a freezing mixture, metaldehyde or meta-acetaldehyde, $(\text{C}_2\text{H}_4\text{O})_4$, is produced as a white crystalline solid subliming at $112^\circ\text{--}115^\circ\text{C}$. This substance is insoluble in water and when heated in a sealed tube at 100°C . is reconverted into the monomeric form. Metaldehyde, which is produced commercially, has been recommended as a smokeless fuel.

The simultaneous chlorination and oxidation of ethyl alcohol leads to trichloroacetaldehyde which in its hydrated state is the well-known drug chloral hydrate (see **CHLORAL**).

Aldolization.—The transformation of formaldehyde and acetaldehyde into their polymeric forms is a chemical change which is readily reversible by thermal dissociation. In addition to this change, aldehydes have the capacity for undergoing a polymerization in which the carbon atoms of separate molecules become directly attached, so that β -hydroxyaldehydes are formed. This process also is often reversible, especially in the presence of a basic catalyst. This mode of polymerization, which is termed aldolization, is an important reaction in organic synthesis. Aldol (β -hydroxybutyraldehyde) is formed by a combining of two molecules of acetaldehyde:

By loss of water aldol passes into the unsaturated crotonaldehyde, $\text{CH}_3\text{—CH=CH—CHO}$.

The adding of carbon to carbon in a somewhat different manner occurs to a marked degree in formaldehyde. A sixfold polymerization of this substance in the presence of magnesium hydroxide (Loew) furnishes α - and β -acroses, two synthetic sugars which have been identified as inactive fructose and inactive sorbose, respectively. Contrary to the older views, however, this process is now known not to be involved in the photosynthesis of sugars in green plants. (See **PHOTOSYNTHESIS**.)

Resinification.—Acetaldehyde and certain of its homologues are converted into resins under the influence of alkalis. Acrolein, $\text{CH}_2\text{=CH—CHO}$, the simplest of the unsaturated aldehydes, is obtained by abstraction of water from glycerin by the agency of alkali bisulfates and phosphoric or boric acid. It is a colourless liquid boiling at 52.4°C . with a disagreeable, tear-exciting odour. In the presence of traces of acids, it readily undergoes polymerization to form a solid resinous material, metacrolein (see **RESINS: Synthetic Resins**). Acrolein forms a dibromide from which E. Fischer by the action of aqueous barium hydroxide obtained the synthetic sugars, α - and β -acroses.

Aromatic Aldehydes.—Benzaldehyde, the most important commercially of the aromatic aldehydes, is usually made from the chlorinated derivatives of toluene. Benzyl chloride, $\text{C}_6\text{H}_5\text{—CH}_2\text{—Cl}$, heated with aqueous lead or cupric nitrate furnishes benzaldehyde, which is also prepared by heating benzal or benzylidene chloride, $\text{C}_6\text{H}_5\text{—CHCl}_2$, with aqueous calcium hydroxide. As prepared by either method, benzaldehyde is contaminated with traces of chlorinated benzaldehydes, and when chlorine-free benzaldehyde is needed it is prepared by the direct oxidation of toluene by chemical means (manganese dioxide and sulfuric acid) or by electrolytic means (in acetone-sulfuric acid solution with platinum electrodes).

Benzaldehyde is a colourless, highly refractive liquid boiling at $179^\circ\text{--}180^\circ\text{C}$. with the characteristic odour of oil of bitter almonds

of which oil it is the essential constituent, being derived from the hydrolysis of the glucoside, amygdalin, present in the almond. It readily absorbs oxygen from the air, becoming oxidized to benzoic acid. With aqueous caustic alkalis it undergoes the Cannizzaro reaction. $2\text{C}_6\text{H}_5\text{—CHO} = \text{C}_6\text{H}_5\text{—CH}_2\text{—OH} + \text{C}_6\text{H}_5\text{—CO}_2\text{H}$, yielding molecular proportions of benzyl alcohol and benzoic acid. With alcoholic potassium cyanide, it gives benzoin, $\text{C}_6\text{H}_5\text{—CH(OH)—CO—C}_6\text{H}_5$. Benzaldehyde is also an important intermediate in the production of colouring matters (see **DYES**).

Furfural (*q.v.*) (furfuraldehyde) is an example of a nonaromatic cyclic aldehyde manufactured in the U.S. by the action of steam and dilute acid on oat hulls and corncobs and cornstalks contained in large digesters.

The volatile furfural (b.p. $160^\circ\text{--}162^\circ\text{C}$.) is isolated and purified by fractional distillation.

General Methods of Preparation.—**Direct Synthesis.**—Arising from a study of chemical reactions under high pressure it has been found that when carbon monoxide and hydrogen are heated together at $360^\circ\text{--}380^\circ\text{C}$. under a pressure of 200 atm. in the presence of a mixed catalyst consisting of the oxides of cobalt, copper, manganese and zinc, a mixture of aliphatic aldehydes is produced among which formaldehyde, acetaldehyde, propionaldehyde and higher aldehydes have been identified (see **PRESSURE CHEMISTRY**).

Action of Ozone on Olefines.—During an investigation of the action of ozone on various organic substances, C. D. Harries discovered that this active form of oxygen has a specific action on carbon compounds containing a double or ethylenic linkage. A molecular proportion of ozone attaches itself to the carbon atoms of the double bond, forming an ozonide, which on treatment with water yields an aldehyde and an aldehyde peroxide, the latter becoming transformed into an acid. In the simplest case of ethylene this gas furnishes an explosive ozonide which subsequently gives rise to formaldehyde and formic acid,

A similar ozonization applied to more complex olefines has led to aldehydes which are otherwise prepared only with difficulty:

Dehydrogenation of Primary Alcohols.—The primary alcohols may be dehydrogenated either thermally or by oxidation. It is from such transformations that the word "aldehyde" (alcohol dehydrogenatum) was originally derived by J. von Liebig. In the former process the alcohol is passed over a heated metallic catalyst, preferably copper, although nickel, palladium or platinum or such oxides as vanadium pentoxide, V_2O_5 , may be employed. The oxidation of a primary alcohol to an aldehyde is generally effected by aqueous chromic acid (a solution of sodium bichromate and dilute sulfuric acid), but other oxidizing agents such as manganese dioxide and dilute sulfuric acid, or even atmospheric oxygen in presence of platinum black or bone black, may be employed.

Thermal Decomposition of α -Hydroxycarboxylic Acids.—This process, discovered by H. R. Le Sueur, has been worked out chiefly with the higher fatty acids. For example, stearic acid is converted successively into α -bromostearic and α -hydroxystearic acids. The latter acid, on heating at 270°C ., yields margaric aldehyde, $\text{C}_{16}\text{H}_{33}\text{—CHO}$, and formic acid. Incidentally this method forms a means of passing from common acids such as stearic and palmitic acids, which are readily obtained from natural sources, to acids such as margaric acid, $\text{C}_{16}\text{H}_{33}\text{—COOH}$, which do not occur in nature.

Aldehydes From Calcium Formate and Salts.—Another general method for aldehydes depends on the heating together of an intimate mixture of calcium formate and the calcium salt of some other acid:

Aldehydes From Grignard Reagents.—Grignard reagents (*q.v.*), with the general structure RMgX , react with disubstituted formamides $\text{H}-\text{CO}-\text{NR}'$ to give products which on hydrolysis yield the aldehydes RCHO ; and with ethyl orthoformate $\text{HC}(\text{OC}_2\text{H}_5)_3$ to give the acetals $\text{RCH}(\text{OC}_2\text{H}_5)_2$, from which the aldehydes RCHO can be freed by the action of an aqueous acid.

Aldehydes by Reduction.—Acid chlorides RCOCl , dissolved in quinoline (*q.v.*), can be reduced to aldehydes RCHO by hydrogen H_2 in the presence of a platinum catalyst.

Aromatic Aldehydes From phenols.—A long-known process for the conversion of phenols into hydroxy-aryl-aldehydes is associated with the names of C. L. Reimer and F. Tiemann. It consists in treating the phenolic compound with chloroform in presence of concentrated alkalis. With phenol itself the reaction proceeds as follows:

Two isomerides are produced, parahydroxybenzaldehyde and salicylaldehyde (orthohydroxybenzaldehyde). The latter isomeride occurs in the volatile oils of *Spiraea* and in the glucoside, salicin, of the willow.

Syntheses Catalyzed by Metal Halides.—The two syntheses described under this heading, which are due to L. Gattermann, are, like those of the preceding section, applicable only to the aromatic series. The first depends on the use of carbon monoxide, this gas and hydrogen chloride being passed into a solution of an aromatic hydrocarbon in a dry solvent in the presence of cuprous and aluminum chlorides. In the case of toluene the condensation gives rise to *p*-tolualdehyde. In all probability the carbon monoxide absorbed by the cuprous chloride forms an intermediate compound, $\text{H}-\text{COCl}$, with the hydrogen chloride and this unstable formyl chloride under the influence of aluminum chloride condenses with the hydrocarbon to give rise to the aldehyde:

The second Gattermann synthesis involves the use of hydrogen cyanide (anhydrous prussic acid), and since this reagent is now procurable on a manufacturing scale (see PRUSSIC ACID) the synthesis offers industrial possibilities. The aromatic substance, which may be a hydrocarbon or a phenol, is dissolved in a dry solvent containing anhydrous aluminum or zinc chloride and to this mixture hydrogen cyanide is added while hydrogen chloride is bubbled in to saturation. The two hydrides interact potentially as $\text{HN}=\text{CHCl}$:

The aldehyde-imine thus formed as an intermediate product is hydrolyzed, when boiled with water, into ammonia and the corresponding aldehyde, $\text{HO}-\text{C}_6\text{H}_4-\text{CHO}$.

General Reactions of Aldehydes.—The aldehydes combine additively with sodium hydrogen sulfite to furnish bisulfite compounds, $\text{R}-\text{CH}(\text{OH})-\text{SO}_2\text{Na}$. These compounds, being crystallizable and easily hydrolyzed by dilute acid, are frequently used in the purification of the aldehydes. Sodium hydrosulfite also interacts with aldehydes, giving rise to compounds of the general formula $\text{R}-\text{CH}(\text{OH})-\text{SO}_2\text{Na}$. The formaldehyde compound is the important reducing agent Rongalite, employed in calico printing for discharging the colour of dyes.

Aldehydes react with hydrogen cyanide to form cyanohydrins, $\text{R}-\text{CH}(\text{OH})-\text{CN}$, which are hydrolyzable to α -hydroxycarboxylic acids containing one more carbon atom than the original aldehyde. Aldehydes combine with hydroxylamine to form oximes (*q.v.*), with phenylhydrazine to phenylhydrazones and with semicarbazide to crystallizable semicarbazones. The action of active metals in the presence of acids reduces aldehydes to primary alcohols, whereas with Grignard reagents they are converted into secondary alcohols. Formaldehyde condenses with aqueous am-

monia to form hexamethylenetetramine, $\text{N}_4(\text{CH}_2)_6$, a urinary antiseptic, urotropine, whereas the other aliphatic aldehydes combine with ethereal ammonia to give aldehyde-ammonias, which are usually assigned structures of the type $\text{R}-\text{CH}(\text{OH})-\text{NH}_2$, but which are actually of uncertain composition and molecular weight; from these the aldehydes can be regenerated by distillation with dilute acid. Aldehydes in general are characterized by the colour reaction of H. Schiff, this being the reddish-violet coloration developed with a solution of magenta or fuchsine which has been decolorized by sulfurous acid. See also CHEMISTRY: Organic.

KETONES

Ketones have the general formula $\text{R}-\text{CO}-\text{R}'$ (see above). If the groups R and R' are identical, the ketone is called a simple ketone, of which the best known and simplest example is acetone (*q.v.*), used in large amounts during World Wars I and II as a solvent in the manufacture of the explosive cordite. If the groups R and R' are different, a mixed ketone results, and of this class acetophenone (*q.v.*), $\text{CH}_3-\text{CO}-\text{C}_6\text{H}_5$, may be cited as a typical representative. It is used as a soporific under the name of "hypnone."

The lower members of the aliphatic ketones are liquids and are lighter than water; the higher members containing C_{12} and upward are solid. (For the initial member of the series see ACETONE.) Methyl ethyl ketone, $\text{CH}_3-\text{CO}-\text{C}_2\text{H}_5$, the simplest of the mixed ketones, occurs in the products of thermal decomposition of wood and is also prepared by the dehydrogenation of *sec*-butyl alcohol, $\text{CH}_3-\text{CHOH}-\text{C}_2\text{H}_5$ (see below). This ketone is employed in the preparation of dimethylglyoxime, a useful analytical reagent for nickel (*q.v.*). Pinacolone, or methyl *tert*-butyl ketone, $\text{CH}_3-\text{CO}-\text{C}(\text{CH}_3)_3$, a liquid boiling at 106°C . and having a camphoraceous odour, is produced by the action of dilute sulfuric acid on pinacol (see GLYCOLS), this peculiar reaction being known as the "pinacol rearrangement." The aromatic ketones may be either partly aliphatic or totally aromatic. The simplest and most important examples of these two types of substances are given respectively, by the already mentioned acetophenone and by benzophenone (*q.v.*), $\text{C}_6\text{H}_5-\text{CO}-\text{C}_6\text{H}_5$.

General Methods of Preparation.—(1) from secondary alcohols, either by oxidation or by thermal dehydrogenation in the presence of catalysts, such as heated-reduced copper: $(\text{CH}_3)_2\text{CHOH}-2\text{H}=(\text{CH}_3)_2\text{CO}$; (2) hydration of derivatives of acetylene, preferably in the presence of sulfuric acid and of mercuric salts, $\text{C}_6\text{H}_5-\text{C}\equiv\text{CH} + \text{H}_2\text{O} = \text{C}_6\text{H}_5-\text{CO}-\text{CH}_3$; (3) the interaction of acid chlorides and organo-zinc or organo-cadmium compounds, e.g., $\text{C}_6\text{H}_5-\text{COCl} + \text{Cd}(\text{CH}_3)_2 = \text{C}_6\text{H}_5\text{CO}-\text{CH}_3 + \text{CH}_3\text{CdCl}$; (4) the Friedel and Crafts reaction is applicable to ketones containing one or two aromatic radicals; e.g., acetyl chloride with benzene gives acetophenone; carbonyl chloride or benzoyl chloride with benzene gives benzophenone.

General Reactions.—Oxidation and Reduction.—Ketones are relatively resistant to oxidizing agents. However, they are easily reduced to secondary alcohols by hydrogen and a platinum, palladium or nickel catalyst, and to mixtures of secondary alcohols and pinacols (see GLYCOLS) by aluminum, sodium or magnesium amalgams.

Addition Products.—Such products are formed less readily by ketones than by aldehydes. Nevertheless ketones and mercaptans form addition compounds, the mercaptols, such as $(\text{CH}_3)_2\text{C}(\text{SC}_2\text{H}_5)_2$ from acetone and ethyl mercaptan. This mercaptol on oxidation furnishes the drug sulfonal. Grignard reagents (*q.v.*) add to ketones, and the products when decomposed by water give rise to tertiary alcohols. Hydrogen cyanide and ketones give rise to hydroxynitriles hydrolysable to hydroxycarboxylic acids, and a few ketones unite with sodium hydrogen sulfite, yielding bisulfite compounds from which the ketone can be regenerated by aqueous sodium carbonate.

Condensation Products.—Ketones condense with hydroxylamine, giving ketoximes, although not always so readily as aldehydes give aldoximes. With a mixed ketone, $\text{R}-\text{CO}-\text{R}'$, two oximes, $\text{R}-\text{CR}'=\text{NOH}$, are often obtained, the isomerism of which is explained by assuming a different spatial arrangement of

the groups R, R' and OH about the doubly linked residue —C=N— (A. R. Hantzsch and A. Werner, 1890). In studying the stereoisomeric oximes (see STEREOCHEMISTRY: *Stereochemistry of Nitrogen*), considerable use has been made of a characteristic chemical change undergone by ketoximes, known as the Beckmann rearrangement (1886), which results in each of these isomeric oximes, R—CR'—NOH , changing into the corresponding amide, R—CO—NHR' or R'CO—NHR (see OXIMES). This change is effected by phosphorus pentachloride, benzenesulfonyl chloride or warm concentrated sulfuric acid. Ketones condense with phenylhydrazine and other hydrazines to yield characteristic hydrazones which are useful for the purposes of isolation and identification. Ketones condense with ketones and esters under the action of catalysts. Thus, acetone reacts with itself to give diacetone alcohol, $(\text{CH}_3)_2\text{C}(\text{OH})\text{CH}_2\text{—CO—CH}_3$, and mesityl oxide, $(\text{CH}_3)_2\text{C}=\text{CH—CO—CH}_3$.

Diketones.—Compounds containing in their molecules two ketonic groups are termed diketones, and the group is divisible into subgroups depending on whether the two carbonyl groups are adjacent or separated by one or more carbon atoms.

Diacetyl, $\text{CH}_3\text{—CO—CO—CH}_3$, the simplest member of the 1,2- or α -diketones, is a yellowish-green liquid boiling at 88°C . and of specific gravity 0.9734 at 22°C . It is found in the aqueous distillates of many essential oils; for example, bay, cedarwood, iris and sandalwood oils, to which it communicates its colour and odour. It occurs also in butter, for the characteristic odour of which it is largely responsible. Diacetyl is made from methyl ethyl ketone by treatment of this ketone with amyl nitrite and subsequent hydrolysis of the resulting diacetyl-monoxime with dilute sulfuric acid. Diacetyldioxime or dimethylglyoxime is prepared by treating methyl ethyl ketone successively with amyl nitrite in presence of hydrogen chloride and with hydroxylamine hydrochloride.

Acetylacetone, the simplest member of the 1,3- or β -diketones, is a colourless pungent liquid boiling at 139°C . It is regarded as an equilibrium mixture of two isomeric forms, $\text{CH}_3\text{—CO—CH}_2\text{—CO—CH}_3$ and $\text{CH}_3\text{—C}(\text{OH})=\text{CH—CO—CH}_3$, the latter predominating. Acetylacetone is prepared by adding successively ethyl acetate and acetone to sodium wire under dry ether.

See J. F. Thorpe and M. A. Whiteley, *Dictionary of Applied Chemistry*, 4th ed., vol. vii (1946); J. Houben, *Die Methoden der organischen Chemie*, vol. iii (1930). (G. T. M.; G. W. Wd.)

ALDEN, JOHN (1599?–1687), one of the Pilgrims who in 1620 emigrated to America in the "Mayflower," founded the Plymouth colony. He was a settler of Duxbury, Mass., where he lived for most of his life. From 1633 until 1686 he was an assistant to the governor of the colony, frequently acting as governor. At the time of his death on Sept. 12, 1687, he was the last male survivor of the "Mayflower" company.

He is remembered chiefly because of a popular legend, put into verse as "The Courtship of Miles Standish" by Henry W. Longfellow, concerning his courtship of Priscilla Mullins, whom he married in 1623, after having wooed her first for his friend Myles Standish.

ALDER, KURT (1902–1958), German chemist, was awarded the 1950 Nobel prize for chemistry jointly with Otto Diels for the development of the diene synthesis, one of the outstanding achievements of modern organic chemistry. Born at Königshütte (Chorzów) on July 10, 1902, he studied chemistry in Berlin and Kiel, where he received his doctor's degree in 1926. He was professor at Kiel (1934–36) and worked in the research laboratories of I. G. Farben at Leverkusen (1936–40). In 1940 he became professor of chemistry and director of the chemical institute at the University of Cologne. He died in Cologne, June 20, 1958.

The diene synthesis consists essentially of the addition of substances containing two conjugate double bonds, such as the butadienes, to substances such as maleic acid or quinones. Diels and Alder published their first paper on the reaction of dienes with quinones in 1928. Similar additions had been recorded by others, but it was Diels and Alder who provided the first experimental proof of the nature of the reaction and who demonstrated

its application to the synthesis of a wide variety of ring compounds

A remarkable feature of the diene synthesis is the ease with which it can be effected without the use of powerful chemical reagents. Study of the reaction has contributed greatly to the knowledge of polymerization processes by which valuable plastic materials have been obtained. The discovery is of considerable theoretical interest, because many plant products are probably formed in nature by diene additions. (W. J. BP)

ALDER (*Alnus*), the name given to a group of shrubs and trees belonging to the birch family (Betulaceae), comprises about 30 species distributed through the north temperate zone. In the new world a few extend south over the mountains of Central America and the South American Andes to Peru and Chile. They

JOHN MARKHAM
ALDER (*ALNUS GLUTINOSA*). (LEFT) YOUNG MALE CATKINS; (CENTRE) RIPENING CONES; (RIGHT) DRIED CONES

are readily distinguished from the birches by their stalked, valvate, winter buds, and cones (strobiles) with thick woody scales which persist on the branchlets long after their small winged fruits (nutlets) have been released.

The black alder (*A. glutinosa*), the most important old-world species, is widespread on wet sites in Europe, Asia and northern Africa, and has become naturalized in the eastern United States. It is the only alder indigenous to Great Britain, where it attains a height of 75 ft. and a diameter of 30 in. The soft, light-brown wood is used for many purposes

including furniture, piling and charcoal manufacture. The speckled or hoary alder (*A. incana*), usually a large shrub, is found in Europe and northern Asia and in swamps of eastern United States and Canada. The green alder (*A. viridis*), a small shrub of Europe and Asia, is also found in eastern North America.

The alders of the Rocky mountain region and Pacific slope often become large trees. Among these are the red alder (*A. rubra*), the Sitka alder (*A. sinuata*) and the white alder (*A. rhombifolia*).

The red alder, which attains a height of 120 ft. and a diameter of 40 in., is the most valuable. The wood is soft, works well and is largely used in the manufacture of inexpensive furniture.

In mountain regions alders are among the first woody plants to appear in areas denuded by avalanches and in the rubble around the edges of receding glaciers

Many alders are prized ornamentals, especially horticultural varieties of the black and speckled alder and the Japanese alder (*A. japonica*), which is one of the largest and most beautiful members of the genus. (E. S. Hr.)

ALDER FLY, the name given to insects of the family Sialidae of the order Neuroptera; they are characterized by long filamentous antennae and four large wings, of which the hind pair has the anal area folded fanwise when at rest. They are dark-coloured, sluggish insects, one inch or less in length, and are found only near fresh water. The eggs, often very numerous, are laid in clusters on plants, etc., close to the water. The larvae are aquatic, living in streams, large rivers or lakes; they have biting jaws and breathe by seven or eight pairs of filamentous abdominal gills. The pupae are found in soil, moss, etc., and there is no cocoon.

Sialis lutaria is the common alder fly of Great Britain. In North America there are 18 species, several of which are common and widely distributed.

See NEUROPTERA: Megaloptera.

ALDERMAN, a term indicating membership in the legislative body of a municipal corporation in England and the United States. The word alderman had an extended meaning in early English law, some authorities enumerating 11 classes of aldermen. Among the

Anglo-Saxons, earls, governors of provinces and other persons of distinction received this title; later the term was used to designate the chief magistrate of a county or group of counties.

In the American colonial period city councils resembled their British prototypes, in which aldermen and common councilors commonly sat together as one body under the chairmanship of the mayor. In most colonial boroughs both aldermen and councilmen were chosen by the voters, but in a few cases only councilmen were elected, the aldermen being selected by the councilmen as in England. In addition to their legislative duties as members of the council, aldermen in the colonial period also exercised judicial power in minor civil and criminal cases. The mayor, recorder and aldermen sat together to try important cases where they did not have jurisdiction when sitting singly.

Following the colonial period, all members of the council, including aldermen, were elected by popular vote. During the 19th century extensive use was made of the bicameral legislative principle by municipalities, one house being designated as the board of aldermen and the other as the common council. The bicameral principle was gradually abandoned and by the second half of the 20th century had practically disappeared. The members of this single house came to be referred to in the statutes and city charters of some states as councilmen or members of the council, but they were frequently referred to popularly as aldermen; and in some states the legal terminology as well as the popular designation was alderman. The term was generally reserved for members of the council in mayor- and council-governed cities, members of the council in commission-governed and council-manager cities being referred to both by law and popularly as commissioners or councilmen. Aldermen, as opposed to councilmen and commissioners, are usually elected by wards, and the term has come to have that implication.

By the English Municipal Corporations acts of 1835 and 1882, and by the Local Government act of 1933, the term was used to designate one type of membership in borough and county councils. While local government councils in England are unicameral in nature, county councils and those in county boroughs and municipal boroughs have two types of members—councilors and aldermen. The councilors are elected by the voters; a number of aldermen equal to one-third the whole number of councilors are then selected by the councilors. In the case of the London county council and the metropolitan borough councils, the number of aldermen is one-sixth the number of councilors. Anyone may be selected as alderman who is a councilor or is eligible to be elected as councilor. Aldermen serve for a term of six years while councilors serve for three years. Councilors who have had a long period of service are frequently selected as aldermen. The office of alderman is also found in Ireland; in Scotland the office of bailie corresponds to the English alderman.

See Eugene McQuillin, *The Law of Municipal Corporations*, 20 vol. (1949-51). (C. M. KR)

ALDERNEY (French, *AURIGNY*), the northernmost of the larger Channel Islands. It is $3\frac{1}{2}$ mi. long from north-northeast to west-southwest, about 1 mi. wide and a little over 3 sq mi. in area. The French coast is 9 mi. away across the Race of Alderney; the nearest English coast is about 55 mi distant.

Physiography.—Alderney is a tableland cut partly in crystalline rocks and partly in sandstones. Granite and granulite in the south-east and syenite in the centre are thought to be of Pre-Cambrian Age; the coarse sandstone of the east, with its outlier on the south coast, belongs to the Lower Cambrian. Superficial deposits include weathering-products, loess, raised beaches and the blown sand which occurs north of Longy bay. The plateau, mostly over 200 ft. above sea level and just below 300 ft. at the highest, is very little dissected, but the terrain becomes lower and hillier in the east where it is additionally complicated by quarries. Steep cliffs between 175 and 275 ft. in height line the south and west coasts, while old cliffs rise behind raised beaches in the north and east. The two main inlets are Braye harbour, protected by a 1,000-yd. breakwater, on the north, and Longy bay, backed by an almost-filled lagoon, on the southeast.

Local tides are dangerous and strong. Races include the Swinge,

a narrow channel on the west which separates Alderney from the uninhabited Burhou, Ortac and smaller islets. Beyond these, the notorious Casquets carry a lighthouse. (G. H. D.)

History.—The earliest known inhabitants of Alderney were the builders of the megalithic tombs. The Bronze Age is well represented and the Romans appear to have built a small fort ("The Nunnery") on the island, possibly as part of the fortifications of the "Saxon Shore." Nothing is known of the island during the dark ages until it appears as part of the domain of the duke of Normandy early in the 11th century. Then and later the chapter of Coutances and Cherbourg abbey acquired important properties on the island. During the 13th and 14th centuries the administration of Alderney was similar to that of the other islands, on a reduced scale, the king's court being composed of a *prévôt* and seven jurats. (In the 13th century the chapter of Coutances claimed that it shared the lordship with the king and that the court was presided over alternately by the chapter's *prévôt* and the king's; but no evidence survives to support this claim.) The history of Alderney during the later middle ages is obscure. The island was occupied by the French from 1338 to 1340, and, though it never seems to have been left uninhabited as Sark was, it was frequently raided until late in the 16th century. In 1559 it was leased to George Chamberlain, and granted by letters patent to his brother John in 1584. John Chamberlain transferred the grant to the earl of Essex, whose descendants held it until the Civil War, though they never visited the island. From the Restoration, the government of Alderney was separated from that of Guernsey, being granted in 1660 to Edward de Carteret, who transferred it in 1661 to George de Carteret. George's widow sold it to Edmund Andros of Guernsey (c. 1682) from whom it descended to the Le Mesurier family, who held the island as hereditary governors until 1825, when it was reabsorbed into the government of Guernsey. During the 19th century Alderney was heavily fortified by the British government, which maintained a large garrison there until 1930. Immediately before the German occupation of June–July 1940, Alderney was completely evacuated. Repatriation of the Alderney community, which had been held together in England, was carried out between Nov. 1945 and July 1946. As a result, it has been necessary to re-create the island's economy and to make important changes in its government (1948–49). (See also CHANNEL ISLANDS.) (LE P.)

Population, Local Government and Communications.—Inhabitants were estimated at 1,350 (1956). The total has exceeded 1,000 since the late 17th century, except during the World War II evacuation and was above 1,500 at the censuses of 1921 and 1931. During the mid-19th century numbers were at times brought above 3,000 by a military garrison and by workers on the admiralty breakwater and war office forts constructed between 1845 and 1860. Exceptionally for the Channel Islands, settlement on Alderney is nucleated, most inhabitants living in the only town, St. Anne's, on the brow of the plateau overlooking Braye harbour. (Until the 16th or 17th century St. Anne's appears to have been called Sainte-Marie.) Newtown forms an appendage of St. Anne's at a lower level. Nucleation of settlement was associated with the holding of land in common; the cultivated area of the plateau top, the Blaye, is the common arable attached to St. Anne's; former common grazings, however, were distributed in 1831.

Alderney is included in the bailiwick of Guernsey (*q.v.*), but has its own local administration. Under the reformed constitution of 1949, the president and states of Alderney (nine members) are popularly elected; the court of Alderney administers justice.

Communications are directed through Guernsey, to which Alderney is linked by air and shipping services. In addition to regular sailings of passenger and cargo vessels between the two islands; there are excursions in the summer season.

Production and Economy.—With external traffic delayed by transit through Guernsey, Alderney is poorly placed to share in the cropping for export which distinguishes the two largest Channel Islands. Tillage declined steeply between the two world wars, dairying becoming the leading type of farming and much of the Blaye being put to ley grass. Dairy farming and the tourist trade

are the bases of the present economy. Little fishing is practised and the stone quarrying which flourished during the 19th century has almost ceased. (G. H. D.)

See L. L. Clarke, *The Island of Alderney* (1851); articles in *Transactions of La Société Guernesiaise*, esp. vol. xvi, A. H. Ewen, "The Town of St. Anne, Alderney", *Report of the Committee of the Privy Council on the Island of Alderney* (1949: Cmd 7805); for general works see CHANNEL ISLANDS.

ALDERSHOT, a municipal borough in the Aldershot parliamentary division of Hampshire, Eng., 34 mi. S.W. of London by road. Pop. (1961) 31,260. Area 6.5 sq. mi. Aldershot was a mere village until 1854 when a permanent military camp was established there on the advice of Lord Hardinge, commander in chief of the British army. He had already formed a temporary training camp on Chobham ridges, north-northeast of Aldershot, in 1852. During World War II Aldershot became a district and part of Southern command.

The borough, incorporated in 1922, is governed by 35 council members, 3 of whom are directly appointed by the secretary of state for war, in which respect Aldershot is unique. The military area in the immediate vicinity of the town is more than 4 sq mi, including training grounds adjacent to the buildings. The borough now entirely built up, has extended its houses over the county boundary into Surrey. There are several recreation grounds covering an area of more than 153 ac. The industries include printing and the manufacture of briar pipes and cosmetics.

On a hill to the west of the town is an equestrian statue of the duke of Wellington which was brought there from London in 1835.

ALDRIFRITH (d. 704), king of Northumbria from 685 to 704, was notable as a patron of literature. An illegitimate son of Oswiu, he succeeded to the throne when his brother Egfrith was killed at the battle of Nechtansmere, after which Bede says that "he nobly restored the ruined state of the kingdom, though within narrower bounds." Aldfrith was educated for the priesthood probably studying at Malmesbury and in Ireland. Bede, Eddi (Eddius) and Alcuin praised his learning and Aldhelm dedicated to him, under the name of Acircius, his work on Latin metres. He was visited by Adamnan, abbot of Iona, whose work on the Holy Places he caused to be copied and he gave to the monastery of Wearmouth a large estate in exchange for a work on cosmography brought from Rome by Benedict Biscop. Stimulated by his interest, Northumbrian scholarship flourished, producing the conditions under which Bede was educated. Aldfrith resisted Bishop Wilfrid's claims to the whole of Northumbria as his see and expelled him in 691; in 702 he held a council at Austerfield on this question, but, although Wilfrid appealed to Rome, he was not restored in Northumbria until after Aldfrith had died, in Driffield, on Dec. 14, 704.

ALDHELM (c. 639–709), abbot of Malmesbury in Wiltshire, Eng., the most learned teacher of 7th-century Wessex, a pioneer in the art of Latin verse among the English and author of numerous writings in Latin in both verse and prose which are still extant, was born about 639 in southwest England, of the royal house of the west Saxons. His education gave him training both in Celtic-Irish scholarship, then eagerly sought by the Saxons, and in knowledge from continental sources. As a boy of about 15 he entered the monastic enclosure which had been established at Malmesbury, where he learned Latin, with something of the Latin Bible and its interpretation by the Latin Fathers, from Maelduib (Maildulf) Malmesbury's Irish founder. Soon after he was 30 he went on to study in the famous School of Canterbury under Theodore of Tarsus, consecrated archbishop in 668, and Hadrian, once abbot of a monastery near Naples, who was head of the abbey of St. Peter and St. Paul. There Aldhelm studied biblical and patristic writings and canon and civil law. He read widely in Latin poetry and prose, pagan as well as sacred, he learned Greek, he followed the arithmetic and the astronomy of his day, and he worked hard at the varied forms and intricacies of metrical science. But these secular studies were to him but handmaids in the service of the

church.

Eventually he returned to Malmesbury, where, about 675, he succeeded Maelduib as abbot. From this time until 705 he carried on a threefold work, as monk and priest, as encourager of learning, and as Latin poet.

His work as monk and priest was both pastoral and concerned with the development of the west Saxon church. At Malmesbury he trained Saxon youths as novices in the rule of St. Benedict, then making its way into English houses of religion; he built three churches; and he taught the people of the surrounding countryside. A pleasant story tells that he was skilled in his native Anglo-Saxon song, and that on Sunday mornings he would stand on the bridge over the Avon to try to attract by his singing lazy peasants who had stolen out of church before the sermon which followed the liturgy. He also founded a monastery at Bradford-on-Avon, in Wiltshire, and another at Frome in Somerset. About 693 he journeyed to Rome as a pilgrim at the invitation of the pope and brought back for the monasteries under his control a written privilege of exemption from papal control. At the request of the Saxon bishops he composed a letter of remonstrance addressed to the British king and the clergy of Devon and Cornwall, exhorting them to give up their stubborn adherence to their own Celtic dating of Easter and to their Celtic tonsure in favour of the Roman discipline, which was followed by Canterbury.

As scholar and teacher Aldhelm's influence was chiefly exerted through the aid and encouragement he gave to other scholars by his vigorous letters. Those still extant show evidence of his Celtic training. They are written in an almost unreadable Latin: a mixture of words foreign, hybrid, artificial, piled one on another in long, alliterative sequences, in swollen, bombastic sentences. Such concoction of "Latin" prose was the delight of many Celtic scholars in the early middle ages. In similar prose he also wrote a lengthy treatise on the celibate life for the nuns of Barking in Essex. Its flood of learning and its difficult style so delighted the community that he promptly proceeded to make a version in Latin hexameters.

For it was on metrical science that Aldhelm spent the time he could spare from his duties as abbot and counselor. The riddles of Symphosius, a 5th- or 6th-century Latin poet, inspired him to compose 100 brief poems of the same kind in Latin hexameters; these he inserted as illustrations in a treatise on metrics sent to his friend Aldfrith, king of Northumbria from 685 to 704. Usually of four or five lines, they describe everyday objects both natural and man-made in riddles and double acrostics intended to puzzle and delight the reader. There are pictures in verse of sun, clouds, wind, fire and water; of beast, bird and insect (lion, elephant and camel; eagle, nightingale and swallow; spider, caterpillar and bee); of household utensils and tools (candle, spindle, bellows, even a "double cooker"); of pen and writing tablets; and of an organ. Finally all is summed up in 83 lines praising the Lord who created all.

At the end of his treatise Aldhelm asked Aldfrith to study and to defend this new venture in writing: "no one of Saxon race has toiled in this way before myself." In the 8th century Saxon writers—Tatwine, archbishop of Canterbury; Eusebius, probably abbot of Wearmouth in Durham; St. Boniface, apostle of Germany—found in Aldhelm's work inspiration for their own Latin riddles.

In 705 Aldhelm was consecrated bishop for the region west of Selwood forest: Somerset and parts of Dorset and Devon, with his seat at Sherborne in Dorset. He died in 709 at Doulting in Somerset. Its church bears his name, as do those of Broadway in Somerset and Bishopstrow in Wiltshire.

The best edition of Aldhelm's work is *Aldhelmi S. Opera*, by R. Ehwald, in *Monumenta Germaniae Historica, Auctores Antiquissimi*, xv (1919). There is also an edition by J. A. Giles, *Patres Ecclesiae Anglicanae*, i (1844), reprinted in J. P. Migne, *Patrologia Latina*, lxxxix, 87 ff.; it includes a *Vita S. Aldhelmi* (by Faricius, abbot of Abingdon, d. 1117).

ALDOBRANDESCHI, in medieval Italy, a Tuscan feudal family, which was probably descended from a Count Hildebrand recorded in the late 9th century. The period of the Aldobrandeschi's greatest power was in the 11th and 12th centuries, when their lands extended from Colle di Val d'Elsa near Siena to the lake of Bolsena and included the Tuscan Maremma, Mt. Amiata and the towns of Grosseto and Pitigliano. While the size and situation of their lands enabled the Aldobrandeschi to hold out against the communes longer than most other feudal families of Tuscany, they gradually yielded ground to Siena and Orvieto, being much weakened after 1208 by the division of their lands among the four sons of Count Aldobrandino. After 1216 Orvieto gained control of the territory situated south of the Albegna river, and Siena, to which the Aldobrandeschi had submitted in 1221, captured Grosseto in 1224. In the course of the 13th century Orvieto and Siena increased their effective hold over the Aldobrandeschine lands. The division of these between the Aldobrandeschi of Santa Fiora and those of Sovana-Pitigliano became definitive in 1274. The lands of the Aldobrandeschi of Sovana-Pitigliano passed to the Orsini in the following century.

See G. Ciacci, *Gli Aldobrandeschi nella storia e nella "Divina Commedia"* (1935); D. Waley, *Mediaeval Orvieto* (1952). (N. R.)

ALDRED (EALDRED) (d. 1069), Anglo-Saxon archbishop of York who played an important part in politics at the Norman conquest. He became bishop of Worcester in 1046 but was made to relinquish this see in 1062 by the pope, having become archbishop of York at Christmas 1060. He nevertheless retained for some time all but 7 of the Worcester estates and kept 12 until his death. He unsuccessfully claimed jurisdiction over Lindsey against the bishop of Dorchester. He was prominent even before his elevation to York and in 1054 he went to Germany to negotiate the return of the heir to the throne, Edward, son of Edmund II "Ironside." He administered the see of Ramsbury (Wiltshire) from about 1055 to 1058, and that of Hereford from 1056 to 1060. In 1058 he made a pilgrimage to Jerusalem. As archbishop, he established prebends at Southwell and added to the buildings there and at York and Beverley, which he enriched with treasures. He was a friend of Earl Godwin's sons, and it was probably he who crowned Harold as king. After the battle of Hastings he was among those who wished to elect Edgar the Atheling, but soon after he submitted to William at Berkhamsted. He crowned William on Christmas day 1066. He died in York on Sept. 11, 1069.

ALDRICH, NELSON WILMARTH (1841–1915), U.S. senator and financier, was born in Foster, R.I., Nov. 6, 1841. Highly competent in politics and business, he rose from the Providence common council through the Rhode Island legislature to the U.S. congress (representative 1879–81, senator 1881–1911), meanwhile amassing a modest fortune through investments in banking, electricity, gas, rubber, sugar and traction. A member of the small inner coterie setting Republican legislative policy, he was distinguished for his great skill in handling both friendly and unfriendly individuals. Attackers could not disturb his equipoise. He was exceptionally free from presidential ambitions, political resentments and oratorical compulsions. He quietly and effectively implemented conservative Republican doctrines, shouldering much of the labour in securing the rising rates in the tariffs. Through his influence the Interstate Commerce act of 1887 and the Sherman Anti-Trust act of 1890 were modified in a conservative direction. By his work on the Aldrich-Vreeland Currency act of 1908 and his chairmanship of the national monetary commission, 1908–12, he helped to prepare the way for the Federal Reserve act of 1913 (see FEDERAL RESERVE SYSTEM, THE.) He died in New York city, April 16, 1915.

See N. W. Stephenson, *Nelson W. Aldrich, a Leader in American Poli-*

tics (1930).

(J. P. N.)

ALDRICH, THOMAS BAILEY (1836–1907), U.S. author and editor, was born on Nov. 11, 1836, in Portsmouth, N.H., a town portrayed in his popular classic *The Story of a Bad Boy*. His education was interrupted at the age of 13, when his father died, and shortly after he became a merchant's clerk in New York city. He began to contribute to various newspapers and magazines. After publication of his first book of verse, *The Bells* (1855), he became junior literary critic on the *New York Evening Mirror*, and later subeditor of the *Home Journal*. For the remainder of his life he devoted himself to literary work. He acted as adviser to various publishing houses, but his chief work was as a contributor to and editor of various magazines. He was editor of the *Atlantic Monthly* (1881–90).

The cultural atmosphere of New England and his frequent European tours were the most influential factors in ripening his art. Few poets have so ruthlessly discarded early poems in later editions. His verse is therefore better studied in later volumes such as *Cloth of Gold* (1874), *Flower and Thorn* (1877), *Mercedes and Later Lyrics* (1884), *Windham Towers* (1890), and the various collected editions. These show him to be a poet of lyrical skill and felicitous conceit. His long narrative and dramatic poems are less successful.

His best-known prose works are the autobiographical *The Story of a Bad Boy* (1870), and *Marjorie Daw and Other People* (1873), a collection of short stories. His effective use of the surprise ending influenced the development of the short story. He died in Boston, Mass., March 19, 1907.

Aldrich's writings were collected in 1897 and in 1907 (Ponkapog edition). See also Ferris Greenslet, *Life of Thomas Bailey Aldrich* (1908), and Lilian W. Aldrich, *Crowding Memories* (1920).

ALDRIDGE, IRA FREDERICK (called the AFRICAN ROSSCIUS) (1804–1867), U.S. Negro tragedian, considered one of the finest actors of his time, was probably born in New York city. Little is known of his early life; he may have begun his acting career at the African theatre in New York. He went to England around 1824 and made his English debut in 1825. He appeared in such roles as Othello, Lear, Macbeth and Rolla. It is debatable whether he ever returned to the United States; if so, it was in an unsuccessful engagement at Baltimore, Md., during the 1830s. After 1853 he played primarily on the European continent where he amassed a considerable fortune and received many honours, including tributes from the emperor of Austria and the king of Prussia. In 1863 he became an English citizen. He died in Lodz, Poland, on Aug. 7, 1867, while on his way to Russia to fill an engagement.

See Herbert Marshall and Mildred Stock, *Ira Aldridge, the Negro Tragedian* (1958). (O. G. B.)

ALDRIDGE, an urban district (1934) in the Walsall South parliamentary division of Staffordshire, Eng., lying about 10 mi. N. of the centre of Birmingham. Pop. (1961) 50,981. Area 1.5 sq.mi. The district comprises the parishes or villages of Aldridge, Great Barr, Pelsall, Pheasey, Rushall and Streety. At the time of Domesday Book in the 11th century Aldridge (Alrewic) and Great Barr (Barre) were both held by the knight, Robert, from William Fitz Ansculf of Dudley castle. Later Aldridge became a separate manor. In the 12th century Aldridge was included in the royal forest of Cannock, while Great Barr was in Sutton Chase. In the later middle ages Great Barr was a charcoal-burning centre. This "Colefield"—a lawless district—stretched northward and eastward to Sutton and Aldridge. The destruction of trees left a waste or common for sheep, which was enclosed in 1795; on this former common is the 700 ft. high ridge, Barr beacon, which served as a signal point from Tudor times. The park on the summit is a World War I memorial. Until the 19th century Aldridge and Barr were largely agricultural, but from 1880 to 1936 coal mining was the chief occupation at Aldridge. Limestone beds at Rushall were quarried from the 13th century to 1939; local ironstone maintained an iron industry there from the later middle ages.

Notable buildings are Great Barr hall (now St. Margaret's hospital) and the timber-framed Old hall. Local products include bricks and tiles, especially the Staffordshire blue brick, while ma-

chinery making, metallurgy and general. electrical and light engineering are the chief industries in the local authority's industrial estate. Considerable expansion in industry had taken place by the early 1960s, but the convenient distance of the district from Walsall and Birmingham helped to preserve its residential character.

ALDROVANDA (*Aldrovanda vesiculosa*) is a small carnivorous (insectivorous) plant that traps and digests insects. See also YENUS'S-FLYTRAP; CARNIVOROUS PLANTS.

ALDROVANDI, ULISSE (1522-1605), distinguished Italian naturalist and author of a famous work on natural history, was born at Bologna. He became page to a bishop, then to a merchant at Brescia and subsequently went on a pilgrimage to Spain. Returning to Bologna he studied law both there and at Padua but eventually changed to medicine. In 1549 he was accused of Lutheranism and arrested and sent to Rome but was conditionally released by the Inquisition. He returned to Bologna and after becoming doctor of medicine in 1553, took up the study of botany and became professor of natural history and logic at the university in 1560. Aldrovandi persuaded the senate to found a botanical garden and was its first director. He was also inspector of drugs and pharmacies and incurred the enmity of local apothecaries who tried to have him dismissed, but his appointment was confirmed by Pope Gregory XIII. His book *Antidotarii Bononiensis epitome* (Bologna, 1574) is a model for subsequent pharmacopoeias. He formed a museum at Bologna, still in existence. He employed artists and engravers for more than 30 years in connection with the production of his immense compilation on natural history. Only four volumes of this great work appeared during his lifetime but another ten volumes were prepared from his manuscripts by his pupils at the expense of the senate of Bologna university and even this represents only a part of the material he had accumulated. In addition Aldrovandi wrote an account of various ancient statues in Rome (see L. Mauro. *Le Antichità della città di Roma, etc.* [Venice, 1556]). (Ed. HE.)

ALE: see BEER.

ALEANDRO, GIROLAMO (HIERONYMUS ALEANDER) (1480-1542), Italian cardinal and humanist, who was an important opponent of the Lutheran Reformation, was born at Motta di Treviso, near Venice, on Feb. 13, 1480. A remarkable scholar, particularly of classical languages, he was in his youth closely associated with Erasmus. He lectured at Venice, Orléans and Paris where he was appointed rector of the university. In 1520 Pope Leo X sent him to Germany to lead the opposition against Luther at the Diet of Worms. This brought about his break with Erasmus. The edict against Luther, which was adopted by the Diet, was drawn up and proposed by Aleandro, and in Brussels it was Aleandro who was responsible for the death of the first martyrs of the Reformation. In 1523 Clement VII sent him as nuncio to the court of Francis I with whom he was taken prisoner at the battle of Pavia (1525). He was subsequently employed on various papal missions, especially to Germany, but was unable to check the progress of the new doctrines. He was created cardinal in 1538 by Paul III, and died at Rome on Feb. 1, 1542.

Apart from Latin verses and a scholastic work on Greek grammar, Aleandro's chief work is his unfinished treatise, *De habendo Concilio*, setting out his views on the Council of Trent of which he was the ardent supporter. This and other documents of Aleandro in the Vatican library, relating to his opposition to Luther, were used in Sforza Pallavicino's *Istoria del Concilio Tridentino* ("History of the Council of Trent"; 1656).

See also J. Paquier, *L'Humanisme et la Réforme* (1900); J. Paquier (ed.), *Lettres familières de Jérôme Aleandre* (1909).

GIROLAMO ALEANDRO (1574-1649), the grandnephew of the cardinal, was a poet, scholar and antiquarian. He was a founder of the Roman Academy of Humorists and wrote scholarly works on archaeology, ancient costumes and religion.

ALEARDI, ALEARDO, CONTE (1812-1878), whose life and work are typical of the 19th-century Italian poet patriots. Born at Verona, Nov. 4, 1812, he was brought up to resent Austrian rule. He was associated with the poet Giovanni Prati in pub-

lishing a political journal, *Il Caffè Pedrocchi*, and for his part in the revolutionary movements of the 1840s and 1850s was twice imprisoned and finally exiled. His best political poems are the ode *Le città italiane marinare e commercianti* (1856) and *I Tre Fiumi* (1857). He also wrote popular love poems, *Lettere a Maria* (1847). Returning to Verona after the expulsion of the Austrians, he became professor at the academy of fine arts, and published his *Il canto politico* (1862). He sat in the Italian parliament and was eventually made a senator. He died at Verona, July 17, 1878. A collection of his poems, *Canti scelti di Aleardo Aleardi*, was edited by L. Grilli (1918).

See V. Primavera, *Aleardi e la sua fortuna* (1929).

ALECSANDRI, VASILE (1819 or 1821-1890), Rumanian lyric poet and dramatist, was the first collector of Rumanian popular songs and one of the leaders of the movement for the union of the Rumanian principalities. Born at Bacău in Moldavia, he was educated at Jassy and subsequently in Paris (1834-39). He published his first collection of folk songs in 1844 and was also active in the Rumanian revolutionary cause. His lyrical poems, *Doine și Lăcrimioare*, appeared in Paris in 1853 and during 1852-53 he published at Jassy two volumes of ballads and songs. In 1867 he published his descriptive poems of landscapes entitled *Pasteluri*. As a playwright he created Rumanian social comedy, but his most important contributions to the theatre were his poetic dramas: *Despot Vodă* (1879), *Fântâna Blanduziei* (1884) and *Ovidiu* (1885). In later life Alecsandri played an important part in his country's affairs. As minister for foreign affairs (1859-60), he went to London as Prince Alexander Cuza's special envoy to seek British recognition of the United Rumanian Principalities. In 1885 he was appointed Rumanian minister in Paris. He died at Mîrcești, on Aug. 22, 1890. (G. Ns.)

ALEGRÍA, CIRO (1909-), Peruvian novelist, was born in Sartimbamba, Nov. 4, 1909. He is Spanish America's foremost writer of the Indianist novel, for which he draws on firsthand knowledge acquired in his native province of Huamachuco. From 1930 to 1934 active in the Aprista party's program of social reform, he was twice jailed and finally exiled to Chile. His best novel, *El mundo es ancho y ajeno* (1941) (English trans. by H. de Onís, *Broad and Alien Is the World* [1941]), the story of an Indian tribe struggling to survive against the greed of land-hungry white men, won first prize in an international competition judged at New York. In that same year he came to the United States and remained until 1948. All his novels have to do with the Peruvian Indians, sympathetically portraying them as communities engaged in conflict with an unfriendly environment. Accurate observation of folkways and a flexible, simplified style contribute to the powerful effect. *La serpiente de oro* (1935) (English trans., *The Golden Serpent* [1943]) tells of the diversified human life along the Marañón river; *Los perros hambrientos* (1938) concerns the difficulties faced by shepherding Indians of the highlands.

See Jefferson Rea Spell, *Contemporary Spanish-American Fiction*, pp. 253-268 (1944).

ALEKHINE (ALJECHIN), **ALEXANDER** (originally **ALEKSANDR ALEKSANDROVICH ALEKHIN**) (1892-1946), champion chess player, was born in Moscow on Nov. 1, 1892. He displayed precocious ability as a chess player, and in 1910 he did well at the Hamburg tournament at the age of 17. When World War I broke out in 1914 he was playing at the Mannheim tournament and escaped from internment to serve in the Red Cross division of the Russian army. After the Revolution he became a naturalized Frenchman, and studied law at the University of Paris. The victor in many international tournaments, he won the world championship for blindfold chess in 1924, 1925 and 1933. In 1927 he won the world championship from Capablanca (champion since 1921), lost it in 1935 to Max Euwe, but regained it from Euwe in 1937.

Alekhine died March 24, 1946, in Estoril, Port.

See his book, *My Best Hundred Games* (Eng. trans., 1927).

ALEKSEEV, MIKHAIL VASILIEVICH (1857-1918), Russian general, a leading champion of the White cause in the civil war following the Russian Revolution, was born in Tver on Nov. 15 (new style; Nov. 3 old style), 1857, the son of a private soldier. Entering the army in 1876, he graduated in 1890 from

the staff college and became a general in 1904. In World War I, as chief of staff to the southwest army group, he planned the successful Russian offensive into Galicia (1914). After five difficult months in command of the northwestern front he became chief of the general staff in Aug. 1915 and assumed control of all Russian armies in the European theatre. As a strategist he was capable, but was reluctant to delegate responsibility. His task was hampered by the groning isolation of the court from public opinion, and in the autumn of 1916 he prepared a somewhat desperate plan whereby the emperor Nicholas II was to be presented with an ultimatum and forced to grant reforms. But Alekseev's intentions became known; he fell ill and was suspended from duty.

In March 1917 he helped to bring about Nicholas' abdication and was appointed commander in chief; but, considering the provisional government insufficiently resolute in combating the dissolution of the army, he resigned his post on May 21. Subsequently he sympathized with Gen. L. G. Kornilov and attempted to effect a compromise between him and A. F. Kerenski. After the Bolshevik revolution Alekseev escaped to the Don, where he started to organize an anti-Bolshevik volunteer army. Command of this force, however, soon passed to Kornilov, succeeded on his death by A. I. Denikin, while Alekseev retained control of political affairs. He died in Ekaterinodar (now Krasnodar) on Oct. 8, 1918.

(J. L. H. K.)

ALEMÁN, MATEO (1547-1614?), Spanish picaresque novelist, a master stylist and rhetorical moralizer, was born at Seville, the son of the physician to the royal prison. His forebears were Jews forcibly converted to Catholicism, and consciousness of this background coloured his life's work. Alemán graduated at Seville in 1564. He studied medicine at Salamanca and Alcalá for four years but never practised. In 1580 he was imprisoned for debt. His literary career began with the publication of a prologue to a book of moral proverbs in 1598. The first part of his chief work, *Guzmán de Alfarache*, the quintessential example of the picaresque novel, appeared in 1599, and had the most immediate success of any Spanish classic. There were 23 editions (50 000 copies) in five years and translations into several languages, including English (1624; mod. ed. 1924); since almost all the editions were pirated, the financial position of the author was not improved, and he was again imprisoned for debt. The second part of *Guzmán* appeared in Lisbon in 1604. Alemán's view of humanity was one of suspicious pessimism. He made two important journeys: to Italy and to Mexico, where he died, probably in 1614.

(A. Y. K.)

ALEMÁN, MIGUEL (1902-), Mexican political figure, president of Mexico from 1946 to 1952, was born on Sept. 29, 1902, in Sayula, Veracruz, where his father was a village shopkeeper and subsequently a revolutionary general. He was educated in Mexico City and in 1925 entered the National Autonomous university to study law. At the age of 26 Alemán set up practice in Mexico City, specializing in labour cases. In 1930 he entered politics. He was appointed senator from Veracruz and in 1936 became governor of his native state. In 1940 he resigned to manage the successful presidential campaign of Manuel Ávila Camacho (*q.v.*), who rewarded him with the powerful post of minister of *gubernación* ("interior"). Alemán became the official candidate for the presidency (Partido Revolucionario Institucional, or Revolutionary Institutional party) in 1946 and easily defeated Ezequiel Padilla. His administration saw a slowdown in Mexico's agrarian reform, but greatly accelerated industrial development. Though there were charges of extensive graft and corruption in government, nonetheless, economic progress was marked during Alemán's term of office. See MEXICO: *History*.

(R. E. Q.)

ALEMBERT, JEAN LE ROND D' (1717-1783), French mathematician and philosopher is remembered for his enunciation of "D'Alembert's principle," a basic concept in mechanics, and for his work in connection with Diderot's *Encyclopaedia*. He was born in Paris in Nov. 1717. He was a founding but it afterward became known that he was the illegitimate son of the Chevalier Destouches and Madame de Tencin. Destouches, without disclosing his identity, provided for the boy, who was educated at the

Mazarin college under the Jansenists.

Having studied law, he was admitted as an advocate in 1738, but did not enter upon practice. He next devoted himself to medicine; but within a year he resolved to give his whole time to mathematics. In 1741 he received his first public distinction in being admitted a member of the Academy of Sciences? to which he had previously presented several papers, including a *Mémoire sur le calcul intégral* (1739). In his *Mémoire sur la réfraction des corps solides* (1741) he was the first to give a theoretical explanation of the phenomenon which is witnessed when a body passes from one fluid to another more dense in a direction not perpendicular to the surface which separates the two fluids. In 1743 he published his *Traité de dynamique*, a work famous as developing the mechanical principle, known as "D'Alembert's principle," first enunciated in 1742. In 1744 D'Alembert applied this principle to the theory of the equilibrium and the motion of fluids, *Traité de l'équilibre et du mouvement des fluides*, and all the problems before solved by geometers became in some measure its corollaries.

This discovery was followed by that of the calculus of partial differences, the first trials of which were published in his *Réflexions sur la cause générale des vents* (1747). In 1747 he applied his new calculus to the problem of vibrating chords. In 1749 he furnished a method of applying his principles to the motion of any body of a given figure; and in 1754 he solved the problem of the precession of the equinoxes, determined its quantity and explained the phenomenon of the nutation of the earth's axis. In 1752 he published an *Essai d'une nouvelle théorie sur la résistance des fluides*, which contains a large number of original ideas and new observations. In 1746 and 1748 he published in the *Memoirs* of the Academy of Berlin "Recherches sur le calcul intégral," a branch of mathematical science which is greatly indebted to him. In his *Recherches sur différents points importants du système du monde* (1754-56) he perfected the solution of the problem of the perturbations of the planets, which he had presented to the academy some years before.

D'Alembert's association with Diderot in the preparation of the *Dictionnaire Encyclopedique* led him to a wider range of work. He contributed the *Discours préliminaire* on the rise, progress and affinities of the various sciences. He also wrote several literary articles for the first two volumes of the encyclopaedia, and to the remaining volumes he contributed mathematical articles chiefly. Of D'Alembert's works on other than mathematical subjects the most important is the *Éléments de Philosophie* (1759) in which he discussed the principles and methods of the different sciences. D'Alembert was much interested in music both as a science and as an art, and wrote *Éléments de musique théorique et pratique* (1779).

D'Alembert died in Paris on Oct. 29, 1783.

BIBLIOGRAPHY.—The scientific works of D'Alembert have never been published in a collected form. The most important of them have been mentioned above, with the exception of the *Opuscules mathématiques* (1761-80). His literary and philosophical works were collected and edited by Bastien (1805). A better edition by Bossange was published at Paris in 1821. See J. L. F. Bertrand, *D'Alembert* (1889).

ALEMBIC, an apparatus for distillation (*q.v.*) used chiefly by the alchemists, and now superseded by more convenient forms of still, both in the laboratory and in the factory. It consisted essentially of three parts: a vessel containing the material to be distilled and called, from its gourdlike shape, the cucurbit, or mat-rass; a vessel to receive and condense the vapour, called the head, capital or alembic proper; and a receiver for the distillate, connected by a pipe with the capital. The entire apparatus was sometimes constructed of glass, but more usually the cucurbit was of copper or earthenware, and the capital alone of glass.

ALENÇON, DUCS D'. The French peerage duchy of Alençon was created in 1415, when the countship of Alençon was raised to that rank. The town of Alençon in Normandy (now in the French *département* of Orne), is known to have been held as a seignior by the house of Bellême at least from the time of Guillaume I (d. 1028). By the marriage of Guillaume's granddaughter Mabile (d. 1082) to Roger de Montgomery, who first took the title of count, Alençon passed to a new line, but the last heiress

of this line sold her rights to Philip II of France about 1220. Louis IX of France in 1268 granted the countship as an appanage to his fifth son, Pierre, who held it until his death in 1284. It was next, in 1293, granted to Charles of Valois, on whose death in 1325 it passed to his second son Charles (killed at the battle of Crécy in 1346). This Charles's grandson, Jean (1385–1415), was created duc d'Alençon on Jan. 1, 1415 (new style; 1414 old style) but did not long enjoy his duchy, as he was killed the following October in the battle of Agincourt. His son and successor Jean II (1409–76), who was at first dispossessed of Alençon by the English but recovered it in 1449, conspired first against Charles VII of France on behalf of the future Louis XI, then against Louis on behalf of the English, with the result that he spent many years in prison. The last duc of the first line, Jean II's grandson Charles (1489–1525), disgraced himself when Francis I of France was taken prisoner at the battle of Pavia, and died soon afterward leaving no heir. His widow Margaret of Angoulême (Francis I's sister, later queen of Navarre) then held the duchy until her death in 1519, whereupon it was reunited to the French crown. Catherine de Médicis, to whom it was granted for her lifetime in 1559, transferred it in 1566 to her youngest son François Hercule (1554–84), later duc d'Anjou, who is remembered for his intrigues under Charles IX and Henry III, for his persistent wooing of Elizabeth I of England (1579 and 1581–82) and for his campaign in the Spanish Netherlands (1582–83) with a view to securing the duchy of Brabant for himself. On his death it passed back again to the French crown. Louis XIV's uncle, Gaston, duc d'Orléans, to whom the appanage was granted in 1646, transferred it to his daughter Elizabeth (1646–96), who married Louis Joseph, duc de Guise. On the death of their son François Joseph, duc de Guise, in 1675, Alençon again returned to the crown. Louis XIV's grandson, Charles, duc de Berry, had the appanage from 1710 to his death in 1714 and Louis XVI's brother, the future Louis XVIII, received it in 1785. The title duc d'Alençon was revived for Ferdinand (1844–1910), second son of Louis d'Orléans, duc de Nemours, and passed from him to his son Emmanuel (1872–1931), who has also duc de Vendôme.

ALENÇON, a town and prefecture of Orne *département* in northwest France, lies 30 mi. N. of Le Mans by road at the confluence of the Sarthe and Briante rivers and in the centre of a plain surrounded by wooded hills. Pop. (1954) 19,427. Of the castle of Alençon, taken by William of Normandy in 1048, a pepperpot tower and a 15th-century fortified gateway remain; the 18th-century law courts incorporate the living quarters. In the church of Notre Dame (13th–18th century) Thérèse Martin (St. Thérèse de Lisieux), born at Alençon in 1873, was baptized. The town hall (1783) contains an art gallery and an exhibition of Alençon lace, and the 15th-century Maison d'Oze contains historical documents. The municipal library is in the former Jesuit chapel (16th-century). There is an airfield for local services at Valframbert, about 2 mi. N.E. The chief industry is lacemaking, especially point *d'Alençon*, copied from Venice and introduced by Jean Baptiste Colbert in the mid-17th century. Printing, dyeing and the manufacture of household goods and sewing machines are also carried on, and Alençon is an agricultural market centre. It was the capital of the county and duchy of Alençon and passed to the French crown in 1549. Heavily damaged in World War II, it was the first town to be liberated by Gen. Jacques Philippe Leclerc in 1944. (A.-M. JA.)

ALENI, GIULIO (1582–1649), Italian Jesuit missionary, author of a Chinese Life of Christ used even by Protestant missionaries, was born in Brescia. He landed at Macao in 1610 and penetrated into China three years later. During his more than 30 years residence in China he adopted the dress and manners of the country, was the first Christian missionary in Kiangsi and built several churches in Fukien. In addition to the Life of Christ (8 vol., 1635–37; often reprinted), he wrote a cosmography (*Iche fang wai ki Hang-chow*, 6 vol., 1623) which was translated into Manchu under the title *The True Origin of 10,000 Things*. A copy was sent from Peking to Paris in 1789. Aleni died in Foochow on Aug. 3, 1649.

ALENTEJO, an ancient province of southern Portugal, lies

mostly south of the Tagus valley, and is bounded on the east by the Guadiana river, which forms part of the Portuguese-Spanish frontier. Pop. (1950) 780,610. Area 10,152 sq.mi. It is a vast, rolling plain, four-fifths of it at 300–600 ft., rising gradually to 900–1,500 ft. in the south and the northeast. It has a monotonous landscape of large, open fields with cereal crops, isolated in the poorer lands by wastes of gum cistus or woodlands of cork and evergreen oaks. Prevalently poor schistose soils and the traditions of latifundia explain the low densities of population, 10–70 per square mile.

In 1933 Alentejo was divided into two provinces, Alto Alentejo (*q.v.*) in the north whose capital is Evora (pop. 25,409) and Baixo Alentejo (*q.v.*), of which Beja is the capital (14,028).

(J. M. Ho.)

ALEPPO (Arabic, HALEB or HALAB), a city and administrative district of Syria, stands on a series of limestone hills at 1,220 ft. above sea level, and on a small stream, the Kuwaik (anc. Chalys). It is the largest city in Syria and the mercantile centre of the country. Pop. (1960) 957,000. The inhabitants are mainly Muslims, but there are large Christian-Arab, Armenian and Kurdish communities. The climate is healthful and bracing, though of continental type; in summer maximum temperatures of between 110° and 115° F. are tempered by breezes. The region has always suffered from severe earthquakes; the town was damaged in 1157 and partially destroyed in 1822 and 1830.

After World War II Aleppo expanded considerably, particularly to the north and west of the old square town which frames the citadel. In the new quarters there are many fine streets shaded with trees and modern buildings of cement and stone, including banks, hotels, hospitals and factories. Water is piped from the Euphrates. Part of the University of Syria, including the engineering faculty, is housed there, and the new museum, with its important collection from Ras Shamra (anc. Ugarit) and Mari, is centrally situated. The old quarter has the most famous covered bazaars in the middle east, extending over 15 mi., and many khans, mosques and merchants' houses. These are all stone built, many dating from the 16th or 17th centuries. The most spectacular building is the citadel, on a semiartificial mound dominating the city. The present building, erected on the site of earlier fortifications of Byzantine date, was constructed in the 12th century A.D. and restored in the 16th. Its gate bears an inscription of the Mameluke sultan Khalid, who restored it after the sack of the city by the Mongols in 1258. The earliest remains excavated under the citadel are Hittite; on top is a mosque dedicated to Abraham, on the site of a Byzantine church. Five of the original nine gates of Aleppo were still visible in the second half of the 20th century, the best preserved being the Bab al-Hadid ("the Iron gate"), 15th century, the Bab al-Antakya ("the Gate of Antioch"), 12th century, and the Bab Kinnesrin. The city walls, built in the

AUTHENTICATED NEWS

12TH CENTURY TURKISH CITADEL IN ALEPPO, AROUND WHICH THE OLD CITY WAS BUILT

Hellenistic period and reconstructed first in the 12th century and again in the 15th, here also still partially intact.

There are many mosques: the largest is the Jami Zakariyah (the Great Mosque), built in 715 on the site of the Christian cathedral and named after Zacharias, the father of John the Baptist. Its finest feature is the minaret, of Seljuk workmanship, built in 1090. The mosque was destroyed twice by fire and rebuilt (in 1159 and in 1258). The oldest mosque in the Jami Tut ah, mid-7th century South of the main town is the madrasah and mosque of Al-Firdaus ("the School of Paradise"), founded by the widow of Al-Zahir Gazi, as a monument to him, the finest surviving piece of medieval architecture in Syria. The theological schools include the madrasah Hallawiyah, built on the site of the 5th-century Byzantine cathedral, a foundation of the empress Helena, and converted into a mosque in the 12th century, and also the Sultaniyyah and the Sharafiyah, the latter containing a fine library of Arabic manuscripts. Nearby is the Khan al-Gumruk ("Inn of the Customs"), the 16th-century headquarters of the European merchants. The largest khan is that of the vizier (16th century), well decorated in black and white stone, and the most ornamental is the khan al-Sabun, early 16th century. Houses in the older quarters, often fine examples of 17th- or 18th-century building, with open courtyards surrounding a pool with shady trees and with beautifully carved interior woodwork, have in many cases been transformed into schools or orphanages.

Aleppo is situated on the Istanbul-Baghdad railway and is also linked by rail with Beirut and with Tripoli, Lebanon, and by narrow-gauge line with Damascus, Syria. It is a focal point for transdesert routes to Mosul and Baghdad in Iraq, and is linked by motor roads with Antakya (Antioch), in Turkey, Latakia and Damascus. There is an airfield, 2 mi. S.E., at Nerab. The town is an important centre for the textile trade; its chief industries are silk weaving and cotton printing, and subsidiary industries include wool, hides, dried fruit and nuts. There are cement and cotton-ginning factories.

History. — Haleb (Halpa) is believed to be a place where Abraham grazed his cows; it is said to derive its name from the Semitic term for milk. It is first mentioned in the 3rd-millennium texts of the Agade period, but the existence of an earlier settlement is indicated by the remains of prehistoric Tell Halaf pottery of the 6th millennium B.C. on the hills now incorporated within the city boundary. The presence of the Islamic citadel on the ancient hill of Aleppo precluded extensive excavations, but material from the 2nd millennium B.C. has been unearthed. According to the Mari letters of that period the city in the 18th century B.C. had a powerful ruler in Yarim-Lim of Yamkhad, who rivaled Hammurabi and was followed into battle by 20 subsidiary kings. To the Hittites this Amorite city linking the vital trade routes was of considerable importance strategically; it was sacked by Mursilis, and again by Tudhalyias in 1596 B.C. After the decline in Hittite fortunes Halpa became part of the Hurrian confederacy, and during the 15th and 14th centuries it fell intermittently within the Egyptian, Mitannian and Hittite spheres of influence. It was finally conquered by the Hittite king Suppiluliumas (c. 1375–35), who placed his son Telepinus on the throne. Later relations between the Hittites and Aleppo are referred to in the preamble to the treaty between Muwatallis (1306–1282 B.C.) and Rim-Sharma, king of Aleppo, found in the Boğazköy archives. One of the Hittite allies in the battle of Kadesh (c. 1286 B.C.) against the Egyptians was the king of Halpa. After the fall of the Hittite empire Halpa became an independent kingdom until its conquest by Assyria in 853 B.C. For a short time it was in the hands of Sarduris, king of Urartu, but was reconquered in 743 by the Assyrians and appears to have been held by them until their fall in 612. During the Assyrian period it was known as Halman.

The city subsequently fell into the hands of the Neo-Babylonians, Persians and Seleucids. It was largely rebuilt by Seleucus Nicator (312–280 B.C.), who renamed it Beroea after a Macedonian city. It became a first-ranking city of the Hellenistic period and, after the destruction of Palmyra, the great commercial entrepôt between the Mediterranean region and the lands further to the east. By the 4th century A.D. it had developed as an important

Christian centre and the seat of an archbishopric, but Chosroes II of Persia reduced the town to ashes and in 638 it fell without resistance into Arab hands. The city then reverted to its old name, Haleb, and prospered under the Umayyads, for whose cause it was to pay dearly on the Abbasid conquest. The house of Hamdan next established itself in Aleppo as an independent principality and fought with varying success against the Byzantines, who captured the town, but not the citadel, in 962. Of this period the best-known ruler is Saif al-Daula, who had a brilliant court and surrounded himself with poets and men of letters. After this golden age Aleppo fell successively under the Fatimids in 1015 and the Seljuk Turks from 1086 to 1117. It was besieged by the crusaders in 1124 and again the following year, later submitting to the prince (atabeg) of Mosul, Imad al-Din Zengi, under whom it became a centre for Muslim resistance against the crusaders. After the death of his son, however, the city became part of the Ayyubite dominion Iliitz under Al-Zahir Gazi, son of Saladin, who rebuilt it and made it Saladin's northern base. In 1260 it was taken by the Mongols under Hulagu and its inhabitants massacred. After an interval of several centuries under the Mamelukes Aleppo surrendered to the Turks in 1516, and with the exception of seven years under Egyptian control in the 19th century it formed part of the Ottoman empire until 1918. In 1920 it was independent for a short time, before becoming part of the Syrian mandated state under French control, an arrangement which came to an end in 1941.

The Aleppo administrative district has an area of 8,849 sq.mi. and a population (1953 est.) of 1,094,447. It comprises several *kazas* or subdistricts, under the administration of kaimakams, responsible to the governor of Aleppo. It is a rich agricultural area, extending to the banks of the Euphrates on the east and to the Bab al-Hawr ("Gate of the Winds"), the frontier with Turkey on the west. There are several small towns and a number of large villages, the average population of which is between 4,000 and 5,000 inhabitants. The main products of the region are grapes, wheat, barley, cotton, fruit, nuts and sesame.

ALÈS, a town in the Gard *département* of southeastern France, lies 27 mi. N.N.W. of Nîmes at the foot of the Cévennes on the left bank of a loop of the Gardon d'Alès river. Pop. (1954) 20,259. Vauban's fortress (1788), containing a museum and library, stands on a hill dominating the town and round it are the Bosquet gardens. The cathedral of Saint Jean and the town hall were built in the 18th century. The narrow streets in the centre of the town are being replaced by modern roads and squares with gardens, and new suburbs have been built. Alès is on the main railway line from Paris and Clermont-Ferrand to Nîmes. It is the chief industrial town in southeastern France and a tourist centre for exploring the Cévennes (*q.v.*). There are commercial houses, metallurgical workshops, coal mines and factories for making ovens and underwear.

In the 10th century B.C. the Phoenicians settled at Alès, giving it the name Alest (Phoenician word for "industry"). The Romans called it Alestium. It received its charter in 1200 and was made part of the French kingdom by Louis IX in 1243. It suffered in the religious wars of the 16th century and in 1629 the Grbce of Alais, the treaty which ended the last War of Religion, was signed there. Little affected by the French Revolution, it became industrialized 100 years later. In 1926 the name was changed from Alais to Alès. (R. M.)

ALESIA (on Mont Auxois, above the village of Alise-Sainte-Reine in the *département* of Côte d'Or, France) was a hill-fort town of the ancient Gallic tribe of the Mandubii, succeeded on the same site by a Roman town. It is famous for the siege of Vercingetorix by Julius Caesar in 52 B.C., decisive in his conquest of Gaul. Vercingetorix, who had raised a widespread revolt in Gaul against Caesar, withdrew after some successes and reverses into the prepared fortress of Alesia. Caesar invested the position, surrounding it with lines of contravallation (ten miles in perimeter) and, outside these, building lines of circumvallation against relieving

ing forces of the Gauls. When the Gauls gathered in large numbers they were repulsed, being inadequately organized; and a sortie by Vercingetorix was equally ineffectual. A final attempt at relief was made at the weakest spot on the northwest (which could not be enclosed by the lines of circumvallation), but this also failed, and Vercingetorix was forced to surrender from lack of supplies.

Excavations sponsored by Napoleon III in 1861–65 revealed siege works fitting Caesar's detailed description. Napoleon III also erected the statue of Vercingetorix on Mont Auxois. Excavations in the 20th century (notably from 1942 onward) revealed a mixture of Gallic and Roman elements: traces of the Gallic town and mall, with circular and rectangular huts, together with evidence of metalworking. Remains of the Roman town include the forum, a three-apsed basilica, a theatre, a temple and other sanctuaries.

ALESSANDRIA, a town in Piemonte, Italy, capital of Alessandria province, lies 35 mi. E.S.E. of Turin. Pop. (1957 est.) 85,964 (commune). Area 78.7 sq.mi. Situated 342 ft. above sea level at the confluence of the Bormida and the Tanaro rivers and at the junction of railways and important highways, its previous domination of the valley of the Alpine passes gave rise to its military importance. As a stronghold it could not expand beyond its defensive works. These were destroyed in the time of the Napoleonic empire but were restored during the War of Independence. Expansion outside them is of recent date. The historic churches and civil edifices were for a long time built to comply with military need. The cathedral church of Sta. Maria del Castello and the Carmelite church date from the 13th century; the latter, built on the hexagonal ground plan of a basilica, contains a 15th-century register of prelates. The episcopal palace is of the 15th century and there are the Ghilini, Cuttica, Guasco and Sambuy palaces. There are a museum, picture gallery and library. The chief industries are hatmaking (especially the Borsalino), the manufacture of foodstuffs, coloured leads, textiles and chemicals and ironworking and machinemaking. The leading commercial activity is marketing agricultural products, especially wines.

Alessandria was founded in 1168 by the Ghibelline marquis, Guglielmo del Monferrato, who called it first Civitas Nova and later Cesaria. It pursued an anti-imperial policy, took part in the struggles against the communes and Frederick Barbarossa, and was named Alessandria in honour of Pope Alexander III, head of the Lombard league. It has been an episcopal see since 1175. After resisting Barbarossa the town was left defenseless by its confederates and was ceded to the emperor, adopting once again the name of Cesaria. On achieving its freedom as a commune it was transferred to the Visconti in the 14th century, and in 1702 passed to Savoy. After the battle of Marengo it was subject to Napoleon I, and when he fell it suffered damage at the hands of the Austrians. It was the centre of the movement for freedom in Piedmont in 1821 and of the conspiracy of Giuseppe Mazzini in 1833. A vital stronghold, it was garrisoned by the Austrians after their victory at Novara (1849). For later history see ITALY: History.

See C. Patrucco, *Perché e come fu fondata Alessandria* (1927); G. Jachino, *Storiografia Alessandrina* (1938). (M. T. A. N.)

ALESSANDRI PALMA, ARTURO (1868–1950), Chilean president and statesman, was born near Linares, the son of an Italian immigrant. Dec. 20, 1868. He graduated in law from the University of Chile in 1893 and four years later was elected to the chamber of deputies. During a political career that spanned more than 50 years he was minister of industry, minister of finance, congressman (elected six times), senator (elected twice) and president (1920–25, 1932–38). He won his reputation as a liberal and the title "Lion of Tarapacá" by defending the working groups, especially the nitrate miners of the north. His concern for the less-privileged elements during the years before 1920 permitted him to capitalize upon the rapidly expanding working and middle-class vote.

Alessandri was elected president of Chile in 1920 as the candidate of a liberal coalition. He was forced into exile in 1924 by

the military forces but was recalled the following January with the understanding that the constitution would be rewritten to give the president greater power. This was done. Alessandri returned to the presidency in 1932 as a strict constitutionalist. Before the end of his term he had come to depend primarily upon the political right. This helped to promote economic recovery from the depression but alienated most of his labour and middle-class supporters who joined the Popular Front, which had communist affiliations. In 1946 Alessandri was elected to the senate for a second time and as a senator he again displayed liberal leanings. He died Aug. 24, 1950. (J. J. J.)

ALESSI, GALEAZZO (1512–1572), Italian architect, was born at Perugia and was probably a pupil of Caporali. He was an enthusiastic student of ancient architecture, and his style gained for him a European reputation. Genoa is indebted to him for a number of magnificent palaces, and his art may be studied in the churches of San Paolo and Santa Vittoria at Milan, in certain parts of the Escorial, and in numerous churches and palaces throughout Sicily, Flanders and Germany.

ALESUND (AALESUND), a town on the northwest coast of southern Norway, lies 185 mi. N. of Bergen. Pop. (1959 est.) 19,015. It was rebuilt in stone after the old wooden town was destroyed by fire in 1904. Alesund has a history dating back to Rollo (Rolf) the Ganger, who in the 9th century was expelled from Norway by Harald Fairhair (Harald I; *q.v.*) and settled with his followers in the lower Seine valley in what is now Normandy. The winters are mild and the temperature seldom falls below zero. The economy of the town depends on fishing and sealing in northern and arctic waters and on its position as a market for agricultural produce, chiefly milk and fruit, from the surrounding districts. There is an airport, opened in 1958. There is no railway, but there are good land and sea connections with the rest of the country.

ALEURITES, tropical and subtropical trees of the genus *Aleurites* (Euphorbiaceae), producing apple-sized fruits containing large seeds or nuts rich in drying oils, used in the manufacture of many products. Five species are known: *A. cordata*, Japanese woodoil tree; *A. fordii*, tungoil tree; *A. molluccana*, candlenut tree; *A. montana*, mu-oil tree; and *A. trisperma*, soft Iumbang. The first two are the most valuable, since they produce the best oils. Orchard planting in the U.S. began about 1910. Extensive plantings were made thereafter in states from Florida west to eastern Texas. Important planting began about 1925 in Argentina, Australia, Brazil, New Zealand and Nyasaland.

ALEUT, a native of the Aleutian Islands and western portion of the Alaska peninsula. With the closely related Eskimos (*q.v.*) they constitute the Eskimo-Aleut stock sharing basic similarities in language, race and culture. At the time of their discovery in 1741 they occupied all the Aleutian Islands and the western part of the Alaska peninsula to a line running from Port Moller on the north side to Kupreanof point on the south side where they met their Eskimo-speaking neighbours, the Koniags, who also occupied Kodiak Island. Linguistically they comprise three mutually intelligible dialect groups. Aleut, though having diverged from Eskimo about 4,600 years ago, can no longer be understood by an Eskimo. Structurally the languages are still much the same but share less than 25% of their vocabulary. (See ESKIMO-ALEUT LANGUAGES.)

Racially Aleuts, like Eskimos, are most similar to Siberian peoples and easily distinguishable from American Indians. They possess straight black hair, eye folds, long trunks and relatively short legs, small hands and feet, large head and face with small nose. One of the largest skulls in the world is that of a mummified Aleut from Kagamil Island with over 2,000 c.c. cranial capacity. Serologically they possess a large proportion of blood group A, close to 50%, and varying amounts of group B, very low frequencies of type N, and all are Rh positive. Blood group B is not found in American Indians but is found in Asia. Physically the western Aleuts of Attu Island (the westernmost) and Atka show more traces of the earliest people who moved into the islands from the Alaska mainland about 4,000 years ago. The earliest people, termed Paleo-Aleuts, were more narrow headed than the

later. Like their Koniag neighbours the present Aleuts are more broad headed.

The rich animal and plant life of the area was skilfully exploited by the Aleut hunters and explains their high population, conservatively estimated at 16,000, and their early exploitation by Russian traders. Sea otters, the most valued of pelts, were hunted by harpoon cast with throwing board from kayaks (one-man skin boats also known as bidarka). Whales, sea lions, seals and, in the eastern area, walrus were also hunted from the kayak. The Russians employed Aleut hunters transporting many to Fort Ross in California, the northern Kurils, the Pribilof Islands and the Commander Islands of Russia. The large open skin boat (Eskimo umiak) was extensively used. Nets, spears and hooks were also employed. The annual runs of salmon were trapped, then sun-dried and stored in containers made of the stomachs of seals and sea lions. While the bow and arrow was little used in the islands it was more commonly used on Unimak Island and the peninsula for caribou and bear hunting.

From their earliest appearance in the islands, about 2,000 years B.C., they had a rich material culture with many things made of stone, lamps, chipped knives and points; bone: harpoon heads, fish hooks, wedges for splitting driftwood; and ivory: lip decorations (labrets), figurines and needles. These are found in the old village middens, particularly in the refuse under the semisubterranean houses, often situated at mouths of the salmon streams.

The Aleuts possess an exceptional knowledge of human anatomy based upon extensive butchering of sea mammals and use of ordinarily discarded parts (intestines, pericardia) for fabricational purposes (waterproof parkas); comparative anatomy of sea otter; dissection of deceased persons to find out why they died; rational medicine and health practices; and true mummification (removal of intestines) of distinguished persons such as whalers.

In the last half of the 20th century about 500 Aleuts occupied 11 villages in the islands and on the Alaska peninsula, another 500 lived in the Pribilof Islands and approximately 300 lived on the Russian Commander Islands. Most are members of the Russian Orthodox Church. A small amount of the famous fine grass basketry is still made and many of the native foods are still eaten.

ALEUTIAN ISLANDS, a chain of small islands situated in the North Pacific ocean, and extending about 1,200 mi. westward from the extremity of the Alaskan peninsula toward the peninsula of Kamchatka; they constitute a district (6,821 sq.mi.) of the state of Alaska. The islands, also called Catherine archipelago, comprise four groups—the Fox, Andreanof, Rat and Near islands. They are all included between 52° and 55° N. and 172° E. and 163° W.

The axis of the archipelago near the mainland of Alaska has a southwest trend, but near the 179th meridian its direction changes to the northwest. This change of direction corresponds to a curve

THE ALEUTIANS AND NEIGHBOURING ISLANDS IN THE BERING SEA

in the line of volcanic fissures which have contributed their products to the building of the islands. The island chain is really a western continuation of the Aleutian range on the mainland. The great majority of the islands bear evident marks of volcanic origin, and there are numerous volcanic cones on the north side of the chain, some of them active; many of the islands, however, are not wholly volcanic, but contain crystalline or sedimentary rocks, and also amber and beds of lignite. The coasts are rocky and surf worn and the approaches are exceedingly dangerous, the land rising immediately from the coasts to steep, bold mountains.

The climate of the islands is oceanic, with moderate and fairly uniform temperatures and heavy rainfall. Fogs are almost constant. The summers are much cooler than on the mainland at Sitka, but the winter temperature of the islands and of southeastern Alaska is very nearly the same. The mean annual temperature for Unalaska, the most important island of the group, is about 38° F. The growing season lasts about 135 days, from early in May till late in September, but agriculture is limited to the raising of a few vegetables. The islands are practically destitute of trees, but are covered with a luxuriant growth of herbage, including grasses, sedges and many flowering plants. Attempts have been made to raise sheep and reindeer on the islands, but the industry is still in its infancy with some uncertainty as to future results. The principal occupations of the native Aleuts (see ALEUT) have always been fishing and hunting, and the women weave basketry of exquisite fineness. From the end of the 18th century the Russian fur traders had settlements there for the capture of the seal and the sea otter and the blue and the Arctic fox. After the U.S. purchase of Alaska, seal fishing off the Aleutians, save by the natives, was declared illegal, but the rapid depletion of animals threatened the Aleuts with starvation. In later years the raising of foxes, especially of blue fox, was conducted quite extensively throughout the islands and with a fair measure of success. This industry furnished employment to many natives. Fish and sea fowl are extremely abundant.

It is stated that before the advent of the Russians there were 25,000 Aleuts on the archipelago, but that the barbarities of the traders nearly extinguished the native population. In 1883 it was estimated that there were 2,950 Aleuts. The total population of the archipelago in 1950 was 5,600, there being 3,892 Aleuts mainly in the Aleutians. In 1960 the population was 6,011. The principal settlements are on the Unalaska Islands. Of these Unalaska, the oldest, settled in 1760-75, has a customhouse, a Russian-Greek church and a Methodist mission and orphanage; it is the headquarters for a considerable fleet of United States coast guard vessels which patrol the sealing grounds of the Pribilofs. Adjacent is Dutch Harbor, where a U.S. naval base was established in 1941.

The Commander Islands group near the Asiatic coast is geographically but (since the acquisition of the Russian possessions in America) not politically a part of the Aleutian system.

In 1741 the Russian government sent out Vitus Bering, a Dane, and Alexei Chirikov, a Russian, in the ships "Saint Peter" and "Saint Paul" on a voyage of discovery in the North Pacific. After the ships were separated by a storm, Chirikov discovered several eastern islands of the Aleutian group, and Bering discovered several of the western islands, finally being wrecked and losing his life on the island of the Commander group that now bears his name. The survivors of Bering's party reached Kamchatka in a boat constructed from the wreckage of their ship, and reported that the islands were rich in fur-bearing animals. Siberian fur hunters at once flocked to the Commander Islands and gradually moved eastward across the Aleutian Islands to the mainland. In this manner Russia gained a foothold in North America. The Aleutians belonged to Russia until that country, in 1867, transferred to the United States all its possessions in America.

During World War II Japan threatened the Aleutians. On June 3, 1942, the Japanese bombed Dutch Harbor, and they occupied the islands of Attu, Agattu and Kiska. The following year, on May 11, U.S. amphibious forces landed on Attu, and after 19 days of heavy fighting the island was secured. On Aug. 15, 1943, U.S. and Canadian troops were landed on Kiska, only to find that the Japanese had evacuated the island. After the war Aleutian radar stations became an important link in the air defense net surrounding North America.

ALEWIFE, a fish (*Alosa pseudoharengus*) of the Clupeidae family, which also includes herring, shad and sardines. Alternative common names for the alewife are sawbelly, grayback, gaspereau and branch herring. During the spring, the alewife spawns in ponds and sluggish rivers of eastern North America between Newfoundland and Florida. Except for a few landlocked populations, the rest of the life history is spent in the sea, where the alewife congregates in large schools. The adults usually return to their native stream after three or four years in the ocean, and those that survive will return in subsequent years. Their food is chiefly plankton. They grow to a length of one foot and are an important food fish. (C. H. U.)

ALEXANDER, the name of eight popes.

ST. ALEXANDER I "followed this Euaestus" (Evaristus), according to St. Irenaeus in his *Against Heresies*, and was the fifth pope after St. Peter. His rule of approximately ten years (105-115 or 109-119) is attested by Eusebius. The *Book of Popes* (*Liber Pontificalis*, edited by L. Duchesne) confirms the foregoing. (J. M. F. M.)

ALEXANDER II (Anselm of Lucca) (d. 1073), pope from 1061 to 1073; was a native of Milan. As bishop of Lucca he worked for the abolition of simony and the enforcement of clerical celibacy. Though he was elected pope, the German court nominated Peter Cadalus of Parma as Honorius II. But in 1062 the antipope was dropped by the German regents and the schism ceased to be important. In co-operation with Hildebrand (later Gregory VII, *q.v.*) and Peter Damian (*q.v.*), Alexander laid the foundations of the reform movement which reached its climax under Gregory VII. It was his deposition of the imperial bishop of Milan for simony which led to the investiture struggle between papacy and empire. (R. E. McN.)

ALEXANDER III (Roland Bandinelli of Siena) (d. 1181), one of the outstanding popes in history, occupied the throne from Sept. 7, 1159, to Aug. 30, 1181. As theologian and canonist, Roland was a celebrated professor at Bologna, and as cardinal (1150) and papal chancellor (1153-1159), he was the adviser of Adrian IV, whom he succeeded. An open opponent of the universal claims of Emperor Frederick I, Alexander was opposed by three imperial antipopes during a 17-year schism. Seldom in Rome. Alexander in exile became the symbol and leader of Italian resistance to German domination, and Frederick's final defeat by the Lombard league at Legnano made possible the Peace of Venice (1176) with the pope and his Italian confederates. (See also **FREDERICK I.**)

First of the great lawyer-popes, Alexander convoked the third

Lateran council (1179) to repair the schism, and at this council was instituted the two-thirds majority rule for papal elections. He supported Thomas Becket and imposed penance on Henry II for the archbishop's murder. His reign furthered the development of church law and papal government. His merits and moral stature were recognized even by his adversaries.

BIBLIOGRAPHY.—F. L. Cross (ed.), *The Oxford Dictionary of the Christian Church* (1957); H. K. Mann, *The Lives of the Popes in the Middle Ages*, 2nd ed., vol. x (1925); M. Pacaut, *Alexandre III* (1956); Z. N. Brooke, *The English Church and the Papacy*, reprint (1952).

ALEXANDER IV (Rinaldo, family of the counts of Segni of Anagni) (d. 1261), pope from Dec. 12, 1254, to May 25, 1261, was a nephew of Gregory IX. Following Innocent IV's anti-Hohenstaufen policies, he continued war on Manfred (*q.v.*), Frederick II's bastard (crowned king of Sicily in 1258), and offered the crown of this papal fief to Henry III of England for his son Edmund. He supported the friars at Paris against the secular professors, extended the Inquisition in France and worked for reunion between eastern Christians and Rome.

See H. K. Mann, *The Lives of the Popes in the Middle Ages*, vol. xv (1929); S. Runciman, *The Sicilian Vespers: A History of the Mediterranean World in the Later Thirteenth Century* (1958). (J. J. RN)

ALEXANDER V (Pietro di Candia or Petros Philargos) (c. 1339-1410) was an antipope (1409-10) unanimously elected by the invalid council of Pisa in 1409. Of Greek parentage, Alexander became a Franciscan theologian, then archbishop of Milan. He was 70 years old at the time of his election and reigned only ten months.

See Philip Hughes, *A History of the Church*, vol. iii (1947); Ludwig Pastor, *The History of the Popes . . .*, vol. i (1801).

ALEXANDER VI (Rodrigo Borgia) (1431-1503), pope from 1492-1503, was one of the worst of the Renaissance popes. Born Jan. 1, 1431, at Xativa, Spain, he studied law at Bologna and then served for 35 years at the papal court, where he proved himself an able administrator. As pope, Alexander became deeply involved in the political turmoil in Italy, the struggles of Italian

families like the Orsini, della Rovere and Colonna for power and wealth, the conflict between France and Spain for control of Italy and his own efforts to endow his children—he had at least four before he became pope—with estates in Italy.

When Charles VIII (*q.v.*) of France invaded Italy, seized Rome and Naples, Alexander helped organize an alliance with Milan, Venice, Spain and the Holy Roman empire which forced Charles to leave Italy. When Alexander's son the duke of Gandia sought to punish the Orsini for having sided with the French he was mysteriously murdered. The pope then abetted the marriage of his infamous son Cesare Borgia (*q.v.*) to a French princess, annulled the marriage of Louis XII of France and Jeanne Valois and thus won an ally in France and aid for Cesare's attempt to win Romagna and to punish Borgia enemies. Alexander's neglect of the spiritual interests of the church worsened the prestige of the papacy. See also SAVONAROLA, GIROLAMO.

ALEXANDER VII (Fabio Chigi) (1599-1667), pope from 1655 to 1667, was born at Siena on Feb. 13, 1599. He served the church as nuncio at Cologne between 1639 and 1651. During the negotiations leading to the Peace of Westphalia (1648) he urged the Catholic princes not to sacrifice the rights of the church. They, however, were tired of war and yielded to France and the Protestants. Secretary of state to Innocent X in 1651 and made cardinal in 1652, Chigi was elected pope on April 7, 1655. His pontificate was marked by disputes with the Catholic powers, especially with France. When Alexander resisted the French claims, Louis XIV forced him to accept the humiliating peace of Pisa (1664) by a threat of war. Alexander took measures against the Jansenists who failed to submit (see JANSENISM). He died on May 22, 1667.

ALEXANDER VIII (Pietro Ottoboni) (1610-1691), pope from 1689 to 1691, was born at Venice on April 22, 1610. Made cardi-

nal in 1652, he was elected pope on Oct. 6, 1689. Alexander tried to make a settlement with Louis XIV and succeeded in initiating the measures which led eventually to a solution. He maintained the condemnation of the Gallican articles of 1682 (see GALLICANISM) and opposed Jansenism. He died on Feb. 1, 1691. See also PAPACY. (E. A. R.)

ALEXANDER (870–913), Byzantine emperor from 912 to 913, was the third son of Basil I of the Macedonian dynasty. He was crowned co-emperor about 879 but came to power only on the death of his brother Leo VI (May 12, 912), when the latter's son Constantine VII was a minor. Alexander then acted as senior emperor, using the title "autocrator" on his coins. He was vicious and irresponsible, and his foolish policy aggravated tension at home and abroad. He replaced Leo VI's ministers with his own friends, and Zoe, the dowager-empress, was banished from the palace. Leo's opponent, the deposed Nicholas Mysticus, was restored to the patriarchal throne, which Euthymius was forced to vacate. Alexander's refusal to pay the annual tribute owed to the Bulgars by the treaty of 896 precipitated war with Simeon, their powerful and aggressive king. Alexander's rule was brought to an early end by his death on June 6, 913. He left a divided front at home and the empire threatened with invasion by Simeon, who coveted the imperial throne.

BIBLIOGRAPHY.—G. Ostrogorsky, *History of the Byzantine State*, p. 207, p. 231 (1956); A. Rambaud, *L'Empire grec au X^e siècle: Constantin Porphyrogénète (1870)*; S. Runciman, *The Emperor Romanus Lecapenus and His Reign* (1929). (J. M. Hy.)

ALEXANDER I (ALEKSANDR PAVLOVICH) (1777–1825), emperor of Russia, son of the grand duke Pavel Petrovich (afterward Paul I) and Maria Fedorovna (Sophia Dorothea of Wdrtemberg), was born on Dec. 23 (new style; Dec. 12, old style), 1777. The strange contradictions of his character make Alexander one of the most interesting as well as most important figures of the 19th century. Autocrat and Jacobin, man of the world and mystic, he was to his contemporaries a riddle which each read according to his own temperament. Napoleon thought him a "shifty Byzantine." To Metternich he was a madman to be humoured. Castlereagh gave him credit for "grand qualities," but said that he was "suspicious and undecided." His complex nature was the outcome of the complex character of his early education. Reared in the free-thinking atmosphere of the court of Catherine II, he had imbibed from his Swiss tutor, Frédéric César de La Harpe, the principles of J. J. Rousseau's gospel of humanity and from his military governor, Count N. I. Saltykov, the traditions of Russian autocracy, while his father had inspired him with his own passion for military parade. These contradictory tendencies remained with him through life and were revealed in the fluctuations of his policy.

When, upon the murder of his father, of which he had had knowledge in advance, Alexander succeeded to the throne on March 24 (N.S.; 12, O.S.), 1801, he was young, impressionable, well-meaning and egotistic and plunged with all the ardour of youth into the task of realizing his political ideals. While he retained for a time the old ministers who had served and overthrown his father, one of the first acts of Alexander's reign was to appoint a secret committee, called ironically the "committee of public safety," consisting of young and enthusiastic friends of his own—Viktor Pavlovich Kochubei, Nikolai Nikolaevich Novosiltsev, Pavel Aleksandrovich Stroganov and Adam Jerzy Czartoryski—to draw up a scheme of internal reform. Their aims were far in advance of the possibilities of the time, and even after they had been raised to regular ministerial positions little of the group's program could be realized. Russia was not ripe for liberty, and Alexander was—as he himself said—but "a happy accident" on the throne of the tsars. He spoke bitterly of "the state of barbarism in which the country had been left by the traffic in men." "Under Paul," he said in 1807 to A. J. M. Savary, the French ambassador, "three thousand peasants had been given away like a bag of diamonds. If civilization were more advanced, I would abolish this slavery, if it cost me my head." But the universal corruption, he complained, had left him no men, and the filling of the government offices with Germans and other foreigners merely accentuated the sullen resistance of the "old Russians" to his reforms. That his

reign, which had begun with so large a promise of amelioration, ended with the Russian people still more firmly oppressed was, however, mainly due to the defects of the tsar himself.

His love of liberty, though sincere, was in fact unreal. It flattered his vanity to pose before the world as the dispenser of benefits, but his theoretical liberalism was mated with an autocratic will which brooked no contradiction. Moreover, with this masterful temper was joined an infirmity of purpose which seized upon any excuse for postponing measures the principles of which he had publicly approved. Codification of the laws initiated in 1801 was never carried out during his reign, nothing was done to improve the status of the Russian peasantry, and the constitution drawn up by M. M. Speranski (*q.v.*) and passed by the emperor remained unsigned. Alexander experimented in the outlying provinces of his empire, and the Russians complained that, not content with governing through foreign instruments, he was conferring on Poland, Finland and the Baltic provinces benefits denied to themselves. In Russia, too, certain reforms were carried out; but they could not survive the suspicious interference of the autocrat and his officials. The newly created council of ministers and the senate, endowed for the first time with certain theoretical powers, became in the end slavish instruments of the tsar and his favourites of the moment. The elaborate system of education culminating in the reconstituted or new-founded universities of Dorpat (Tartu), Vilna (Vilnius), Kazan and Kharkov was strangled in the supposed interests of "order" and of orthodox piety, while the military colonies which Alexander proclaimed as a blessing to both soldiers and state were forced on the unwilling peasantry and army with pitiless cruelty.

Alexander's grandiose imagination was, however, more strongly attracted by the great questions of European politics arising from the French Revolutionary and Napoleonic wars than by attempts at domestic reform. Immediately after his accession he reversed his father's policy, denounced the League of Neutrals, made peace with England (April 1801) and opened negotiations with Austria. Soon afterward, at Memel, he entered into a close alliance with Prussia. The development of this alliance was interrupted by the short-lived peace of Oct. 1801, and for a while it seemed as though France and Russia might come to an understanding. Carried away by the enthusiasm of Frédéric César La Harpe, who had returned to Russia from Paris, Alexander began openly to proclaim his admiration for French institutions and for the person of Napoleon Bonaparte. Soon, however, came a change. La Harpe, after a new visit to Paris, presented to the tsar his reflections on the true nature of Bonaparte's life consulship, which, as Alexander said, revealed Bonaparte as "the most famous tyrant the world has produced." His disillusionment was completed by the murder of the duc d'Enghien, and diplomatic relations with Paris were broken off.

The tsar's attitude during the war that followed was governed by his vision of the future history of Europe. In opposing Napoleon, "the oppressor of Europe and the disturber of the world's peace," Alexander believed himself to be fulfilling a divine mission. In his instructions to Novosiltsev, his special envoy in London, he elaborated the motives of his policy as directed toward a general treaty for collective security that would govern the relations of states in a "European confederation," provided that at the conclusion of the general war it were possible to establish on clear principles the prescriptions of the rights of nations. Napoleon, however, never gave up hope of detaching Alexander from the coalition. He had no sooner entered Vienna in triumph than he opened negotiations with him. He resumed them after Austerlitz. Russia and France, he urged, were "geographical allies": there was between them no true conflict of interests; together they might rule the world. But Alexander was still determined "to persist in the system of disinterestedness in respect of all the states of Europe which he had thus far followed," and he again allied himself with Prussia. The campaign of Jena and the battle of Eylau followed, and Napoleon, though still intent on the Russian alliance, stirred up Poles, Turks and Persians to break the obstinacy of the tsar. A party in Russia itself was clamorous for peace, but Alexander, after a vain attempt to form a new coalition, summoned

the Russian nation to a holy war against Napoleon as the enemy of the Orthodox faith. The outcome was the Russian defeat in the battle of Friedland (June 1807). Napoleon saw his chance and seized it. Instead of making heavy terms, he offered to the chastened autocrat his alliance and a partnership in his glory.

The two emperors met at Tilsit on June 25. Alexander, dazzled by Napoleon's genius, was completely won. Napoleon knew well how to appeal to the imagination of his new-found friend. He would divide with Alexander the empire of the world; as a first step he would leave him in possession of the Danubian principalities and give him a free hand to deal with Finland; afterward, they would together drive the Turks from Europe and march across Asia to the conquest of India. A program so stupendous awoke in Alexander's impressionable mind an ambition to which he had hitherto been a stranger. The interests of Europe were forgotten. "What is Europe?" he exclaimed to Savary: "Where is it, if it is not you and we?"

It was not long before the first enthusiasm of Tilsit began to wane. Napoleon promised much and performed little. The French remained in Prussia, the Russians on the Danube. Each accused the other of breach of faith. Meanwhile, however, the personal relations of Alexander and Napoleon were cordial, and it was hoped that a fresh meeting might adjust all their differences. The meeting took place at Erfurt on Oct. 12, 1808, and resulted in a treaty which defined a common policy. But Alexander's relations with Napoleon none the less changed. He saw that Napoleon had never intended his proposed "grand enterprise" seriously and had only used it to preoccupy the mind of the tsar while he consolidated his own power in central Europe. From this moment the French alliance was for Alexander also an affair of pure policy. He used it, in the first instance, to remove "the geographical enemy" from the gates of St. Petersburg by wresting Finland from the Swedes (1809), and he hoped by means of it to make the Danube the southern frontier of Russia. Events were in fact rapidly tending to the rupture of the Franco-Russian alliance. Alexander, indeed, assisted Napoleon in the war of 1809, but he declared that he would not allow Austria to be crushed, and Napoleon complained bitterly of the inactivity of the Russian troops during the campaign. The tsar in his turn protested against Napoleon's encouragement of the Poles. In the matter of the French alliance he knew himself to be practically isolated in Russia, and he declared that he could not sacrifice the interest of his people and empire to his affection for Napoleon. He complained that the treaty of Vienna (Oct. 14, 1809), which added largely to the duchy of Warsaw, had "ill requited him for his loyalty," and he was only mollified for the time by the Franco-Russian convention of Jan. 4, 1810, declaring that "the kingdom of Poland will never be restored."

But if Alexander suspected Napoleon, Napoleon was no less suspicious of Alexander; and, partly to test his sincerity, he sent an almost peremptory request for marriage with the grand duchess Anna, the tsar's youngest sister. After some delay Alexander returned a polite refusal. Napoleon's answer was to refuse to ratify the convention of Jan. 4 and to announce his engagement to the Austrian archduchess Marie Louise. Relations between the two emperors were further embittered by Napoleon's seizure of Oldenburg (the ducal house there being closely linked with the Romanovs) and by the ruinous effect of Napoleon's "continental system" on Russian trade. An acid correspondence followed, and ill-concealed preparations for war, which culminated in the summer of 1812 in Napoleon's invasion of Russia. Yet, even after the French had passed the frontier, Alexander still protested that his personal sentiments toward Napoleon were unaltered. It was the occupation of Moscow and the desecration of the Kremlin, the sacred centre of Holy Russia, that changed his sentiment into passionate hatred. In vain the French emperor, within eight days of his entry into Moscow, wrote him a letter revealing the desperate straits of the invading army and appealing to "any remnant of his former sentiments." Alexander returned no answer.

The campaign of 1812 was the turning point of Alexander's life. Its horrors, for which he felt himself largely responsible, over-set still more a mind never too well-balanced. At the burning of Moscow, he declared afterward, his own soul had found illumina-

tion and he received the divine revelation of his mission as the peacemaker of Europe. He tried to calm the unrest of his conscience by correspondence with the leaders of the evangelical revival and sought for guidance in texts of Scripture. It was not, however, according to his own account, till he met the baroness Barbara Juliane von Kriidener (*q.v.*) at Basel, in the autumn of 1813, that his soul found peace. From this time a mystic pietism influenced his policy.

Such was Alexander's mood when the downfall of Napoleon left him the most powerful sovereign in Europe. With the memory of Tilsit still fresh in men's minds, it was not unnatural that to cynical men of the world like Metternich he merely seemed to be disguising "under the language of evangelical abnegation" vast and perilous schemes of ambition. The puzzled powers were, in fact, the more inclined to be suspicious in view of other, and seemingly inconsistent, tendencies of the emperor, which yet seemed all to point to a like disquieting conclusion. At the congress of Vienna Alexander's attitude accentuated this distrust. Castlereagh, whose aim was the restoration of "a just equilibrium" in Europe, reproached the tsar to his face for a "conscience" which suffered him to imperil the concert of the powers by keeping his hold on Poland in violation of his treaty obligation.

Yet Alexander was sincere. The Holy alliance (*q.v.*) was the pet offspring of his pietism and seemed to him the only means of placing the "confederation of Europe" on a firm basis of principle. So far from its being directed against liberty, he declared roundly to all the signatory powers that "free constitutions were the logical outcome of its doctrines." To the other powers, however, it seemed at best "verbiage" and "exalted nonsense," at worst an effort of the tsar to establish the hegemony of Russia on the good will of the smaller signatory powers. To liberals, it was clearly a hypocritical conspiracy against freedom.

From the end of the year 1818 Alexander's views began to change. A revolutionary conspiracy among the officers of the guard and a foolish plot to kidnap him on his way to the congress of Aix-la-Chapelle are said to have shaken the foundations of his liberalism. At Aix he came for the first time into intimate contact with Metternich, who was swift to take advantage of the psychological moment. From this time dates the ascendancy of Metternich over the mind of the Russian emperor and in the councils of Europe. It was, however, no case of sudden conversion. Though alarmed by the revolutionary agitation in Germany, which culminated in the murder of his agent, the dramatist August von Kotzebue (*q.v.*), Alexander approved of Castlereagh's protest against Metternich's policy of "the governments contracting an alliance against the peoples," as formulated in the Carlsbad decrees in 1819. He still declared his belief in "free institutions, though not in such as are forced from feebleness, nor contracts ordered by popular leaders from their sovereigns." "Liberty," he maintained, "should be confined within just limits. And the limits of liberty are the principles of order."

It was the apparent triumph of the principles of disorder in the revolutions of Naples and Piedmont, combined with increasingly disquieting symptoms of discontent in France, in Germany and among his own people, that completed Alexander's conversion. In the seclusion of the little town of Troppau (Opava in Silesia), where in Oct. 1820 the powers met in conference, Metternich found an opportunity for cementing his influence over Alexander which had been wanting amid the turmoil and feminine intrigues of Vienna and Aix. The issue was momentous. In the preceding January Alexander had still upheld the ideal of a free confederation of the European states, symbolized by the Holy alliance, and had still protested against the claims of collective Europe to interfere in the internal concerns of the sovereign states. On Nov. 19 he signed the Troppau protocol, which consecrated the principle of intervention and wrecked the harmony of the concert (see TROPPAU, CONGRESS OF).

At Laibach (Ljubljana), whither in the spring of 1821 the congress had been adjourned, Alexander first heard of the revolt of the Greeks. From this time until his death his mind was torn between his anxiety to realize his dream of a confederation of Europe and his traditional mission as leader of the Orthodox cru-

sade against the Turks. At first, under the careful nursing of Metternich, the former motive prevailed. He directed his foreign minister, Count I. A. Kapodistrias, (*q.v.*), himself a Greek, to disavow all sympathy of Russia with the Greek enterprise; and, the next year, a deputation of the Greeks of the Morea on its way to the congress of Verona was turned back by his orders. He made, indeed, some effort to reconcile the principles at conflict in his mind. He offered to surrender the claim that the affairs of the east were the "domestic concerns of Russia" and to march into Turkey, as Austria had marched into Naples, "as the mandatory of Europe." Metternich's opposition to this first opened his eyes to the true character of Austria's attitude toward his ideals. Once more in Russia, far from the fascination of Metternich's personality, the immemorial spirit of his people drew him back into itself; and when, in the autumn of 1825, he took his dying empress for change of air to the south of Russia, in order—as all Europe supposed—to place himself at the head of the great army concentrated near the Ottoman frontiers, his language was no longer that of "the peace-maker of Europe," but of the Orthodox tsar determined to take the interests of his people and of his religion "into his own hands." Before the momentous issue could be decided, however, Alexander died at Taganrog on Dec. 1 (N.S.; Nov. 19, O.S.), 1825, "crushed," to use his own words, "beneath the terrible burden of a crown" which he had more than once declared his intention of resigning.

Modern history knows few more tragic figures than that of Alexander. His early years had been full of brilliant promise, and he had countenanced a crime in order to obtain the power to realize his ideals; but in the end he left a terrible legacy to Russia: a principle of government which, under lofty pretensions, veiled a tyranny supported by spies and secret police; an uncertain succession; an army permeated by organized disaffection; an armed Poland, whose hunger for liberty the tsar had whetted but not satisfied; the quarrel with Turkey, with its alternative of war or humiliation for Russia; an educational system rotten with official hypocrisy; a church in which conduct counted for nothing, orthodoxy and ceremonial observance for everything; economical and financial conditions scarce recovering from the verge of ruin; and serfdom.

In private life Alexander displayed many lovable qualities. All authorities combine in praising his handsome presence and the charm of his address. His personal friendship, too, once bestowed, was never lightly withdrawn. By nature he was sociable and pleasure-loving; he proved himself a notable patron of the arts and took a conspicuous part in all the gaieties of the congress of Vienna. In his later years, however, he fell into a mood of settled melancholy and, though still accessible to all who chose to approach him with complaints or petitions, withdrew from all but the most essential social functions and lived a life of strenuous work and of Spartan simplicity. His gloom had been increased by domestic misfortune. He had been married on Oct. 9 (N.S.; Sept. 28, O.S.), 1793, without his wishes being consulted, to the beautiful and amiable Luisa Maria Augusta of Baden (Elizaveta Alekseevna), a political match which proved the misfortune of both. The only child of the marriage, a daughter, died on May 12, 1808, and their common sorrow drew husband and wife closer together. Toward the close of his life their reconciliation was completed by the wise charity of the empress in sympathizing deeply with him over the death of Sophia, his second daughter by his mistress Maria Antonovna Nasyshkina (*née* Princess Czertwertynska).

(W. A. P.; G. A. LN.)

ALEXANDER II (ALEKSANDR NIKOLAEVICH) (1818–1881), emperor of Russia from 1855 to 1881, was born in Moscow on April 29 (new style; April 17, old style), 1818, the eldest son of the emperor Nicholas I. Up to the time of his accession in 1855, no one imagined that he would be known to posterity as a great reformer. In so far as he had any political convictions he seemed to be animated with the reactionary spirit which at that time was suppressing all freedom of thought and all private initiative. Educated so as to have a smattering of a great many subjects and a good practical acquaintance with the chief modern European languages, he lived the life of an officer of the guards modified by the ceremonial duties incumbent on him as heir to the throne. His natural kindness and his disposition for a military life, however, had been fostered by his tutor V. A. Zhukovski, the amiable humanitarian poet, and they remained with him all through life. On April 28 (N.S.; April 16, O.S.), 1841, he married the daughter of the grand duke Louis II of Hesse, Marie, thenceforward known as Maria Aleksandrovna, who bore him six sons and two daughters. Though his father, in his desire to exclude western ideas from Holy Russia, disapproved of foreign tours and could not encourage in his own family what he tried to prevent among the rest of his subjects, Alexander was allowed to visit England in 1839 and, in the years immediately preceding his accession, was entrusted with several missions to Berlin and Vienna.

At his father's death Alexander succeeded to the throne, March 2 (N.S.; Feb. 18, O.S.), 1855, during the Crimean War. The peace treaty of Paris was signed in the following year, and then began a period of radical reforms, recommended by public opinion and carried out by the imperial government. The policy of Nicholas I of sacrificing all other interests to that of making Russia an irresistibly strong military power had been discredited by the war. A new system had, therefore, to be adopted. All who had any pretensions to enlightenment declared loudly that the only way of restoring Russia to its proper position in Europe was to develop its natural resources and to reform thoroughly all branches of the administration.

Basically a conservative, Alexander nevertheless appreciated the necessity for reforms. At first he moved so slowly that the impatient reformers began to murmur. Important changes, however, were made in the legislation concerning industry and commerce, and the new freedom thus accorded produced a large number of limited liability companies. At the same time a great network of railways was planned, partly for economic and partly for military purposes.

Further progress was blocked by a great obstacle, the existence of serfdom, and Alexander grappled with this dangerous problem. Taking advantage of a petition presented by the Polish landed proprietors of the Lithuanian and Belorussian provinces, praying that their relations with the serfs might be regulated better, he authorized the formation of committees "for ameliorating the condition of the peasants" and laid down the principles on which the amelioration was to be effected. Without consulting his ordinary advisers, he then ordered a copy of these instructions to be forwarded to the provincial governors of European Russia and suggested that perhaps the landed proprietors of other provinces might express a similar desire. In all provinces where serfdom existed emancipation committees were formed. Emancipation meanwhile was bound to affect the economic, social and political future of the nation profoundly, the main question being whether the serfs should become agricultural labourers dependent economically and administratively on the landlords or be transformed into a class of independent communal proprietors. The emperor gave his support to the latter project. On the numerous other questions submitted to him he began by carefully consulting the conflicting authorities and, while leaning as a rule rather to the liberals, never went so far as they desired and always sought some middle course. On March 3 (N.S.; Feb. 19, O.S.), 1861, the emancipation law was signed and published.

Other reforms followed in quick succession during the next five or six years: army and navy organization; a new judicial administration on the French model; a new penal code and a greatly simplified system of civil and criminal procedure; an elaborate

scheme of local self-government for the rural districts and the large towns, with elective assemblies possessing a restricted right of taxation; and a new rural and municipal police under the direction of the minister of the interior. These new institutions were better than the old ones which they replaced, but they did not work such miracles as inexperienced enthusiasts expected and had, in fact, many real defects. Hence arose a general feeling of disappointment which showed itself in different natures in different ways. In the educated classes two extreme groups appeared: on the one hand, the discontented conservatives, who recommended a return to a more severe disciplinarian regime; and on the other, the discontented radicals, who would have been satisfied with nothing less than the adoption of a socialist program. Between the two extremes stood the discontented liberals, who grumbled freely without knowing how to remedy the state of things. For several years the emperor held the balance fairly between the two extremes, but when radicalism assumed more and more the form of secret societies and revolutionary agitation he felt constrained to adopt repressive measures.

Revolutionary agitation was confined to a section of the educated classes and emanated from the universities and higher technical schools. At the beginning of the reform period there had been much enthusiasm for scientific as opposed to classical education, on the ground that the country needed practical scientists capable of developing its natural resources. The government, in agreement with this view, had encouraged scientific studies until it found cause to believe that there was some mysterious connection between natural science and revolutionary tendencies. Thereafter the zealous guardians of political order were in conflict with the youthful, hotheaded partisans of revolutionary physical science, whose nihilism (*q.v.*) eventually assumed the form of terrorism and aimed at the assassination of prominent officials and even of the emperor himself. The natural result of this was that the reactionary tendencies of the government were strengthened.

In foreign policy Alexander followed a course dictated by circumstances. When he came to the throne the Crimean War was still going on, but he concluded peace with the allies when the impossibility of continuing the war became clear. Prince A. M. Gorchakov (*q.v.*) for 15 years avoided foreign complications, while national pride and ambition were gratified by the expansion of Russian power in Asia. Twice, indeed, during that period Gorchakov ran the risk of provoking war—first in 1863, when the western powers seemed inclined to interfere in the Polish question and Russia declared categorically that no interference would be tolerated; then during the Franco-German War of 1870–71, when the Russian government declared that it considered itself no longer bound by the Black Sea clause of the Paris treaty of 1856. On both occasions hostilities were averted because the western powers were unwilling to take up the challenge. Between these two occasions, in 1867, Alexander visited the emperor Napoleon III in France where on June 6 an unsuccessful attempt on his life was made by a Polish nationalist, Antoni Berezowski.

In 1875, however, when Hercegovina rose in insurrection against the Turks, Alexander found himself in a more delicate position. Though he still had no wish to provoke a European war, he had inherited the claim that his predecessors had sporadically made to be the protectors of the Orthodox Christians of the Ottoman empire, he came forward as the champion of oppressed Slav peoples and he also hoped to be able to take advantage of the situation in order to recover, with Austria-Hungary's diplomatic support, the part of Bessarabia that had been taken from Russia by the treaty of Paris (see EASTERN QUESTION). Gradually, then, he allowed himself to drift into a position from which he could not retreat without obtaining some tangible result. Supposing that Turkey would yield to diplomatic pressure and make some reasonable concessions, he delivered on Nov. 10 (N.S.; Oct. 29, O.S.), 1876, his famous Moscow speech, in which he declared that if Europe would not secure a better position for the oppressed Slavs he would act alone.

Diplomatic pressure failed and war became inevitable (see RUSSO-TURKISH WARS). While it lasted he refused to yield to extremes. He would not listen to those who began to despair and

advised him to conclude peace on almost any terms, but when more headstrong advisers urged him to insist on terms which would probably have produced a conflict with Great Britain and Austria-Hungary, he resolved, after some hesitation, to make the requisite concessions. The discovery during the war that he could not rely on support from Germany made him waver in his devotion to the German alliance, which had been the main pivot of his foreign policy; but his personal attachment to the emperor William I and the pressure of powerful partisans of the German alliance in the Russian foreign service prevented his adopting a hostile attitude toward the German empire that he had helped to create. His surprising support of Pan-Slavism during the Turkish war proved but a passing fad; it ended with the abandonment of the treaty of San Stefano (*q.v.*) and the substitution of another treaty at the congress of Berlin (*q.v.*).

The patriotic excitement produced by the war did not weaken the revolutionary agitation. The struggle between the terrorists and the police authorities became more and more intense, and attempts at assassination became more and more frequent. Alexander succumbed by degrees to the mental depression produced originally by the disappointments which he experienced in his home and foreign policy; and in 1880, when he had reigned 25 years, he entrusted to Count M. T. Loris-Melikov (*q.v.*) a large share of the executive power. In that year the empress died, and a few weeks afterward he married Princess Ekaterina M. Dolgoruky, with whom he had entertained intimate relations for many years. Early in 1881, on the advice of Loris-Melikov, he determined to try the effect of some moderate liberal reforms on the revolutionary agitation, and for this purpose he caused an ukaz to be prepared creating a special commission, on which the zemstva and the municipal councils were to be represented, to examine legislative bills. On the very day on which this ukaz was signed—March 13 (N.S.; March 1, O.S.)—he fell victim to a plot sponsored by the executive committee of an organization called Narodnaya Volya ("People's Will"). When driving in one of the central streets of St. Petersburg, near the Winter palace, he was mortally wounded by the explosion of some small bombs and died a few hours afterward.

ALEXANDER III (ALEKSANDR ALEKSANDROVICH) (1845–1894), emperor of Russia, second son of Alexander II and of Maria Aleksandrovna (Marie of Hesse), was born in St. Petersburg on March 10 (new style; Feb. 26, old style), 1845. In natural disposition he bore little resemblance to his softhearted, impressionable father and still less to his refined, philosophic, sentimental, chivalrous, yet complex granduncle, Alexander I. He rather gloried in the idea of being of the same rough texture as the great majority of his subjects. His straightforward, abrupt manner savoured sometimes of gruffness, while his direct, unadorned method of expressing himself harmonized well with his roughhewn, immobile features and somewhat sluggish movements. His education was not fitted to soften these peculiarities. During the first 20 years of his life he had no prospect of succeeding to the throne, because he had an elder brother, Nicholas, who seemed of a fairly robust constitution. Alexander received only the perfunctory and inadequate training usually given to grand dukes of that period, which did not go much beyond primary and secondary instruction, practical acquaintance with French, English and German and a certain amount of drill. When he became heir apparent by the death of his elder brother in 1865, he began to study the principles of law and administration under K. P. Pobedonostsev (1827–1907), who influenced the character of his reign by instilling into his mind hatred for representative government and the belief that zeal for Orthodoxy ought, as an essential factor of Russian patriotism, to be specially cultivated by every right-minded tsar.

The tsarevitch Nicholas, on his deathbed, had expressed a wish

that his affianced bride, Princess Dagmar of Denmark, thenceforward known as Maria Fedorovna, should marry his successor. The marriage was celebrated on Nov. 9 (N.S.; Oct. 28, O.S.), 1866, and the union proved a most happy one to the end. During those years when he was heir apparent—from 1865 to 1881—Alexander allowed it to become known that he had certain ideas of his own which did not coincide with the principles of the existing government. He deprecated undue foreign influence in general and German influence in particular. His father, however, who had strong German sympathies, occasionally ridiculed the exaggerations of the Slavophiles and based his foreign policy on the Prussian alliance. The antagonism between father and son first appeared publicly during the Franco-German War, when the tsar sympathized with Prussia and the tsarevitch with the French. It reappeared in an intermittent fashion during the years 1875–79, on the Eastern question (*q.v.*). At first the tsarevitch was more Slavophile than the government, but any of the prevalent popular illusions that he may have imbibed were soon dispelled by personal observation in Bulgaria, where he commanded the left wing of the invading army in the Russo-Turkish War. He did not, however, make himself conspicuous during the campaign, but fulfilled his military duties in a conscientious and unobtrusive manner. After many mistakes and disappointments the army reached Constantinople and the treaty of San Stefano was signed; but much that had been obtained by that important document had to be sacrificed at the congress of Berlin (*q.v.*), when Bismarck failed to do what the Russians had confidently expected of him. To this disappointment, moreover, Bismarck shortly afterward added the German alliance with Austria for the express purpose of counteracting Russian designs in eastern Europe. Although the existence of the Austro-German alliance was not disclosed to the Russians until 1887, the tsarevitch reached the practical conclusion that for Russia the best thing to do was to prepare for future contingencies by a radical scheme of military and naval reorganization. In accordance with this conviction he called his father's attention to the grave disorders and corruption in the army. His representations were not favourably received.

On March 13 (N.S.; March 1, O.S.), 1881, Alexander II was assassinated, and the following day autocratic power passed to his son. In the last years of his reign, Alexander II had been much exercised by the spread of Nihilist conspiracies. On the very day of his death he signed an *ukaz* creating a number of consultative commissions which might have been transformed eventually into a representative assembly. Alexander III at once canceled the *ukaz* before it was published and in the manifesto announcing his accession to the throne let it be clearly understood that he had no intention of limiting or weakening the autocratic power which he had inherited. Nor did he afterward show any inclination to change his mind. All the internal reforms which he initiated were intended to correct what he considered as the too liberal tendencies of the previous reign. In his opinion Russia was to be saved from anarchical disorders and revolutionary agitation, not by the parliamentary institutions and so-called liberalism of western Europe, but by the three principles enunciated by Count S. S. Uvarov (minister of education from 1833 to 1849) and the elder generation of the Slavophiles; viz., Orthodoxy, autocracy and *narodnost*, or belief in the Russian people.

Alexander's political ideal was a nation containing only one nationality, one language, one religion and one form of administration, and he did his utmost to prepare for the realization of this ideal by imposing the Russian language and Russian schools on his German, Polish and Finnish subjects, by fostering Orthodoxy at the expense of other confessions, by persecuting the Jews and by destroying the remnants of German, Polish and Swedish institutions in the outlying provinces. In the other provinces he sought to counteract the liberalism of his father's reign. For this purpose he clipped the feeble wings of the *zemstvo* (an elective local administration resembling the county and parish councils in England) and placed the autonomous administration of the peasant communes under the supervision of landed proprietors appointed by the government. At the same time he sought to strengthen and centralize the imperial administration and to bring it more under

his personal control. In foreign affairs he was emphatically a man of peace, but not at all a partisan of the doctrine of peace at any price. Though indignant at the conduct of Bismarck toward Russia, he avoided an open rupture with Germany, and even revived for a time the Three Emperors' alliance. It was only in the last years of his reign, especially after the accession of William II as German emperor in 1888, that Alexander adopted a more hostile attitude toward Germany. The initiative of the termination of the Russo-German alliance in 1890 came from G. L. von Caprivi, the new German chancellor, and drove Alexander reluctantly into an alliance with France, a country which he strongly disliked as the breeding place of revolutions. The Franco-Russian alliance was signed in St. Petersburg on Dec. 31, 1893 (N.S.). With regard to Bulgaria the tsar exercised similar self-control. The efforts of Prince Alexander and afterward of Stefan Stambulov to destroy Russian influence in the principality excited his indignation, but he persistently vetoed all proposals to intervene by force of arms. In central Asian affairs he followed the traditional policy of gradually extending Russian domination without provoking a conflict with Great Britain, and he never allowed the bellicose partisans of a forward policy to get out of hand.

As a whole Alexander's reign cannot be regarded as one of the eventful periods of Russian history; but it is arguable that under his hard, unsympathetic rule the country made some progress. He died at Livadia, in the Crimea, on Nov. 1 (N.S.; Oct. 20, O.S.), 1894, and was succeeded by his eldest son, Nicholas II.

ALEXANDER (1893–1920), king of the Hellenes from 1917 to 1920, was born in Athens on Aug. 1, 1893, the second son of King Constantine and Queen Sophia. He came to the throne of Greece on the deposition of his father (June 12, 1917) during World War I. The government itself was for the time in the hands of Eleutherios Venizelos, who had the confidence of the Allies, and Venizelos' diplomatic triumphs at the peace conference and treaty of Sèvres (Aug. 10, 1920) seemed to offer the new king the prospect of being the ruler of that "Greater Greece" to which national aspirations had long been directed (*see GREECE: History*). These hopes were cut short by his death at the Tatoï palace on Oct. 25, 1920, through blood poisoning from the bite of a pet monkey.

In Nov. 1919, Alexander had made amorganatic marriage with an Athenian lady, Aspasia Manos; after his death a daughter was born to her in Paris on March 25, 1921. On Oct. 12, 1922, the daughter became his legal heir, though she did not thereby acquire any rights in respect to the throne. (B. S.-E.)

ALEXANDER III THE GREAT (356–323 B.C.), king of Macedonia from 336 to 323 B.C., who created a Greek empire extending eastward as far as India, northward as far as Scythia and southward as far as Egypt and the Persian gulf, thereby introducing a new age, known as the Hellenistic age, in the history of the world, was born in 356 B.C. in Pella, son of Philip II of Macedonia and his wife Olympias, a princess of Epirus.

When Alexander succeeded to the throne in 336 after the assassination of Philip, he also succeeded him in the role of champion of Greece against external enemies. Isocrates, the Athenian philosopher, had appealed to Philip in 346 B.C. to undertake the difficult task of uniting the Greek city-states against the menace of Persia; this was not effected, however, until Philip, at the battle of Chaeronea (*q.v.*) in 338, defeated Athens and Thebes. Philip treated Thebes without mercy but gave clement peace terms to Athens, for he admired the Athenians and therefore emulated them in improving his own capital, Pella, that it impressed even Athenian visitors. After the battle of Chaeronea all the Greek states except Sparta combined under the leadership of Philip to join the League of Corinth, an offensive and defensive alliance to protect both the security of the Greek states as a whole against an external enemy and the independence of each individual state (*see GREECE: History*). Philip announced that he was undertaking a

HEAD OF ALEXANDER ON A COIN OF LYSIMACHUS

campaign in Asia against the Persians. This was the first effective attempt at Hellenic unity.

On Philip's death Alexander had to confirm his own position as head of the league for the invasion of Asia. Many in Thessaly were against him. He avoided the pass of Tempe, cut steps over Mt. Ossa and gained Thessaly without any fighting, thus securing the valuable Thessalian cavalry. The other states of the league accepted him, though Sparta still refused to join. Meanwhile Alexander's succession to the Macedonian throne was assured by the allegiance of Alexander of Lyncestis, a rival claimant, and by the murder of Philip's second wife and her child in 336 at the instigation of Olympias; his position as leader of the Greek states was assured. He now had to make Macedonia secure as a base by defeating the tribes on the northern frontier and the Illyrians to the west (335). In the same year Thebes rebelled against Alexander, but he swiftly captured the city, and after a conference had been called of those members of the League of Corinth who had suffered at the hands of the Thebans it was decided that the city should be destroyed, with the exception of the temples and the house of the poet Pindar. The disaffection which had arisen in other states (including Athens) in sympathy with Thebes came to an end. Alexander followed his father's policy of leniency toward Athens.

The Invasion of Asia. — Greece was now ready for the offensive war against Persia. Alexander having declared his purpose to carry on this aim of his father's as head of the league. Appointing Antipater as regent of Macedonia during his absence, Alexander in the spring of 334 B.C. crossed the Hellespont, sending the army across in a fleet of 160 triremes under Parmenio, while he visited Ilium and took from the temple of Athena the sacred shield. His mixed army of Macedonians and Greeks (including allies, mercenaries and special bodies like the Agrianian javelin throwers) comprised, according to Arrian, about 30,000 infantry and more than 5,000 cavalry. Its composition must be briefly outlined.

Of the Macedonian infantry, one section, the phalanx, consisted of six infantry battalions, each of 1,500 heavily armed men in close rows, carrying the *sarissa*, a long pointed spear; the other consisted of 3,000 hypaspists or shield-bearers, of which one battalion, the *agema*, was Alexander's foot guard. Of the cavalry, the most important section was the Companion cavalry, consisting of eight squadrons of Macedonian nobility, of which the first, called the royal squadron, was Alexander's cavalry guard (*agema*). The cavalry were relied upon chiefly for attack; Alexander usually led the Companion cavalry. He was to make considerable alterations in the composition and organization of the army during the course of his campaigns: before the invasion of India in 327 he absorbed into the Companion cavalry Bactrians, Sogdians, Sacaeans and Arachosians and introduced into the royal squadron members of the Persian nobility. Sections of the army, especially the phalanx, had to be modified from time to time to meet varying conditions in Asia. Distinct from his personal staff or "bodyguard" were the Companions proper (after whom the Companion cavalry was called), men of high rank acting as an informal council and filling Alexander's high offices; military and administrative. With the army, Alexander took specialists in various sciences: engineers, builders, well-sinkers, surveyors and geographers. Philosophers and historians also accompanied him, and many representatives of the arts joined him later.

From the Granicus to Issus. — Confronted by Alexander's invasion, the policy of Darius and his generals was to wait for him on the right bank of the Granicus river, hoping that Alexander would be killed in the ensuing battle and that the invasion would collapse therewith. This policy proved fatal to them, however, for

the Macedonians attacked vigorously and after severe fighting (in which Alexander himself escaped death only by the intervention of Cleitus the Black) won their first victory against the Persians. (See GRANICUS, BATTLE OF THE.)

Alexander now turned his attention to gaining possession of the Greek cities on the coast of Asia Minor by advertising himself as their liberator from pro-Persian oligarchy. Many towns spontaneously overthrew their oligarchies: Miletus gave in after a siege. The Persian fleet was still to be reckoned with, but though it offered battle outside Miletus, Alexander preferred to "conquer the Persian fleet on land" and dismissed most of his own fleet accordingly. These tactics succeeded. As the Greek cities were freed the Greek squadrons of the Persian fleet defected, and the death of its commander, the Rhodian Memnon, early in 333 further reduced its power. (It was to disintegrate finally after Alexander's conquest of Phoenicia in 332.)

Alexander then proceeded into Caria, where he reinstated as satrap Ada, who had been dispossessed by her brother. He besieged Memnon at Halicarnassus and eventually drove him out of the city. Sending Parmenio to Phrygia with part of the army, he marched eastward and during the winter of 334–333 gained Lycia, Pamphylia and western Pisidia. It was during this winter that Alexander of Lyncestis, to whom Alexander had given command of the Thessalian cavalry, was arrested on suspicion of treachery. In the spring of 333 B.C. Alexander joined Parmenio at Gordium, where he untied the Gordian knot (*q.v.*), an act which according to local legend foretold possession of the whole of Asia. The army now marched into Cilicia, entering the narrow defile known as the Cilician Gates, intending to seek out Darius and give battle. Darius in the meantime had taken up a position favourable to his army in Assyria; but misinterpreting Alexander's delay (caused by a fever caught at Tarsus) as hesitation, he proceeded to Issus, a town in Cilicia near the coast at the head of the gulf now known as the Gulf of Iskenderun. There Alexander inflicted a heavy defeat on the Persian army (see ISSUS, BATTLE OF). Darius fled while his mother, wife and children were taken captive; near Issus Alexander founded Alexandretta (modern Iskenderun).

Phoenicia and Egypt. — His next objective was the conquest of Phoenicia: as he advanced many cities welcomed him, but Tyre did not submit until Aug. 332 B.C., after a siege of eight months. While Alexander was at Marathus (a town in Phoenicia north of modern Tripoli), Darius had written to him offering friendship and alliance and asking for the return of his family. Alexander replied that he had come to avenge the wrongs inflicted on Greece by the Persian invasions and that henceforth Darius must address him as king of all Asia. Toward the end of the siege of Tyre Darius again wrote, offering to cede to Alexander all his empire west of the Euphrates, a ransom of 10,000 talents and marriage with his daughter. Alexander, against the advice of Parmenio, refused these terms, declaring his determination to conquer all Asia.

Pressing on southward through Palestine; where he met resistance only in Gaza, Alexander reached Egypt late in 332. He was welcomed by the Egyptians, who had hated Persian rule, and was crowned as pharaoh at the capital Memphis; he sacrificed there to the deity Apis. At the mouth of the Nile in 331, he laid plans for the building of Alexandria, the greatest of all the cities of that name. He then visited the oasis of Siwa and the temple of Amon (Ammon), where the priest addressed him as son of Amon, the normal address to a pharaoh. Entering the inner shrine unaccompanied, Alexander emerged with a radiant countenance. To Olympias he wrote that he would reveal to her alone the secret of that interview. But as mother and son never met again, no one ever learned it. Alexander always showed intense anger if any slighting reference was made to this experience. Returning to Memphis, he instituted a new form of government, separating military and fiscal authority but retaining Egyptian officials under two Egyptian governors. While Alexander was in Egypt during the summer of 331 B.C. there was trouble in Greece, Sparta having invaded Megalopolis. Antipater defeated the Spartans, whose king Agis was killed. The Spartans were then coerced at last to join the League of Corinth, and Alexander had no more anxiety about Greece.

Gaugamela and Babylon.—Pursuing the aim that he had declared to Darius, Alexander in the summer of 331 crossed the Euphrates at Thapsacus (modern Dibse in eastern Syria) with 40,000 infantry and 8,000 cavalry (according to Arrian), his first objectives being the treasuries of Babylon and the Persian capital, Susa. Mazeus, the former satrap of Cilicia, had been waiting at Thapsacus with part of Darius' army but withdrew as Alexander approached, eventually joining Darius. Darius again took up a position favourable to his own cavalry at Gaugamela (a village northeast of Mosul) but in vain. The victory won there by Alexander (see GAUGAMELA, BATTLE OF) was decisive in his conquest of the Persian empire.

Mazeus advised the Babylonians not to resist Alexander, who then occupied Babylon, appointing Mazeus satrap but placing the financial and military posts in Macedonian hands. He himself accepted the title of king of Babylonia. He promised to rebuild the temple of E-Sagila (destroyed by Xerxes) and sacrificed according to Babylonian rites. Good relations between Greeks and Persians developed in the civilized atmosphere of Babylonia; satraps gladly co-operated with Alexander. He proceeded next to Susa, where he took possession of the treasury, sending money to Antipater in Greece and also returning to Athens the statues that Xerxes had taken from Greece. He left the family of Darius in a palace at Susa, having arranged for them to study the Greek language and culture.

The Death of Darius.—Alexander next invaded Persis, having first subdued the Uxii and defeated Ariobarzanes, satrap of Persis, at a narrow defile called the Persian Gates. He pressed on to Persepolis, where he found treasures even greater than at Susa. According to some sources he burnt Xerxes' palace there, against Parmenio's advice, in revenge for Xerxes' destruction of Athens. Treasure was also taken from Pasargadae nearby.

Now, it seemed, only the capture of Darius himself remained to complete Alexander's conquest of the Persian empire. After Gaugamela Darius had retired to Ecbatana (Hamadan), his summer capital, with his relative Bessus, satrap of Bactria and Sogdiana, and other satraps. In midsummer 330, hearing that Darius was reinforcing what was left of his army, Alexander advanced into Media in pursuit, causing Darius to withdraw from Ecbatana and soon from Media itself into Tapuria, the satrapy southeast of the Caspian sea. Bessus and several of the satraps had already advised Darius to abdicate, without avail; they now deposed him. Alexander, hearing this at the Caspian Gates (a defile at the eastern end of the Caucasus), pursued Bessus for three days (including all-night marches), twice missing him by hours. Thereupon he mounted 500 infantry on cavalry horses and rode all night across desert, surprising Bessus and his troops at dawn. Bessus and his confederates murdered Darius and fled. Alexander sent Darius' body to Persepolis for burial with military honours.

Bactria and Sogdiana.—After the death of Darius Bessus assumed the diadem and the royal title. He was supported by Barsaentes, satrap of Arachosia and Drangiana, by Satibarzanes, satrap of Aria, and by the Sogdian barons Chorienes, Oxyartes and Spitamenes. The reduction of Bactria and Sogdiana was to involve Alexander in more than two years of bitter and continuous fighting (summer 330—spring 327).

Without taking quarters for the oncoming winter, Alexander pressed on northward to Hyrcania with Craterus to secure communications before proceeding into Bactria. This he achieved partly by coercion and partly by conciliating local tribes. In Hyrcania he received the submission of the satraps of Tapuria and Persis. Turning to Aria, he received there the feigned submission of its satrap Satibarzanes. He now set out by the shortest, that is, the northeastward, route to Bactria but had to turn back when Aria revolted behind him. Instead of resuming his northerly route, after he had pacified Aria (which was not, however, secure till 329), he marched south and entered Drangiana, having founded on the way Alexandria of the Arians (Herat).

While he was in Drangiana Alexander encountered trouble among his generals. Parmenio's son Philotas, whom Alexander had put in charge of the Companion cavalry, was suspected of complicity in a plot to kill him and was tried, convicted and executed by

the army. Parmenio was put to death also, in accordance with the Macedonian custom of executing the male relations of a traitor (330).

Early in 329 Alexander crossed the Hindu Kush, known to the Greeks as the Paropamisus or Caucasus. Before crossing, he had founded another town, Alexandria by the Caucasus, and appointed a Persian satrap of the district (Paropamisadae). Bessus, together with Oxyartes and Spitamenes, was waiting at Aornos (Tashkurgan), but Alexander unexpectedly crossed by the Khawak pass farther east and then continued to Drapsaca, east of Aornos. Bessus fled across the Oxus river (Amu-Darya) into Sogdiana while Alexander, unopposed, took possession of his capital Bactra-Zariaspa and appointed as satrap the Persian Artabazus. Alexander pursued Bessus across the Oxus and finally captured him. Later in the year, Bessus was put to death, having had his nose and ears mutilated (the traditional Persian punishment for regicides).

Late in the summer of 329 Alexander occupied Maracanda (Samarkand) in Sogdiana and garrisoned it. He then took and garrisoned Cyropolis and the seven fortresses built by the Persians in Sogdiana; in taking Cyropolis he was seriously wounded. Advancing to the Jaxartes river (Syr-Darya), he founded a new town, Alexandria Eschate ("the Farthest"; now Leninabad), as a defense against the Scythian nomads outside the northwestern confines of the Persian empire. He also crossed the Jaxartes against these Scythians and succeeded in routing them, but not without difficulties (including a severe attack of dysentery). In the meantime Spitamenes had attacked Maracanda and defeated Pharnuches, who had gone to relieve it. Alexander raced back from Alexandria Eschate in three days, whereupon Spitamenes withdrew to Bukhara. Instead of following him, Alexander returned to winter in Bactra-Zariaspa (329–328).

In spring 328 Alexander again crossed the Oxus to Maracanda. Spitamenes fled to the territory of the Massagetae (northwest of Sogdiana), who helped him to make repeated raids during 328, even to the outskirts of Bactra-Zariaspa itself. He was eventually defeated by Coenus and deserted by the Massagetae, who cut off his head and sent it to Alexander.

During this year Alexander had further trouble with his generals. At an important banquet at Maracanda, Cleitus the Black, one of Alexander's most trusted commanders from the beginning of the campaign in Asia, intoxicated by Iranian wine, was provoked by the flattery being accorded to Alexander and exclaimed that all had been able to approach Philip, but that Philip's son wanted men to crawl on their knees to him as the Persians did. Alexander remarked to a Greek near him, "Does it not seem to you that Greeks in comparison with Macedonians are like demigods beside wild animals?" Cleitus shouted that Alexander's victories were due to soldiers who got no praise and that he himself had saved Alexander's life at the Granicus. Hristobulus and Ptolemy, ashamed, dragged Cleitus out of the tent as Alexander sprang up with a weapon. But as Cleitus ran back, Alexander flung his spear at him; Cleitus fell dead. Horrified, Alexander turned the blade against himself; his officers removed it. For three days and nights Alexander lay prostrate in his tent lamenting that he had taken the life of his foster brother. Anaxarchus and others could not rouse him from despair. Aristobulus and Ptolemy state that Cleitus deserved his fate, but from that day Alexander was a changed man—he never forgot the bitter lesson. Arrian wrote that though all great men who did evil made excuses for their deed, only Alexander expressed remorse.

In the same year 328, at a feast with distinguished guests in Bactra-Zariaspa, a debate was held on *proskynesis*, the custom of prostrating oneself before the king, which Alexander had adopted from Persian etiquette at court receptions. Anaxarchus spoke in its favour but Callisthenes maintained that the practice implied to Greeks and Macedonians that the monarch was a god. The audience sat silent; then the Persians, Medes and Macedonians, except Callisthenes, followed the usual procedure. From that date, however, Alexander agreed that Macedonians should be exempt from *proskynesis*.

Another indication in 328 that there was resentment among

members of Alexander's entourage was the conspiracy against his life among the royal pages. One of them, Hermolaus, who had been punished for some fault, regarded Alexander as a tyrant. When arrested, the conspirators blamed Callisthenes as their instigator. He was executed (or merely imprisoned—the records vary) in the same year.

After the death of Spitamenes it only remained to take the Sogdian Rock, the stronghold of Oxyartes, and the stronghold of Chorienes to complete the pacification of Sogdiana. Alexander took the Sogdian Rock with 300 volunteers early in 327 and gave clement terms. He asked and obtained from Oxyartes the hand in marriage of his daughter Roxana and thus won the adherence of many other influential Sogdians, including Chorienes, who supplied the army with provisions for two months. The Scythians also offered to supply troops.

The Invasion of India.—Returning to Bactra-Zariaspa for the last time Alexander now made preparations for an expedition to India. Pharasmanes, ruler of Chorasmia (Khiva) had during the winter of 329 offered him alliance and help in exploring the Caspian sea, but Alexander was anxious to explore the country of the Indus which had been part of the empire of Darius I. After arranging the administration of Bactria he left Bactra-Zariaspa in the summer of 327 B.C., with an army which included Bactrians, Sogdians and Arachosians as well as Phoenicians and Egyptians, and recrossed the Hindu Kush. Taxiles, the rajah of Taxila, east of the Indus river, fearing his neighbour Porus, whose land lay between the Hydaspes (Jhelum) and the Acesines (Chenab) rivers, assisted Alexander. Dividing the army, Alexander proceeded along the northern bank of the Cophen (Kabul) river, sending Hephaestion and Perdikkas along the southern bank with Taxiles to bridge the Indus near Attock. But the tribes on the north bank put up such stubborn resistance that Alexander took more time than he had expected to secure the rear. He had to take many towns and when he entered the valley of the Swat river, the territory of the Assaceni, he had to besiege their capital Massaga, which surrendered when its prince was slain. Alexander gave mild terms on condition that the Indian mercenaries join his army, but on learning their intention to escape at night he sent troops to slay them. He took two other towns, Ora and Bazira, then moved on to the Aornos mountain, whither many Indians had fled, and eventually captured it. Leaving Sasigupta, an Indian, to hold Aornos, Alexander joined Hephaestion on the Indus and crossed that river in the spring of 326. Taxiles was now at war with Porus, and Porus in his turn was at war with the Cathaei, the Oxydracae and the Malli beyond the Acesines river and had allied himself with Abisares, ruler of some hill states in Kashmir. Alexander advanced to the Hydaspes and inflicted a great defeat on Porus. (*See HYDASPES, BATTLE OF THE.*)

The Return from India.—Alexander founded the town of Nicea on the site of the battle, and, nearby, another town called Bucephala after his favourite horse, Bucephalus, which had died in the battle. Then, with the aid of Porus, now a friendly ally, he marched to reduce the Cathaei, taking their capital Sangala. In the meantime Craterus was left to build a fleet, for Alexander had determined to return down the Hydaspes and the Indus and reduce Sind. Before that, however, he meant to go farther eastward beyond the Hyphasis (Beas) river in search of the eastern ocean which he believed to be nearby. But when his soldiers reached the Hyphasis they refused to advance farther. Their spokesman explained that few of the original army remained and all desired to go home. After making a reply, which his soldiers heard with tears, Alexander retired to his tent for three days. When he consented to return, the army joyously cried that their king had vanquished all foes but had permitted his men to conquer him. Twelve altars were built to mark the point of return and Alexander marched back toward the Hydaspes (Nov. 326).

When he reached Nicea, Alexander discussed with the Indians their future relationship; he desired no territory, only safe passage for the fleet down the Indus to the sea. He confirmed Abisares in his kingdom and gave to Porus all the territory between the Hydaspes and the Hyphasis. On the Hydaspes he joined Craterus and completed his fleet; then in Nov. 326 he set sail with part of

the army down the Hydaspes while the rest followed on either bank under Craterus, Hephaestion and Philippus. Porus warned Alexander that he would soon meet dangerous foes—the Malli and the Oxydracae. After much fighting in the territory of the Malli, Alexander reached their citadel where a high wall had to be surmounted. Impatient, Alexander seized a ladder and began to climb with Peucestas and Leonnatus. The ladder broke; he leapt to the top of the wall and sprang down into the fort; with his back to the wall he slew those who approached. Thousands of arrows were thrown from high towers; one pierced his chest. Bleeding and unconscious, he was carried out on the shield of Ilium. For a week he hovered between life and death. When his bravery became known, the Malli hastened to submit and the Oxydracae sent gifts and offered to pay tribute. Alexander asked them to send a thousand of their nobles to aid him against enemies on the voyage to the sea. Many former enemies joined his army. After building more ships, Alexander resumed his voyage down the Hydaspes and then down the Indus itself, suffering losses because of the strength of the current. Somewhere near the point where the course of the Indus was joined by the combined streams of the Hydaspes, Acesines, Hydraotes and Hyphasis rivers he founded an Alexandria and constructed a dock. On the voyage down the lower Indus he obtained the submission of the rulers of various tribes and at some stage before reaching Patala (at the bifurcation of the Indus) sent Craterus homeward with part of the army, including the sick and wounded (probably through the Mulla pass). Reaching Patala about July 325 he built a harbour for the fleet and explored both arms of the Indus delta. Alexander intended to dispatch the fleet under Nearchus from the Indus mouth to the Persian gulf, the aim of this expedition being to establish regular sea communication between the Indus and the Euphrates. Nearchus was to make notes of bays and suitable sites for harbours and to explore botanical and other scientific subjects. As his ships were not built for the open sea and there were no supply ships, the success of this hazardous expedition depended on Alexander's army being able to march close to the shore through Gedrosia (Baluchistan), sinking wells and creating supply depots at points along the coast for Nearchus' fleet.

Nearchus set off in Sept. 325 after a delay because of the monsoon winds, but Alexander was detained by the revolt of the Oritae which held up his arrangements for supplies. Then he found an unexpected obstacle in the Taloi mountains and had to strike inland. The guides lost the way and he had to abandon the coast, continuing instead to Pura and thence into Carmania where he rejoined Craterus and founded an Alexandria (Gulashkird). The 60 days of traveling over the Gedrosian desert had caused great suffering to men and animals. Often overpowering heat obliged the men to march by night; insects and sudden storms added to their misery. Alexander shared in his soldiers' privations, refusing water when there was not enough to go round. In the meantime Nearchus continued the voyage, finding food and water with difficulty along the coast and making several discoveries (he encountered a primitive people living on fish and employing whale bones for constructing huts). Because of the privations suffered through Alexander's failure to provide depots, the crew were mutinous when they at last reached Carmania and heard that Alexander was a few days' march inland. When Nearchus with five officers arrived at the camp, emaciated, with ragged clothing, disheveled hair and unkempt beards, they were not recognizable. Overcome with emotion, Alexander held Nearchus' hand and wept. After expressing his delight to see them alive, haltingly he asked how the ships and crews had perished. When Nearchus answered that the fleet was safely moored, Alexander exclaimed that this news gave him more joy than the conquest of the whole of Asia. Sacrifices and thanksgivings were given to the gods. Nearchus described his victory to the whole army and all marched in triumph through Carmania and reached Susa in the spring of 324. While he was in Carmania Alexander was met by the governors of Aria, Drangiana and Hyrcania.

The Last Year.—After five years of absence Alexander found that it was indeed time for his return. Trusted satraps had oppressed the people, taken bribes, stolen and plundered and hired

mercenaries to settle their quarrels. Alexander dealt with all severely; after a fair trial, some were executed. The tomb of Cyrus the Great had been broken into, the body thrown out, the treasures removed. Aristobulus was commissioned to repair the monument. Even Harpalus, an old school friend, had lived in luxury with two successive mistresses whom the people had to obey as if they were queens. With most of the Persian treasures that he was guarding he fled to Athens, where he was refused admission; at Cyrene one of his fellow robbers killed him.

In Susa Alexander arranged many marriages. In addition to the Sogdian Roxana, he himself married Barsine, Darius' eldest daughter; to Seleucus he gave the orphaned daughter of Spitamenes. To other officers were given noble Persian ladies. Ten thousand troops married the concubines who had followed them through Asia. In Susa also, Calanus, a hermit who had followed the army from India, desired to be burnt on a funeral pyre according to the custom of his country. Alexander reluctantly agreed. Calanus said farewell to all the generals, but to the king he said, "We shall meet soon in Babylon."

In 324 Alexander decided to repatriate about 20,000 Greek exiles. This was largely a security measure to prevent their being used as mercenaries by satraps for their own ends. As it involved a breach of the covenant of the League of Corinth with the various cities which had exiled them, Alexander, in order to have authority to carry out this measure, requested the honour of deification. Few Greek cities objected to the proposal. At Opis, Alexander explained to his army that the old and disabled could go home under safe escort and with money enough to secure them for life. A number of young, eager Persians had been drafted into the army, a change not welcomed by the Macedonians. His kindly intentioned speech was therefore received with angry shouts that as they were no longer wanted they would all go home and the king had better go to his father Amon. Furious, Alexander leapt from the platform and pointed out 13 ringleaders to be dealt with as traitors. In an angry speech he told the army to return home and tell those in Macedonia how they had deserted their king and left him to the care of the foreigners whom he had defeated. He retired to the palace and prepared a plan for a complete new army of Persians. The loyal army, in despair, waited outside the palace, begging to see their king. After two days he appeared; he wept when he saw the unhappy veterans. Craterus and Polyperchon escorted the old and disabled back to Macedonia. But before their departure a great feast of reconciliation was held at Opis. To a large company of 9,000 guests from many nations, Alexander spoke of his mission to reconcile the world and prayed that Persians and Macedonians would always live as equal partners.

Alexander then traveled to Ecbatana to supervise a week of festival rejoicing. There Hephaestion fell ill and died. For several days and nights Alexander was inconsolable; he had lost his closest friend. Near the end of 324 he resolved to return to Babylon. On the way he and Ptolemy subdued the Cossean tribe in the hills and taught them how to cultivate their land and build villages instead of robbing travelers on the roads. On the way to Babylon, he was met by envoys from Italy, Libya and Ethiopia. Plans were drawn up for towns, temples, docks, harbours and new cities. Ships were built for exploration of the Caspian sea and the coast of Arabia. When he approached Babylon, Chaldean seers begged him to enter from the western side of the town, but as the road proved too marshy for army transport he was obliged to enter by the forbidden side. While ships were being built he examined the Babylon canal system and devised methods for carrying off surplus flood water from the Euphrates. Then all the serious predictions by the augurs were fulfilled. At the banquet in Babylon arranged to welcome his return from the east, Alexander recited a scene from a play by Euripides. During a banquet held on the second evening he felt feverish and on subsequent days his temperature rose. Nothing is known as to the treatment given for his malady, which was probably malignant malaria or an amoebic abscess. His condition rapidly deteriorated and he died on the 12th day, June 13, 323 B.C. He was not yet 33 years old.

Character and Policy.—Even in early youth Alexander impressed distinguished men. When about ten years old he aston-

ished Persian ambassadors whom he questioned about their form of government; they foretold a great future for so intelligent a young prince. When he heard of his father's victories he asked his school companions, "What will be left for you and me to do when we grow up?" Appreciating the unusual ability of his son, Philip invited Aristotle to settle in Meiza and sent Alexander to his school. When Alexander was about 15, Isocrates wrote expressing his delight to hear that the boy loved good literature and chose associates with fine character and intelligence. Aristotle discussed with his pupil the duties of kings and the need of a high moral code. In later life Alexander said that Philip had given him life but that Aristotle had taught him to live worthily; never to let the body rule but always to make the spirit master the body. Hence his chastity and respect for women. He forbade his soldiers to violate captive women: such was the conduct of wild animals. When told that two beautiful boys had been brought for him, he was furious. "What evil has been seen in me?" he cried "Tell the dealer to take his wares to hell." When he sent Persian girls to study with the family of Darius, he ordered that they must not see or hear of evil. Always abstemious at meals, he reproved young officers who ate and drank too much and who ordered menials to do what they could do for themselves. According to Aristobulus, who accompanied Alexander throughout his campaigns, he did not drink heavily; he loved to converse at meals and usually introduced fresh topics with a glass of wine. He had pity for the suffering, an emotion which at that time was regarded as unmanly. Despite the grumbling of his men he steadfastly pursued his policy of giving as much to the Persians as to the Greeks and Xlacedonians. He declared: "I have not come to destroy nations; I have come that those who are subdued by my arms have nought to complain of my victories." He believed he had a mission he would exclaim that he was "seized with a longing" when he desired to explore and to reach the unknown, whether of the earth or the spirit. His personal charm attracted many foes to become his friends. Possibly only his closest friend, Hephaestion, understood Alexander's mystic temperament.

Alexander never lost a battle. When possible, he explored the territory alone or with a local guide. He studied the psychology of his foes, their weapons and methods of warfare. He conquered trained and disciplined troops and was equally successful with the nomad guerrilla type encountered in the mountains. No one advanced so swiftly over long distances; he often arrived before his enemy was aware that he was near. He never made an advance until certain that he had secured his flank and rear and never gave up a plan without seeing it through to the end. On St. Helena, Napoleon spoke of Alexander as his model hero, for not only was he supreme as a general but also as a statesman, who in his 33rd year left an immense and well-established empire and had the rare art of making friends of the people whom he had conquered.

The Greek historian Polybius in the 2nd century B.C. stated that Alexander was a man "by universal consent of a superhuman elevation of spirit." He describes how Philip and his son raised Macedonia from insignificance to the first rank of nations; how Alexander and his friends endured numerous labours, dangers and sufferings; and how, though put in possession of ample wealth and means to gratify all desires, they never lost their bodily vigour nor contracted tastes for debauchery. "Those acquainted with him became truly royal in greatness of soul, temperance of life and courage." Plutarch (c. A.D. 46–120) tells in his *Moralia* how Alexander weaned barbaric nations from their savage modes of life and stresses his humanity: he believed that he came as a heaven-sent harmonizer and reconciler for the whole world. Plutarch attributed Alexander's achievements to his philosophical education, saying that he invaded Persia with greater assistance from Aristotle than from his father Philip.

Arrian (2nd century A.D.) wrote the best history of Alexander. He studied all the available evidence before basing his own work on the reliable memoirs of Ptolemy and Aristobulus, who had accompanied Alexander throughout his campaigns. Arrian described Alexander as a "lover of hardship, quick and untiring, indifferent to sensual pleasures, insatiable for the noble enjoyments: most brilliant to seize upon the right course of action, even when all

was obscure; most swift to weigh up the probabilities for success: most masterly in marshaling his army and equipping it; without equal in commanding his troops . . . dispelling their fears by giving them the example of facing danger with unshakeable courage. In doubtful enterprises his daring decided the victory; he was most skilled in swift anticipation and gripping of his enemy before anyone had time to suspect his presence; he was most reliable in keeping promises or agreements; most guarded in not being trapped by the fraudulent; very sparing of money for his own use. most generous in gifts to others. It is not without the special will of the gods that he appeared among men, not one of whom can be compared with him."

Strabo in his *Geographica* stated that the historian Cleitarchus accompanied Alexander throughout his campaign in Asia. As Cleitarchus' writing was believed to be true, his discreditable tales long damaged Alexander's reputation. But Sir William Tarn (1869–1957) proved that Cleitarchus did not accompany Alexander in Asia and could not have written before 280 B.C. Thus the correct order of the Alexander historians is: (1) Aristobulus; (2) Ptolemy; (3) Cleitarchus. Aristobulus and Ptolemy did accompany Alexander throughout Asia and made no mention of a history by Cleitarchus.

Alexander's life was cut short just as his work as an organizer for peace was due to begin. He had already adopted new methods of civil and military administration. At first only Macedonians were given government posts; later Persians also. Finance and taxation remained in Macedonian control; a universal currency system benefited trade. During the later years of his life Alexander's health was impaired by overwork and many wounds, especially that inflicted at the Malli fortress. How, therefore, could he have been other than more impatient and irritable? It is said that he retained his capacity for work only by sleeping sometimes for 36 consecutive hours. At the time of his death he had vast plans for building more cities and also ships for the examination of the Arabian coast as well as of the Caspian sea (with Pharasmanes, as had been decided before he went to India). No other conqueror ever founded so many towns; these spread Greek culture throughout Asia.

The German historian J. D.roysen (1808–84), after studying every record, good and bad, concluded that Alexander was not only a military genius but a far-seeing statesman and a philosopher. Droysen believed that at critical periods of the world a spiritual upheaval was necessary, and that then destiny, providence or God produced the man who will lift it to a higher level. Arrian also regarded Alexander as such a man.

Sir William Tarn, the greatest of Alexander scholars, studied minutely all the sources in ancient history concerning the astonishing career of Alexander. He wrote: "What his force of character was like can best be seen, not in his driving-power, great as it was, but in his relations with his generals. Here was an assembly of kings, with passions, ambitions, abilities beyond those of most men; and while he lived, all we see is that Perdikkas and Ptolemy were good brigade leaders, Antigonus an obedient satrap, Lysimachus and Peithon, little noticed members of his Staff . . . To be mystical and intensely practical, to dream greatly and to do greatly, is not given to many men; it is this combination which gives Alexander his place apart in history . . . He was one of the supreme fertilizing forces in history. He lifted the civilized world out of one groove and set it in another; he started a new epoch; nothing could again be as it had been." (Sir William Tarn, *Alexander the Great*, vol. i, pp. 124, 145, Cambridge University Press, 1948).

ALEXANDER I (c. 1080–1124), king of Scotland, probably

the fifth son of Malcolm III and Margaret (later St. Margaret), succeeded to the throne on the death of his brother Edgar in 1107. He relinquished Strathclyde and the area between the Lammermuir hills and the river Tweed to David, his brother and heir. Alexander probably ruled as vassal of Henry I of England; he married Henry's illegitimate daughter Sibylla and in 1114 led a Scottish contingent in Henry's Welsh campaigns. Alexander founded an Augustinian priory at Scone c. 1115 and planned to found others; but he quarreled with Turgot, bishop of St. Andrews, and with Eadmer, elected to succeed Turgot, and he did little to revive the secular church. Alexander died, probably at Stirling, in April 1124.

(A. A. M. D.)

ALEXANDER II (1198–1249), king of Scotland, only legitimate son of King William (later called "the Lion"), was born on Aug. 24, 1198, and succeeded to the throne in 1214. Hoping to regain territory in northern England he supported the English baronial rebellion against King John, but after its collapse in 1217 he did homage to Henry III whose sister, Joan, Alexander married in 1221. She died childless in 1238 and a year later Alexander married Mary de Coucy. Their son (afterward Alexander III) was betrothed to Henry's daughter Margaret in 1242. The friendly relationship between the kings was strained by Henry's claim of suzerainty over Scotland and by Alexander's claim to the northern counties of England which he only abandoned in 1237 in return for some English estates. Renewed friction in 1244 nearly precipitated a war. About that time Alexander tried unsuccessfully to buy the Isle of Man and the Hebrides from Norway. In Scotland he exterminated a rival line in 1230, and suppressed disorders in Caithness in 1222 and in Galloway in 1235. He was on an expedition to Argyll when he died at Kerrera on July 8, 1249.

See A. O. Anderson, *Early Sources of Scottish History A.D. 500 to 1286*, vol. ii (1922).

ALEXANDER III (1241–1286), king of Scotland, was born at Roxburgh on Sept. 4, 1241, the only son of Alexander II, whom he succeeded in 1249. Henry III of England tried to take advantage of Alexander's youth to obtain suzerainty over Scotland, but he failed to obtain the support of Pope Innocent IV and at the marriage in 1251 of Alexander to Henry's daughter Margaret, Alexander evaded doing homage for Scotland. In 1255 Henry's nominees secured the regency of Scotland until Alexander should be of age, but they lost it through conciliar changes made in 1257 and 1258 partly because Gamelin, bishop of St. Andrews, persuaded Pope Alexander IV to excommunicate them. When in 1278 Alexander attended the court of Edward I. who had succeeded his father Henry III in 1272, he did homage for his English estates only.

Alexander's rumoured intention to annex the Hebrides in 1263 provoked Haakon IV of Norway to lead a force to Scotland. After inconclusive campaigning and a repulse at Largs in Ayrshire, Haakon withdrew to Orkney where he died in Dec. 1263. By the treaty of Perth (1266) his son Magnus VI (IV) ceded the Isle of Man and the Hebrides to Alexander in return for a down payment and an annual rent.

Alexander's first wife died in 1275 and all their children predeceased him. In 1285 the king married Yolande, daughter of Robert, count of Dreux. Riding to join her at Kinghorn in Fife on the night of March 18–19, 1286, he was thrown from his horse and killed. His grandchild, Margaret, was proclaimed queen of Scotland, but died in 1290. Alexander left Scotland independent, united and prosperous, and in the troubled years that followed the extinction of his line his reign was remembered as a golden age.

See A. O. Anderson, *Early Sources of Scottish History A.D. 500 to 1286*, vol. ii (1922).

ALEXANDER (ALEKSANDAR OBRENOVICH) (1876–1903), king of Serbia from 1889 to 1903, was born in Belgrade on Aug. 14 (new style; Aug. 2, old style), 1876, the only child of Milan (*q.v.*) Obrenovich and his consort Natalie. After his father's abdication he succeeded, on March 6 (N.S.; Feb. 22, O.S.), 1889, as king of Serbia, under a regency. He dismissed the regency council on April 13 (N.S.; April 1, O.S.), 1893, and proclaimed himself ruler before attaining his majority.

In order to govern through the Liberals and Progressives, whose parties were in decline, or through politically neutral governments

at a time when the Radical party was at its peak in Serbia, Alexander in 1894 abolished the liberal constitution of 1889 and restored the constitution of 1869. Cabinets came and went. Alexander appointed his father commander in chief (1898–1900). In 1900, however, while his prime minister and his father were abroad, he announced his engagement to Draga Masin, née Lunjevica (1866–1903), ten years his senior, a childless widow with a dubious past, former lady in waiting to his mother. His government then resigned, and Alexander had great difficulty in forming the new one, which was composed mainly of civil servants. The Russian tsar Nicholas II agreed to act as best man at the wedding, which took place on Aug. 5 (N.S.; July 23, O.S.), 1900. Alexander then tried to placate the political parties by granting a more liberal constitution (1901) and by instituting a senate as a second chamber. In 1903, however, he suspended the constitution for only a few hours in order to dismiss some senators appointed by him for life, to remove some irremovable judges and to grant a new electoral law which would enable his supporters to get a majority. To spare the country from further disaster, members of an already existing conspiracy thereupon decided to act, and on June 11 (N.S.; May 29, O.S.), 1903, Alexander and Draga were assassinated. The Obrenovich dynasty was extinguished.

Torn since childhood between his parents, who were divorced in 1888 after years of quarreling, Alexander's loyalty was divided. Save in his last three years, he was always under the influence of one or the other of them. His father pushed him toward Austria-Hungary and authoritarian rule, his mother toward Russia and the Radical party. His ten years' personal rule was but a succession of four *coups d'état* and 17 governments. Nevertheless the conversion of the national debt, the appointment of Serbian instead of Greek bishops in Macedonia, the reorganization of the army and his attempt to revive the Balkan alliance go to the credit of his reign.

See C. Mijatovich, *A Royal Tragedy* (1906); S. Jovanović, *Vlada Aleksandra Obrenovića*, 2 vol. (1929–31). (K. St. P.)

ALEXANDER I (1888–1934), king of the Serbs, Croats and Slovenes from 1921, of Yugoslavia from 1929 to 1934, was born at Cetinje on Dec. 16 (new style; Dec. 4, old style), 1888, the second son of Peter Karageorgevich (*q.v.*) and of Zorka of Montenegro. He spent his early childhood at Geneva with his exiled father. Sent to St. Petersburg in 1899, he entered the Russian imperial corps of pages in 1904. In 1909 he returned to Serbia, where his father had been reigning since 1903. Incidents provoked by the fiery temper of his elder brother George resulted in the latter's renouncing his right of succession (March 28, 1909) so that Alexander became the heir to the throne. On the outbreak of the first Balkan War (1912) he assumed command of the Serbian 1st army and won fame at the battle of Kumanovo (Oct. 24, 1912), subsequently distinguishing himself in the second Balkan War (1913). His father, being in poor health and advanced in years, appointed him regent of Serbia (June 24, 1914), and Alexander then became commander in chief of the armed forces.

During World War I, Alexander remained permanently at army headquarters, sharing with his troops the retreat across Albania to the Adriatic (Nov.–Dec. 1915). Although dangerously ill, he refused to be evacuated until the last soldier had been transported to safety. He established himself (Jan. 1916) with the Serbian government at Corfu and with the help of the Allies reorganized the Serbian army, which in Aug. 1916 was moved to the Salonika front. He and his prime minister, Nikola Pasic (*q.v.*), paid visits to Paris (March) and London (April 1916), where they were warmly welcomed. During the rest of the war he remained at Serbian headquarters, sharing his army's victorious advance (Sept. 1918) and returning in triumph to Belgrade (Oct. 31, 1918).

The kingdom of the Serbs, Croats and Slovenes was proclaimed on Dec. 1, 1918, with Alexander as regent. A new constitution was passed by the constituent assembly on June 28, 1921. As he was returning from the *skupština* after taking the oath to this constitution an attempt was made upon his life. On his father's death (Xug. 16, 1921) Alexander succeeded as king of the Serbs, Croats and Slovenes. On June 8, 1922, he married Marie (1900–61), second daughter of Ferdinand I of Rumania. An heir was

born (Sept. 6, 1923) who received the name of Peter; a second son (1928) received the Croatian name Tomislav and a third (1929) the Slovenian name Andrei.

Political conditions were somewhat unsettled, as centralist tendencies prevailed among the Serbs while the Croats were federalist or even separatist, and on June 20, 1928, two Croatian leaders were shot dead and three wounded on the floor of the *skupština* by a Serbian member from Montenegro who felt that he had been deeply insulted by one of them. Although the crime was unanimously condemned by the Serbs, the Croatian members withdrew from the *skupština*. Alexander, convinced that the very existence of the state was threatened, abolished the constitution (Jan. 6, 1929), assumed full powers in order to reduce tension, changed the name of the country to Yugoslavia (Oct. 3, 1929) and proclaimed a new constitution (Sept. 3, 1931). He tried to establish friendly relations with neighbouring countries, but met with bitter enmity in Italy and Hungary. A second attempt upon his life, planned abroad in 1933, was prevented, but on a state visit to France he was murdered at Marseilles (Oct. 9, 1934) by hired assassins who had been trained at Janka Puzta (Hungary) and at Borgo di Taro (Italy). He was succeeded by his eldest son, Peter II, under a regency.

A soldier-statesman who never avoided responsibilities, authoritarian whenever he considered that firmness was needed, immensely popular with the army and among the Serbian peasantry, disliked by a minority, and respected by all, Alexander was the strongest ruler of his country since the rebirth of Serbia in the 19th century.

See A. R. Dimitrijević, *Naš veliki kralj* ("Our Great King") (1936); S. Graham, *Alexander of Yugoslavia* (1938). (K. St. P.)

ALEXANDER (ALEKSANDAR KARAGEORGEVICH) (1806–1885), prince of Serbia from 1842 to 1858, was born at Topola on Oct. 11 (new style; Sept. 29, old style), 1806, the third son of Karageorge (*q.v.*) and of Yelena, née Yovanovich. Alexander went into exile with his father in 1813, but in 1842, after the deposition Michael Obrenovich, he was elected prince of Serbia. The validity of this election was contested by Russia, but at a second election next year he was chosen again. During the Hungarian revolution of 1848–49 he helped the Serbs and Croats of the Austrian empire against the Hungarians. Under Russian pressure he dismissed his pro-western prime minister Ilija Garashanin (*q.v.*) in 1853, but despite the pro-Russian majority in his council he maintained neutrality in the Crimean War. As a reward, the treaty of Paris (1856) placed Serbia's autonomy within the Turkish empire under the collective guarantee of the European powers. During Alexander's reign the embryo of a university, a national library and museum (1844), a supreme court (1846) and the first code of civil law were established and more than 200 schools were opened.

Well-intentioned but weak and impulsive, Alexander had to share power with a council of members appointed for life. A struggle for supremacy ensued, and after the discovery of a plot against his life (1857) Alexander overthrew the oligarchy. In 1858, however, he was compelled to abdicate. He died in exile at Temesvar (Timisoara) in the Banat on May 3 (N.S.; April 21, O.S.), 1885. By his marriage in 1830 with Persida Nenadovich (1813–75) he had ten children, one of whom, Peter, became king of Serbia in 1903. (K. St. P.)

ALEXANDER of APHRODISIAS, Greek philosopher, who wrote commentaries on most of the Aristotelian works, was born in Aphrodisias in Caria and was a pupil of Aristocles of Messene. Toward the end of the 2nd century A.D. he became head of the Lyceum at Athens. His commentaries were intended to restore the pure doctrine of Aristotle and free the tradition of the Lyceum from the syncretism of Ammonius. His commentaries on the *Prior Analytics I*, on the *Topics*, on the *Meteorologica*, on the *De sensu* and on the *Metaphysics I–V* are extant; and fragments of his lost commentaries are found in all later commentaries. In antiquity his commentaries constituted the most influential section of his writings, causing him to be styled, by way of pre-eminence, "the expositor"; but in the middle ages it was rather for his original works that he was known, both to Arabic and to Christian philosophers. The most important of these later works

are *On Fate*, in which he defends free will against the Stoic doctrine of necessity, and *On the Soul*, in which he tries to explain Aristotle's doctrine of the soul and the intellect. Reason, being the form of the body in man, is mortal and may be called material intellect as it may become all things, or virtual intellect, because of its potentiality of thinking. This mortal intellect has to be actualized by the active intellect, which comes from outside and is identical with God. This doctrine, revived by Averroes, was warmly debated in the 13th century, as it raises the problem of personal immortality.

BIBLIOGRAPHY.—Alexander's works are printed in *Commentaria in Aristotelem Graeca*, vol. i-iii, and in vol. ii of the supplement (1883-1901); the Latin translations appeared in 16th-century editions. See also P. Moraux, *Alexandre d'Aphrodise* (1942); H. Thery, *Alexandre d'Aphrodise* (1926); P. Wilpert, "Reste verlorener Aristotelesschriften bei Alexander von Aphrodisias," *Hermes*, vol. 75 (1940), "Die Ausgestaltung der aristotelischen Lehre vom Intellectus agens," *Beiträge zur Geschichte der Philosophie und Theologie des Mittelalters*, suppl. 3 (1935). (P. A. W.)

ALEXANDER OF BATTENBERG (1857-1893), prince of Bulgaria, was born at Verona, Italy, on April 5, 1857, the second son of Prince Alexander of Hesse and Julia the Countess von Hauke. hismorganatic wife (see BATTENBERG). In 1877 he served with the Russian forces in the war with Turkey, which resulted in the autonomy of Bulgaria (see RUSSO-TURKISH WARS). The emperor Alexander II of Russia, who had married a sister of Alexander of Hesse, showed much interest in his nephew Alexander and gave decisive support to his election on April 29, 1879, as prince of Bulgaria. The prince, however, who was impulsive and not particularly shrewd by nature, had little chance of success in his new position after the assassination of Alexander II (1881), as he soon lost the favour of the new emperor Alexander III. Germany, moreover, under Bismarck, supported Russian policy in Bulgaria; both deterred Austria-Hungary from helping the prince and frustrated British efforts to do so.

On July 8, 1879, the prince took the oath to the Bulgarian constitution. This constitution, however, was ill-suited to conditions in a new country. The two political parties (one pro-Russian, the other anti-Russian) were in violent conflict, and the opposition soon became so obstructive that Alexander dissolved the national assembly on Nov. 24, 1880. In May 1881, he suspended the constitution, declared that fresh elections were to be held on a new basis and assumed plenary powers for seven years. This policy was approved by the new national assembly in June 1881, and Alexander appointed a government headed by Gen. J. C. Ehrnroth, a Finn in the Russian service. Russia reacted strongly against Alexander's unlimited powers, particularly in military matters, and Ehrnroth was recalled. Alexander then went to St. Petersburg to negotiate a *modus vivendi* with the Russians. A new Bulgarian government was appointed with the Russian generals L. N. Sobolev and A. I. Kaulbars as ministers of the interior and war so that they could keep Bulgaria in the Russian fold and restrict the prince's control of the army. By their political ineptitude and arrogance they caused such resentment that the two Bulgarian parties temporarily united behind the prince. The constitution of 1879 was restored in Sept. 1883 and Sobolev and Kaulbars were dismissed—to Alexander III's great indignation.

Alexander of Battenberg was now in open opposition to Russia, and the breach was widened when Bulgaria annexed Eastern Rumelia, in Sept. 1885 without consulting Russia. The Russian emperor denounced this *fait accompli*, had the prince's name removed from the Russian army list and recalled all Russian officers in Bulgaria. The Serbs invaded Bulgaria, with Austria-Hungary's connivance, in Nov. 1885 but were driven back, and the Bulgarian army's advance into Serbia was halted only by strong pressure from Vienna (see SERBO-BULGARIAN WAR). Bulgaria gained nothing from the war, and disappointment and propaganda against the "German" prince prepared the ground for a *coup d'état*. In the night of Aug. 20-21, 1886, Bulgarian officers forced Alexander to abdicate, abducted him and delivered him to the Russians at Reni (Ismail province, Rumania). Two weeks later, however, he was back in Bulgaria at the insistent request of the people. Before assuming power, he sent a telegram to St. Petersburg incautiously

putting his crown at the Russian emperor's discretion. This altered nothing of the emperor's hostility, and the prince abdicated for good on Sept. 8, 1886. Assuming the title of Graf von Hartenau, he took service as a general in the Austrian army. He died at Graz on Oct. 23, 1893, leaving two children by his marriage (Feb. 6, 1889) with the opera singer Johanna Loisinger.

See A. Koch, *Prince Alexander of Battenberg* (1887); E. C. Corti, *Alexander von Battenberg* (1955). (N. I. M.)

ALEXANDER OF HALES (c. 1170 or 1185-1245), English theologian and philosopher, known to the scholastics as *Doctor irrefragabilis*, was born at Hales in Gloucestershire. He studied and taught in Paris (master of arts before 1210, of theology in 1229), was archdeacon of Coventry in 1235, became a Franciscan c. 1236 and then founded in Paris the Schola Fratrum Minorum, thus being the first holder, possibly until his death, of the Franciscan chair in that university. Much of the teaching of such theologians as St. Bonaventure and John of La Rochelle developed from this master's doctrine. The *Summa Theologica* for centuries ascribed to him ("Summa Fratris Alexandri," ed. by the Bonaventure institute, Quaracchi, 1924-48) is largely the work of followers, among them William of Milton; Roger Bacon had already denounced the wrong attribution. Only the most general features of Alexander's theology and philosophy have been made clear: basically an Augustinian, he had taken into account, to some extent, the psychological, physical and metaphysical doctrines of Aristotle, while discarding popular Avicennian tenets.

The "Franciscan" theories of matter, and form in spiritual creatures, of the multiplicity of forms and of illumination combined with experience are probably Alexander's adaptations of similar theories of the Augustinian and other traditions.

Alexander's original works, apart from sections of the *Summa* and of an *Expositio Regulae*, include a commentary on the *Sentences* (ed. by the Bonaventure institute, Quaracchi, 3 vol., 1951-54); *Quaestiones antequam esset frater* (some of them, on matrimony, ed. by K. F. Lynch in *Franciscan Studies*, xi, pp. 131-139); *Quodlibeta*; sermons; and a treatise on difficult words, *Exoticon*.

BIBLIOGRAPHY.—Apart from the *Prolegomena* to vol. iv of the *Summa* and to vol. i of the commentary on the *Sentences*, see V. Doucet, "Alessandro di Hales," *Enciclopedia Cattolica*, vol. i (1949); I. Herscher, "A Bibliography of Alexander of Hales," *Franciscan Studies*, xxvi, pp. 434-454. (L. M.-Po.)

ALEXANDER (NEVSKI) (1220-1263), Russian grand prince and canonized a saint of the Russian Orthodox Church in 1380, was a son of Yaroslav Vsevolodovich, who for a time was ruler of Novgorod. Alexander's greatest achievements took place early in his life, in defense of Novgorod's frontiers. First, in 1240, he defeated the Swedes on the Neva (hence the name Nevski), but then he quarreled with the princes of Novgorod and went to Pereyasavl. In 1241, however, he returned at the urgent request of the Novgorodians, who were being hard pressed by the knights of the Teutonic Order (*q.v.*). Having freed all Russian districts which had been captured by the knights, he carried the war into German-occupied Estonia and, in April 1242, defeated the knights on the ice of Lake Peipus. The grand master of the order then renounced all previous conquests in Russia. This was not the end of aggression against Russia from the west, but the wave of enemy attack was stemmed at its most dangerous moment. At the same time, by his decisive action against the Lithuanians, Alexander secured relative peace in the west and was able to turn his attention eastward.

When Yaroslav Vsevolodovich, who had become grand prince of Vladimir and Kiev in 1243, died in 1246, Alexander and his brother Andrei were sent by Batu Khan to Karakorum in Mongolia. There Andrei was appointed grand prince of Vladimir; Alexander became prince of Kiev. But when Andrei was crushed by the Mongols for disobedience (1252), Alexander became grand prince. Henceforth his policy was marked by cautious collaboration with the Mongols and profound mistrust of the west. By his conciliatory attitude to the Golden Horde (*q.v.*) he managed to avert further disastrous attacks. He did what he could to assist Mongol officials carry out a census of the population; in Novgorod he even arrested his son and quelled a rebellion in order that the census might be peaceably completed. After a general uprising in Suzdal in 1262

he managed to persuade Berke Khan not to take punitive measures. He died in Nov. 1263 at Gorodets, on the Volga, returning from the Golden Horde. Stalin pronounced him one of the great national heroes in 1941 and in 1942 there was established by the supreme soviet of the U.S.S.R. the order of Alexander Nevski.

See George Vernadsky, *Kievan Russia* (1948). (J. L. I. F.)

ALEXANDER THE PAPHLAGONIAN (2nd century A.D.), a celebrated impostor and worker of false oracles, was born at Abonouteichos (mod. Inebolu) in Paphlagonia. The vivid narrative of his career given by his contemporary Lucian (*q.v.*) is corroborated by certain coins of the emperors Lucius Verus and Marcus Aurelius and by Athenagoras, also writing in the 2nd century, who mentions that a statue of Alexander stood in the forum of Parium in Phrygia. Alexander succeeded in establishing an oracle of Aesculapius at his native town, having staged a "re-birth" of the god in the form of a snake which he called Glycon. His usual methods were those of the numerous oraclemongers of the time, of which Lucian gives a detailed account. The reputation of the oracle spread, and Alexander set up an intelligence bureau in Rome! instituted mysteries like those of Eleusis, from which the Christians and Epicureans were alike excluded as profane, and celebrated a mystic marriage between himself and the moon. Lucian's own close investigations into Alexander's methods of fraud led to a serious attempt on the writer's life. Alexander lived to be 70 and amassed great sums of money.

ALEXANDER OF PHERAE (d. 358 B.C.), despot of Pherae in Thessaly from 369 B.C., whose tyranny caused the intervention of a number of states in Thessalian affairs. The other Thessalian cities, refusing to recognize him as *tagos* or head magistrate in succession to his father Jason, led by the Aleuadae of Larissa, appealed first to Macedonia and later, in 368, to the Thebans, who sent Pelopidas (*q.v.*) to their assistance. Alexander, who had procured an alliance with Athens, imprisoned Pelopidas, and the Thebans had to send Epaminondas with a large army to Thessaly to secure his release. In 364, under Pelopidas, the Thebans defeated Alexander at Cynoscephalae, Pelopidas being killed in action. Alexander was at last compelled by Thebes to acknowledge the freedom of the Thessalian cities, to limit his rule to Pherae and to join the Boeotian league. He was finally murdered at his wife's instigation in 358.

See N. G. L. Hammond, *A History of Greece* (1959).

ALEXANDER OF TRALLES (ALEXANDER TRALLIANUS) (525?-605?), widely traveled Byzantine physician who practised and taught in Rome, was among the most famous medical writers of his day. His most important work, a pathology and therapy of internal disease in 12 books, indicates that he was the only one of the Byzantine medical compilers who displayed distinct originality. Although he made careful use of the writings of the established authorities and avowed his agreement with the theories of Galen, his independence in practical questions is obvious and his opinions were clearly based on his own observations. The diseases described by him in the order "from head to foot" include those of the nervous system (including psychoses), the eye, the respiratory tract, the genitourinary system and gout. Although his anatomical and physiological knowledge was scanty, his disease descriptions and his discussion of general pathology and therapeutics reveal him as a physician of wide experience and a talented writer. His writings, translated into Arabic and Latin (*Libri duodecim de re medica*), served as a basis for instruction long after his death. Greek, Latin and Greco-Latin editions were printed throughout the 16th century.

(I. V.)

ALEXANDER, JEROME (1876-). U.S. chemist, best known for his work in physical and colloid chemistry applied to semibiological problems and industrial medicine. He was born Dec. 21, 1876, in New York city, and graduated in 1896 from the College of the City of New York, from which he received a master of science degree in 1899. For 25 years he was a chemist for companies manufacturing glues, sizing and chemical specialties.

From 1922 he was a consulting chemist and chemical engineer. Alexander was an early expert with the ultramicroscope in the United States. He published *Colloid Chemistry* (1919; 4th ed., 1937); *Glue and Gelatin* (1923); *Life, Its Nature and Origin* (1948); was editor of seven volumes of *Colloid Chemistry, Theoretical and Applied* (1926); and in 1909 translated Richard Zsigmondy's *Colloids and the Ultramicroscope*. (V. Bw.)

ALEXANDER, JOHN WHITE (1856-1915), U.S. painter, was a leading portrait and figure painter of the academic style. He was born in Allegheny, Pa., Oct. 7, 1856. From magazine illustration he proceeded in 1877 to study painting in Europe. After 1890 his manner of sweeping curves and suffused light popularized his portraiture and figure painting, but proved imaginatively inadequate for his extensive mural decorations in Carnegie institute, Pittsburgh, Pa. He executed six lunettes for the library of Congress. As adviser to Maude Adams on lighting and colour, he contributed much to the distinction of her stage productions. President of the National Academy of Design (1909-11), he was also active in many other art organizations. His honours included gold medals, many lesser prizes and the rank of chevalier of the Legion of Honour. He died in New York city May 31, 1915.

(V. L. B.)

ALEXANDER, NATALIS (properly NOËL ALEXANDRE) (1639-1724), French Dominican theologian and ecclesiastical historian, born at Rouen, Jan. 19, 1639, was doctor of the Sorbonne and regent of studies at Saint-Jacques, Paris. In 1701 he signed the *Cas de conscience*, a document allowing "silent submission" to a Jansenist asking for absolution but when it was condemned by the pope he submitted to the latter. He appealed against the bull *Unigenitus* (1713), which condemned propositions of the Jansenist Pasquier Quesnel, but again later submitted to the pope. His chief work, *Selecta historiae ecclesiasticae capita*, 26 vol. (1676-86), was placed on the Index in 1684 and 1688; because of its defense of Gallican claims. Alexander brought out a revised edition entitled *Historia ecclesiastica veteris et novi testamenti*, 8 vol. (1699) but it was not until after his death that the edition with explanatory notes by C. Roncaglia (1734) was removed from the Index. Alexander died in Paris on Aug. 21, 1724.

See A. Hanggi, *Der Kirkenhistoriker Natalis Alexander* (1955).

(H. J. Cr.)

ALEXANDER, SAMUEL (1859-1938), one of the few British philosophers in the first half of the 20th century who produced a comprehensive metaphysical system, was born in Sydney, N.S.W., Austr., on Jan. 6, 1859. He was educated at Wesley college, Melbourne, at the University of Melbourne for two years and at Balliol college, Oxford, where he was a scholar. He read mainly in classics, philosophy and mathematics and gained the Green moral philosophy prize in 1888 for an essay published under the title *Moral Order and Progress* (1889).

As his interest in philosophy developed, he felt the need to connect it with the study of experimental psychology, still in its infancy in Great Britain. Accordingly he left his fellowship at Lincoln college, Oxford (he had been the first Jew to be elected to a fellowship at an Oxford or Cambridge college), and during 1890-91 studied experimental psychology in Germany under Hugo Münsterberg. In 1893, after a brief return to Oxford, he was appointed professor of philosophy at Owens college, Manchester, holding this chair until his retirement in 1924 and continuing to reside in Manchester until his death, which took place on Sept. 13, 1938. During the early part of his tenure he was one of a distinguished group of Manchester professors in the formative period in which Owens college, then a constituent college of the federal Victoria university, was turned into the independent University of Manchester.

In 1920 Alexander published *Space, Time, and Deity* (Gifford lectures), a comprehensive metaphysical system. Space time is represented as a cosmic matrix out of which different levels of organization emerge with the characteristic properties of matter, life and mind. Each level presupposes those preceding and shows a tendency or "nisis" toward a higher level, "deity" being the name given to the next level toward which the cosmic order is tending. Within this framework Alexander gave a detailed treatment of some of the main traditional philosophical problems such as uni-

versals, the mind-body relation, values and the nature of knowing. In his last years his interest turned mainly to aesthetics. In *Beauty and Other Forms of Value* (1933) he described art as the expression of a constructive impulse turned contemplative.

Alexander was awarded the Order of Merit in 1930. A notable bust of him by Jacob Epstein stands in the entrance hall of the Arts building of the University of Manchester. *Philosophical and Literary Pieces*, a collection of occasional papers, with a memoir by John Laird, was published posthumously (1939). (D. M. E.)

ALEXANDER AETOLUS (fl. c. 280 B.C.), Greek poet of Pleuron in Aetolia, was commissioned by Ptolemy Philadelphus to arrange the tragedies and satyric dramas in the library of Alexandria. In 276 he went to the court of the king of Macedonia. He was one of the Alexandrian Pleiad (a group of seven tragic poets), but only the title of one of his plays, *Astragalistae* ("The Dice Players"), survives. He also wrote short epics, epigrams and elegies. Two of the last are known, the *Apollo*, a collection of love stories with unhappy endings, and the *Muses*, dealing with literary criticism. Alexander's powers as a critic are further displayed by an appreciation of Euripides in anapaestic tetrameters (fr. 7).

For the fragments of his works see J. U. Powell (ed.), *Collectanea Alexandrina*, 121-130 (1925); Auguste Couat, *Alexandrian Poetry Under the First Three Ptolemies, 324-222 B.C.*, trans. by James Loeb, 109-115 (1931). (E. A. B.)

ALEXANDER BALAS (d. 145 B.C.), ruler of the Seleucid kingdom from 150 to 145 B.C., was a native of Smyrna. His claim to the Seleucid throne on the ground that he was the son of Antiochus IV Epiphanes (d. 163) was sponsored by the kings of Pergamum and Egypt and supported by the Roman senate. Powerfully aided by the Egyptian king Ptolemy VI Philometor (whose daughter Cleopatra he later married), he defeated and killed Demetrius I in 150 and took over his kingdom. He proved a bad ruler, and Ptolemy eventually changed sides and supported Demetrius' son Demetrius against him. This led to Alexander's defeat and death after a short campaign. (See SELEUCID DYNASTY.)

(R. H. St.)

ALEXANDER OF TUNIS, HAROLD RUPERT LE-OFRIC GEORGE ALEXANDER, 1ST EARL (1891-), British field marshal and prominent figure in World War II. Of North Irish stock and third son of the 4th earl of Caledon, he was born in London on Dec. 10, 1891, and educated at Harrow and Sandhurst. He joined the Irish guards (of which regiment he later became colonel) and served with distinction in World War I and on the Indian frontier. In World War II he held with uniform success a series of important commands at home and overseas. After commanding the rear guard at Dunkirk he showed remarkable coolness and skill in extricating British and Indian forces from Burma. He next reorganized the middle east command and coordinated the Allied advances from Egypt and Algeria which led to the German surrender at Tunis in May 1943. He then commanded the forces drawn from many Allied nations which drove the Germans from Sicily and southern Italy, forced the Italians to surrender, and finally liberated the whole of Italy. After the war Alexander served as governor general of Canada (1946-52) and later as minister of defense (1952-54) under Sir Winston Churchill. Alexander was created a viscount in 1946 and an earl in 1952. (J. R. M. B.)

ALEXANDER POLYHISTOR, CORNELIUS (fl. c. 70- c. 60 B.C.), Greek polymath whose fragments provide valuable information on antiquarian and especially Jewish subjects, was born at Miletus, and became a Roman citizen in 82 B.C. after being taken prisoner in the Mithradatic war.

See F. Jacoby, *Die Fragmente der griechischen Historiker*, pt. 3A, pp. 96-121 (1940), and part 3a, pp. 248-313 (1943).

ALEXANDER ROMANCES. The personality and career of Alexander the Great, (q.v.) led early to the development of legends about him, based partly on historical sources and partly on attribution to him of marvelous deeds. As with the romance cycles connected with other great figures, the stories about Alexander were retold with different emphasis and interpretation by each civilization and age. Thus, for example, some philosophers

of antiquity stressed his career as an illustration of the workings of the wheel of fortune; the early Christian fathers used it to justify the working out of God's judgments; the middle ages saw him as a pattern of knightly chivalry; and Jewish and eastern storytellers connected him with historical events in their own history.

Ancient Sources. — The first version of the Alexander Romance was written in Greek by a hellenized Egyptian in Alexandria during the time of the Ptolemies. c. 200 B.C. In its original form it is no longer known to us, since it was copied, rewritten, translated into more than 30 languages and expanded with fresh episodes until the original was completely lost sight of. Yet it is possible to reconstruct roughly the contents of the national Egyptian folk epic. It began by praising the wise Egyptians, skilled in astrology and magic, and went on to tell of the Egyptian king Nectanebes, who, fleeing from the enemies who had invaded his country, came to Macedonia, where he seduced with his magic arts Olympias, the wife of King Philip, and thus became the father of Alexander. An oracle had meanwhile proclaimed to the Egyptians that their departed king would return to them as a young man and would overcome their enemies, the Persians. When Alexander was grown up he immediately led his army through Italy to Africa. In the temple of Amon he was hailed as the son of the god; he founded Alexandria, after which he continued his march through Tyre to Persia, whose king, Darius, he defeated in two battles. When Darius was murdered by his own people, Alexander hunted down the murderers and had them executed. He next moved against Porus, king of India, and defeated him in a single battle. In India he talked with the wise Brahmans and also met the race of Amazons. Finally he returned to Babylon where he was poisoned at the instigation of Antipater.

This folk epic was considerably expanded in a number of early Greek versions and was sometimes attributed to the ancient Alexandrian historian Callisthenes, who, however, could not possibly have been its author. For this reason it later became known as the pseudo-Callisthenes. The episodes added to the original romance were taken partly from historical accounts and partly from reports of marvelous events which in the first romance had played only a subsidiary part. These reports were mainly contained in letters supposed to have been written by or to Alexander or other important persons in the story. Thus, for example, Alexander's visit to the palace of the Ethiopian queen, Candace, was developed into a major event, and a group of letters described more fully the marvels of the east, while a number of Jewish legends told of his visit to Jerusalem and his establishment of the Jewish quarter in Alexandria. That we can still follow the broad outlines of the romance from the Egyptian epic through to its Byzantine versions is due to the fact that we possess not only a considerable number of Greek manuscripts dated from the 11th century onward and a Byzantine epic of approximately the 13th century but also several earlier translations. These are: two Latin translations, one by Julius Valerius from the beginning of the 4th century A.D. (*Res Gestae Alexandri Macedonis*) and the other by the archpriest Leo of Naples from the 10th century (originally called *Nativitus et Victoria Alexandri Magni*; see below); an Armenian translation from the 5th century; a Syrian translation from the 7th century; and a very late Ethiopian translation, which, through the Arabic, leads back to the Syrian version. Some fragments of a Coptic version have also survived.

Besides the different recensions of the so-called pseudo-Callisthenes itself, there existed in Greek shorter accounts of Alexander's legendary exploits, as well as the letters already mentioned. Some of these existed also in Latin; for example, the *Epistola Alexandri ad Aristotelem de mirabilibus*, which played a considerable part in the development of the Alexander legend in the west during the middle ages. Further, there was a group of Indian tractates about the Brahmans, which, in Latin versions, were widely read during the middle ages, and an account of Alexander's last days, containing his testament, which is also found in pseudo-Callisthenes (III, 33). This text has also been preserved in Latin: it forms the second part of the so-called Metzger Epitome. Finally, among these secondary sources, reference must be made to the independent legend of Alexander's capture of the wild people of Gog

and Magog, which occurs in several texts, the most important being the *Revelationes* of the pseudo-Methodius, and is frequently mentioned in both oriental and occidental literature.

Vernacular and Medieval Latin Versions.—These romance tales are the basic material from which all the stories subsequently told of Alexander both in the east and the west derive, and the historical person of the king was increasingly eclipsed by them. They found their way into history and re-emerged in a wide variety of literatures. In the west Old English was the first vernacular language in which comprehensive accounts of Alexander are found, in the translation, made during the reign of Alfred the Great, of Orosius' history of the world. In the section dealing with Alexander use is made of the romance and its derivatives as well as of historical sources, and mention is made of Nectanebes. In the 10th century the *Epistola Alexandri* was translated into Anglo-Saxon, and in the 11th appeared the Middle Irish Alexander romance, based on Orosius, Josephus, the *Epistola* and the letters purporting to have been written between Alexander and the Brahman Dindimus. The early Middle High German *Annoled*, in which some of Alexander's fabulous deeds are related, dates from c. 1100. Soon after, in the 12th century, during the time of the crusades, came the succession of great poems about Alexander, beginning with the French epic, the *Roman d'Alexandre* begun by Alberich of Besançon, who takes the story up to the death of Darius, from which point it was later continued in other French verse romances. The first German Alexander epic, by "Pfafe" Lamprecht, is based on Alberich, and it also was later revised and supplemented. To the end of the 12th century also belongs the Anglo-Norman epic by Thomas of Kent, *Le Roman de Toute Chevalerie*, which, c. 1275, was refashioned into the Middle English *Kyng Alisaunder*. At this period also, two historical sources for the life of Alexander, by Curtius and Justinus, came into prominence, particularly through the *Alexandreis*, the great Latin epic by Gautier de Châtillon (second half of the 12th century) which is based on them and which, in the 13th century, was translated into Spanish (*Libro de Alexandre*), Icelandic (by Brand Jónsson), Middle Dutch (*Alexanders Geesten*, by Jacob van Maerlant [q.v.]), German (by Ulrich von Eschenbach) and Czech. The German epic by Rudolf von Ems (c. 1230–55) also uses Curtius as its main source.

Besides the Alexander poems and prose tales in the vernacular, versions in Latin continued to appear. Thus the translation by the archpriest Leo was completely reshaped in a number of revisions, to form the *Historia de proeliis*, which in its turn has been translated into many European languages; world histories from that of Ekkehard of Aura (early 12th century) onward generally contained a version of the Alexander story; and the great succession of the Latin encyclopaedias, from Isidore of Seville to Vincent of Beauvais (q.v.), followed the tradition established by Pliny and included fabled accounts of Alexander's career. New legends also came into being, such as that of Alexander's journey to Paradise which first appeared in the 12th-century *Iter ad Paradisum*.

In the 14th century the Italian Alexander romances began to appear, in both prose and verse, closely followed by the Swedish verse *Konung Alexander* and also by versions in Scots, Danish and, dating originally from a little earlier, in the Slavonic languages. These had been begun by the translation into Bulgarian of the pseudo-Callisthenes, on which are based the various Russian Alexander romances. In the Slavonic romances are found episodes unknown elsewhere, as for instance, in the works of the Polish chronicler Kadlubeck (d. 1223), and as late as the Renaissance period we find the first mention of the *Privilegium Slavicum* supposed to have been granted to the Slavonic peoples by Alexander.

Eastern Versions.—Alexander romances developed equally prolifically in the east. Besides the eastern translations of pseudo-Callisthenes already mentioned, particular emphasis was there given to the Christian legend based on Jewish traditions of Alexander's capture of Gog and Magog, which is told in prose in Syrian and later, in verse, by Jacob of Serugh (d. 521), and is also included in the Koran (Sure 18, 82ff.) The Arabs also translated the Syrian romance, expanded it, combined its contents with

their own chronicles, and passed on these versions to the many peoples with whom they had contact, by conquest and trade, reaching as far as Java, where, in about the 16th century, a version of the romance was translated into Malay. Through them, too, it again entered Spain, where a partly new tradition was introduced, which in its turn was spread further in Latin, Hebrew, Spanish and other languages. The Arabs also carried the romance to Persia where the poets Firdausi (c. 935–1020) and Nizami (d. c. 1200) gave it new forms. The works of Nizami were, toward the end of the 14th century, translated into Turkish, and the sultan of that period, Bayazid, claimed descent from Alexander. His great grandson, Mohammed II, conqueror of Constantinople, modeled himself on Alexander, and poems about him were his favourite reading. With the revival of classical scholarship during the Renaissance, however, literature based on the various versions of the Alexander romance in both east and west gradually gave way to historical accounts, in which use was made of the more reliable sources of Plutarch, Arrian and Diodorus.

ALEXANDERS (*Smyrniun olusatrum*, family Umbelliferae), a stout herbaceous plant with a furrowed, much-branched stem, one to five feet high, and large, dark-green, shiny compound leaves with broad sheathing stalks and broad cut segments. Small yellow-green flowers, in compound umbels (see UMBELLIFERAE), are pollinated by flies attracted in swarms by their heavy odour. The fruits are nearly black. The plant is native of the Mediterranean region and was formerly commonly cultivated as a vegetable. It is now found wild throughout the British Isles.

In the United States the name is applied to *Angelica atropurpurea*, and the name golden alexanders to *Zizia*, especially *Z. aurea*. (M. E. M.)

ALEXANDER SEVERUS (MARCUS AURELIUS SEVERUS ALEXANDER) (208–235), Roman emperor from A.D. 222 to 235, was born in Phoenicia in 208. His grandmother was sister-in-law of the emperor Septimius Severus, who died in 211 and whose son Caracalla was murdered in 217. Then, after the brief rule of Macrinus, the Syrian legions in 218 proclaimed Alexander's 14-year-old cousin Elagabalus emperor. Elagabalus was persuaded to adopt Alexander as his heir, and on the murder of Elagabalus (March 222) Alexander became emperor, also at the age of 14. In the words of Herodian, he "always did everything his mother told him." To advise his mother, Julia Mamaea, the senate appointed a regency council of 16, without whose vote "nothing was to be said or done." To Herodian the "form of government was changed from the excesses of tyranny to the type of aristocracy." He and Dio Cassius, the contemporary chroniclers of the reign, both

combine general praise with an embarrassed lack of detail. The regency was unable to control the conflicts within the empire. The people of Rome fought a three-day street battle with the guards regiments, but people and guards united in dislike of the government; provincial armies elevated short-lived local emperors, while provincial civilians sheltered army deserters, runaway slaves and outlaws. The guards murdered their commander Ulpian, the chief minister of state, in the presence of the emperor and his mother, and the government could only take vengeance on the chief murderer by sending him to Egypt as governor and there assassinating him. Alexander is said to have wished to include Christ among the Roman gods.

Alexander's government survived its internal weakness; it was destroyed by its military incompetence. On the eastern frontier, the Arsacid dynasty of Parthia was overthrown by the Sasanians, who revived the ancient Persian claim to rule all Asia Minor and the eastern Balkans. A massive Roman counteroffensive, based on the co-ordination of three army groups, was disastrously defeated because the army under Alexander's personal command failed to advance. This failure was followed by operations on the Rhine, which Alexander ended by buying peace from the Germans, to the indignation of his army. His mother was hated for her fussing about small details, especially in matters of money. Early in 235 Alexander and his mother were murdered, the army of the Rhine proclaimed Gaius Julius Verus Maximinus emperor, and the "type of aristocracy" again gave way to the "excesses of tyranny." Senatorial pamphleteers of the 4th century, the writers of the *Augustan History* (*q.v.*), chose to found upon his inconspicuous person their picture of the ideal prince, gifted with a wide range of conflicting virtues and the supposed author of the governmental reforms that they themselves desired. (J. N. R. M.)

ALEXANDERSON, ERNST FREDERIK WERNER (1878–), Swedish-American electrical engineer and inventor, best known for his contributions in the field of radio communications, was born at Uppsala, Jan. 25, 1878. He graduated from Royal Institute of Technology at Stockholm and did graduate work in Berlin. In 1901 he went to the United States with an ambition to work with C. P. Steinmetz and the following year did start work under Steinmetz at the General Electric company at Schenectady, N.Y. During 45 active years with that company, he did pioneering work in railroad electrification, ship propulsion and electric motor control. In the field of radio communications he invented and developed the Alexanderson alternator for transoceanic communication as well as antenna structures and radio receiving and transmitting systems. In 1930 he demonstrated a complete television system, including projection of a large picture on a theatre screen.

The General Electric company loaned his services to the Radio Corporation of America to be its chief engineer for a few years following its organization in 1920. In that capacity he supervised the installation of a number of powerful Alexanderson alternator radio transmitters.

Alexanderson was decorated by King Gustavus V of Sweden and received the Valdemar Poulsen, John Ericsson, Cedergren and Edison medals. He wrote numerous technical articles and had more than 300 patents to his credit. (W. C. WH.; X.)

ALEXANDRA (ALEKSANDRA FEDOROVNA) (1872–1918). empress of Russia, consort of Nicholas II (*q.v.*), was born at Darmstadt in Germany on June 6, 1872, the youngest daughter of the grand duke Louis IV of Hesse-Darmstadt. Her original name, Alix, was changed when she married the Russian emperor Nicholas II on Nov. 26 (new style; Nov. 14, old style), 1894, four weeks after his accession. Unpopular in court society because of her reserved temperament, she withdrew into embittered seclusion, seeking solace in religion and her immediate family circle. Her inclination toward mysticism was increased by her almost fanatical acceptance of Orthodoxy and the medieval doctrine of God-given autocracy; she conceived it as her sacred duty to assist Nicholas in resisting popular pressure and maintaining his powers intact for posterity. Her relations with her weak-willed husband, whom she dominated completely, were idyllic; she bore him four daughters and, in 1904, a long-awaited male heir. But the tsarevich Aleksei

suffered from hemophilia, a disease hereditary in Alexandra's family. Her neurotic concern lest the slightest injury to the prince might prove fatal and imperil the future of the dynasty led her to seek the aid of a debauched "holy man" with hypnotic powers, Grigory Efimovitch Rasputin (*q.v.*). She came to venerate Rasputin as a saint, sent by God to save the throne and "holy Russia." and as the true voice of the common people who, she believed, still preserved their traditional loyalty to the autocracy—unlike educated society, which she feared and despised. Rasputin's influence was a public scandal, but Alexandra silenced all criticism.

World War I widened the breach between the monarchy and Russian society. Alexandra, more convinced than ever of the need for autocracy, persuaded Nicholas to assume supreme command at the front (Aug. 1915), while she ruled the country in his stead. Distrusting the *duma* and even the loyally conservative government, she arbitrarily dismissed capable ministers, replacing them by nonentities or dishonest careerists who enjoyed Rasputin's favour. The administration was paralyzed, the whole regime discredited. Alexandra was widely, but erroneously, believed to be a German agent. Yet she disregarded all warnings; even Rasputin's assassination failed to shake her confidence. She was thus largely responsible for the collapse of the autocracy in March 1917; like a Greek tragic heroine, she destroyed all that she sought to preserve. After the Bolshevik revolution she acquitted herself with great courage. She was put to death, with Nicholas and their children, at Ekaterinburg (now Sverdlovsk) on July 17, 1918.

ALEXANDRA (1844–1925), queen consort of Edward VII of Great Britain, was born at the Gule palace, Copenhagen, on Dec. 1, 1844, and was christened Alexandra Caroline Maria Charlotte Louise Julia. Her father was heir to the Danish throne, which he ascended as Christian IX in 1863. With three brothers and two sisters, she was a member of a boisterous and carefree family circle which remained the abiding influence of her life. Alexandra became engaged to Edward, prince of Wales, on Sept. 9, 1862, when both were staying at Laeken palace, Brussels, as the guests of Leopold I of Belgium. They were married in St. George's chapel, Windsor, on March 10, 1863. The exceptional beauty and graceful manner of the princess made her an immediate and lasting favourite with the British public; and her affection for Denmark and dislike of Prussia were generally respected. She had six children—Albert Victor, George (afterward King George V), Louise, Maud (afterward queen of Norway), Victoria and John: who died in infancy. Alexandra devoted herself to her children by whom she was always known as "Mother-dear," and she regarded the calls of the official world as an unwelcome intrusion on her family life. This tendency was strengthened by a serious illness in 1867 which left her lame and accentuated a hereditary deafness. As queen she devoted much of her income and time to the poor and suffering; she founded the Imperial Military Nursing service in 1902, and started Alexandra Rose day for British hospitals in 1913. Although she did not share her husband's taste for fashionable society, and her incurable lack of punctuality offended his meticulous standards, he greatly admired her and one of the first acts of his reign was to admit her to the Order of the Garter, from which all the female relations of the sovereign had been excluded since Tudor times.

After King Edward's death in 1910 Queen Alexandra lived at Marlborough house, London, and at Sandringham in Norfolk, where she died on Nov. 20, 1925.

ALEXANDRETTA: see ISKENDERUN; HATAY.

ALEXANDRIA, the name of a number of ancient cities as well as the great Alexandria (*q.v.*) in Egypt, founded by Alexander the Great in the course of his campaigns from 334 to 323 B.C. Fifteen of these are listed here.

ALEXANDRIA TROAS, founded in 334 B.C. on a site about 15 mi. S. of Hisarlık, a mound in Turkey 4 mi. S.E. of the mouth of the Dar-

danelles which is identified with the site of ancient Troy.

ALEXANDRIA in Cilicia, founded after the battle of Issus in 333 B.C., the modern Iskenderun (*q.v.*) or Alexandretta in southern Turkey.

ALEXANDRIA, founded after the battle of Gaugamela in 331 B.C.; the modern Irbil (*q.v.*) in northern Iraq.

ALEXANDRIA OF THE ARIANS, founded in Aria in 330 B.C., the modern Herat (*q.v.*) in northwestern Afghanistan.

ALEXANDRIA PROPHASIA, founded in 330 B.C., according to W. W. Tarn (*The Greeks in Bactria, and India*, 1951) on an unidentified site on the Helmand lake in the Seistan region of eastern Iran and southwestern Afghanistan; others place it at Farah in the province of Farah in southwestern Afghanistan. The name *Prophasia* ("anticipation") was probably an allusion to the detection and suppression in 330 B.C. of the conspiracy of Philotas.

ALEXANDRIA OF THE ARACHOSIANS, founded in 330-329 B.C. According to Tarn the site is at Ghazni (*q.v.*) in eastern Afghanistan; others identify it with Kandahar (*q.v.*) in southern Afghanistan.

ALEXANDRIA BY THE CAUCASUS, founded in 329 B.C. near the Paropamisus or Caucasus (the Hindu Kush), not far from the modern town of Charikar in the Kabul province of eastern Afghanistan.

ALEXANDRIA ESCHATE, that is, "the Farthest," founded in Sogdiana in 329 B.C. to mark the northeastern extremity of Alexander's conquests, the modern Leninabad, or Khojent (*q.v.*), in the Tadzhik S.S.R.

ALEXANDRIA on the Oxus (Amu-Darya) river, founded in 329 B.C. on an unidentified site southwest of Stalinabad in the Tadzhik S.S.R.

ALEXANDRIA IN MARGIANA, founded in 327 B.C. but destroyed soon afterward by nomads. The site is identified with that of Merv (*q.v.*) in Turkistan.

ALEXANDRIA On the Indus, founded in 325 B.C. near the confluence of the Indus river with the combined streams of the Hydaspes (Jhelum), Acesines (Chenab) and Hyphasis (Beas) rivers, perhaps identifiable with Uch in Bahawalpur (West Pakistan).

ALEXANDRIA OF THE SOGDI, founded in 325 B.C. at an unidentified site farther down the Indus than the above.

ALEXANDRIA in Gedrosia, founded in 325 B.C., the modern Bela, in southeastern Baluchistan.

ALEXANDRIA in Carmania, founded in 325 B.C., the modern Gulashkird, a village in southeastern Iran.

ALEXANDRIA on the Persian gulf, founded by Alexander in 324 B.C. and refounded with the name Antioch by Antiochus IV Epiphanes in the 2nd century B.C.; renamed as Charax when the provincial governor of Mesene revolted against Seleucid rule after the death of Antiochus VII Sidetes.

ALEXANDRIA (Arabic AL ISKANDARIYAH), a city, governorate (*muhafaza*) and the chief seaport of Egypt. For more than 1,000 years from its foundation it was the capital of the country. It lies on the Mediterranean 129 mi. N.W. of Cairo by rail.

The population of Alexandria in 1957 was 1,277,819. The nationality analysis of 1947 was 855,489 Egyptians, 9,659 British, 3,259 French, 12,370 Italians, 30,753 Greeks, 2,000 Turks, 1,565 Syrian, Lebanese and other Arab nationalities and 3,926 others. Since the end of 1956 many of the European and Jewish inhabitants have departed.

In Alexandria the climate from December to March is variable with predominantly cool sunny days but occasional heavy falls of rain or hail, and stormy winds. The coldest month is January with a mean day temperature of 64° F. In summer the heat is moderated by sea breezes but there is much humidity; in August, the hottest month, the average day temperature is 87°.

The city is built on the strip of land separating the Mediterranean from Lake Mareotis (Maryut), and on a T-shaped promontory that forms harbours east and west. The stem of the T was originally a mole leading to the island of Pharos which formed the crosspiece. In the course of centuries this mole has been silted up and is now an isthmus half a mile wide. On it a part of the modern city is built. The western end of the original Pharos Is-

land is the cape of Ras al-Tin ("cape of figs"); the eastern cape is still known as Pharos. On the eastern point of Pharos Island stood the great lighthouse, one of the Seven Wonders of the World, reputed to be 400 ft. high. The first Ptolemy began it and the second completed it at a total cost of 800 talents. It is the prototype of all lighthouses in the world. The eastern cape is also known as Qa'itbay from the 15th-century fort and mosque.

The customs house and chief warehouses are by the western harbour, but the principal buildings of the city are in the eastern and southeastern quarters. One of the main features of modern Alexandria is a fine seacoast road (completed 1934), formerly called the Corniche but now Rue al-Geish (army avenue). It runs eastward for about 16 mi. and along most of its length are bathing beaches. A focal point of the city is the Mohammed Ali square with an equestrian statue of Mohammed Ali the Great. Known in the 19th century first as the Place des Consuls and then as the Grand square, it has always been colloquially called al-Manshia, but in 1952 its name was officially changed to Midan al-Tahrir (Liberation square). On its northern side is the Anglican church of St Mark's built on land originally given to the British community by Mohammed Ali in 1839 as a free grant. Looking on to this tree-lined square, the starting point of the numerous buses and electric trams, are the cotton bourse and law courts. Further east and giving on to the sea is the Saad Zaghlul square called after the nationalist leader who died in 1927 and whose statue stands among grass plots in the centre. The chief hotel in the town, the Hotel Cecil, is here and close by is the middle east headquarters of the World Health organization.

Southeast from Mohammed Ali square is the shopping and commercial part of the town through which run Rue Sherif and Rue Tewfik. One of the main east-west streets is Rue Rosette (formerly Rue Fuad al-Awal), to the north of which is the Graeco-Roman museum, an excellent collector of antiquities. The Municipal library, formerly in Rue Rosette and now near the waterworks, houses about 65,000 volumes in Arabic and European languages. Beside it is an art gallery. There are two fine botanical gardens in the city, the Nouzha gardens and the Antoniadés park, and near the railway station is a sports stadium to accommodate 25,000 spectators, where the Arab Olympic games are held. South from Rue Rosette is the mosque of Nebi Daniel containing the tomb of Said Pasha and other royal tombs. Nearer the western harbour is the Place Ibrahim, often called the Place Ste. Catherine from the Roman Catholic church there. St. Catherine was said to be martyred in Alexandria under orders of the emperor Maximinus. The northern quarter of Alexandria is oriental in style. It is crossed by Rue Ras al-Tin, leading to the promontory of that name. The smart Yacht club which overlooked the harbour at Ras al-Tin is now the Egyptian naval officers' mess, and the Yacht club has been moved to the eastern harbour. Also on the promontory is the palace built by Mohammed Ali, which since the abdication of King Faruk in 1952 has been open to the public.

The eastern bay is rocky and exposed, and is used only by fishing craft and yachts. The two ancient Egyptian obelisks now in London (Cleopatra's Needle) and New York city looked onto this bay.

In the district between Mohammed Ali square and the western harbour, one of the poorest quarters of the city is an open space in the centre of which is Fort Caffarelli, so named because it was fortified by the comte de Caffarelli, Napoleon's engineer. This quarter has been pierced by several straight roads, one of which, crossing the Mahmudiya canal (built by Mohammed Ali in 1819) by Pont Neuf, leads to Gabbari, an industrial and manufacturing region. In the southern part of the city are the Arab cemetery, Pompey's Pillar and the catacombs. Pompey's Pillar (actually dedicated to Diocletian soon after AD. 297), which stands on the highest spot in Alexandria, is about 88 ft. high including the pedestal with a diameter of 9 ft. at the base and 63 ft. at the pinnacle. Close by are the famous Hadrianic catacombs of Kom al-Shugafa containing a very beautiful central tomb surrounded by many passages with loculi and a large triclinium.

East of Alexandria is the university (formerly the Faruk university); in 1956-57 it had 14,158 men and 1,519 women students

Close by is the Mowassah hospital and school of nursing. This hospital is among the best equipped in Europe or the middle east. Two sports clubs, close to this district, comprise a race course, polo fields, golf links, tennis courts, etc. Farther down the coast is the boys' boarding school, Victoria college, where many past and present leaders of the middle east were educated. It has been under Egyptian management instead of British since the Suez conflict of 1956-57, but it is still run on English public school lines. There is a girls' college nearer the town. The great sea road Rue al-Geish ends at the former royal palace of Montaza. This is now a casino where only foreigners are admitted, but the royal gardens and bathing beaches are open to all on payment.

The Port. — The harbour is on the west of Pharos and is partly formed by a breakwater (built 1871-73 and prolonged 1906-07) two mi. long. Opposite is Ras al-Tin, on which is a lighthouse (180 ft.) built by Mohammed Ali. Another breakwater, starts from the Gabbari side, the opening between the two being about half a mile. The enclosed water is divided into an outer and inner harbour by a mole 1,000 yd. long. The inner harbour ($\frac{3}{4}$ sq.mi. in area) is lined for 2½ mi. by quays, affording accommodation for ships drawing up to 28 ft. The outer harbour (23 sq.mi.) has a graving dock, 520 ft. long, and quays and jetties.

The city is the headquarters of most of the merchants and companies engaged in the development of the delta. More than 80% of the total exports and imports of the country pass through the port. During 1958, 2,810 vessels of 6,000,000 tons aggregate, with 26,000 passengers, entered Alexandria harbour. The large suburb oi al-Raml (Ramleh) stretches eastward from Alexandria in an unbroken line for about 16 mi.

Communications. — Alexandria is linked to other towns of Egypt by railway, telegraph and telephone lines, roads and air services. It also has good canal connection with the interior for merchandise. Two main roads run to Cairo, one through the western desert, passing by the salt-and-soda works of Wadi Natrun and the famous ancient Coptic monasteries, the other through the delta. Another road leads west along the coastal desert, past al-Alamein to the Libyan frontier, and connects with the north African coastal road. The civil airport is 1¼ mi. south of the city. Electric trams and buses connect al-Raml with Alexandria and link different quarters of the town together. Buses go to outlying towns and along the coastal desert road to al-Sallum. There is also a train service to this Libyan frontier town. Motor coaches go to Cairo through delta and desert.

Industries. — The region of Gabbari contains asphalt works, oil, rice and paper mills. On either side of the canal are the warehouses of wholesale dealers in cotton, wool, sugar, grain, onions, etc. Close by is the Mina al-Bassal area with the important cotton exchange where the varieties are graded and valued. Beyond Gabbari to the southwest is al-Maks with considerable salt and tanning industries and stone quarries. The area south and southeast of Alexandria has been greatly developed as an industrial area. There are important cotton textile and dyeing works, as well as factories for ginning and pressing cotton; paper, chocolate and confectionery works; food processing and canning; leather, soap and soda works; plastics, pottery and car-assembly workshops. A Ford factory set up in Alexandria produced 7,000 cars and tractors in 1952. An oil refinery has been established and electric power available to the city has been much increased. In the Abis district an area of some 24,000 ac. was being drained and reclaimed from marsh in the mid-1950s. Model villages were built and landless peasants from overcrowded areas were given a new start. The resulting crops are marketed in Alexandria. In the desert to the west extensive agricultural experiments were also taking place and olives, vines, figs and tomatoes were successfully grown. By far the largest and most valuable export from Egypt via Alexandria is cotton, followed by cereals and vegetables. Tea, coffee, textiles, coal, fertilizers and machinery are imported. The inhabitants of Alexandria are mostly occupied in trade and transport of merchandise in all its branches, harbour work, industries, shipping and fishing.

History. — From about 1,500 B.C. there existed the pharaonic city of Rhacotis. When Alexander the Great came to Egypt (332

BY COURTESY OF INFORMATION DEPARTMENT, CAIRO, EGYPT

QA'ITBAY FORT ON THE EASTERN CAPE OF ALEXANDRIA: 15TH CENTURY

B.C.) he added a suburb called Neapolis to the west, Rhacotis and Neapolis being included under the general name of Alexandria. The great Macedonian intended the city to supersede Naucratis as a Greek centre in Egypt, and to be a naval base for his designs on Persia and a link between Macedonia and the rich Nile valley. Alexander occupied Pharos, and had a walled city marked out by Deinocrates on the mainland to include Rhacotis. A few months later he left Egypt for the east and never returned to his city; but his body was ultimately entombed there. His viceroy, Cleomenes, continued the creation of Alexandria. Inheriting the trade of ruined Tyre and becoming the centre of the new commerce between Europe and the Arabian and Indian east, the city grew in less than 100 years to be larger than Carthage; for several centuries it had to acknowledge no superior but Rome. It was a centre not only of Hellenism but of Semitism, and the greatest Jewish city in the world. Here the Septuagint (*q.v.*) was produced. The early Ptolemies fostered the development of its museum into the leading Greek university, and, as a free Greek city, it retained its own senate into Roman times. The famous Alexandrine libraries founded by Ptolemy I decreased in importance with the political decline of the city and were eventually destroyed. (*See LIBRARIES: Ancient Libraries.* In 80 B.C. it passed formally under Roman jurisdiction according to the will of Ptolemy Alexander, though it had been under Roman influence for more than 100 years previously. Julius Caesar dallied with Cleopatra in 47 B.C. and was mobbed by the rabble in Alexandria and his example was followed by Mark Antony, for whose favour the city paid dearly to Octavian (later Augustus), who placed over it a prefect from the imperial household.

Alexandria seems from this time to have regained its old prosperity, commanding as it did an important granary of Rome; in the Augustan age its free population was estimated at 300,000, in addition to an immense number of slaves. In A.D. 215 the emperor Caracalla (Marcus Aurelius Antoninus) visited the city, and, in order to repay some insulting satires that the inhabitants had made upon him, a general massacre was perpetrated. Notwithstanding this terrible disaster, Alexandria soon recovered its former splendour and for some time longer was esteemed the first city of the world after Rome. While it now acquired fresh importance as a centre of Christian theology and church government. Tradition has it that St. Mark had come in person and converted Alexandrians to Christianity. There Arianism was formulated and there Athanasius the Great, bishop of Alexandria (328-373), opponent of both heresy and pagan reaction, worked and triumphed. As native influences, however, began to reassert themselves in the Nile valley, Alexandria gradually became an alien city, more and

more detached from Egypt; and, losing much of its commerce as the peace of the empire broke up during the 3rd century A.D., it declined fast in population and splendour. In 616 it was taken by Khosrau II, king of Persia; and in 646 by the Arabs, under Amr ibn al-As (*q.v.*), after a siege that lasted 14 months. The building of Cairo in 969 and, above all, the discovery of the route to the east by the Cape of Good Hope in 1498, nearly ruined Alexandria's commerce. The canal which supplied it with Nile water became blocked and although it remained a principal Egyptian port Alexandria played no great part in history until Napoleon's Egyptian expedition thrust it into prominence. The French troops stormed the city on July 2, 1798, and it remained in their hands until the arrival of the British expedition of 1801. Sir Ralph Abercromby defeated the French at the battle of Alexandria on March 21 of that year and the city surrendered to the British five months later.

By the beginning of the 19th century Alexandria had sunk to a small town of about 4,000 inhabitants; it owes its modern renaissance to Mohammed Ali, who wanted a deep port and naval station for his viceregal domain. Being the starting point of the "overland route" to India, and the residence of the chief foreign consuls, it quickly acquired a European character. At Alexandria most of the negotiations between the great powers and Mohammed Ali were conducted; thence started the Egyptian naval expeditions to Crete, the Morea (Peloponnesus) and Syria. It was connected with Cairo by railway in 1855 and remained the real capital of Egypt till Said Pasha died there in 1863 and Ismail Pasha came into power. Though this prince continued to develop the city, giving it a municipality in 1866 and new (but inadequate) harbour works in 1871-78, he developed Cairo still more; and the centre of gravity definitely shifted to the inland capital. In 1881 a mutiny of soldiers occurred and in the following year the arrival of an Anglo-French fleet led to a rising under Arabi Pasha, in which many Europeans were killed. The rising was put down by the British and this action was followed by the British occupation of the whole country.

In World War I Alexandria was the chief Allied naval base in the eastern Mediterranean and it played the same role in World War II during which it was bombed many times by the Germans. The British forces left in 1946. Alexandria is an increasingly important base for the country's naval and mercantile fleets, and as a resort has gained much in general popularity with Egyptians. See also EGYPT: *History*.

G. Elgood, *The Ptolemies of Egypt* (1938). (M. Ro.)

ALEXANDRIA, a city of Louisiana, U.S., on the south bank of the Red river, in the centre of the state; the seat of Rapides parish. (For comparative population figures see table in LOUISIANA: *Population*.) The city is on a level plain in the centre of extensive forests of longleaf pine, interspersed with various hardwoods. Corn, cotton, sugar, alfalfa and vegetables are the principal crops raised in the vicinity. There are about 100 factories in and near the city, including sawmills, a creosoting plant, foundries and machine shops, cottonseed oil mills, brickyards, an oil refinery, broom handle and talcum factories and railroad repair shops. Alexandria has a large wholesale and retail trade.

Free traffic bridges lead to the town of Pineville, on the north side of the river, where there is a national cemetery. A state hospital for the insane, Huey P. Long Charity hospital, Louisiana college (a Baptist coeducational institution which was opened in 1906), a U.S. veterans' hospital, the state industrial school for girls and the state colony for the feeble-minded are also near by.

Alexandria was named after Alexander Fulton, on whose grant from Spain the first settlement was made in 1785. In 1805 Fulton formally laid out the city at the rapids which then marked the head of navigation in the river. It was incorporated as a town in 1818 and received a city charter in 1882. The rich, level farm

land to the south already produced cotton, sugar cane and cattle, and the city thrived on river commerce before the American Civil War. In May 1863 and again in March 1864 it was occupied by Union forces under Adm. David D. Porter and Gen. N. P. Banks. When finally vacated, May 12-13, 1864, the city was almost entirely burned and all city records were lost. Union gunboats, which had passed up the river toward Shreveport at high tide, were caught above the falls at Alexandria; Banks' forces, retreating from defeat at Mansfield, escaped entrapment when Lieut. Col. Joseph Bailey built wing dams to allow passage of the fleet. Railroad growth and exploitation of the dense pine and hardwood forests helped restore the city after the war. (W. M. Lo.)

ALEXANDRIA, a city and a port of entry in northern Virginia, U.S., on the west bank of the Potomac river below its falls, 6 mi. below Washington, D.C.; contiguous to, but independent of, Arlington county.

Alexandria is primarily a residential city, with quiet, shady streets. Many buildings date from the 18th century; Christ church (1773), in which George Washington and, later, Robert E. Lee worshiped; Carlyle house (1752), where Gen. Edward Braddock made his headquarters in 1755 while preparing for the ill-fated expedition to Fort Duquesne, and where, in the same year, the five royal governors met; Gadsby's tavern (1752), where Washington had his headquarters while recruiting rangers for the campaign of 1754; Alexandria academy (1785), first free school in northern Virginia; Friendship Engine house (1774); the home of "Light Horse Harry" Lee, father of Robert E. Lee; Presbyterian meeting house (1774), housing the oldest pipe organ in America; Ramsay house (1748); and many others. The *Alexandria Gazette* is one of the oldest daily newspapers in the United States, founded in 1784 and in continuous circulation since.

On the hill in the western part of the city is the George Washington Masonic National memorial which was dedicated in 1932. Just over the western boundary line is the Protestant Episcopal seminary of Virginia, opened in 1823.

Alexandria is the commercial centre for northern Virginia. A large plant for construction and repair of refrigerator cars is near the city. The products of the industrial plants in Alexandria include fertilizers, beverages, shirts, chemicals, sewer pipes and lumber products.

The first settlement was made in 1695. In 1731 Scottish merchants founded the community of Belhaven, which in 1749 was established as a town under the name of Alexandria in honour of John Alexander, who originally owned the land. It was incorporated as a city in 1779. Before the American Revolution the city reflected its loyalty to the British crown by giving its streets such names as King, Queen, Prince and Duke. George Washington helped lay out the town's streets and lots, drilled his troops there in 1754 before marching against the French and Indians and at-

BY COURTESY OF ALEXANDRIA CHAMBER OF COMMERCE, INC.

tended its religious services, balls, fairs and political rallies. Alexandria enjoyed a flourishing trade with the interior and became an important port for the products of northern Virginia, shipping flour and tobacco to the West Indies and to Europe. Improved roads were built for wagon trains and "rolling roads" were constructed on which hogsheads of tobacco were rolled down from the plantations to the port. The city's economic development was checked, however, after Baltimore developed railroad connections with the west.

From 1791 to 1847 Alexandria was part of the District of Columbia, at first with a vague and uncertain status and later overshadowed by the development of the capital. It was ceded back to Virginia in 1847. At the outbreak of the Civil War its sympathies were with the Confederacy. But in May 1861, federal troops took possession of the city and occupied it for the duration of the war, making it a base for the invasion of Virginia. After the creation of the state of West Virginia (1863) and until the close of the war, it was the seat of the "Alexandria government" (see VIRGINIA). After the Civil War Alexandria resumed its normal existence whose quiet for the next half-century was broken only by the movements of the railroad establishing connections with Richmond and by the activities of the Potomac railroad yard.

A small town until the 20th century. Alexandria's population increased almost 500% in 50 years, from 15,239 in 1910 to 91,023 in 1960. Its rapid growth is attributable, in large measure, to the increasing settlement there of people employed in the nation's capital. The city is a part of the Washington, D.C.-Maryland-Virginia standard metropolitan statistical area. For comparative population figures see table in VIRGINIA. *Population*.

(F. B. S.)

ALEXANDRIA, GREEK ORTHODOX PATRIARCHATE OF. The pope and patriarch of Alexandria, generally called the Greek Orthodox patriarch of Alexandria, is regarded by the Eastern Orthodox as the successor of St. Mark the evangelist, the second in rank of the patriarchs after the ecumenical patriarch, and the head of the church in Africa. At the time of the Council of Nicaea (325), his jurisdiction was considered to extend over Egypt, Libya and the Pentapolis. He has the title of "judge of the world" (Gr. *Krites tes ozkoumenes*), because in early Christian times Alexandria decided the date of Easter for the whole world. His see is regarded by the Orthodox as one of the sees of St. Peter, since St. Mark was the companion and interpreter of St. Peter. After the Council of Chalcedon in 451, the great majority of the Egyptian Christians refused to recognize the deposition of Dioscorus, patriarch of Alexandria, in that council and ceased to be in communion with the church of the Roman empire (see COPTIC CHURCH). The small minority that remained in communion with the other Orthodox Christians at the time of this separation consisted of Greeks living in Egypt. When Egypt came under Muslim rule in the 7th century this Greek minority became smaller still, but it continued to exist in the city of Alexandria and in Cairo as a minority group within the Christian minority after most people became Muslims.

In the 19th century the prosperity of Egypt caused thousands of Greeks and Syrians to settle there, and with these immigrants the Greek Orthodox Church in Egypt grew rapidly, although it remains much smaller than the Coptic or Egyptian Church. In the 20th century many Greeks and other Eastern Orthodox Christians settled in Sudan, Ethiopia, South Africa, Madagascar and elsewhere within the jurisdiction of the patriarch of Alexandria, so that Greek sees have been established in African countries outside Egypt. But in the middle of the century there was a rapid reduction in the Greek population of Egypt itself.

There are Greek Orthodox metropolitans in Egypt (Zagazig, Tanta, Mina and Port Said), at Tripoli in Libya, Addis Abbaba, Tunis, Khartoum and Johannesburg. The number of members in Africa is difficult to estimate, but by 1960 it was probably less than 150,000, including 12,000–15,000 Arabic-speaking "Egyptian national Orthodox," mainly of Syrian origin and sometimes described as Syrian Orthodox (Gr. *Syrorthodoxoi*) in Egypt, a small number of African congregations in Uganda that had become Orthodox

and a few Russians.

The patriarchs of Alexandria well known in history include St. Athanasius, St. Cyril, St. John the Almsgiver, Cyril Lucaris and Metrophanes Critopoulos.

See J. Faivre, "Alexandrie," in A. Baudrillart (ed.), *Dictionnaire d'histoire et de géographie ecclésiastiques*, vol. ii, col. 289–369 (1914); C. Papadopoulos, *Historia tes ekklesias Alexandreias* (1935).

(E. E.)

ALEXANDRINA, LAKE, lies in South Australia, 40 mi. S.E. of Adelaide. With the associated Lake Albert and the long narrow Coorong lagoon it forms the outlet of the Murray river. Although merely a large (220 sq. mi.) lagoon, after its exploration by Charles Sturt (*q.v.*) in 1830 it attracted attention (especially from South Australian publicists) as a possible maritime outlet for that river. It is unfitted for this purpose because its depth is only 5–15 ft. and the seaward approach is over an extremely difficult shifting sand bar. Later interest centred on the possibility of reclaiming portions of the lakes for agriculture. In 1940 barges were built at the entrance to prevent the intrusion of salt water, which in times of drought penetrated well upstream. With increasing freshness, irrigation is developing along the estuarine shores. However, the lake's main interest may remain geomorphological. (O. H. K. S.)

ALEXANDRINE VERSE. The Alexandrine is the leading measure in French poetry, and consists of a line of 12 syllables, rhyming in alternate masculine and feminine couplets. The name probably derived from the early use of the verse in the *Roman d'Alexandre*, a collection of romances compiled in the 12th century, of which Alexander of Macedon was the hero. Application of the name has been traced back to a text of 1432: "*sont dites telles lignes alexandrines pour ce que une ligne des fais du roy Alexandre fu fait de ceste taille.*" Rarely used until the Renaissance, the Alexandrine was deliberately cultivated by the poets of the Pleiad (*q.v.*), especially Ronsard, and it has been said that three-quarters of French verse written after 1600 is in this measure.

The reason would seem to lie in the adaptability of the Alexandrine to a wide range of subjects and feelings. It has been condemned by foreign critics as monotonous. Walter Savage Landor compared its regular beats to "the handle of a pump" and said that the caesura "split it down the back like a mackerel." This is to ignore its structural metrical principle. It is based not on accentual feet, as is English verse, nor on quantitative feet as in Latin, but on stress according to the sense. There is indeed in the regular form of the line a caesura after the sixth syllable, but the secondary stress within each group of six can be on any syllable, and the charm of the Alexandrine to a French ear consists largely in this variety. Thus what Landor thought to be invariably 6:6 may be any two divisions of six: e.g., 1,5:2,4, as in *Ah, ne puis-je savoir si j'aime ou si je hais*; 3,3:4,2, as in *Voulez-vous que je dise? Il faut qu'enfin j'éclate*; or even 1,5:5,1, as in *Rien ne me verra plus, je ne verrai plus rien*. Six syllables is as it happens a normal breath group. (A passage of prose by Bossuet has been analyzed into the normal pauses of a reading voice and yields the following consecutive groups of syllables: 6,6,7,4,4,6,3,7,5,5,8,7.) Thus the two halves of the Alexandrine lend themselves equally well to plain and ornate statement. The line may be made up of two short prose statements; e.g., *Il ouvre un large bec, laisse tomber sa proie*. But in the hands of a poet the 12 syllables can be used to suggest all the emotions, from the sensuous *Tout m'afflige et me nuit et conspire à me nuire*, to the grand definition of an attitude, *Rome n'est plus dans Rome, elle est toute où je suis*, or Victor Hugo's description of the guard's last fight, *Puis à pas lents, musique en tête, sans fureur . . . La garde impériale entra dans la fournaise*.

The last example shows that even the caesura is not the fetter that quotations from Boileau have suggested. The classical French poets occasionally, and the 19th-century poets frequently, wrote a three-part line, known as *vers romantique* or *trimètre*: *Il vit un oeil tout grand ouvert dans les ténèbres*. Paul Verlaine perhaps went furthest in this loosening of structure: *Lamentable ami qui me cherches O3 je suis*.

The secret of the Alexandrine can perhaps be related to what may be described as the French approach to life: its greatest effects are those of balance, contrast, synthesis. The single line, it has been said, can be used to express logical form, tragic tension or unlimited suggestion. It is perhaps not surprising that it has not often been successfully used as a continuous form outside France. Michael Drayton (1563–1631) used it for his long topographical poem, *Polyolbion*, as did Browning for the shorter *Pifñe at the Fair* (1872), and Robert Bridges in his *Testament of Beauty* (1927–29). It has also been successfully used, notably by Dryden, as an occasional variant in heroic and blank verse, and is perhaps seen at its best in English poetry as the concluding line of the Spenserian stanza. (W. G. ME.)

ALEXANDRISTS, the name given to those Renaissance philosophers who, in the controversy about personal immortality, followed the explanation of Aristotle's *De Anima* given by Alexander (*q.v.*) of Aphrodisias. The orthodox Thomism of the Roman Catholic Church maintained that Aristotle, who regarded reason as eternal, also regarded it as a faculty of the individual soul and so could be cited as believing the individual soul to be immortal. The Latin Averroists, on the other hand, evolved a doctrine of universal, as opposed to individual, immortality, holding the individual intellect to be reabsorbed after death into the eternal intellect which had been individualized in it. The Alexandrists, however, led by Pietro Pomponazzi (*q.v.*), denied that either the Thomist or the Averroist view could justly be attributed to Aristotle. Instead they held that Aristotle considered the soul as a material and therefore a mortal entity, operating during life only under the authority of universal reason and organically connected with the body, on the dissolution of which it would become extinct. See also AVERROISM, LATIN.

ALEXANDRITE, a variety of chrysoberyl (*q.v.*) discovered in the Urals in 1833, on the day set apart for celebrating the majority of the Russian tsarevitch, afterward the tsar Alexander II, in whose honour the stone was named. It is remarkable for being strongly dichroic (that is, exhibiting different colours depending on the direction from which it is viewed), generally appearing dark green by daylight and raspberry red by artificial light or by daylight transmitted through the stone. As red and green were the military colours of Russia, the mineral became highly popular as a gem stone.

ALEXANDROUPOLIS (Turkish DÉDÉAGATCH), a seaport of western Thrace, Greece, lies 10 mi. N.W. of the Maritza (Evros, Meriç) estuary, on the gulf of Enos (Enez), an inlet of the Aegean sea. Pop. (1951) 16,632. Its Turkish name is derived from the settlement there of a Dervish community of the Dédé sect in the 15th century, but it remained a mere fishing village until 1871, when the products of its valonia oak woods were first marketed. The opening of the Istanbul–Salonica railway in 1896 increased its prosperity, but it was for a long time a bone of contention between Greece and Bulgaria. After the Balkan War in 1913 the town was ceded to the Bulgarians and provided them with an outlet to the Aegean sea until the end of World War I. The peace treaty granted it to Greece, and by the treaty of Lausanne (1923), which gave Enos to Turkey. Alexandroupolis became a Greek frontier town on the Maritza river. In 1941 it was again occupied by Bulgarian troops but was restored to Greece in 1944. It is now the seat of the metropolitan bishop of Alexandroupolis–Samo-thrace, capital of Evros nome, and forms one of the principal centres of the import trade of mainland Greece; its chief export is tobacco. (D. M. N.)

ALEXIS (ALEKSEI MIKHAILOVICH) (1629–1676), tsar of Russia from 1645 to 1676, was born in Moscow on March 20 (new style; March 10, old style), 1629, the son of the first Romanov tsar, Michael. He came to the throne at the age of 16, having received a superficial education in reading, writing and church singing from his tutor, Boris Ivanovich Morozov. During the first three years of Alexis' reign, Morozov (who in Jan. 1648 became the tsar's brother-in-law) was actually in charge of affairs of state, but his friendship with foreign merchants and the government's attempt to raise revenue by increasing the salt tax led, in the summer of 1648, to violent popular disturbances in Moscow.

Alexis was compelled to grant most of the rebels' demands, to exile Morozov and to convene a land assembly (*zemski sobor*), which in 1649 produced a new code of laws (*ulozhenie*) for Russia. There were further disturbances, however, in Pskov, Novgorod and other cities in 1650. Morozov's place as the court favourite was taken first by Prince N. Odoevski and then by the metropolitan Nikon (*q.v.*). Russia accepted sovereignty over the Dnieper Cossacks in Jan. 1654 and, in the following May, entered into a drawn-out war with Poland. This also involved a conflict with Sweden from 1656, terminated by armistice in 1658 and by the peace of Kardis in 1661. By the treaty of Andrussovo (Jan. 1667), which ended the Polish war, Russia gained Smolensk, Kiev and the lands lying east of the Dnieper river.

Perhaps the most momentous event of Alexis' reign was the church schism. The tsar backed Nikon's efforts to revise Russian liturgical books and certain rituals which in the course of the preceding century had departed from their Greek models. Although before long he became estranged from Nikon, whose violent temper and authoritarian inclinations had earned him many enemies, the revisions which Nikon initiated were retained, and the opponents of the reform were excommunicated. After the disgrace of Nikon, A. L. Ordyn-Nashchokin (*q.v.*) was the tsar's principal adviser till A. S. Matveev took his place in 1671.

The reign of Alexis was characterized by some important legislative activity—the effects of which, however, were often unintentional. The duties and obligations of each estate of the realm were firmly defined; the peasants were tied to the land and to the landlord and thus finally enserfed; the land assemblies were allowed to fall into gradual disuse; the professional bureaucracy and regular army grew in importance. Foreign influences also began to crack the hitherto fairly solid wall separating Russia from its Roman Catholic and Protestant neighbours. Dissatisfaction with the reign centred in the cities (which chafed under the competition of foreigners and of the tax-free groups of the population) and in the peasantry (which was deprived of the last vestiges of freedom). The social dissatisfaction expressed itself in frequent rebellions, the most savage of which was the rising on the eastern borderlands led by Stepan Razin (*q.v.*) from 1667 to 1671. In general, the "middle classes"—the gentry and the wealthy merchants—fared best under this administration.

Virtually all the sources agree that Alexis was a gentle, warm-hearted and popular ruler. He was extremely pious and attached great importance to the strict fulfillment of all churchly (as well as courtly) rituals, so much so that some contemporaries called him a "little monk?"; but there is also evidence that his religious sentiment had a deeper, more spiritual foundation. He was generous to his friends and, though occasionally short of temper, tended to err rather on the side of kindness. He liked falconry (for which he wrote a manual) and the theatre, which he introduced to the Russian court. By Russian standards of the time he was fairly well-read; his numerous extant writings display an unsophisticated humour and homespun philosophy. His main fault, in the opinion of contemporaries, was indolence. Indeed, through most of his reign matters of state were handled by favourites. Platonov characterizes Alexis as "interesting and pleasant, but more virtuous than effective."

He was married twice, first to Maria Ilinishna Miloslavskaya (who bore him two sons, the future tsars Fedor and Ivan, as well as several daughters), then to Natalia Kirillovna Naryshkina, whose son became Peter the Great. Alexis died in Moscow on Feb. 8 (N.S.; Jan. 29, O.S.), 1676.

See R. Nisbet Bain, *The First Romanovs* (1905); S. F. Platonov, *Tsar Aleksei Mikhailovich* (1913). (R. E. PR.)

ALEXIS (ALEKSEI PETROVICH) (1690–1718), Russian tsarevich, son of Peter the Great and the tsaritsa Eudoxia (*qq.v.*), was born on Feb. 28 (new style; Feb. 18, old style), 1690. In 1698 Peter obliged Eudoxia to take the veil, and Alexis was temporarily entrusted to the tsarevna Natalia Alekseevna. Baron Heinrich von Huyssen was appointed tutor to the tsarevich in 1702, but the ambitious curriculum drawn up by him was never put into practice. In 1704, during the Great Northern War, Alexis took part in the siege of Narva. After the capture of the fortress from the

Swedes. Peter warned Alexis that he would disown him if he did not act in conformity with his wishes. Most of the next five years Alexis spent at Preobrazhenskoye near Moscow. Under the influence of a coterie centred round his confessor, Yakov Ignatiev, Alexis' estrangement from his father turned to hostility. In 1707, re-enlisted in Peter's service, Alexis took charge of fortifying Moscow against a possible Swedish attack. Though he showed administrative competence and worked conscientiously, Peter reproached him with lack of zeal. In Oct. 1709 he was sent to Dresden in Saxony to complete his education. His marriage with Princess Sophia Charlotte of Brunswick-Wolfenbüttel took place at Torgau in Oct. 1711. Alexis' frequent absence at the wars and his growing attraction to drink made the marriage an unhappy one, and the princess died on Nov. 2 (N.S.; Oct. 22, O.S.), 1715, ten days after giving birth to the future Peter II. On Nov. 8 (N.S.; Oct. 23, O.S.) Peter the Great's second consort, the future empress Catherine I, also gave birth to a son. On the previous day Peter had handed Alexis a letter accusing him of persistently burying his talents and calling on him to mend his ways or forfeit his right to the succession. Alexis chose the latter course, but Peter, knowing how strongly Alexis was imbued with the spirit of old Muscovy, as opposed to the westernization that the tsar was sponsoring, declared that he could not accept Alexis' renunciation, since one day the clergy might persuade him to change his mind and use him as their tool: Alexis should therefore reform or become a monk. The order to make his final decision followed in Sept. 1716. Leaving Russia for Austria with his mistress Afrosinya and a few servants, Alexis in November arrived in Vienna and placed himself under the protection of the Holy Roman emperor Charles VI, who gave him sanctuary first in the Tirolean fortress of Ehrenberg and later in the castle of Sant' Elmo near Naples. In Oct. 1717 Count P. A. Tolstoi, on Peter's instructions, prevailed on Alexis to go back on the understanding that he would be pardoned and allowed to marry Afrosinya. On Feb. 11 (N.S.; Jan. 31, O.S.), 1718, he arrived in Moscow. Three days later Peter qualified his promise with new conditions: Alexis must forswear the succession and denounce those who had assisted his flight. This done, the trial of Alexis' partisans began on the following day. The investigation, conducted with the utmost cruelty, revealed the existence of a potential movement of reaction for which Alexis might become a rallying point. On March 26 and 28 (N.S.) the principal accused were put to death; on March 29 Peter moved to St. Petersburg, taking Alexis with him. In mid-April Afrosinya was questioned and confronted with Alexis by Peter himself. In the tsar's eyes, Alexis' daydreams of his father's death, of rebellion aided by the Austrians and of a return to the Muscovite way of life amounted to high treason and released him from his promise of clemency. On June 28 Alexis was forced to confess his guilt before the senate. During the following week he was tortured and questioned; on July 4 a special tribunal condemned him to death; and on July 7 (N.S.; June 26, O.S.), 1718, he died in the SS. Peter and Paul fortress, in all probability under the knout.

See A. Briickner, *Der Zarewitsch Alexei* (1880). (L. R. LR.)

ALEXIS (4th–3rd century B.C.), Greek poet of the Middle and New comedy, is said to have been Menander's uncle and to have written 24½ comedies, of which 130 titles are preserved. The fragments (about 1,000 lines) attest his wit and poetic talent. Born at Thurii, he became a citizen of Athens. According to Plutarch he lived to the age of 106 and died on the stage while being crowned.

For the fragments of his work see T. Kock, *Comicorum atticorum fragmenta* (1880–88).

ALEXIS, WILLIBALD (pseudonym of GEORG WILHELM HEINRICH HÄRING) (1798–1871), a versatile and prolific German writer and critic best known for his historical novels. Born at Breslau on June 29, 1798, from his boyhood he lived in Berlin, where he attended the *Friedrich Werdersche Gymnasium*. After service as a volunteer in the campaign of 1815, he studied law at Berlin and Breslau, but abandoned his legal career for writing after the success of his literary hoax *Walladmor* (1824), an amusing parody of Scott published as "freely translated from the English of Walter Scott." The joke, detrimental to Alexis' literary

reputation, was repeated in the more ambitious and original novel *Schloss Avalon* (1827). Although his home was in Berlin, where he edited the *Berliner Konversationsblatt* (1827–35) and contributed essays and reviews to literary journals, he traveled widely in Europe and recounted his experiences in some readable travel books; e.g., *Herbstreise durch Skandinavien* (1828).

With *Cabanis* (1832), a story of the age of Frederick the Great, Alexis embarked on a cycle of novels with the aim of making known forgotten but significant periods of Prussian history. He was not content to abide by Scott's formula for the historical novel and was continually experimenting with methods of presentation. *Der Roland von Berlin* (1840) portrays the struggle for power in the 15th century between the municipal authorities of Berlin-Kölln and the ruler of Brandenburg; *Der falsche Wolde-mar* (1842) the rise and fall of a pretender a century earlier. In the first part of *Die Hosen des Herrn von Bredow* (1846–48) Alexis reveals outstanding qualities as a humorist and is unusually successful in organizing his material. The concluding section, describing the elector Joachim's ineffectual opposition to Luther's teaching, strikes a more serious note. Diffuseness spoils *Ruhe ist die erste Bürgerpflicht* (1852), in which the activities of criminals are presented as symptomatic of Prussian degeneracy in 1806. The sequel *Isegrim* (1854) foreshadows a rebirth of patriotism.

Alexis was the first writer to reveal the poetic aspects of the Brandenburg landscape. His writing is uneven, passages of effective realistic description alternating with others in which romantic mystification predominates. His stories, poems and dramas are largely derivative. From 1842 until 1860 he edited, almost singlehanded, a remarkable collection of famous lawsuits, *Der neue Pitaval*. In 1856 he suffered a stroke and later retired permanently to Arnstadt in Thuringia, where he died, Dec. 16, 1871.

Alexis' novels were published as *Vaterländische Romane*, edited by L. Lorenz and A. Bartels (1912–25). His *Erinnerungen* ("Memoirs") were edited by M. Ewert (1900).

See L. H. C. Thomas, *The Life and Work of Willibald Alexis* (1952); *Goedekes Grundriss zur Geschichte der deutschen Dichtung*, vol. ix (1910), vol. xiv (1955). (L. H. C. T.)

ALEXIUS I (ALEXIS COMNENUS) (1048–1118), Byzantine emperor from 1081 to 1118, was the third son of John Comnenus and nephew of Isaac I Comnenus, emperor 1057–59. Under Romanus IV Diogenes (1068–71) Alexis served with distinction against the Seljuk Turks. Under Michael VII Ducas (1071–78) and Nicephorus III Botaniates (1078–81) he was also employed, along with his elder brother Isaac, against rebels in Asia Minor, Thrace and Epirus. The Comneni, however, belonged to the military magnates who were opposed to the ineffective rule of the civil aristocracy, and, when Nicephorus III (though of the military nobility) proved incapable of restoring order, Alexis Comnenus emerged successful in the competition for the throne. In this he was supported by his brother Isaac and by his mother Anna Dalassena; he then placated the powerful Ducas family by marrying Irene Ducas. Nicephorus abdicated and Alexis I was crowned on April 4, 1081.

Alexis found the empire faced with disaster on all sides. In 1081 the Normans of southern Italy, led by Robert Guiscard, attacked Greece. They took Corfu and Durazzo and advanced in Epirus, Thessaly and Macedonia. With Venetian help, Alexis halted them, and the danger was temporarily removed by Robert's death (1085). On the northern frontier the empire was constantly threatened by the Pechenegs, who raided the Balkans and were supported by the dualist sects there, especially the Bogomils. In 1091 a crushing defeat was inflicted on the Pechenegs at Mt. Levunion (near Enos) in Thrace, with the help of their rivals, the Kumans. In the east Alexis faced the Seljuk Turks, who occupied the greater part of Asia Minor, but he had already come to terms with Sulaiman of Iconium (Konya) in 1081, and in 1091, by skilfully utilizing Muslim rivalries, he made a treaty with the latter's son Kilij Arslan. By 1095 Alexis could consider taking the offensive, but at this point he encountered his greatest danger, the first crusade (see CRUSADES).

Alexis had always been willing to use western mercenaries,

but he had not visualized an independent feudal force, nor an undisciplined pilgrim rabble such as accompanied Peter the Hermit. The crusaders came through Constantinople, where Alexius exacted from the western lords an oath of allegiance and a promise to restore former Byzantine territory. In the event, Alexius recovered control over much of western Asia Minor (as Nicaea, Smyrna, Ephesus and Sardis), but not over the Latin principalities established in Syria and Palestine. The real contention arose over Antioch, which was in the hands of Robert Guiscard's son Bohemund, the bitter enemy of Byzantium. Advancing toward Antioch, Alexius captured Adana, Tarsus and Mamistra, as well as towns farther south on the Syrian coast. Bohemund, under pressure both from the Byzantines and the Turks, returned to Italy, where he spread false reports of Alexius' perfidy toward the Latin crusaders. He then launched an offensive against the Byzantine empire, attacking Avlona (Vlone or Valona in Albania) in 1107, but was defeated by Alexius and forced to agree to the treaty of Devol (1108) whereby he recognized Alexius as overlord of Antioch. This treaty was not implemented. Alexius, however, had steadily restored Byzantine prestige and recovered much lost territory.

At home Alexius vigorously opposed the widespread dualist heresy of the Bogomils; he also had the scholar John Italus tried for heresy, perhaps from political motives. He tried to stabilize the currency and to build up Byzantine trade, but was forced to grant substantial trading privileges to Venice in return for naval help. He made no attempt to curb the great landed magnates. His reign appears to have seen the first instance of a grant in *pronoia* (see BYZANTINE EMPIRE) in return for military service. Alexius resisted the efforts of his wife Irene and his daughter Anna Comnena to get him to recognize the latter's husband Nicephorus Bryennius as his successor instead of his son John. He was an able general and a distinguished diplomat but could not permanently restore the Byzantine empire, though he temporarily checked its enemies.

ALEXIUS II (ALEXIUS COMNENUS) (1169-1183), Byzantine emperor from 1180 to 1183, was the son of Manuel I Comnenus and Mary, daughter of Raymond, prince of Antioch. When his father died on Sept. 24, 1180, he became emperor at the age of 11, with his mother as regent. She unwisely entrusted the government to her favourite, the unpopular and incapable Alexius (Manuel's nephew), who had the title *protosebastus*. She was hated as a Latin, and there was widespread opposition to this regime, but the conspirators, including Alexius II's sister Mary and her husband John, failed to overthrow the regency. The victory lay with Andronicus I Comnenus, Manuel I's cousin, who advanced through Asia Minor and was waiting at Chalcedon when anti-Latin riots broke out in the capital (May 1182). The *protosebastus* Alexius was captured and blinded, and Andronicus entered the capital as the protector of Alexius II. He promptly had his opponents executed, including the dowager-empress Mary, whose death warrant her son Alexius had to sign. Crowned co-emperor in Sept. 1183, Andronicus soon after had Alexius strangled. He subsequently married Alexius' young widow Agnes, daughter of Louis VII of France.

See G. Ostrogorsky, *History of the Byzantine State* (1956). (J. M. Hy.)

ALEXIUS III (ALEXIUS ANGELUS) (d. 1211 or later), Byzantine emperor from 1195 to 1203, was the second son of Andronicus Angelus, grandson of Alexius I. In 1195 he was proclaimed emperor by the troops; he captured his brother, the emperor Isaac II, at Stagira in Macedonia and had him blinded and imprisoned. Crowned in April 1195, Alexius III was a weak and greedy emperor and his coup *d'état* had disastrous results. Byzantine prestige declined in the Balkans, where his failure to aid his son-in-law Stephen Nemanya obliged the latter to turn to the Bulgars for help. Byzantine campaigns against the Bulgars ended in defeat (1195 and 1196), and intrigues and diplomacy were equally unsuccessful since the new Bulgarian ruler Kaloyan acknowledged

the pope's supremacy instead of that of Constantinople. Then the Hohenstaufen emperor Henry VI had designs on the Byzantine empire and had to be bought off by the heavy "German" tax. So depleted were imperial resources that Alexius was reduced to despoiling the imperial tombs of their ornaments.

The danger from the west was only temporarily postponed by Henry VI's death (1197). Shortly afterward the fourth crusade was launched (see CRUSADES). One factor which contributed to its diversion to Constantinople was an appeal for help from Isaac II's son Alexius, who had escaped to Philip of Swabia, his brother-in-law. In 1203 the crusaders succeeded in restoring Isaac II and his son (now crowned Alexius IV). Alexius III fled from the capital with what treasure he could collect and escaped to Mosynopolis in Thrace.

After an unsuccessful attempt to recover the throne he wandered about Greece and surrendered to Boniface of Montferrat, then master of a great part of the Balkan peninsula, but left his protection and then sought shelter with Michael Angelus, despot of Epirus. Finally he went to Asia Minor, where his son-in-law Theodore Lascaris was holding his own against the Latins. Alexius, joined by the sultan of Iconium (Konya), demanded Theodore's crown and, when it was refused, marched against him. Taken prisoner by Theodore in 1210, he was sent to a monastery at Nicaea, where he died on some date unknown.

BIBLIOGRAPHY.—J. M. Hussey in *Cambridge Medieval History*, new ed., vol. 4, ch. 4 (1963); G. Ostrogorsky, *History of the Byzantine State* (1956); E. Pears, *The Fall of Constantinople, being the Story of the Fourth Crusade* (1885). (J. M. Hy.)

ALEXIUS IV (ALEXIUS ANGELUS) (d. 1204), Byzantine emperor from 1203 to 1204, was the son of the emperor Isaac II, whom Alexius III dethroned and blinded in 1195. Alexius IV, however, escaped in 1201 to Germany, where he persuaded his brother-in-law, Philip of Swabia, and Boniface of Montferrat, the leader of the crusaders, to divert the fourth crusade to Constantinople (see CRUSADES). In Aug. 1203 Isaac was restored, with Alexius IV as joint emperor, but they were unable immediately to fulfill the promises made to the crusaders to contribute men and money for the expedition to Jerusalem and to bring about the reunion of the Greek and the Latin church. At the beginning of 1204 quarrels broke out between the crusaders and the Greeks, who revolted under the leadership of Alexius Ducas Murtzuphlus, Alexius III's son-in-law. Proclaimed emperor as Alexius V in Jan. 1204, Murtzuphlus had Alexius IV strangled, while Isaac died of shock. On April 9 the crusaders stormed and captured Constantinople and elected Baldwin of Flanders as Latin emperor.

See G. Ostrogorsky, *History of the Byzantine State* (1956); E. Pears, *The Fall of Constantinople, being the Story of the Fourth Crusade* (1885). (J. M. Hy.)

ALEXIUS V (ALEXIUS DUCAS MURTZUPHLUS) (d. 1204), Byzantine emperor in 1204, was related to the imperial family of Ducas and was a son-in-law of Alexius III Angelus, who had been deposed in 1203. He was brought to the throne late in Jan. 1204 by the revolution of the Greeks against Isaac II and Alexius IV, who owed their crowns to the Latins of the fourth crusade. As leader of the anti-Latin party in Constantinople, he conducted its defense with great bravery. When it became hopeless he fled (April 12) and joined the fugitive Alexius III, who blinded him. He was then captured by the crusaders, who put him to death as the murderer of Alexius IV by casting him from the top of a column in Constantinople.

See G. Ostrogorsky, *History of the Byzantine State*, Eng. trans. by J. M. Hussey (1956). (D. M. N.)

ALFA or **HALFA**: see ESPARTO.

ALFALFA (LUCERNE or PURPLE MEDICK), known botanically as *Medicago sativa*, is a leguminous forage plant famed in the regions of its adaptation for its tolerance of drought, heat and cold; for the remarkable productivity and the quality of its herbage; and for its incidental value in soil improvement. It is grown primarily for hay, pasturage and silage. The plant is an erect, long-lived, tap-rooted, perennial herb with numerous thin, hollow and branching stems arising from a much-branched crown which is partially embedded in the surface layer of soil. As the

plant develops, numerous stems bearing many trifoliolate leaves arise from the crown buds and attain lengths of from one to five feet. Racemes of small flowers arise from the upper axillary buds of the stems. The flowers of all commercial varieties are predominantly purple. This is particularly true of the types grown in Russian Turkistan and the regional strains of common alfalfa grown in North and South America. However, from 5% to 40% of variegated and yellow flowers occur in such well-known hardy commercial varieties as Vernal, Grimm, Cossack, Ladak and Canadian variegated. These were derived from crosses between the purple *M. sativa* and the wild yellow-flowered species, *M. falcata*. With approaching maturity, coiled pods containing from two to eight or more seeds develop abundantly in regions with much sunshine, moderate heat and dry weather.

Growth Characteristics.— The primary root of alfalfa attains great depths. When 20 or more years of age, this tap root may descend as much as 50 ft. or more where the subsoil is porous. This accounts for the unusual ability of the plant to tolerate drought. The roots of seedling plants are known to penetrate the soil for three feet at two months, and for six feet with plants five months of age. Not infrequently, newly established fields of alfalfa survive severe summer drought and heat when stands of red, alsike and white clover, and other members of the genus *Trifolium* may succumb, partly because the roots are much shallower and more branching.

Alfalfa has remarkable capacity for rapid and abundant regeneration of dense growths of new stems and leaves following cutting. This makes possible from one to as many as 13 crops of hay in one growing season. The frequency of harvest and the total seasonal yields are dependent largely on the length of the growing season, the adaptability of the soil, the abundance of sunshine, and especially the amount and distribution of rainfall or irrigation during the growing season. On nonirrigated lands, yields of from two to four tons per acre are common, but with long growing seasons and with irrigation as much as ten tons of dry hay per acre are obtained. Green leafy alfalfa hay is very nutritious and palatable, containing about 16% proteins and 8% mineral constituents. In addition it is rich in vitamins A, E, D and K.

Although alfalfa is highly tolerant to drought and heat, it utilizes very large quantities of water to produce forage. A yield of three tons of dry herbage per acre requires the absorption by the roots from the soil of approximately 2,490 tons of water, the equivalent of about 22 in. of rainfall. Such heavy utilization of water greatly reduces the reserves of subsoil moisture and yields may decline markedly unless the moisture supply is replenished adequately by rainfall, surface irrigations or subirrigation. Most all water utilized for growth is lost in transpiration, being evaporated through the leaf pores or stomates after passage through the stems and the veins of the leaflets. In the course of growth, some of the water is combined with carbon dioxide in the synthesis of sugar and numerous other organic compounds, of which the dry matter of the plant is largely constituted.

Although a native of the old world, the acreage of alfalfa occurs primarily in the western hemisphere. Estimates vary, but in the second half of the 20th century more than 60,000,000 ac. of alfalfa were ordinarily grown in the world each year, of which nearly 50% was grown in the United States and about 40% in Argentina.

History of Cultivation.— It is likely that alfalfa had its origin in the dry, hot regions east of the Mediterranean. It occurs in the wild state in the Transcaucasian mountains of southern U.S.S.R. with many other species of *Medicago*. Historically alfalfa has been grown for a longer period for forage than any

other plant. Incident to the invasion of Greece it was introduced into that country by Medes and Persians about 400 B.C. It was grown extensively in Italy in the 1st century and the Romans introduced it into other parts of Europe. It is probable that the Moors also introduced alfalfa into Spain. It was the Spaniards who, coincident with their lure for gold, brought alfalfa to the new world, having introduced it into South America in the 16th century.

Alfalfa was introduced into eastern United States by the early colonists. George Washington and Thomas Jefferson attempted to grow it, but its culture met with but little success in this humid region with its leached and highly acid soils. In only a few areas of the eastern states, where soils derived from limestone were abundant in mineral residues, did the culture of alfalfa persist. While alfalfa may have been introduced into southwestern United States from Mexico through Spanish influence, it was the discovery of gold in California in 1848 which gave alfalfa culture its great impetus in the western states. The gold seekers from the eastern states brought alfalfa from Chile to California in 1854 where it became known as "Chilean clover" and later as Spanish or common alfalfa. Subsequently, alfalfa culture spread through the west as this vast territory was settled by the migrations of settlers from the eastern states.

In the western states, with arid or semiarid climates, soils were high in mineral residues containing calcium, phosphorus and potassium compounds and other sources of nutrients which are requisites for successful alfalfa culture. In addition, the climate with its abundant sunshine and favourable winters was, in the main, ideal for alfalfa culture. It is not surprising, therefore, that alfalfa culture was predominantly a western enterprise for more than 70 years after its introduction into California in 1854. In 1899, 2,000,000 ac. of alfalfa were harvested for hay and 97% of this was grown in the 17 western states, Nebraska, California, Kansas, Idaho, Oregon, Washington, Nevada, Utah, Arizona, New Mexico, Colorado, Wyoming, Montana, North and South Dakota, Oklahoma and Texas. In 1929 the total acreage of alfalfa harvested for hay was 11,500,000 ac., of which 71% was grown in the aforementioned western states. By this time, however, extensive researches, demonstrations and experience had established clearly the significant fact that alfalfa could be grown successfully in the northern humid states by adjusting the soil environment with applications of various forms of lime and of phosphate and potash fertilizers. These practices, along with the development of artificial cultures for the inoculation of seed with nitrogen-fixing bacteria; the improvement of seeding techniques; the establishment of proper managerial practices; and the utilization of winter-hardy varieties such as Vernal, Ranger, Narragansett, Grimm, Canadian variegated, Cossack and Ladak instead of the less hardy regional strains of American Common, presaged the remarkable eastward expansion of alfalfa culture. As a consequence, by mid-century the central states—Minnesota, Wisconsin, Michigan, Iowa, Illinois, Indiana, Ohio, Kentucky and Missouri—grew approximately 43% of the 28,000,000 ac. grown for hay in the U.S. compared with 45% for the 17 western states and 12% for the remaining eastern and southern states.

Alfalfa culture is widely distributed throughout the nations of the world, and particularly where arid and semiarid climates and irrigation prevail. In a sense, alfalfa is a crop par excellence for drylands. Its culture, however, increased in humid regions in the 20th century.

Diseases and Insects.— Like all crops, alfalfa is beset with hazards of climate, diseases and insects. Among the more serious of these are winterkilling, bacterial wilt disease, grasshoppers, spotted aphid and leafhoppers. In the humid and in the irrigated areas, stands three or more years of age have often become badly thinned by the infections from the soil-borne bacterial wilt organism, *Phytophthora infestans*. Severe damage is caused periodically by winter manifestations of the humid areas such as enduring and contacting sheets of ice, or protracted periods of extremely cold weather without the insulation of snow or vegetative cover or both, or long periods of alternate freezing and thawing which on heavy, water-saturated soils lift or "heave"

the plants, exposing the crown to harmful aerial temperatures and desiccation. Such losses are greatly reduced through the selection of soils with good surface and underdrainage; through managerial treatments; and by the use of winter-hardy and wilt-resistant varieties such as the new synthetic varieties, Vernal and Ranger. Orestan, Ladak and Cossack alfalfas are winter-hardy and moderately resistant to wilt but Grimm and Canadian variegated, while winter-hardy, are very susceptible to the wilt disease. The tiny leafhoppers, *Empoasca fabae*, which cause stunting and yellowing of summer growths of alfalfa in warm humid areas, may be controlled by cutting management under some conditions.

ALFARO SIQUEIROS, DAVID: see SIQUEIROS, DAVID ALFARO.

ALFASI (AL-PHASI), **ISAAC BEN JACOB** (1013–1103), Jewish rabbi and codifier, known as Rif from the initials of Rabbi Isaac Fasi, was born near Fez, in north Africa, and died at Lucena, Spain.

His fame rests on his talmudic digest, which omitted all homiletical passages and also passages relating to religious duties practicable only in Palestine. He occupies an important place in the development of the Spanish method of studying the Talmud (*g.v.*). As opposed to the French rabbis, the Spanish sought to simplify the Talmud, and to free it from casuistical detail. Alfasi's digest was the forerunner of the great codes of Maimonides and of Joseph Caro.

ALFIERI, VITTORIO, CONTE (1749–1803), the greatest Italian tragic poet, was born of rich and noble parents at Asti in Piedmont on Jan. 16, 1749. Educated at the military academy of Turin, he left it in 1766 with the rank of ensign. He conceived, however, a strong distaste for the military profession and obtained leave to travel. After a tour of the principal cities of Italy (1766–67), he visited France, England and Holland (1767–68) and then set off, after a few months in Piedmont, to visit Germany, Denmark, Sweden and Russia, then England, Holland and France again and finally Spain and Portugal (1769–72). During these travels he indulged in a number of amorous adventures, several of them leading to duels, one culminating in an attempt at suicide by Alfieri (at The Hague in 1768) and another involving him in a divorce suit (London, 1771). Nevertheless, though much time was wasted in dissipation, he found in England the political liberty that became his ideal and in France the literature that influenced him most profoundly. He studied Voltaire, J. J. Rousseau and, above all, Montesquieu; and his reading confirmed in him that love of freedom and hatred of tyranny which were to dominate his thought.

On his return to Piedmont in 1772, Alfieri settled in Turin, where he continued his life of dissipation. After an illness at the end of 1773 he resigned his commission. Then, in 1774, to divert himself, he began to compose a play. The result was *Cleopatra*, a tragedy, which was performed with great success in 1775. Thereupon Alfieri, who had serious misgivings about the merit of his first work, decided to devote himself to literature.

To the fulfillment of his new ambition he brought all the energy that had previously driven him to wander from city to city in Europe. He began a methodical study of the classics and of the Italian poets and, having been accustomed to express himself mainly in French, the language of the ruling classes in Turin, decided to go to Tuscany to familiarize himself with pure Italian. After a visit in 1776, he returned for a longer stay in 1777. By the end of 1782 he had composed 14 tragedies as well as many poems (including four odes in the series *L'America libera*, on American independence, to which a fifth was added in 1783) and a political treatise in prose, *Della tirannide* (composed in 1777). Ten of the tragedies were printed at Siena in 1783.

Meanwhile, in Florence in 1777, Alfieri had met the countess of Albany, wife of the Stuart pretender to the English throne, Charles Edward. He fell in love with her and remained deeply attached to her for the rest of his life. Renouncing his Piedmontese prop-

erties (1778), he lived first in Florence, then in Rome (1781–83) and then, after a year of separation from the countess, mainly at Colmar in Alsace (1784–86). At the end of 1786 he moved with her to Paris, where a new edition of his tragedies was published (1787–89), containing 19 plays in all.

Alfieri hailed the French Revolution with an ode on the fall of the Bastille, *Parigi sbastigliata* (1789), but the later excesses of the populace disgusted him. After an excursion to England (1791), he and the countess left France in 1792, returning to Florence. Occupied to the last with his literary activity, particularly with his autobiography (which he had begun to write in 1790 and which he continued to the last year of his life) and with his six comedies (begun in 1800), Alfieri died in Florence on Oct. 8, 1803.

The Tragedies.—Alfieri's genius was essentially dramatic. His great aspiration was to act upon the society of his time. He sought to wage war against tyrants and he learned to use his lines of verse as a substitute for weapons. The conciseness of his style, his disdain for euphony and musicality, the power of his jarring words, even his strict adherence to the classical form of tragedy with its "unity of action" and its rejection of subordinate episodes and secondary characters—all are to be explained by his one pre-occupation: to make the Italians accept his political ideas and his philosophy of life, to inspire them to "heroic deeds." Nearly always Alfieri's tragedies present the struggle between a champion of liberty and a tyrant. The hero has all the qualities of the heroes of Plutarch and is generally lost by his loyalty. The tyrant is evil personified, Machiavellian and reminiscent of some character from Tacitus. Love has little place in a world so shaken by political passions.

Alfieri had a systematic and conscientious method of composing his plays. Inspired by a theme, he would first draw up a plan, then draft a text in prose and then versify the text. Even then, the verse might be subjected to recurrent revisions. Moreover, he was usually engaged simultaneously on several works at varying stages of composition. The 19 tragedies which he finally approved for publication in the edition of 1787–89 were *Filippo*, *Polinice*, *Antigone*, *Virginia*, *Agamemnone*, *Oreste*, *Rosmunda*, *Ottavia*, *Timoleone*, *Merope*, *Maria Stuarda*, *La congiura de' Pazzi*, *Don Garzia*, *Saul*, *Agide*, *Sofonisba*, *Bruto primo*, *Mirra* and *Bruto secondo*. The best are *Filippo*, in which Philip II of Spain is presented as a tyrant whose hatred for his liberal-minded son, Don Carlos, is exacerbated by jealousy; *Antigone* and *Oreste*, adaptations of themes handled by ancient Greek dramatists; and, above all, *Mirra* and *Saul*. In *Mirra* Alfieri deals with love, but the love is incestuous. *Saul*, his masterpiece, is the most powerful drama in the Italian theatre. The Godforsaken king of Israel who kills himself on the battlefield is much more than the usual tyrant: his character is a portrait of Alfieri himself and reflects the poet's own rage, the poet's own despair. *Saul* is a forerunner of Byron's heroes.

Other Works.—Alfieri's autobiography, published posthumously as *La vita di Vittorio Alfieri, scritta da esso* (1804), is his chief work in prose. He takes pleasure and pride in portraying his rise from provincial nobleman to poet, and the lifelong conflict between his generous, heroic ambitions and the weaknesses, whims and vanity of the man of the world. Some of his childhood recollections are affecting.

Alfieri's *Rime* (published 1804; mainly sonnets) is also a kind of autobiography, inspired by the various incidents of his life. He reveals lyrical feeling in the sonnets, expressing romantic loneliness, bitter pessimism and melancholy, but his style is always too concise for formal elegance and his prosody too rough to be musical.

In his comedies (*L'uno, I pochi, I troppi, L'antidoto, La finestrina* and *Il divorzio*), and in his 17 satires, Alfieri is concerned with the overthrow of tyrannies, with the defects of the new democracies or with the way in which Italian society should be reformed. These works, however, are less important than the *Misogallo* ("Francophobe"), a collection of epigrams and sonnets, with five prose pieces, chiefly inspired by resentment at the French occupation of Florence in 1799. In a section of the *Misogallo*

Alfieri turns from generalizations about freedom to make a direct appeal to the Italians to recover their own. By that appeal and by many of his lyrics and dramas he helped to revive the national spirit of Italy and so earned the title of precursor of the Risorgimento.

BIBLIOGRAPHY.—For Alfieri's complete works see the collected edition by F. Maggini, 2 vol. (1940–41) or the critical edition by L. Fassb, F. Maggini *et al.* (1951–). There are English translations of the *Tragedies* by C. Lloyd (1813) and ed. by E. A. Bowering (1876) and of the *Life* by Sir Henry McAnally (1933). See also E. Bertana, *Vittorio Alfieri studiato nella vita e nel pensiero e nell'arte* (1903); B. Croce, *Poesia e non poesia* (1935); C. R. D. Miller, *Alfieri: a Biography* (1936); M. ALFONSO, the name of five kings of Aragon.

ALFONSO I (c. 1073–1134), called "the Battler," king of Aragon and of Navarre from 1104 to 1134, was the son of Sancho V Ramirez. Alfonso was a single-minded man of action and a very successful general, but a poor diplomat. He was persuaded by Alfonso VI of León and Castile to marry the latter's heiress, Urraca, widow of Raymond of Burgundy. In consequence, when Alfonso VI died (1109) the four Christian kingdoms were nominally united and Alfonso I took his father-in-law's imperial title. If the union had succeeded, the reconquest of Islamic Spain might well have been greatly accelerated and the fractionalist tendencies of the Christian-held territories might perhaps have been checked. It failed, however, because León and Castile felt hostility toward an Aragonese emperor; because Urraca disliked her second husband; because Bernard, the French Cluniac archbishop of Toledo, wanted to see his protegee, Alfonso Ramirez (infant son of Urraca and her Burgundian first husband), on the imperial throne; and probably because Alfonso handled all opposition too brusquely. At Bernard's prompting, the pope declared the Aragonese marriage void but Alfonso continued to be involved in civil strife in the central kingdom until he eventually gave up his claims in favour of his stepson after the death of Urraca (1126). Despite these embroilments, he achieved spectacular victories against the Almoravids in the Ebro valley. Saragossa, capital of an important Moorish kingdom, fell to him (1118), as did many other places far to the south of the river. With these victories, Aragon ceased to be a Pyrenean kingdom. In 1125 Alfonso led a spectacular military raid far into southern Andalusia and returned with many thousands of Mozarab immigrants, whom he settled in the newly conquered territories. In his campaigns he received much help from the rulers of the counties north of the Pyrenees, and in 1116 the count of Toulouse became his vassal. This led to the political involvement of Aragon in the affairs of southern France. Alfonso was fatally wounded in battle at Fraga in 1134 and died in September. Despite his hostility to Cluny he was a deeply religious man, a supporter of the Cistercians and of the Templars and Hospitallers, and he bequeathed his kingdom to the two latter orders. His former subjects, however, refused to accept the donation.

ALFONSO II (1152–1196) was born in Barcelona, the son of Ramón Berenguer IV, count of Barcelona, and Petronilla, daughter of Ramiro II of Aragon. He succeeded his father as count of Barcelona in 1162 and his mother as ruler of Aragon in 1164. The two countries thus became associated under the house of Barcelona—a union which was destined to be permanent. Aragonese involvement in France became steadily greater in Alfonso's reign. Nevertheless, the conquest of Teruel (1171) opened the way for the conquest of Valencia and, in 1179, the pact of Cazoria with his ally, Alfonso VIII of Castile, fixed the future zones of reconquest for the two countries. Alfonso died in Perpignan in 1196. In his will he followed the Spanish custom of dividing his kingdom. Provence was thus lost to the Aragonese crown.

ALFONSO III (1265–1291) was the son of Pedro III, whom he succeeded in 1285. A weak king, he was involved in an unsuccessful constitutional struggle with the Aragonese nobles. In 1287 he was compelled to grant the so-called "Privilegio de la unión," which handed over a number of important royal prerogatives in the old kingdom to baronial control. He died in Barcelona, June 18, 1291.

ALFONSO IV (1299–1336) was the son of James II, whom he succeeded on Nov. 2, 1327. He was well-intentioned, but weak. His reign was marked by a serious revolt in Sardinia, which led to war with Genoa, and by the establishment of diplomatic relations with the Moorish kingdoms of north Africa. The failure of the king to resist the efforts of his second wife to further the future of her sons at the expense of Alfonso's heir, Pedro, led to serious political disturbances. Alfonso IV died in Barcelona on Jan. 24, 1336.

ALFONSO V (c. 1396–1458), called "the Magnanimous," was the son of Fernando de Antequera (afterward Ferdinand I of Aragon), whom he succeeded on April 2, 1416. His military campaigns in the central Mediterranean made him one of the most famous men of his day. He subdued the refractory Sardinians (1420) and restored order in Sicily. In 1421 Joan II of Naples, her throne gravely threatened by Louis III of Anjou, made Alfonso her heir. His attempt to make good his claim to Naples involved him in hostilities with the papacy, Louis of Anjou, Genoa, Milan and other Italian rulers, and an immensely complicated diplomatic and military struggle followed in which Alfonso showed masterly understanding of Italian power politics. He was disowned by Joan in favour of René of Anjou and defeated at sea by the Genoese off Ponza (1435), being taken prisoner. He charmed his captor, the duke of Milan, into an alliance and, in 1442, Naples fell to him at last. He transferred his court there permanently in 1443, much to the annoyance of his Aragonese and Catalan subjects. Alfonso certainly established the basis of subsequent Spanish power in Italy and was much admired there for his skill as soldier and politician. Though he was friendly with a number of Italian humanists, the cultural significance of his court at Naples has probably been exaggerated. A restless, energetic person, he kept Italy in turmoil for years and was planning the conquest of Genoa when he died, in Naples, on June 27, 1458. His long absence from the Iberian peninsula was politically disastrous for his dominions there. In his will he left his Italian possessions to his illegitimate son, Ferdinand, so dissolving the empire that he had built up.

(P. E. R.)

ALFONSO, the name of 11 kings of Asturias, León and Castile.

ALFONSO I (693?–757), king of Asturias from 739 to 757, was probably the son-in-law of the first Asturian king, Pelayo. The rebellion of the Berber garrisons in Islamic Spain (741) and the civil strife there which followed gave him the opportunity to incorporate Galicia into his kingdom. He also campaigned far to the south of the Asturian mountains, but lack of manpower made it impossible to exert permanent control on the plains and, in his time, a wide, largely uninhabited no man's land came into being between Asturias and the settled territories of the amirate of Córdoba.

ALFONSO II (c. 759–842), king of Asturias from 791 to 842, was born at Cangas in about 759, the son of Fruela I. He had to face frequent and determined attacks by the armies of the amirate of Córdoba and was often defeated, but his doggedness saved Asturias from extinction. He built a new capital, Oviedo, on a strategic site in the mountains and set about giving the Asturian kingdom a national identity by restoring Visigothic tradition in its administrative and ecclesiastical life. He did not hesitate to make common cause with Muslim rebels against the authority of the amirs. He tried to enter into relations with Charlemagne, but although he seems to have failed to get Carolingian support, there are some traces of Frankish influence in Asturias. During Alfonso's reign the discovery of the supposed tomb of St. James the Apostle in Galicia made the kingdom the guardian of an important Christian shrine and this, too, helped to give it a national identity. Alfonso died in Oviedo in 842.

ALFONSO III (c. 838–910), "the Great," king of Asturias from 866 to 910, succeeded his father, Ordoño I, on May 26, 866. The political troubles in the amirate of Córdoba which followed the death of Mohammed I (886) gave Alfonso his chance to take the offensive. He occupied the line of the Duero, founded Burgos and extended his rule as far east as Osma. These new territories, especially in León, were settled largely by Mozarabic immigrants

from the amirate. His reign saw a further development of neo-Visigothic traditionalism in Asturias, reflected in two contemporary chronicles (*Chronica Visigothorum* and *Crónica Albedense*), which claimed that the rulers of Asturias were direct descendants of the Toledan royal line and stressed their duty to proceed to the early and complete reconquest of Spain. Alfonso, like his predecessors, saw the wisdom of interfering to his advantage in the political troubles of the amirate when he could, and perhaps reached some sort of *modus vivendi* with the amirs themselves in the later years of his reign. He also did much to develop the cult of St. James at Santiago de Compostela. As his successors were so often and so disastrously to do, Alfonso II wished to divide his kingdom between his sons when he died. Given the position of the country in relation to Muslim Spain, this proposal reveals serious limitations in his political vision. As a result of it, his reign ended in internal confusion. He probably died on Dec. 20, 910.

ALFONSO IV (d. 933), king of León and Asturias from c. 926 to c. 931, was the son of Ordoño II and the successor of Fruela II. He became a monk, abdicated and then thought better of it and tried to recover his throne. His short reign was, in consequence, one of political chaos, ending in about 931.

ALFONSO V (994–1028), king of León from 999 to 1028, came to the throne when, because of the devastating campaigns of Almanzor (see MANSUR, AL) against the Leonese kingdom (981–1002), his father, Bermudo II, had been forced to accept Almanzor's de facto suzerainty over León. This position continued under Almanzor's son, Abd-al-Malik al-Rluzaffar. The Leonese were forced to take part in the latter's campaign (1003) against the Catalans, and invited Abd-al-Malik to mediate (1004) in a dispute between Count Sancho Garcia of Castile and Alfonso's tutor, Menendo González. In 1005, supported by the Castilian count, the army of the Córdoba dictator penetrated far into northern León. The latter's death (1007) and the political troubles which continued until the fall of the caliphate (1031) relieved León of Islamic pressure, but Alfonso was soon faced by the growing power of Sancho III of Pamplona (Navarre). His marriage (1024) to Sancho's daughter Urraca ended this threat, and, in the last years of his life, he was able to undertake the reconquest of the Portuguese territories lost during Almanzor's time. He was killed at the siege of Viseu. Lack of adequate sources makes it difficult to interpret Alfonso's character and reign; emergence from subordination to Córdoba seems to have been made possible more by events there than by Leonese military recovery.

ALFONSO VI (c. 1042–1109), king of León from 1065 and of Castile from 1072, was an outstanding personality among medieval Spanish kings. His vision and generalship at last established Christian hegemony in the peninsula. During his reign the isolation from the rest of Europe which had so far characterized the history of León and Castile was abandoned, though not until he had hesitatingly tried the possibility of setting up, under Christian political direction, a mixed Christian and Muslim state. Alfonso was the second son of Ferdinand I. The latter, who died in 1065, partitioned his realm, allotting León to Alfonso, whose elder brother, Sancho of Castile, regarded this as an affront and deposed him by force. Alfonso took refuge at the court of Yahia I, king of Toledo—an experience which gave him expert knowledge of Hispano-Moorish politics. Sancho's death at Zamora (1072) made Alfonso king of León and Castile. By 1077 he had assumed the title *imperator totius Hispaniae* ("emperor of all Spain"), in which role the other Christian kings accepted him. From 1072 to 1086 his military genius dominated Spain, and Toledo, the former Visigothic capital: fell to him (1085). The Moorish kingdom of Saragossa was already under the tutelage of Rodrigo Diaz de Vivar, the Cid, so that the effective frontiers of Muslim Spain were now pushed south of the Tagus. Moreover, the petty kingdoms (taifas) of Moorish Andalusia were forced to recognize his suzerainty and pay him tribute. Alfonso was inclined to grant a wide degree of tolerance toward the religion and culture of his new Islamic subjects—his son and heir was the offspring of his liaison with the daughter of the Moorish king of Seville—but this attitude was frustrated by the antagonism of the French

Cluniac monks, whom the emperor had brought into Spain to reform the Spanish church. Led by Bernard, archbishop of Toledo, these refused to allow toleration and insisted on liturgical and other reforms calculated to approximate Spanish religious life and attitudes more closely to those of the rest of Europe. Alfonso also committed the political error of putting too much financial pressure on the taifa kingdoms. These, in consequence, asked the Almoravid amir of north Africa to come to their aid. In 1086 Alfonso was routed at Sagrajas by an army of fanatical African tribesmen and the rest of his reign became a desperate struggle to survive a series of similar defeats. He was probably saved by the tendency of Almoravid armies to disintegrate when victory had been won, and by their rulers' political incompetence. Only in the east did defeat come to the Almoravids when the Cid captured Valencia (1094). In a new defeat at Uclés (1108) the emperor's heir was killed. It was characteristic of his indomitable spirit that he at once arranged for his daughter, Crraca, to marry Alfonso I of Aragon so that the battle against the Almoravids should be competently continued after his death even if it meant that León and Castile would be ruled by an Aragonese prince.

Alfonso VI was long remembered for his success in establishing the rule of law throughout his dominions. Also very important for Spanish relations with northern Europe was the attention he gave to making the pilgrim road to Santiago both safe and easily passable. He died in Toledo on June 30, 1109.

ALFONSO VII (c. 1104–1157), king of León and Castile from 1126 to 1157, was the son of Raymond of Burgundy and the grandson of Alfonso VI, whose imperial title he assumed. Though his reign saw the apogee of the imperial idea in medieval Spain and though he won notable victories against the Moors, he remains a somewhat hazy figure. His childhood was complicated by the struggle between his mother Urraca and her second husband, Alfonso I of Aragon, for control of Castile and Leon. Only on Urraca's death (1126) did his stepfather finally relinquish his claims. Alfonso was then formally accepted as emperor by the kings of Aragon and Pamplona (Navarre), by the count of Barcelona and by various Hispano-Moorish rulers. His capture of Almeria (1147) from the Moors won him renown, as did other victories, but in the end these led to little expansion of territory. Almeria was lost again in 1157 and Córdoba only remained in his hands for three years. In 1146 a new invasion of north African fanatics, the Almohads, began. Alfonso now allied himself with the Almoravids and devoted the rest of his life to a series of campaigns to check Almohad expansion in southern Spain. Despite the importance of the imperial idea at this time, peninsular fractionalist tendencies were by no means dormant. Alfonso was unable to prevent the establishment of Portugal as an independent kingdom (1140) and, in his will, he himself divided his realm between his two sons, Sancho III of Castile and Ferdinand II of León. This act finally destroyed the concept of empire in medieval Spain. Alfonso VII died in Fresnada in Aug. 1137.

ALFONSO VIII (1155–1214), king of Castile from 1158 to 1214, was the son of Sancho III, whom he succeeded when 3 years old. His minority was troubled by internal strife and Navarrese intervention in Castilian affairs. In 1170 he married the younger Eleanor of Aquitaine, daughter of Henry II of England. His reign was characterized by a close alliance with Aragon and in 1179 he concluded the pact of Cazorra which settled the future line of demarcation between Castile and Aragon when the reconquest of Moorish Spain was completed. In 1188 Alfonso IX of León did homage to him—a dramatic demonstration of the fact that the ancient hegemony of León had now passed to Castile. The main task of Alfonso's reign was resistance to the Almohad invaders who, by 1172, had secured control over almost all the Moorish states. In 1195 they inflicted a great defeat on him at Alarcos while, in collusion with them, the kings of León and Navarre invaded Castile. Alfonso remained calm in this dangerous situation. Aided by Peter II of Aragon, he dealt with León and Navarre, forcing the king of León to marry his daughter and annexing Álava and Guipúzcoa from Navarre. In 1212, at Las Navas de Tolosa, he finally secured a great victory over the Almohad sultan which broke Almohad power in Spain. He died on Oct. 6, 1214.

ALFONSO IX (cousin of Alfonso VIII of Castile and numbered next to him as a junior member of the family) (1171–1230), king of León from 1188 to 1230, was a forceful personality who brought the restless nobles under firm control and favoured the power of the municipalities. His father was Ferdinand II of León. Alfonso IX was determined to recover Leonese territory lost to Castile and, despite the fact that he had done homage to Alfonso VIII, did not hesitate to ally himself with the Almohads to further this end. As a result, his kingdom was placed under papal interdiction and he was finally compelled to marry the Castilian king's eldest daughter. He refused, however, to join his father-in-law in the crusade against the Almohads in 1212 unless the lost lands were first restored by Castile. This was not done and the Leonese army was, therefore, absent from Las Navas de Tolosa. Nevertheless, operating on his own, Alfonso IX won important victories beyond the southern frontiers of León, taking Cáceres (1227) and Mérida and Badajoz (1230) from the Almohads. These victories opened the road for a future reconquest of Seville. He died at Villanueva de Sarria on Sept. 24, 1230.

ALFONSO X (1221–1284), "the Wise," king of Castile and León from 1252 to 1284, was "wise" as a patron of learning and literature but not as a politician. He was born at Burgos on Nov. 23, 1221, the eldest son of Ferdinand III. He was a farsighted lawmaker, as his great corpus of constitutional, civil and criminal law—the *Siete Partidas*—reveals, but his reign was inept. It was dominated by his costly and unpopular attempt to become German king and Holy Roman emperor. In 1257 he was actually elected German king, but the pope refused to accept the election and Alfonso fruitlessly pursued the matter for years. In 1275 his heir, Ferdinand (Fernando de La Cerda), died. According to the *Siete Partidas*, primogeniture had been established in the succession and the king recognized Ferdinand's son, Alfonso, as his successor. His own second son, Sancho, refused to accept this decision and, posing as the defender of the nobles against the crown, took up arms against his father, whose reign ended, with his death in Seville on April 4, 1284, in civil war. Despite these misfortunes he captured Cartagena and Cádiz from the Moors.

ALFONSO XI (1311–1350), king of Castile and León from 1312 to 1350, succeeded his father, Ferdinand IV, when he was only a year old. His minority was marked by violent strife between factions of nobles, but when he came of age (1325) he restored order with unprecedented vigour. He gave new powers to the municipalities and to the *cortes*, in exchange for their support against the nobles, and furthered the power of the crown by choosing officials without aristocratic affiliations. He then turned his attention to the Benemerin kings of north Africa, who had seized Gibraltar and routed the Castilian fleet at Algeciras (1340). He won, with the Portuguese, a great victory over the invaders at Rio Salado (1340) and recaptured Algeciras (1344). On March 26, 1350, after promulgating important administrative and legal reforms in the ordinances of Alcalá de Henares (1348), he died of the plague while besieging Gibraltar. Alfonso was assiduously courted by both France and England, who wished for an alliance which would give them the support of his powerful fleet. He avoided committing himself to either party. Though a highly successful king, Alfonso left his heir, Pedro, an unfortunate legacy—his formidable mistress, Leonor de Guzmán, and a succession of ambitious and powerful bastard sons he had had by her. (P. E. R.)

ALFONSO XII (1857–1885), king of Spain from 1874 to 1885, was born in Madrid on Nov. 28, 1857, the son of Isabella II. After his mother's deposition by the revolution of Sept. 1868, he accompanied her into exile, receiving his education at the Theresianum in Vienna, and at the Royal Military college, Sandhurst, in England. On June 25, 1870, Isabella abdicated her rights in his favour. Four years later (Dec. 29, 1874) Alfonso was proclaimed king of Spain by Gen. A. Martínez Campos at Sagunto. He landed in Barcelona on Jan. 9, 1875.

The two most urgent problems of the new reign, ending the Carlist war and drafting the constitution, were both settled in 1876; peace was also established in Cuba by the treaty of Zanjón (1878) and for most of Alfonso's reign Spain enjoyed an unac-

customed tranquillity. The pattern of political life was determined by Antonio Cánovas del Castillo (*q.v.*), prime minister from 1875 to 1881 and again from Jan. 1884. Alfonso XII, although politically inexperienced, showed himself to possess great natural tact and a sound judgment, which gave rise to hopes that the monarchy would not suffer if the democratic constitution enacted by Cánovas in 1876 was fully implemented in practice. Attempts made on the king's life (Oct. 1878 and Dec. 1879) and a military pronunciamiento against the regime (1883) were not indicative of any general discontent with the restored monarchy; on the contrary, Alfonso enjoyed considerable popularity. His early death, from tuberculosis, on Nov. 25, 1885, was therefore a disappointment to those who looked forward to a constitutional monarchy in Spain.

In Jan. 1878 Alfonso married Maria de las Mercedes, daughter of the duc de Montpensier, but she died six months later. He then married (Nov. 1879) a daughter of the archduke Charles Ferdinand, Maria Cristina, by whom he had two daughters and a son, born posthumously, who became king as Alfonso XIII.

ALFONSO XIII (1886–1941), king of Spain from 1886 to 1931, was born in Madrid on May 17, 1886, the posthumous son of Alfonso XII, and was immediately proclaimed king under the regency of his mother Maria Cristina. Alfonso proved a lively and intelligent boy, but was brought up by a doting mother in an ultraclerical and reactionary atmosphere. From an early age he reacted against the unexciting nature of court life and, encouraged in this by his military attachés, began his long-lasting attachment to the Spanish army. He began to rule in 1902 on his 16th birthday. (For details of the political history of his reign, see SPAIN: The Later Bourbons, 1875–1931.)

Alfonso was immediately seen to relish his position of authority. For a time the system, initiated by Antonio Cánovas del Castillo (*q.v.*) in 1876, of alternating Conservative and Liberal governments, based on "made" elections, continued, but the politicians depended upon the king for their ability to "make" elections and Alfonso began increasingly to intervene in politics. The result was instability—33 governments in Spain were formed between 1902 and 1923—and a steady discrediting of the parliamentary system. Inevitably some of this discredit was shared by the monarchy and the king's popularity began to decline. After the celebrated attempt on the life of Alfonso and his bride, Victoria Eugénie of Battenberg, on their wedding day (May 31, 1906), there was a constant succession of plots to assassinate the king. But at the same time, Alfonso's great personal courage in the face of these attacks won him considerable admiration.

After the failure of the government of Antonio Maura in 1909, the last hopes for the parliamentary regime seemed extinguished and the king's position grew more and more difficult. During World War I his conduct was irreproachable; he observed a scrupulous neutrality and rendered considerable services to humanitarian causes. In the postwar period he began to move toward a system of more personal rule and sought a means to rid himself of parliament. To this end the king intervened directly in the Moroccan war in 1921 with disastrous effect. A subsequent commission of inquiry placed the blame squarely on the king; a week before its report was due to be published, however, Alfonso was rescued from a humiliating situation by the coup *d'état* (Sept. 13, 1923) of Gen. Miguel Primo de Rivera (*q.v.*).

However, by directly associating himself with the overthrow of the parliamentary regime, the king linked his fortunes with those of the dictatorship and, when Primo de Rivera fell from power in Jan. 1930, the fall of the monarchy became a certainty. A temporary government under Gen. Dimas Berenguer was brought in to attempt to save the king, and various expedients were tried by Alfonso to bring about a return to a constitutional regime without the risk of elections. Eventually he agreed to hold municipal elections (April 1931). The results, at least in the important towns, showed a landslide for the Republican parties. They demanded the king's abdication; the army withdrew its support and Alfonso, though refusing to abdicate, was forced to leave Spain (April 14, 1931).

He never returned in his lifetime, though Gen. Francisco Franco

reinstated him as a Spanish citizen and, by a decree of April 24, 1939, restored his property which had been confiscated in 1932. He died in Rome on Feb. 28, 1941, and was buried in the Escorial, near Madrid. On Jan. 15, 1941, he had abdicated his rights to his third son, Don Juan.

ALFRED (ÆLFRED) THE GREAT (848 or 849–899). Anglo-Saxon king of Wessex (q.v.) from 871 to 899, was born at Wantage, the fifth son of King Aethelwulf and his wife Osburh. When Alfred was four or five his father sent him to Rome where Pope Leo IV stood sponsor to him at his confirmation and invested him with the honorary dignity of a Roman consul, in a ceremony misinterpreted as a kingly consecration by the writer of the *Anglo-Saxon Chronicle*. He went to Rome again in 855 with his father, who stayed there a year. Aethelwulf died in 858; his eldest son, Aethelstan, was already dead and the next sons, Aethelbald and Aethelberht, had short reigns. The fourth son, Aethelred I, succeeded in 865, the year of the great Danish invasion. The Danes were bought off from East Anglia and then destroyed the kings of Northumbria. King Aethelred and Alfred went to help King Burgred when the Danes invaded Mercia in 868, but the Danes avoided battle and the Mercians made peace. Late in 870 the Danes came to Reading in Wessex and nine battles were fought against them in the following year, although the *Chronicle* names only six. Ealdorman Aethelwulf defeated them at Englefield early in 871, but the king and Alfred failed to capture Reading four days later. Yet the English reassembled their forces in another four days and won the great battle at Ashdown on the Berkshire downs, where Alfred attacked the Danish earls while his brother, who was to oppose the division led by the Danish kings, was still attending divine service. One Danish king and five earls were killed and the Danes fled. A fortnight later, however, the king and Alfred were defeated at Basing and again two months later at a place called Meretun.

A great reinforcement joined the Danes at Reading and Aethelred died (soon after Easter 871). Alfred thus became king at a critical juncture. He was defeated at Wilton, and may at this time have fought some of the engagements unnamed in the *Chronicle*. The West Saxons then made peace; they may have purchased it, but the quality of their resistance explains their freedom from attack during the next few years. Alfred was not idle and he probably began at once to increase the fleet, as the surest defense for a long coast line. In 875 he went to sea with a fleet which repelled seven ships and captured one. The Danes marched across Wessex in 876, but Alfred surrounded them at Wareham, where they gave hostages and swore to leave Wessex; but they broke their oaths and occupied Exeter. Alfred pursued them and again they came to terms, the more readily because a storm had destroyed their fleet.

Early in Jan. 878 the Danes made a surprise attack, established themselves at Chippenham and almost conquered Wessex. Alfred withdrew to the Somerset marshes and harassed the enemy from a fort which he built at Athelney. In the seventh week after Easter he assembled a force from the surrounding shires, defeated the Danes at Edington in Wiltshire and besieged them in their stronghold for a fortnight until their king, Guthrum, promised to leave Wessex and to be baptized. This baptism took place at Aller on the river Parret, Alfred standing as sponsor, and Guthrum stayed 12 days with the king at Wedmore (Somerset), where the ceremony of the unbinding of the chrim took place and the details of the treaty were probably settled. This victory not only gave Alfred peace until 885 but ensured that the Danes never again overcame Wessex. In saving his own kingdom Alfred prevented England from becoming a Scandinavian country and retained a base from which the Danelaw (the area of Danish occupation) was later reconquered and Christianity re-established.

In 885 a Danish invasion of Kent was repelled and the next year Alfred occupied London and placed it under his future son-in-law Aethelred, ealdorman of the Mercians. As a result the English not under Danish rule, that is, those of southwest Mercia and per-

haps those of Northumbria beyond the river Tyne, accepted Alfred's rule. The extant treaty between Alfred and Guthrum must be assigned to a date after this capture of London. Another large Danish force from the continent, which landed in Kent in 892, was constantly harried by the English and finally returned to France in 896 without gain, despite the support it had received from the Danes of East Anglia and Northumbria which caused Alfred to send an expedition as far as York in 896. Land and sea raids from these last two areas harassed Alfred in the years 896–899.

During his last years King Alfred reaped the benefits of his defensive measures. He reorganized the English levies to keep an army constantly in the field and established the burghal system to defend his kingdom with a ring of fortified centres, regularly maintained and garrisoned. Although this plan received inadequate support from Alfred's subjects and was not completed until his son's reign, the boroughs already built proved their value in the campaigns of 892–896. The reconquest of the Danelaw by his son Edward the Elder and daughter Aethelflaed after his death was probably planned by Alfred.

King Alfred's first biographer, Asser, a contemporary Welsh scholar, tells that the rulers of various parts of Wales sought Alfred's support against their rivals or against the Mercians. There was a Welsh contingent with the English forces in 893, and an entry in the Welsh annals mentions Englishmen in the army with which the Welsh king Anaraut raided a rival's territory in 894. There is evidence to support Asser's claim that Alfred's court was much visited by foreigners, and that he received letters and gifts from the patriarch of Jerusalem.

Alfred reorganized his finances and also the attendance of thegns (noble followers) at his court. He issued a code of laws after examining the legal principles implied in the book of *Exodus* and studying the codes of Aethelbert of Kent, Offa of Mercia (whose laws are lost) and Ine of Wessex. Many of his pronouncements are not found in earlier legislation; the more important defined the rights of sanctuary, regulated and limited the blood feud, and imposed penalties for breach of oath and pledge, stressing especially the enormity of treason to one's lord.

A decay of Latin scholarship in England had set in before the Danish invasions, and these accelerated it. To further his own studies and to raise the level of learning in his country by providing vernacular translations of "some books which may be most necessary for all men to know," Alfred first obtained help from Mercia, the western part of which had suffered little devastation. Thence came Waerferth, bishop of Worcester, Plegmund, who later became archbishop of Canterbury, and the priests Aethelstan and Werwulf. Then Alfred looked further afield. Asser probably first came to his court early in 886, and two continental helpers were Grimbald, of the monastery of St. Bertin at St. Omer, and John, a priest and monk from the land of the Old Saxons. According to Asser, on Nov. 11, 887, the king began to translate Latin and compile the lost "Handbook," apparently a collection of quotations. The first translation to be produced was Bishop Waerferth's version of the *Dzalogzces* of Pope Gregory the Great. The order of Alfred's translations is uncertain. They are Gregory's *Cura pastoralis*, a copy of which was sent to every see in his kingdom at a date not before 890; the *De consolatione philosophiae* of Boethius, which Alfred rendered entirely in prose, adding later a verse translation of the metrical portions; the *Historia adversum paganos* of Orosius, regarded as a textbook of universal history; and a free rendering of the *Soliloquies* of St. Augustine of Hippo, which was probably Alfred's last work. An Old English version of Bede's *Ecclesiastical History* was ascribed to Alfred a century later, but its vocabulary and syntax contain so many Mercian features that although it may have been planned by Alfred, it must mainly be the work of a Mercian writer. There is no evidence that Alfred had any hand in the writing of the *Anglo-Saxon Chronicle* (q.v.), but it is probable that the prose version of the Psalms in Old English in the Paris Psalter preserves part of the translation of the psalms attributed to him by writers after the Norman conquest. Although these works were translated as part of an educational scheme, there is no doubt that Alfred himself was keenly

ALFRED JEWEL. 9TH CENTURY, FOUND IN 1693 AT NEWTON PARK, NEAR THE ISLE OF ATHELNEY, ENGLAND. (LEFT) FRONT SET WITH PLAQUE OF CLOISONNE ENAMEL HELD IN PLACE BY GOLD FRET OF OLD ENGLISH WORDS: "AELFRED MEC HEHT GEWYRCAN" ("ALFRED ORDERED ME TO BE MADE"); (RIGHT) ENGRAVED BACK OF JEWEL. IN THE ASHMOLEAN MUSEUM, OXFORD

interested in their content, especially that of the Boethius and the *Soliloquies* of St. Augustine, and that he pondered deeply on the theological and philosophical problems which they raise.

Asser relates that Alfred caused children both of noble and of humble birth to be taught to read English and Latin at his court, and his preface to the *Cura pastoralis* outlined an education for the sons of all free men who could afford it; all were to learn to read English, and those destined for the church were to read Latin also. Alfred founded a nunnery at Shaftesbury and a monastery at Athelney, with John the Old Saxon as its abbot, but his attempt to revive monasticism received little support from his subjects.

Although Alfred's laws reveal a deep concern for the rights of the church, and Asser speaks of his generosity to it, the pope complained that he infringed its privileges. The reason for this complaint is unknown, but possibly Alfred refused to allow as much immunity as the church claimed from necessary defense works. The sources show him as a deeply religious man, who regarded the government of his kingdom as a divine charge.

Alfred died on Oct. 26, 899, and was buried at Winchester. Subsequent generations regarded him rightly as the saviour of his people from the Danes and as a lawgiver; many of his administrative reforms were permanent, and his books continued to be copied and read throughout the Anglo-Saxon period and beyond it. Many legends grew up about him, including the famous incident of his being reproved by a peasant woman for letting her cakes burn, which is recorded in the 11th century. The 12th-century *Proverbs of Alfred* calls him "darling of the English." There seems to have been a continuous oral tradition concerning him.

BIBLIOGRAPHY.—The main sources for Alfred's reign are the *Anglo-Saxon Chronicle*; Asser, *Life of King Alfred*, ed. by W. H. Stevenson (1959 reprint with chapter on recent work by D. Whitelock); *English Historical Documents*, vol. i, ed. by D. Whitelock, pp. 33 ff., 492, 501 ff., 810–820 (1955); F. Liebermann (ed.), *Die Gesetze der Angelsachsen* (1903); F. L. Attenborough, *The Laws of the Earliest English Kings* (1922).

For his own works, see *King Alfred's West Saxon Version of Gregory's Pastoral Cave* (1871) and *King Alfred's Orosius* (1883), both ed. by H. Sweet; *King Alfred's Old English Version of Boethius*, ed. by W. J. Sedgefield (text 1899, trans. 1900); *King Alfred's Old English Version of St. Augustine's Soliloquies*, ed. by H. L. Hargrove (text 1902, trans. 1904). The Old English version of Bede's *Ecclesiastical History* was edited by T. Miller (1890–1898) and Waerferth's translation of Gregory's *Dialogues* by H. Hecht (1900).

Of biographies of Alfred, C. Plummer, *The Life and Times of Alfred the Great* (1902) and B. A. Lees, *Alfred the Great, the Truth Teller* (1915), still retain some value, but should be compared with F. M. Stenton, *Anglo-Saxon England*, 2nd ed. (1947) and *English Historical Documents*, vol. i. A popular account is given by E. S. Duckett, *Alfred the Great and his England* (1957). (D. WK)

ALFUR, a term applied to those people in the Celebes, Moluccas and other parts of the Lesser Sunda Islands who represent a transition-mixed type between the Malayan and the Papuan-Melanesian peoples of New Guinea. They do not make up a distinct type either culturally or physically. The people in the Moluccas (Timor, Flores, Sumba, etc.) who have often been called Alfur, according to Raymond Kennedy, are taller than the Malay, with features ranging from Mongoloid to the narrow faces and Semitic type of nose of the Papuan. There is great range in skin colour and hair type.

See R. Kennedy, *Islands and Peoples of the Indies* (1943).

(F.-C. CE.)

ALGAE are primitive plants without true leaves, stems or roots and, except for a few isolated cases, containing chlorophyll. The reproductive organs are simple. In most algae they are one-celled and in algae where they are composed of more than one cell every cell is fertile.

Familiar examples of algae are the pond scums and "water mosses" of fresh waters and the seaweeds of the ocean. Marine algae include all algae growing in the ocean and in brackish coastal waters. Fresh-water algae include all nonmarine algae irrespective of whether they grow submerged in water or in habitats where they are not submerged. The distinction between marine and fresh-water algae is ecologically sound because each of the 18,000 species of algae normally is exclusively marine or exclusively fresh-water. Taken together the marine and fresh-water algae exhibit a diversity of form not found in any other group of plants, ranging from one-celled organisms through manifold colonial forms to simple or branched rows of cells (filaments) and onwards to elaborate massive plants comparable in size with the flowering plants. As a general rule, fresh-water algae are minute and can only be distinguished one from another with the help of a microscope. On the other hand, the great majority of species of marine algae are visible to the naked eye and readily recognizable when found growing or cast ashore on the beach.

GEOGRAPHICAL DISTRIBUTION AND OCCURRENCE OF FRESH-WATER ALGAE

Many species of fresh-water algae are found in all parts of the world, from the tropics to the polar regions, and in a variety of habitats. Other species are restricted to particular habitats, but even these may be found at stations thousands of miles apart.

Some of the fresh-water algae, such as *Trentepohlia* and *Pithophora*, are more abundant in the tropics than in temperate regions, and a few genera are never found in colder regions. The best known of the latter are *Cephaleuros*, a green alga parasitic on leaves of several flowering plants, and *Compsopogon*, a red alga found in the southern part of the United States, the West Indies, Central America and the India subcontinent.

The only group of fresh-water algae in which there is striking evidence of endemism is that of the desmids (fig. 1, E-F, G). A specialist shown a collection rich in species of desmids, but not told the source of the collection, would be able to tell whether it came from Europe, Australia, the Indo-Malay region or the Americas.

Aquatic Fresh-water Algae.—These include all algae growing permanently submerged and either attached (benthos) or free-floating (plankton). Filamentous grass-green and blue-green algae predominate in the benthos and they grow attached to stones, twigs, aquatic seed plants or other algae. The chief habitats of benthonic algae are flowing waters, ponds and lakes, pools and ditches, bogs and swamps. Each of the foregoing types of habitat has characteristic species but the composition varies from lake to lake or from bog to bog.

Members of the plankton are chiefly unicellular or nonfilamentous colonial algae and are found in lakes, ponds or slowly

flowing streams. Many of the plankton algae are structurally adapted to a free-floating life. Examples of this are the algae where the colony is a flat plate (e.g., *Pediastrum*, fig. 1, D, *Merismopedia*, fig. 4, G) or where, as in *Golenkinia*, the cell bears numerous bristles. As a general rule, soft-water lakes are rich in species but the total number of individuals is small. The reverse condition is true of hard-water lakes. Here the algae may suddenly become so numerous as to make the water appear coloured and to cause what is known as a "water bloom." Diatoms, blue-green algae and grass-green algae predominate in the plankton; golden brown algae (*Chrysophyceae*) and dinoflagellates are present in smaller numbers.

Aerial Fresh-water Algae.—Aerial algae are frequently defined as algae that obtain their water wholly or in large part from moisture in the air. However, it is difficult to draw precise limits between aerial algae that obtain all their water from moisture in the air and terrestrial algae that obtain their moisture partly from the air and partly from the ground water. The primary feature distinguishing aerial from aquatic algae is their ability to endure drought without entering upon special resting stages and this, in turn, depends more upon the water-retaining than upon the water-absorbing capacity of the cells. Strictly aerial algae are found on the bark and leaves of trees, woodwork, stones and rocky cliffs. A familiar example is the greenish incrustation on the shaded side of tree trunks. Aerial algae are more abundant in tropical than in temperate regions and in humid tropical areas filamentous grass-green and blue-green algae form a felty coating on every stone and tree trunk.

Soil-inhabiting algae are more nearly aerial than aquatic but all of them obtain a part of their moisture from the ground water. Terrestrial algae may grow on the surface of the soil or a few feet below the surface. Those growing at the soil's surface may form a powdery or felty encrustation an acre or more in extent. Grass-green and blue-green algae predominate in this flora, and the particular species present at any given locality are in large part dependent upon the soil's texture and chemical composition. The length of time that soil algae can withstand desiccation is remarkable, and some are able to resume growth after drying for more than 50 years. Terrestrial algae play an important role in the colonization of bare surface by plants. They aid in preventing erosion of exposed surfaces; their decay affords the first available supply of humus; and they afford a moisture-retaining substratum for spores and seeds of more advanced plants.

Fresh-water Algae of Unusual Habitats.—There is a surprisingly long list of algae restricted to unusual environmental conditions or to particular substrata. Certain of them are adapted to extraordinary conditions of temperature. Several species grow in the snow and ice of polar regions or of high mountain peaks. These algae are found both in regions of perpetual snow and in snow fields at the top of mountains where the snow melts every summer. Most of them are grass-green algae and they may be present in sufficient abundance to colour the snow. This colour is usually red because practically all snow-inhabiting green algae have the green colouring matter (chlorophyll) masked by a red pigment (haematochrome). The algae growing in hot springs are in an environment directly antithetical to that of snow algae. Such algae are found in various parts of the world including Iceland, New Zealand and the United States. The best known and most spectacular of all hot springs are those in Yellowstone National park. Here the algae have been found growing and multiplying where the temperature of the water is 187° F. With a few exceptions all of the hundred or more algae recorded from hot springs are blue-greens.

The "brine lakes" found in arid regions of the United States and other countries represent another unusual type of environment with a distinctive algal flora. Most of the species in these lakes belong to the grass-green algae and, strange as it may seem, algae closely related to them are found in fresh waters instead of in the ocean. The ability of these algae to live in a salt solution 2-17 times stronger than that in the ocean seems to rest upon a different permeability to salts as compared with that of other fresh-water or marine algae.

There are many fresh-water algae found only in association with specific plants or animals. Most of the animals bearing particular algae live in or about the water but there are a few land animals regularly harbouring algae. The most striking of the latter is the three-toed sloth, where a *Protococcus*-like alga growing upon the hairs gives the animal a distinctly greenish coloration. Algae associated with aquatic animals may grow upon the surface of them, as is true of the filamentous green alga (*Bacillaria*) found only on the backs of turtles; or the alga may grow within the tissues of the animal, as is the case with the unicellular green alga (*Chlorella*) found within *Hydra*. Algae associated with specific plants may grow upon their surfaces or within their tissues. Those growing within tissues may be space endophytes or true parasites. The *Nostoc* growing within the liverwort *Anthoceros* is an example of a space endophyte. The best known of the parasites is *Cephaleuros* which at times causes serious damage to certain cultivated tropical plants, notably tea and pepper.

GEOGRAPHICAL DISTRIBUTION AND OCCURRENCE OF MARINE ALGAE

The marine algal flora differs from the fresh-water flora in that more than 95% of the benthic species are red or brown algae. Red algae predominate in warmer waters of the oceans, brown algae in the colder waters. Each ocean has its distinctive flora and a very large percentage of the species in any one of the oceans is not found in other oceans. This is well illustrated by the fact that of the algae found along the shores of the United States less than 10% are found along both the Atlantic and the Pacific coasts. There is also a rather definite geographical distribution of species of a particular ocean and this distribution is correlated with average water temperatures during the warmest month of the year. When this temperature difference between two portions of the shore is 10° F. there are marked differences in composition of the flora. On the Pacific coast of North America the differences in temperature produce four distinct floras: the boreal, extending from Alaska to Puget sound; the temperate, extending from Puget sound to Point Conception, California; the subtropical, from Point Conception to Magdalena bay, Mexico; and the tropical, from Magdalena bay to the Isthmus of Panama.

At a given place along the shore of any ocean there is a distinct vertical distribution of benthic algae, especially of those growing between the high tide and low tide levels. The number of species growing at or just below high tide level is small because relatively few marine algae are able to withstand the severe wilting produced by several hours exposure to air. The number of species increases progressively to extreme low tide level because of the progressive shortening of the period of intertidal exposure. Other factors especially penetration of water by sunlight, affect the vertical distribution. The maximum depth at which algae grow is primarily dependent upon penetration of light into the water. In high latitudes the lowest depth at which algae occur is 150-180 ft. In tropical and subtropical seas, where the sun's rays are more nearly vertical, algae may grow at a depth of 300-600 ft.

Plankton algae of the ocean are either diatoms or dinoflagellates but the number of strictly planktonic species is large. Most species are restricted to a single ocean and in many cases the distribution within an ocean is quite definite.

UTILIZATION OF ALGAE

Several marine algae are used as food by man. The amount consumed in Europe and America is insignificant and is chiefly the utilization of the seaweed known as Irish moss in making blancmange and other puddings. In the orient, on the other hand, certain algae are highly esteemed as foodstuffs and are used both in the making of soups and as condiments. The most widely used for such purposes is the red alga *Porphyra*. Most of the *Porphyra* eaten in the orient comes from Japan. The yearly market value runs in the millions of dollars. Some is sold fresh, but most of it is sun-dried before reaching the consumer. The supply is obtained almost exclusively from plants cultivated

on suitable tidelands.

Tidelands are prepared by anchoring nets made of rope just beneath the surface of the water in portions of bays where the water is 15–25 ft. deep. The nets afford a lodgment for spores of *Porphyra* floating through the water and the spores grow into plants with blades several inches in diameter.

Kombu, a product made from various kelps, is one of the standard foods of Japan. Kelps harvested by fishermen are dried and then sent to manufacturers for conversion into kombu. The manufacturer boils the dried algae for a few minutes and then spreads them out one by one in flat wooden presses where the whole mass is compressed as tightly as possible, dried, and then shredded or powdered for the market.

There is great interest in the possibility that fresh-water algae may be cultivated as a source of food for man and domestic animals. Most studies on mass cultivation of fresh-water algae have been with *Chlorella*. It is a one-celled green alga with spherical cells about 4/1000 in. in diameter. Its rate of multiplication is rapid, the increase per day in number of cells being about eightfold under the most favourable circumstances. Increase in number of cells may continue until there are about 1,000,000,000 cells per millilitre of liquid. *Chlorella* may be cultured in such a manner that the cells have either a high fat or a high protein content. When cultured so that there is a high protein content it may comprise more than 50% of the dry weight. Cultivation of *Chlorella* on a large scale out of doors involves many engineering problems. By the latter 1950s, cultivation had been confined to pilot plants with a capacity of 1,000 or more gallons of culture medium. For one pilot plant it has been estimated that when operated under optimum conditions the dry weight yield would be at the rate of 100 lb. per acre per day. This is at the rate of 17.5 tons per acre per year. The costs per pound of *Chlorella* for running pilot plants were so high that it was economically unprofitable.

Products from marine algae have a wide variety of industrial uses. At one time kelps and rockweeds were of considerable importance as sources of potassium and iodine. The discovery of mineral deposits containing these elements has, however, made their recovery from algae unprofitable. Agar-agar is a gelatinous substance obtained from the red alga *Gelidium* by a rather involved process of extraction. Most of the agar-agar sold in world markets comes from Japan. Under normal conditions the United States imports about 500,000 lb. The production of agar-agar in the United States has increased significantly. The best-known use is that of a solidifying agent in culture media in bacteriological laboratories. It is also used as a stiffening agent in certain food products, as a sizing material and in clarifying liquids. The red algae *Chondrus crispus* and *Gigartina mamillata*, both known as Irish moss or carrageen, are a source of a gelatinous substance widely used in industry. The algae are dried and bleached before being sold to manufacturers. Manufacturers use Irish moss as an agent that helps keep substances in suspension. Examples of this are various pharmaceutical preparations, especially hand lotions, and the chocolate milk sold by milk dealers. Irish moss is also used by brewers to clarify and to give body to beer. Alginates, salts of alginic acid, are jellylike substances obtained from the brown algae known as kelps. All alginates sold in the United States are extracted from a giant kelp, *Macrocystis*, which grows in extensive stands along the coast of southern California. One widespread use of alginates is in the manufacture of ice cream. Alginates have also replaced the use of agar and of Irish moss in a considerable number of manufactured products.

STRUCTURE AND REPRODUCTION

The Cell.—Cells of algae (except Cyanophyta, see below) are essentially like those of more advanced plants. There is a distinct wall and the protoplasm within the wall is differentiated into cytoplasm and nucleus. The chlorophyll and other pigments that give different algae their distinctive colours are localized in chromatophores which are of distinctive size and shape from genus to genus. The chromatophores usually lie in the portion of the cytoplasm just within the cell wall (fig. 1, A; 1, H; 1, I) but

they may lie at the centre of the cell. Chromatophores of grass-green algae contain one or more rounded bodies, the pyrenoids (fig. 1, A; 1, H), which are intimately concerned with the formation of platelets of starch.

The Plant Body.—The simplest algae are one celled and the most primitive of these have threadlike extrusions (flagella) protruding through the cell wall. Flagella (fig. 1, A) are motile organs which, by lashing backward and forward, propel the cell through the water. Nonmotile unicellular algae are usually of microscopic size and globose or angular. Certain unicellular algae are of macroscopic size and variously branched. The most highly differentiated of all macroscopic unicellular algae is *Caulerpa* (fig. 1, P), an alga differentiated into leaf-, stem- and rootlike branches superficially resembling the leaf, stem and root of a seed plant.

If the plant body is composed of more than one cell the cells may not have a definite orientation with respect to one another (*Gloeocapsa*) or the cells may be joined end to end in branched or unbranched filaments (*Ulothrix*, fig. 1, I; *Ectocarpus*, fig. 2, E). Branched filamentous algae may have the various branches free from one another, or have them compacted to form a plant body of characteristic macroscopic form. The great majority of red algae (e.g., *Chondrus*, fig. 4, A) are of the compacted type and the plant body thus formed may be a foot or more in height. The largest and most complex plant bodies among algae are those of the kelps. These brown algae have a rootlike holdfast, a stemlike stalk and one or more leaflike blades. Kelps of the Atlantic ocean are rarely more than 5 ft. tall, but certain kelps found along the Pacific coast of North America and in the Antarctic ocean attain a length of more than 100 ft. Kelps also have the highest differentiation of tissues found in any algae. Here the blades, the stipe and the branches of the holdfast are each internally differentiated into cortex and medulla. The cortex is composed of approximately cubical cells with chromatophores; the medulla is composed of colourless interwoven filaments and in a few genera, as *Nereocystis* and *Macrocystis*, certain of the filaments develop into sieve tubes similar to those found in flowering plants.

Asexual Reproduction.—Algae may multiply vegetatively by fragmenting into two or more parts, but in most cases they reproduce asexually by means of spores formed within and liberated from ordinary vegetative cells or from special cells (sporangia). Spores of red algae are of types peculiar to that group (see *Rhodophyta*, below); those produced by other algae are either flagellated self-propelling zoospores or nonflagellated passively transported aplanospores. Zoospores and aplanospores may be formed singly, in multiples of two or in indefinite numbers within a cell or a sporangium. Liberation of the spores may be by rupture or gelatinization of the surrounding wall, or through a pore in the wall.

Sexual Reproduction.—Sexual reproduction is effected by a fusion in pairs of special reproductive bodies (gametes) produced within ordinary vegetative cells or within special modified cells (gametangia). Gametic union (sexual reproduction) is of frequent occurrence among grass-green, brown and red algae: it occurs very infrequently among yellow-green and golden-brown algae; and not at all among blue-green algae. The most primitive type of gametic union is where both gametes of a fusing pair are motile and of equal size (fig. 1, I). More advanced than such an isogamous union of gametes is that where both are motile but one small and active, the other large and sluggish. In such an anisogamous union of gametes the smaller gamete is male and the larger is female. Anisogamy, in turn, leads to the condition of oögamety where there is a union of a small flagellated male gamete (antherozoid) with a large nonflagellated immobile gamete (egg!) (fig. 1, H). In oögamous algae the male gametangium (antheridium) is usually much smaller than the female gametangium (oögonium) (fig. 1, H). Antherozoids of oögamous algae may swim into the oögonium and unite with the egg or eggs within it; or the eggs may be discharged from an oögonium and the antherozoids swim to and unite with the eggs floating passively in the water.

Fusing gametes (whether isogamous, anisogamous or oögamous) are devoid of a membrane hut the resultant zygote soon secretes

a wall. In most grass-green algae the zygote enters upon a dormant period and secretes a thick wall; in a few grass-green algae and in all brown algae there is no dormant period and the wall is always thin. A feature of deeper significance in the formation of a zygote is the union into a single nucleus of the two nuclei derived from the two gametes.

Life Cycle.—All plants more advanced than algae have a life cycle with two distinct phases or generations and one in which sexual (gametophytic) and asexual (sporophytic) generations follow one another in alternate succession. Sexually reproducing algae have or have not such an alternation of generations, depending on whether there is or is not a reduction division (see CYTOLOGY) of the zygote nucleus.

Zygotes of most grass-green algae secrete a thick wall and do not germinate until they have undergone a ripening period lasting weeks or months. All such algae have a reduction division of the zygote nucleus and, consequently, the development of a gamete-producing generation (gametophyte) when the zygote germinates. The life cycle of these algae consists of a succession of gametophytic generations with a one-celled phase, the zygote, intervening between successive generations. Many algae with this type of a life cycle have the gametophyte also producing zoospores or aplanospores. This results in a life cycle where there is a reduplication of the gametophytic generation and not one where there is an alternation of gametophytic and sporophytic generations.

A few grass-green algae and all brown algae except Fucales have an immediate germination of the zygote, no reduction division of the zygote nucleus, and the production of a generation in which each cell has the same number of chromosomes as a zygote. This generation is strictly asexual (sporophytic) and there is a reduction division of nuclei in the cells producing zoospores or aplanospores. These spores develop into sexual (gametophytic) plants. In these algae with an alternation of generations in the life cycle the two generations may be identical in size, shape and vegetative structure, or the two may be markedly unlike. Certain algae (as *Dictyota* and *Laminaria*) have the two alternating generations following each other in regular sequence; other algae (as *Ectocarpus*) may have the regular alternation interrupted by a reduplication of either the sporophytic or gametophytic generations.

All red algae except Bangiales have an alternation of generations but here there may be three generations in the life cycle, one gametophytic, the other two sporophytic.

CLASSIFICATION OF ALGAE

Algae fall into seven groups, each with distinctive pigments in the chromatophores, distinctive food reserves and distinctive reproductive cells. The groups are sufficiently distinct from one another to be placed in separate divisions at the bottom of the plant kingdom. These divisions are the Chlorophyta, Euglenophyta, Pyrrophyta, Chrysophyta, Phaeophyta, Cyanophyta and Rhodophyta.

Chlorophyta.—Chromatophores of Chlorophyta are green and with the same pigments as vascular plants. The chief food reserve is starch. All flagella of a motile reproductive cell are the same length and the number of flagella is usually two or four. There are two classes: the Chlorophyceae (grass-green algae) and the Charophyceae (stoneworts).

The plant body of members of the Chlorophyceae never grows by means of an apical cell and the reproductive organs are always one-celled and without a sheath of vegetative cells. There are approximately 350 genera and 5,500 species of Chlorophyceae. Arrangement of the genera in major groups (orders) is primarily on the basis of cell structure, organization of the plant body and structure of reproductive cells.

The most primitive order (Volvocales) includes all Chlorophyceae with motile vegetative cells. Most genera are fresh-water and either unicellular (*Chlamydomonas*, fig. 1, A) or colonial. The number of cells in a colony is a multiple of two and usually less than 128 (as in *Eudorina*, fig. 1, B) but as in *Volvox* it may be several thousand. Colonies with a small number of

cells have all cells fertile; those with a large number of cells have reproduction restricted to a few greatly enlarged cells.

Somewhat advanced over the Volvocales are the Tetrasporales in which the cells are irregularly distributed through a colourless jelly. Vegetative cells of Tetrasporales may develop flagella at any time and temporarily live in the manner of a *Chlamydomonas* cell. The number of species in the order is about 100 and most of them are found in fresh waters.

Members of the Ulotrichales have uninucleate cells with a single band-shaped chromatophore and the cells are united end to end in filaments. There are approximately 80 genera and 450 species. Most genera are exclusively fresh-water; a few are exclusively marine or have both marine and fresh-water species. The filaments may be unbranched, as in *Ulothrix* (fig. 1, I), or branched. Genera with branched filaments may have the branches standing free from one another (*Stigeoclonium*) or have the branches laterally compacted to form a solid disk (*Colochoaete*). A considerable number of genera are of microscopic size and epiphytic on coarse filamentous fresh-water algae or endophytic within tissues of marine algae.

Ulvales have cells resembling those of Ulotrichales but have the cells laterally adjoined in flat sheets or in hollow tubes. The plant body is macroscopic and often several inches tall. There are approximately 100 species and the majority of them are strictly marine. Two genera, *Ulva* (fig. 1, N; 1, O) and *Enteromorpha*, are abundant in all oceans. These two genera have an alternation of generations; certain other genera (as *Monostromaj*) do not have this type of life cycle.

The Schizogoniales include three genera where the plant body is either filamentous or sheetlike. These genera differ from other Chlorophyceae in structure of chromatophore, lack of sexual reproduction and in reproducing exclusively by aplanospores. *Prasiola*, the most widely distributed genus, usually grows only where the substratum is rich in soluble nitrogenous compounds and marine species of the genus are restricted to the high tide level of rocks covered with droppings from sea birds.

The Cladophorales have cylindrical multinucleate cells joined end to end in branched or unbranched filaments. The most widely distributed of the dozen genera is *Cladophora* (fig. 1, L), a genus with more than 150 species. It is one of the branched genera and is a common alga in both fresh and salt waters.

Oedogoniales are exclusively fresh-water and are the only filamentous Chlorophyceae in which flagella of zoospores are numerous and arranged in a ring near one end. Sexual reproduction is oogamous and the antherozoids resemble the zoospores. There are 3 genera and approximately 350 species. *Oedogonium* (fig. 1, H), the genus with the largest number of species, is one of the commonest filamentous algae of pools and ditches.

Zygnematales are the only green algae in which sexual reproduction is by a union of two amoeboid gametes. In some genera this is by establishment of a tube connecting two cells (fig. 1, K). The order includes approximately 40 genera and 3,000 species; all fresh-water and a large majority strictly aquatic. Some genera have the cells permanently united in unbranched filaments; other genera are unicellular or have the cells temporarily united in filaments. *Spirogyra* (fig. 1, K), the most widely distributed genus of all fresh-water algae, is representative of the permanently filamentous genera. The unicellular genera have cells constricted into two symmetrical halves (*Staurastrum*, fig. 1, E; 1, F; *Micrasterias*, fig. 1, G). These algae, the desmids, have long been favourites of microscopists because of their symmetrical shapes.

Chlorococcales have approximately isodiametric cells that do not divide vegetatively and are algae in which an increase in number of cells is brought about by production of spores or gametes. The order is a large one and most of the species are fresh-water. Some genera, as *Chlorella* and *Golenkinia*, are unicellular; other genera (*Scenedesmus*, fig. 1, C; *Pediastrum*, fig. 1, D) have the cells united in nonfilamentous colonies in which there is no increase in number of cells once a colony has been formed.

The Siphonales are unicellular, multinucleate branched tubes capable of indefinite elongation. Most of the 50 genera are marine and found in tropical or subtropical seas. Many marine Siphonales

are of macroscopic size, freely branched, with the branches of different shape and free from one another (*Caulerpa*, fig. 1, P), or with the branches alike and densely interwoven (*Penicillus*, *Codium*). Reproduction of many Siphonales is exclusively sexual and frequently anisogamous.

The Siphonocladales have multicellular thalli attached by a system of rhizoids. The cells are multinucleate and divide in a unique manner. There are about 18 genera and 150 species; all marine and usually restricted to warm seas.

The Dasycladales have an erect central axis bearing whorls of branches from top to bottom or only at the upper end. Some of the order are known only as fossils. Seven genera have living species. These are all marine and found only in warm seas.

The Charophyceae (stoneworts) have a multicellular plant body differentiated into nodes and internodes, and one in which terminal growth is initiated by an apical cell. The sex organs (antheridia and oogonia) are surrounded by envelopes of sterile cells. There is but one order, the Charales. Some genera are known only as fossils. The 6 genera with 200 living species grow submerged in fresh or brackish waters.

The plant body consists of a slender cylindrical axis bearing whorls of short branches ("leaves") separated at regular intervals by relatively long internodes. The plant surface is frequently encrusted with lime, hence the popular name stonewort.

Asexual reproduction is exclusively vegetative and usually by a shedding of special reproductive branches. Sexual organs are produced one above the other at the nodes, as in *Chara* (fig. 1, M). The oogonium with its covering of spirally twisted cells crowned by 5 or 10 small cells comprises the nucule. The antheridia are united in a branching filament and several antheridial filaments are surrounded by a globose envelope composed of 8 shield-shaped cells. The mass of antheridial filaments and the envelope surrounding them jointly constitute the globule. When the globule is mature the shield cells separate from one another and the antherozoids escape from the exposed antheridial filaments. They swim down through the apex of the nucule and unite with the egg. The zygote formed within the nucule develops a thick wall and ripens for several weeks before germinating to form a new plant.

Euglenophyta.—The Euglenophyta have grass-green chromatophores with a pigmentation similar to that of Chlorophyta. The food reserves are either paramylum (an insoluble carbohydrate related to starch) or fats. Flagella differ from those of other major groups (divisions) in that they are inserted in a small interior chamber at the anterior end of a cell. Reproduction is by cell division but several genera are known to form thick-walled resting stages. Sexual reproduction is not definitely known for any species.

There is but one class, the Euglenophyceae, and most genera of this class are naked motile unicellular organisms similar to *Euglena* so frequently present in stagnant fresh waters. All genera with motile cells are placed in a single order, the Euglenales. One genus (*Colacium*) has nonflagellate cells organized in dendroid colonies similar to those of certain Tetrasporales. It is the sole member of the order Colaciales.

Pyrrophyta.—Members of this division are the only algae with yellowish to brownish chromatophores that store reserve foods as starch or starchlike compounds. Motile cells are biflagellate, usually with the flagella unequal in length and movement. For a long time all known members of the group were unicellular biflagellate organisms but in 1912 five nonmotile genera were discovered and the list of truly algal genera has been increased since then. The division has three classes (Cryptophyceae, Desmokyntae, Dinophyceae) primarily distinguishable by the structure of the flagella.

The Cryptophyceae (cryptomonads) include 12 genera; 10 unicellular and motile; 2 with a colonial organization similar to that of *Tetraspora*. Cells of Cryptophyceae have one or two brownish-yellow chromatophores and granules of starch. Motile vegetative cells and zoospores are biflagellate with the two flagella alike except for slight differences in length. Some phycologists exclude the Cryptophyceae from the Pyrrophyta and consider the class one of uncertain systematic position.

Desmokyntae differ from other Pyrrophyta in having a cell wall vertically divided into two homogeneous halves (valves). Motile cells have two apically inserted flattened flagella that differ from each other in type of movement. All members of the class are rare organisms and most of them are marine.

Cells of most Dinophyceae have numerous golden-brown to chocolate-brown chromatophores, but cells of certain species lack chromatophores. Motile cells and zoospores are encircled by a transverse groove—the girdle. The two flagella are inserted in or near the girdle; one of them encircles the girdle, the other extends vertically backward. The class includes about 120 genera and 950 species, almost all of which are marine and restricted to the plankton. Ninety per cent of the genera are unicellular and motile; the remainder are either unicellular and immobile, or *Tetraspora*-like, or filamentous. Motile genera are placed in three orders: one (Gymnodiniales) without a wall, the other two (Peridiniales and Dinophysidales) with a wall and with one made up of a definite number of plates. The Peridiniales, as in *Glenodinium*, have a wall that is not longitudinally divided into two halves; the Dinophysidales have a wall longitudinally divided into two halves. Immobile genera have the cells regularly producing one or more *Gymnodinium*-like zoospores. According to organization of the plant body they are placed in the following orders: Dinocapsales, with nondagellate cells irregularly distributed through a gelatinous matrix; Dinotrichales, with nonflagellate cells joined end to end in filaments; Dinococcales, with solitary nonflagellate sessile or free-floating cells. These three orders correspond, respectively, to the Tetrasporales, Ulotrichales and Chlorococcales of the Chlorophyceae.

Chrysophyta.—The Chrysophyta have yellowish-green to yellowish-brown chromatophores in which there is a preponderance of carotinoid pigments. The chief food reserves are leucosin (an insoluble carbohydrate of unknown composition) and oils. Cell walls are usually composed of two overlapping halves and are frequently impregnated with silica. Various types of spores are formed and sexual reproduction, when present, is usually by an isogamous fusion of zoogametes or aplanogametes. There are approximately 300 genera and 5,700 species, three-quarters of which are fresh-water. The division has three classes—Xanthophyceae, Crysochyceae and Bacillariophyceae.

The Xanthophyceae (Heterokontae), familiarly known as yellow-green algae, are almost exclusively fresh-water. They have yellowish-green chromatophores and store foods as leucosin or as oils, never as starch. Motile stages are regularly biflagellate and with the two flagella markedly unequal in length (fig. 2, A). Asexual reproduction by zoospores or aplanospores is of frequent occurrence; sexual reproduction very rarely occurs, and is definitely established for but few genera. Although the number of genera and species (about 75 and 200) is much smaller than in Chlorophyceae, the Xanthophyceae exhibit much the same range in form, and most orders of Chlorophyceae have their counterpart among the Xanthophyceae.

The nine genera with motile vegetative cells are placed in the Heterochloridales and all genera are unicellular. The Rhizochloridales with naked amoeboid cells united in colonies comprise an order without counterpart among the Chlorophyceae. All of the eight genera are exceedingly rare and most of them are fresh-water. The Heterocapsales include a few rare fresh-water genera with colonies similar to those of Tetrasporales. The Heterotrichales have cylindrical cells joined end to end in branched or unbranched filaments. *Tribonema* (fig. 2, B), with unbranched filaments composed of cells surrounded by walls with two overlapping halves, is very common in fresh-water pools during the spring months.

Similar to Chlorococcales, the Heterococcales have no vegetative cell division and are unicellular or with the cells united in nonfilamentous colonies. This is the largest order and all but a couple of the 45 genera are fresh-water. *Ophiocytium* (fig. 2, D) is the most frequently encountered genus of the order, but it is never found in abundance. The Heterosiphonales, an order corresponding to the Siphonales, have but three or four genera. *Vaucheria*, the commonest genus, is usually aquatic. It consists of a single, sparingly branched, tubular cell. *Botrydium* (fig. 2, C),

FIG. 4. — A-F, RED ALGAE; G-L, BLUE-GREEN ALGAE

the other common genus, is always terrestrial. The serial portion is spherical; the subterranean portion is tubular.

Typical Chrysophyceae have golden-brown chromatophores and a storage of reserve foods as leucosin or fats. They form a distinctive type of spore, the endospore. For a long time the only known members of the class were motile organisms (chryso-monads), but after 1900 several immobile coccoid and filamentous genera with a truly algal organization were discovered.

About half of the 70 genera belong to the Chrysomonadales, the only order in which the vegetative cells are motile. Cells of Chrysomonadales may be uni- or biflagellate and solitary or in colonies. The Rhizochrysidales have immobile amoeboid cells that may be naked or may have a wall-like envelope (lorica). All 12 genera of the order are fresh-water; some are unicellular, others colonial. Members of the Chrysocapsales are colonial and with cells irregularly distributed through a colourless jelly as in Tetrasporales. There are ten genera, of which the most widely distributed is *Hydrurus*, an inhabitant of swiftly flowing cold-water streams.

The Chrysotrichales have cells united end to end in branched or unbranched filaments. Some of the branched genera have the branches standing free from one another; others, as *Thallochrysis*, have the branches laterally united. The five genera of the order are rare algae and are found in fresh water. The Chrysococcales correspond to the Chlorococcales of the Chlorophyceae. All six genera referred to the order are imperfectly known; and all, as *Chrysosphaera*, are found in fresh water.

The Bacillariophyceae (diatoms [*q.v.*]) have cell walls composed of two overlapping halves and a bilateral or radially symmetrical ornamentation of the wall. These algae are dealt with in a separate article.

Phaeophyta.—Phaeophyta (brown algae) have chromatophores in which carotinoid pigments, chiefly fucoxanthin, predominate. The primary food reserve is a carbohydrate, laminarin, dissolved in the cell sap. Motile reproductive cells, whether zoospores or gametes, have two laterally inserted flagella of unequal length.

All but 3 of the 900 species are strictly marine. Brown algae predominate in the algal flora of colder seas, but certain brown algae, notably Dictyotales and *Sargassum*, are found only in tropical or subtropical waters. Marine Phaeophyta grow along rocky ocean shores and usually where the water is less than 50 ft. deep. All of the brown algae are multicellular and either filamentous or with a more complex plant body. In all except the Fucales there is an alternation of two free-living generations, but the gametophyte and sporophyte may be vegetatively similar or dissimilar. Gametophytes usually produce multicellular gametangia in which each cell contains a gamete but they may produce unicellular gametangia containing a single gamete. Gametic union ranges from isogamy to oogamy. The sporophyte produces unicellular sporangia containing spores in multiples of two (usually 64 or 128). In addition to unicellular sporangia, a sporophyte may also produce multicellular sporangia indistinguishable in appearance from gametangia. The reduction division of nuclei within a unicellular sporangium and the lack of this in a multicellular sporangium is of fundamental significance since it determines whether a plant growing from a spore is to be gametophytic or sporophytic.

The primary difference between the three classes of the Phaeophyta is in the life history. These differences are: the alternation of similar generations in Isogeneratae, the alternation of dissimilar generations in Heterogeneratae and the lack of a gametophytic generation in the Cyclosporeae.

The simplest Isogeneratae, the Ectocarpales, have a filamentous plant body. The type genus, *Ectocarpus* (fig. 2, E-2, G) is a common epiphyte on other marine algae. Its plant body is freely branched and it grows by division of cells a short distance back from each branch tip. The gametophyte produces multicellular gametangia and union of gametes may be isogamous or anisogamous. Sporophytes developing from a zygote typically produce unicellular sporangia and have the zoospores released from them developing into gametophytes. However, a sporophyte may also

produce multicellular sporangia whose zoospores reduplicate the sporophytic generation.

Another one of the filamentous types are the sphaclariales which have a branched threadlike plant body with cells regularly arranged in transverse tiers. Growth of each branch is initiated by an apical cell (fig. 2, H). Reproductive organs resemble those of Ectocarpales and the life cycle is similar. The order has 15 genera and 17 species, most of which are restricted to the Atlantic ocean. Tilopteridales have a freely branched plant body in which the lower portions are similar to Sphaclaria and the upper portions of the branches are *Ectocarpus*-like. The Cutleriales include two anomalous genera with filaments laterally compacted to form a blade- or disklike plant body. Gametophytes have multicellular gametangia borne in groups and gametic union is markedly anisogamous. Sporophytes produce unicellular sporangia only; hence there is a regular alternation of generations.

Members of the Dictyotales are branched ribbon- or fanlike algae (fig. 3, A) with growth initiated by solitary or laterally adjoined apical cells. There are about 20 genera and 100 species. Dictyotales are the predominant brown algae of tropical seas and many of them grow in abundance. The gametophytes produce sex organs in patches (sori): female gametangia (oogonia) are one celled (fig. 3, B) and the male gametangia (antheridia) are many celled. Unicellular sporangia of sporophytes are unique for brown algae both in the small number of spores (four or eight) and in the absence of flagella on the spores (fig. 3, C).

Gametophytes of Heterogeneratae are always irregularly branched filaments; sporophytes may be filamentous, or of a modified filamentous construction, or nonfilamentous. Genera with a filamentous organization are placed in the subclass Haplostichineae; those with a nonfilamentous organization in the subclass Polystichineae. The Haplostichineae are grouped in three orders (Chordariales, Sporochnales, Desmarestiales) differing in organization of the sporophyte. Sporophytes of Chordariales and Sporochnales are obviously filamentous; those of Desmarestiales (fig. 2, I; 2, J) are obscurely so because the branches become covered with irregularly arranged cells. Gametophytes of Chordariales resemble irregularly branched gametophytes of *Ectocarpus*; those of the other two orders are oogamous and with both antheridia and oogonia, one celled.

The Polystichineae are also divided into three orders; two (Punctariales and Dictyosiphonales) without internal differentiation of tissues in the sporophyte; the third (Laminariales) with an internal differentiation of tissues. Sporophytes of Punctariales are of medium size and usually bladelike or saccate; those of Dictyosiphonales are profusely branched and threadlike. Sporophytes of Laminariales (kelps; fig. 2, M) vary from 1 to more than 100 ft. in height. Most of the 30 genera of Laminariales are restricted to the North Pacific ocean but certain genera, as *Laminaria* (fig. 2, K-M) are found in all oceans. The sporophyte of *Laminaria*, which is rarely more than six feet tall, has a rootlike holdfast, a stemlike portion and a single blade terminating the stem.

Many Pacific ocean kelps are notable for their complexity of external form and for their size. These "giant kelps" have numerous blades borne either at the apex of a branched stem (*Nereocystis*, fig. 2, O) or at regular intervals along a branched stem (*Macrocystis*). Giant kelps grow where the water is 20-40 ft. deep and attain a length of 20-150 ft. Some are perennial; one is an annual that grows to a length of more than 100 ft. in a single season. Sporophytes of all kelps produce unicellular sporangia on the blade portion of the plant and have the sporangia grouped in sori. The gametophytes are microscopic irregularly branched filaments that rarely have more than 50 cells. Male gametophytes (fig. 2, L) bear many antheridia, each containing a single antherozoid; female gametophytes (fig. 2, K) have one to six oogonia, each containing a single egg.

The Cyclosporeae have a sporophytic plant body whose spores function as gametes instead of developing into gametophytes. Cyclosporeae differ from other brown algae in that the reproductive organs are borne in round cavities (conceptacles) within tips of the plant body. The single order, the Fucales, contains approxi-

mately 40 genera and 350 species. Fucales are world-wide in distribution but most genera are restricted to oceans of the northern or the southern hemispheres. Those growing on rocks high in the intertidal zone are often called rockweeds, and of them *Fucus* (fig. 3, D-H) is a common rockweed along seacoasts of the temperate region of the northern hemisphere. Its leathery, repeatedly forked plant body (fig. 3, D) is anchored to rocks by a disk-shaped holdfast.

Conceptacles are produced in abundance on somewhat inflated tips of branches. Each conceptacle contains many sex organs. In some species both antheridia and oogonia are borne in the same conceptacle, in other species the two are in separate conceptacles, in still others the two are borne on separate plants. Oogonia (fig. 3, F) have 8 large nonflagellated eggs; antheridia (fig. 3, E) have 64 small biflagellate antherozoids. Oögonia become detached from the side of a conceptacle, float out through the opening at the apex of a conceptacle and then liberate their eggs (fig. 3, G). Eggs liberated from oogonia become surrounded by many antherozoids (fig. 3, H). The zygote produced by union of egg and antherozoid immediately begins to develop into a new plant.

Sargassum is the commonest genus in warmer portions of the oceans. Its plant body (fig. 3, I) is differentiated into stem-like and leaflike branches. Many branches terminate in small air-filled bladders, and if a plant becomes detached, it floats freely. Gametic union is similar to that of *Fucus*. Some species, as the two growing free-floating in the Gulf stream and the Sargasso sea, multiply exclusively by fragmentation.

Rhodophyta.—The Rhodophyta (red algae) have chromatophores in which the photosynthetic pigments are masked by a red pigment (phycoerythrin); sometimes there is also a blue pigment (phycocyanin). The chief food reserve is an insoluble carbohydrate, floridean starch. Sexual reproduction is unique in that nonflagellate male gametes (spermatia) are passively transported to female sex organs. Red algae also differ from all other except the blue-green algae in lacking flagellated asexual spores. All Rhodophyta are placed in a single class, the Rhodophyceae, with about 400 genera and 2,500 species. About 50 species, belonging to a dozen genera, are fresh-water; all others are marine.

Rhodophyceae predominate in the algal flora of tropical seas but they are present in all seas, including those of polar regions. Almost all marine species grow attached and the great majority of them grow at or a few feet below the intertidal levels. In northern portions of the Atlantic and Pacific oceans red algae rarely grow in water more than 100 ft. deep; in portions of these oceans nearer the equator they have been dredged from a depth of 500 ft. Species growing in fresh water, as *Batrachospermum*, are usually restricted to clear, cool, swiftly flowing streams.

The plant body is usually a simple blade, a much-divided blade (fig. 4, E) or more complex and differentiated into stem- and blade-like portions (fig. 4, A). None of the red algae attain a size comparable to that of the larger brown algae. The coralline red algae have their plant bodies heavily impregnated with lime. They have been shown to be of greater importance than coral animals in the formation of "coral" reefs and atolls.

The Rhodophyceae are divided into two subclasses, Bangioideae and Florideae. The Bangioideae have two distinctive characters: (1) cell division may take place anywhere in the plant body; and (2) the direct division of the zygote into carpospores. The single order (Bangiales) includes about 15 genera and 60 species. A few species are fresh-water, the remainder are marine. The most conspicuous and abundant of the marine genera is *Porphyra*. Its plant body is a tough leathery blade one or two cells in thickness. *Porphyra* usually grows on rocks in the intertidal zone and its blades may be more than a foot in length.

All Florideae have a filamentous plant body but in the majority of genera this is not obvious because the filaments are laterally compacted to form a structure of definite macroscopic form. Cell division is restricted to terminal cells of the branches. In Florideae the male sex organ (spermatangium) is unicellular and contains a single nonflagellate spermatium (fig. 3, K). A spermatium liberated from a spermatangium floats to and lodges against a hairlike

prolongation (trichogyne) of the one-celled female sex organ (carpogonium) (fig. 3, K) borne at the apex of a carpogonial filament. Gametic union is followed by a development of special filaments (gonimoblast filaments) that bear sporangia (carposporangia) containing carpospores (fig. 3, K). In some Florideae the gonimoblast filaments grow directly from the base of a carpogonium. In other Florideae fertilization is followed by growth of a delicate tube (ooblast) (fig. 3, N) from the carpogonium to another cell of the plant. The zygote nucleus migrates to this auxiliary cell and then gonimoblast filaments grow from the auxiliary cell. The mass of gonimoblast filaments and carposporangia, whether growing from a carpogonium or an auxiliary cell, jointly constitute the cystocarp or "fruit" of the sexual plant. Many phycologists interpret the cystocarp as a small asexual generation, the carposporophyte, that grows parasitically on the sexual plant (gametophyte). Each carposporangium of the carposporophyte liberates a single spore.

Primitive Florideae have a reduction division of the zygote nucleus and have the carpospores developing into gametophytes. More advanced Florideae have no reduction division of the zygote nucleus and produce carpospores in which the chromosome number is the same as that of the zygote. Carpospores of these Florideae develop into free-living asexual plants of the same size and vegetative structure as gametophytes. This asexual plant, the tetrasporophyte, bears sporangia (tetrasporangia) in which the single nucleus divides reductionally before the sporangial contents divide to form four tetraspores (fig. 3, M). Tetraspores liberated from a tetrasporangium develop into gametophytes.

Classification of Florideae into orders is based on mode of development of the carposporophyte and on the presence or absence of a tetrasporophyte. The Semaliales, the most primitive order, have no tetrasporophyte and usually have gonimoblast filaments developing from the carposporangium. There are approximately 35 genera in the order. All other orders have tetrasporophytes and of these the Gelidiales, a small order with about six genera, are the only ones where gonimoblast filaments grow directly from the carpogonium. All other orders with tetrasporophytes have the gonimoblast filaments growing from an auxiliary cell. In Cryptonemiales, an order with 85 or more genera, the auxiliary cell is borne in a special filament resembling a carpogonial filament. In the 70 genera placed in the Gigartinales the cell functioning as an auxiliary cell is an ordinary vegetative cell of the plant body.

The two remaining orders, Rhodymeniales and Ceramiales, have a special auxiliary cell borne adjacent to the base of a carpogonial filament. Rhodymeniales have this cell developing before fertilization; Ceramiales have it formed after fertilization. The two orders contain, respectively, approximately 25 and 160 genera.

Cyanophyta.—The Cyanophyta (blue-green algae) are the only algae in which photosynthetic pigments are not localized in definite chromatophores and in which the nuclear substances are not localized in definite nuclei. The photosynthetic pigments are evenly distributed through the cytoplasm and are masked by a blue pigment (phycocyanin); sometimes there is also a red pigment resembling phycoerythrin of Rhodophyta. Cyanophyta have no motile flagellated cells, either vegetative or reproductive, and no members of the division reproduce sexually. There are about 150 genera and 1,400 species, more than 80% of which are fresh-water and either aquatic or terrestrial.

The division contains but one class, the Myxophyceae (Cyanophyceae). All members of the class are of microscopic size but in some cases (e.g., *Nostoc*, fig. 4, H) many plants may be aggregated to form a macroscopic mass of definite shape. Some genera are unicellular; the majority are multicellular and either filamentous or nonfilamentous. The most primitive order, the Chroococcales, has solitary cells or has them united in nonfilamentous colonies (fig. 4, G). Some of the species occasionally produce spores but the usual method of reproduction is by vegetative division of cells and fragmentation of colonies. The order includes about 31 genera and 230 species, almost all of which are fresh-water. Members of the Chamaesiphonales regularly have the contents of a cell dividing into a number of minute nonmotile

endospores. The plant body is usually unicellular and epiphytic on other algae. There are about 30 genera and 130 species, most of which are marine. The Hormogoneales have their cells united end to end in filaments. There are approximately 90 genera and 1,000 species, the great majority of which are fresh-water. The filaments may be unbranched (fig. 4, H-4, J) or branched (fig. 4, L). Some genera have the filaments breaking at certain points and the ends growing out at the point of rupture. This results in a "false branching" of a filament (fig. 4, K). Practically all genera multiply by fragmentation of a filament into short parts, each composed of a few cells. These hormogones then develop into long filaments. Many filamentous genera form special thick-walled cells with transparent contents. These cells, the heterocysts (fig. 4, H; 4, J-4, L), are sporelike in nature but rarely germinate to form new plants. Filaments of some species regularly break into shorter filaments at points next to the heterocysts; those of other species do not.

Genera with heterocysts also produce large spores (akinetes, fig. 4, J) densely filled with protoplasm rich in reserve foods. Akinetes regularly germinate into new filaments. See DIATOMS; PROTOPHYTA. See also Index references under "Algae" in the Index volume.

ALGARDI, ALESSANDRO (1595-1654), after Bernini the most important Roman sculptor of the 17th century, was born at Bologna in 1595 and trained under Lodovico Carracci. After a short period of activity in Mantua (1622), he moved to Rome (1625), where he designed the stucco decorations in S. Silvestro al Quirinale and gained some success as a restorer of classical sculptures. With the monument of Cardinal Millini (d. 1629) in Sta. Maria del Popolo, the Frangipani monument in S. Marcello al Corso and the bust of Cardinal Laudivio Zacchia (Berlin), Algardi emerged as the principal rival of Bernini in the field of portrait sculpture. After the election of Pope Innocent X (1644), he superseded Bernini in papal favour, and between this date and his death in Rome on June 10, 1654, he produced some of his most celebrated works, among them the seated statue of the pope now in the Palazzo dei Conservatori (1645) and a colossal marble relief of the "Meeting of Attila and Pope Leo the Great" in St. Peter's (1646-50). At this time he also designed the Villa Doria Pamphili and a fountain in the Cortile di S. Damaso of the Vatican. Algardi's style was less ebullient and pictorial than Bernini's and, even in such characteristically baroque works as the tomb of Pope Leo XI in St. Peter's (1642-44) and the high altar of S. Paolo at Bologna (1641), the restraining influence of the antique is strongly felt.

(J. W. P.-H.)

ALGAROTTI, FRANCESCO, CONTE (1712-1764), Italian connoisseur of the arts and sciences, esteemed by the philosophers of the Enlightenment for his wide knowledge and elegant presentation of advanced ideas, was born in Venice on Dec. 11, 1712, and educated in Rome, Bologna and Florence. At the age of 20 he went to Paris, where his great physical beauty, his urbanity and his versatile intelligence quickly made an impression in intellectual circles. His Newtonianismo per le dame (1737; written 1733), a popular exposition of Newtonian optics, was highly praised by Voltaire. After a visit to England, Algarotti in 1739 went to Russia, whence he returned to England by way of Saxony. In 1740 he received a flattering invitation to Prussia from Frederick

the Great, which led to his staying more than nine years in Germany. Ill health eventually obliged him to return to Italy, to live first in Venice, then in Pisa, where he died of consumption on May 3, 1764. Frederick the Great caused a fine monument to be set up on his tomb, with the famous epitaph "Algarottus non omnis" ("[Here lies] Algarotti [but] not all").

Algarotti's many writings include several studies on classical themes and stimulating essays on architecture (1753), the opera (1755; Eng. trans. reprinted with essay by R. Northcott, *Francesco Algarotti*, 1917) and painting (1762). Lord Chesterfield, Lord Hervey, Thomas Gray, Metastasio, Voltaire, Maupertuis and Heinrich von Brühl were among his correspondents.

(1791-94); *Letters From Count Algarotti to Lord Hervey and the Marquis Scipio Maffei*, with miscellaneous other works, Eng. trans. (1769). See also I. F. Treat, *Un Cosmopolite italien du XVIIIe siècle* (1913); F. Viglione, *L'Algarotti e l'Inghilterra* (1919); A. Ambrogio, *L'Estetica di Francesco Algarotti* (1925).

ALGARVE, an ancient kingdom (established by Afonso III in 1253) and province in southern Portugal, now corresponds with the administrative district of Faro. Pop. (1950) 325,971. Area 1,958 sq.mi.

A fundamental distinction can be made between the interior hills bordering Baixo Alentejo and the limestone scarplands and coastal plain to the south, running about 85 mi. between Cape St. Vincent and the mouth of the Guadiana. The uplands, composed of Carboniferous slates, culminate in the Serra do Caldeirão (1,893 ft.) although the western massif of Monchique (2,959 ft.), composed of eruptive rocks, is the only mountainous area. Much of this zone is a waste of cistus scrub (matorral) only partially colonized, with seldom more than 10 to 20 persons per square mile. Only at Monchique (pop. [1950] 2,160) and Caldas de Monchique, a thermal spa, is the population denser. The coastal lands of Algarve are however densely populated, reaching 200-400 persons per square mile in areas of the coast. The scarplands and plateaus of the barrocal, composed of Jurassic limestones, are thickly covered with groves of figs, almonds, carobs, olives, and the alluvial lands along the coast have horticultural crops wherever irrigation from well supplies is possible. Maize is widely grown. East of Faro the coast called Sotavento is fringed for 30 mi. with sand bars and lagoons. Algarve (Arabic al-Gharb meaning "the west") is the most Moorish part of Portugal and hedges of prickly pear give it an African look. The whitewashed stone houses are elaborately decorated. Three-quarters of the urban population is concentrated in a series of 32 fishing and small seaports. Loulé (6,532) and Silves (4,361) are the only centres of note in the interior. Faro (q.v.), the capital, Olhão (16,583), Portimão (11,950) and Vila Real de Santo António (5,973) carry on coastal trade and tunny fishing. There is little industry apart from some cork manufactures, flour milling and mining. (J. M. HO.)

ALGEBRA. To the layman, algebra means elementary algebra, that branch of mathematics in which one learns to calculate with variables instead of just the numbers of arithmetic and to solve polynomial equations. To the professional mathematician, however, as well as to increasing numbers of scientists in other fields, algebra means rather what is called modern, higher or abstract algebra. Loosely speaking, this is the study of abstract mathematical structures in which there are operations having the properties of addition or multiplication.

Essential to both elementary and higher algebra is the fact that the calculations should always involve only a finite number of quantities and end after a finite number of steps; in other words, processes in which the answers are obtained "in the limit" generally do not belong to algebra (see LIMIT). Thus

$$1 + x + x^2 + x^3 + \dots + x^n = \frac{1 - x^{n+1}}{1 - x}$$

is algebra, but

$$1 + x + x^2 + x^3 + \dots + x^n + \dots = \frac{1}{1 - x}$$

is not.

A second characteristic of algebra is its abstractness. Even in

elementary algebra calculations are made not with numbers but with letters that represent numbers. In higher algebra the letters may represent much more general objects, and the system of calculation is itself an abstraction of systems having similar properties. This abstract, general viewpoint has become closely associated with modern algebra, so that to the professional mathematician the word "algebraically" sometimes means only "abstractly and axiomatically."

The demands placed on algebra by other branches of mathematics have been the richest and most significant source of new results in algebra, while, at the same time, the axiomatic, abstract algebraic viewpoint has simplified and clarified work in other fields, providing techniques leading both to new results and to unexpected connections between work in widely separated fields. This "algebraization" of mathematics has been one of the most characteristic features of 20th-century mathematics. In this way the influence of algebra has actually been far greater than its results. At the same time, modern algebra has brought a clearer understanding of the processes of elementary algebra and has enabled mathematicians to "get behind" the calculations to an understanding of the principles that underlie them. A general, nonrigorous survey of both algebras is presented here. Detailed treatments of specific subjects are contained in the articles named as cross references.

ELEMENTARY ALGEBRA

Content. — Elementary algebra includes a miscellany of topics representing the accretions of several centuries (*see* ALGEBRA; HISTORY OF). Some of them can by no stretch of the imagination be called algebra, while others are included in algebra only out of hospitality because they have no other place to go.

The basic task of elementary algebra is the solution of polynomial, *i.e.*, "algebraic," equations and the stepwise introduction of new types of numbers—negative, real and complex—to use in solving them. Some interest is added by applying equation-solving to verbal problems of varying degrees of removal from reality. There is also usually a great deal of drill in calculation with polynomials (*q.v.*) and letters—the binomial theorem (*q.v.*) and formulas for the sum of arithmetic and geometric progressions belong in this category. Determinants and matrices are devices for facilitating the solution of simultaneous equations and thus have their place (*see* DETERMINANT; MATRIX). The quadratic formula is the explicit solution of the quadratic equation, and so also merits attention. It is regrettable that the strong emphasis on drill often makes students equate "algebra" with "calculation"; the concentration on details of technique, short cuts for factoring, and so on, seriously obscures the logical outline of the subject.

Two traditional topics deserve mention. Permutations and combinations (typical problem: in how many ways can six men choose their wives from among six women, assuming no bigamy) are really elementary probability theory, but they use only algebraic arguments and the formulas are occasionally useful—the binomial coefficients, for instance (*see* COMBINATORIAL ANALYSIS). Exponentials and logarithms, on the other hand, are certainly not algebra, since they involve passage to the limit in their definition. Of course, the emphasis in elementary algebra is not on the precise definition of these functions but rather on the formal rules for operating with them, such calculation with formal rules being universally interpreted as "algebra."

Kinds of Numbers. — Elementary arithmetic uses only positive rational numbers—the natural numbers 0, 1, 2, 3, . . . and the common fractions such as $\frac{1}{2}$, $\frac{7}{8}$, These, however, do not suffice to solve even the simplest equation: $x + 3 = 0$, for instance. To solve such equations, negative rational numbers are introduced. To use these negative numbers, however, it is necessary to know how to calculate with them, and so the law $(-1)j(-1) = 1$ is given. Where does this law come from? The answer is that the calculation rules for negative numbers are adopted so that the five rules or laws

1. $a + b = b + a$
2. $a + (b + c) = (a + b) + c$
3. $ab = ba$
4. $(ab)c = a(bc)$
5. $a(b + c) = ab + ac$

which are valid for positive numbers will continue to be valid for the larger system including the new negative numbers. Rule 5 gives

$$0 = -1(1 - 1) = (-1)1 + (-1)(-1) = -1 + (-1)(-1)$$

so that adding 1 to both sides gives $1 = (-1)(-1)$. In other words, this last result is to be interpreted as a consequence of the five laws viewed as axioms, an interpretation very much in the spirit of modern algebra.

The introduction of negative rational numbers suffices for the solution of linear equations, those of the form $bx + a = 0$, and for simultaneous linear equations:

$$\begin{aligned} ax + by &= c \\ a'x + b'y &= c' \end{aligned}$$

to give an example of two equations in two variables x and y —there could be more variables and more equations, of course. It is inadequate, however, for solving equations of higher degree, such as the quadratic $ax^2 + bx + c = 0$. Two roads are open: one can develop methods for determining when an equation with rational coefficients does have a rational solution, or one can extend again the number system in the hope of solving more equations.

Following the second alternative, the extension is first made to the system of all real numbers. This permits the solution of some equations not solvable in rational numbers, $x^2 - 2 = 0$, for instance. Another extension leads to the set of complex numbers $a + b\sqrt{-1}$, where a and b are real (*see* COMPLEX NUMBERS). With each extension, it is necessary to explain how to calculate with the new types of numbers. For the real numbers this explanation is taken for granted, while for the complex numbers the familiar laws are given, again with the purpose of preserving the validity of the five previously given axioms. The employment of complex numbers makes the extension complete by virtue of the so-called fundamental theorem of algebra, which says that every polynomial equation with complex coefficients has a solution in complex numbers; it only remains, then, to describe processes and to give formulas when possible for actually finding the solutions.

Unfortunately, however, this fundamental theorem is not a theorem of algebra at all—indeed, it is never proved in algebra courses. The difficulty begins with the introduction of the irrational numbers. These are represented in the familiar way by the points on a line. Now the rational numbers, when plotted on the line, are dense on the line in the sense that any line segment, no matter how small: will always contain points representing rational numbers. Thus, constructing the irrational numbers from the rational numbers is essentially a process of filling in the gaps on the line, which, no matter how it is done, will involve notions of limit and therefore will not be describable in terms of a finite number of operations. For example, the most familiar way of describing an irrational number is as an infinite decimal: $\pi = 3.14159\dots$. But what this means is only that the infinite sequence of rational numbers 3, 3.1, 3.14, 3.141, . . . , is approaching π ; to stop after a finite number of steps will not give the precise value of π .

The real numbers (and thus the complex numbers, also) being so defined by the use of nonalgebraic processes, a proof of the fundamental theorem must inevitably be achieved through some nonalgebraic argument. For example, the most "algebraic" proof known starts from the following result: a polynomial $x^n + a_1x^{n-1} + \dots + a$, of odd degree and with real coefficients has a real root. Now if the graph of such a polynomial is considered, the result is "self-evident," because for large positive values of x the graph of the polynomial always lies above the x -axis, whereas for large negative values of x it always lies below; therefore it must cross the axis somewhere in-between, and this is where the root will be. This argument assumes, however, that the graph is represented by an unbroken curve; and the careful explanation of just what this means, coupled with a careful proof of it and the foregoing statement about the necessity for crossing, can only be achieved by appealing to the infinite process of passing to a limit.

The fundamental theorem of algebra being of essentially non-algebraic character, the same should be true of any of the well-

known approximation methods for actually obtaining a solution, such as Newton's and Horner's methods. Yes and no: they are nonalgebraic because they must be infinitely repeated to obtain the exact solution, but algebraic insofar as that, at any finite stage, only algebraic arguments and techniques—simple additions and multiplications—are employed.

The other road that was mentioned, the determination of when a polynomial with rational coefficients does have a rational root, leads to the problem of factorization. If a is a root of the polynomial $f(x)$, then according to the factor theorem $f(x) = (x - a)g(x)$, where $g(x)$ is also a polynomial with rational coefficients, and there exist criteria for determining when such a factorization is possible. More generally, there is the problem of determining whether a given polynomial will factor into the product of two smaller ones. The important thing to observe here is that the problem is relevant only when the types of numbers to be available as coefficients are made clear. Thus $x^2 - 2$ does not factor if only rational coefficients are permitted, but it does if irrational coefficients can be used; and any polynomial of degree greater than one factors if complex coefficients can be used. In other words, the problem of factorization is connected with the process of extending the number system; how far one has gotten with the latter determines the success in factorization.

MODERN ALGEBRA

Modern algebra evolved from elementary algebra in a series of jumps beginning essentially with the work of Bvariste Galois in 1830. It includes all of elementary algebra and a great deal more, but in an extensively generalized form; each topic of elementary algebra is thus viewable as the starting point of one of the theories of modern algebra. However, modern algebra is somewhat different in spirit and method, as the following example, carried out in some detail, will show.

Abstract Axiomatic Systems; Commutative Rings.—Take as a starting point the set of integers, including zero and the negative integers, with the operations of addition and multiplication obeying the five laws previously given. Division is forbidden, because the quotient of two integers is not usually an integer. Subtraction is permitted, because $a - b$ can be interpreted as the addition of a to $-b$; however, because there is nothing in the five laws that says that the negative integers are really in the set (the laws apply equally well, as has been seen, to just the positive integers), a sixth law must be added:

Rule 6. There exists an object 0 such that, for all a , $0 \dagger a = a$, and there is a unique object $-a$ such that $a \dagger (-a) = 0$.

Thus there is on hand a collection of objects (the integers) with two operations ($-$ and \cdot) which satisfy six laws. The viewpoint of abstract algebra is now: forget that this is a collection specifically of integers—what follows from these six laws without any further assumptions? This is the axiomatic viewpoint, for the laws are interpreted as the axioms that give the rules for calculation with the objects. Such a collection with two operations satisfying the given laws is called a commutative ring.

Another example of a commutative ring is given by the set of even integers. The polynomials in one variable with real coefficients form such a ring, if the operations are taken to be the usual polynomial addition and multiplication. The numbers from 0 to $n - 1$ form a ring which will be denoted by Z_n if one adds and multiplies as usual, but subtracts a multiple of n from the answer so as to make it a number between 0 and $n - 1$ again. For instance, to calculate in Z_6 , $4 \dagger 5 = 3$, $4 \cdot 5 = 2$, $2 \cdot 3 = 0$. Here 6 has been subtracted from the first answer, 3×6 from the second and 6 from the third. (This procedure is familiar in "casting out nines.") As a more bizarre example of a commutative ring, take as the objects of the collection all possible sets A, B, C, \dots of points in a plane; for instance, A might be the set of all points inside some circle, B might be a single point, C might be the set of all points on some line, and so on. Include in the collection also the empty set—the set with no points at all. Define the operations \dagger and \cdot in this way: $A \dagger B =$ all points in either A or B but not in both, while $A \cdot B =$ all points in both A and B . It can be shown that these operations do indeed satisfy the six axioms. The

empty set is the element 0, and one has the calculation rules $A \dagger A = 0$, $A \cdot A = A$.

To be of value, the axioms must not be so peculiar and special that they reflect no significant mathematical reality, nor must they be so general that nothing very significant follows from them alone; in other words, the axioms must really summarize a large part of what is important in the systems being studied abstractly. Here one is on weaker ground, for it must be admitted that, although there are plenty of commutative rings in nature, usually their most significant properties do not follow just from their being commutative rings alone—some additional axiom is required.

For instance, although one cannot in general divide one integer by another, the integers are contained in a larger commutative ring in which division by any nonzero element is possible, namely the ring of rational numbers. Such a commutative ring admitting division is called a field. The ring of polynomials with real coefficients also has this property; it is contained in the field of rational functions $f(x)/g(x)$, where f and g are polynomials with real coefficients. The rings Z_2 , Z_3 and Z_5 themselves turn out to be fields; for instance, in Z_5 , $\frac{3}{4} = 2$, since $3 = 4 \cdot 2$. On the other hand, Z_4 and Z_6 are not contained in any field, nor is the ring of sets described above. On analyzing the matter, one can prove that the necessary and sufficient condition for a commutative ring to be contained in a field is that it satisfy a seventh axiom: whenever $ab = 0$, then either $a = 0$ or $b = 0$. One now can check that Z_n has this property exactly when n is a prime number; certainly the ring of sets does not have it, because if A and B are sets with no points in common, then $A \cdot B = 0$, although neither A nor $B = 0$. Commutative rings satisfying this additional axiom are called integral domains, and thus the statement that the integers are contained in the rational numbers generalizes to the statement that every integral domain is contained in a field.

Here is another example. What underlies and justifies the effort spent in factoring polynomials in elementary algebra is the result that any polynomial with, say, rational coefficients is in one and only one way (up to a constant factor) the product of irreducible polynomials with rational coefficients (those that cannot be further factored). There is an analogous result for the integers: a positive integer is in one and only one way the product of prime numbers.

One may ask now, in general, for which integral domains is there such a unique factorization theorem? This is not an easy question, and no universal criterion is known; there are, however, several reasonable axioms, any one of which will guarantee unique factorization. One that works for both the integers and the polynomial rings is the Euclidean axiom: if a and b are given, and $b \neq 0$, then one can divide a by b with a remainder r which is "smaller" (in a precise sense which shall not be described) than b ; that is, $a = bq \dagger r$. For integers, the size is to be measured by the absolute value, while for polynomials, by the degree. Thus, an integral domain satisfying the Euclidean axiom (such are called Euclidean domains) admits unique factorization.

Thus far the given set of axioms has been added to in order to obtain worthwhile results. A common practice is to drop axioms, or substitute weaker ones for them, and see what results. If axiom 3 is dropped, the resulting system is called a ring. If 3, 4 and 5 are dropped while 1, 2 and 6 are retained, there results a system with one law called an abelian group. Groups are of vast importance in modern algebra (see GROUPS; GROUPS, CONTINUOUS; GROUPS, TRANSFORMATION; GROUPS AND ALGEBRAS, REPRESENTATIONS OF).

To sum up, therefore, one gains by this process of abstraction great generality, because a theorem about an abstract commutative ring automatically holds for any specific example of such a ring and therefore need not be tediously proved for every special case. On the other hand, the process has its dangers, and the goal must always be the attainment of the richest consequences with the minimum number of assumptions.

To reiterate an earlier remark, there is an implicit limitation to those axiomatic systems whose operation laws involve only finite processes using a finite number of elements. Though there is in principle no objection to laws of infinite type, the resulting systems would be outside the domain of algebra.

Scope of Study.— Now that the type of object studied in modern algebra has been outlined, the scope of the study will be indicated in some detail. The scope will be divided, somewhat artificially, into three parts: first, some general comments about what sorts of results one tries to obtain for an abstract axiomatic system, then a brief survey of the existing types of systems and what is known about them, and, finally, a discussion of the interaction of algebra with other parts of mathematics and with science in general.

Classification of Systems.— Given an abstract system (such as a group, or a commutative ring) defined by operations satisfying certain axioms, the basic problem is to classify the different types of such a system. It may help the reader to consider an analogous classification problem in biology. To "classify all birds" would mean: to the list of properties that make an animal specifically a bird, add other distinguishing sets of properties—the species properties—so that each bird belongs to one and only one species and the birds of each species are essentially indistinguishable biologically. This is not quite enough; one would also like a specimen, or at least a picture, of a representative member of each species.

A similar situation exists in the classification of algebraic structures. One adds properties which narrow down the possibilities sufficiently, then seeks to obtain a specimen of each "species." For example, to classify all commutative rings is certainly a hopelessly formidable task—there are too many different kinds. If the category is limited to all integral domains, the class is still too wide. If, however, one asks for the integral domains with only a finite number of elements, they can be classified completely. In this case, the species are completely determined by telling how many elements they contain. Let this number of elements be designated by n . Then if n is a prime number, Z_n is a representative of the species; if n is not prime, no such integral domain exists.

To clarify the foregoing, the meaning of the term species must be explained: this should consist of a class of algebraic structures which are essentially indistinguishable. The relevant algebraic notion is that of isomorphism: two collections A and A' of objects with given laws of operations are isomorphic if one can associate each object of A with a definite object of A' so that all the objects in A' are associated with something in A and so that different objects in A are associated with different objects in A' (in short, make a one-to-one correspondence between A and A'), and so that the operation laws are preserved; *i.e.*, if a and a' correspond, and b and b' correspond, then to $(a + b)$ should correspond $(a' + b')$, and so on. If A and A' are isomorphic, then their algebraic structures are indistinguishable; algebraically they differ only in that their objects have different names. It is easier to give examples of isomorphic groups than of isomorphic rings, since there is one less operation to worry about. The positive real numbers form an abelian group under multiplication, and the whole set of real numbers forms an abelian group under addition. These two groups are isomorphic, because if to each positive real number x one associates the real number $\log x$, then the correspondence is one-to-one, and the operation is preserved, because to xy corresponds $\log(xy) = \log x + \log y$; that is, addition in the second group corresponds to multiplication in the first group. Again, the additive group Z_6 that has been described is isomorphic to the group of rotations of a regular hexagon (where to "add" two rotations means to perform first one, and then to follow it with the other).

The explanation of the classification problem can now be completed in this manner: once there have been added enough additional properties to determine uniquely the species, designate a specimen of it; then the species consists of all systems isomorphic to the given specimen. Thus in the earlier illustration, the species whose members are all integral domains containing p elements has Z_p as a specimen, and any other such integral domain is isomorphic to Z_p .

Kinds of Algebraic Systems.— The principal abstract objects of study are groups, rings, fields, vector spaces and algebras. Groups have one operation (usually called addition if the group is abelian,

otherwise multiplication); rings have two; fields ($(q.v.)$ are commutative rings in which one can divide; vector spaces ($(q.v.)$ are additive groups in which there is a scalar multiplication by elements of some field; algebras (sometimes called linear algebras) are vector spaces with a multiplication law defined (see ALGEBRAS [LINEAR]).

Most of these abstract systems grew naturally out of elementary algebra. The theory of rings came, as has been seen, from study of the formal properties of integers and polynomials; a noncommutative ring differs from a commutative ring in that one drops axiom 3: $ab = ba$. Fields arose, as has been seen, from the attempts to provide solutions for algebraic equations. The proof that the equation of fifth degree could not be solved by a formula analogous to the quadratic formula gave rise to group theory. Finally, the solution of simultaneous linear equations in elementary algebra led directly to the theory of vector spaces and matrices; the square $n \times n$ matrices themselves give one of the most important examples of an algebra.

The classification problem has been solved most completely for several types of algebras. There are the famous Wedderburn theorems: if the algebra is a finite division algebra (has only a finite number of elements and always permits division by a non-zero element), then the multiplication law must be commutative, so that the algebra is actually a finite field, and it is not hard to classify all of these. If it is what is called a "central simple" algebra, then it is isomorphic to the algebra of all $n \times n$ matrices, whose entries come from a certain division algebra. Other algebras that have been classified are Lie algebras, Jordan algebras and division algebras over number fields.

For groups, the solution of the general classification problem is far from complete. If the group is finite, one general procedure is, first, to classify all of the simple groups (those without nontrivial normal subgroups), and then to describe how an arbitrary group is built out of simple subgroups. New simple groups are still being discovered, however, and it is not even known whether there are any with an odd number of elements, except for the groups Z_p (where $p \neq 2$). The study of infinite groups has not progressed far. Even the abelian ones can be very complicated—for instance, the additive group of rational numbers is one of the most difficult.

Every field contains a uniquely determined smallest field, called the prime field, which is isomorphic either to the field of rational numbers or to one of the finite fields of Z_p . This fact provides, therefore, a first basis for classifying them. The next step is to decide whether every element in the field is a root of some polynomial equation with coefficients in the prime field. If this is the case the field is called algebraic; if not, it often is possible to attach a number to the field (called its transcendence degree) which measures roughly how far away it is from being algebraic. The further classification of the algebraic fields is called algebraic number theory; the classification of fields with transcendence degree properly belongs to algebraic geometry.

Effect of Modern Algebra on Other Subjects.— In mathematical analysis, the influence of algebra has produced the so-called functional and abstract analysis. The subject matter of classical analysis is, more or less, the study of functions in ordinary real or complex Euclidean space, particularly on the line. One studies both the behaviour of the functions themselves and the properties of the integral and differential equations they satisfy. The algebraic viewpoint is that suitable classes of these functions form vector spaces satisfying certain additional axioms, generally of a nonalgebraic character (Hilbert spaces or Banach spaces, for example). The study of the integral equation or the differential equation may now be formulated as a study of the properties of a certain linear transformation on this vector space. From this point of view, the theory is the generalization to infinitely many dimensions of the theory of linear transformations on a finite-dimensional vector space; *i.e.*, the theory of matrices. Many theorems bear a resemblance to the corresponding theorems about matrices, although, of course, they are far more difficult to prove. Again, the classical theory of periodic functions and trigonometric series, which is basically a theory of functions on the circle, is

generalized to functions on more general groups, the topological groups; this, then, is abstract harmonic analysis. Although algebra has systematized and clarified many theorems here, it seems that the crux of any significant theorem always turns out to be a piece of "hard" analysis of the old-fashioned sort. (See ANALYSIS; ANALYSIS, ABSTRACT.)

The influence of algebra on geometry can be divided into applications to differential geometry, topology and algebraic geometry. Dominating much of differential geometry (*q.v.*) in the 20th century has been the theory of Lie groups, those groups in which the multiplication law is given "analytically" by differentiable functions; the group of all $n \times n$ matrices with real or complex entries is an important example. To each such Lie group one can associate an algebra (vector space with multiplication)—its Lie algebra—which in turn determines many of the properties of the group. The classification of Lie algebras is a purely algebraic problem, whose solution gives in turn a classification of Lie groups, or, at least, a wide class of them.

An even more striking example of the application of algebra to geometry is afforded by topology. This is the branch of mathematics that studies the properties of those geometric objects that remain invariant under continuous deformation ("stretching"). At first glance it might seem that the rigidity of the structures in algebra would have little light to shed on the elastic objects of topology, but this is not so. The basic method of algebraic topology is to associate with the geometric object (called a topological space) certain algebraic structures—groups and rings, for the most part—which remain unchanged by a deformation of the space. Properties of the spaces are then reflected in properties of the algebraic structures, and the goal is to find enough associated algebraic structures to effect a complete classification of topological spaces: two spaces can be deformed one into the other (the surface of a sphere and that of a sausage, for instance, or that of a teacup and a doughnut) if and only if their associated algebraic structures are isomorphic. (See TOPOLOGY, ALGEBRAIC; TOPOLOGY, GENERAL.)

As an example of such a structure, consider a point fixed in the space, and assume that all closed paths in the space begin and end at this point. If one does not consider two paths to be different if one path can be deformed into the other, the set of paths forms a group (to multiply two paths, first follow one, and then the other: the result is still a closed path) called the fundamental group of the space. The fundamental group of a cylinder, for instance, is isomorphic to the group of integers, since two paths which go around the cylinder the same number of times can always be deformed one into the other. The fundamental group alone is enough to classify all closed surfaces in three-dimensional space which have no edge and do not cross themselves. For instance, if the fundamental group consists of 0 alone, the surface can be deformed into the surface of a sphere. This group is also the main tool in describing when two knots in three-dimensional space can be deformed one into the other.

Perhaps the most intimate of all the influences of modern algebra on other branches of mathematics is the relation of algebra to algebraic geometry and algebraic number theory: indeed, in the works of some authors one gets the feeling that these last two subjects are only chapters in algebra. Algebraic number theory is the study of the properties of algebraic numbers—those complex numbers that are the roots of polynomials in one variable with rational coefficients. Algebraic geometry (*q.v.*) is the study of geometric loci in space defined by algebraic equations in several variables: algebraic curves, surfaces and similar objects in n -dimensional space, called simply "varieties." These are, then, the sets of points forming the zeros of a finite set of polynomials in n variables, with coefficients from some field (for example, the complex numbers).

In these studies, certain groups, rings and fields keep recurring constantly as the natural structures which summarize and characterize the properties of number fields and varieties. In algebraic number theory, for instance, the group of admissible permutations of the roots of an algebraic equation (see EQUATIONS, THEORY OF) plays a decisive role; it is called the Galois group. In algebraic

geometry, the field of all rational functions on the variety is one of the most important invariants of the whole variety. The geometric behaviour of the variety in the neighbourhood of a point p on it is described algebraically by the properties of the integral domain consisting of all rational functions that do not become infinite or undefined at the point p . For instance, whether the variety is or is not smooth around p (a cone would be smooth everywhere except at the vertex) can be expressed entirely in terms of this ring. The purely algebraic study of these integral domains (called local rings), which has become so popular, is a good example of the influence of other fields on algebra itself.

Most amazing of all perhaps has been the success of the so-called homological methods; these abstract algebraic methods of handling the groups which arise in algebraic topology (the homology groups) have turned out to be the natural way to describe the most advanced portions of algebraic number theory, and they are rapidly invading much of the rest of mathematics as well.

Finally, a word should be said about some of the applications of algebra to science other than mathematics. In theoretical physics, the theory of groups and their representations has played an important part in the development of quantum theory, particularly in connection with solid-state physics. The theory of Boolean algebras (the ring of point sets in the plane, described earlier, is an example of one) has been widely used in the design of computing machines. In the social sciences, psychology and economics are finding use for matrices and linear algebra in what is called linear programming. In all of these subjects, too, the introduction of algebra has stimulated algebra as well.

See also Index references under "Algebra" in the Index volume.

BIBLIOGRAPHY.—The classical works on algebra are: W. Weber, *Lehrbuch der Algebra*, vol. 1, 2, 3 (1898); M. Bôcher, *Introduction to Higher Algebra* (1907). For elementary algebra there are many textbooks, for instance, M. Knebelman and T. Thomas, *Principles of College Algebra* (1942). Somewhat more advanced are the books on theory of equations, for example: L. Weisner, *Introduction to the Theory of Equations* (1947); L. Dickson, *New First Course in the Theory of Equations* (1939). Some books on modern algebra, in increasing order of difficulty, are: M. Weiss, *Higher Algebra for the Undergraduate* (1949); A. Albert, *Introduction to Algebraic Theories* (1941); G. Birkhoff and S. MacLane, *A Survey of Modern Algebra* (1953); B. van der Waerden, *Modern Algebra* (1949). (A. P. M.)

ALGEBRA, HISTORY OF. Algebra separated from arithmetic early in the development of mathematics, probably in Babylonia when equations and methods for reducing them were introduced. A considerable number of cuneiform mathematical tables from the period of the Hammurabi dynasty (1800–1600 B.C.) deal with problems now classified as algebra. The calculations of the examples from this period are presented in a way that makes clear that the general methods, and not the numerical results, are the main goal. A mastery of quadratic equations is evident; often they were presented in the standard form $x + x^{-1} = a$, which could be solved by means of tables or by reduction to a square root extraction as at present. Another normal form for quadratic problems in two unknowns was $x \& y = a$, $x \cdot y = b$. More complicated problems were reduced to these. Closely related to these questions are studies of the integral solutions of Pythagorean triangles, that is, determination of integers satisfying $x^2 + y^2 = z^2$. There occur instances of fourth degree equations reducible to quadratic equations and also special cases of cubic equations, presumably solved by tables. Summation of arithmetical progressions and the sums of squares of integers also were known.

The Egyptian knowledge of algebra seems to have been much more limited than that of Babylonia and may have developed under Babylonian influence. The problems as are known from the Rhind mathematical papyrus (copied by Ahmes, c. 2000–1800 B.C.) are in the main limited to linear equations. A first approach to formal algebra is the use of a standard symbol h (*aha*, *hau*), meaning quantity, to denote the unknown to be determined.

The cultures of Asia Minor and Babylonia influenced Greece strongly, and the Greeks undoubtedly received much of their basic knowledge of algebra from these sources. However, within Greek mathematics algebra took on a geometric aspect primarily, it is believed, because of the logical difficulties created by irrational

numbers. In the geometric language, for instance, of Euclid's *Elements* (about 300 B.C.) the quantities were represented by lengths of lines, products of two quantities by the area of rectangles and products of three factors by volumes of rectangular solids. In this manner all problems appear in the form of homogeneous relations between quantities of the same dimension. Thus the quadratic equation can be written $b^2 = x(x \pm a)$ and the solution consists in finding a rectangle with sides x and $x \pm a$ whose area is equal to that of a given square b^2 . The actual construction can be made by right triangles or mean proportionals. In line with this geometric view of algebra is the development of the theory of conic sections, which reached its zenith in the *Conica* by Apollonius of Perga (220 B.C.). The solution of such problems as the duplication of the cube and the trisection of the angle also were given in terms of the intersection of special curves.

The later Alexandrian period of Greek mathematics seems to have been closer to Babylonian sources. From the point of view of algebra the most noteworthy work is the *Arithmetica* of Diophantus (date uncertain, about A.D. 200). His problems are mostly of the so-called Diophantine type whose solutions are positive fractions or integers; usually the equations are linear or quadratic in several unknowns, but these are systematically reduced to a single unknown. Remarkable are the beginnings of algebraic notation or shorthand. The unknown is denoted by s (perhaps the final letter in the Greek arithmos, "number") with special terms for the first powers. Terms to be added are simply written together while a special sign is used for minus.

Concerning the development of algebra in the orient, in India, China and Japan there is still a good deal of dispute, partly with a nationalistic flavour. The very beginnings of algebra in all these countries seem to have been influenced by the Babylonian and Greek schools. Among the Hindu algebraists one should mention especially Brahmagupta (about A.D. 630), whose work on indeterminate equations in many ways goes beyond Diophantus. Somewhat later (about A.D. 1150) are the outstanding works of Bhaskara, the Lilavati and the Vija-ganita. Here one finds rules for dealing with negative quantities: a dot over a number was used to indicate minus. It was realized that square roots of positive numbers have two roots, and Bhaskara also mentions that there are no roots of negative numbers. Unknowns were denoted by the names of various colours. Powers and roots were indicated by the initial letters or first syllables in the corresponding words, giving a close approach to algebraic symbolism.

With the ascendancy of Mohammedanism the Arab world became the centre for mathematical studies. A number of Arab mathematicians wrote commentaries upon Greek works in the geometric tradition, but there also were notable original algebraic contributions. The cubic equation was a favourite topic for such writers as al-Mahani (about A.D. 850), Tabit ibn Korra (870), Alhazen (1000) and particularly the poet and mathematician 'Omar Khayyam (about 1100), who dealt with it extensively in his algebra; the solutions were obtained by intersections of conics.

The most influential algebraic work from this period was the *Kitab al jabr w'al-muqabala* of al-Khwarizmi composed in Baghdad (about 825). The title may be translated: "The Rules of Restoration and Reduction." The influence of the book on Europe was so great that its name became synonymous with equation theory. The unknown was called shai, "the thing"; otherwise al-Khwarizmi shows little tendency to algebraic symbolism.

Arab algebra was introduced to Europe, especially to Italy, in the 13th and 14th centuries. Most important in this process was Leonardo of Pisa's *Liber abaci* (1202) from which later Italian algebra books borrowed freely. Under the influence of Arab usage the unknown was called res in Latin, cosa ("the thing") in Italian, while algebra itself became known as *l'arte della cosa*, cosmic art or the rule of coss. Occasionally algebra was termed the *Ars magna*, "the great art," in contradistinction to the lesser art of arithmetic.

Italian algebraists, for instance Fra Luca Pacioli (1494), had expressed the belief that the general cubic equation could not be solved algebraically (by means of radical expressions). Thus it was a remarkable achievement when around 1515 Scipione del

Ferro, professor at the university of Bologna, succeeded in solving the cubic equation in the special form $x^3 + ax = b$. Del Ferro did not reveal his formula, but after his death it passed to his pupils. In a mathematical tournament with one of them, Niccolò Tartaglia from Brescia rediscovered the method and confided it to Girolamo Cardano, a physician in Milan, under promise of secrecy. In 1545 Cardano published his *Ars magna*, the most important algebraic work of the Renaissance. It contained the solution of the cubic equation, still erroneously called Cardano's formula, and also the method for solving fourth-degree equations discovered by Cardano's former servant and protégé, Lodovico Ferrari. The *Ars magna* contained novel ideas concerning the relations between roots and the coefficients of equations; Cardano even calculated formally with imaginary numbers. Publication of this work had a considerable influence on the rapid growth of algebra in Europe.

The presentation in the *Ars magna* is partly geometric in the Greek tradition and partly verbal with scant use of symbols. For problems as complicated as these, such form became very cumbersome, and evidently a stage had been reached at which effective simplification was required. It should be observed that some standard notations had already become common in arithmetic, for instance \bar{p} and \bar{m} were used for plus and minus. The latter symbol was reduced to the bar to denote minus while the present plus sign $+$ is a condensed form for the Latin et. The \times sign for multiplication appeared in England around 1600; the radical sign $\sqrt{\quad}$ may originally have been the letter r as an abbreviation for radix.

Cardano's compatriot Raphael Bombelli (about 1560) had made some attempts at simplified writing of algebraic formulas, but the credit for a first systematic effort to introduce an algebraic sign language must go to the French mathematician François Vieta. In his *Isagoge in artem analyticam* (1591) the quantities are denoted by letters, often vowels for the unknowns and consonants for given numbers. The powers of a number A were written Aq (quadraticus), Ac (*cubus*), Aqq (*biquadraticus*), and so on. The present usage of denoting unknowns by the last letters (x, y, z) of the alphabet and known quantities by the first letters (a, b, c) is attributed to Descartes (1637); he was the first to write powers with exponents in the modern form, although this notation had been used sporadically by earlier writers. John Wallis (1655) and Sir Isaac Newton (1669) introduced fractional exponents for roots. The equality sign is attributed to Robert Recorde (1557). From the middle of the 17th century the algebraic notations were close to the modern ones. Once initiated, the advantage of symbolic writing was obvious, and the development of an effective and logical mathematical sign language has since been a continuous process.

The rapid use of algebraic technique in the 16th and 17th centuries rendered obsolete some of the medieval algebraic methods, particularly the popular rule of false position inherited from the Arabs. This rule was used to solve linear problems by trying out one or two particular values and adjusting them to satisfy the given conditions. As Recorde states in his *Ground of Artes* (1542):

Suche falsehode is so good a grounde
that truth by it will soone be founde.

The idea of solving systems of linear equations by determinants seems to have been originated by Leibniz (1693) although Chinese and Japanese sources contain some indications of similar methods. The first systematic treatments of determinant theory were given by A. T. Vandermonde (1771) and Pierre Laplace (1772), but they were not commonly used until further phases of the theory had been developed by Augustin Cauchy (1812) and Karl Jacobi. A standard tool of algebra, the binomial theorem, is ancient and was quite well known by the middle of the 16th century. The more general multinomial theorem is usually ascribed to Leibniz. The interest in equation theory stimulated the study of symmetric functions of roots. The fundamental facts about them were developed particularly by Newton, Wallis, Edward Waring and other members of the English school of mathematicians studying combinatorial analysis.

The introduction of such new fields of mathematics as analytic geometry by Descartes and the calculus by Newton and Leibniz

also contributed greatly to the development of algebra. For instance, one may say that the Greek idea of a geometric algebra was now reversed into an algebraic geometry. The study of algebraic curves advanced the field of algebra itself by introducing methods of reduction and elimination for general algebraic equations in several unknowns, together with the various concomitant concepts such as resultants and discriminants (Étienne Bézout, 1764).

The properties of algebraic equations indicated the desirability of recognizing complex numbers as roots on a par with real roots. Only then would the so-called fundamental theorem of algebra be valid. The theorem states that an equation of n th degree always has n roots. This was realized as early as Cardano for third- and fourth-degree equations. It was expressed by Albert Girard (1629) and Descartes. A fully rigorous proof was given first by Karl Gauss (1799) in his doctoral thesis. The representation of complex numbers graphically by co-ordinates in the plane is also sometimes ascribed to him, but the credit for this idea must be awarded to the Norwegian surveyor Caspar Wessel (1795).

Methods for numerical resolution of equations, in particular for extracting square and higher roots, were devised by all the ancient schools of mathematics. Leonardo of Pisa gives a numerical solution of a cubic equation with the root accurate to more than six sexagesimal places. The calculus facilitated the development of a large number of such methods; among them are those proposed by Vieta (1600), Newton and a method by W. G. Horner (1819) that is still in use. Various criteria were devised to determine the general locations of the roots, for instance, the number of positive roots or roots in an interval. Theorems of this kind were proved by Newton, Jean Fourier, Jacobi and others; most complete is a criterion by Jacques Sturm (1835).

The Renaissance discovery of methods for the solution of equations of third and fourth degree left open the puzzling question of whether similar radical expressions could be found for roots of fifth and higher degree equations. This was a central problem in algebra in the 17th and 18th centuries and many excellent mathematicians, notably Joseph Lagrange, expended much effort on it. A feeling that the problem was insoluble became widespread. A first proof was published by Paolo Ruffini (1803, 1805), but the proof by Niels Henrik Abel (1824, 1826) is generally regarded as the first rigorous one for what has come to be known as the Abel-Ruffini theorem which states: the general algebraic equation of degree higher than four cannot be solved by radical expressions. Abel attacked the general problem when an algebraic equation of higher degree can be solved by radicals.

His papers inspired Évariste Galois (1831) to his remarkable Galois theory of equations based upon the new and fundamental concept of group theory. Although the importance of Galois' work was not realized until long after his death, group theory now permeates all fields of mathematics and has become one of the most important branches of algebra.

The 19th century saw a great surge in algebraic research with the creation of several new branches of algebra. Introduced were such topics as invariant theory, originally inspired by the desire to determine those algebraic quantities of a curve that are independent of the choice of the co-ordinate systems; the theory of algebraic functions: the theory of algebraic numbers created by Ernst Kummer and Julius Dedekind, including the theory of ideals, one of the most fertile concepts of modern algebra; further extensions of the number concepts, first through the quaternions of Sir William Hamilton and later through the general hypercomplex numbers, which in turn are closely related to the theory of matrices, an all-pervading part of recent mathematics.

The algebraists of the 20th century have continued the work in these and many other domains. With increased knowledge in so many branches of algebra has come the realization that the various theories are related through certain general principles underlying them all. This has led to the development of a so-called abstract algebra with two chief aims: (1) A deduction problem comprised of the derivation of the properties of a system with given axioms. These axioms are of algebraic nature, and the operations on the elements correspond in some way to addition, subtraction, mul-

tiplication and division. (2) A completeness problem consisting of the construction and classification of all systems that can exist for a given family of axioms. A typical example of an analysis of the latter kind is a work by Ernst Steinitz (1910) deriving all types of fields; that is, an algebraic system in which all the ordinary axioms for the four basic operations are satisfied. The theory of rings has become equally fundamental, uniting the principles of many domains of algebra; this theory deals mainly with operations, corresponding to the first three fundamental ones. Finally, intense efforts have been made in the study of groups and grouplike systems with only one operation, sometimes called an addition but more often a multiplication.

ALGEBRAIC GEOMETRY, a branch of mathematics in which the properties of a geometrical structure are described by means of algebraic expressions.

The origins of algebraic geometry go back to the introduction of co-ordinates into geometry. It was not, however, until the early 19th century that the subject began to stand on its own, and indeed for nearly half a century after that its role was mainly to supplement the synthetic methods of dealing with projective geometry. Nevertheless, it is convenient to date the modern subject of algebraic geometry from the introduction of homogeneous co-ordinates into projective space by August F. Möbius and others. From this time onward algebraic methods of investigating figures and loci in projective space became of increasing importance, and during the great period in the history of projective geometry in the later 19th and early 20th centuries the use of algebraic methods was all-important. The achievements of this form of algebraic geometry belong, however, more properly to projective geometry.

Nevertheless this association with projective geometry is the basis on which all the modern developments in algebraic geometry are founded. One of the most usual methods of establishing algebraic geometry on a rigorous basis is to define first a projective space over an algebraic field and then to define algebraic varieties in it. The field may be any algebraic field, but it is usually assumed to be commutative. Further restrictions that are often imposed are that the field should be algebraically closed, or that it should be of characteristic zero; *i.e.*, if a is any nonzero element of the field, a , $2a = a + a$, $3a = 2a + a$, . . . are all distinct. The case in which the field is the field of complex numbers is usually referred to as the classical case, and until quite recent times was the only one that had received thorough study. Since this article follows chronological order in general, it shall be assumed that the classical case is being discussed, until the section on Developments After 1920.

Definitions. — The following definitions are most convenient when approaching algebraic geometry from the classical point of view. Recent advances have shown that a more abstract approach is desirable, but this will be referred to only in later sections.

Let (x^0, \dots, x^n) be a co-ordinate system in a projective space P_n of n dimensions. The subset U of points whose co-ordinates satisfy a system of homogeneous polynomial equations,

$$f_\alpha(x^0, \dots, x^n) = 0$$

where α runs over some indexing system (not necessarily finite), is called an algebraic variety of P_n . It can be proved that any

algebraic variety can be defined by a finite set of equations, and that a set of points that satisfies the definition of an algebraic variety in one set of co-ordinates in P , does so in any other permissible co-ordinate system. If V is another algebraic variety in P , given by the equation

$$g^i(x^0, \dots, x^n) = 0 \quad (i = 1, 2, \dots)$$

the intersection $U \cap V$ is defined to be the set of points satisfying the combined system of equations

$$\begin{aligned} f^a(x^0, \dots, x^n) &= 0 \\ g^i(x^0, \dots, x^n) &= 0 \end{aligned}$$

(all possible a, i); and the join $U + V$ of U and V is given by the equation

$$f^a(x^0, \dots, x^n) g^i(x^0, \dots, x^n) = 0$$

(all possible a, i). A variety U is said to be irreducible if, whenever it is written as a join $U = V + W$, then either $U = V$ or $U = W$; and it is shown that every algebraic variety in P , can be expressed in one and only one way as the join of a finite number of irreducible varieties.

Two irreducible algebraic varieties U and V are said to be in birational correspondence if there exists a correspondence (expressible by means of algebraic equations) between their points such that to a general point of U (or V) there corresponds just one point of V (or U). An elaboration of the definition of a birational equivalence makes it possible to define at least one point, but in general a locus of points, of V which corresponds to any point of U . Points that have a locus of corresponding points are called fundamental points of the correspondence.

The term algebraic geometry embraces the study of all, general properties of algebraic varieties, as opposed to properties of special loci like planes, quadrics, and so on, which belong to projective geometry. The most highly developed part of algebraic geometry, called birational geometry, concerns the study of those properties common to all members of a class of birationally equivalent varieties.

Algebraic Curves.—In the case $n = 2$, the only irreducible algebraic varieties in the plane (x^0, x^1, x^2) , other than the plane itself, are single points, or loci given by a single irreducible equation

$$f(x^0, x^1, x^2) = 0$$

Such a locus is called an irreducible plane curve; in general a plane curve is the join of a finite number of irreducible plane curves. The earliest investigations in algebraic geometry concerned the properties of plane curves. These deal with the notion of multiple point, bitangents and inflexions. (See CURVES.) A rigorous definition of the intersection multiplicities of plane curves is also possible, satisfying Étienne Bézout's theorem that the sum of the multiplicities of the intersections of two curves in a plane of orders m, n is mn . A slightly later development concerns the behaviour of a curve under a birational transformation of the plane into itself. The simplest such transformations are the collineations (projective transformations) of the plane. These have no fundamental points. But there is a much wider class of self-transformations of the plane into itself, namely the Cremona transformations, which can be shown to be generated by collineations and quadratic transformations of the type

$$x^0y^0 = x^1y^1 = x^2y^2$$

An important theorem is that given any curve C in a plane there exists a Cremona transformation which transforms it into a plane curve D whose multiple points are ordinarily singularities. An ordinary singularity is an r -fold point having r distinct linear branches through it with distinct tangents. If D is a curve of order n having ordinary singularities of multiplicity r_1, r_2, r_3, \dots , the genus of D is defined to be

$$\frac{1}{2}(n-1)(n-2) - \frac{1}{2}\sum r_i(r_i-1)$$

The orders and multiplicities of the singularities of the curve D with ordinary singularities obtained from C by Cremona transformations depend on the transformation used, but the genus of D

depends only on C and hence is called the genus of C . Two curves that are equivalent under Cremona transformations thus have the same genus.

Parallel with this theory of curves G. F. B. Riemann developed his theory of algebraic functions of a complex variable. His problem was to study a function w of the complex variable z defined by an irreducible algebraic equation

$$f(z, w) = 0$$

Since, if z, w are interpreted as nonhomogeneous co-ordinates in a plane, this is the equation of an irreducible curve and the problem is essentially the same as in algebraic geometry. Riemann's method consists in constructing a complex manifold, the Riemann surface of the curve, on which he studies the more elementary functions.

Two sets of points S_1 and S_2 on the Riemann surface are said to be equivalent if they are the poles and zeros, respectively, of a rational function on the surface. Given any set of points S on the surface the sets equivalent to S are S itself and the zeros of the rational function which have their poles at S : the aggregate of equivalent sets is called the complete linear system $|S|$ defined by S .

The celebrated theorem of Riemann-Roch asserts that the sets of points equivalent to a given set S can be represented by the points of a projective space of dimension

$$r = n - p + i$$

where n is the sum of the multiplicities of the points of S , p is the genus of the curve and i is an invariant of S called its index of speciality.

The properties of complete linear systems can be interpreted in geometrical terms on the curve C . Two sets S_1 and S_2 on C are then equivalent if and only if there exists a set S such that there exist two curves $\phi_1(x^0, x^1, x^2) = 0$ and $\phi_2(x^0, x^1, x^2) = 0$ whose intersections with C are $S + S_1$ and $S + S_2$ respectively. A system of curves

$$\sum_{i=0}^r \lambda_i \phi_i(x^0, x^1, x^2) = 0$$

none of which contains C identically, which passes through a fixed set S cut C residually in a linear system of sets of n points, denoted by g_n^r , and the existence of a unique complete system containing a given set S is easily proved. By writing $\lambda_i = a_i \rho + b_i \sigma$ when ρ and σ are parameters, a one-dimensional system can be defined g_n^1 . In this g_n^1 there is a finite number of sets in which a point counts twice; if the set of double points is denoted by J , the various "Jacobian" sets J which arise from different g_n^1 taken from the complete system g_n^r defined by S are all linearly equivalent, and the system $|K|$ which can be defined symbolically by $|K| = |J - 2S|$ is independent of the system S chosen and is an invariant system—the canonical system—on C . The sets of it, indeed, correspond to the zeros of the differentials of the first kind.

Starting from these ideas a complete geometrical theory corresponding to the theory of rational functions on a Riemann surface can be built up. Now it is easy to show that if D is any curve (not necessarily plane) which is birationally equivalent to C , the sets of points on D cut by hyperplanes on D determine the sets of a linear system on C ; and conversely, if g_n^r is a linear system on C

$$y^i = \phi^i(x_1, x_2) \quad (i = 0, \dots, r)$$

determines a curve D in P_r which is, in general, birationally equivalent to C . Thus the theory of linear systems on a curve contains the theory of birational transformations of the curve. A result of particular importance is that there exists a linear system on C that transforms it birationally into a curve with no singular points.

Algebraic Surfaces.—M. Noether, A. Cayley, H. G. Zeuthen and others in different ways tackled the problem of constructing a theory of surfaces in P_3 , but the systematic development of a general theory of surfaces was first undertaken, and largely carried through, by the Italian school of geometers, led by C. Segre, G.

Castelnuovo, F. Enriques and F. Severi. Their method was to generalize the idea of a linear system of sets of points on a curve to linear systems of curves on a surface. However, the generalization is not straightforward. One immediate difficulty is that while it is possible to analyze the nature of a curve in the neighbourhood of a singular point in complete detail, a similar analysis presents very great difficulties in the case of a singular point of a surface. The natural remedy for this is to try to obtain a surface birationally equivalent to the given one which has no singularities. Various attempts were made on this problem, but it was not until 1935 that R. J. Walker gave a proof on classical lines which has withstood all criticism. (Since then O. Zariski has given two proofs, based on advanced algebraic techniques.)

Even with the result that a surface can be transformed into one without singular points there is a further difficulty. Let F and F' be two nonsingular surfaces obtained from a given surface by birational transformations. F and F' are birationally equivalent to one another, but in the one-to-one correspondence between their points there may be fundamental points where the correspondence ceases to be one-to-one. For this reason the invariants of nonsingular surfaces are divided into "absolute" invariants, unaltered for all birational transformations; and "relative" invariants, which are unaltered only for birational transformations in which there are no fundamental elements.

In practice, when it is desired to make use of projective properties of P_3 in proving theorems, it is convenient to project the nonsingular surface, from a generally chosen vertex, into P_3 . The resulting surface has singularities consisting of a double curve and triple points which are also triple for the double curve. The surface is then said to have ordinary singularities. The situation is illustrated by the degenerate case of three planes; the double curve is of order three, consisting of the intersection of pairs of planes, and the common point is triple for the double curve and the surface. The procedure now is to take a surface in P_3 with ordinary singularities and to consider linear systems of curves on it. The relation between linear systems and birational transformations is as in the case of curves. Given any linear system $|C|$ of dimension at least three, a subsystem can be selected from it and a Jacobian curve can be defined of the subsystem. The various curves J that are obtained by taking different subsystems for $|C|$ are all equivalent and the complete system $|K|$ defined by $|J^* - 3C|$ is independent of $|C|$; here J^* means a Jacobian curve J if there are no curves on the surface having zero intersection with the general curve of $|C|$, but is J suitably modified by a combination of these curves where they exist. $|K|$ is called the canonical system. The number of linearly independent curves on $|K|$ is called the geometric genus (denoted by p_g) of the surface. It is an absolute invariant.

A Riemann-Roch theorem can be established for a complete system of curves $|C|$ on a surface, but in its classical form it appears as an inequality

$$r \geq n - \pi + 1 + p_a - i$$

where r is the dimension of the complete system $|C|$, n is the intersection number $C \cdot C$, a is the genus of C , p_a is an absolute invariant of the surface, called the arithmetic genus, and i is the index of speciality of $|C|$ defined in a similar way to the index of speciality on a curve. In comparing this formula with the Riemann-Roch theorem for a curve two points should be stressed. First, the relation is an inequality. A good deal is known about sufficient conditions for equality to hold, but until recent times, when other methods became available, no simple interpretation of the excess of the dimension over the expression given on the right was known. Second, p_a corresponds to the genus p which appears in the formula for curves and which also corresponds to the geometric genus p_g . In general, however, p_g is not equal to p_a , but $p_g \geq p_a$ always. The invariant $p_g - p_a = q$ is called the irregularity of the surface and is of fundamental topological importance.

A number of other invariants play an important role in the theory of surfaces:

(1) The linear genus $\omega - 1$ is equal to the intersection number $K \cdot K$ of two canonical curves.

(2) The Zeuthen-Segre invariant $I + 4$ is defined as follows: let $|C|$ be any one-dimensional linear system of curves on the surface, let $C \cdot C = n$ and let δ be the number of curves of $|C|$ with double points (curves with higher singularities count an appropriate number of times), and let π be the genus of C . Then $I + 4 = \delta - n - 4(\pi - 1)$. Both $\omega - 1$ and $I + 4$ are relative invariants but

$$(\omega - 1) + (I + 4) = 12(p_a + 1)$$

is an absolute invariant.

(3) The bigenus of the surface P_2 is the number of linearly independent curves of the complete system $|2K|$.

A great deal of the literature on algebraic surfaces is devoted to the study of special surfaces, such as hyperelliptic surfaces, or to the classification of surfaces having given values of the invariants, particularly for low values of the invariants. Two results may be mentioned. First, if $p_g = p_a = P_2 = 0$, the surface is rational (that is, birationally equivalent to a plane). Second, if $p_g = 0$, $p_a < -1$, the surface is birationally equivalent to a ruled surface of genus $-p_a$.

On a curve a set of n points defines a unique linear system whose dimension is, in general, less than n , but clearly they belong to a system of sets which can be represented by the points of an algebraic variety of dimension n , namely the variety which represents all the sets of n points on the curve. This notion of algebraic systems on a curve is trivial, but when its generalization to surfaces is considered an important new field of investigation emerges. The problem is simply: do there exist systems of algebraic curves on a surface that are represented by points of an irreducible algebraic variety and are not all contained in a linear system? A consideration of the generators of a nonrational ruled surface shows that such systems may exist. The general result is that a complete linear system belongs to an algebraic system of systems represented by an algebraic variety of dimension $p_g - p_a$. (A modification of this statement is necessary when the given linear system is "virtually nonexistent"; *e.g.*, when it is a combination of irreducible curves some of which are counted negatively.) Hence for a regular variety every algebraic system is contained in a linear system.

The existence of these algebraic systems of curves enables us to group the curves on a surface into wider equivalent groups, but this generalized notion of equivalence requires careful formulation. It is not sufficient to say that two algebraic curves C and D are equivalent in this wider sense if there exists a curve E and that $E + C$ and $E + D$ belong to the same irreducible algebraic system, for this relation may not be transitive. If this relation is defined by $C \equiv D$, two curves C, D have to be defined to be algebraically equivalent, $C = D$, if there exists a sequence C_1, C_2, \dots, C_r of curves such that

$$C \equiv C_1, C_1 \equiv C_2, \dots, C_r \equiv D$$

Then the fundamental result is that the classes of algebraically equivalent curves on a surface form, under the addition of curves, a group which is the direct sum of a finite number p of infinite cyclic groups and a finite group (the torsion group). Let C_1, \dots, C_p be curves of the surface that define algebraic systems that are generators of the p infinite cyclic groups. Then any curve C on the surface satisfies as again

$$C = \lambda_1 C_1 + \dots + \lambda_p C_p + \Gamma \quad (\Gamma \text{ in the torsion group})$$

Further, the $\rho \times \rho$ intersection matrix $(C_i \cdot C_j)$ is nonsingular. The curve C_1, \dots, C_p is called a base.

The theory of algebraic functions of two variables and their integrals, which is related to the theory of surfaces as the theory of the Riemann surface is related to the theory of curves, was developed about the same time by E. Picard. Most of the methods used have, however, been superseded by the new methods of topology and sheaves (see below).

Generalizations — Attempts in the same manner to generalize the theory of curves and surfaces as outlined above to varieties of higher dimension will be briefly summarized.

The generalization of the theory of linear systems, as far as "sufficiently general" linear systems are concerned, was made by

Severi in 1907, who established the form of the Riemann-Roch theorem in suitably restricted cases. The same author later generalized in some measure the theory of the base to higher varieties. Of more significance, however, is the theory of systems of equivalence. In this theory, instead of considering linear systems of varieties of dimension $n - 1$ on a variety of dimension n , consideration is given to "systems of equivalence" of varieties of dimension r ($0 \leq r \leq n$), so defined that when $r = n - 1$ a system of equivalence is a linear system. Severi established the existence of a relatively invariant system of equivalence of points on a surface closely related to the Zeuthen-Segre invariant. In the definition given above of the Zeuthen-Segre invariant δ is interpreted as the set of double points, n as the set of intersections and $2\pi - 2$ as a canonical set K on C ; then $\delta - n - 2K$ is an invariant system of equivalence (the canonical system of points of the surface). This result of Severi's was generalized to varieties of three dimensions by B. Segre, and a complete set of canonical systems of equivalence of dimension r , for $r = 0, \dots, n - 1$ on a variety of n dimensions was obtained by J. A. Todd. Similar results were obtained by other methods by M. Egar.

Developments After 1920.—Developments in algebraic geometry after 1920 merit special mention. In 1921 S. Lefschetz began using the new science of topology in the study of algebraic varieties (defined over the complex field). By making a direct study of the topology of a nonsingular algebraic variety he achieved his first objective of giving a simplified account of Picard's work on algebraic integrals associated with a surface and of generalizing the results to varieties of higher dimensions. In doing this, however, he did much more, and his work really forms the starting point of a great new field of research. His investigations of the topology of an algebraic variety established the existence of a large number of properties of the topology of an algebraic variety V of dimension m . Among these are the following properties: the p th homology group of V is isomorphic to the p th homology group of a prime section, if $p < m - 1$ and the $(m - 1)$ th homology group of a prime section is epimorphic to that of V . The Betti numbers of odd dimensions are even, and those of even dimensions are at least one. Such properties are special to algebraic varieties but do not characterize them. (See TOPOLOGY, ALGEBRAIC; TOPOLOGY, GENERAL.)

A further contribution made by Lefschetz concerns the cycles defined by the algebraic subvarieties of V . Lefschetz's contribution was the theorem that on an algebraic surface a two-cycle is homologous to the cycle which represents a curve on the surface if and only if every nonsingular double integral $\iint R(xyz) dx dy$ attached to the surface has no period on it. This result has subsequently been generalized to deal with two-cycles on V_m (W. V. D. Hodge) and $(2m - 2)$ -cycles on V_m (K. Kodaira and D. C. Spencer). Lefschetz's investigation further led to a very simple and significant interpretation of the theory of the base for curves on a surface. The main result is that two curves on a surface are algebraically equivalent, in the sense just described, if and only if they are homologous as two-cycles. The additive group of algebraic systems is then isomorphic to a subgroup of the Betti group of two-cycles.

The foregoing investigations by Lefschetz form the starting point of the modern theory of complex manifolds (*q.v.*). A complex manifold of m dimension is a manifold (which is assumed in this article to be compact) with the property that it can be covered by a set of neighbourhoods each of which can be parametrized by m complex co-ordinates in such a way that where these neighbourhoods overlap the two sets of co-ordinates are analytically related. A nonsingular algebraic variety is the simplest example of a complex manifold, but not all complex manifolds are algebraic varieties. Various powerful methods have been developed for studying the properties of complex manifolds, such as the theory of harmonic integrals (W. G. D. Hodge and G. de Rham) and the theory of sheaves (or *faisceaux*) (H. Cartan and J. Leray). Using harmonic integrals, it is possible to show that a considerable number of Lefschetz's results on the topology of algebraic varieties follow from the fact that the complex manifold defined by an algebraic variety is a Kahler manifold; that is, it can be given a

hermitian metric that can be written in terms of local co-ordinates as

$$\sum_{\alpha\beta} g_{\alpha\beta} dz^\alpha d\bar{z}^\beta$$

whose associated differential form

$$\omega = i a_{\alpha\beta} dz^\alpha \wedge d\bar{z}^\beta$$

is exact. Still more properties follow from the fact that on an algebraic manifold the Kähler matrix can be chosen so that the value of the integral of ω over any integral cycle is an integer; Kodaira has shown that this additional property is sufficient to ensure that the complex manifold arises from an algebraic variety. This is one of a series of results which go beyond the strict confines of algebraic geometry, dealing with the possible differential structures which can be imposed on a topological manifold.

Kodaira and Spencer (1952-55) systematically applied the theory of sheaves to investigate properties of algebraic varieties of dimension m . Their main task was the relation, between linear systems of subvarieties of dimension $m - 1$ and simple analytic 1-vector bundles. (r -vector bundles are defined over any topological space: over an open set U the bundle is the direct product of U by a vector r -space, but when these local products are fitted together they are "twisted" in a certain way, so that the total bundle on the variety is not, in general, a direct product.) The system of tangent spaces at the points of an algebraic variety is an important example of a bundle, the tangent bundle. Associated with a complex analytic r -bundle are important cohomology classes, the Chern classes of the bundle.

In the case $r = 1$ there is only one Chern class, which is dual (in a certain sense) to the cycles representing the subvarieties of a complete linear system associated with the bundle.

Their most important contributions are as follows: (1) They developed the general form of the Riemann-Roch theorem for varieties of dimension $m - 1$. The form of the theorem obtained made it possible to express the dimension of a complete linear system in the form obtained by Severi for "sufficiently large systems" (this expression is called the virtual dimension) but including additional terms (index of speciality, etc.) that make it exact in all cases. These additional terms are expressed as dimensions of certain cohomology groups but can be given an interpretation in terms of classical algebraic geometry. (2) They obtained a very simple proof of Lefschetz's conditions (see above) for a $(2m - 2)$ -cycle on a variety of m dimension to be algebraic. (3) They reconciled various definitions of the arithmetic genus of an algebraic variety whose equivalence had been conjectured by Severi.

The Chern classes of an r -bundle are dual to cycles representing varieties of dimension $m - 1, m - 2, \dots, m - r$. In particular, the Chern classes of the tangent bundle define algebraic varieties of dimension $m - 1, m - 2, \dots, 0$. These varieties vary in some way in systems, but except in the first case: where the varieties vary in a complete linear system, the exact nature is not known, though they are contained in systems of equivalence as defined by B. Segre and Todd. These systems are, indeed, the canonical systems of Todd and Egar. Using these notions F. Hirzebruch was led to a considerable generalization of the Riemann-Roch theorem for r -bundles. The "sections" of such bundles form a module over the complex field which in the case $r = 1$ is isomorphic to the set of subvarieties of the corresponding complete linear system. The Riemann-Roch theorem for r -bundles is represented by the equality of two expressions: one that gives the virtual division of the module of sections of the bundle and is equal to the effective dimension plus a series of terms that are the dimensions of a set of cohomology groups associated with the bundle, and the other is expressible entirely in terms of the intersection numbers of the varieties that represent the Chern classes of the r -bundle and those of the tangent bundle. A still wider generalization of the Riemann-Roch theorem is due to A. Grothendieck.

Another development in recent years of classical algebraic geometry is the formulation and development of the basic concepts in terms of modern abstract algebra. Here two distinct lines may be distinguished. In a series of papers (1931-39) B. L. van der Waerden gave a precise algebraic formulation of algebraic geometry

over any field (the definition of an algebraic variety at the beginning of this article is based on his work) and led up to a rigorous definition of the central concept of geometry, the intersection of subvarieties. Zariski then made notable contributions by his analysis of the notion of a simple point of an algebraic variety and developed his general theory of birational transformations of varieties in which he made great use of the algebraic theory of valuations of a field. In addition to his proof that any algebraic surface may be birationally transformed into one without singularities, already referred to, he succeeded in proving a similar, but much more difficult, result for varieties of three dimensions. It seems probable that the problem for varieties of m dimensions is of the same order of difficulty, but a complete proof for values of m greater than three has not yet been given.

In the course of his investigations in valuation theory Zariski was led to introduce a topology into algebraic geometry. In this topology, now called the Zariski topology, the closed sets on an algebraic variety are the algebraic subvarieties, their complements being, of course, the open sets. This topology has proved fundamental in modern algebraic geometry. As a first instance of its use it enables us to extend the notion of sheaves to general algebraic varieties, and results of great generality have been achieved in this way by J. P. Serre, Grothendieck and others.

A parallel development is due to A. Weil, whose approach is rather different. While van der Waerden and Zariski began by considering varieties as subsets of projective space, and led on to the notion of the function field of an algebraic variety and the generic point of a representation of it, which subsequently plays a fundamental role in Zariski's work, Weil started from these notions, and his book *The Foundations of Algebraic Geometry* (1946) is to a great extent a chapter in the theory of algebraic fields. A minor difference is that originally he defined algebraic varieties in affine space instead of projective space, but this led to the very important concept of an abstract variety. A Zariski topology can be defined on a variety on affine space and is useful in defining open sets (as in the projective case). Weil then constructed an algebraic variety by piecing together open sets. Since two open sets meet in an open set, which is nearly the whole of an algebraic variety, the correspondence must be a birational one, but it is subject to an important restriction: if U_1 and U_2 are the two open sets, and if U_1' is that part of U_1 that has corresponding points on U_2 and U_2' that part of U_2 that has corresponding points on U_1 , the birational correspondence between U_1' and U_2' must be one-to-one without exception. This makes it possible to identify U_1' and U_2' and so piece U_1 and U_2 together. Corresponding to the notion of a compact manifold is the notion of a complete variety: a variety is complete if any specialization (similar to a limit) of a generic point is represented by a point of at least one covering open set. Most of Weil's general theorems can be proved for abstract varieties; but many other results are proved only in the case of projective varieties; *i.e.*, varieties defined as projective space by the van der Waerden methods. Clearly any projective variety can be regarded as an abstract variety: M. Nagata has shown by examples that there exist abstract varieties that cannot be represented as projective varieties.

ALGEBRAIC NUMBERS: see NUMBERS, THEORY OF: *Generalizations of Arithmetic.*

ALGEBRAS (LINEAR), also called hypercomplex systems, may be described as vector spaces ($q v$) in which a multiplication of vectors can be performed that behaves like the ordinary multiplication of numbers. More precisely, an algebra over a field F (see FIELDS) consists of a set of elements (which may be thought of as "numbers" and, in the older literature, are actually called "hypercomplex numbers") and three operations that may be performed on these elements, *viz*, addition, multiplication and multiplication by elements of F . Moreover, it is necessary that the first and third of these operations satisfy the postulates for a vector space, that the first and second satisfy the postulates for a ring and that the second and third satisfy the condition $a(ab) = (a\alpha)b = a(\alpha b)$ for every a and b in A and every α in F . Even more general systems are sometimes called algebras, especially those in which F is allowed to be any commutative ring, and the nonassociative algebras discussed later.

According to the theory of vector spaces, there can always be found a basis of the algebra, *i.e.*, elements u_1, \dots, u_n in the algebra such that every other element is uniquely expressible in the form $\alpha_1 u_1 + \dots + \alpha_n u_n$ for suitable $\alpha_1, \dots, \alpha_n$ in F . Here n , the number of elements in the basis, is the same for every basis and is called the dimension of the algebra. (Algebras need not be finite dimensional; however, the most extensive theory has been developed for algebras of finite dimension.) Using the multiplication in the algebra reveals that every product $u_i u_j$ of basis elements is again an element in the algebra. The n^2 product elements $u_i u_j$ ($i, j = 1, \dots, n$) comprise a multiplication table of the algebra. Once it is specified, the product of any two elements in the algebra is determined because of the postulated relations among the three algebra operations:

$$(\sum \alpha_i u_i)(\sum \beta_j u_j) = \sum_i \sum_j \alpha_i \beta_j (u_i u_j)$$

Conversely, given a basis u_1, \dots, u_n of an n -dimensional vector space over F and a multiplication table, there is a multiplication defined in the vector space by the preceding equation. This multiplication will make the vector space an algebra if the associative law $(u_i u_j) u_k = u_i (u_j u_k)$ is satisfied for all i, j, k .

Examples.—Zero Algebras.—Any vector space can be made into an algebra by defining all products to be zero.

The Algebra of Complex Numbers.—Let F be the field of real numbers and A the set of all complex numbers. The ordinary addition and multiplication of complex numbers and multiplication by real numbers make A a two-dimensional algebra over F . To describe this algebra by a multiplication table, choose the usual basis $u_1 = 1, u_2 = \sqrt{-1}$; the multiplication table is then $u_1 u_1 = u_1, u_1 u_2 = u_2, u_2 u_1 = u_2, u_2 u_2 = -u_1$.

The Algebra of Quaternions.—The quaternions (discovered by W. R. Hamilton in 1843) form a four-dimensional algebra over the field of real numbers with a basis $1, i, j, k$ and a multiplication table defined by the conditions $ij = k, jk = i, ki = j; ji = -k, kj = -i, ik = -j; ii = jj = kk = -1$; and $1a = a1 = a$ for every a . The multiplication of quaternions, like that of real and complex numbers, has the property that division is uniquely possible, except by zero: given quaternions a and b with $a \neq 0$, there always exist unique quaternions x and y such that $ax = b$ and $ya = b$. This fact is expressed by saying that the quaternions form a division algebra. In 1878 G. Frobenius proved that there are no n -dimensional division algebras over the field of real numbers (with $1 \leq n < \infty$) other than the real numbers, the complex numbers and the quaternions. Unlike the multiplication of real or complex numbers, the multiplication of quaternions is not commutative; *e.g.*, $ij \neq ji$.

Matrix Algebras.—The set of all n by n matrices with entries from a field F forms an n^2 -dimensional algebra over F , using the ordinary definition of addition of matrices, multiplication of

matrices and multiplication of matrices by elements of F (see *MATRIX*). This algebra is often denoted by F_n . The most usual basis consists of the matrices e_{ij} ($i, j=1, 2, \dots, n$), which have all entries equal to zero except for an entry 1 in the i th row, j th column. The multiplication table is $e_{ij}e_{kl} = 0$ if $j \neq k$, and $e_{ij}e_{jl} = e_{il}$. More generally, the n by n matrices with entries from another algebra A form an algebra which is denoted by A_n . If A has dimension k , then A_n has dimension kn^2 .

Homomorphisms. — If A and B are algebras over the same field F , a homomorphism from A to B is a function f associating to each element a of A a single element $f(a)$ of B in such a way as to preserve the three algebra operations. That is, for a function f to be a homomorphism, whenever f sends a in A to b [$=f(a)$] in B , and sends a' in A to b' in B , then f must send $a+a'$ to $b+b'$, aa' to bb' and αa to αb for every a in F . If every element of B corresponds to some element of A by the homomorphism, B is said to be a homomorphic image of A . A homomorphic image of A may be thought of as a condensed version of A . If there is no condensation, i.e., if each element of B corresponds to exactly one element of A so that f is a one-to-one correspondence, the homomorphism f is called an isomorphism, and B is an isomorphic image of A . For many purposes an isomorphic image of A may be considered to be identical to A .

One measure of how far a homomorphism f is from being an isomorphism is the kernel of f ; i.e., the subset of A consisting of all elements that f sends to zero in B . If the homomorphism is an isomorphism, its kernel consists of zero alone; otherwise its kernel contains nonzero elements. An ideal in an algebra A is a subset of A that is the kernel of some homomorphism; a subset I of A is an ideal if and only if it is a vector subspace and contains all products of elements of I with elements of A .

Direct Sums. — The direct sum of two algebras A_1 and A_2 is an algebra, denoted by $A_1 \oplus A_2$, consisting of all pairs (a_1, a_2) with a_1 ranging over A_1 and a_2 ranging over A_2 . The algebra operations are performed componentwise: $(a_1, a_2) + (a_1', a_2') = (a_1 + a_1', a_2 + a_2')$, $(a_1, a_2)(a_1', a_2') = (a_1 a_1', a_2 a_2')$, and $\alpha(a_1, a_2) = (\alpha a_1, \alpha a_2)$. The direct sum of n algebras $A_1 \oplus A_2 \oplus \dots \oplus A_n$ is defined similarly as the set of n -tuples (a_1, a_2, \dots, a_n) with componentwise operations.

Structure Theory. — The aim of the structure theory of algebras (as of any structure theory in mathematics) is to give a list of concrete examples of algebras which shall contain one and only one isomorphic image of every algebra. For finite-dimensional algebras, this aim is approached fairly closely, as follows.

An algebra is termed simple if every homomorphism from the algebra either is an isomorphism or sends every element to zero. The first structure theorem asserts that the algebra of all n by n matrices with entries from a division algebra (see *The Algebra of Quaternions*, above) is a simple algebra and, conversely, that every simple algebra is an isomorphic image of such a matrix algebra.

Next, for an arbitrary finite-dimensional algebra A , the radical of A is defined as the set of elements of A that are sent to zero by all homomorphisms from A to simple algebras. The second structure theorem asserts that there is a single homomorphism whose kernel is exactly the radical of A and such that the corresponding homomorphic image of A is the direct sum of simple algebras. This homomorphic image is uniquely determined by A . If the multiplication in A is commutative, the homomorphism and direct-sum statements can be interchanged: A is isomorphic to the direct sum of algebras $A_1 \oplus \dots \oplus A_n$ and each A_i has a simple homomorphic image, with the kernel of the homomorphism being the radical of A_i .

Finally, the radical N of an algebra is itself an algebra and is nilpotent, meaning that for some positive integer k , $N^k = 0$; i.e., all products of k elements of N are zero. (This is a generalization of the zero algebras mentioned above.)

These theorems reduce the structure theory to three problems: (1) to what extent an algebra is determined once its radical N and the corresponding direct sum S of simple algebras are given; (2) the structure theory of nilpotent algebras; and (3) the structure theory of simple algebras, which the first structure theorem has already reduced to the structure theory of division algebras.

A partial answer to (1) is the principal Wedderburn theorem: if F contains the ordinary integers, then the algebra is an isomorphic image of an algebra consisting of all pairs (s, n) with s ranging over S and n ranging over N , with addition of pairs and multiplication of pairs by elements of F defined componentwise, as in the direct sum $S \oplus N$. However, multiplication of these pairs is only partly componentwise: $(s, n)(s', n') = (ss', nn' + f)$, where f is a function of s, s', n and n' which is zero if n and n' are zero. The lack of complete information about f is the reason for calling this a partial answer.

Little is known concerning problem (2). The answer to (3) varies, depending on the field F . If F is the field of complex numbers, the only division algebra is F itself, thus the only simple algebras are the matrix algebras F_n . If F is the field of real numbers, the Frobenius theorem asserts that there are exactly three division algebras. If F is the field of rational numbers, or, more generally, a field algebraic over the rational numbers, every division algebra over F is a cyclic algebra, which is a specific kind of generalization of the algebra of quaternions.

This last theorem is due to the combined efforts of R. Brauer, E. Noether, H. Hasse and A. A. Albert (1932–33). The proof involves the theory of numbers in an essential way. The other theorems were proved by J. H. M. Wedderburn in 1907. (In the special case where F is the field of complex numbers, they had already been proved by É. Cartan in 1898 and, somewhat less completely, by T. Molien in 1893.) The first three structure theorems were generalized to a theory of rings with suitable finiteness conditions by E. Artin in 1928 and E. Noether in 1929. Since then, more or less close analogues of these Wedderburn–Artin theorems have been proved for some infinite-dimensional algebras and for arbitrary rings.

Tensor Products. — The tensor product $A \otimes B$ of two algebras A and B over the same field F (also called the direct product or the Kronecker product) is an algebra consisting of all the formal finite sums of expressions $a \otimes b$ with a in A and b in B , manipulated according to the rules $a \otimes \alpha b = \alpha a \otimes b = a(\alpha \otimes b)$ and $(a \otimes b)(a' \otimes b') = aa' \otimes bb'$, for all a, a', b, b' in B and a in F . If a_1, \dots, a_n form a basis of A and b_1, \dots, b_m form a basis of B , then the elements of $A \otimes B$ are uniquely expressible in the form $\alpha_{11}a_1 \otimes b_1 + \dots + \alpha_{mn}a_m \otimes b_n$ (i.e., the set of all $a_i \otimes b_j$ forms a basis of $A \otimes B$). If A is an algebra over F , then $A \otimes F_n$ is just A_n , (see *Matrix Algebras*, above). Similarly, $F_m \otimes F_n$ is F_{mn} . This construction is as vital to the theory of algebras as is the direct sum. Some instances of its use are as follows.

The centre of an algebra A is the subset consisting of all elements c such that $ca = ac$ for every a in A . An algebra is called central if there is a one-to-one correspondence between the centre and F such that when c and a correspond, then $ca = aa$ for every a in A . Two algebras A and B are termed similar if $A \otimes F_n$ is an isomorphic image of $B \otimes F_m$ for some matrix algebras F_n and F_m . The similarity classes of central simple algebras then form a group with \otimes as the group operation. This group is called the Brauer group of F . Its structure both depends on and illuminates many properties of the field F . If A is a central simple algebra over F , there is a normal extension field K such that $A \otimes K = K_n$. This gives rise to the theorem that every central simple algebra is similar to a crossed product, a specific type of algebra generalizing the cyclic algebras mentioned earlier.

The tensor product $V \otimes W$ of two vector spaces V and W is defined in the same way as the tensor product of algebras, except, of course, that no attempt is made to define a multiplication in $V \otimes W$. The infinite direct sum of the vector spaces $F, V, V \otimes V, V \otimes V \otimes V, \dots$ is denoted by T ; its elements are merely polynomials in a basis v_1, \dots, v_n of V with coefficients in F , except that in writing and multiplying polynomials, the v 's are not assumed to commute; e.g., $v_1 \otimes v_2 \neq v_2 \otimes v_1$. Now define the product $(a_1 \otimes \dots \otimes a_r)(b_1 \otimes \dots \otimes b_s)$ to be $a_1 \otimes \dots \otimes a_r \otimes b_1 \otimes \dots \otimes b_s$ whenever the a 's and b 's are in V , and define the products of other elements of T in terms of these special products by using the distributive laws. This transforms T into an infinite-dimensional algebra generated by the elements of V , called the tensor algebra of V . Every algebra whose dimension is the di-

mension of V , or which is generated by a subspace of this dimension, is a homomorphic image of T . The elements of $V \otimes \dots \otimes V$ (with r factors) are called tensors of rank r , or homogeneous elements of degree r . (See TENSOR ALGEBRA.)

The homomorphic image of the tensor algebra T which is obtained by setting $a \otimes b$ equal to $-b \otimes a$ when a and b are elements of V is called the exterior algebra (or Grassmann algebra) of V . When this equality is assumed, all homogeneous elements of degree $n+1$ or more are forced to be zero, so that if V is n -dimensional, the exterior algebra of V has finite dimension (in fact, exactly 2^n). This algebra was first introduced by H. G. Grassmann in 1844 for geometric purposes; the linear manifolds of dimension r in projective n -space are best described by the homogeneous elements $a_1 \otimes \dots \otimes a_{r+1}$ in the exterior algebra of an n -dimensional vector space.

Nonassociative Algebras.—A vector space with a multiplication satisfying all the postulates for an algebra except the associative law of multiplication is called a nonassociative algebra (see A. A. Albert, "Non-Associative Algebras," *Annals of Mathematics*, 43:685-723 [1942]).

Undoubtedly the most important nonassociative algebras are the Lie algebras, in which two postulates provide a substitute for the associative law: $aa = 0$ and $a(bc) + b(ca) + c(ab) = 0$ for every a, b, c in the Lie algebra. The set of vectors in three-space with cross product as multiplication form a Lie algebra. The structure theory for Lie algebras over the real and complex fields is as complete as that of associative algebras. The importance of Lie algebras stems from their connection with Lie groups (see GROUPS AND ALGEBRAS, REPRESENTATIONS OF; GROUPS, CONTINUOUS). With each Lie group is associated a Lie algebra which reflects essentially all the local properties of the group.

Nonassociative division algebras over the field of real numbers are of importance in topology; the existence of such an algebra of dimension n gives a continuous vector field on the $(n-1)$ -dimensional sphere. H. Hopf proved in 1940 that the only possible values of n are powers of 2. For $n=2$ there is the algebra of complex numbers, and for $n=4$ the algebra of quaternions (both are associative). For $n=8$ there is a nonassociative algebra discovered by A. Cayley in 1843 called the algebra of Cayley numbers and defined from the quaternions much as the quaternions can be defined from the complex numbers. In 1958, using topological results of R. Bott, J. Milnor and M. A. Kervaire each proved that there are no nonassociative division algebras of dimension 16 or higher over the real numbers.

ALGECIRAS, a town and seaport in the province of Cádiz, Spain, lies at the extreme south of the country, 6 mi. W. of Gibraltar on the opposite (western) side of the Bay of Algeciras. Pop. (1950) 52,392 (mun.). In Arabic the name means "the island," from the Isla Verde which stands at the entrance to the port. The town has a mild and healthful climate which attracts tourists and invalids. It was perhaps the Roman Portus Albus, but was probably refounded in 713 by the Moors, who held it until 1344; it was then taken by Alfonso XI of Castile after a famous siege of 20 months. It was reoccupied in 1704 by Spanish colonists from Gibraltar and in 1760 rebuilt by Charles III on the present rectangular plan. The Algeciras conference (*q.v.*), held in 1906, introduced effective administration in Morocco and a new alignment of the powers in Europe. The modern town is without great interest, though there is a splendid view of Gibraltar across the bay. A little way inland along the railway, which runs northeast to Córdoba, are several arches of a Moorish aqueduct. The main commercial activity is that connected with the port, which is a stopping place for transatlantic liners and handles many passengers; especially from the ferry services to and from north Africa (Ceuta and Tangier); there are also ice-making and preserving plants.

(M. B. F.)

ALGECIRAS CONFERENCE, an international conference

that opened on Jan. 16, 1906, to discuss France's relationship to the government of Morocco. Two years earlier an entente cordiale, signed by Great Britain and France, had provided, among other things, for British support of French special interests in Morocco. France's attempt to implement the agreement by presenting the Moroccan sultan with a program of economic and police "reforms" brought the indignant German kaiser to Tangier in March 1905. The kaiser challenged French intentions by affirming the sovereignty of the sultan and demanding the retention of the "open door" for commerce.

Tension was relieved as U.S. Pres. Theodore Roosevelt was prevailed upon by the kaiser to help bring about the 1906 conference in Algeciras, Spain. Contrary to German expectations, only Austria-Hungary supported Germany's views; Italy, Russia and, more significantly, Britain and the United States lined up behind France. On the surface, nevertheless, the convention, signed April 7, 1906, appeared to limit French penetration. It reaffirmed the independence of the sultan and the economic equality of the powers, and provided that the French and Spanish police officers were to be under a Swiss inspector general.

The real significance of the conference is to be found in the substantial diplomatic support given France by Britain and the United States, foreshadowing their roles in World War I, of which the Moroccan crisis was a prelude. See also MOROCCO: History.

See Joseph B. Bishop, *Theodore Roosevelt and His Time Shown in His Own Letters* (1920); Eugene Anderson, *The First Moroccan Crisis, 1904-1906* (1930). (W. S.)

ALGER OF LIEGE (KNOWN also as ALGER OF CLUNY and ALGERUS MAGISTER) (1060?-1131?), French priest who had, in his time, a wide reputation for learning and ecclesiastical writing, was born in Liege about 1060. He was first a deacon of the church of St. Bartholomew at Liège and was appointed (*c.* 1100) to the cathedral church of St. Lambert. He declined many offers from German bishops and finally retired to the monastery of Cluny, where he died about 1131.

His *History of the Church of Liège* and many of his other works are lost. The most important of those extant are: *De misericordia et justitia*, a collection of biblical and patristic extracts with a commentary, an important work for the history of church law and discipline, in the *Anecdota* of Martène, vol. v; *De sacramentis corporis et sanguinis Domini*, a treatise in three books against the Berengarian heresy, highly commended by Peter of Cluny and Erasmus; *De gratia et libero arbitrio*, in B. Pez's *Anecdota*, vol. iv; and *De sacrificio missae*, in the *Scriptorum veterum nova collectio* of Xngelo Mai, vol. ix, p. 371.

See J. P. Migne, *Patrologia Latina*, vol. clxxx, pp. 739-972; article by S. M. Deutsch in Herzog-Hauck, *Realencyklopädie für protestantische Theologie*.

ALGER, HORATIO (1834-1899), was the most popular author in the United States in the last 30 years of the 19th century. Neither the number of his books, mostly juveniles, nor their total sales has been precisely determined, but the former figure is certainly over 100, the latter probably in the neighbourhood of 30,000,000 copies.

Alger, born in Revere, Mass., the son of a Unitarian clergyman, was educated at Gates academy and at Harvard. Alger attempted to earn his living after college as a private tutor and as a newspaperman, but he eventually gave in to his father's pressure and enrolled in the Harvard divinity school. He graduated in 1860, but not until 1864, after several futile attempts to enlist in the Union army and a brief trip to Paris, was he ordained minister of the Unitarian church in Brewster, Mass. Two years later, he resigned and moved to New York. There he became associated with the management of the Newsboys' Lodging House, which had been founded by the philanthropist Charles Loring Brace as a home for foundlings and runaway boys.

Alger had published several earlier works, *e.g.*, *Bertha's Christmas Vision* (1856), but in the atmosphere of the lodging house he began to write those stories of poor boys who rose from rags to riches which would make him famous and contribute the term "Alger hero" to the American language. Beginning with *Ragged Dick* (1867), the Alger hero fired the imagination of millions of

impressionable readers because, with his pluck and luck, he embodied a whole constellation of popular aspirations. With the exception of the western frontiersman, no other myth figure has exerted so powerful an influence on American culture. Particularly popular during Alger's lifetime and on into the 20th century were the "Ragged Dick," "Luck and Pluck" and "Tattered Tom" series

See Herbert R. Mayes, *Alger, a Biography Without a Hero* (1928). (K. S. LN.)

ALGER, RUSSELL ALEXANDER (1836–1907), U.S. business man, soldier and Republican politician, was born in Medina county, O., Feb. 27, 1836. He practised law in Cleveland for a few months in 1859, then moved to Grand Rapids, Mich., and entered the lumber business. At the outbreak of the American Civil War in 1861 he enlisted as a private and by 1864 had risen to the rank of colonel. He resigned that year and was later brevetted major general. Alger then returned to his Michigan lumber business and accumulated a large fortune. He served one term as governor of Michigan, 1885–87; was Michigan's "favourite son" candidate for the presidential nomination in 1888; and served as national commander of the Grand Army of the Republic, 1889–90. Alger's gift of \$10,000 to Gen. Philip Sheridan drew criticism from Charles Dana of the New York Sun who claimed to have discovered irregularities in Alger's discharge papers. Though Dana and others later exonerated him, the disclosure nullified his presidential chances in 1892. As secretary of war in 1897–99 Alger was criticized and ridiculed for inefficiency of the supply services and for other errors during the Spanish-American War. More recently, scholars have noted that, although Alger undoubtedly lacked initiative and resolution, the chief fault lay with the American people and the nation's moribund military establishment. In 1902 Alger was appointed to the U.S. senate to fill the vacancy caused by the death of Sen. James McMillan, and was elected in 1903. He died on Jan. 24, 1907, in Washington, D.C.

See Margaret Leech, *In the Days of McKinley* (1959). (L. L. S.)

ALGERIA (Fr. ALGÉRIE), a country in north Africa under French dominion, is bounded west by Morocco, north by the Mediterranean, east by Tunisia and Libya and south by the republics of Niger, Mali and Mauritania. Algeria proper has an area of 113,912 sq.mi. between latitude 37° and 34° N. and longitude 2° 10' W. and 8° 36' E.; it measures over 600 mi. east to west and 160–250 mi. north to south. The Sahara areas adjacent to Algeria were set up as a separate administrative unit, the Southern Territories, in 1902; since 1958 they have comprised the two Saharan *départements*. Their area is 805,679 sq.mi., and their southernmost point is at latitude 19° N., 1,200 mi. from Algiers. The population of Algeria (1954) was 9,529,726 (1960 preliminary census 10,642,569). The capital is Algiers (*q.v.*).

PHYSICAL GEOGRAPHY

Geology and Structure.—The two physical divisions of Algeria are the Sahara, an ancient platform or shield, locally disturbed, against which the Atlas were forced, and the Atlas, folded chains of Tertiary Age, including remnants of ancient massifs. The Saharan shield is of peneplained Pre-Cambrian rocks overlain by Paleozoic deposits (exposed in the Ahaggar), the whole frequently masked by the later limestones of shallow Cretaceous seas. The Atlas lands of northern Algeria consist of a former geosyncline squeezed and folded into mountain chains by pressure from the two flanking continental masses of Tyrrhenia to the north and the Saharan shield. The mountain building epoch lasted throughout the Tertiary period, the two chief stages being the Pyrenean (Cretaceous–Eocene) and Alpine (Miocene). Thick limestone deposits, mainly of Jurassic, Cretaceous and Eocene Ages, mingled with sandstones and conglomerates, form the bases of the Atlas ranges. Archean and Paleozoic rocks are little represented except where remnants of Tyrrhenia, such as the Djurdjura (Jurjura) range, provide mountain fastnesses with cores of Archean and Pre-Cambrian schists and gneisses.

Relief and Drainage.—Articulated Alpine structures dominate northern Algeria where two series of young fold mountains, the Maritime Atlas and the Saharan Atlas, are separated by a less

disturbed plateau zone, the trend being southwest to east-north-east. In the north is the Tell, comprising discontinuous coastal hills and inland ranges of the Maritime Atlas. The coastal hills average 1,500 ft. in the west but attain 7,572 ft. in the crystalline Djurdjura east of Algiers. Between them and the Maritime Atlas lie a series of discontinuous valleys and plateaus extending from Oran to Bougie. The broken mountains of the Maritime Atlas include the Tessala and Ouarsenis and extend from eastern Morocco into Tunisia.

To the south, between the Maritime Atlas and the Saharan Atlas, lies the undulating steppe land of the High Plateaus with an average altitude of 3,500 ft. Numerous muddy salt flats (shatts or chotts) are characteristic, notably Chott al Chergui (100 mi. in length), Zahrez Gharbi and Zahrez Chergui, salt lakes almost dry in summer, and Chott al Hodna (1,283 ft.), now almost entirely a salt marsh. The Saharan Atlas, in a vast sweep from the High Atlas of Morocco to the Aurbs mountains and the Tunisian boundary, shuts off northern Algeria from the Sahara proper. In the southwest the Ksour mountains attain 7,333 ft. but toward the east-northeast altitude diminishes, denudation is more intensive and the mountains practically merge into the High Plateaus, their tops projecting like islands from an accumulation of debris. The Zab mountains south of Chott al Hodna drop to 1,500 ft., offering useful passes north to the Algerian Tell. Immediately to the east rise the Aurbs mountains of folded Jurassic and lower Tertiary sediments weathered into a formidable terrain of peaks and gorges, containing the highest mountain in Algeria, Djebel Chelia, 7,648 ft. In the Aurès spurs of the Maritime Atlas meet the Saharan Atlas and the mountains, high above the Sahara, permit the vegetation of the Tell to continue south toward Biskra. The Algerian Sahara presents an undulating plateau surface, rising in the south to the crystalline Ahaggar massif. In the north Cretaceous limestones are overlain with a veneer of sands and pebble beds. The area is not entirely barren; depressions in the limestone plateaus make accessible water-bearing strata sustaining palm groves and oases.

The limited amount of rainfall and its seasonal regime and the porous nature of much of the rock accounts for the paucity of surface drainage. Most of the wadis (oueds) are periodic; even those flowing from the Maritime Atlas to the sea, the Sig, Isser and Soummam, are feeble trickles in summer. Only four streams from the High Plateaus break through to the Mediterranean: the Chélif, Bou Sellam, Rummel and Seybouse. They flow strongly in their lower courses in winter, but in summer they are practically dry. In the southern High Plateaus and the Sahara interior drainage within closed basins prevails. The coast line, about 620 mi. long, trends with the ranges. It is little indented, frequently steep and rocky to the shore and offers few good port sites.

Climate.—Algeria's position between the Mediterranean and the Sahara causes a marked seasonal contrast in climate. In winter depressions passing eastward along the Mediterranean (then a region of low pressure) bring considerable rainfall to the north. In summer low pressure systems develop over the Sahara and High Plateaus, drawing in dry winds from the northeast. Winters are cool and wet, summers hot and dry; sunshine is plentiful in all months. On the coast winter temperature averages 50°–54° F., summer temperature 75°–79°, and rainfall 30 in. Away from the coast continental conditions become very marked. On the High Plateaus winter temperature averages 39°–42° with much frost, summer temperature averages 78°–83° with maxima near 95° or even 105° in the Sahara; rainfall 8–16 in. Biskra on the edge of the desert records Jan. 53°, July 92°, annual rainfall 7 in. The desert itself is virtually rainless.

Vegetation and Animal Life.—In northern Algeria as far as the southern edge of the Saharan Atlas the vegetation is largely Mediterranean. Of 3,500 species only 500 are peculiar to the country. Vegetation becomes progressively poorer with diminishing rainfall from north to south and develops greater African characteristics. Evergreen trees and shrubs predominate: olives in the coastal hills and depressions, the Aleppo pine, cork oak, cedars, thuja on higher areas. Thick brushwood undergrowth of

plants such as rosemary, lentisk (mastic plant), buckthorn, myrtle, strawberry tree and various woody climbers clothe the lower slopes. Steppe communities are abundant on the poorly watered High Plateaus where alfa or esparto grass (*Stipa tenacissima*) is widespread, with occasional woods of red juniper in the higher parts and drinn grass on the sandier soils. The Saharan region has a poor xerophilous, or drought-resistant, vegetation of which many species grow rapidly after rain; the oases are characterized by the date palm; the sand dunes and ergs, or deserts of shifting sands, have drinn steppe; the gravelly areas support dwarf perennials including a number of herbs (chenopods and crucifers) and grasses; the rock deserts (hammada) are practically devoid of vegetation.

The animal life is similar to that of other Mediterranean countries but has been considerably modified within historic times, mainly through the disappearance of old forms. The elephant and lion have become extinct; the panther and hyena are rare. A single variety of monkey (*Pithecus immuus*) occurs. Jackal and wild boar are abundant where there is cover and there are various antelopes (gazelles). Birds of prey include several varieties of eagle, vulture and hawk; ostrich, becoming scarce, is found on the Saharan border. In the desert horned vipers and scorpions are fairly common. Five of the 31 species of fresh-water fish are peculiar to Algeria.

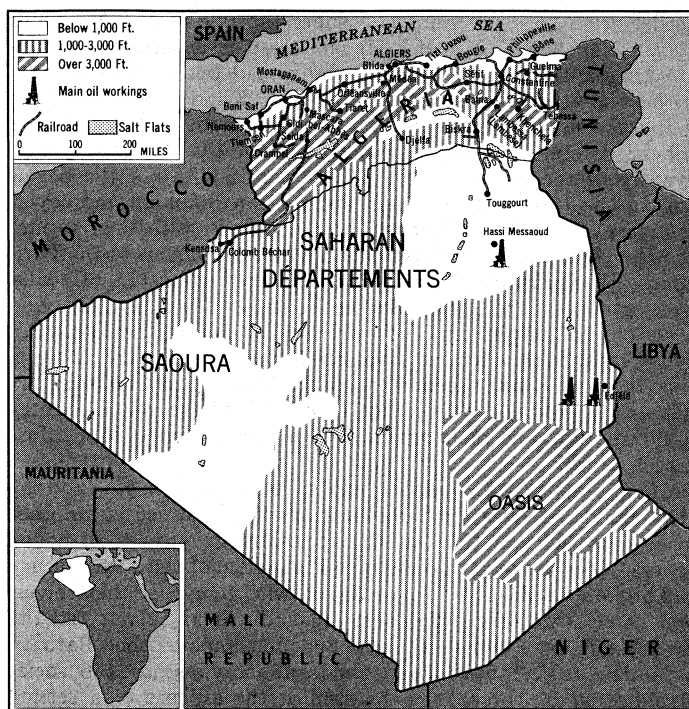

GEOGRAPHICAL REGIONS

Algeria may be divided into five distinctive regions: the Tell, the High Plateaus, eastern Algeria, the Saharan Atlas and the Sahara.

The Tell comprises the hills and plains adjacent to the coast, the series of ranges and plateaus inland forming the Maritime Atlas and the intermediate valleys and basins. There is considerable diversity of geology, soils and relief. The climate is characteristically Mediterranean, although frequently modified by local position and aspect. The climatic and geological affinities with southern France, the proximity of the coast and ports, relative ease of movement along the valleys and the poverty and harshness of the rest of the country have caused this region to become the principal area of French settlement and the most productive part of Algeria. The soils of the Tell are poorer in humus than comparable soils in northern Europe. Upland soils are thin and contrast markedly with the deep alluvial soils and loams of the plains. Agricultural development is most marked in the Sahel of Oran, the Mitidja (the Algiers plain) and the plain of Bougie, alluvial plains exposed to rain-bearing winds where magnificent vineyards, citrus groves and flowers for scent making surround the substantial modern buildings of European farms. Some interior valleys (e.g., the Chélif) are poorly developed because of aridity and excessive heat in summer. The mountains, of limestones, sandstones and much dissected clays and marls, support brushwood, evergreen oaks and pine forests. Occasional springs near their base provide sites for settlement and agriculture. This region supports nearly 90% of the total population and contains practically all the towns.

The High Plateaus are undulating steppe lands, here and there varied by ridges and rocky outcrops and with a chain of chotts, brackish lakes and marshes. Ruins of agricultural and irrigation works suggest a more pluvial and prosperous period in the middle ages. Today the sparse rainfall (10–12 in.) supports a steppe vegetation including tufts of alfa. Sheep range widely over these pastures along regular tribal routes and the alfa is collected for export or weaving into baskets, ropes and mats. The scanty population is mainly nomadic.

Eastern Algeria differs from western in being a compact massif, much dissected into mountains, plateaus and basins not paralleling the coast. Spurs from the Maritime and Saharan Atlas stretch out to become the formidable Aurès massif, providing an effective termination to the High Plateaus. The coastal mountains from Bougie eastward are higher than to the west and provide the best-watered parts of Algeria (over 40 in.) with abundant forests of cork oak and cedar. Population is light, communications difficult. Inland a number of former lake basins provide upland

ALGERIA AND THE SAHARA, SHOWING ELEVATION, SALT DEPOSITS AND PRINCIPAL PETROLEUM FIELDS

plateaus, such as the plains of Sétif where cereal crops survive under near steppe conditions or the more saline marshes of the Constantine chotts which offer good grazing. Nearer the Tunisian border the scanty population is related to mineral working, particularly hematite and phosphate, along the Souk-Ahras-Tébessa railway.

For discussion of the Saharan Atlas and Sahara see ATLAS MOUNTAINS and SAHARA.
(A. B. M.)

HISTORY

The early history of Algeria cannot clearly be distinguished from that of northwestern Africa as a whole (see AFRICA: History: sections North Africa and Sahara and Sudan), since the territory unified by the French under the name Algeria extends from the Mediterranean coast and its immediate hinterland—of which there is recorded history since the beginning of classical times—far into the south across the Sahara, which does not emerge from prehistory until very much later. (For the ancient history of Mediterranean Algeria from the time of the Phoenician or Carthaginian settlements to the end of the Roman empire and the Vandal kingdoms see NUMIDIA; MAURETANIA.)

Arabs and Berbers.—Muslim armies (see CALIPHATE) had begun their westward advance from Egypt in A.D. 647, but their conquest of northwestern Africa or Barbary—so named because of its predominantly Berber (*q.v.*) population—was not completed until 711. The eastern part of what is now Algeria, in particular the Aurès mountains and the surrounding area, was, under the leadership of two Berbers, Kosaila and the chieftainess Kahenna, the main centre of resistance to the invaders. The Muslim conquest did not, however, lead to the settlement of the country by Arabs.

While Arab leaders and soldiers were installed in small numbers in the towns (in Tunisia, moreover, to a greater extent than in Algeria), the rural areas remained Berber, and the problems posed by the introduction and evolution of Islam (*q.v.*) were decided among the Berbers themselves.

Barbary was at first a province of the Omayyad caliphate, which ruled from Damascus in Syria, but by 742 almost the whole of Barbary, under the influence of a Muslim heresy, Kharijism, had freed itself from eastern control. Several Berber and Kharijite kingdoms were founded in Algeria, the most important being that of the Rostemids at Tahert (in the region of Oran). The eastern

border area, however, remained under the rule of the Aghlabids (*q.v.*), who made Kairouan, their capital, an active centre of orthodox Islamic thought, which gradually spread westward again and, during the 9th–11th centuries, supplanted Kharijism.

It was the support of the Kabyles, a confederation of Berber tribes in eastern Algeria, that made possible the rise of the Arab dynasty of the Fatimids (*q.v.*), who were Shi'ites, at the beginning of the 10th century. Zeiri and his son Bulukkin, moreover, founders of the Berber dynasty of the Zeirids, with their capital at Achir, held the central area round Algiers as vassals of the Fatimids. Western Algeria, however, remained almost continually under groups of the Zenata Berbers (enemies of the Fatimids and allies of the caliphs of Cordoba in Spain, where the Omayyad dynasty survived after the Abbasids had taken its place in Syria and Iraq) until, in the second half of the 11th century, an orthodox Berber dynasty, the Almoravids (*q.v.*), added the whole country as far as Algiers to their empire, which they governed from Marrakech in Morocco.

The Zeirids, who moved their capital to Kairouan in 972, and the Hammadids, who early in the 11th century had set up another dynasty at Qalaa (in the Constantine region), reverted to orthodox beliefs under pressure of opinion in the middle of the 11th century and broke with the Fatimids of Egypt, who, to avenge themselves, sent three Arab tribes, the Beni Hilal, the Beni Sulaim and the Beni Maqil, against them. These Bedouins impoverished Barbary by ruining its peasant economy and profoundly disturbed its social organization by spreading nomadism at the expense of a settled existence. Though they did little to change the religious state of the country, they brought the Arabic language to the plains and steppes. Within 100 years they had spread over the whole of eastern Algeria.

Western Algeria received the Spanish-Moorish civilization under the Almoravids, and the Almohads (*q.v.*), another Berber dynasty, who overthrew the Almoravids in the middle of the 12th century and extended their authority over the whole of Barbary, brought this civilization to the towns of eastern Algeria also, checking the Bedouin menace. In the 13th century, however, the Almohad empire began to break up, and Barbary was partitioned between three new Berber powers, the Marinids of Fès, the Abd-al-Wadids of Tlemcen and the Hafids of Tunis.

The Abd-al-Wadid dynasty (*q.v.*) of Tlemcen was never able to wrest Bougie and Constantine from the Hafids and had to endure invasions of its territory by them and by the Marinids. Revolts by Arab or Berber tribes drained much of its strength. Tlemcen nevertheless became one of the centres of Spanish-Moorish civilization.

The Turkish Conquest.—The Christian reconquest of Spain was followed, in the first years of the 16th century, by the Spanish occupation of places on the Algerian coast (Mers al Kebir, Oran, Bougie and the island part of Algiers itself) and by the levying by Spain of tribute from other cities. The Abd-al-Wadid sultan accepted a Spanish protectorate. The Muslim population then appealed to Turkish pirates for help (see BARBAROSSA), and these pirates in turn appealed to the Ottoman sultan, who sent strong forces to their support (1518). This led to the expulsion of the Spaniards from Algiers (1529), to the fall of the Abd-al-Wadids (1554) and to the reduction of Algeria to a vassal state of the Ottoman Turkish empire.

The Barbary pirates (*q.v.*) made Algiers a flourishing city in the 17th century but were less active in the 18th and in the early years of the 19th, when Algiers, weakened also by epidemics, declined in importance.

Turkish Algeria was theoretically governed by a dey nominated by the officers of the militia, whose despotism was tempered by the presence of a council or *diwan* and undermined by revolts among the soldiers. The country was divided into three provinces under beys and subdivided into cantons under *caïds*, who were in most cases chosen from the heads of tribes. Both beys and *caïds* enjoyed a large measure of autonomy, and Algeria was never really unified under the control of the central government.

Revolts by tribes and Marabout groups gradually weakened the power of the deys, who by 1830 were exercising effective authority

over only a small part of the country. (H. L. E. T.)

The French Conquest.—The government of the deys was brought to a violent end by French intervention in 1830. A claim by two Algerian citizens for payment for wheat delivered to France under the Directory had been outstanding since the end of the 18th century. In April 1827 an altercation arose over this between the dey Hussein and the French consul during an audience. The dey threatened to withdraw the concession by which the French maintained a fortified trading post, named the Bastion, near Bône, and, becoming exasperated at the consul's rudeness, flicked him with his fly whisk. To avenge this insult to France the government of Charles X instituted a naval blockade; this had little result beyond causing the loss of the Bastion. A naval and military expedition was then sent under Adm. V. Duperré and Marshal de Bourmont. The expedition landed at Sidi Farruj on June 14, 1830, and the dey, after his forces had been defeated, capitulated on July 5. The enterprise was presented by the French as one of common interest to the civilized world in that it put an end to Algerian privateering. This, however, had already ceased to be a serious menace, and the desire for prestige and for the maintenance of a privileged trading position was the basic motive. Aware that the dey's government was that of a Turkish minority, the French government issued a proclamation in Arabic (a French version appeared in *Le Moniteur* of June 2, 1830) declaring that it was not coming to take possession of the city but merely to drive out the Turkish tyrants. In fact, after the Turkish officials had been expelled, the July monarchy which succeeded Charles X's regime had no clear idea of what it wanted to do with the conquest.

Eventually the French retained Algiers, and by degrees a sort of protectorate (without the name) was established over the coastal areas. Resistance to the French appeared wherever there was a leader to organize it. The beys of Oran and Titteri submitted, but the bey of Constantine, Ahmed, held out, and it was only after seven years that the city fell (Oct. 13, 1837). In the west resistance was organized by Abd-el-Kader (*q.v.*), a leader who depended on his own talents and the unifying influence of Islam. In 1834 the French government appointed a governor general of French possessions in North Africa. The same year was marked by the signing of an abortive treaty with Abd-el-Kader; this was followed by the more important treaty of Tafna (May 30, 1837). Seeing, however, that this did not put an end to French progress, Abd-el-Kader proclaimed a holy war on Nov. 18, 1839.

In 1840 the French government finally decided on the conquest and colonization of the whole country. This task was entrusted to Gen. (later Marshal) T. R. Bugeaud de la Piconnerie (*q.v.*), who was the real creator of the army of Africa. Abandoning the system of blockhouses, Bugeaud sent out columns in all directions, seizing cattle and crops and often destroying the olive and other fruit-bearing trees. Abd-el-Kader's arsenals at Takdemt, Saïda and Boghar were destroyed and Mascara and Tlemcen occupied by 1842, and part of his *smala* or movable capital (with a population of 50,000) was captured in May 1843. When the sultan of Morocco gave his support to Abd-el-Kader, the French bombarded Tangier and Mogador and defeated the Moroccan army at Isly (Aug. 15, 1844). It was not, however, until Dec. 23, 1847, that Abd-el-Kader finally surrendered. In the course of a heroic struggle he had shown high military and administrative talents and had established the beginnings of a system of regular taxation and a standing army, but the heritage of an anarchic medieval system, which had made Algeria a collection of more or less independent units, had prevented his becoming unchallenged leader of a united nation.

Abd-el-Kader's disappearance marked the end of the main resistance, but many further campaigns were necessary, notably in the advance toward the south (Zaatcha, 1848–49; Laghouat, 1852; Touggourt, 1854) and in the Kabyle country (uprising of Bu Baghla, 1851) which was not finally subdued until 1857. There was a large-scale uprising (Aulad Sidi Sheikh) in 1864 and another under Mohammed al-Moqrani which lasted from March 1871 to Jan. 1872. Less important uprisings occurred in 1879 and 1884. From the latter date there was no serious challenge to French authority until 1954.

The French Colonization. — Two major changes took place in Algeria under French rule from 1830 to 1954. First, a new Algerian people, of European outlook, was created, numbering 800,000 by 1954. Of these, half were of Spanish, Italian, Maltese or other non-French origin. The Algerian Jews, numbering 150,000, were completely assimilated to this group politically. Secondly, the Muslim population increased from 3,000,000 to 9,000,000 in the same period. The guiding threads of Algerian history during this period are therefore to be sought in the development of European settlement on the one hand and the problem of finding a satisfactory status for the conquered Muslim inhabitants on the other. It was failure in the latter respect which brought about the great uprising of 1954.

The first major impulse to colonization was given by Marshal Bertrand Clauzel in the 1830s and by Bugeaud while he was governor general (1840–46). At Bugeaud's retirement, 40,000 Europeans, largely ex-soldiers, had been settled. Settlement of individuals was the practice also under the second republic and was to be so under the third. The second empire, on the other hand, granted large concessions and sought to attract capital on a large scale. Colonization received a fresh impulse after the 1871 uprising, which was followed by the confiscation of much tribal land, while an act to reduce communal holdings facilitated the acquisition of land by Europeans. By 1881 the European population was 376,000, of whom 140,000 lived in rural areas. The maximum European settlement in rural districts (234,000) was reached about 1926. By 1954 migration to the towns had reduced it to 196,000.

During the conquest the government was military. The ordinance of July 22, 1834, provided that the governor general should be a soldier and created a service of bureaux arabes staffed by officers. The second republic moved toward civil administration. In 1848 Algeria was declared French territory. The three former provinces of the Turkish regency were made départements, each headed by a prefect, who was concerned with the administration of the settlers, while the military organization remained for other purposes.

The emperor Napoleon III aroused the indignation of the settlers by two letters which he published after visiting Algeria. "Algeria," he said, "is not a colony properly so-called, but an Arab kingdom . . . I am just as much emperor of the Arabs as I am of the French." Administration, which had been entrusted in 1858 to a minister in Paris, was subsequently given back to the military authorities. These on the whole tended to act as arbitrators between the settlers and the Muslims and to be less under the influence of the settlers than was the civil administration. A *sénatus-consulte* of 1865 declared that the native Muslim was a Frenchman. In fact he became a French subject rather than a French citizen, having no political rights and being subject to special police regulations. These regulations were promulgated as the Code de l'*indigénat* in 1881, modified in 1914 and finally abolished in 1944.

On the fall of the second empire civil administration was set up and the bureaux arabes confined to the Southern Territories. Where settlers were numerous the community was administered by an elected mayor, as in France (*commune de plein exercice*); where the settlers were few, it was administered by an appointed official (*commune mixte*). From 1881 to 1896 each administrative service worked under the relevant ministry in Paris; then they were again placed under the governor general. By 1900 the administrative and budgetary autonomy of the government general was complete, the budget being voted by *départements financiers*, of whom one-third were Muslims elected by their coreligionists. These changes, however, had little bearing on the Muslims' legal status. In 1936 the Blum-Violette proposals, which would at once have given the vote to 21,000 Muslims on equal terms with the Europeans, were defeated by settler opposition.

The Beginnings of Nationalism. — By 1936 two political tendencies had become apparent among the Muslims. One, connected with the name of Ferhat Abbas (*q.v.*), a pharmacist at Sétif in the *département* of Constantine, aimed at the complete assimilation of the Muslims through increased education and the franchise. "Algeria is French soil," said Ferhat Abbas, "and we

are Frenchmen with the personal status of Muslims." He added that he had been unable to find any trace of an Algerian nation.

The other movement was nationalist. The *Étoile Nord Africaine* was founded in Paris in 1926 to improve working conditions for all north African workers. Later, as the Parti Populaire Algérien and then as the Mouvement pour le Triomphe des Libertés Démocratiques (M.T.L.D.), under an Algerian working-class leader, Messali Haj, it became simply an Algerian nationalist movement. An ideological background was given to Algerian nationalism by the Association des Ulémas Algériens, founded by Sheikh Abdulhamid ben Badis in 1931. This was primarily a cultural and religious movement, designed to free Algerian Islam from the practices of saint worship and to restore the study of the Arabic language. All these movements derived momentum, within the general Arab renaissance, from the fact that in the 1930s the immigrant Christian minority enjoyed a standard of living as high as that of western Europe, while the Muslim majority was underemployed and undernourished, with a school-age population of about 2,500,000, of whom only one in eight could find a place in a primary school.

In Feb. 1943 Ferhat Abbas, disillusioned with assimilation, presented to the French and Allied authorities in North Africa a manifesto embodying Algerian claims. In December of that year Gen. Charles de Gaulle declared that the loyalty of French territories during World War II had put France under an obligation to them, particularly in the case of the Muslims of North Africa. Accordingly an ordinance of March 7, 1944, extended citizenship to certain categories of Muslims, and in 1946 a law granted them 15 deputies in the national assembly and 7 senators in the council of the republic. Meanwhile, however, in May 1945 demonstrations at Sétif in celebration of the Allied victory in Europe had led to a scuffle between the police and demonstrators carrying Algerian nationalist flags. This developed into an unorganized uprising in which 88 French lost their lives. Repression by the French authorities in the villages in the Sétif area resulted—according to French official statements—in the deaths of 1,500 Muslims. Qualified observers, however, claimed that the figure was as high as 5,000 or even 10,000. The massacre and the reprisals were a great shock to French as well as to Muslim opinion, and many proposals were put forward. Nevertheless the French constituent assembly later refused even to discuss a proposal by Ferhat Abbas for the creation of an autonomous Algerian state federated with France. Instead, after long discussion, it passed, with the 15 Algerian deputies abstaining, the Statute of Algeria (Sept. 20, 1947). This declared Algeria to be "a group of départements endowed with a civic personality, financial autonomy and an organization of its own." An Algerian assembly was created, far-reaching reforms were promised and 58,000 Algerians with high qualifications were allowed to vote with the European electoral college which elected one-half of the 120 members of the assembly. The other 60 members were to be elected by Muslims possessing only local status. An important proviso stated that for any legislation there must be a two-thirds majority whenever this was demanded by at least 30 members. During the succeeding years the promised reforms were in general not implemented, as the assembly failed to pass the necessary legislation.

The Nationalist Uprising.—On the night of Oct. 31–Nov. 1, 1954, a concerted uprising began. Organized by a group of activists who had seceded from the M.T.L.D. after a congress held by it during the summer, this uprising had been in preparation probably since 1947. In the first place it consisted of co-ordinated attacks on such establishments as police posts and forest guard posts in the Aurès mountains and in the Kabyle country, causing several deaths. The rebels took the name of Front de Libération Nationale (F.L.N.) and issued a manifesto. This stated that their objective was the restoration of a sovereign Algerian state, of which any resident of Algeria could become a citizen with full rights provided that he was prepared to adopt Algerian nationality. A second more extensive outbreak occurred on Aug. 20, 1955. A massacre of French near Philippeville had as its sequel large-scale executions of Muslims in the stadium of that city. Reforms proposed by the new governor general of Algeria, Jacques Soustelle,

were not sufficiently striking to win over hesitant Muslims, and during 1956 nearly all the outstanding Muslim political leaders, who had at first held back, left the country and joined the rebels' political headquarters in Cairo. On Jan. 31, 1956, a Socialist prime minister. Guy Mollet, came into power in France with a program of peace in Algeria. Having announced the appointment of the liberal, Gen. G. Catroux as minister resident in Algeria, he went himself to visit Algiers (Feb 6, 1956): where he was greeted by the Europeans with hostile demonstrations. Catroux resigned and was replaced by Robert Lacoste. It was proposed to secure a cease fire by force of arms and then to hold elections and to negotiate with the elected representatives of the Algerian people; meanwhile, certain reforms were to be introduced, as far as the fighting permitted. This policy involved the dispatch of large numbers of soldiers to Algeria to deal with the increasing military and political activity of the rebels. *Sections administratives spéciales* (S.A.S.) were established wherever possible. These corresponded to the original *bureaux arabes* and had the task of promoting Muslim village welfare wherever rebel influence could be eliminated. For this purpose 1,250,000 villagers were resettled under the supervision of the army. Another 150,000 took refuge in Tunisia and Morocco.

In Oct. 1956 an aircraft chartered by the Moroccan government to convey five Algerian rebel leaders from Rabat, where they had been the guests of the sultan of Morocco, to a conference at Tunis was diverted to Algiers and the five men arrested by the French (this action provoked a popular outbreak at Meknès, in Morocco, resulting in the massacre of 40 French settlers). Widespread terrorism in Algeria was suppressed early in 1957 by the use of parachute troops and, it seemed, by the use of torture to extract information from prisoners. In spite of French objections the subject of Algeria was discussed at the United Nations general assembly in Feb. 1957 and on subsequent occasions. The activities of the rebels were much hindered by fortified fences on the Tunisian and Moroccan frontiers. In Feb. 1958 a French air raid on the village of Sakiet Sidi Yusuf in Tunisia, alleged to contain Algerian rebels, provoked an international reaction.

In May 1958 suspicions on the part of the settlers that the French government intended to negotiate with the rebels led to demonstrations in Algiers on May 13 and to a political crisis in France which ended with the assumption of power by General de Gaulle. General de Gaulle ignored a *loi-cadre*, laboriously passed by the French national assembly, which provided for the setting up of regional assemblies in Algeria. He also showed no favour toward the idea of integration, but seemed to be working for a self-governing Algeria associated with France. Army control was sufficiently effective to permit a referendum to be held (Sept. 26-28, 1958) which gave a large majority for the new French constitution. On Oct. 3 General de Gaulle announced a vast plan for Muslim economic and educational betterment. On Oct. 23 he offered to discuss the terms of a cease fire with what he called an "external organization"; *i.e.*, the F.L.N. This had meanwhile constituted itself into a *Gouvernement Provisoire de la République Algérienne* (G.P.R.A.) on Sept. 19 with offices in Cairo and in Tunis. No response being forthcoming, fighting continued and during the 12 months from Nov. 1958 to Nov. 1959 resulted (according to French sources) in the deaths of 68,000 rebels and 5,800 French soldiers. This total almost equalled the numbers killed over the whole preceding four-year period. By the early 1960s there were about 560,000 French troops stationed in Algeria.

On Sept. 16, 1959, General de Gaulle announced that Algerians would, within four years of the restoration of peaceful conditions, settle their future by a free vote. They would choose between association with France and secession. If they voted for association they would have a choice between complete integration or association as a separate entity. An insurrection of Europeans broke out in Algiers in Jan. 1960 in protest against De Gaulle's Algerian policy, but quickly collapsed. De Gaulle visited Algeria in March and Dec. 1960 but unrest continued, culminating in a second revolt, this time initiated by army officers, which began on April 22, 1961. It was led by four retired generals (Maurice Challe, André Zeller, Edmond Jouhaud and Raoul Salan) but collapsed

on April 25-26 after De Gaulle assumed extraordinary powers.

The signing of a cease-fire with the G.P.R.A. was announced at Évian-les-Bains on March 18, 1962, following months of protracted negotiations. In a desperate attempt to block the agreement a wave of terror was instigated by the O.A.S. (Secret Army Organization of European extremists) but De Gaulle's program for an Algerian accord was overwhelmingly ratified by a referendum held April 8, 1962, in metropolitan France.

French Sahara.—The conquest of the fertile areas of Algeria led to the occupation also of the Saharan regions to the south of Algeria and, after the occupation of Morocco, of what used to be called Moroccan Sahara. From 1902 these were administered as a separate unit, the Southern Territories. Following the discovery of valuable sources of oil and other minerals after World War II, that administrative unit was abolished and the whole Saharan area under French control was grouped, together with parts of French West Africa, Chad and Sudan, to form a body known as the Organisation Commune des Régions Sahariennes (O.C.R.S.). This body was to be responsible for the economic and social development of the region but could broaden its field of action; it was divided into two *départements*, Oasis and Saoura, and made the responsibility of a special minister in the French government. (N. BA.)

POPULATION

The major indigenous element in the population is Berber (q v.), affected in varying degrees by Arab influences. There are few pure Arabs in the country, the Arab invasions having had little influence upon racial types, although spreading Islam and the Arabic language. The Berbers have preserved their national temperament and customs, and whereas the Arab remains essentially a tent-dwelling herdsman, the Berber is a highlander and a cultivator, living in towns and villages. Berber dialects survive in western Kabylia, in the Aurès mountains and among the Tuareg. Muslim peoples have increased rapidly under French rule, from about 2,310,000 in 1856 to 9,240,000 in 1958 (*see* Table I).

TABLE I.—Population*

Nationalities	1906	1948	1954
Algerian Muslims	4,447,149	7,611,777	8,364,652
Non-Algerian Muslims	30,639	67,301	84,680
Total Muslims	4,477,788	7,679,078	8,449,332
French { by origin:	278,976	876,686	934,052
naturalized	235,089§		
Spaniards	117,475	45,586	49,979
Italians	33,153		
Other Europeans	15,570		
Total Europeans	680,263	922,272	984,031
Total	5,231,850	8,681,785	9,529,726

*Population figures include the Southern Territories (which became the Saharan *départements* in 1957). †Mainly Moroccans and Tunisians. ‡French settlers, their descendants and descendants of the naturalized. §Including 64,645 Jews. ||Including 6,217 Maltese.

In 1957, 835,900 Muslim people (9%) lived in the Southern Territories. The urban element in the Muslim population was about 15% in 1958.

In 1954 the crude birth rate of Europeans was 19 per 1,000 population, of Muslims 44 per 1,000; crude death rates: Europeans 8.8, Muslims 14 per 1,000 population. The rapid increase in the Muslim population has raised numerous social and economic problems. One-half of the Muslim population is under 20 years of age. Non-Muslims in 1958 numbered about 1,033,000, one-fourth

TABLE II.—Commune Populations

of whom lived in Algiers and its vicinity and 18,000 in the Southern Territories.

ADMINISTRATION AND SOCIAL CONDITIONS

Government.— Algeria is not a colony in the usual sense, for because of the early desire of the French colonists to be ruled by the home government rather than by military authorities, a very close connection with France developed whereby Algeria has come to be regarded as an integral part of France, sending representatives to the French parliament. Assimilation, however, was never complete and a considerable measure of autonomy is exercised. Under the Statute of Algeria (1947) the country became a group of three *de'partements*: Algiers, Oran and Constantine. In 1956 these became regional prefectures, being subdivided into *départements*. By a further administrative reorganization in 1958 the country was divided administratively into two parts: Northern Algeria and the Saharan *de'partements*. Northern Algeria comprises 13 *de'partements* (Algiers, Tizi-Ouzou, Orléansville, Médéa, Oran, Tlemcen, Mostaganem, Saïda [created in 1959], Tiaret, Constantine, Bône, Sétif, Batna) divided into 76 *arrondissements*. French Sahara comprises two *de'partements* (Saoura, Oasis) divided into 5 *arrondissements*.

The government is centralized at Algiers under a minister resident who is a member of the French government. Except for justice and education the public services are under his direction and financial autonomy has been granted since 1900. The Algerian assembly votes the budget and has limited legislative powers. Two electoral colleges, Muslim and European, send equal numbers of representatives to the Algerian assembly (the national assembly), to the council of the republic and to the assembly of the French Community in Paris. New assemblies were elected in Nov. 1958. Since 1944 all Muslims have been regarded as French citizens; their personal and legal status under the law of the Koran has not been affected. The fiscal system is like that of France.

Living conditions.— The rapid increase in the Muslim population since World War II has contributed to unemployment problems in town and country, to a movement from country to town in search of work and to political unrest.

Styles and types of housing are influenced by the way of life. In the scantily peopled districts used by pastoral nomads, mainly the Sahara and steppe of the High Plateaus, the tent, made of material woven from wool, goats' hair and esparto grass, predominates. In the Tell the seminomad owns fields as well as herds and the stone or clay hut or gourbi is common, standing alone near the fields and used only while crops are sown or reaped. The poorer permanent dwellings, clay-walled and flat-roofed, stand in groups, usually on hilly defensive sites, often terraced. Their owners cultivate tree crops and live permanently near their orchards. These occur in the Aurès, the Maritime Atlas and the Djurdjura. Tiled houses similar to those of the French peasant are found in parts of the Djurdjura and Babor mountains. Houses of European style have increased markedly since 1945, but are still confined principally to the main towns.

Land Tenure.— At the French occupation in the 1830s three main types of land tenure were operative: *beylik*, *arch* and *nzelk*. The *beylik* lands were the property of the state; the *arch* lands belonged to tribes in communal tenure and were most common in the east; *melk* included all forms of freehold in land and was most common in the mountain areas. French colonization and the necessity of defining boundaries led to private ownership supplanting the traditional system, and in 1863 the tribes were declared owners of the land they had been using and private ownership was recognized by the issue of title deeds for *melk* land. In 1873 the conversion of tribal and family property into freehold was legalized; this was reinforced by subsequent laws in 1897 and 1926, but not all natives have taken advantage of these opportunities. Wherever crops could be grown, however, collective ownership has given way to private ownership since 1926. To the French citizen free grants of land with obligatory residence have been the rule. The decree of 1904 recognized four modes of land transfer: sale at a fixed price at a public office, sale by auction under public control, sale by private treaty and free concession with

a 10-year period of obligatory residence. A decree of 1924 lengthened the latter period to 20 years and the period during which the lands may be transferred only to French colonists from 20 to 40 years. The proportion of colonization land reserved to natives was increased from one-third to one-half. In 1953 there were about 5,650,000 ha. (mostly in the Tell) under the French system; European property covered 2,690,000 ha. (50% in the *département* of Oran). Of this, official colonizing schemes accounted for 1,680,000 ha.; private colonization, 1,010,000 ha.

Justice.— Muslim common law is administered by justices of the peace and *cadis*, with appeal to French courts. Criminal justice is organized as in France. There are 17 courts of first instance in the *arrondissements* and appeal courts at Algiers, Oran and Constantine. There are also commercial and industrial dispute courts.

Education.— Since 1882 primary instruction for Europeans and Jews has been compulsory, with the establishment of schools for the natives at the discretion of the governor general. Early attempts at mixed French and Arab primary and secondary schools had little success, but improvement has been marked since 1920 and in 1949 French and Muslim primary schools were amalgamated. In 1958 only 12% of the children of all communities attended school, but a huge program of elementary education was designed to have two-thirds of Algeria's children in school by 1963. Few natives go beyond the primary schools but secondary education by means of *lycées* and the former Muslim *médersas* can lead to the University of Algiers. There are also special high schools for commerce, fine arts, agriculture and hydrography. The University of Algiers, founded in 1879, has faculties of law, medicine, science and letters.

THE ECONOMY

The greater part of Algeria is of limited value for agriculture and not exceptionally well-endowed with mineral wealth. Most of the agricultural wealth of the country accrues from the limited area of highly fertile valleys and basins, mainly European-owned, near the coast. Here farming is up-to-date and on a commercial scale. Elsewhere the mountains and plateaus offer forests and grazing rather than agricultural opportunity. With mainly subsistence cultivation the majority of the native population is poor.

Agriculture.— The area under cultivation totals about 15,600,000 ha., one-third of which is farmed by Europeans. Cereals (wheat, barley and oats) form the chief crops. The best cereal growing regions are the Tell and the high plains of Constantine around Sétif, Constantine and Guelma. The grape is the principal commercial fruit grown and is limited to a belt about 65 mi. wide along the coast. The expansion of vineyards was particularly rapid from 1865 to 1870 when the grape phylloxera (an insect) ruined the French vines and led to the emigration of many growers to Algeria. Viticulture is related to European settlement and is most important in the *de'partement* of Oran. France is the chief market for wine. The olive is widespread, mostly in Kabylia, but other fruits grow in abundance, particularly citrus (of which half are oranges), figs and apricots, almonds and, in the south, dates. The mildness of the winter along the coast has led to the growing of early vegetables and their export, particularly to France. Native farmers produce two-thirds of the tobacco crop, chiefly in the *département* of Constantine. Irrigated crops are limited by the paucity of water resources. Twelve large dams and reservoirs supply about 50,000 ha. In the Saharan *de'partements* there are about 5,500,000 date palms in production.

Stock raising, particularly sheep, is important especially among the natives and large flocks belonging to nomadic and seminomadic tribes traverse the High Plateaus to the Maritime Atlas during the summer.

Forestry.— The area of state forests in the second half of the 20th century was more than 2,250,000 ha. Much is of little value, but particularly in the east there are valuable stands of Aleppo pine, evergreen oak, cedar and cork oak. Timber is cut for firewood, railway sleepers, telegraph poles, etc., and cork is the main commercial forest product.

Mining.— The principal mining takes place in the east (Constantine *département*). The phosphate workings at Djebel-Kuif

near Tebessa have an average annual yield of 700,000 metric tons. The three Barbary states (Algeria, Morocco and Tunisia) lead the world in phosphate production. In the 1950s 200,000–300,000 tons of iron ores per annum were mined near the Tunisian frontier (Djebel Ouenza, Djebel bou Kadra), in the Miliana region (Djebel Zaccar) and near Oran (Béni-Saf). Iron content averages 55%. Zinc and lead ores are widely present and mainly worked in the east. Coal is almost entirely produced from one small coal field at Kenadsa, 20 mi. W. of Colomb-Béchar. Rich discoveries of petroleum (including natural gas) have been made in the northern Sahara, and wells at Hassi-Messaoud in eastern Algeria 120 mi. S. of Touggourt began commercial production early in 1958. Early production was by pipeline to Touggourt and to Bougie (1959) and by rail to Philippeville. Another oilfield at Edjélé 200 mi. to the southeast also commenced production.

Fisheries.—There are extensive fisheries for sardines, anchovies, tunny, shellfish and whitefish. Much of the annual catch is used by the local canning factories.

Industries.—World War II, with the isolation of north Africa from France, gave an impetus to the rise of varied industries, which has since continued, assisted particularly by a five-year development plan announced in 1958. The country, however, remains essentially agricultural; there is virtually no export of manufactured goods, whereas the import trade in them is heavy. The principal industries include food processing, notably flour milling, fish canning, wine and oil manufacture, the preserving of fruit and vegetables, tobacco, leather and textile manufacturing. Other industries produce fertilizers, fats, soaps, matches, glass, paper, bricks and tiles and telephone equipment and there are metal-rolling works. Native craftsmanship is of little importance except for such products as carpets and leather goods.

TRADE AND FINANCE

From 1835 onward France granted Algeria preferential treatment and since 1867 there has been complete reciprocity in customs dues. The greater part of the imports consists of products required for industry and agriculture (machinery, metal manufactures and fuel) followed by food products (25%, including sugar, dairy produce, oils and fats) and textiles, mostly cotton goods. The principal exports include iron ore, wine, phosphates, citrus fruits, esparto grass and vegetables.

Banking and Currency.—The Bank of Algeria, founded in 1851 and nationalized in 1946, carries out those functions performed by the Bank of France in France itself. It is a bank of issue with a capital of 25,000,000 francs. Other banks include co-operative agricultural banks and those of private banking companies. The Algerian franc, which is tied to the French franc, is the sole legal tender.

TRANSPORT AND COMMUNICATIONS

A good road network exists in the Tell and there are established routes and motor transport for both passengers and freight across the Sahara. There were 4,491 km. (2,791 mi.) of railway in use in 1955, almost equally divided between the standard and narrow gauges. A central line runs from the Moroccan to the Tunisian frontier with branches to the chief ports as well as lines southward to Crampel and Kenadsa (770 km. [478 mi.] from Oran); to Burdeau and Djelfa; to Touggourt (570 km. [354 mi.] from Philippeville) through Biskra, and to Khenchela and Tebessa. The major port, Algiers, is almost entirely artificial. It resembles an L in shape and has a frontage of almost 2½ mi. Annual imports amount to about 1,800,000 metric tons; exports (wine, vegetables, fruit, iron ore) average 1,500,000 metric tons. Oran is the major port of its *département*, but is rivaled by Mostaganem (wines, vegetables, fruit), Nemours (manganese and anthracite from eastern Morocco) and Béni-Saf (iron ore). Oran's imports average nearly 1,000,000 tons and exports (mainly wine) just over 1,000,000 tons annually. Bône is the principal mineral port of eastern Algeria with annual exports totaling 3,000,000 tons. By the law of 1889 only French ships may trade between France and Algeria. Algeria provides essential air fields on the air routes between Europe and farther Africa and between the Americas and the east.

ALGIERS (Fr. ALGER; Arabic AL JAZAIR), the capital and chief seaport of Algeria, stretches for 10 mi. along the west side of the Ray of Algiers. It is built on the slopes of the Sahel hills which run parallel to the coast and rise to 1,240 ft. in Mt. Bouzaréa behind the town. The city faces east and north, offering from the sea a view of dazzling white terraces below green-topped hills. The population of Algiers, in particular the Muslim population, increased rapidly after World War II. Pop. (1954) 355,040; including the seven suburbs of Bouzaréa, Al Biar, Hussein Dey, St. Eugène, Maison-Carrée, Kouba and Birmandreïs, which are continuous with the town, 570,086, of whom more than one-half were of European stock.

The City.—Turkish Algiers was a town of nearly 100,000 people in the 17th century, with the kasbah, or citadel, forming the apex of a triangle of which a line of rocky sea cliffs, now the Boulevard de la République, formed the base. The highest part, on steeply scarped hills, has best preserved its native character with its maze of high buildings with balconies overhanging very narrow lanes. Through the old town two roads, the Rue Randon and the Rue Marengo, have been cut. The kasbah, 387 ft. above sea level, still dominates the old town. Built in the 16th century, it was the residence of the two last deys. It was there that the dey Hussein struck the French consul with a fly whisk on April 30, 1827, an incident which led to the end of Turkish rule and the capture of the city by the French in 1830.

French Algiers grew piecemeal around the Muslim town. The three main thoroughfares are a long street with different names (part of it is the Boulevard de la République) running north-south from St. Eugène along the sea front, through the harbour to Maison-Carrée; the Rue Charles-Péguy, a narrow street carrying the main north-south city traffic; and the tortuous Boulevard du Telemy which runs from the Gouvernement Général to the Summer palace. Along the shore some corsairs' houses built in the 18th century have been preserved. Wide, handsome boulevards skirt the port 45 ft. above the quays. The chief official and commercial buildings of Algiers are on these boulevards. At the base of the old town is the Place du Gouvernement. This was long the centre of the town with several important roads starting from it. One of these, the Rue Bab Azoun, leads south to Opera House square, Rue Charles-Péguy and the University of Algiers (1879) at the modern city centre. The university's 12 specialized institutes include an institute of Islamic studies and a nuclear research centre. To the west of the Place du Gouvernement is the modern cathedral (1845–60) built on the site of a mosque. Nearby are the old palace of the archbishops, formerly the Jénina or palace

BY COURTESY OF THE INFORMATION SERVICE OF THE GENERAL DELEGATION OF THE GOVERNMENT IN ALGIERS

COURT OF THE GREAT MOSQUE. 1322-23, IN THE OLD TOWN OF ALGIERS

of the dey, and the Winter palace, now used as an office building, which was for long the residence of the governor general. In the vicinity of the cathedral is the ancient National library in one of the finest Moorish houses in Algiers (1798). There are several learned societies, including the Pasteur institute and an astronomical observatory.

To the north is the suburb of St. Eugene, dominated by the basilica of Notre Dame d'Afrique. Mustapha, once a southern suburb, grew greatly after the fortifications between it and Algiers were demolished, and the two are now continuous. The lower part of Mustapha is the industrial area while up the hillside are residential villas and a number of skyscrapers. After World War II many houses were built in the outskirts of the town.

The airport, Maison Blanche, is 12½ mi. from the city.

The **Port**.—Khair ed-Din (Barbarossa) created the old Turkish port by building a jetty in 1529 from the mainland to an islet, one of several called in Arabic Al Jazair ("the islets"), corrupted to Algiers. (The others have disappeared under harbour works.) On this island are a lighthouse and the admiralty buildings. In the shallow pool to the north fishing and pleasure boats are moored; to the south lies the modern port. The heavy merchandise traffic includes imports of vehicles, petroleum products, wheat, cement, metal products, cotton cloth, sugar and coffee; the main exports are wine, potatoes and other vegetables, citrus and dried fruits, olives, vegetable fibre: iron and phosphate.

History.—The islet of Algiers was occupied by the Phoenicians, who called it Icosim (meaning, probably, the gulls' island). In Roman times a small town named Icosium existed where the marine quarter of the city is located and there were Roman cemeteries near the present streets of Bab Al Oued and Bab Azoun. Bishops of Icosium are mentioned as late as the 5th century. The Muslim city was founded toward 950 by Bulukkin ben Zeiri, the founder of the Zeirid-Sanhaja dynasty, which was overthrown by Roger II of Sicily in 1148. (See FATMIDS.) The Zeirids had before that date lost Algiers, which in 1082 was occupied by the Almoravids, and in 1152 by the Alrnohads and in the 13th century came, under the dominion of the Abd-al-Wadid sultans of Tlemcen. Nominally

part of the sultanate of Tlemcen, Algiers had a large measure of independence under amirs of its own, the chief seaports of the Abd-al-Wadids being Oran, Rashgun and Honain. The islet in front of the harbour, subsequently known as the Peñón, had been temporarily occupied by the Spaniards as early as 1302. Thereafter! a considerable trade grew up between Spain and Algiers, which, however, remained comparatively unimportant until after the expulsion from Spain of the Moors, many of whom sought an asylum in the city. In 1510, following their occupation of Oran and other towns on the coast of Africa, the Spaniards reoccupied and fortified the Peñón. In 1516 the amir of Algiers, Salim-et-Teumi, invited the brothers Aruj and Khidr to expel the Spaniards. Aruj went to Algiers, had Salim assassinated and seized the town. Khidr succeeded Aruj, who had been killed by the Spaniards in 1518, took the name Khair ed-Din and placed himself under the authority of the Ottoman sultan. He drove the Spaniards from the Peion in 1529 and was the founder of the pashalik (afterward deylik) of Algeria. (See also BARBAROSSA.) Algiers from that time became the chief seat of the Barbary pirates. In Oct. 1541 the Holy Roman emperor Charles V sought to capture the city but was defeated owing to a storm which destroyed most of his ships in the bay.

Repeated vain attempts were later made by various nations to quell the pirates and in 1816 the British and Dutch burned the corsair fleet. But the piracy continued, though much weakened, until 1830, when a French army captured the city.

From Nov. 1942 until Aug. 1944 Algiers was the headquarters of the Allied forces in north Africa and the seat of the French Committee of National Liberation.

ALGIRDAS (Polish OLGIERD) (d. 1377), grand prince of Lithuania from 1345 to 1377, made his country one of the largest European states of his time (see LITHUANIA: History). One of the seven sons of Gediminas (Gedymis), he came to power when his brother Kestutis put him in possession of Vilnius, the capital, in the place of their incapable younger brother Jaunutis.

Algirdas planned to consolidate all Lithuanian lands. In the west his plan to eliminate the rival power of the Teutonic Order (*q.v.*) in the Baltic area by diverting it to the Ukraine (where it might protect his Slavonic subjects from the Tatars) failed, but kept the order from increasing its hold on Lithuania, despite continual attacks. In the east and in the south Algirdas won considerable successes; chiefly by matrimonial alliances. Himself twice married to Russian Orthodox princesses (Maria of Vitebsk and Yuliana of Tver), he acquired a number of Russian principalities by placing most of his 12 sons in Slavonic lands and by marrying his 7 daughters to Russian and Polish princes. The area of Smolensk came under his control in 1351. Rzhev in 1355, Bryansk in 1356 and Chernigov and Novgorod Seversk soon after. His victory over the Tatars at Sinie Vody (the Sinucha river, a tributary of the Southern Bug) in 1362 gave him possession of all the fertile lands of Podolia and the steppes north of the Black sea to the Dnieper in the east. He annexed the grand principality of Kiev in 1363. In the north, Algirdas was on friendly terms with the republic of Novgorod.

Desiring to reduce the growing power of the grand princes of Muscovy, Algirdas fought them three times. In 1368 he defeated the Muscovite army at the Trostna river and left Moscow in flames. Dimitri Donskoi was forced to withdraw from the principality of Tver, whose prince, Michael, was Algirdas' ally and brother-in-law. In 1370, after a victory at Volokolamsk, Algirdas held Moscow's *kremi* for eight days until an armistice was made. Finally in 1372 he again helped Michael against Dimitri. Thereafter the German danger made him refrain from intervening between Tver and Moscow.

Algirdas did not accept Christianity from the Teutonic Order.

He was convinced that the Germans wanted Lithuanian lands and were not concerned for the souls of their inhabitants. He was, however, quite tolerant about religion and permitted the Orthodox faith in all the Russian lands that he controlled.

Algirdas died a pagan in 1377 and was cremated with 18 horses near Vilnius. He was an able diplomat and a clever leader.

ALGOL (β PERSEI) is the second brightest star in the constellation of Perseus and is the prototype of a large class of variable stars called eclipsing binaries. Its variation in light, which was noted in 1670 by G. Montanari of Italy, was closely watched by the English amateur astronomer John Goodricke, who found (1782) that it repeated itself every 2 days 20 hr. and 49 min. Goodricke suggested that the variation might be caused by partial eclipses of the star by a dark body, a hypothesis that was proved correct in 1889, when spectroscopic observations of its velocity in the line of sight showed that the bright star was traveling round an orbit in the period given above. Further, the reduction of light occurs when the bright star is most remote from the earth; that is, just at the time when the dark companion passes between the earth and the bright star. Algol remains of almost constant brightness for 59 hr., the remaining 10 hr. of its cycle being occupied by the eclipse. The comparatively long duration of the eclipse shows that the dimensions of the two stars are by no means small in comparison with the distance between them. Accurate observations show that the light is not absolutely constant even during the 59 hr., because the dark component reflects (or reradiates) light from the bright star, and thus goes through phases like the moon. Accordingly, after the eclipse is over, the total light still continues to increase a little because the "moon" is progressing from new to full. In the middle of the 59-hr. interval the light dips again when the bright star is hiding its companion.

Small fluctuations in the period of the light variation of Algol can be partly explained by assuming that, besides the eclipsing binary, the system contains two other stars for which the periods of orbital revolution are 1.873 years and 188.4 years; these stars take no part in the eclipses. The presence of a companion with a period of 1.873 years was confirmed by spectroscopic observation, but the presence of the fourth star had not been confirmed by the late 1950s. From analysis of the light variation of Algol, combined with the spectroscopic observations, the following dimensions for the system have been deduced: radius of Algol, $3 \times$ sun's radius, and of eclipsing companion, $3.2 \times$ sun's radius; mass of Algol, $5 \times$ sun's mass, of eclipsing companion, $1 \times$ sun's mass, and of star with 1.873-year period, $1.5 \times$ sun's mass; density of Algol, 0.16 (water = 1), and of eclipsing companion, 0.01; separation of eclipsing stars, 6,000,000 mi. (O. J. E.)

ALGONKIAN TRIBES. A widely dispersed series of North American Indian groups which, although diversified in their aboriginal mode of life and speaking many mutually unintelligible languages, can, nevertheless, be identified as a unit because the basic structure of their speech indicates affiliations linking them together as members of a single linguistic family. The name applied to this group of languages is of Indian origin. It is derived from a small ethnic group of Indians called Algonkin by the French when first encountered on the Gatineau river, east of Ottawa. While the significance of the name remains uncertain, it has been said to mean "at the place of spearing fish and eels from the bow of a canoe." Subsequently spelled in various ways, "Algonquian" being the form adopted by the Bureau of American Ethnology, the name came, in time, to be applied to linguistically related groups and finally, as a consequence of systematic scholarly work, to a family of languages comparable in degree of relationship to the Romance or Germanic languages of Europe. Tribes belonging to the Algonkian linguistic stock were found to occupy a more extensive geographical area than any other linguistic family on the continent in aboriginal times. In American colonial history Algonkian tribal groups played a prominent role in the relations between Indians and whites and some aspects of Algonkian culture

and language influenced the earliest settlers. Many Indian leaders, such as King Philip, Ponhatan, Tecumseh and Pontiac, captured the imagination of American historians, dramatists, poets and novelists.

In Canada, southwest, south and east of Hudson bay were to be found the Cree-Rontagnais-Naskapi. It is likely that the Beothuk of Newfoundland, who became extinct in the 18th century, also spoke an Algonkian tongue. So did the Indians of the maritime provinces and New England; e.g., the Micmac, Malecite, Passamaquoddy and Penobscot. The Puritans met Algonkian speakers, tried to convert them and fought them. The first Bible printed in the colonies (1663) was in an Algonkian language (Natick), a translation by John Eliot. In the conflict between whites and Indians the redoubtable Wampanoag sachem, King Philip, became the most notorious of all New England Indians. Algonkian-speaking groups extended southward down the Atlantic seaboard to Cape Hatteras, the Lenape (Delaware) and the Virginia Algonkians, made famous by Poahatan and Pocahontas, being the best known. In the Ohio valley, among other tribes were the Miami, Peoria and Illinois. There Tecumseh, a Shawnee, failed in uniting the Indians for a last stand against the whites when this region was becoming a new frontier. In the area of the Great Lakes were found the Sauk and Fox, Menominee, Kickapoo, Potawatomi, Ojibwa and the Ottawa whose leader Pontiac also achieved fame in frontier history. On the Great Plains, Algonkian-speaking tribes were represented by the Arapaho, Cheyenne and the aggressive Blackfoot, whose languages comprise distinct subdivisions of the family and were mutually unintelligible although their mode of life was similar. Far across the mountains in California, the Wiyot and Yurok have, in recent years, been shown conclusively to belong to the Ritwan subgroup of the Algonkian family. And, it now appears that there is likewise a genetic relation between the Muskogean family of languages, which once prevailed in the Gulf states, and the Algonkian family.

The Algonkian tribes which occupied the forests in Canada, north of the Great Lakes and in the Labrador peninsula, were food gatherers and hunters. They were among the first Indians to come into contact with the men of the Hudson's Bay company and to become involved in the fur trade. It was from these Indians that the use of the birch bark canoe was learned by whites. The Algonkians of the Great Plains were typical buffalo hunters. They lived in tepees and belonged to a culture area distinct from that of their linguistic kinsmen in the woodlands. South of the Great Lakes and on the eastern seaboard, a sedentary existence, combined with the occasional hunting and fishing, was adopted. Maize was the staple crop of these Algonkians and it was from them, both at Jamestown (1609) and later in New England, that the early colonists learned to plant and raise corn. From these Indians, too, the whites learned to make hominy and johnnycake and to use maple syrup. From the same source were derived the earliest Americanisms—words for animals, plants, food products, utensils, clothing—unfamiliar to the first settlers. Indian words in American English are predominantly Algonkian words. A. F. Chamberlain compiled a total of 132, of which about 30, dating back to 17th-century borrowings, are still current; e.g., hickory, hominy, moccasin, moose, opossum, persimmon, raccoon, sachem, skunk, squash, squaw, terrapin, tomahawk, totem, wigwam and woodchuck.

H.)

ALGORITHM (**ALGORISM**), in modern mathematics, a set of operations reduced to a uniform procedure for solving a specific type of problem, for example, the algorithm of continued fractions. In the middle ages, the name was applied to arithmetic employing the Indo-Arabic numerals. (See **ALGEBRA**, **HISTORY OF**, for al-Khwarizmi, who wrote *Liber algorism*, "the Book of al-Khwarizmi.") In the middle ages the abacists computed on the abacus (*q.v.*), while the algorists computed by algorithm. Robert Recorde wrote in his *Ground of Artes* (c. 1542): "Some call it Arsemetrick, and some Augrime. . . Both names are corruptly written: Arsemetrick for Arithmetick, as the Greeks call it, and Augrime for Algorisme, as the Arabians found it" (1646 edition).

ALGUAZIL (from Arabic *al-wazir*, "vizier"; mod. Sp. *alguacil*), a Spanish title originally applied to the official responsible for the local administration of justice. Often, he was also the governor of a town or fortress. Later, however, the term came to be applied to subordinate officers of the court, entrusted with the service of writs and certain police duties. The title is also given to inspectors of weights and measures in market places, and similar officials, and to an official of the bull ring, who is charged with communicating the orders of the president to those taking part in the fight.

ALGUM (**ALMUG TREE**). The Hebrew words *Algummin* or *Almuggim* are translated *Algum* or *Almug* trees in the authorized version of the Bible (see 1 Kings x, 11-12; 2 Chron. ii. 8, and ix, 10-11); *almug* is an erroneous form. The wood of the tree was very precious, and was brought from Ophir (probably some part of India), along with gold and precious stones, by Hiram, and was used in the formation of pillars for the temple at Jerusalem, and for the king's house; also for the inlaying of stairs, as well as for harps and psalteries. It is probably the red sanders or red sandalwood of India (*Pterocarpus santalinus*). This tree belongs to the large family Leguminosae, suborder Papilionaceae. The wood is hard, heavy, close-grained and of a fine red colour. It is different from the white fragrant sandalwood, which is the produce of *Santalum album*, a tree belonging to another family, the Santalaceae.

ALHAMBRA, a city of Los Angeles county, Calif., U.S., 8 mi. N.E. of Los Angeles, at the western entrance to the San Gabriel valley. Its population totaled 54,807 in 1960. (For comparative population figures see table in **CALIFORNIA: Population**.) It was named after the Moorish palace in southern Spain by Benjamin D. Wilson when he set aside a tract for a city out of his vast ranch holdings. Wilson (after whom Mt. Wilson was named) and his son-in-law, J. de Barth Shorb, were primarily responsible for the city's development in the 1870s. They brought to Alhambra the first piped water in southern California, making possible an early diversification of agriculture, with vineyards, apple and apricot orchards and orange groves. The city was incorporated in 1903 and adopted a commission-manager form of government in 1914. By the second half of the 20th century commercial agriculture had given way to industrial and residential development. Alhambra's inhabitants work in Los Angeles or in the numerous light industries in the city. Products manufactured include plastics, oil refinery machinery, steel equipment, paper materials, furniture and precision instruments. Although it is a part of the Los Angeles metropolitan area, Alhambra retains its identity as a small community with its own school system, library, parks and commercial recreational facilities. On the outskirts of Alhambra is the San Gabriel mission (founded 1771 by the Franciscans). (J. A. Sz.)

ALHAMBRA, THE, an ancient palace and fortress of the Moorish monarchs of Granada, in southern Spain. Its plateau, which measures about 2,430 ft. in length by 674 ft. at its greatest width, extends from west-northwest to east-southeast, and covers an area of about 35 ac. It is enclosed by a strongly fortified wall and 13 towers. The Darro river, which foams through a deep ravine on the north, divides the plateau from the Albaicín district of Granada. The name Alhambra, signifying in Arabic "the red," is probably derived from the colour of the sun-dried tapia, or bricks made of fine gravel and clay, of which the outer walls are built.

History. — (For an account of the period to which the Alhambra belongs, see **GRANADA** [city].) The palace was built chiefly between 1238 and 1358, in the reigns of Al Ahmar and his successors. The splendid decorations of the interior are ascribed to Yusuf I, who died in 1354. After the expulsion of the Moors in 1492, the open work was filled up with whitewash, the painting and gilding effaced, the furniture soiled, torn or removed. Charles V (1516-1556) rebuilt portions in the modern style of the period, and destroyed a part of the Alhambra to make room for an Italian palace by Pedro de Machuca in 1526. In 1812 some of the towers were blown up by the French under Count Sebastiani, and the rest of the buildings narrowly escaped the same fate. In 1821 an earthquake caused further damage. The work of restoration undertaken in 1830 by the architect José Contreras was ended in 1830 by Ferdinand VII; and after the death of Contreras in 1847 it was continued by his son Rafael (d. 1890) and his grandson Mariano.

Description. — The situation of the Alhambra is one of rare natural beauty. The park (Alameda de la Alhambra), was planted by the Moors with roses, oranges and myrtles; its most characteristic feature, however, is the dense wood of English elms taken there in 1812 by the duke of Wellington.

The Moorish portion of the Alhambra included a castle, a palace and a residential annex for subordinates. The Alcazaba or citadel, its oldest part, is built on the precipitous foreland on the northwest. Only its massive outer walls, towers and ramparts are left. Beyond the Alcazaba is the palace of the Moorish kings, or Alhambra properly so-called, and beyond this is the Alhambra Alta (Upper Alhambra), originally tenanted by officials and courtiers.

The lower entrance to the park is the Puerta de las Granadas (Gate of Pomegranates), a massive triumphal arch dating from the 16th century. A steep ascent leads past a fountain erected in 1554 to the main entrance of the Alhambra. This is the Gate of Judgment, a horseshoe archway, surmounted by a square tower, and used by the Moors as an informal court of justice.

The present entrance through the Oratory leads to the Patio de los Arrayanes (Court of the Myrtles). This court is 140 ft. long

C. J. BROWN

PRINCIPAL COURTS OF THE ALHAMBRA: (LEFT) PATIO DE LOS LEONES (COURT OF THE LIONS); (RIGHT) PATIO DE LOS ARRAYANES (COURT OF THE MYRTLES)

by 74 ft. broad, and in the centre there is a large pond set in the marble pavement, full of goldfish, and with myrtles growing along its sides. There are galleries on the north and south sides; that on the south is 27 ft. high, and supported by a marble colonnade.

The Sala de los Embajadores (Hall of the Ambassadors) is the largest in the Alhambra, and occupies all the Torre de Comares. It is a square room, the sides being 37 ft. in length, while the centre of the dome is 75 ft. high. This was the grand reception room, and the throne of the sultan was placed opposite the entrance.

The Patio de los Leones (Court of the Lions) is an oblong court, 116 ft. in length by 66 ft. in breadth, surrounded by a low gallery supported on 124 white marble columns. A pavilion, perhaps modeled upon a Cistercian lavabo, projects into the court at each extremity, with filigree walls and light domed roof. The square is paved with coloured tiles, and the colonnade with white marble, while the walls are covered 5 ft. up from the ground with blue and yellow tiles, with a border above and below enameled blue and gold. In the centre of the court is the Fountain of Lions, a magnificent alabaster basin supported by the figures of 12 lions in white marble, emblems of strength and courage.

The Hall of the Abencerrages derives its name from a legend according to which Boabdil, the last king of Granada, having invited the chiefs of that illustrious line to a banquet, massacred them there. This room is square, with a lofty dome and trellised windows at its base. The roof is exquisitely decorated in blue, brown, red and gold. Opposite to this hall is the Sala de las dos Hermanas (Hall of the Two Sisters), so-called from two large white marble slabs laid as part of the pavement. There is a fountain in the middle of this hall, and the roof—a dome honeycombed with tiny cells, all different, and said to number 5,000—is an example of the stalactite vaulting of the Moors.

The original furniture of the palace is represented by a splendid vase dating from 1320, and belonging to the first period of Moorish porcelain.

Of the outlying buildings, the foremost in interest is the Generalife (the Moorish *Jenmat al Arif*, or "Garden of the Builder"). This villa probably dates from the end of the 13th century, but has been several times restored. The Villa de los Mártires (Martyrs' Villa), on the summit of Monte Mauror, commemorates by its name the Christian slaves who were employed to build the Alhambra, and confined there in subterranean cells.

ALHAZEN (Arabic ABU-'ALI AL-ḤASAN IBN AL-HAYTHAM), Arabian mathematician, was the first great discoverer in optics since the time of Ptolemy. He was born at Basra and died at Cairo in 1038. He is distinguished from another Alhazen who translated Ptolemy's *Almagest* in the 10th century. Having boasted that he could construct a machine for regulating the inundations of the Nile, he was summoned to Egypt by the caliph Hakim; but, aware of the impracticability of his scheme, and fearing the caliph's anger, he feigned madness until Hakim's death in 1021.

According to Giovanni Battista della Porta, Alhazen was the first to explain the apparent increase in size of heavenly bodies near the horizon, although Roger Bacon gives the credit for this discovery to Ptolemy. His treatise on optics was translated into Latin by Witelo (1270), and afterward published by F. Risner in 1572, with the title *Opticæ thesaurus Alhazeni libri VII, cum ejusdem libro de crepusculis et nubium ascensionibus*. Works on geometrical subjects were found in the Bibliothèque Nationale de

Paris in 1834 by E. A. Sédillot; other manuscripts are preserved in the Bodleian library at Oxford and in the library of Leiden.

ALHUCEMAS (Arabic AL KHUZAMA), the name of a bay, islands and a small port on the Mediterranean coast of Morocco, about 50 mi. W. of Melilla. The bay is about 14 km. wide and 8 km. long (about 9 mi. wide and 5 mi. long) and lies between Cape Nuevo, which is of Triassic limestone, and the Miocene volcanic hills of Cape Quilates. Its sandy bottom is an extension of the alluvial plain of Wadi Nekor. The coast is dry but misty in summer. At the southwest of the bay are three small islands: Land Island and Sea Island are low, rocky and uninhabited; the Peñón of Alhucemas is a limestone rock 820 ft. high, separated from the coast by a channel 1,422 yd. wide, and on it is the building of the former Spanish presidio. Occupied by the Spanish from 1673 to 1961, the Peñón had a small garrison and a few families; all provisions and water were brought from Spain. On the mainland the settlement of Alhucemas (called Villa Sanjurjo by the Spanish) contained 11,239 inhabitants in 1960, the majority of whom were still Spanish. (J.-J. DS.)

ALI ('ALI IBN ABI TALIB) (c. 600-661), fourth caliph of the Muslim Arab empire and Mohammed's cousin and son-in-law (see CALIPHATE). His father, Mohammed's uncle, Abu Talib, was for a time chief of the clan of Hashem of the tribe of Quraysh at Mecca. Ali, living in Mohammed's household when Islam was first proclaimed, became one of the first Muslims though still a boy. Soon after the Hégira (Mohammed's migration to Medina), in 622, he married Mohammed's daughter Fatima (q.v.), who bore him two sons, Hasan and Husain (q.v.). Ali is said to have been a brave fighter and to have taken part in nearly all of Mohammed's expeditions and battles. He led an important expedition to the Yemen in 632 but otherwise was not prominent in Mohammed's lifetime nor under the first three caliphs. To the rebels against Othman he apparently gave encouragement but no active support.

On the assassination of Othman (June 656), the Muslims in Medina recognized Ali as caliph. Two leading Meccans, Talha and al-Zubayr, along with 'A'isha, daughter of Abu Bakr and widow of Mohammed, organized armed opposition at Basra, but, when Ali moved against them from Kufa, were defeated (Dec. 656) at the "battle of the Camel" (ridden by 'A'isha).

More serious was the refusal of Mu'awiya, governor of Syria, to recognize Ali. Demanding vengeance for his kinsman Othman, he led the Syrian army against that of Ali from Iraq. An indecisive battle at Siffin (657) in Syria was followed by the "arbitration," at which a representative of each of the rivals tried to reach agreement. The accounts of this series of events have been falsified by later propaganda, but Ali, disappointed, apparently denounced the decision. No further battle took place against Mu'awiya, but the latter gained control of Egypt and launched raids of increasing severity against Iraq. Meanwhile Ali had to fight against former supporters who opposed his policies. The annihilation of a body of these at Nahrawan (July 658) did not extinguish this Kharijite movement (from *khariji*, "outgoer"). Ali had lost control of Khurasan to local rebels by 659 and of the Hejaz by 660. His fortunes were clearly declining when in Jan. 661 he was assassinated by a Kharijite, Ibn Muljam, outside the mosque in Kufa.

The real personality is hidden in the mass of legend that has gathered round Ali, but he seems to have been genuinely religious though not highly gifted as a statesman. The legends are due to those Muslims who sought a superhuman or charismatic leader and found him in Ali or his descendants. These are the Shi'ites (collectively Shi'a; i.e., "the party" [of Ali]). Round his supposed tomb near Kufa they have formed the town of Al Najaf. From Ali the charismatic leadership, which he supposedly received from Mohammed, passed to his sons Hasan and Husain (or to another son Mohammed ibn al-Hanafiya), then to the descendants of Husain.

Among some of the strange sects on the fringes of Islam, Ali is regarded as an incarnation of God. See SHI'ISM; FATIMIDS. (W. M. WT.)

ALI (called THE LION OF JANINA) (1741-1822), Turkish brigand who became pasha of Janina in 1788 and eventually established within the Ottoman empire his authority over much of Albania and

Macedonia, Epirus, Thessaly and the Morea. His father, Veli, bey of Tepeleni, died a poor man when Ali was 14. His ferocious mother, Khamco, formed a brigand band to restore the political and material fortunes of the family. Ali respected his mother, learned her ways and became a notorious brigand leader. After service with the pasha of Negropont (Euboea) he joined the wealthy pasha of Delvino whose daughter, Eminé, he married in 1768. He turned treachery and murder to his own account, neglecting the interests of his father-in-law. Becoming lieutenant to the derbend-pasha of Rumelia, he policed the highroads, enriched himself and sent presents to Constantinople. At length he was rewarded with the pashalik of Trikkala and after a series of murders and intrigues obtained that of Janina. His son Veli took over Trikkala and later the Morea; while another son, Mukhtar, became pasha of Lepanto. Though constantly thwarted by the Christian Souliots, whom he finally subdued in 1803, Ali obtained control of the Gulf of Arta and took the ports of Butrinto, Preveza and Vonitsa. He also gained control of the pashaliks of Elbasan, Delvino, Berat and Valona (Vlore).

At this time, by murders and extortions, he increased his wealth and by intriguing with Greeks and Albanians extended his authority over beys and townships. Though appointed viceroy of Rumelia, he repeatedly failed to carry out the orders of the sultan, to whom he sent plausible excuses and many presents. Indeed, he acted as an independent sovereign and was treated as such by the British and French, with whom he intrigued, hoping to found a sea power. Aiding first one and then the other, he tried in vain to obtain possessions in the Ionian Islands; and he coveted the mainland dependency of Parga which, through British help, he ultimately obtained in 1819. By that time the sultan, Mahmud II, who intended to centralize the government of his empire, was determined to remove Ali; and Ali's old enemy, Ismail Pasho Bey, was plotting his immediate downfall. Assassins sent by Ali to Constantinople to murder Ismail were caught (Feb. 1820) and made to disclose their master. Ismail was appointed to Janina and ordered to remove Ali. He found the task beyond him and was replaced by Khurshid Pasha. Ali might have bid for the support of the Greeks who were planning insurrection, but he knew instinctively that his power could not be based on the Greeks, who had separatist aims. He therefore tried to save himself by his old methods but was deserted by his sons and allies. His end came on Feb. 5, 1822, when (according to tradition) he was shot by Khurshid's men at a small island monastery in the lake of Janina.

In Ali's time, Janina was the foremost centre of Greek culture, for Ali employed Greeks and founded Greek schools. His court (described by Lord Byron, J. C. Hobhouse [Lord Broughton], T. S. Hughes, W. M. Leake, Sir Henry Holland, C. R. Cockerell and F. C. H. L. Pouqueville) was one of barbarous refinement and bestial cruelty. Ali ruled by cunning, by bribery and by ample intelligence upon which, whether true or false, he acted ruthlessly and swiftly. From those who survived his capricious rule he received loyal service; and even the liberated Greeks looked back upon him with some respect.

BIBLIOGRAPHY.—W. C. F. Plomer, *Ali the Lion* (1936), with bibliography including the works of the travelers. For Ali's dealings with Great Britain and France, see J. W. Baggally, *Ali Pasha and Great Britain* (1938); and G. Remérand, *Ali de Tébélen* (1928). (D. D.N.)

ALICANTE, a city of southeastern Spain in the region of Valencia and capital of the province of the same name, lies on the centre of Alicante bay 113 mi. S. of Valencia by road. Pop. (1960 est.) 111,875 (mun.). Situated on the amphitheatre formed by the Santa Pola and Huerta headlands, Alicante is dominated by Benacantil hill (721 ft.) and the citadel of Santa Bárbara, whose earliest foundations date from 230 B.C. Arrabal Roig, the old quarter, dominates the sea from its Balcón del Mediterráneo. The modern city has wide streets and a three-coloured marble pavement along the esplanade. The town hall (1701) and the church of Santa María (14th century) are baroque; the cathedral of San Nicolás (18th century) is in Renaissance style. Alicante is the commercial port of Madrid. Its mild climate makes it a winter resort and the beaches of Costa Blanca attract summer tourists. Alicante is on the railway from Murcia to Valencia; another line

runs inland to Albacete and Madrid. Steamers ply to Barcelona, Valencia, Marseilles, the Balearic Islands, Algiers, Oran and the Canary Islands. There are air services to Madrid, Oran and Algiers. Wine, tomatoes, bricks and tiles, cigarettes, fertilizers, aluminum utensils, diesel motors, furniture and embroideries are the main products. Founded as Acra-Leuca ("white summit") by the Phocaeans in 325 B.C., the city was captured by the Romans in 201 B.C. who called it Lucentum. Moorish domination lasted from 718 to 1249, when it was named Al-Akant. Besieged by the French in 1709 and the federalists of Cartagena in 1873, it was under Republican control during the civil war of 1936–39.

ALICANTE PROVINCE is a seaboard province formed (1833) from parts of the provinces of Valencia and Murcia. Pop. (1960 est.) 660,312. Area 2,264 sq.mi. In the north and west there are mountain ranges cut by deep ravines; farther south the land is flatter and more fertile. The 168-mi.-long coast has salt marshes, beaches at Calpe, Benidorm, San Juan, Alicante, Guardamar, and huertas (market gardens) at Denia and Alicante. The only large river is the Segura, flowing from the highlands of Jaén and Albacete through Murcia and Orihuela. The scanty but torrential rainfall makes irrigation from wells and the Segura with its canals important. The principal towns are Alicante, the capital (pop. [1960 est., mun.] 111,875), Alcoy ([1958 est.] 51,900), Crevillente (13,964), Denia (12,256), Elche (69,091), Orihuela (46,040), Torrevieja (9,451), Villajoyosa (10,565) and Villena (21,070). The dialect is a variety of Valencian. The tourist trade is rapidly becoming important; Denia, Calpe, Altea, Benidorm and Alicante are well-known summer and winter resorts of the Costa Blanca. Half the province is cultivated, 33% is forest and 17% unproductive. The principal products are wine and liquors, fruits and vegetables, fish, almonds, fertilizers, textiles, embroideries, cement, bricks and tiles, salt, products of the palm, turrones (nougats), toys, cigarette paper, marble, rubber shoes, carpets, medicinal or industrial herbs. Almonds and turrones have made the names of Alicante, Alcoy and Jijona world-famous.

See F. Figueras Pacheco, *Geografía general del reino de Valencia, prov. de Alicante* (1920); José Pastor de la Roca, *Historia general de la ciudad y castillo de Alicante* (1854). (F. F. G.U.)

ALICE SPRINGS, a town of Northern Territory, Austr., lies at an altitude of 1,900 ft. virtually in the centre of the continent among the beautiful scenery of the Macdonnell ranges. Its main importance has been as a telegraph station on the overland route from Adelaide to Port Darwin. The temperature range is from 19° to 117° F., but is seldom above 80° from May to October. Annual rainfall (average 10.55 in.) varies from 4.3 in. to 28.37 in. Pop. (1954) 2,785. There are Anglican and Roman Catholic churches and the John Flynn Memorial (United) church, a hospital, schools, banks, hotels and motel camps. Radio school courses were begun in 1951. To the west are reserves for the native peoples, and Hermannsburg, about 80 mi. W. on the Finke river, is the home of aboriginal artists. Alice Springs is the rail-head for the line from Adelaide (981 mi.), opened in 1929, and is linked by road with the northern railway at Birdum and so with Port Darwin (1,105 mi.). The principal train is still known as "the Ghan" after the Afghan camel drivers who helped to develop the route before the line was built and whose descendants still live there. The airport links the town with north and south and the flying doctor service operates from there for a radius of about 500 mi. Besides cattle raising the district has mines for gold, copper, wolfram, mica, etc.; and citrus fruits, grapes and dates are grown. There are light industries for local needs.

The town was formerly known as Stuart after John McDouall Stuart who first crossed the continent near there in 1860. From 1926 to 1931 it was the capital of the short-lived territory of Central Australia. About 1930 the official name was changed to the more popular one of Alice Springs, the water hole found in 1871 which made the town's existence possible and which was named after the wife of Sir Charles Todd, then superintendent of telegraphs.

ALIEN. Numerous passages in the Old Testament command equitable treatment of the alien—e.g., "Love the sojourner therefore; for you were sojourners in the land of Egypt" (Deut. 10, 19)

and "You shall have one law for the sojourner and for the native" (Lev. 24, 22). The alien was to be protected, the German neo-Kantian philosopher Hermann Cohen has said, "not because he was a member of one's family, clan, religious community; but because he was a human being. In the alien, therefore, man discovered the idea of humanity."

In the early history of the human race, the tendency was to look upon the alien as an enemy and to treat him as a criminal or outlaw; the legal or religious expression of the idea of humanity as exemplified in the alien is a relatively modern development.

The biblical commandment of just treatment of the alien sojourner summarizes the universal tension created by the stranger—on the one hand, to hate and abuse him; on the other hand, to welcome him as a fellow human being, to respect in him "the idea of humanity." This tension between the feeling of enmity and the sentiment of charity has nowhere at any time been wholly resolved.

Aliens in Antiquity. — Aristotle, probably in this instance reflecting the view that obtained generally in the ancient world, conceived of non-Greeks as barbarous peoples who were slaves "by nature." He advised Alexander to make a sharp distinction between Greeks and barbarians, and to be to the former as a leader and to the latter as a master. To Aristotle there was no room in the *polis* or city-state for foreigners except as "natural" slaves. But Alexander envisioned an empire in which he would be the ruler equally of Greeks and of non-Greeks, in which persons belonging to different nations would intermarry and would render common military service. Alexander in fact displaced the *polis* with a *cosmopolis*, a world state in which there was equality between Greek and barbarian. The Stoics began to teach the equality of all men; and Plutarch, writing four centuries after Aristotle and Alexander, said that one should reckon all men as his fellow citizens, "and there should be one Life and one order (*cosmos*), as it were one flock on a common pasture feeding in common under one joint law."

At the same time St. Paul preached that in the universal church there was "neither Greek nor Jew, . . . barbarian, Scythian, bond nor free." This was the idea of the *cosmopolis*, founded on the ideals of equality and fraternity embracing all men, subject to a common law of God or of nature; yet when Paul was arrested in Jerusalem and treated roughly, the centurion and the tribune restored his liberty when he disclosed that he was a Roman citizen (Acts 22)—the alien and the citizen obviously did not enjoy equality before the law.

Later Attitudes. — The rise of national states and their development from the 16th century on left the alien even more exposed to mistreatment, for imperial demands ceased to exist, and the creation of national churches under Protestantism tended to confine the universal ideals of religion to those who could claim membership in the same state and church. The alien with a different citizenship or religion was an enemy or a heretic.

But the idea that the alien has rights was not altogether lost or destroyed. Many factors favoured the idea: improvements in facilities for travel; large migrations of peoples and intermarriage; the Judaeo-Christian idea of the unity of mankind; the *jus gentium*, that Roman law which was applied both to citizens and foreigners; international law writings, especially of Francisco de Vitoria, Samuel Pufendorf, Emeric de Vattel; the spread of diplomatic agents and their efforts to protect nationals of their countries; treaty provisions providing for the reciprocal fair treatment of aliens; the ideal of cultural pluralism; international forums for the public expression of grievances against a country charged with mistreatment of aliens, such as the League of Nations, the United Nations and the International Labour organization; international press services and the reporting of events by newspapers and other communication mediums.

Against these liberalizing influences are factors that tend to place the alien in an unfavourable economic and social position: intense national feelings; religious intolerance; ideas of racial superiority; fear of the alien as a possible enemy agent or as a subversive radical; the desire to maintain the "purity" of the country's culture; the desire to protect citizens in their jobs, pro-

fessions and businesses against unemployment and competition; fear that aliens may lower the standard of living; the feeling that a country's natural resources are for the use and enjoyment of its citizens exclusively; the notion that aliens are not to be entrusted with the conduct of enterprises that may be turned against social interests; the idea that a state may go far in its efforts to protect the public interest in health, safety, morals and the general welfare.

Concept of Juristic Natural Rights and Treaty Arrangements.—As sovereign national states began to develop in modern times, founders of international law asserted against these states juristic natural rights that were vested in all persons, without regard to citizenship or alienage, of which they ought not to be deprived by civilized societies or their governments. There was no general agreement on the content or scope of these rights as they affected aliens; but the existence of some minimum standard of civilized treatment was asserted. The minimum standard, however, did not include the right of the alien to own realty or to enter gainful professions. To meet this situation, states entered into treaties that provide that each of the contracting states will treat the nationals of the other state on an equal footing with its own nationals in the admission into trades and professions, ownership or possession of property, access to courts, enjoyment of liberty of conscience and freedom of worship; but some treaties will purport to extend rights to aliens unless the rights are, by municipal law, reserved exclusively to nationals of the country, thus making municipal law, rather than conventional international law, controlling.

Common economic needs of nations, however, have had some liberalizing effects on the status of aliens; e.g., the treaty constituting the European Coal and Steel Community (signed in 1951) binds the member states to renounce restrictions, based on nationality, against employment in the coal and steel industries of qualified workers who possess the nationality of one of the member states, and prohibits discrimination in remuneration and working conditions between nationals and aliens. This treaty may in time serve as a model to raise the so-called minimum standards in the treatment of aliens.

English Law.—The emergence of higher juristic standards may be illustrated from the history of English and U.S. law. As England in the 13th century lost most of its continental possessions, insular prejudices led to the view that aliens, though protected by the king, were virtually without rights. They had no capacity to hold official positions or franchises. They could not hold land; an alien's inheritance or purchase of land was a nullity, and his land could be seized by the king. This harsh law was justified in Calvin's case (1609) by the statement that, were the law otherwise, "the secrets of the realm might thereby be discovered. The revenues of the realm. . . should be taken and enjoyed by strangers born. It should tend to the destruction of the realm." The prohibition on the alien's acquisition of land, and the right of the king to seize the alien's land, ended in 1870.

As to personal rights, Sir Thomas de Littleton in the 15th century wrote that an alien could bring no legal action, real or personal. This meant that the alien was rightless, that he had no remedy for the vindication of any rights he might assert. Sir William Holdsworth asserts that Littleton was mistaken except as to actions affecting land; according to Holdsworth, aliens had rights in the courts of England.

Magna Carta asserted that "all merchants shall have safe and secure . . . entry to England, with the right to tarry there and to move about . . . for buying and selling by the ancient and right customs . . ."—a provision which implies personal rights essential to a merchant. (These rights were, however, curtailed by the privileges of boroughs.)

As the law merchant was absorbed into the common law, the rules made for the alien merchant were extended to all aliens, so that by the end of the 16th century an alien could bring personal actions and could own personal property. An exception was made, however, in the case of the alien enemy, who continued to be rightless.

The Status of Aliens act, 1914, not repealed by the British

Nationality act, 1948, provided that real and personal property of every description might be taken, acquired, held and disposed of by an alien in the same manner in all respects as by a British subject; but acts of parliament provide that no alien may be appointed to any office or place in the civil service; there are restrictions on his employment on ships; without express official permission, he may not use any name other than that by which he is ordinarily known; and, from 1920, aliens must register. Restrictions on aliens are, however, sometimes varied by administrative action; and international conventions and treaties affect the rights and freedoms of aliens.

U.S. Law.—Although feudalism was not imported into the American colonies from the mother country, phases of feudal real-property law were imported as part of the common law. The supreme court in *Fairfax Devisee v. Hunter's Lessee* (1813) recognized the feudal real-property law as obtaining in the United States insofar as it affected aliens. An act of congress, adopted in 1887, restricted the ownership of land by aliens in the District of Columbia and in territories of the United States. Most states, however, by statute accorded aliens the same rights with respect to real property as those enjoyed by citizens. States on the west coast had laws which radically restricted the rights to own or lease land by aliens who were ineligible for citizenship; these laws affected particularly Chinese and Japanese immigrants; but the legal base of these state enactments was removed by acts of congress of 1943, 1946 and 1952, which wiped out all racial bars on naturalization. Beginning in 1940, on the other hand, all aliens had to register.

The supreme court in *Truax v. Raich* (1915) held that the equal protection clause of the 14th amendment applies to aliens as well as to citizens; that a state may not deny to aliens the ordinary means of earning a livelihood; that if a special public interest is shown with respect to a particular business in which the employment of aliens might reasonably be shown to be a peril to the public welfare, a state may prohibit employment of aliens in that particular business. Notwithstanding constitutional limitations, many states restrict the employment of aliens. There is no consistent pattern among the states, nor is there a consistent formula to rationalize the restrictive legislation within any state.

Constitutionally, said Justice Robert H. Jackson in a case decided by the U.S. supreme court in 1952, the alien in the United States is afforded a large measure of economic opportunity; he may invoke the writ of habeas corpus; in criminal proceedings he is entitled to the guaranties of the Bill of Rights; and his property cannot be taken without just compensation. But to remain in the country "is not his right, but is a matter of permission and tolerance"; the government has the power to terminate its "hospitality," for his domicile is held by a "precarious tenure"—the power to deport him is "inherent" in the United States as a sovereign state. This has been and continues to be the law of the United States. As long as the alien is in the United States, the mantle of the constitution is thrown over him to protect his life, liberty and property; but congress, not the constitution, decides whether or not he is to remain. Justices Hugo L. Black and William O. Douglas dissented from the latter proposition and urged that the deportation process be made subject to the limitations of the Bill of Rights.

ALIENATION, in law, the act of transfer of property by voluntary deed and not by inheritance. In regard to church property the word has come to mean a transfer from religious to secular ownership (see REAL PROPERTY AND CONVEYANCING, LAWS OF). For the term as applied to mental derangement, see INSANITY. A discussion of alienation of affection, one of the grounds for which

divorce may be granted, can be found in DIVORCE.

ALIEN PROPERTY, a term used to describe foreign-owned property located in the United States or its possessions that has been vested, i.e., seized, by the United States government under wartime authority granted by the Trading With the Enemy act. The vesting of property results in ownership by the government subject to a return of the property, or the proceeds of its liquidation, upon a judicial or administrative finding that the former owner is not an enemy as defined in that act.

World War II vesting action was generally limited to the property of enemy powers and their nationals. Legislation enacted after the end of hostilities made the victims of persecution by those powers eligible for return regardless of their enemy nationality. Other postwar legislation disposed of additional enemy assets as follows: virtually all assets of Italy and its nationals were returned; assets of Germany. Japan and their nationals were devoted to the compensation of Americans mistreated by enemy forces; certain assets of Bulgaria, Hungary, Rumania and their nationals were devoted to the compensation of U.S. claimants against those countries, and the remainder was made subject to return.

Vested property held by the United States is administered by the office of alien property, department of justice.

See also NATIONALIZATION; LAWS OF WAR. (S. Lm.)

ALIGARH, a town, and headquarters of the district of the same name, lies in Uttar Pradesh, India, about 80 mi S.E. of Delhi on the Grand Trunk road. It has rail connections with Delhi, Calcutta and Bombay, but the city itself lies west of the railway and is generally called Koil or Kol, Aligarh being the name of a fort beyond the civil station east of the railway. The population (141,618 in 1951) greatly increased after about 1940.

The town of Koil has a handsome appearance, the centre being occupied by the lofty site of the old Dorfortress (1524), now crowned by a mosque, built early in the 18th century, which was repaired during 1898-99 at a cost of more than Rs 90,000 subscribed by residents in the district. A pillar erected in 1253 to commemorate the victories of Sultan Nazir-ud-din Mahmud was pulled down in 1862. In and about the town are several tombs of Muslim saints. Koil contains a civil general hospital and a women's hospital; the Lyall library, opened in 1889, is known as Malviya library. A large part of the city is built on swampy land around the fort; there are a number of good metaled roads. Its principal manufactures include locks, metal works and cotton rugs and carpets.

Aligarh town has a number of degree colleges but it is chiefly celebrated for the Aligarh Muslim university, founded by Sir Sayyid Ahmad Khan. The university consists of a number of allied institutions of which the engineering college, the polytechnic and the Ophthalmic institute are outstanding. The Ophthalmic institute is the only one of its kind in Asia. The Azad library, named after the central education minister, Maulana Abul Kalam Azad has a fine building in the heart of the university campus.

ALIGARH DISTRICT has an area of 1,941 sq mi. Pop. (1951) 1,543,506. It contains a farm owned by the state government, and butter forms an important article of export. There is a glass factory at Sarni, and locks are also exported; sugar, rice, piece goods, metals and timber form the chief imports. (S. M. T. R.)

ALIMENTARY CANAL: see GASTROINTESTINAL TRACT.

ALIMONY, maintenance and support refer, in general, to the payments that a man is obligated to make, after separation or divorce, to the woman who is, or formerly was, his wife. The terms are also applied to the payments that under modern statutes a woman may have to make to her present or former husband. The more precise legal meanings of these terms differ in England and the commonwealth on the one hand and in the United States on the other.

The United States.—In the United States, alimony usually refers to the payments a court may order a party to a divorce or a judicial separation, usually the husband, to make for the other party's support. Alimony must thus be distinguished from separate maintenance, which one of the parties to a marriage may be ordered to pay to the other while they are living apart but not

divorced. The payments that a parent, before or after divorce from his spouse, may have to make for the maintenance of a child are known as child support. During the pendency of a suit for divorce, one spouse may be ordered to pay temporary alimony (alimony pendente *lite*); in addition, a husband may be ordered to pay suit money to give the wife the funds necessary to pursue or defend a divorce suit. In a suit for divorce, judicial separation or separate maintenance, it may be necessary also to decree a property settlement; *i.e.*, an allocation of the parties' property.

In a broader sense, the term alimony may cover all the various provisions just stated.

Alimony in both the strict and the broader senses has come to serve a number of different functions. Where, as under the common law, marriage gave a husband title to all personal property and to all income from real property of his wife, it was necessary in the case of a separation that the husband be ordered to provide her with the means to live. Where, as in the official law of many states, divorce is treated as the privilege of an innocent party to cast out a spouse who has committed an unforgivable act of misconduct, alimony tends to assume the character of damages to be granted to the innocent party for the loss of marital support at the home, but is refused altogether to a guilty party or fixed at a minimum subsistence level which keeps that party, from becoming a burden on the taxpayers. Where courts do not clearly distinguish between alimony and child support, the award made to a wife having child custody tends to combine support for both mother and children. Where, as in many U.S. courts, alimony is awarded in a lump sum to be paid either at once or in fixed installments, it tends to merge with property settlement and to afford the court an opportunity to grant the wife a portion of the property that she has helped the husband to accumulate and that she would have inherited had the marriage lasted until the husband's death. Courts can thus produce results similar to those of community property, which prevails (in Anglo-American countries) only in a few jurisdictions of the United States and in a few parts of the commonwealth.

The different purposes served by alimony are reflected in the variety of statutory rules and the even greater variety of judicial practices. While in one jurisdiction alimony is strictly refused to a guilty party without regard to need, in another it is awarded to a party in need without regard to guilt. Traditionally, alimony is ordered to be paid in periodic installments, the amount of which may be revised by the court in accord both with changing need and changing ability to pay.

In accord with the mores of a time in which men were the breadwinners and women were supposed to live on their husbands' incomes, alimony was once a privilege of women. Gradually the law is realizing not only that women are able to earn their own living but also that a man may be dependent for his livelihood on the income of his wife. But even where the law allows an alimony award to be made to a husband, the courts are inclined to limit the exercise of that power to cases where he is without means of his own and is too handicapped to earn a living.

The obligation to pay money under a judicial award of alimony can, as a general rule, be enforced like any other money judgment; *i.e.*, by attaching the debtor's property or by garnishing his bank account, his claim for wages or his other claims. In addition to these generally available remedies, the payment of alimony can also be enforced by imprisoning the one who fails to pay or earn the necessary money although he is able to do so.

A judicial award for alimony will, as a general rule, not be made unless it has been applied for. It was estimated in the 1950s that applications for permanent alimony were made in no more than about 10% of the divorces pronounced in cases in which no provision had to be made for children. In some of the remaining 90% of these cases, the parties may have made an alimony agreement out of court. But in the majority of cases it seems that alimony was not asked for, either because early remarriage was contemplated by the wife, or out of pride or absence of need, for other personal reasons, or because the husband's income and earning capacity were regarded as too low to allow a realistic expectation of payments.

English Law.—In English law, alimony refers to the payments a husband may be ordered to make to his wife by a decree of the high court rendered in formal proceedings of judicial separation, a decree that does not dissolve the tie of marriage. Payments, however, ordered by the high court in a decree of divorce, by which the marriage is terminated, are called maintenance. The same term also applies to the payments a husband may be ordered to make to his wife by a separation or maintenance order issued by magistrates in informal proceedings in which a marriage cannot be dissolved. These three forms of matrimonial relief differed at one time not only in procedure but also with respect to the circumstances under which they would be granted and the amounts to be paid. These differences have gradually disappeared, except that under the legislation in force in 1960 the maximum amount of maintenance obtainable in a magistrates' court was limited to £5 a week for a wife and 30 s. a week for a child. In general, however, the determination of the amount of alimony or maintenance is left to the discretion of the court. In a case before the divorce court the husband may be ordered either to make periodic payments to the wife, to set aside a special fund for her support, or both. This order may be altered from time to time in accord with changing circumstances. The divorce court may also grant maintenance to a wife found guilty of marital misconduct; in a magistrates' court the power to grant maintenance is limited in cases where the wife has been guilty of adultery, and no alimony can be granted to the wife in a decree of judicial separation obtained by the husband on the ground of adultery.

A wife is under a duty to provide for the maintenance of a husband only if she divorces him on the ground of incurable insanity. She may generally be ordered, however, to reimburse the National Assistance board for any sums it had to pay as assistance to her husband, just as a husband may be ordered to reimburse the board for sums paid to his wife.

In addition the court may adjust property rights arising out of a divorce or separation settlement, and this power may be exercised in favour of the husband and the children.

ALI PASHA, MOHAMMED EMIN (1815-1871). Ottoman Turkish grand vizier distinguished for his liberal policies, was born in Istanbul on March 4, 1815, of a poor family. He had no regular education, but learned French and obtained the post of secretary to the divan (council) of the Sublime Porte. After being ambassador in London (1841-44), he became foreign minister under Mustafa Reshid Pasha and took part in the congresses of Vienna (1855) and Paris (1856). He was five times grand vizier (1852, 1855-56, 1858-59, 1861, 1867-71). He resisted attempts by the sultans to take away the powers of the Sublime Porte; he settled the troubles in Serbia and in Moldavia-Wallachia by peaceful measures; and, in 1868, he pacified the Cretan revolt by the grant of a measure of local self-government. He was one of the most zealous advocates of westernizing reforms and of friendship with France and Great Britain during the reigns of the sultans Abdul-Mejid I and Abdul-Aziz. He was also a devout Muslim but nevertheless forced the sultans to allow men of all creeds to hold public office. He died in Istanbul on Sept. 7, 1871. (E. Z. K.)

ALQUIPPA, a borough of Pennsylvania, U.S., situated on the Ohio river, approximately 18 mi. N. of Pittsburgh, is the largest municipality in Beaver county. (For comparative population figures see table in PENNSYLVANIA: *Population*.)

The legal incorporation of Aliquippa dates from Jan. 22, 1894. In 1900 there were only 620 inhabitants in the community; the town developed rapidly with the expansion of the Pittsburgh district steel industry in the early part of the 20th century. About two-thirds of the working force of the borough, which is an integral

part of the Pittsburgh industrial complex, is engaged in steel production.

(P. R. J.) *

ALIQOT PART, an exact divisor of a number or quantity (that is, a divisor giving an integral quotient). For example, 2 is an aliquot part of 10, 333 is an aliquot part of 100, a line $2\frac{1}{2}$ in. long is an aliquot part of one that is $7\frac{1}{2}$ in. long, and $\frac{1}{3}$ is an aliquot part of 1; but $\frac{2}{3}$ is not an aliquot part of 1, the quotient of 1 divided by $\frac{2}{3}$ not being an integer.

ALISHAR HUYUK. The mound known as Alishar Huyuk is situated on a river plain between Yozgat and Bogazliyan in north-central Turkey, about 50 mi. S.E. of the ruins of the Hittite capital Hattushash at Bogazkoy. It was the scene of thorough and extensive excavations by an expedition of the Oriental Institute of The University of Chicago, led by H. H. von der Osten and E. F. Schmidt, between 1927 and 1932. From a technical point of view this undertaking represented a new departure in Anatolian archaeology: in contrast with the hitherto largely limited and haphazard excavations of European scholars at other sites, the resources of the U.S. team enabled it to submit every habitation layer of the mound to exemplary archaeological scrutiny.

The Alishar excavation, then, was the first systematic stratigraphic investigation on the Anatolian plateau. The finds justified the enterprise, and the field work, the recording and the publication of the results were all of remarkable quality. It had been hoped, however, that another great Hittite metropolis, complete with archives comparable to those of Bogazkoy, would be uncovered. Yet in the long succession of archaeological strata revealed at Alishar—from Chalcolithic to Phrygian (*cf.* ASIA MINOR: *Archaeology*)—the only era that was not represented was in fact the Hittite, from the 17th to the 13th century B.C., so that it seems clear that the mound was not inhabited in that period.

In addition to the stratigraphic discontinuity created by this gap, a further complication was the irregular shape of the mound itself, consisting of an off-centre top elevation, known as the citadel, and a sloping terrace. Irregular habitation of one or both of these sections at various periods made collations of occupation levels extremely difficult; the designations applied by the excavators were subject to frequent revisions in successive reports and considerable controversy persisted for a long time regarding the proper inclusion of the Alishar periods in a wider framework of Anatolian stratigraphy. On the basis of Osten's final report the archaeological history of Alishar may be summarized.

The deepest and earliest phase is called "Neolithic" by Osten, but it more probably comprises layers from the late Chalcolithic and early Copper Age. The most conspicuous finds are large jars and bowls of dark clay on footed stems (so-called "fruit-stands"). Metal (copper, then bronze) first appears in the succeeding layers, showing dried-brick walls on stone foundations, which represent the Copper Age. Then follow two controversial, more or less contemporaneous, phases in parallel layers from the full Bronze Age, one of which is represented chiefly on the citadel and is characterized by the sudden appearance of brightly painted polychrome pottery known as "Cappadocian ware." It may point to an intrusion of foreign invaders, possibly Indo-European Hittites or related tribes, whose culture was subsequently rapidly assimilated to the more continuous native Anatolian tradition represented by the elegantly shaped monochrome pottery of the other, probably somewhat later, phase. The latter has yielded a number of "Cappadocian tablets," best known as records of Old Assyrian merchant colonists at Kültepe (*q.v.*) farther south, and datable to the 19th century B.C. At that time strong fortifications surrounded both the citadel and the sprawling community below it. Besides bronze, stone and bone implements were still used. The dead were buried in huge clay jars.

At the end of that period the occupation of Alishar was interrupted. At least five or six centuries later, however, the emplacement of the pre-Hittite citadel mound was chosen as the site of a Phrygian fortress, with a walled section on the slope below. Some centuries later the walls were extended to include additional new inhabited areas in the immediate vicinity. The settlement perhaps survived down to the time of Lydian hegemony in the 6th century B.C. In the end the citadel was destroyed by fire.

FIG. 1.—ARROWHEAD (*SAGITTARIA LATIFOLIA*), SHOWING SUBMERGENT RHIZOMES AND EMERGENT FLOWERS AND LEAVES

several radiating, stolonlike rhizomes or rootstocks which develop a corm at the end and from which a new plant is generated the following year. Leaves are produced basally. Often when submerged they are linear with little or no development of a blade. Usually, however, the leaves are emergent from the water and there is a distinct arrow-shaped, triangular or elliptic blade on a long slender stalk or petiole, often very variable in a species. Flowers are usually bisexual or with stamens and carpels in different flowers, often showy, in whorls in simple or compound inflorescences that are usually taller than the leaves. They are regular with three green sepals and three showy, white, pink or sometimes purple, spotted petals; stamens are six to many, carpels six to many and free. The fruit is a head of achenes or less commonly follicles, sometimes (as in *Damasonium* and *Echinodorus*) bur-like.

FIG. 2.—ALISMACEAE, REPRESENTATIVE SPECIES

(A) American water plantain (*Alisma plantago-aquatica*): (left) flower; (centre) flower with petals removed showing swollen sepals; (right) ring of mature achenes. (B) Starfruit (*Damasonium californicum*): bud, flowers and maturing fruit. (C) Burhead (*Echinodorus cordifolius*): maturing fruits

In conclusion, Alishar has provided little of conspicuous epigraphic or architectural interest. Its importance lies in the ample and detailed scope of its general archaeological testimony rather than in any specific find of intrinsic significance.

See H. H. von der Osten, *Discoveries in Anatolia 1930-31* (1933) and *The Alishar Hüyük Seasons 1930-32* (1937); S. H. F. Lloyd, *Early Anatolia* (1956).

ALISMACEAE (ALISMACEAE), the water plantain

family of plants belonging to the monocotyledonous order Alismales, of which the water plantain (*Alisma plantago*), arrowhead (*Sagittaria*) and burhead (*Echinodorus*) are of frequent

occurrence. They are typically marsh plants and often occur as weeds in rice paddies. Although most species are perennial, any may behave as annuals, producing an abundance of seed the first year. Some produce

several radiating, stolonlike rhizomes or rootstocks which develop a corm at the end and from which a new plant is generated the following year. Leaves are produced basally. Often when submerged they are linear with little or no development of a blade. Usually, however, the leaves are emergent from the water and there is a distinct arrow-shaped, triangular or elliptic blade on a long slender stalk or petiole, often very variable in a species. Flowers are usually bisexual or with stamens and carpels in different flowers, often showy, in whorls in simple or compound inflorescences that are usually taller than the leaves. They are regular with three green sepals and three showy, white, pink or sometimes purple, spotted petals; stamens are six to many, carpels six to many and free. The fruit is a head of achenes or less commonly follicles, sometimes (as in *Damasonium* and *Echinodorus*) bur-like.

Pollination is by insects. About 11 genera and 75 species occur in warm and temperate regions of both hemispheres. The largest group is the arrowheads (*Sagittaria*), with about 40 or more species.

See ARROWHEAD.

Entire plants are eagerly sought after and eaten by migrating waterfowl; for that reason, some wildlife refuges provide plantings of arrowheads. Corms of *Sagittaria sinensis* are cultivated for food in the orient; *S. latifolia* is the "wapato" of northwest American Indians, who gathered the large corms for food. Some taxonomists point to the differentiated perianth and free carpels of Alismaceae as possible evidence of an evolutionary connection of the monocotyledons

with the dicotyledonous family Ranunculaceae (*q.v.*), the crowfoots.

(H. L. Msn.)

ALIZARIN, a vegetable dyestuff prepared from the root of the madder (*Rubia tinctorum*), was known to the ancients, and was prepared entirely from this source until 1868. It is now prepared synthetically.

The value of alizarin as a dyestuff depends on its power of forming insoluble compounds (lakes) with metallic oxides. It is in the form of these lakes that it produces coloured effects on textile fibres. Alizarin red on wool is a complex lake of alizarin with the oxides of calcium and aluminum.

The pure substance crystallizes in red prisms melting at 290° C. It is insoluble in water, and not very soluble in alcohol. It dissolves readily in caustic alkalis on account of its phenolic character, and it forms a yellow-coloured diacetate.

Alizarin has the chemical constitution 1,2 dihydroxyanthraquinone and the molecular formula $C_{14}H_8O_4$.

AL JAZIRAH, a *liwa* (province) of Iraq, formed after 1947 by reconstitution of a geographically distinctive unit formerly divided between the older *liwas* of Dulaim and Mosul. Area 9,670 sq.mi. Jazirah means "island," here referring to the rolling and irregular plateau (800–1,500 ft.) lying between the Euphrates and Tigris rivers, and defined to the north by the Jabal Sinjar. The region is dissected by now dry river valleys trending mainly southward to the Euphrates and there are several closed drainage basins with salt marshes. Most is desert, but there is a remarkable spring vegetation; hence the Jazirah is occupied almost entirely by nomads of the Shammar Jarba and Dulaim tribes. The former are "camel" nomads, the latter chiefly shepherds who also include an increasing number of semisettled groups.
(W. B. Fr.)

ALKALI. In modern chemistry the term alkali is specifically applied to the very soluble hydroxides of lithium, sodium, potassium, rubidium and cesium which are known as the alkali metals. An alkali is distinguished from an acid or a neutral substance by its characteristic action on litmus, phenolphthalein and other indicators.

The term is shared by the less soluble hydroxides of the alkaline earth metals, calcium, strontium and barium, also by ammonium hydroxide and thallos hydroxide. Industrially the term is extended to include other compounds which are soluble and which behave actively as bases. (See ALKALI MANUFACTURE.)

The term was originally applied to the ashes of plants from which the carbonates of sodium and potassium were lixiviated or leached. The conversion of these "mild" alkalis into "caustic" alkalis by treatment with lime was practised in Pliny's time and was utilized in the manufacture of soap, the ashes of sea plants yielding a hard soap and those of land plants a soft one. The distinction between the two components of this fixed alkali was made by the French chemist, Henri Louis Duhamel du Monceau, who in 1736 established that the ashes of sea plants contain the same base as is found in natural deposits of sodium salts or mineral alkali, and that this substance was different from the vegetable alkali obtained from the ashes of land plants (potashes). Later, Martin Heinrich Klaproth, who found the vegetable alkali in certain minerals, proposed the name potash. The symbol for potassium, K, was taken from the modernized Latin word *kalium* (from the Arabic word for "calcined").

(J. B. Ps.)

ALKALI MANUFACTURE. The manufacture of alkali, which in an industrial sense refers usually to soda ash (Na_2CO_3 , or sodium carbonate) and caustic soda (NaOH, or sodium hydroxide), is one of the most important activities of chemical industry. At mid-20th century, the production of almost every manufactured consumer item depended on the use of alkali at some stage. Alkali was essential to the production of glass, soap, miscellaneous chemicals, viscose rayon and cellophane, paper and pulp, cleansers and detergents, textiles, water softeners, certain

metals (especially aluminum), bicarbonate of soda, and gasoline and other petroleum derivatives. Per capita annual consumption of alkali at mid-20th century ranged from 9 to 110 lb., the highest rates of consumption being in the heavily industrialized countries.

Man has been using alkali for centuries, obtaining it first from the leachings (water solutions) of certain desert earths. Near the end of the 18th century, the leaching of wood or seaweed ashes became the chief source of alkali. Shortcomings of cottage industry methods induced the French Academy of Sciences in 1775 to offer monetary prizes for new manufacturing methods. The prize for soda ash was awarded to Frenchman Nicolas Leblanc, who in 1791 patented a salt conversion process that dominated world production until late in the 19th century. Following World War I the Leblanc method was completely supplanted by a salt conversion process introduced in 1863 by Ernest Solvay of Belgium after the method had failed earlier in both England and France.

Late in the 19th century, electrolytic methods for the production of caustic soda appeared and grew rapidly in importance until by the mid-1940s more than half of all caustic was produced by electrolysis.

Solvay Process of Soda Ash Manufacture.—By the early 1960s the Solvay process (also called the ammonia-soda method) was being employed in approximately 65 factories in 24 countries. The Solvay factories had a range of daily production capacity from about 100 to 2,000 tons, with the larger ones able to produce more efficiently and economically than the smaller ones. Ten factories in North America, with a combined capacity of more than 6,000,000 tons annually, accounted for nearly half the world's soda ash production. Comparatively little soda ash was being handled in international trade, mainly because the importing countries were buying products made from soda, rather than soda itself.

In the Solvay process, common salt in saturated brine, usually obtained from wells drilled into underground deposits of rock salt, is chemically treated to eliminate calcium and magnesium impurities and then is saturated with recycling ammonia gas in towers originally of the bubble-cap type but now more often tile-packed. The ammoniated brine is carbonated in a different type of tower with carbon dioxide gas at pressures of three to four atmospheres. Both these gas absorption processes evolve considerable heat and require precise cooling control and considerable investment in water pumping equipment and heat transfer surfaces.

Ammonia absorption proceeds readily as the brine showers down the tower through a rising stream of gas. In contrast, carbonation requires pressure as a driving force to bubble the gas up through the tower full of liquid, thus enabling crystals of sodium bicarbonate, while in suspension, to grow to filterable size. This kind of carbonation equipment is often called a "Solvay" tower, and its development laid important groundwork for theories concerning the chemical behaviour of liquids falling through rising streams of gases under conditions of continuous feed and discharge.

The carbonator discharge stream, consisting of a slurry of crystals of sodium bicarbonate, is filtered continuously on rotary vacuum filters, although several European plants use continuous centrifuges. The filter cake is then continuously heated at atmospheric pressure to decompose bicarbonate to monocarbonate and simultaneously to drive off water and ammonia. The need for a high degree of recovery of undiluted ammonia (NH_3) and carbon dioxide (CO_2) and the inherent caking and scaling tendency of crude bicarbonate combine to make the calcination (roasting) step the most difficult one in the process. Originally, this procedure was carried out in stationary pans with stirrers over direct fire. Later, externally fired rotary kilns were used. At mid-20th century, steam-heated rotary driers were the rule, especially in the U.S. The trend appeared to be for future factories to calcine under pressure sufficient for direct carbonation, possibly using the fluidized solids techniques of the petroleum industry.

Gases produced during calcination are recycled to the NH_3 and CO_2 absorption steps; other CO , required for the process comes from the burning of limestone in coke-fired kilns controlled to effect high carbonate decomposition without excess fuel or combustion air. The kiln gas is compressed for the carbonators. The

lime produced is used to decompose the ammonium chloride while heating the mother liquor resulting from the bicarbonate filtration. This distillation returns the ammonia to the absorption process already described. The resultant calcium chloride solution or "distiller waste" is sent to waste or (in small part) to refinement and dewatering for market.

Electrolytic Production of Caustic Soda.—This process also begins with a saturated and purified salt brine. Electrolytic cells of two main types and many subtypes are used most of which have graphite anodes and steel cathodes. Diaphragm cells use an asbestos diaphragm to keep chlorine gas separate from the sodium hydroxide solution obtained at the cathode by the interaction of the sodium ion with water in the brine. The resulting caustic solution is of the order of 130 to 150 g. of caustic soda per litre and must be concentrated in large evaporator equipment from which unreacted salt is recycled to the cell. Mercury cathode cells react sodium amalgam with water in a separate compartment of the cell, giving a salt-free solution generally of 750 g of sodium hydroxide per litre. Both diaphragm and mercury cathode cell types produce about a ton of caustic per ton of chlorine, but, because chlorine is expensive to store and hazardous to dispose of as waste, the process is limited and scheduled according to chlorine sales.

Refining Natural Alkali.—In a few places in the world there are substantial deposits of the mineral form of soda ash, or "natural alkali." The mineral usually occurs as sodium sesquicarbonate or trona ($\text{Na}_2\text{CO}_3 \cdot \text{NaHCO}_3 \cdot 2\text{H}_2\text{O}$), which contains soluble and insoluble impurities. In the U.S., soda ash is produced commercially from trona deposits at dry bed lakes in California and from underground mines in Wyoming. Soda ash also is produced from wet surface lakes in Kenya, and minor amounts are mined or refined in Egypt, Mexico, Turkey, Chile, South Africa, Canada and elsewhere. At mid-20th century, natural alkali production comprised only 5% of total alkali production but has increased at a faster rate than production from the Solvay process.

Marketing.—The soda ash and caustic soda now being produced are extremely pure compounds that meet rigid specifications. Most soda ash is shipped in bulk by barges and boxcars. When bagged, it usually is shipped in single-trip multiwalled paper sacks. Caustic soda is usually shipped in tank cars as a 50% or 70% solution; anhydrous caustic soda is shipped in steel drums, either in the flaked or solid condition.

Soda ash is marketed either as "light," a fine ponder weighing about 35 lb. per cubic foot, or as "dense" (65 lb. per cubic foot), a much coarser grain material made especially for glassmakers by recrystallization or mechanical densification. Some soda ash is converted to other carbonates and hydrates, such as sodium bicarbonate for the baking and pharmaceutical industries and sodium sesquicarbonate for laundering compounds, and also to the monohydrate. The decahydrate, or old-fashioned "crystal soda" ($\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$), is fast disappearing. Some briquettes and fused soda ash, and mixtures of various carbonates and hydroxides, have important markets in small tonnages.

ALKALINE EARTHS. By the early chemists, the term earth was used to denote those nonmetallic substances which were insoluble in water and were unaffected by strong heating; and since some of these substances (e.g., lime) were found to be very similar in properties to those of the alkalis, they were called alkaline earths. Lime, strontia and baryta were assumed to be elements until 1807, when Sir Humphry Davy showed that they were oxides, respectively, of the metals calcium, strontium and barium. These elements and the other members of Group IIa of the periodic system, beryllium, magnesium and radium, are now known as the alkaline earth metals, or the alkaline earths. The

metals are never found in the uncombined condition, but occur most often in the form of carbonates and sulfates; they form oxides of the type RO, and peroxides of the type RO_2 . The oxides of type RO are soluble in water, with generation of heat (e.g., the slaking of lime); the resulting solution possesses a strongly alkaline reaction because of the presence of the hydroxide $\text{R}(\text{OH})_2$, which rapidly absorbs carbon dioxide on exposure. These oxides and hydroxides are basic in character and dissolve readily in acids with the formation of the corresponding salts. As the atomic weight of the elements increases, it is found that the solubility of the hydroxides in water increases although that of the sulfates decreases.

The metals calcium, strontium and barium oxidize rapidly on exposure. Their salts usually crystallize well, the chlorides and nitrates dissolve readily in water, while the carbonates, phosphates and sulfates are either sparingly soluble or insoluble in water.

(J. B. Ps.)

ALKALOIDS, complex compounds in plants that may produce pronounced physiological effects when consumed by or administered to man and animals. Examples of alkaloids are morphine, quinine, nicotine, strychnine and reserpine.

Although it is virtually impossible to frame a definition for which there are no exceptions, alkaloids are usually understood (1) to be of plant origin; (2) to possess a basic, salt-forming, ammonialike character, a property from which they derive their name (alkaloid means alkali-like); (3) to contain nitrogen; and (4) to produce physiological effects on man and animal.

History.—Man has from very early times made use of natural drugs for medicinal or spiritual purposes. However, his knowledge about the active constituents of such plant preparations or extracts, which may contain alkaloids, glycosides or other components, is of relative late date. The first reported attempt to isolate an alkaloid dates back to 1803 when Charles Derosne observed that a sirupy extract of opium, when diluted with water, deposited crystalline matter, which he separated and tried to purify and so prepared the first alkaloid, probably impure narcotine. When he added alkali to the diluted opium sirup he obtained a different substance that undoubtedly contained the alkaloid morphine. About the same time A. Séguin obtained impure morphine by a similar procedure.

But the credit for first isolating a typical alkaloid in a pure state and describing its properties in unmistakable terms was reserved for F. W. A. Sertürner, who in 1806 announced he had isolated morphine, a new organic base that apparently was related to ammonia. He prepared a number of salts and was able to demonstrate the physiological activity of the alkaloid. In 1810 B. A. Gomes treated an alcoholic extract of cinchona bark with alkali and obtained a crystalline precipitate that he called cinchonino. Subsequent work on this material by Pierre Pelletier and J. B. Caventou resulted in the discovery that it was a mixture of two alkaloids, which were separated and called quinine and cinchonine. In the years between 1820 and 1830 a large number of alkaloids were isolated and purified and their properties described in the literature. Important alkaloids discovered during that period are veratrine, strychnine, piperine, berberine, coniine, atropine, codeine, thebaine, hyoscyamine, curarine, emetine, quinidine, aconitine and colchicine. Because of the complex chemical structure of most of these alkaloids very little progress was made during the 19th century in the difficult task of elucidating their molecular structure. Only after the theory and technique of organic chemistry had developed to a sufficiently high level could this problem be attacked successfully. By the early 1960s the structure of almost all important alkaloids had been established. A large number of them had also been synthesized by that time. New alkaloids were being reported in the chemical literature almost every month, and the establishment of their structure constituted an important part of natural-product chemistry.

Classification.—More than 900 alkaloids are known, but they are comparatively restricted in their distribution among plants. They occur chiefly in Rubiaceae, Papaveraceae, Fumariaceae, Solanaceae, Leguminosae and Apocynaceae and to a lesser extent in the Rosaceae, Gramineae, Labiatae and Compositae. It has

been generally observed, although there are exceptions, that the same genus, and in some cases related genera, yield the same or at least structurally related alkaloids; *e.g.*, seven distinct genera of Solanaceae yield the alkaloid hyoscyamine, the optically active form of atropine. Because of this observed distribution of chemically related alkaloids in related plants there is some similarity between the two commonly used systems that classify alkaloids either according to the plant genera in which they occur or on the basis of similarity in molecular structure. Examples of important groups of alkaloids containing generically related members are strychnos alkaloids, opium alkaloids, cinchona alkaloids, lupine alkaloids, ephedra alkaloids, aconitum alkaloids and rauwolfia alkaloids. Names for alkaloid groups that are classified for chemical reasons are usually derived from the name of that part of the molecule that all members of any given group have in common. Thus, members of the pyrrolidine group contain the heterocyclic ring system pyrrolidine, whereas indol alkaloids are more or less complex derivatives of indol. Other examples of this classification include quinoline alkaloids, isoquinoline alkaloids and pyridine alkaloids.

Pharmacology.—Physiological actions of some alkaloids are widely known; *e.g.*, quinine is usually associated with the treatment of malaria, morphine with the relief of severe organic pain, cocaine with minor surgical operations and atropine with the work of the ophthalmologist. Although almost all alkaloids exert a distinct physiological action on higher animals and man, only about 20 are used for medicinal purposes. The large majority of alkaloids produce either no favourable effect at all or are too toxic to be useful drugs. Similar to many other drugs, those alkaloids that are used in medicine are not free from undesirable side effects. For example, morphine, which is still unsurpassed as an analgesic drug, is strongly habit-forming and may lead to addiction. Codeine and cocaine suffer from the same drawback. It is the aim of the pharmaceutical chemist to modify the chemical structure of these alkaloids in such manner that the resulting drug is superior to the natural product by maintaining the desired activity but producing less severe side effects.

Although very little is known about the biochemical action of the various alkaloids when administered to man, it is possible to divide them into groups whose members produce similar effects by acting upon the same part of the central nervous system. Examples of some of these groups with representative members are pressor alkaloids (ephedrine, gramine), which are capable of raising the blood pressure; cardioactive alkaloids (quinidine, erythropleine), capable of altering some function of the heart; respiratory stimulants (nicotine, atropine), acting upon the respiratory system; uterine stimulants (ergotarnine, quinine), causing increased activity of the uterus; and phrenotropic alkaloids (reserpine, mescaline), drugs that influence the function of the mind and the affective behaviour. Many alkaloids show activity in two or more of these groups; *e.g.*, reserpine, which can be listed as a hypotensive agent, a central nervous depressant or sedative, in addition to being a phrenotropic agent.

An important factor of physiological activity of alkaloids is the dose in which they are administered. Strychnine, for example, is used in small doses as a heart stimulant but can cause death in larger doses. The alkaloids of curare, the deadly arrow poison of the South American Indians, can be useful drugs for treatment of cerebral palsy when administered in small doses.

Detection and Preparation.—The processes by which alkaloids are obtained from plants depend upon the complete extraction of the dry ground material (bark, roots; leaves or seeds) with a suitable solvent, usually alcohol or slightly acidified water. The solvent is then distilled off under vacuum and the resulting extract diluted with water, made distinctly acidic and left to stand to deposit impurities. It is next made alkaline, preferably with sodium carbonate or ammonia; the bulk of the alkaloid is then usually precipitated and can be filtered off. If the alkaloid is soluble in water, other procedures involving the use of immiscible solvents (*i.e.*, liquids that, when shaken with watery fluids, will remove soluble substances therefrom and then form a separate layer) and sometimes special precipitants or absorbents have to

be adopted. These processes almost invariably yield a mixture of alkaloids, since the latter rarely occur singly in plants. The separation of these mixtures into their components can generally be achieved by fractional crystallization of the bases or their salts with suitable acids. More efficient processes for separation of alkaloid mixtures are adsorption or partition chromatography or countercurrent distribution between two solvents. Final purification of the alkaloids is usually carried out by repeated recrystallization from selected solvents.

Each kind of alkaloidal plant requires different treatment; the preparation process has been greatly simplified for most of the alkaloids produced on a large scale for use in medicine, though the standard of purity is constantly rising. The criteria of purity for alkaloids are the same as those for any other organic compound, *viz.*, determination of physical constants such as melting point or boiling point (for liquids), optical rotation and the chemical composition as determined by ultimate analysis. The use of infrared and ultraviolet or visible absorption spectra has become quite common as additional means for control of purity.

The analytical work of the toxicologist in connection with alkaloids is important. The methods by which poisonous alkaloids are extracted from viscera and stomach contents do not differ in principle from those for the extraction of alkaloids from plant material, but in these cases the problem is greatly complicated by the smallness of the quantities of alkaloids to be recovered. Again, spectroscopic methods have proved to be quite useful in this field in the detection and identification of alkaloids. Other methods for detecting and identifying micro quantities of alkaloids are colour tests, which most of the alkaloids give with certain reagents, and in a few cases special pharmacological tests; these methods give quite satisfactory results in the hands of experts.

Determination of Molecular Structure.—A few of the alkaloids are liquid and volatile, but most of them are colourless crystalline solids. If a new alkaloid has been isolated and obtained in a pure state the rather complicated process of elucidating its structure is usually started by determining its molecular formula. By quantitative analysis for the elements present (always carbon, hydrogen and nitrogen and in most cases oxygen as well), the chemist derives the ratio at which these elements are present in the molecule. Determining the molecular weight enables him to write the molecular formula that expresses the number of carbon, hydrogen, nitrogen and oxygen atoms that comprise the molecule.

Next, the chemist may direct his work to obtaining information about the nature of the nitrogen atoms in the compound. Since the alkaloids can be regarded as extensively substituted ammonias, those containing two atoms of nitrogen may be expected to be capable of forming salts derived from two molecules of monobasic acids. This is true with some alkaloids such as quinine ($C_{20}H_{24}O_2N_2$) but quite frequently, as in the case of strychnine, only one of the two nitrogen atoms is capable of binding one molecule of acid whereas the second nitrogen is not basic enough to form a salt. This difference in basicity of the two nitrogen atoms must be taken into account in assigning a structural formula to such alkaloids. In most cases, the nitrogen atoms are tertiary; that is, each is united to three carbon atoms, one of which is frequently in a methyl group. Qualitative and quantitative procedures are available for recognizing the presence of such a grouping. Sometimes, a secondary nitrogen group is present, in which only two of the hydrogen atoms of ammonia have been replaced by carbon linkages. The hydrogen of a secondary nitrogen group can be easily detected by infrared spectroscopy and chemical tests.

By similar means it is possible to discover how the oxygen atoms in an alkaloid are built into the molecule. Most frequently they are present as hydroxy ($-OH$), methoxy ($-OCH_3$), acetoxy ($-OCOCH_3$) or benzoxy ($-OCOC_6H_5$) groups. Occasionally a carboxyl group ($-COOR$) is present, and this, together with the basic nitrogen, may form a betaine. Frequently this carboxyl group occurs as its methyl ester. There are well-established methods of ascertaining the presence or absence of these groups. Spectroscopic methods (infrared, ultraviolet, visible, nuclear magnetic resonance) are employed to supplement the chemical tests.

Next, the chemist has to ascertain how the alkaloid nucleus,

the carbon-hydrogen skeleton to which these groups are attached, is built up and to determine the position at which each functional group is joined to this framework. No general scheme exists for this phase of the work. Success depends strongly on the skill and ingenuity of the chemist. The most frequently followed approach is to break up the alkaloid into small pieces by suitable reactions, to examine each piece in the same way as the parent alkaloid was examined and to continue with this process until a recognizable fragment, which may be any of the thousands of known organic compounds, is found. With that first clue to guide him and within the limits rigidly prescribed by all he knows regarding the composition and reactions of the alkaloid, the chemist can then proceed to visualize a structural formula.

This breaking-down process is generally accomplished by carefully regulated oxidation with such reagents as potassium permanganate, chromic acid or nitric acid—substances that burn off a few carbon atoms at a time and leave products that generally become simpler in character. Exhaustive methylation is another example of a valuable reaction that is frequently used to eliminate the nitrogen atom from a molecule and to leave a simpler compound that may be more easily recognized. The final part of an elucidation of structure is usually concerned with obtaining information as to the stereochemistry of the alkaloid, viz., deriving a complete three-dimensional expression for the arrangement of the atoms in the molecule. The structural formulas of the more important alkaloids are usually confirmed by total synthesis of the natural product from simple chemicals.

Biogenesis of Alkaloids.—Because of the complicated structure of most alkaloids, the question of their synthesis in the plant is of general interest. In addition, any knowledge of their biosynthesis may also give valuable information about the function of the alkaloids in the living plant. Therefore, chemists and biologists have speculated on this subject and developed many theories about biosynthetic schemes for various alkaloids. The concept with the widest support maintains that alkaloids are derived from amino acids, the building blocks of proteins. This idea is supported by the observation that the structure of most alkaloids can be derived from one or more simple derivatives of the naturally occurring amino acids, which are linked together by well-known chemical reactions. Some of the less complicated alkaloids have been synthesized in the laboratory in accordance with such biogenetic theories from derivatives of amino acids under physiological conditions (room temperature and neutral reaction media). With the advent of isotopically labeled compounds these theories became subject to experimental tests. For example, it has been demonstrated that morphine is produced in the plant from the common amino acid tyrosine. When opium poppy was grown in water containing isotopically labeled tyrosine, the extracted morphine had the isotopic atoms located at the same positions as expected from the biogenetic theory that maintains morphine is built from two molecules of tyrosine. Several other alkaloids (hyoscyamine, nicotine and ergotamine) have been shown by similar techniques to be products derived from amino acids.

Very little is known about the function of alkaloids in plants. Any theory concerned with this subject has to take into consideration that about 90% of all plants manage very well without ever producing alkaloids. Suggested theories, however, without much experimental evidence, are based on the idea of protection against higher animals, of the function of alkaloids as regulating agents in such activities as growth, general metabolism and reproduction, and finally of their function as detoxicating agents that eliminate substances whose accumulation might otherwise cause damage to the plant.

ALKAN (real name CHARLES HENRI VALENTIN MORHANGE) (1813–1888), French pianist and composer of virtuoso works for the piano, was born in Paris, Nov. 30, 1813. He was a pupil at the Paris conservatoire of P. Zimmermann, and became known as a pianist and, later, as a teacher. As a composer, he displayed considerable imagination and ingenuity in advancing keyboard virtuosity; Busoni considered him, in this respect, second only to Liszt and Brahms, and César Franck paid homage by transcribing, for the organ, several of his preludes (*Préludes et Prières de Ch.-V.* Alkan, 1889). His numerous works include sets of both preludes and studies in all the major and minor keys; 12 pieces, *Les Mois*; the sonata, *Les Quatre Ages*; the Piano Concerto in C sharp minor; and the Duo Dantesque for piano and violin. He died in Paris, March 29, 1888. (F. E. G.)

ALKMAAR, a town in the province of North Holland, Neth., is situated several miles from the coastal dunes in flat country 25 mi. by road north-northwest of Amsterdam. Pop. (1957 est.) 42,060. Alkmaar is a colourful town with canals and red-brick houses. It is a marketing centre for cattle, eggs and vegetables and is world-famous for its Friday cheese market, held from May to October in the Kaasmarkt. The weighhouse (rebuilt from a 14th-century chapel in 1582) has a tower with a carillon added in 1595–99 and is just north of the main street, Langestraat, in which are the public library, the town hall (1520, west part 1694) and museum (1873). St. Laurence's church (1470–1520) has one of the oldest organs in the Netherlands (1511). In Laet is St. John's chapel (1443). Other old buildings include Sonoy court (16th century), the New Doelen (Archery house, c. 1600) and several almshouses. There is a park with a monument to the town's resistance to the Spanish siege of 1573. Industries include the manufacture of church organs, railway signaling apparatus, yachts, furniture, clothing and foodstuffs. In the 8th century Saints Willibrord and Adalbert from England preached Christianity in the district. The original charter was dated 1254; charters of Philip the Good of Burgundy established an oligarchy. Much damage was done in wars between the Hollanders and Frisians, the Gelderlanders and Frisians capturing the town in 1517. Alkmaar acquired an important trade after the reclamation of the surrounding swamps from 1564 onward. In 1799 it gave its name to a convention by which the Russo-British army evacuated Holland. In World War II Alkmaar was in German hands from May 1940 until May 1945.

ALLAH, the Arabic word for God, used by Christians as well as by Muslims and known to Arabs even in pre-Islamic times. The probable etymology is the contraction of *al-Ilah*, "the God," although the Aramaic *Alaha* also has been proposed.

The one and only God is the pivot of the Muslim faith. The Koran constantly preaches Allah, his inaccessible mystery, his names and his actions on behalf of his creatures. Three themes preponderate: (1) God is creator, judge and rewarder; (2) he is unique (*wahid*) and inherently one (*ahad*), "He begets not, nor is he begotten"; (3) he is omnipotent and all-merciful, the "Lord of the Worlds," the most high, "nothing is like unto him," and this in itself is to the believer a request to adore him as protector and to glorify his powers of compassion and forgiveness.

God, says the Koran, "loves those who do good," and two texts (iii, 31 and v, 54) express a mutual love between God and man; but the precept of love in its absolute cast, "thou shalt love thy God with all thy heart," is nowhere formulated. The emphasis is rather on his inscrutable sovereignty, to which one must abandon oneself. God speaks to man through his prophets, and the "surrender to God" (*islam*) is the religion (*din*) itself (Khoran v, 3).

Many verses require "reflection on the signs of the universe" through which appear the "signs of God." Guided by him, human reason will find in transitoriness a testimony to the necessary and transcendental existence of the creator: "All must perish save his visage."

The Koran proclaims the "most beautiful Names" that are the

glory of God. He is One and Only, the Living One, the Subsisting, the Real Truth, the Sublime All-high, the Redoubtable, the Light and the Light of Lights, the Wise, the Omnipotent, the Absolute and Unceasing Creator, the One who is unlike all else, the Hearer, the Seer, the Omniscient, the Witness, the Giver, the Protector, the Generous, the Benefactor and the Merciful, the constant Remitter, the Compassionate, the Benevolent, the Best of Judges. Muslim piety has collected, in the Koranic text and in tradition, the 99 "fairest names," which it loves to repeat and meditate upon.

At all times there have been freethinkers in Islam, but rare indeed are those who have denied the existence of God. The profession of faith by which a person is introduced into the Muslim community is the affirmation that God is one and that Mohammed is his envoy. This is the *shahada* or "testimony," the first phrase of which proclaims "There is no god but God," *la ilah illa' Allah*. According to Koranic doctrine, the *shahada* uttered in sincerity is a means of salvation.

At the beginning of any obligatory action or one bringing merit, the pious Muslim invokes the divine name; thus, each chapter of the Koran opens with *bismillah al-Rahman al-Rahim*, "In the name of God, the Merciful, the Compassionate"; in everyday life it often appears in the shortened form *bismillah*.

Every contemplated action and every hope are subject to the divine will, hence the frequent use in daily speech of the formula *in sha' Allah*, "if God wills"; this use is known to Christian tradition also (*cf.* James iv, 15: "if the Lord will"). In Islam it is the reminder of an ever-present divine intervention in the order of the world and the acts of men. This is not in fact fatalism, as one might at first sight suppose, but a keen realization that nothing happens and nothing is performed unless it is by the will or commandment of God. Muslim schools pose the question: should one add *in sha' Allah* to "I believe"? Most agree that this should be so.

The treatises of religious knowledge devote long chapters to God and his existence and attributes. Briefly summarized, the personal attitude of a Muslim believer (*mu' min*) is and must be a complete and confiding submission, in the dark, to God "whom one does not question," but whom one knows according to his (Koranic) word to be the fair judge, at once formidable and benevolent, and the supreme help. It is this above all that is in the Muslim's mind when he names Allah.

See H. A. R. Gibb (ed.), *Encyclopaedia of Islam*, 2nd ed., vol. i, pp. 406-417 (1956), pp. 714-717 (1958), pp. 1084-85 (1959); and H. A. R. Gibb and J. H. Kramers (eds.), *Shorter Encyclopaedia of Islam* (1953). (L. GA.)

ALLAHABAD, a city in Uttar Pradesh, India, is located at the confluence of the Ganges and Jumna (*qq.v.*) rivers, 110 mi. S.S.E. of Lucknow and 365 mi. S.E. of Delhi. It is the headquarters of Allahabad district and division and seat of the state judicature. Pop. (1961) 431,007. Allahabad was raised from municipality to city corporation status in 1959.

Allahabad is divided into two parts by the railway: to the north are the military cantonment and the "civil lines" (the administrative and professional quarter); to the south the city proper. The latter is congested and its streets are narrow, except for a few that were widened after World War II. The civil lines and cantonment are well planned with a rectangular pattern of good straight roads lined with single-story residences. Apart from historic monuments (*see below*), there are several modern buildings of note: Government house (built for the city's former role as provincial capital), Anglican and Roman Catholic cathedrals, the Juma Masjid or "great mosque," Mayo hall (a civic memorial to a 19th-century British viceroy) and the museum.

The university, founded in 1887, comprises central teaching departments and a number of constituent and associated institutions including colleges of agriculture, engineering and medicine. There are two open spaces, the Khusru Bagh (*see below*) and Alfred park.

The Grand Trunk road connecting Calcutta with Delhi and Amritsar passes through Allahabad, and other main roads link it eastward with Mirzapur and southward with the Varanasi-Cape Comorin national highway. It is at the junction of the Delhi-Calcutta railway with the line from Bombay. The city is mainly

an educational, administrative and legal centre, but there is some industry, including the manufacture of steel trunks and the canning of guava products. Development of an industrial estate was begun on the south side of the Jumna in 1958.

History and Monuments.—Allahabad is on the site of the ancient Prayag, "place of sacrifice," a holy city comparable in fame with Varanasi (Benares) and Hardwar (*q.v.*). Its religious and commercial importance in the Buddhist period is attested by inscriptions of 243-232 B.C. on the pillar of Asoka (*q.v.*) standing within Allahabad fort. Its religious importance persists: in the month of Magh (December-January) each year a religious fair is held at the river confluence. Every 12th year this Magh Mela is replaced by the great Kumbh Mela during which an estimated 500,000 persons come from all over India to bathe simultaneously at the confluence. The Kumbh of 1954 was the scene of disaster when about 500 people were killed during the rush to bathe.

The present city owes its origin to the Mogul emperor Akbar (*q.v.*), who in 1583, with an eye to the strategic position of the confluence, began the great fort and named the settlement Allahabad, "city of God." Allahabad became the capital of a *suba*, or province, of the Mogul empire. From 1599 to 1604 it was the headquarters of the rebellious prince Salim (later the emperor Jahangir, *q.v.*); and in 1622 it became the burial place of his ill-starred son Prince Khusru, whose domed tomb in a garden—the Khusru Bagh—is still a popular resort.

With the decline of the Moguls, Allahabad changed hands many times before it was finally ceded by the nawab of Oudh to the British in 1801, in commutation of the subsidy paid for protection. Allahabad was the scene of a great massacre during the 1857 revolt against the British, but in general it prospered under their rule. Until 1888-89 it was at the focus of the only rail routes linking Delhi, Calcutta and Bombay. From 1901 to 1949 it was the capital of the United Provinces (now Uttar Pradesh). It was a notable centre of the Indian national movement before 1947 and the home of the Nehru family.

ALLAHABAD DISTRICT comprises an area of 2,800 sq.mi. spread over the confluence of the Ganges and Jumna rivers. These rivers divide the district into three regions. The Doab (*q.v.*), the western region between the rivers, is agriculturally the most productive, while the trans-Ganges region to the north contains many small lakes and is less fertile. The trans-Jumna region to the south extends into the Vindhyan hill tract. About 80% of the district's population (2,422,558 in 1961) depend on agriculture. Rice, wheat, barley, millets, gram and oilseeds are the main crops.

ALLAHABAD DIVISION comprises the districts of Etawah, Farrukhabad, Fatehpur, Kanpur (*qq.v.*) and Allahabad. Total population (1961) 8,339,947. Area 10,096 sq.mi. (M. N. K.)

ALLAN, SIR HUGH (1810-1882), Canadian financier and a figure in the so-called Pacific scandal, was born on Sept. 29, 1810, at Saltcoats, Ayrshire, Scot. He immigrated to Canada in 1826 and in 1831 entered the employ of the chief shipbuilding and grain-shipping firm of Montreal, of which he became a junior partner in 1835. In 1853 he organized the Allan line of steamships, plying between Montreal, Glasgow and Liverpool. Until his death he was closely associated with commerce, and in 1871 was knighted in recognition of his services. In 1872-73 he headed the Canada Pacific Railway company of Montreal and obtained from the Canadian government a charter for building a transcontinental railway, outmaneuvering a rival Toronto company that was also seeking a charter. It was subsequently disclosed that Allan was associated with a Chicago financial syndicate and that he had contributed about \$300,000 to the Conservative campaign of 1872. This "Pacific scandal" led to the overthrow of the government and the dissolution of Allan's railway company. He died in Edinburgh on Dec. 9, 1882. *See CANADA: History.*

ALLBUTT, SIR THOMAS CLIFFORD (1836-1925), British physician, who made important contributions in several areas of medicine, invented the short clinical thermometer and was, in addition, a distinguished historian of medicine. He was born on July 20, 1836, at Dewsbury, Yorks. He received his M.B.

in 1861 (Cambridge) and his M.D. in 1868. Among his teachers were Sir George Humphrey, Sir George Paget, Henry Bence Jones and Armand Trousseau. Allbutt settled in Leeds, becoming in 1864 physician to the Leeds General infirmary. In 1892 he became regius professor of physic at Cambridge, where he remained for the rest of his life. Allbutt was elected a fellow of the Royal society in 1880; in 1878 he gained membership of the Royal College of Physicians, of which he was elected fellow in 1883. He delivered the Goulstonian lectures in 1884 (on "Visceral Neuroses"), and in 1891 gave the Harveian lecture (on "Common Neuroses"). He was created a knight commander of the Bath in 1907, and in 1920 was made a privy councillor. He died at Cambridge on Feb. 22, 1925.

While working as a clinical clerk under Bence Jones in 1860, Allbutt became interested in acute aortitis, working later with J. A. Lockhart in microscopic neurology. He invented the short clinical thermometer in 1866. In 1868 he gave the first description of the histologic changes in syphilitic disease of the cerebral arteries. In 1885 he introduced surgery of tuberculous glands in the neck. His monograph *On the Use of the Ophthalmoscope in Diseases of the Nervous System and of the Kidneys* appeared in 1871, his *Diseases of the Arteries Including Angina Pectoris* in 1915. His excellent study on *Greek Medicine in Rome* was published in 1921. Allbutt's chief work, however, was his *System of Medicine*, 8 vol. (1896-99).

ALLEGHENY MOUNTAINS or THE ALLEGHENIES, a name formerly applied to all the Appalachian mountains (*q.v.*), and now, sometimes, to all that system lying west and south of the Hudson river, being steep and narrow-crested in Pennsylvania (1,500-1,800 ft.), in Maryland, Virginia and West Virginia rising to 4,800 ft. (Spruce Knob) and with broader crests. It is also used to include the ridges (the Allegheny ridges) parallel to the Blue ridge; the northwestern part of this region is called the Allegheny Front, and is characterized by a bold southeastward facing escarpment and a gentle northwestward slope. The Allegheny plateau is the northwesternmost division of the Appalachian system; it is an eroded mass of sedimentary rock sloping northwestward to the Lake plains in the region of the Great Lakes and reaching southwest from the Catskill (*see* CATSKILL MOUNTAINS) region of New York state to the Cumberland plateau region in Tennessee. The Alleghenies, which once formed a barrier to western communication, have long since been crossed by numerous railways and highways which follow the lower elevations or the "water gaps" of the eastward-flowing streams.

ALLEGHENY RIVER, a river of western Pennsylvania and southern New York and a major headwater of the Ohio river, whose source is the confluence of the Allegheny and Monongahela rivers at Pittsburgh. The Allegheny rises in the high, hilly plateau region of Potter county, Pa., at an elevation of about 2,250 ft. above sea level. From its source it flows in a general northwesterly direction about 80 mi., crossing into New York, to a point 11 mi. N. of the state line. There it turns abruptly southwest and continues in this direction for 120 mi. to the central part of Venango county, Pa. It then turns to the southeast and again southwest to its confluence with the Monongahela at Pittsburgh. Its total length is about 325 mi., and it drains an area of 11,410 sq. mi. The average fall of the river is 2.2 ft. per mile, making the stream a potential source of water power. The chief tributaries of the Allegheny are Kiskiminetas, Clarion and Cone-maugh rivers, and Red Bank, Oil and French creeks. The drainage basin has resources of coal, oil and natural gas. The Allegheny once served as an important highway for keel-boat navigation before the beginning of railway competition. Between 1903 and 1938 nine dams were completed to make the river navigable with a 7-ft.-deep channel for 70 mi. from Pittsburgh to East Brady. Because of periodic flooding of the Allegheny, flood control dams have been built on many of its major tributaries. (E. W. MI.)

ALLEGIANCE: *see* LOYALTY.

ALLEGORY is the intentional conveying, by means of symbol and image, of a further, deeper meaning than the surface one. Allegory may thus be said to be extended metaphor, worked out in many relationships. It is of greater length and complexity than

parable or fable and is imaginative where analogy is rational. The chief application of the word is to literature, both theological and secular.

Most languages are known to use allegory to convey difficult or metaphysical truths. Allegorical layers of meaning were used extensively in the Hindu and Buddhist scriptures and in ancient Persian and Arabian heroic legends. The Christian scriptures used allegorical symbols in the Song of Solomon, the Revelation and Psalm 80; medieval scholars, influenced undoubtedly by the writings of the ancient east, propounded a fourfold allegorical interpretation of the Christian scriptures. This attempt to relate the outer world of phenomena to the inner world of man's aspiration became stylized, and Prudentius (A.D. 348-c. 405) in his *Psychomachia* ("the battle of the soul") describes a series of combats in which faith conquers idolatry, patience anger, shame passion, and humility pride. This has been called the first allegory.

At the Renaissance, allegory came to mean the intellectual substitution or interpretation of one symbol or image by another. Thus distinction grew between religious and secular allegory; Dante (1265-1321) applied the theological fourfold interpretation to his own poetry. But St. Thomas Aquinas (c. 1225-74) made a clear distinction between the two kinds. In 1477 Plato was said to have taught "his sapyence by allegorye." Little allegory can be found in Latin classical writing, but that of the belly and its members in Livy and in Plutarch's *Life of Coriolanus* are worth mentioning.

The 13th and 14th centuries saw the composition of many allegories, both religious and secular, in Europe. Guillaume de Lorris began and Jean de Meun completed the *Roman de la Rose*, an elaborate secular allegory of the quest in the garden of life for the desired rose of love's happiness. William Langland wrote *The Vision of Piers Plowman*, a religious allegory which may be interpreted, though not consistently, as a vision of Christ on earth as Everyman. Chaucer's *Parlement of Foules* (1382?) is a humorous allegory of man's similarities to and kinship with the birds. The *Faerie Queene* (1596) of Edmund Spenser is a threefold allegory of physical and spiritual chivalry. Jonathan Swift's *Tale of a Tub* (1704) and *Gulliver's Travels* (1726) are satirical allegories. But perhaps the most widely read is John Bunyan's *Pilgrim's Progress* (1678), the story of the perils and burdens of man until he sees the light of Christian faith.

Allegory has been less often used in the 19th and 20th centuries, but George Orwell's *Animal Farm* (1945) may be said to belong to the genre, and C. S. Lewis's *Pilgrim's Regress* (1933) is subtitled "An allegorical apology for Christianity, reason and romanticism."

See also Index entries under "Allegory" in the Index volume.

See G. Highet, *The Classical Tradition* (1949); C. S. Lewis, *The Allegory of Love* (1936). (J. W. T.)

ALLEINE, JOSEPH (1633-1668), English Nonconformist minister, regarded by contemporaries as second only to Richard Baxter (*q.v.*) in sanctity and scholarship and one of those ejected under the Act of Uniformity of 1662. Born at Devizes, Wiltshire, in 1633, he went to Oxford in 1649 and after graduation (1653) was appointed chaplain of his college, Corpus Christi. In 1655 he was ordained by the presbyters as assistant to George Newton, vicar of St. Mary Magdalene, Taunton, where he was as much respected for his wide learning as loved for his gentle piety. Ejected in 1662, he suffered hardship as a wandering preacher, often in hiding and in prison. He died on Nov. 17, 1668. His *Alarime to Unconverted Sinners* (1672) became a classic of evangelical appeal and his lost treatise, *Theologia philosophica*, was highly praised by Baxter.

ALLELOMORPH, in biology, the name applied to the alternative forms of a gene (*q.v.*). *See also* HEREDITY; GENETICS.

ALLEMANDE (Fr. "German"), a German dance in 3/4 time, a forerunner of the waltz; and an 18th-century German national dance in lively 2/4 time. It is also the name of a slow, stately dance in 4/4 time, first appearing about 1550. After introduction at the French court it became the only court dance in which partners held both of each other's hands and performed flowing *enchainements* while walking and balancing. Likewise, the music

freely employed flowing 16th notes in its melodic structure. After 1620 it became the opening movement of the suite, occasionally preceded by a prelude. See COURANTE; DANCE. (L. Ht.)

ALLEN, ETHAN (1738–1789), American soldier, frontiersman, author of several books and pamphlets and Vermont folk hero, was born in Litchfield, Conn., Jan. 21, 1738 (new style: Jan. 10, 1738, old style), of humble backwoods stock. Little is known of his early life other than that he was preparing for college when his father died in 1755, that he had military service during the French and Indian War and that he came under the intellectual influence of Thomas Young, an erudite, unorthodox rationalist. By 1769 Allen's enterprising nature led him into the New Hampshire grants, an area then claimed by both New Hampshire and New York. Allen and his brothers formed the nucleus of the Green Mountain Boys, an irregular but effective force for resistance to the "Yorkers." Superb propagandists as well as efficient soldiers, they exploited the grievances the backwoodsmen had against lower New York and identified the cause of the land speculators with the cause of the settlers. (See VERMONT; History.) When the news of Lexington and Concord arrived. Ethan Allen's energies were turned toward the larger conflict. Following instructions from the Connecticut assembly he raised a force and with considerable skill and dispatch took the British fort at Ticonderoga on May 10, 1775, as Allen reported "in the name of the great Jehovah and the Continental Congress." What might have been a brilliant military career for this bold and impulsive man was thwarted when he was captured during a foolhardy attempt to capture Montreal in Sept. 1775. He was held prisoner until an exchange could be arranged on May 6, 1778. The following year he published his *Narrative of Colonel Ethan Allen's Captivity*. Congress gave him the brevet rank of colonel with back pay, but he did not serve in the revolutionary forces after his release. He devoted his time to local affairs in Vermont and to the struggle with New York. Allen was unsuccessful in presenting the Vermont claim for separate statehood to the congress in Sept. 1778. He then entered into a correspondence with Gen. Frederick Haldimand, British commander at Quebec, to see upon what terms Vermont could rejoin the British empire. Allen's apologists have insisted that these actions were a ruse to bring the continental congress to terms. Modern scholars are of the opinion that his actions were at first purely opportunistic and that finally in disgust with the continental congress he threw himself into a wholehearted move to make Vermont a British province. The generous peace treaty wrecked the province scheme and Vermont had to wait until 1791 for statehood. Allen did not live to see this. He died on Feb. 11, 1789, at Burlington.

Ethan's youngest brother, IRA ALLEN (1751–1814), was born at Cornwall, Conn. His career was closely connected with that of his brother. He was less a military man and more the politician and negotiator. He was a member of the convention that declared Vermont's independence (1777), and served as a member of the council of safety (1776–86), assemblyman, surveyor general and treasurer of Vermont. He endowed and was the virtual founder of the University of Vermont. During the Anglo-French struggle following the French Revolution, Ira Allen belonged to a Vermont faction that allied itself with France to wrest Canada from England. He was captured with a cargo of arms and held in Britain for prolonged litigation. During his absence his lands were sold for taxes and he was forced to spend the rest of his life in Pennsylvania to avoid debtors' prison. In 1798 he published in London his *Natural and Political History of the State of Vermont*.

ALLEN, SIR HUGH PERCY (1869–1946), English musician who exerted a far-reaching influence upon the musical life of his time, especially in education, was born at Reading, Berkshire, Dec. 23, 1869. He received his early training at Chichester as an articulated pupil of Frederick Read, organist and composer, and at Cambridge, where in 1892 he became organ scholar at Christ's college. Appointments as organist at Ely cathedral (18983 and

New college, Oxford (1901), gave outlet to his uncommon vision, energy and initiative, and led to his appointment (1919) as director of the Royal College of Music! London. As conductor of the Bach choirs in Oxford (from 1901) and London (1907–20), he did much for English choral music, particularly by performance of Bach's works, and of those of Sir Hubert Parry and Vaughan Williams.

In 1918 he became professor of music at Oxford, a position which enabled him to persuade a conservative university to admit music to its proper position in the curriculum and to make more adequate provision for research and teaching. These developments at Oxford had wide influence elsewhere. Allen's studies in the music of Heinrich Schiitz and J. S. Bach, though unpublished, stimulated musicians and scholars. As a conductor he gave many distinguished and inspiring performances. He was knighted in 1920. He died at Oxford, Feb. 20, 1946.

See C. Bailey, *Hugh Percy Allen* (193-8).

(TH. A.)

ALLEN, SIR JAMES (18j5–1942), New Zealand statesman, chiefly distinguished as minister of defense from 1912 to 1920, was born near Adelaide, South Australia, on Feb. 10, 1855. His parents settled in New Zealand a year later. He was educated in England at Clifton college, Bristol, and at St. John's college, Cambridge, and afterward studied at the Royal School of Mines, London. Returning to New Zealand, he was, in 1887, elected a member of the house of representatives. He was minister of finance, defense and education from 1912 to 1915. He continued as minister of defense in the national coalition government of 1915–19, when he was responsible for making the New Zealand expeditionary force a first-class fighting body. In the absence from the country of his chief, W. F. Massey, during and after 1917, he was acting prime minister. He remained minister of defense in 1919–20, after the end of the coalition government, when he was also minister of external affairs and finance. He was high commissioner for New Zealand in London from 1920 to 1926, his long political experience making him a useful man on committees and at conferences. On returning to New Zealand he was appointed to the legislative council. He was knighted in 1917. He died at Dunedin, New Zealand, on July 28, 1932. (J. C. BE.)

ALLEN, JAMES LANE (1849–1925), U.S. novelist of Kentucky, was born Dec. 21, 1849, on a small plantation near Lexington, Ky., where he passed most of his early life. He studied at Transylvania college, Lexington, Ky., was professor of Latin and English at Bethany college, Bethany, W. Va., and taught languages in various preparatory schools. He began his literary career by writing poetry and criticism but soon shifted to the tales and novels of an idealized plantation society for which he is best known. These include *Flute and Violin* (1891), *The Blue-Grass Region of Kentucky* (1892), *A Kentucky Cardinal* (1894), and its sequel, *Aftermath* (1895). *A Summer in Arcady* (1896) marks his turn to the contemporary problems, particularly of sex, that dominated his subsequent novels.

Allen died in New York city, Feb. 18, 1925.

See G. C. Knight, *James Lane Allen and the Genteel Tradition* (1935).

ALLEN, RICHARD (1760–1831), U.S. Negro clergyman, a founder and first bishop of the African Methodist Episcopal Church, was born of slave parents in Philadelphia, Pa., in 1760. Soon after his birth his parents were sold and moved to Delaware. At 17 he joined the Methodist Episcopal Church and when 22 years old was licensed to preach. Four years later (1786) he purchased his freedom for \$2,000, continental money, and returned to Philadelphia. There he joined St. George's Methodist Episcopal church in which he was permitted to preach to Negroes at 5 o'clock meetings. Dissatisfied with the restrictions placed upon those who attended these meetings, he decided to withdraw. He purchased a lot at the corner of 6th and Lombard streets and moved onto it an old blacksmith shop which he refurbished as a house of worship. There he organized in 1787 the first church for Negroes in the United States. His followers were called Allenites. Despite opposition and a series of obstructive lawsuits, a charter was secured from the general assembly of Pennsylvania. A new church building, erected and opened in 1794, was dedicated by Bishop Francis Asbury (*q.v.*) and called Bethel. In 1799 Allen became the first

Negro to be regularly ordained in the ministry of the Methodist Episcopal Church and in 1816, upon the organization of the African Methodist Episcopal Church, he was elected bishop. He died in Philadelphia on March 26, 1831.

See *Centennial Encyclopaedia of the African Methodist Church* (1916).

ALLEN, VIOLA (1869–1948), U.S. actress, was born in Huntsville, Ala., Oct. 27, 1869, the daughter of C. Leslie and Sarah (Lyon) Allen, actors. She was educated in Boston, Toronto and New York city and made her debut at 13, succeeding Annie Russell in the title role of *Esmeralda* at the Madison Square theatre, New York city. In 1884 she appeared with John McCullough, and at the opening of the Lyceum theatre in New York in 1885 she played Madeleine in *Dakolar*. Engagements with Tommaso Salvini and with Joseph Jefferson followed. In 1889 she created the role of Gertrude Ellingham in Bronson Howard's *Shenandoah*, the success of which established Charles Frohman as a producer. From 1893 to 1898 Miss Allen was a member of Frohman's Empire theatre stock company, where she enhanced her reputation in a variety of leading roles in comedy and drama. She left to star in the role of Gloria Quayle in Hall Caine's *The Christian* (1898). From 1903 to 1907 she played Viola, Rosalind, and both Hermione and Perdita in *A Winter's Tale*. For eight years she starred in modern plays, but in 1915 returned to Shakespeare as Lady Macbeth opposite James K. Hackett. She last appeared in 1916 as hlistress Ford in *The Merry Wives of Windsor*. In 1906 she married Peter Duryea. She died May 10, 1948, in New York city. (B. HT.)

ALLEN, WILLIAM (1532–1594), English cardinal and scholar who founded the English college at Douai, was born at Rossall, Lancashire, and educated at Oxford. He became principal of St. Mary's hall but was deprived for refusing the oath of supremacy, and in 1561 he moved to Louvain, Belg. He returned to England in 1562, but left finally in 1565 for Mechelen, where he was ordained priest and lectured in theology in the Benedictine college. He was principally responsible in 1568 for setting up a college at Douai for training Englishmen as "missionary priests." This college, of which he was president and lecturer until 1585, gave its name to the Reims-Douai translation of the Bible into English, in which project the translator, Gregory Martin, worked under Allen's direction. Allen was also on the Sixtine commission for the revision of the Vulgate. In 1576 he supported the foundation of the English college in Rome. The college at Douai withdrew to Reims in 1578, and Allen spent seven years at Reims. In 1585 he went to Rome where he spent the rest of his life. In 1587 he was made cardinal at the request of Philip II of Spain. In 1589 he supported the foundation of the English seminary at Valladolid, Spain. He died in Rome on Oct. 16, 1594. Allen has been criticized for political intrigue; he undoubtedly encouraged the intervention of Spain in English affairs, but in the seminaries his rule against political discussions or planning was rigorously observed.

See Martin Haile, *An Elizabethan Cardinal, William Allen*, with bibliography (1914). (M. DK.)

ALLEN, BOG OF (MÓIN ALMHAINÉ), a group of peat bogs between the Liffey and Shannon rivers in the counties of Kildare, Offaly, Laoighis (Leix) and Westmeath, Ire. They occupy an area (about 370 sq.mi.) of confused drainage behind the great terminal moraine of debris left after the Ice Age. The higher ground on the eskers and moraines carries strips of cultivation between bogs so that the latter really occupy only half the area. Much peat has been cleared and the land used for grazing. The Grand canal, cut through the bog, carries considerable traffic, but the Royal canal is disused. (T. HER.)

ALLENBY, EDMUND HENRY HYNMAN ALLENBY, 1ST VISCOUNT (1861–1936), British field marshal, whose campaign in Palestine in World War I showed his genius for war and served as a classic example of the military art, was born at Brackenhurst, near Southwell, Kottinghamshire, on April 23, 1861. Joining the Inniskilling dragoons in 1882, he took part in the Bechuanaland expedition (1884–85) and in the South African War (1899–1902). He commanded the 5th lancers (1902–05) and on the outbreak of World War I in 1914 took the cavalry division to France. After periods in command of the cavalry and the 5th

corps, he became commander of the 3rd army in Oct. 1915 and was prominently engaged in the battle of Arras (April 1917). His efforts to achieve surprise by improving on the then accepted tactical methods of position warfare were unfavourably regarded by general headquarters. In June 1917, Allenby took command of the Egyptian expeditionary force. The strength of his personality created a new spirit throughout the army, and after careful preparation and reorganization he gained a decisive victory over the Turks at Gaza (Nov. 1917), which led to the capture of Jerusalem (Dec. 9, 1917). Further advances were checked by calls from France for his troops, but after receiving reinforcements from elsewhere he struck the enemy decisively at Megiddo (Sept. 1918) and, using his cavalry to exploit the victory, captured Damascus and Aleppo. This brought about the capitulation of Turkey. He was created a viscount in Oct. 1919. As high commissioner for Egypt from 1919 to 1925 Allenby steered that country firmly but impartially through a succession of political disturbances. It was during his tenure of office that Egypt was recognized as a sovereign state in 1922. He died in London on May 14, 1936, and his ashes were interred in Westminster abbey.

See A. P. W. Wavell, *Allenby, Soldier and Statesman* (1946).

(R. G. TH.)

ALLENTOWN, a city in eastern Pennsylvania, U.S., is located on the Lehigh river about 55 mi. N.W. of Philadelphia and 93 mi. W. of New York; it is the seat of Lehigh county. The population was 108,347 in 1960. The population of the Allentown-Bethlehem-Easton standard metropolitan statistical area, comprising Lehigh and Northampton counties in Pennsylvania and Warren county in New Jersey, was 492,168 in 1960. (For comparative population figures see table in PENNSYLVANIA: *Population*.) The city derives its name from its founder, William Allen, a chief justice of Pennsylvania, who acquired the land in 1735, erected a hunting and fishing lodge on it in the 1750s, and eventually, in 1762, laid out the town. His settlement was incorporated as the borough of Northampton in 1811 and became the seat of Lehigh county the following year when the latter was separated from Northampton county. In 1829 the construction of a canal along the Lehigh and Delaware rivers, linking Philadelphia with the northern coal regions, brought new economic opportunities to the borough of Northampton. An iron industry was started in 1847, a cement plant in 1850 and a rolling mill in 1860—all of these presaged an important industrial future. Anticipating this future, Allentown was incorporated as a city in 1867.

Allentown owes its steadily expanding prosperity to the rich mineral deposits and the fertile farm land of the surrounding countryside. Although iron ore, slate and zinc have contributed to its economy, limestone has made Allentown the centre of the greatest concentration of the cement industry in the U.S. After mid-20th century there were more than 300 manufacturing establishments employing about 30,000 workers. The largest of these industries produced electronic equipment, automobile trucks, cotton textiles, food products, machinery and machine tools. One-fifth of the inhabitants migrated originally from eastern and central Europe. The descendants of the Germans, who came to Pennsylvania during the first part of the 18th century, form the dominant segment of the population; they cling to their Pennsylvania Dutch dialect—a frontier mixture of German and English.

Muhlenberg college was founded in 1848 as Allentown seminary, and later came under the management of the Lutheran Church. In 1867 the Evangelical and Reformed Church founded Cedar Crest college for women. These two church-affiliated colleges reflect the prominence of the Lutheran and the Evangelical and Reformed (now the United Church of Christ) denominations in a city of many churches.

Trexler-Lehigh county game preserve, north of the city, contains the largest herd of buffalo in eastern United States and also large herds of elk and deer. The buffalo were originally native to the territory but were driven west by the early settlers. When the game preserve was created the animals were brought back to their original habitat. (R. G. Co.)

ALLEPPEY, a seaport and district in Kerala state, India. The town is on a narrow spit between the Arabian sea and a great

backwater. the Vembanad "lake," 34 mi. S. of Cochin (*q.v.*). Municipal area 12.5 sq.mi.; pop, (1951) 116,278. It is the seat of two colleges affiliated with Kerala university. There is no railhead, but Alleppey is on the main road from Cochin to Trivandrum, and there is considerable barge traffic on the backwater and by canal north to Tirur and south to Trivandrum. Alleppey is a roadstead port, with a safe anchorage protected by a mud bank about a mile offshore. Alleppey's main industry and commerce stem from the coconut. the district's chief product: coconut oil is milled, coir ropes, mats and carpets manufactured and copra exported. Lesser exports include pepper and ginger.

The port was opened to foreign trade by the British in the late 18th century to end the commercial supremacy of the Dutch factory at Porkad, 10 mi. away.

ALLEPPEY DISTRICT (711 sq.mi.) was formed in 1958 by transferring six *talukas* (subdivisions) from Quilon district and one from Kottayam district. Pop. (1961) 1,809,530. (G. K.N.)

ALLERGY AND ANAPHYLAXIS are terms describing the exaggerated reactivity of a living organism to foreign substances that sometimes occurs following exposure to those substances. The terms have different historical origins and slightly different connotations but refer to essentially the same phenomenon. The word allergy was first proposed by Clemens von Pirquet in 1906 as a broad term to cover all specifically induced changes in reactivity. but with time its meaning has become more and more restricted. It is now generally used to describe only increased (*i.e.*, not decreased) reactivity occurring following exposure to foreign substances, or any increased reactivity (hypersensitivity), whether inherited or acquired. It is also frequently used by laymen to refer to a specific symptom, as when a patient refers to his asthma as his allergy.

The term anaphylaxis was introduced by Charles Richet in 1898 to describe the sometimes fatal reaction of an animal to a second injection of eel serum. Since a first injection of this serum did not produce any noticeable reaction, Richet used the term anaphylaxis to signify a state that was the antithesis of prophylaxis, the latter being a condition of immunity commonly produced by injections of bacterial toxins. Anaphylaxis is a technical term generally used to describe severe reactions of animals following immediately on the second injection of a foreign protein. Allergic and anaphylactic reactions occur in both animals and men under a wide variety of circumstances and with a wide variety of manifestations. All of these may be considered as phenomena of the adaptation of an individual to his environment. (D. W. TE.)

The Anaphylactic Reaction.—The anaphylactic reaction is characteristic for the species of animal in which it occurs and is not determined by the foreign protein that produces it. If, for example, a guinea pig is injected with horse serum, egg albumin or other protein substance, it gradually becomes sensitized to the protein injected. so that, after an interval (called incubation period) of 10 to 14 days, the reinjection of this protein produces anaphylactic shock. Within a period of a few minutes after reinjection the animal sneezes, scratches its nose, becomes restless, usually discharges urine and feces and has great difficulty in breathing. The latter may increase until the animal dies from asphyxia as the result of inability, in spite of violent effort, to ventilate its lungs effectively. The difficulty in respiration is caused by an intense spastic contraction of the smaller air passages, or bronchioles. In the dog the prominent phenomena are vomiting, defecation, fall in blood pressure, collapse and incoagulability of the blood. In the rabbit the prominent phenomena are alternate and fleeting reddening and pallor of the ears, discharge of urine and feces, weakness, cardiac irregularities and collapse. Many minor phenomena—*e.g.*, decrease in the number of circulating white blood cells and increase in the formation of lymph—also occur in these animals. If an animal survives, it is for a short time (one to two days) refractory to a subsequent injection of the foreign protein and is said to be antianaphylactic as the result of the desensitization produced.

Anaphylactic phenomena occur in various isolated tissues taken from sensitized animals; *e.g.*, the isolated uterus or a small portion of the intestine from guinea pigs, when suspended in an oxy-

genated and warm saline bath, contracts markedly when minute amounts of the foreign protein are added to the bath. This reaction, referred to as the Schultz-Dale test, is so delicate and specific that fractions of a milligram of foreign protein can be detected by it.

Localized anaphylactic phenomena are seen in some animals. When the specific foreign protein is injected under or into the skin of a sensitized rabbit, there may result within the ensuing 48 hours swelling, hardening and gangrenous slough at the site of the injection. This local reaction was first described by Maurice Arthus and is referred to as the phenomenon of Arthus. (C. A. Dr.)

Manifestations of Allergy.—In contrast to the classical anaphylactic reactions of animals, allergic reactions of human beings are seen in a great variety of forms. Hay fever, asthma and eczema are typical, but fever, hives, rashes, headaches, abdominal cramps, diarrhea and a great variety of other symptoms also may have an allergic basis. Serious illnesses such as nephritis and rheumatic fever may be considered as allergic reactions to streptococcal products. The manifestation of allergy in any particular case depends on at least three factors: (1) the mode of contact, or portal of entry; (2) the localizing character of the foreign substance (allergen); and (3) the responding tendencies of the individual. For example, ragweed pollen most commonly produces symptoms in the nose and eyes, where it first makes contact with the body fluids. Some persons, however, respond to ragweed by developing asthma without hay fever, and an occasional patient may have headache or hives. Allergic reactions to foods (*e.g.*, fish, peanuts, fruit) commonly manifest themselves as hives or rashes of the skin, although the food makes first contact with the body in the gastrointestinal tract. The same person may have hay fever when exposed to ragweed pollen or hives when he eats fish, and may break out in a rash if he is given phenobarbital. The only characteristic feature common to all these reactions is that the manifestation of the allergy to a given substance is qualitatively different from the toxic or pharmacological response of most individuals of the same species. For example, the pharmacological response to phenobarbital is drowsiness. The allergic response may be a rash.

Diagnosis of Allergy.—The problem is twofold: (1) to determine whether a given reaction is allergic in nature; and (2) to identify the causative agent or allergen. The first question cannot be answered with certainty without the second. Allergy may be suspected because of the nature of the reaction (*e.g.*, hives) or because of frequent recurrences separated by periods of complete freedom from symptoms. However, a diagnosis of allergy cannot be made with certainty without identifying the allergen. The reason for this difficulty is that a living organism is a reacting system with a relatively small number of ways of reacting. Just as a rubber ball is likely either to bounce or to roll regardless of what force is applied to it, so a human being may respond to many different stressful and injurious stimuli in exactly the same way. For example, typical asthmatic symptoms may be produced by ragweed allergy, inhaling cold air, coughing, bronchial infection, heart disease, emotional stress or tumours pressing on the bronchus. In fact, several of these factors frequently operate in the same person.

Since identification of the allergen is essential to the diagnosis of allergy, it is important to know something of the types of foreign substances likely to induce allergy. The most important are drugs, pollens, molds, lints, animal danders, dandruff, cosmetics, industrial chemicals, bacteria and food. While this list includes nearly everything a person is likely to contact, considerable information is obtained from observing the nature and course of the allergic reaction. In fact, a clear and complete history is the most important factor in a correct diagnosis. Allergy to inhalants such as pollens, molds, lints and danders is most likely to give symptoms in the eyes, nose and bronchus. Cosmetics affect the face and hands. Allergy to pollens is noted only in season; *i.e.*, spring for trees, early summer for grasses and late summer for weeds. Allergy to an occupational contact will diminish during a vacation.

Testing Procedures.—The purpose of all testing procedures is

to obtain more history by exposing the person suspected of allergy to a variety of substances to which he might be allergic. It is important that the testing procedure be rigidly controlled and reproduce as nearly as possible the conditions of natural exposure. If a suspected allergen is a skin contactant, such as lipstick, it is possible to apply some of the allergen to an unaffected portion of skin and observe the developments. A food may be added to or withdrawn from the diet. For this purpose, careful food diaries should be kept. In some cases it is necessary to use strict elimination diets consisting of only a few items of rarely allergenic foods. Suspected foods are then added one at a time. Difficulties arise because there is sometimes a lag of several days between exposure to the allergen and the allergic reaction. In the case of food allergies this may require long periods of dieting. In the case of skin contactants, the allergen may be applied on an adhesive patch and left for several days. With inhalant allergens it is impractical and frequently dangerous actually to inhale a sample of each suspected allergen. In this case, solutions or extracts of the allergens are applied to the skin through a small scratch or directly into the outer layers of the skin with a hypodermic syringe and needle. Unfortunately, these two methods are not very reliable.

Mechanism of the Allergic Reaction.—A large number of theories have been advanced to explain the allergic reaction, but no single one has been found satisfactory to account for all the observed phenomena. It seems likely that a great variety of things happen as a result of the introduction of allergen into a sensitive person. One of these is the liberation of histamine, a powerful substance that causes smooth muscle contraction, capillary dilatation and fall in blood pressure. Other substances liberated probably include acetylcholine, heparin and serotonin. It is probable that many more such substances are liberated by the cells of the body when they are injured. The mechanism by which the cells are injured is equally obscure. It is generally believed, however, that the basis of allergy is a reaction between the allergen and a body protein called an antibody.

Allergy and Immunity.—The usual response of a person to infectious disease is the production of protein substances called antibodies that circulate in the blood. Antibodies give immunity (protection) against second attacks of the disease that stimulated their production. Antibodies are highly specific; e.g., the antibody to the measles virus does not provide immunity to chicken pox. Antibodies act by first combining with the corresponding virus or bacterium and then destroying it with the aid of other bodily substances or cells. The production of antibodies may be stimulated by dead virus or bacterial particles and by their toxic products, and this fact provides the basis for many immunization procedures. Antibodies are also produced against completely harmless substances when they find their way into the body's tissues. As a result the antibody response, which is an adaptive response necessary for survival, sometimes causes the unpleasant side effects known as allergy. This is partly due to the body's inability to distinguish between harmful and harmless substances. It is also due to the fact that against harmful bacteria and toxins allergic symptoms may be important for survival by warning the invaded person and stimulating his other bodily defenses. (See also IMMUNITY.) (D. W. TE.)

Treatment.—Whenever the specific factor can be identified, the patient should avoid it. To remove the cat or dog, to change the kapok ("silk floss") pillow, to clean house and remove the dusty rug or the old stuffed sofa may be all that is necessary, and the clue lies in the clinical history. When elimination is not possible, then desensitization, by a series of injections of small doses of the specific allergen, can be attempted, but the technique is difficult. In hay fever, particularly, where the large number of patients makes it easy to compare one with another, the results are good. Moreover, the study of the same patient in successive years has made it possible to reduce greatly the number of doses and sometimes to omit them entirely.

Beginning about 1945, a series of useful antihistaminic drugs was discovered and developed. In addition, in May 1949, Philip S. Hench, Ednard C. Kendall and their associates at the Mayo clinic

announced the discovery of cortisone and ACTH—hormones derived from the adrenal cortex and the pituitary gland, respectively. These extraordinarily active substances are concerned with the defense of the body against the damages of stress and strain. They can relieve the symptoms of many diseases, including the so-called allergic diseases, as long as they are administered in adequate doses. The allergic reaction is not inhibited, but the effects of it are modified in some way. When continued for too long a time, however, these drugs may lead to serious complications and they do not represent the final answer to the problem of allergy. See IMMUNITY and articles on such conditions as ASTHMA; HAY FEVER; see also Index references under "Allergy and Anaphylaxis" in the Index volume. (F. M. RN.)

ALLERTON, ISAAC (1586-1659), born in England, was one of the Pilgrims who came to America on the "Mayflower" in 1620. He was one of those to sign the "Mayflower Compact," and upon arrival at Plymouth took a leading part in the affairs of the colony. He journeyed to England as a representative of the community and aided in the negotiations of the settlers with the Indians. But in 1631 Allerton broke with the governing powers in Plymouth and took up residence in the Massachusetts Bay colony. He later moved to New Amsterdam (now New York city) where he was made a member of the governing council in 1643. He died in New Haven, Conn., in 1659. His daughter Mary, who died in 1699, was the last survivor of the original Plymouth colony.

See William Bradford, *History of the Plymouth Plantation* (1856); and Edward Beaman Patten, *Isaac Allerton, First Assistant of Plymouth Colony* (1908). (E. E. R.)

ALLESTREE (ALLESTRY), RICHARD (1619-1681), English theologian who was regius professor of divinity at Oxford from 1663 to 1679 and provost of Eton college from 1665 until his death, was born at Uppington, Shropshire, in March 1619. He was educated at Christ Church, Oxford, and took up arms on behalf of Charles I in the English Civil War. During the Commonwealth, by which time he had taken holy orders, he frequently carried dispatches between the exiled Charles II and the English royalists. He was imprisoned for a brief period after one of these missions. At the Restoration he became canon of Christ Church, D.D., city lecturer at Oxford and chaplain to the king, before gaining his appointment as regius professor. As provost of Eton from 1665, he introduced order into the disorganized finances of the college and procured the confirmation of Archbishop Laud's decree, which reserved five of the Eton fellowships for members of King's college, Cambridge. His additions to the college buildings were less successful, for the Upper school, constructed by him at his own expense, was falling into ruin almost in his lifetime and had to be rebuilt in 1689. Allestree died on Jan. 28, 1681, and was buried in the college chapel at Eton.

Allestree's writings include many controversial tracts. It is possible that he had a share in the composition of the books published under the name of the author of the *Whole Duty of Man* (Nichols' *Literary Anecdotes*, ii, 603).

ALLEYN, EDWARD (1566-1626), English actor and founder of Dulwich college, London, was born in London on Sept. 1, 1566, the son of an innholder. By 1586 his name was on the list of the earl of Worcester's players, and he was eventually rated as the foremost actor of his time, especially in Christopher Marlowe's plays. Ben Jonson bestowed unstinted praise on Alleyn's acting (*Epigrams*, no. 89); Thomas Nashe expressed, in *Pierce Penilesse*, his admiration of him; while Thomas Heywood called him "inimitable," "the best of actors," "Proteus for shapes and Roscius for a tongue." After his marriage on Oct. 22, 1592, to Joan Woodward, stepdaughter of the theatrical manager Philip Henslowe, Alleyn became part owner in Henslowe's ventures and, in the end, sole proprietor of several playhouses and other profitable pleasure resorts in London. Among these were the Rose theatre at Bankside, the Paris garden and the Fortune theatre in St. Luke's—the last occupied by the lord admiral's company, of which Alleyn was the

head.

He filled, too, in conjunction with Henslowe, the post of "master of the king's games of bears, bulls, and dogs." On some occasions he directed the sport in person, and John Stow, in his *Chronicles*, gives an account of how Alleyn baited a lion before James I at the Tower.

Alleyn's connection with Dulwich began in 1605, when he bought the main part of the manor of Dulwich from Sir Francis Calton. The landed property, of which the entire estate had not passed into Alleyn's hands until 1614, stretched from the crest of that range of Surrey hills on whose summit the Crystal Palace stood to the crest of the parallel ridge, 3 mi. nearer London, known in its several portions as Herne hill, Denmark hill and Champion hill. He began the task of building and endowing in his own lifetime the College of God's Gift at Dulwich. Tedious delays over the charter or deed of incorporation occurred in the Star Chamber, but the college was founded and endowed under letters patent of James I, dated June 21, 1619. In 1623 Alleyn's first wife died and he married Constance, daughter of John Donne.

Alleyn died in Nov. 1626 and was buried in the chapel of the college he had founded. See also DULWICH.

See George Hosking, *Life and Times of Edward Alleyn* (1952).

ALL FOOLS' DAY: see APRIL FOOLS' DAY.

ALLIANCE, a city of Stark county, Ohio, U.S., on the Mahoning river, 55 mi. S.E. of Cleveland. (For comparative population figures see table in ОНЮ: *Population*.) Among the manufactured products are electric traveling cranes, first invented and produced at Alliance, ladle and soaking pit cranes, steel forgings and castings, railroad equipment, steel bathtubs, rubber bands, sub-fractional horsepower electric motors, tools and seamless tubing.

Mount Union college, a coeducational school of the Methodist Church, was founded in 1846 and received its charter as a college in 1858; Scio college (1857) was merged with it in 1911. Alliance was settled and laid out in 1838, incorporated as a village in 1854 and as a city in 1888. It was named for the junction and crossing of the New York Central and Pennsylvania railroads.

(E. T. HE.)

ALLIANCE. In a state system of multiple sovereignties, such as that of modern times which encompasses the whole world, those of the ancient Greek city-states or the principalities of Renaissance Italy, those of China in the "Spring and Autumn" period (722-481 B.C.) or of the Indian state system of Kautilya's *Arthashastra* (c. A.D. 325), it is almost a law of nature that one's enemy's enemy is one's own ally. Although Rome in a series of wars was able to establish its ascendancy over the ancient Mediterranean world, characteristically the aspirant for leadership, or hegemony, in a multistate system finds alliances formed against it long before the hegemony can be established. Thus, Louis XIV overreached himself and provoked the formation of a grand alliance against France. Napoleon's ambitions were thwarted by a series of coalitions formed against him. Ideology need not play the primary role in such coalitions. The Catholic Francis I of France made common cause in 1541 with the infidel Turks against the Catholic Charles V whose possessions almost encircled France. Protestant Sweden and Catholic France were able to act together in the Thirty Years' War.

In a state system in which none is able to establish hegemony, it follows that none is strong enough to stand completely alone against the united strength of the remaining states in the system. Threatened by any power or combination of powers greater than itself, a state may supplement its capacity for self-protection by pooling its strength with others. The end point of the alliance-building process may come when the great powers of a given era are formed into opposing armed camps, and conflict involving any two of them carries with it the threat of general war. The European great powers of the pre-World War I period, divided as they were into the triple alliance and the triple entente, typify the "two-camp" pattern.

Alliances are often designed to deter a would-be aggressor as well as to defeat the aggressor if the effort to deter fails. Secret agreements of alliance have the disadvantage of misleading the state which is the "target" of the agreement. British diplomacy

before 1914 is sometimes criticized for having, by military staff conversations, created an obligation of honour toward France in the event of a German attack without making it clear to Germany that Great Britain would range itself alongside France in the event of war. It has also been asserted that a commitment by the United States to support Great Britain and France might have discouraged Germany from embarking on either World War I or II.

Smaller states, when their geographical situation permits, often seek to avoid being aligned while the bipolar alliance pattern is being formed in periods of international tension. Thus, the Low Countries, the Scandinavian states, Switzerland and Spain avoided alliance commitments with either side before World Wars I and II. Other small states, perhaps making a virtue of necessity when they were clearly dependent for their security on a powerful neighbour, have entered into alliances in which they have for all practical purposes surrendered their policy-making initiative to their great-power partner. In the post-1945 era, in which the two great superpowers, the United States and the Soviet Union, dominated the world scene, such alliances became common. Within the Soviet-dominated world particularly, the alliance relationship seemed to have become a satellite relationship. (See WARSAW TREATY ORGANIZATION.)

Alliance by Treaty.—An alliance, under circumstances carefully defined in the treaty on which it is based, provides for combined action on the part of two or more independent states. The most critical clauses in a treaty of alliance are those which define the *casus foederis*, that is, the circumstances under which an ally becomes obligated to aid a fellow ally. Alliances are almost always defensive in form, although agreements among revisionist powers may obligate an ally to aid its partner even if that partner is the aggressor.

The North Atlantic treaty (1949), by which the United States and 15 other signatories in the post-1949 period committed themselves to support each other against attack in the North Atlantic-Mediterranean areas, is an outstanding example of an alliance which is meant to deter. As military technology has lengthened lead times in rearming and shortened the prospective period of decisive fighting in a general war, alliances have had to be supported by detailed military planning and co-ordinated protracted peacetime mobilization if the alliance is to be both credible in its objective of deterrence and effective if war should come. This is the explanation for the elaborate political and military organization created to put teeth in the North Atlantic treaty. Two years earlier the Inter-American Treaty of Reciprocal Assistance, "the Rio treaty," had provided "that an armed attack against an American state shall be considered as an attack against all American states." (See NORTH ATLANTIC TREATY ORGANIZATION.)

United States.—Although an alliance with France in 1778 helped the infant North American republic make good its challenge to Great Britain in the American Revolution, the government of the United States was not again to enter into a treaty of alliance until after World War II. It followed for more than a century and a half a diplomacy of "no prior commitment," although it did not thereby escape participating in any of the general wars of Europe which occurred after 1776. The Jeffersonian shibboleth, "entangling alliances with none!" reflected, however, prevailing U.S. belief that alliances would get the country into "other people's wars" without any compensating advantage. The country, it was believed, had more than enough power to protect itself against its new world neighbours or against the forces which any of the European nations could safely spare from the power struggle in Europe for a new world adventure.

Collective Security Agreement.—A collective security agreement differs from a treaty of alliance in a number of ways. It is more inclusive in its membership. The target of the agreement is an unnamed aggressor who may be one of the signatories. The object of the agreement is to deter the aggressor by the prospect that preponderant power will be organized against him. The threats to security after 1945 seemed so identifiable and precise that regional alliances and collective defense agreements underpinned by detailed military planning, as exemplified by the North Atlantic Treaty organization, supplemented, if they did not dis-

place, the collective security provisions of the charter of the United Nations. See COALITION; BAGHDAD PACT; SOUTHEAST ASIA TREATY ORGANIZATION; WAR; AGGRESSION. (W. T. R. F.)

ALLIBONE, SAMUEL AUSTIN (1816–1889), U.S. bibliographer and librarian is best known for his monumental three-volume *Critical Dictionary of English Literature and British and American Authors* (1854–71). He was born in Philadelphia, Pa., April 17, 1816, of French Huguenot and Quaker ancestry. He was privately educated and for many years was engaged in mercantile business in his native city. He, however, acquired a very unusual knowledge of English and American literature and compiled various anthologies and indexes. From 1867 to 1873, and again in 1877–79, Allibone was book editor and corresponding secretary of the American Sunday School union; and from 1879 to 1888 he was librarian of the Lenox library, New York city. He died at Lucerne, Switz., Sept. 2, 1889.

A two-volume supplement to his *Critical Dictionary* by John Foster Kirk was published in 1891.

ALLIER, a *département* of central France on the northern margin of the Massif Central, formed from the old province of Bourbonnais. Pop. (1954) 372,689. Area 2,850 sq.mi. It is bounded on the north by Nièvre, east by Saône-et-Loire, southeast by Loire, south by Puy-de-Dôme, southwest by Creuse and northwest by Cher. The *département* consists mostly of the foreland of the Massif Central and is traversed from south to north by the Allier river. The Loire river forms most of the eastern boundary, and the Cher flows parallel to the Allier across the west. The heights of the Forez region in the southeast are wet, with severe winters. The basin of the Allier, east of its tributary the Sioule, within the *département*, is a northward continuation of the Limagne in Puy-de-Dôme, and is known as the Limagne Bourbonnaise. It is less fertile, however, with ill-drained hollows and much heath, though reclamation has increased the farmland since the middle of the 19th century. Farming is concerned especially with fattening cattle and with production of pigs, poultry and fruit on small holdings.

There are scattered outcrops of coal in the area west of the Allier, especially at Commentry. The local coal, and iron ore brought from Berry by canal, provided early ironworks at Montluçon. Specialized metalworking industries, glass, pottery and chemical works, and a large rubber factory are active, but coal mining has greatly declined. Vichy (*q.v.*), in the south on the Allier, is the best-known spa in France.

Moulins (the capital), Montluçon (*qq.v.*) and Lalpisse are towns that give their names to the constituent *arrondissements*. The *département* is also the diocese of Moulins under the archbishop of Bourges. Its court of appeal is at Riom (*q.v.*), famous for the trials of statesmen of the third republic during World War II. Apart from Moulins, there are noteworthy medieval buildings at Souvigny (Cluniac priory), St. Menoux, Ebreuil, Gannat, Veauce and Ygrande (Romanesque churches), Huriel (castle and fine 11th-century church) and St. Pourçain-sur-Sioule (11th–18th-century church). The castle at Bourbon-l'Archambault was the seat of the first lords of Bourbon (see BOURBONNAIS). (AR. E. S.)

ALLIER RIVER (anc. ELAVER), in central France, flows into the Loire (*q.v.*), and is 255 mi. in length, 153 mi. of which are navigable. Its basin has an area of 5,573 sq.mi. Rising in the *département* of Lozère, its upper course is mostly through deep gorges following structural lines of weakness between the mountains of the Margeride and those of the Velay. It then traverses the basins of Langeac and Brioude, receives torrents from the mountains of Dore and Dôme and flows through a wide but shallow channel in the fertile wheat-growing plains north of Clermont-Ferrand, being joined by the Sioule above Moulins (*q.v.*), the chief town on its banks. It enters the Loire, 4 mi. A. of Nevers. (AR. E. S.)

ALLIGATOR, common name for large, long-snouted, cylindrical reptiles which along with gavials comprise the family Alligatoridae. Alligators, crocodiles, gavials and caymans are all crocodylians (see CROCODYLIA) which live in and along swamps, rivers and lakes of the tropics and subtropics. Two species are

still living: Alligator *mississippiensis*, of the southeastern United States, averaging ten feet in length, and the Chinese *A. sinensis*, along the Yangtze Kiang, reaching five feet. See also Index references under "Alligator" in the Index volume.

ALLIGATOR GAR: see GARFISH.

ALLIGATOR PEAR: see AVOCADO.

ALLISON, WILLIAM BOYD (1829–1908), U.S. senator from Iowa, was born near Ashland, O., March 2, 1829. He studied at Wooster academy, Allegheny college and Western Reserve college and then read law in Wooster, O. He practised law in Ashland, 1852–57. He was first a Whig, then in 1855 a member of the convention that founded the Republican party in Ohio, and a year later a delegate to the national Know-Nothing convention. In 1857 he moved to Dubuque, Ia., where he joined the Iowa Republicans. Elected to the house of representatives from Iowa in 1862, he served until 1871. He attained recognition on the committee on ways and means and was known as a friend of the railroad interests, narrowly missing involvement in the Crédit Mobilier (*q.v.*) scandal. In 1870 he was defeated in his campaign for the senate but won in 1872 and continued to represent Iowa in the senate until his death. A contender for the Republican presidential nomination in 1888 and 1896, he received and declined offers of the treasury portfolio in 1881 and 1889 and the department of state in 1897. Allison, Nelson W. Aldrich, Orville H. Platt and John C. Spooner ("The Four") dominated the senate in the early 1900s. Best known for the Bland-Allison act of 1878, he deserves more credit for his chairmanship of the senate committee on appropriations and his aid to Pres. Theodore Roosevelt in passing a railroad rate regulation bill in 1906 over Aldrich's opposition. Renominated in Iowa's first senatorial primary, he died two months later, Aug. 4, 1908, at Dubuque.

See also Leland L. Sage, *William Boyd Allison: a Study in Practical Politics* (1956). (L. L. S.)

ALLITERATION, the repetition of words with the same initial letter or sound for emphasis or stylistic effect. Like rhyme, it aids the memory, as may be seen in such proverbial phrases as "time and tide," "kith and kin." It is frequently used in titles of books and plays, in names of commercial products, athletic teams and nicknames. Purists in prose style frown upon it, but in fanciful prose, such as that of Robert Louis Stevenson, it is often used for decoration. In poetry it is regarded as legitimate embellishment. Thus A. E. Housman in "The Chestnut Casts His Flambeaux" underscores his bitterness: "Whatever brute and blackguard made the world." See also ALLITERATIVE VERSE (G. W. A.)

ALLITERATIVE VERSE. Although alliteration, the poetic device of beginning two or more words in a line of verse with the same sound, occurs in the poetry of many nations, the ancient Germanic races alone among Indo-Europeans developed a verse using it continuously as a main principle. (In Celtic poetry it was from the earliest times an important, if subordinate, principle, always remaining so in the Gaelic strict metres, while in Welsh it was developed very intricately as *Cynghanedd* [*q.v.*].) Such verse is extensively preserved in Old Norse, Old English (*e.g.*, *Beowulf* [*q.v.*]) and Old Saxon (*i.e.*, Old Low German), and there are considerable traces of it in Old High German. Practically all this surviving poetry represents developments of the common Germanic verse by Old English and Old Saxon monastic poets and Old Norse professional poets (scalds). Yet the Old High German *Hildebrandslied* and the Old English *Fight at Finnsburg* appear to have extensive remains of ancient Germanic heroic lays, which provide evidence for the antiquity of the broad essentials of the alliterative technique as seen elsewhere.

The Germanic alliterative line consisted of two parts. Effective alliteration fell on accented syllables only. unaccented syllables were not effective, even if they began with the alliterating letter. In the first half line, there might be one or two alliterating letters, in the second only one:

wuldres wealdend	woroldare forgeaf (<i>Beowulf</i> , 1.17)
Wedera leode	on wang stigon (<i>Beowulf</i> , 1.225)

However, alliterative verse also has severe rules of accent and quantity. Eduard Sievers by statistical analysis determined that

half lines are of five main rhythmic types (see Bibliography). This variety of rhythm disturbed many, for it leaves doubt how the verses are to be spoken. One theory is that every half line begins effectively from the first accented syllable, any unaccented syllable preceding that syllable being anacrusis. Another is that a half line not beginning with an accented syllable really begins with an initial stress, not in the words but in the musical accompaniment.

In Low German, alliterative verse is not known to have survived after 900 at the latest and in Old High German, rhymed verse was by that time already replacing it, especially in the great gospel poem *Evangelienbuch* of Otfrid. In English, strict alliterative verse is not found after 1066, but alliterative jingling became common in prose and to judge from rough verses inserted in the *Old English Chronicle*, such as those on Prince Alfred's death (1036), was used in popular poetry together with rhyme and parallelism. From such poetry Layamon (*q.v.*) derived his metrical technique and a fund of traditional diction for *Brut*, his epic on the legendary history of Britain (c. 1200). He lived in Worcestershire and alliterative verse clearly survived mainly in western England, for in the 14th century much was produced, often associated linguistically and by internal allusions with the west. The best known poems are *Piers Plowman* and *Sir Gawain* (see ENGLISH LITERATURE). The tradition spread through the north midlands to Scotland, where it was still practised by Alexander Montgomerie (*q.v.*) and Sir Patrick Hume of Polwarth under James VI.

This late alliterative poetry often uses rhyme as well. Sometimes all the verses rhyme; sometimes the succession of alliterative verses is broken by rhymed verses grouped at roughly regular intervals. In the Pearl, the main principle seems to be rhyme, but the sonnet-like 12-line stanzas are heavily ornamented with alliteration. Many poems, however, are purely alliterative. The metrical structure of the lines is less restricted than in the early Germanic languages. The alliteration also is freer: the second half line can contain more than one alliterating word, and restrictions on alliterating finite verbs are no longer regarded. Although the rhythm was very free, the second half line practically always had a feminine ending until the great loss of unaccented syllables in the 15th century. James VI, who had no doubt heard alliterative verses recited by their authors, called them "tumbling verse," as having extreme metrical freedom, but he regarded their basic rhythm as anapaestic. In England the tradition died earlier and the last alliterative poem is usually held to be *Scottish Field*, which deals with the battle of Flodden (1513).

In Old Norse, the Germanic alliterative verse survived least altered in the metre known as Fornyrthislag, but there are also much modified developments of it, especially *Malahattr* and *Ljotshattr*. But at least from 900, Norse poets combined many forms of rhyme and assonance with alliteration, and developed many strophic forms. After 1000, the practice of this verse became practically confined to Icelanders, among whom it continued, so that modern Icelandic poetry may be said to be directly descended from Germanic alliterative verse. See ICELANDIC LITERATURE.

ALLIUM (Lat. for "garlic"), a genus of plants of the family Liliaceae with about 325 species, found in central and south Europe, north Africa, the dry country of west and central Asia and North and Central America. The plants are bulbous herbs, with flat or rounded radical leaves and a central naked or leafy stem, bearing a head or umbel of small flowers, with a spreading or bell-shaped white, pink, red, yellow or blue perianth. Several species afford useful foods such as onion (*Allium Cepa*), leek (*A. Porrum*), shallot or eschallot (*A. ascalonicum*), garlic (*A. ursinum*) and chives (*A. Schoenoprasum*).

See CHIVES; GARLIC; LEEK; ONION; SHALLOT.

In North America there are about 70 native species, most numerous in the Rocky mountain region and in California where the majority are found. Among about ten species occurring in the eastern United States and Canada are the meadow garlic (*A. canadensis*), formerly used for food by the Indians; the wild leek (*A. tricoccum*), found in rich moods; the wild chive or rush garlic (*A. sibiricum*), found from Maine to Alaska; the nodding wild onion (*A. cernuum*), with inverted clusters of handsome flowers; and the prairie wild onion (*A. stellatum*), of rocky banks in the interior. The field garlic (*A. vineale*) of Europe, widely naturalized in meadows and pastures, is a troublesome weed tainting the flavour of butter.

ALLOA, a small burgh and the administrative centre of Clackmannanshire, Scot., lies on the north bank of the river Forth, 8 mi. E. of Stirling and almost equidistant from Edinburgh, Glasgow and Perth. Pop. (1961) 13,895. Much of the material of the 17th-century church, of which only the spire remains, was used in the construction of the 19th-century Gothic parish church of St. Mungo. To the southeast are the ruins of Alloa tower (13th century), once the stronghold of the powerful family of Erskine, descendants of the earl of Mar. Mary, queen of Scots, and James VI of Scotland spent part of their youth at Alloa tower which, in 1566, Mary revisited with Lord Darnley.

The chief industries of Alloa are yarn spinning, brewing, electrical and general engineering, ship repairing, iron founding and the manufacture of hosiery, glass containers, agricultural implements, tiles and bitumen. In the vicinity of the town are two distilleries, a yeast factory, a tanning works and paper mills. Alloa is connected to Stirling and Dunfermline by rail and above the town the Forth is crossed by a railway bridge. Immediately adjoining Alloa are New Sauchie to the northeast and Tullibody to the northwest. Coal mining in the district is extensive.

ALLOBROGES, an ancient Celtic tribe living in the northeast of Gallia Narbonensis; *i.e.*, in the part of southeastern France bounded by the Rhône to the north and west, the Isère to the south and the Graian Alps to the east, and in the part of Switzerland around Geneva. If the name is rightly interpreted as meaning "aliens," they would seem to have driven out the original inhabitants. Their chief towns were Vienna (Vienne), Genava (Geneva) and Cularo (later Gratianopolis, whence Grenoble). The Allobroges are first recorded in history when Hannibal passed through their territory in 218 B.C. After the subjugation of the Salluvii by the Romans in 123 B.C., the Allobroges were attacked and finally defeated (121 B.C.) at the junction of the Rhône and the Isère rivers by Q. Fabius Maximus, who was therefore called Allobrogicus. They were incorporated in the new province of Transalpine Gaul.

Roman extortions at length provoked a brief revolt in 61 B.C., but they refused to listen to the overtures of Catiline (63) or of Vercingetorix (52) and were protected by Julius Caesar against Helvetian attack in 58. Thereafter they remained loyal.

ALLOUTION, before Pius XII, was a term reserved almost exclusively to the address made by the pope in the course of a secret consistory (*q.v.*). With Pius XII (1939-58), however, addresses (*allocutiones*) to various congresses and conventions—of doctors, scientists, jurists, sodalities, sociologists, labourers, etc.—became the occasion of significant papal declarations on points of moral theology especially pertinent to the respective audiences. (J. J. RE.)

ALLOPHANE: see CLAY AND CLAY MINERALS.

ALLORI. CRISTOFANO (sometimes called BRONZINO) (1577-1621): Italian portrait painter, among the foremost exponents of the mannerist late Florentine school, was the son of Alessandro Allori (1535-1607). Cristofano, who was born at Florence, received his first lessons in painting from his father, but becoming dissatisfied with the hard anatomical drawing and cold colouring of the latter he entered the studio of Gregorio Pagani (1558-1605), who was one of the leaders of that later Florentine school which endeavoured to unite the rich colouring of the Venetians with the correct drawing of Michelangelo's disciples. His technical skill is proved by the fact that several copies he made after

Correggio have been taken to be duplicates made by Correggio himself.

The finest of all his works is his "Judith and Holofernes," in the Pitti palace. The model for the Judith was his mistress, the beautiful Mazzafirra, who is also represented in his Magdalene; and the head of Holofernes is generally supposed to represent his own.

ALL-OR-NONE LAW in physiology relates response to stimulus in excitable tissues. It was first established for the contraction of heart muscle by H. P. Bowditch in 1871. Describing the relation of response to stimulus, he stated, "An induction shock produces a contraction or fails to do so according to its strength; if it does so at all, it produces the greatest contraction that can be produced by any strength of stimulus in the condition of the muscle at the time." It was believed that this law was peculiar to the heart and that the other highly specialized and rapidly responding tissues—skeletal muscle and nerve—responded in a different way, the intensity of response being graded according to the intensity of the stimulus. This impression arose because nerves and muscles are composed of hundreds or thousands of individual fibres, and since some of these do not respond to a weak stimulus the total response of the organ is apparently subject to such gradation. It has been established, however, that the individual fibres of both skeletal muscle and nerve respond to stimulation according to the all-or-none principle. This does not mean that the size of response is immutable. Functional capacity varies with the condition of the tissue. The response to a stimulus applied during recovery from a previous response is subnormal. But the size of response is independent of the strength of stimulus, provided this be adequate. These facts show that the functional response is essentially alike in these specialized tissues—heart, skeletal muscle and nerve; its precise nature is not known, but it resembles an explosive reaction in that it depletes for a time the available store of energy on which it depends. (A. Fo.)

ALLOSAURUS, a large carnivorous dinosaur of the Jurassic period (from 160,000,000 to 230,000,000 years ago). Fossils from North American rock strata show it to have been over 30 ft. long (including its counterbalancing tail) and to have progressed on its hind legs. See DINOSAUR.

ALLOTROPY: see POLYMORPHISM.

ALLOTT, ROBERT (fl. 1600), was probably the editor of a book of "elegant extracts!" of Elizabethan poetry entitled *Englands Parnassus* (1600). Nothing more is known of him, except that he compiled a prose anthology called *Wits Theatre of the Little World* (1599). *Englands Parnassus* is a collection of quotations, arranged alphabetically under various subject headings, from the works of contemporary poets. Allott assigns each excerpt to its author, though not always correctly. Although as an editor he was neither scrupulous nor accurate, his work succeeds in preserving some poetry of merit, in identifying the authors of a number of hooks and in giving an indication of contemporary taste. The best modern edition is that of Charles Crawford (1913), who gives reasons for attributing the work to Allott.

ALLOUEZ, CLAUDE JEAN (1622–1689), French Jesuit missionary to New France, who has been called the founder of Catholicity in the west, was born at St. Didier on June 6, 1622. He entered the Society of Jesus at Toulouse, was ordained priest in 1655 and sailed for Quebec in 1658. He was stationed at settlements along the St. Lawrence river until his appointment in 1663 as vicar-general of the northwest. He traveled extensively, preaching to the Indians and establishing missions, chiefly in the territory to the southwest of the Great Lakes. His own accounts of his activities are frequently quoted in *The Jesuit Relations*. He was a predecessor and later a colleague of Jacques Marquette (*q.v.*), for whom he wrote a book of prayers in Illinois and French. Allouez's last years were spent mostly among the Miamis of the St. Joseph river in southeast Michigan, and he died in one of the Ottawa missions near the site of Niles, Mich., on the night of Aug. 27–28, 1689.

delphia, 62.12–24 (1941); F. J. Nelligan, "The Visit of Father Allouez to Lake Nipigon in 1667," *Report of the Canadian Historical Association*, pp. 41–52 (1956). (P. Cx.)

ALLOWAY, a hamlet in Xyrshire, Scot., 2½ mi. S. of Ayr. is famous as the birthplace of Robert Burns (*q.v.*). The thatched cottage where he was born in 1759 became the property of the Burns trust in 1881, and in 1900 a museum was built adjacent to it where many Burns manuscripts and relics are kept. A Grecian round temple with nine fluted Corinthian columns was built in 1820 as a monument to Burns, and inside are the Bibles exchanged by Burns and "Highland Mary," Jean Armour's wedding ring and other mementos of the poet. Figures of "Tam o'Shanter" and "Souter Johnnie" stand in a grotto in the garden.

ALLOYS have been defined as metallic substances which contain more than one chemical element. Logically this definition is unsatisfactory because no metallic element can be obtained in a condition of absolute purity, and if applied strictly the definition would result in all nominally "pure" metals being classed as alloys. The definition may be accepted on the understanding that, when dealing with nearly pure metals, there is no sharp dividing line between an impure metal and an alloy.

Most alloys consist essentially of two or more metallic elements and are classed as binary, ternary, quaternary or more complex according to the number of constituent elements. Nonmetallic elements may also be present, notably carbon, nitrogen, oxygen, phosphorus and sulfur. These are often accidental impurities introduced from the original ore or during the production of the alloy. In some cases, however, such as that of carbon in steel or cast iron: the nonmetallic element is an essential constituent: the presence of which determines the properties of the alloy.

Industrial alloys are classed as ferrous (iron base) and non-ferrous; the first named, having iron as the main constituent, form the larger group. The most important ferrous alloys are those of iron and carbon, and where the carbon content is less than 1.3% by weight they are known as steels, while cast iron and malleable iron contain 2% to 5% carbon by weight. (See IRON AND STEEL INDUSTRY; STEELS, ALLOY; CAST IRON.) The terms "alloy steel" and "special steel" are used to describe steels in which metals other than iron are present in relatively large amounts. Thus stainless steel (*q.v.*) contains chromium (*q.v.*) and nickel, a common composition being 18% chromium and 8% nickel by weight.

Of the nonferrous alloys, those of copper have been known since the Bronze Age. The brasses (see BRASS) are essentially alloys of copper and zinc; the copper content usually varies between 57% and 70% by weight. The bronzes (see BRONZE) are essentially alloys of copper with 5% to 10% tin by weight. In early writings the distinction between these two classes of alloy is not always clear, and the word "brass" is used to describe what were really impure bronzes. The original copper-base coinage alloys were impure bronze.

Coinage bronze (95% copper, 4% tin and 1% zinc) was adopted by France in 1851; the 20th-century copper coins of Great Britain are made of a copper alloy containing 95.5% copper, 3% tin and 1.5% zinc. (See also COBALT.)

The expansion of the aircraft industry during 1910–40 led to the development of light alloys, of which those of aluminum (see ALUMINUM: *Alloys and Uses*), having densities of the order 2.7 g. per cubic centimetre, are the most important. With magnesium-base alloys (see MAGNESIUM) the density can be reduced to 1.81 g. per cubic centimetre, but the mechanical properties of these alloys are not, in general, so good as those of aluminum alloys. The melting points of aluminum (660° C.) and magnesium (650° C.) are relatively low, and the strength of their alloys falls rapidly between 300° and 400° C. The increasing speed of flight of airplanes means that these temperatures may be exceeded as the result of friction between the air and the wing of the airplane, and this stimulated the search for new constituent materials. Great interest was attached to the use of titanium (*q.v.*) which has a melting point of 1,660° C., and a density of 4.5 g. per cubic centimetre, though it appeared unlikely that titanium-base alloys could be used above 700° C.

The following discussion deals with the more technical aspects

of the preparation of alloys, their structure and their electrical properties.

For more general information about manufacture, uses, etc., see articles on various alloys, as **BABBITT'S METAL**; **BRASS**; **BRONZE**; etc., and on processes, as **ANNEALING**; **CHILL HARDENING**; **HEAT-TREATMENT**; **SURFACE TREATMENT**; etc. For discussion of the various concepts and theories of structure and properties referred to, see **CRYSTALLOGRAPHY**; **METALLURGY**; **MINERALOGY**.

PREPARATION OF ALLOYS

The most common way of preparing alloys is by the melting together of the constituent metals. If the melting points of the metals differ widely, or if one is relatively very reactive, it may be convenient to prepare first a master alloy, portions of which are then melted with the remaining metals. According to the nature of the alloy, the melting process may be carried out in furnaces fired by gas, coke or oil. Electrical heating, by resistance, induction or arc-melting methods, is also used. A few alloys are prepared directly by the process in which the metals are extracted from their ores. Thus pig iron is prepared by the reduction of iron ore in the blast furnace, and steels are prepared by the further purification of pig iron (see **BLAST FURNACE**; **CAST IRON**; **IRON AND STEEL INDUSTRY**; **CONVERTER STEEL**; **OPEN-HEARTH STEEL PROCESS**). Alloys may also be prepared by mixing finely divided powders of the constituent metals, and compacting the mixture under high pressure, followed by sintering of the compact.

For further details of the preparation of alloys, see under the names of the constituent metals (see also **FURNACE**, **METALLURGICAL**; **POWDER METALLURGY**; etc.).

STRUCTURE OF ALLOYS

The properties of alloys depend upon their structure, and are best understood by considering the structures of pure metals. Solid metals are crystalline in the sense that, although they may not exhibit external plane faces, their constituent atoms are arranged in definite three-dimensional patterns or lattices. The great majority of the metals crystallize in one or more of the three typical metallic structures shown in fig. 1. In the body-centred cubic structure the unit cell is a cube with one atom at the centre, and one at each corner. In the face-centred cubic structure, the unit cube has one atom at each corner, and one at the centre of each face. In the close-packed hexagonal structure the atoms are arranged in hexagonal layers (fig. 1) stacked so that the third layer is vertically over the first; the axial ratio is equal to the height of the cell divided by the length of the side of the hexagon. Each of the three typical structures gives rise to a characteristic X-ray diffraction pattern (see **CRYSTALLOGRAPHY**; **X-RAYS**) from which the size of the unit cell can be calculated. The "atomic diameter" of an element may be defined as the closest distance between two atoms in the crystal of the element concerned, and these atomic diameters play an important part in determining the structure of alloys.

FIG. 1.—THREE METALLIC STRUCTURES SHOWING (A) FACE-CENTRED CUBE; (B) BODY-CENTRED CUBE; (C) CLOSE-PACKED HEXAGONAL STRUCTURE WITH AXIAL RATIO 1.633

term annealing was originally used to describe the process in which a metal was heated and allowed to cool slowly in a furnace, and in industrial ferrous metallurgy it is used in this sense. In scien-

tific metallurgy the term is used to describe the heating of an alloy.) If the alloy is then rapidly cooled or quenched (e.g., by immersion in cold water) it is sometimes possible to retain the structure of the higher temperature. Examination then shows that in an alloy of two metals, A and B, the first small additions of B to A result in the formation of a homogeneous alloy whose X-ray diffraction pattern is of the same type as that of the metal A. This implies that the essential structure of the alloy is the same as that of the metal A, and such alloys are called primary or terminal solid solutions. A polished and etched section of such an alloy shows a number of polygonal grains (fig. 2), each of which is a single crystal containing, as do single crystals of pure metals, dislocations and other imperfections. (See **CRYSTALS**, **DISLOCATION OF**.)

Solid solutions are of two main types. In the interstitial solid solutions the solute atoms occupy the holes or interstices between the solvent atoms, and in this kind of solid solution there is nearly always an expansion of the solvent lattice. Interstitial solid solutions are formed only if the solute atom is very much smaller than that of the solvent metal. Hydrogen, boron, carbon, nitrogen and oxygen are the main elements which dissolve in metals in this way. The solid solution of carbon in face-centred cubic or γ -iron is stable only at high temperatures, but its existence determines the structure and many of the properties of steels (see **CAST IRON**).

For further discussion of solid solutions see **BRASS**; **METALLOGRAPHY**; *Metals and Alloy Structure*. Many minerals occur in nature as solid solutions: for example, see **FELDSPAR**. See also **GEOCHEMISTRY**: *Crystallization of Magma*; **PETROLOGY**: *Habit of Igneous Rocks and Plutonic Complexes*.

When the two kinds of atom are more nearly equal in size, the solid solution is of the substitutional type, and the atoms of the solute replace those of the solvent so that the two occupy a common lattice.

The extent of a primary solid solution may vary from complete miscibility of two or more metals in the solid state (e.g., silver and gold) to a solubility which is too small to be detected by ordinary methods. Complete miscibility in the solid state is possible only if the metals concerned have the same crystal structure, although a difference between the axial ratios of close-packed hexagonal metals does not prevent the formation of continuous solid solutions between two metals (e.g., magnesium and cadmium).

The fitting together of different atoms on a common lattice is possible only if their sizes do not differ too greatly. If the atomic diameters of two metals (as defined above) differ by more than about 15%, the size factor is unfavourable, and the primary solid solutions are usually restricted to a few atomic per cent. Where the atomic diameters are more nearly equal, the size factor is favourable, and wide solid solutions may be formed, provided that other factors are also favourable, but considerations of size factor alone do not permit the prediction that a wide solid solution must be formed.

When two metals differ greatly in electrochemical characteristics there is a general tendency for the primary solid solutions to be restricted, and for stable intermetallic compounds to be formed.

Thus, with magnesium as solvent, the size factor for antimony is favourable, but antimony is so electronegative compared with magnesium that an extremely stable compound, Mg_3Sb_2 , is formed, and the primary solid solutions in magnesium and antimony are very restricted.

When the proportion of solute is less than the solubility limit at a particular temperature, the alloy will be homogeneous after

annealing to equilibrium at this temperature. When the percentage of solute exceeds the solubility limit a second phase appears and, after polishing and etching, a microstructure will show two phases (in certain alloys the structure is revealed without etching; see fig. 3). In some alloy systems (e.g., copper-silver) the only solid phases formed are the two primary solid solutions. In other alloys (e.g., copper-zinc) intermediate phases with characteristic crystal structures are formed, and on exceeding the limits of the primary solid solution, the alloy consists of a mixture of the primary solid solution and of the intermediate phase.

Short-Range and Long-Range Order: Superlattices.—The formation of a substitutional solid solution is accompanied by distortion and strain of the lattice of a solvent, A, by a solute, B. Primary solid solutions are often said to have a random arrangement of the two kinds of atom on a common lattice; but in most solid solutions there is a tendency for solute atoms to avoid being closest neighbours because in this way the strain energy is lowered. This tendency for there to be fewer B-B neighbours than is required by a random arrangement is said to give rise to "short-range order." In a few alloys (e.g., aluminum-zinc) the reverse effect is found, and solute atoms tend to cluster together to a greater extent than required by a random arrangement.

In many alloys where a wide solid solution is formed but the size factor is not too favourable, solid solutions of some compositions show short-range order at high temperatures but, on annealing at low temperatures, atomic rearrangement takes place so that the different atoms form a definite pattern on the lattice. Thus copper and gold are both face-centred cubic metals and form continuous solid solutions at high temperatures. On annealing the alloy of composition Cu_3Au at low temperatures the atoms rearrange themselves to form the structure of fig. 4. If the distinction between the atoms is ignored this structure is face-centred cubic, but the long-range ordered structure or superlattice of fig. 4 is such that no two gold atoms are closest neighbours, and this arrangement lowers the strain energy of the alloy.

Intermediate Phases and Intermetallic Compounds.—In many alloy systems the only solid phases found are the primary solid solutions, with superlattices in some cases. In other systems some alloys of intermediate composition, after annealing to equilibrium, are homogeneous but with crystal structures different from those of the constituent metals. Such phases may be of fixed or variable composition, and in the early days of metallography it was thought that all such phases were based on definite chemical compounds of the two metals. It was later recognized that, although in some cases intermediate phases may correspond with the existence of definite compound molecules, many or most intermediate phases are structures in which the atoms are held together by electron-sharing similar to that existing in pure metals, and involving no more chemical combination than exists between the atoms in a crystal of a pure metal. Some writers use the term

intermetallic compound to describe those intermediate phases whose compositions are only very slightly variable, and the term intermediate phase to describe those of variable composition (see INTERMETALLIC COMPOUNDS).

When one metal is very electropositive and the other very electronegative, intermediate phases may be formed whose compositions correspond with those expected from the normal valencies of chemistry (e.g., Mg_3Sb_2 , Mg_2Sn). Some intermediate phases are readily understood as examples of covalent bonding (see VALENCE). Thus the well-known diamond structure involves a tetrahedral arrangement of atoms in which each atom completes an octet of electrons by sharing one electron with each of four neighbours (e.g., diamond, silicon, germanium and grey tin). In combinations such as gallium-arsenic, zinc-selenium or copper-bromine there are eight valency electrons to two atoms (i.e., an average of 4) and although these do not form the diamond structure they do crystallize in structures in which each atom has four neighbours arranged tetrahedrally. Some of these covalent phases have valuable properties as semiconductors (see ELECTRICITY, CONDUCTION OF *Semiconductors*).

Most normal chemical compounds are insulators because all the electrons exist in stable groups. The normal valencies are an expression of the way in which these stable groups may be formed by electron-sharing (covalency) or electron-transference (ionic compounds), (see VALENCE). Most intermediate phases in alloys are conductors of electricity and this implies that some electrons are left free and consequently the atomic ratios are in general different from those expected from the normal valencies. (This description is oversimplified and the full explanation involves the Brillouin-zone characteristics.)

In alloys of copper, silver and gold with elements of the B subgroups and the short periods of the periodic table (see PERIODIC LAW: *The Transition Elements*) intermediate phases of definite crystal structures often occur at characteristic ratios of valency electrons to atoms. Thus in copper-zinc, copper-aluminum and copper-tin alloys intermediate phases of variable composition are found whose homogeneity ranges include the atomic ratios CuZn , Cu_3Al and Cu_3Sn respectively. Using the normal valencies (copper 1, zinc 2, aluminum 3, tin 4) these all correspond to a ratio of 3 valency electrons to 2 atoms, i.e., to an electron concentration of 3.2.

Phases of a characteristic γ -brass structure occur at an electron concentration of 21:13 (e.g., Cu_5Zn_8 , Cu_9Al_4). Such phases are known as electron compounds or Hume-Rothery phases, and they are usually of variable composition, and do not entail the formation of compound molecules—the formulas given above are merely to indicate the compositions involved. Ternary electron compounds can be obtained in which the characteristic structure is retained, provided that the composition is adjusted to maintain the required electron concentration.

Electron compounds are formed only when the size factors are not too unfavourable, and the electrochemical factors are small. In some alloy systems where the sizes of the atoms differ appreciably, intermediate phases exist whose structures are determined by characteristic ratios of the atomic diameters of the constituent atoms. Thus the intermediate phases Cu_2Mg , Au_2Bi and KBi_2 have the same Cu_2Mg -type of crystal structure, and if the formulas are regarded as of the AB₂ type, all are characterized by the ratio of the atomic diameters being of the order 1.2. Such phases are called Laves phases. Ternary phases also exist whose structures are determined by the relative sizes of the atoms concerned.

The above examples are of the simplest type of intermediate alloy phase. In most cases all three factors (size factor, electron concentration and electrochemical factor), together with others not yet understood, control the stability of the phase and the science of alloy structures is correspondingly complex.

See SOLID STATE PHYSICS: *Physical Properties of Solids*.

FIG. 4.— Cu_3Au SUPERLATTICE STRUCTURE

PROPERTIES OF ALLOYS

Electrical Properties.—The metallic elements are electronic conductors of electricity, whose electrical resistivities diminish with falling temperature and become zero at the absolute zero. The perfectly free motion of electrons in the strictly periodic field of the crystal of a pure metal is the result of the wavelike properties of the electron (see QUANTUM MECHANICS: *Wave Mechanics*) and anything which tends to destroy the perfect periodicity (*e.g.*, increasing amplitude of thermal vibrations with rise of temperature) tends to increase the electrical resistance.

FIG. 5.—ELECTRICAL RESISTIVITY/COMPOSITION CURVE FOR (A) TWO METALS, X AND Y, WHICH FORM CONTINUOUS SOLID SOLUTIONS AND (B) A SOLID SOLUTION OF LIMITED EXTENT

The lattice distortion accompanying the formation of a solid solution therefore produces an increase in the resistivity.

Where two metals form a continuous solid solution, the typical resistivity/composition curve has the inverted-U shape of fig. 5(A), and where partial miscibility occurs, the relation is of the type of fig. 5(B). The kink in the curve in fig. 5(B) occurs at the boundary of the solid solution, and the subsequent line may slope upward or downward according to the resistivity of the second phase which appears when the limit of

the solid solution is exceeded.

The temperature coefficient of electrical resistance of a pure metal is lowered by the formation of a solid solution, and for this reason solid-solution alloys such as Manganin, a copper-base alloy of manganese and nickel (82% Cu, 15% Mn, with FeNi), are used for instruments whose electrical resistances are required to vary as little as possible with changing temperature.

In the formation of a superlattice (see above) the irregular structure of the solid solution is replaced by an ordered structure, and the change is therefore accompanied by a fall in the resistivity, and an increase in the temperature coefficient of resistance.

Intermediate phases of fixed, or almost fixed, composition have their characteristic resistivities which are generally higher than that of at least one constituent metal, and in some cases are very much higher than those of both constituents. Where an intermediate phase is of variable composition, the resistivity varies with the composition, and if ordering of the atoms (superlattice formation) occurs, the resistivity may have a minimum value at the composition concerned.

Other electrical properties (*e.g.*, thermoelectric power) show analogous behaviour, in that intermediate phases of fixed composition have characteristic values of the property concerned; in phases of variable composition there is a continuous variation with composition, while maximum or minimum values may occur if long-range ordered structures are formed at particular compositions.

Mechanical Properties.—From the earliest times it has been known that many alloys are harder and stronger than pure metals. By far the greatest use of alloys is for construction purposes, and most work on alloys is ultimately directed toward the improvement of mechanical properties.

The weakness of pure metals is the result of the facts (1) that the three typical crystal structures (fig. 1) are such that deformation of the crystal can take place by the slipping of planes of atoms over one another and (2) that real metallic crystals do not possess a perfectly regular arrangement of the atoms, but contain imperfections known as dislocations (see CRYSTALS, DISLOCATION OF) whose presence enables the slipping process to take place relatively easily. When a solid solution is formed the slipping process is hindered because the solute atoms interact with the dislocations, and the lattice distortion makes slip more difficult. Solid solutions are, thus, stronger and harder than their constituent metals. The increase in hardness of a solid solution is generally accompanied by a decrease in ductility. There are, however, some

solid solutions such as cartridge brass (copper 70%, zinc 30%) which retain a remarkable capacity for mechanical deformation. Provided that the loss in ductility is not too great, solid-solution alloys are in general stronger and more useful mechanically than are pure metals, but the degree of strengthening which can be obtained is usually not very great.

Of the intermediate phases of variable composition in alloys, a few of those with suitable crystal structures (*e.g.*, the body-centred cubic β -brasses containing 40% to 50% zinc) have mechanical properties resembling those of primary solid solutions. In general, however, intermediate phases, and particularly those of nearly fixed composition, tend to be hard but brittle, and are seldom of use for construction purposes. Sometimes the hardness is extreme, as in the tungsten carbides which are among the hardest substances known, and are used for the tips of cutting tools.

In many alloy systems the primary or terminal solid solutions are of greater extent at high than at low temperatures. In such cases, if the percentage of solute does not exceed the solubility limit at high temperatures, the alloy on annealing at a suitable temperature will become a homogeneous solid solution, and this structure may be retained on quenching (*e.g.*, in cold water). The resulting alloy is said to be "homogenized," and although harder than a pure metal, it may be sufficiently soft and ductile to undergo the severe deformations which occur in the industrial processes of rolling, pressing, etc. If the product is then reannealed at a temperature sufficiently low for the solid solution to be supersaturated, but sufficiently high for atomic movement to take place, precipitation of the excess of solute will occur with the production of an alloy consisting of small particles of a solute-rich phase embedded in a matrix of solid solution. A polyphase alloy of this kind is in general harder than the same alloy in the form of a homogeneous solid solution, because the small particles of the disperse phase interfere with the slipping process which accompanies plastic deformation. The process is known as precipitation hardening, and in alloys of low melting point the mere holding of the homogenized specimen at room temperature may result in precipitation gradually taking place. The phenomenon was discovered in certain alloys of aluminum, notably duralumin (*q.v.*), which were found to undergo increase in hardness on standing at room temperature, and the process was called age-hardening or aging. Later work showed that, although precipitation of a phase from a solid solution was usually accompanied by an increase in strength and hardness, the greatest hardness did not correspond to complete precipitation. The precipitation process was found to occur in definite stages, and the greatest hardness usually corresponded to an intermediate structure in which distortion and strain of the lattice of the solid solution made the slipping process more difficult. The phenomenon of age-hardening is thus complicated, and the details vary from one alloy to another.

In many alloys the structure stable at high temperatures is different from that stable at low temperatures and, on slow cooling, transformation from one structure to another will occur, while rapid cooling or quenching may retain the high-temperature structure. In some cases even the most rapid cooling may not be able to prevent structural changes from taking place, and intermediate structures of great hardness may be formed. Thus in plain carbon steels, carbon is almost insoluble in body-centred cubic or α -iron which is stable at low temperatures, but is slightly soluble in the face-centred cubic or γ -iron which is stable between 910° C. and 1,389° C.; the solid solution is known as austenite, and is of the interstitial type (see IRON AND STEEL INDUSTRY: *Austenite*). If the alloy is homogenized in the austenitic region, and then slowly cooled, the iron matrix changes from the face-centred cubic to the body-centred cubic form, and the carbon is converted into iron-carbide Fe_3C , known as cementite. If the alloy is quenched, the iron matrix transforms almost instantaneously by a shear mechanism, and the carbon atoms have no time in which to diffuse to form cementite, but are retained in the body-centred modification of iron whose structure is distorted from body-centred cubic to body-centred tetragonal (see CRYSTALLOGRAPHY). The resulting structure, known as martensite, is in a state of great strain, and is extremely hard. If it is reheated or tempered at a comparatively

BY COURTESY OF RESEARCH LABORATORIES, THE BRITISH ALUMINIUM CO. LTD.

FIG. 6.—COMPLEX STRUCTURE IN 1% Fe, 6% Cu, 6% Si, 3% Mg ALLOY, UNETCHED ($\times 200$)

MgSi tarnished black; silicon medium tone in relief; β (Cu-Fe) light needles in relief; CuAl_2 light, slightly in relief; λ (Al-Cu-Mg-Si) very flat, slightly darker than CuAl_2

low temperature, change to the stable structure (a-iron + cementite) begins to occur, but the process is not simple and usually involves the formation and decomposition of intermediate phases. Analogous changes are found in many alloys (e.g., copper + 10% aluminum) in which a phase which is stable at high temperatures decomposes into more than one phase on cooling.

The structures of cast alloys are often very complicated (see fig. 6). In relatively simple cases they can be understood by reference to what are called constitutional or equilibrium diagrams. Such diagrams refer only to conditions of true equilibrium. They are not concerned with the arrangement of the constituents in the alloy, but show the temperature-composition ranges over which different phases, or mixtures of phases, are stable. Thus, fig. 7 shows a hypothetical equilibrium diagram of two metals, A and B. The primary solid solution of B in A is α , and β that of A in B, while γ is an intermediate phase. The curves ae and ce give the temperature composition limits above which the alloy is totally liquid. The line ae is the liquidus curve, representing the beginning of solidification of the solid solution α , and ad is the solidus curve, representing the end of solidification, provided that the rate of cooling is sufficiently slow for equilibrium conditions to be maintained. The corresponding liquidus and solidus curves for the solidification of the solid γ phase of composition between f and c are ce and cf . The liquidus curves ae and ce meet at the minimum or eutectic point e , and at this temperature liquid of composition e is in equilibrium with solid α of composition d and solid γ of composition f . On cooling below this temperature the liquid of composition e solidifies to a mixture of the two solid phases. The lines dl and fm are the solid solubility curves of the α and γ phases, and alloys within the field $adlk$ consist of homogeneous α -solid solution. Alloys within the field $defml$ consist of a mixture of solid α and solid γ , and an alloy x contains a phase of composition y together with γ -phase of composition z . Similar constructions give the compositions of phases in equilibrium in other two-phase fields.

FIG. 7.—HYPOTHETICAL DIAGRAM OF THE EQUILIBRIUM OF TWO METALS, A AND B

Diagrams such as fig. 7 refer to equilibrium conditions, and a consideration of the above description will show that when an alloy is cooled, equilibrium will in general only be maintained if diffusion takes place in the solid phases. Since diffusion is a slow process, the structures of cast alloys tend to show a wider range of constituents and compositions than would result from cooling under equilibrium conditions. Nevertheless, diagrams of this nature are of great value in understanding the structure of cast alloys.

For ternary systems the equilibrium diagram requires two dimensions to represent the composition and a third dimension for the temperature.

The mechanical properties of an alloy depend greatly on the spatial arrangement of the particles of the different phases. They are also profoundly altered by mechanical deformation, but these effects are not shown on the equilibrium diagram. See FUSIBLE ALLOYS; see also Index references under "Alloys" in the Index volume.

ALLPORT, GORDON WILLARD (1897–), U.S. psychologist, noted for his work in the theory of personality, was born in Montezuma, Ind., on Nov. 11, 1897. Trained at Harvard university (B.A., 1919; Ph.D., 1922), he taught psychology there after 1930.

Although Allport made important contributions to the analysis of prejudice (*The Nature of Prejudice*, 1954), he is most respected for his creative work in the theory of personality (*Personality: a Psychological Interpretation*, 1937; *Becoming*, 1951).

Best known is his theory of functional autonomy of motives; i.e., that adult motives develop from, but become independent of, infantile drives, an important shift from Freudian theory. His approach favours emphasis on the present problems of an adult personality as against infantile emotions and experiences. In *Becoming* he stressed the importance of the self and the uniqueness of the adult personality, in contradistinction to behaviourist and Freudian views. The self, he holds, is an identifiable organization within each individual, available for scientific study by suitable methods. As such it accounts for the unity of personality, for the higher motives and for the continuity of personal memories. By showing that a psychology of self need not be mystical, Allport greatly influenced mid-20th-century theorizing about personality.

(R. SR.)

ALL SAINTS, FESTIVAL OF, on Nov. 1, commemorates all the saints of the church, both known and unknown. Its origin cannot be traced with certainty, and it has been observed on various days in different places. A feast of all martyrs was kept in the east by Ephraem Syrus (d. c. 373) on May 13, which may have determined the choice of May 13 by Pope Boniface IV when he dedicated the Pantheon in Rome as a church in honour of the Blessed Virgin and all martyrs in 609. The first evidence for the broadening of the festival to include all saints as well as all martyrs and for its celebration on Nov. 1 is the dedication on that day by Pope Gregory III (731–741) of a chapel in honour of all saints at St. Peter's, Rome. In 800 the solemnity of all saints was kept by Alcuin on Nov. 1, on which day also it appears in a 9th-century English calendar. In 837 Gregory IV ordered its general observance, and in 1480 Sixtus IV gave it an octave.

Eastern Christendom honours all saints on the first Sunday after Whitsunday. In medieval English usage the festival was known as All Hallows, and its eve is still called Halloween (q.v.). See also CHURCH YEAR.

ALL SAINTS BAY (BAHIA DE TODOS OS SANTOS), a land-locked bay and natural harbour on the eastern coast of Brazil, named by its discoverer, Amerigo Vespucci, who, it is said, first entered the bay on All Saints day, Nov. 1, 1501. It has been an important Brazilian naval base since colonial times. The bay is about 20 mi. wide and 23 mi. long and is situated about 738 mi. N.E. of Rio de Janeiro. Salvador or Bahia (pop. [1960 est.] 656,000), the principal seaport and capital of the state of Bahia, is on the peninsula that separates the bay from the Atlantic, at 13° S. and 38° 30' W. The harbour at Salvador is protected by two detached breakwaters, one 1,300 yd. long and the other about 1,000 yd. long. The main channel is dredged from the 2-mi.-wide Atlantic entrance between Salvador and the island of Itaparica to the port of São Francisco do Conde, outlet for the petroleum refinery at Mataripe. Brazil's only producing oil field is on the northeast shore of the bay between Candeias and Lobato.

(R. E. P.)

ALL SOULS' DAY (Nov. 2, or Nov. 3 if Nov. 2 is Sunday), the day appointed in the Roman Catholic Church for a special commemoration of all the faithful departed, those baptized Christians who are believed to be in a state called purgatory because they have died with the guilt of lesser sins on their souls. Catholic doctrine holds that the prayers of the faithful on earth will help cleanse these souls in order to fit them for the vision of God in Heaven.

From antiquity certain days were devoted to intercession for particular groups of the dead. The institution of a day for a general intercession on Nov. 2 is due to Odilo, abbot of Cluny (d. 1048). The date, which became practically universal before the end of the 13th century, was chosen to follow All Saints' day, Nov. 1 (see ALL SAINTS, FESTIVAL OF). Having celebrated the feast of all the members of the church who are believed to be in heaven, the church on earth turns on the next day, Nov. 2, to commemorate the deceased members whose souls are believed to be suffering in purgatory.

Black vestments are worn, the office of the day is that of the dead and the Roman liturgy permits every priest to celebrate three Requiem Masses, one for the intention of the celebrant himself, one for all the faithful departed and one for the intention of the pope.

The feast was abolished in the Church of England at the Reformation but has been revived in Anglo-Catholic churches. Among continental Protestants its tradition was more tenaciously maintained, even without ecclesiastical sanction. (G. L. D.)

ALLSPICE, the dried, nearly ripe berry of the pimento or allspice tree (*Pimenta officinalis*) of the myrtle family. The tree, which attains a height of 25-30 ft., is native to the West Indies and Central America. This highly aromatic spice, widely used in baking and always present in mincemeat and mixed pickling spice, takes its name from the fact its flavour resembles a combination of cloves, cinnamon and nutmeg. Early Spanish explorers, mistaking it for a type of pepper, called it pimenta, hence its botanical name and such terms as pimento and Jamaica pepper. The first record of its import to Europe was in 1601, supposedly as a substitute for the spice cardamom. The name is applied also to other aromatic shrubs, especially to one of the sweet shrubs, the Carolina allspice (*Calycanthus floridus*), a handsome flowering shrub native to southeastern United States and often cultivated in England; to the Japanese allspice (*Chimonanthus praecox*), native to eastern Asia and planted for ornament in England and the United States; and to the wild allspice or spicebush (*Lindera benzoin*), a lauraceous shrub of eastern North America, with aromatic berries, reputed to have been used as a substitute for spice.

See SWEET SHRUB; SPICEBUSH. (M. W. N.)

ALLSTON, ROBERT FRANCIS WITHERS (1801-1864). U.S. planter and governor of South Carolina, provided an important source of information about the agriculture and the political and social history of the south by his papers, South Carolina Rice Plantation.

He was born in All Saints' parish, S.C., on April 21, 1801. A graduate of West Point in 1821, he aided in surveys of the harbours of Plymouth and Provincetown, Mass., and the entrance to Mobile bay. He resigned his commission in 1822 and, applying scientific knowledge of agriculture and engineering to draining and reclaiming swamp country, rose to a high position among southern planters. His was one of the last great rice plantations in the Atlantic coast lowlands.

Allston's *A Memoir of the Introduction and Planting of Rice in South Carolina* (1843) and *An Essay on Sea Coast Crops* (1854) were authoritative works and of great influence among the planters of the time.

Also active in politics, Allston was elected surveyor general of South Carolina (1823-27) and served in the general assembly for many years. He was president of the state senate from 1847 to 1856. As the secession movement of 1847-52 in South Carolina took form, Allston favoured the "co-operationists" as against those who urged the immediate secession of South Carolina regardless of action by any other state. He was a delegate to the Nashville convention of 1850, called in the hope of a general southern secession.

Elected governor by the legislature for the term 1856-58, he did much for the development of agriculture and the improvement of the public schools.

Allston died near Georgetown, S.C., on April 7, 1864.

South Carolina Rice Plantation was edited by J. H. Easterby (1945).

ALLSTON, WASHINGTON (1779-1843), U.S. painter and author, the first important U.S. romantic painter, was born on Nov. 5, 1779, on his family plantation on the Waccamaw river in South Carolina. He was educated at Newport, R.I., and at Harvard, where he graduated in 1800.

In London he studied at the Royal academy, where he learned the colouristic technique destroyed on the continent by neo-classicism. Study at the Louvre in Paris (winter of 1803-04) and in Italy (1804-08) acquainted him with the Venetian and Roman masters upon whom he based his own development. Also during this period he formed his friendships with S. T. Coleridge and Washington Irving.

He returned to Boston in 1808, spent seven fruitful years in London from 1811, settled in Boston in 1818 and finally in Cambridgeport, Mass., in 1828.

Before his final return to the United States, Allston's art was dramatic and large in scale; he delighted in the supernatural. "Dead Man Revived by Touching the Bones of the Prophet Elisha" (1811-13), "The Angel Liberating St. Peter From Prison" (1812) and "Belshazzar's Feast" (1817-43) are memorable works of this phase of romanticism. His dramatic landscapes "The Deluge" (1804), "Diana in the Chase" (1805) and "Elijah in the Desert" (1818) are the first important achievements of American landscape.

After his return to Boston in 1818 Allston's art became quieter, striking a new note of reverie and fantasy. "Moonlit Landscape" (1819) and "The Flight of Florimell" (1819) are the chief works of a period before he became preoccupied with "Belshazzar's Feast," brought unfinished from London. He worked on this from 1820 to 1828 and from 1839 until his death on July 9, 1843, never feeling satisfied with it.

Allston was a significant figure in the experiments in dramatic subject matter and the use of light and atmospheric colour, characteristic of early 19th-century painting. Although his life's production was small, he was a painter of distinction and at his best of remarkable power.

He was also a writer whose verse, *The Sylphs of the Seasons With Other Poems* (1813), and prose, *Monaldi* (1841) gave him a reputation in his own day. His theory of art, published as *Lectures on Art* (1850), is also of interest.

See J. B. Flagg, *Life and Letters of Washington Allston* (1892); E. P. Richardson, *Washington Allston, a Study of the Romantic Artist in America* (1948). (E. P. R.)

ALLUVIUM, the material deposited by rivers. It is usually most extensively developed in the lower part of the course of a river, forming flood plains and deltas, but may be deposited at any point where the velocity of a river is checked; for exam-

ple, where it runs into a lake. Alluvium in the true sense consists mostly of silt, sand and gravel, without much true clay; it often contains a good deal of organic matter and therefore yields very fertile soils. Some of the great alluvial deposits of the world are: the flood plain of the Mississippi, the deltas of the Nile, of the Ganges and Brahmaputra, and of the Hwang Ho in China. Owing to elevation of the land and consequent deepening of the river channel, patches of alluvium are often left forming terraces on the sides of valleys. On such terraces much of London is built.

In some regions alluvial deposits contain gold, platinum or gem stones, and the greater part of the world's supply of tin ore comes from similar sources.

See GEOLOGY: *Stratigraphy*; RIVER AND RIVER ENGINEERING: *Physical Characteristics of Rivers.* (R. H. RA.)

ALMA, BATTLE OF THE, a victory won by Franco-British forces, with some Turkish support, over the Russians on Sept. 20 (new style; Sept. 8. old style), 1854, during the Crimean War (*q.v.*). About 36,000 Russian troops under Prince Aleksandr Menshikov took up position on the heights above the Alma river in the south-western Crimea, thus blocking the way to Sevastopol. This formidable barrier was threatened by about 58,000 men commanded by Lord Raglan and Marshal Armand de Saint-Arnaud. With their right against the sea, and supported by the guns of the allied fleet, the French attacked first. Ascending difficult but lightly defended territory swiftly, they awaited British support. After a delay the British assaulted the Russian centre frontally, moving over the Alma and up the naturally defensible slope in the face of fierce artillery and musket fire. The light division gained the first plateau only to be thrown back because the reserves were slow in coming to its support. The Russians, however, were alarmed and withdrew their artillery, and the next attack by the Guards brigade, in splendid formation and firing disciplined volleys, decided the issue. The Russians retreated toward Sevastopol. Impatient allied cavalry were not permitted to pursue them. Generalship was lacking on the allied side, and the victory was attributable to the disciplined nature of the British infantry. The Russian losses were estimated at about 5,700, the British at about 2,000. The French claimed to have suffered 1,340 casualties.

(D. M. Sc.)

ALMA-ATA (formerly **VERNY**), an *oblast* of the Kazakh Soviet Socialist Republic, U.S.S.R., extends along both sides of the Ili river, from Lake Balkhash to the borders of Sinkiang Uigur Autonomous Region, China. In June 1959 its area was more than doubled to 87,837 sq.mi. by the addition of the former Taldy-Kurgan *oblast*.

The population (1,402,000 in 1959) was 653,000 urban and 749,000 rural. Two-thirds was said to be Kazakh. Other nationalities included Russians, Uigurs (Uygurs), Ukrainians, Czbeks, Tatars and Belorussians. It is very mountainous in the south (Trans-Ili or Zailiyski Alatau, Ketmen and Dzungarski Alatau ranges), and there is a sandy desert southeast of Lake Balkhash and along the lower Ili river. The climate is variable, being continental, with a very cold winter in the north but milder in the foothills. The economy is predominantly agricultural except for important lead and zinc mines and a refining plant at Tekeli. There is a great variety of irrigated crops on the southern mountain slopes, the main ones being wheat and sugar beets, but there are also tobacco, opium and rubber, as well as medicinal plants. The fruit industry is very important.

Near Lake Balkhash, sheep are raised, and saxaul trees are processed for local fuel. Industry consists mainly of food processing (sugar refining, flour milling and fish canning). The Turksib railway crosses the *oblast* from northeast to west. Air transport is used extensively, and the Ili river is used for the transport of goods.

Apart from Alma-Ata, the capital, the principal towns or "settlements of town type" are Burundai, Fabrichny, Imeni Panfilova, Ili and Taldy-Kurgan. In the early 1960s there were more than 880 schools in the *oblast*. Most of the cultural activity is concentrated in the capital.

(G. E. WR.)

ALMA-ATA, the capital of Alma-Ata *oblast* in the

Kazakh Soviet Socialist Republic, U.S.S.R., was founded in 1854 as a fortress with the name of Verny. The population grew from 45,600 in 1926 to 455,000 in 1959. Situated in the picturesque foothills of the Trans-Ili, or Zailiyski Alatau, it is entirely surrounded by apple orchards and is considered one of the most beautiful cities of the U.S.S.R. It has a heavy-machine-building industry (including railway shops), a spinning mill, fruit-preserving and meat-packing plants, wine and tobacco factories, tanneries and sawmills.

There are a number of educational and cultural establishments, including the Kazakh S. M. Kirov State university (established 1928), institutes of foreign languages, agriculture, medicine, zootechnic and veterinary sciences and pedagogy, a music conservatoire, a large library, Kazakh and Russian opera houses, theatres and museums. Alma-Ata is the seat of the Kazakh Academy of Sciences. (G. E. WR.)

ALMADÉN, a Spanish town in the province of Ciudad Real, lies 67 mi. from the city of Ciudad Real. Pop. (1950), 12,707 mun., a reduction, due to emigration, of 4,727, since 1940. In Arabic *almaden* signifies "mine . . .," an allusion to the historic exploitation of the local deposits of mercuric ores, which were known to the Romans, although the identification of Almadén with the Roman Sisapo is doubtful. The seams of mercuric ore are found in quartzite occurring in three ridges. The mineral was deposited by internal thermal waters carrying a solution of mercuric and sodium salts. The town, after being captured from the Moors by Alfonso VII in 1151, was given to the Order of Calatrava which exploited the mines. The king of Spain, Charles I (Holy Roman Emperor Charles V), granted them to the Fugger (*q.v.*) family as security for a loan. From the middle of the 17th century the mines were worked by the royal exchequer.

(M. B. F.)

ALMAGEST, the Arabicized name for *The Great Treatise*, the Greek astronomical and mathematical encyclopaedia written in the 2nd century A.D. by Claudius Ptolemy, of Alexandria. The work was the ultimate authority on astronomy (the Ptolemaic system) until the time of Copernicus, A.D. 1543. The *Almagest* contains a catalogue giving the ecliptical co-ordinates and the magnitudes of more than a thousand stars, based on the lost catalogue by Hipparchus of the 2nd century B.C.; it preserves, therefore, the oldest accurate Greek description of the stars and constellations. See **PTOLEMY: Astronomical Work.** (A. Po.)

ALMAGRO, DIEGO DE (c. 1475–1538), a Spanish soldier and conquistador. He was abandoned as an infant at Almagro, a town near Ciudad Real, Spain. He is believed to have joined Pedrarias Dávila in the new world, in 1524, following service in the Spanish army. In Panamá he became a close friend of Francisco Pizarro (*q.v.*) and joined him, together with Hernando de Luque, in the conquest of Peru (1533). Almagro considered himself poorly rewarded after the first attempt, and the friendship between the two men ceased.

Almagro, nevertheless, co-operated in the subsequent conquest and in 1534 was named *adelantado* of the territory just south of Peru by Emperor Charles V. He organized an expedition to Chile but found it barren and lacking in gold.

Disappointed in this venture, he marched to Cuzco, Peru, then under Indian siege, seized control of the city and jailed the two brothers of Francisco Pizarro. A war with the Pizarro brothers followed, in which Almagro was defeated by Hernando Pizarro at Las Salinas. Convicted of treason, Almagro was executed in Cuzco, in 1538.

(J. L. TR.)

ALMANAC, a book or table containing a calendar of the days, weeks and months of the year, a register of ecclesiastical festivals and saints' days and a record of various astronomical phenomena, often with weather prognostications and seasonal suggestions for the countryman.

The first printed almanac bears the imprint 1457, but almanacs have appeared in some form since the beginnings of astronomy. For example, a crude kind known as clog almanacs were the original calendar of the Norwegians and Danes; they consisted of square blocks of hard wood, about eight inches in length, with notches along the four angles corresponding to the days of the year. The

clog almanacs were in use in some parts of England as late as the end of the 17th century. J. J. Lalande, an investigator of early astronomical works, did not find any express mention of almanacs before those published by Solomon Jarchus in A.D. 1150. Probably

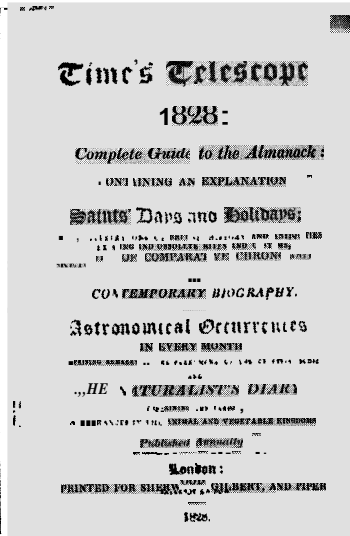

nostication (begun in 1683), a format which in 1837 became *Oliver and Boyd's New Edinburgh Almanac*, the standard reference for Scottish affairs.

The first American almanacs were printed in Cambridge, Mass., under the supervision of Harvard College, the first book issued from a college press was *An Almanac for New England for the Year 1639*, compiled by "William Pierce, mariner." Until near the close of the century an almanac was published yearly from this press.

One of the American myths is that Philadelphia cradled the American almanac and even though Benjamin Franklin founded it. Franklin's brother James printed *The Rhode Island Almanac* in 1728, and Benjamin Franklin (under the nom de plume of Richard Saunders) started his *Poor Richard's Almanack* in Philadelphia five years later. *Poor Richard's* was America's most famous almanac, but Nathaniel Ames of Dedham, Mass., ran a close second with his *Astronomical Diary and Almanack*, published from 1726 to 1764. It reached an annual circulation of 100,000 copies, exceeding that of *Poor Richard's*.

During the 1700s and 1800s in America there were about 100 almanacs for various purposes, organizations, businesses, military and religious groups and finally as an advertising medium.

The 18th-century almanac was actually the forerunner of the modern magazine, departing from newspaper format which until the late 1800s was one sheet of paper folded twice. The earliest magazines were similar, but the almanacs were composed of ten or more sheets stitched together. With the almanac as a guide, the farmer could reset a stopped clock, tell the time of day and estimate the proper season for all farm chores. It also furnished much incidental information—instructive and entertaining as well—which made it greatly appreciated where other reading matter was scarce. (E. S.L.)

(LEFT) COVER OF FIRST AMES ALMANAC, PUBLISHED IN NEW ENGLAND, 1726; (RIGHT) COVER OF TIME'S TELESCOPE, PUBLISHED IN LONDON, 1828

the earliest almanacs now extant are those in manuscripts of the early 12th century, examples of which are to be found in the libraries of the British museum and Cambridge and Oxford universities. The Savilian library at Oxford contains a manuscript copy of an almanac published by Petrus de Dacia in about the year 1300. The first standard almanacs, such as those produced by John Somers (1380) and Nicolas de Lynne (1386), were issued at Oxford.

Most English almanacs were published by the Stationers' Co., the most famous of them being the *Vox Stellarum* of Francis Moore (1657-1715?), the first number of which was completed in July

ALMANZOR: see MANSUR, AL-

ALMA-TADEMA, SIR LAWRENCE (1836-1912), British painter of popular historical idyls and genre, was born Jan. 8, 1836, at Dronrijp, near Leeuwarden, Neth., the son of a notary. Originally intended for medicine, he studied art at the Antwerp academy from 1852-56, under E. C. G. Wappers and later under Baron Hendrik Leys, the medieval history painter, whom he assisted in 1859 with the frescoes in the Stadhuis, Antwerp. He exhibited his first picture, a medieval subject, at the Brussels salon in 1857 and gained a gold medal at Amsterdam in 1862.

During a visit to Italy in 1863, Alma-Tadema became interested in Greek and Roman antiquity and in Egyptian archaeology; thereafter he depicted subjects drawn almost exclusively from these sources. His first paintings exhibited at the Royal Academy in 1869 included "The Pyrrhic Dance" (Guildhall art gallery, London). A year later, following the death of his first wife, he left Brussels for England, and in 1871 married the painter Laura Epps. He became a naturalized British subject in 1873, settling in St. John's Wood, London, in a pseudoantique style house.

His work is remarkable for its clarity of colour, exactness and smoothness of finish; he imagined a Rome of sunlit skies and gentle sentiment. Immensely successful during his lifetime, his reputation did not survive; in a later era his gifts might have been employed in creating vast biblical film sets. Elected associate of the Royal Academy in 1876, he became a full academician in 1879, was knighted in 1899 and was awarded the Order of Merit in 1905. He died in Wiesbaden, Ger., on June 25, 1912; a posthumous exhibition of his work was held in London in 1913. Five representative works are in the Tate gallery, London.

See Helen Zimmern, "L. Alma-Tadema, His Life and Work," *Art Annual*, 1886; C. Monkhouse, *British Contemporary Artists* (1899). (D. L. FR.)

ALMEIDA, FRANCISCO DE (c. 1450-1510), the first viceroy of Portuguese India, was born in Lisbon about the middle of the 15th century. In March 1505 Manuel I appointed him viceroy of the newly conquered territory in India, and he set sail from Lisbon in command of a large and powerful fleet. In July he arrived at Quiloa (Kilwa) which he took almost without a struggle. Mombasa was destroyed and its great treasures went to strengthen Almeida's resources. At the island of Angediva, near Goa, and at Cananor he built forts and adopted measures to secure

Table with columns for days of the month (1-31) and astronomical data including sunrise, sunset, moon phases, and other celestial events for March 1585.

1700 and contained predictions for 1701. Its publication has been continued under the title of *Old Moore's Almanac*.

Scotland pioneered astrological almanacs during the 1500s and 1600s. Notable was *Edinburgh's True Almanack, or a New Pro-*

Portuguese supremacy. Upon his arrival in India he took up residence in Cochin, where a Portuguese fort had been built by Affonso de Albuquerque in 1503.

The most important events of Almeida's brief but vigorous administration were the conclusion of a commercial treaty with Malacca and the discoveries made by his son Lourenço who acted as his lieutenant. The latter was probably the first Portuguese to visit Ceylon, where he established a settlement, and Fernão Soares, captain of a squadron of his fleet, appears to have been the first European to sight Madagascar. In 1508 Lourenço was killed at Chaul in a naval engagement with the Egyptians, who at this time attempted to dispute Portuguese supremacy in the Indian ocean. Affonso de Albuquerque (*q.v.*) then arrived in Cochin and presented a commission empowering him to supersede Almeida in the government. Almeida refused to recognize Albuquerque's commission and put him in prison.

Almeida then avenged Lourenço's death on the Arabs and their Egyptian allies. Sailing along the coast, he pillaged and burned various ports, including Goa and Chaul, and finally he encountered the enemy's combined fleet off Diu in Feb. 1509 and destroyed it completely. On his return to Cochin he held out for a few months against Albuquerque's claims, but in Nov. 1509 he was compelled to yield. He sailed for Europe on Dec. 1 with an escort of three vessels. On the voyage he called at Table bay, then known as Saldanha bay, for water, and there he was killed (March 1, 1510) in an attack upon the Hottentots, during which he showed great personal courage. In this fight, which took place on the site of Cape Town, 65 Portuguese were killed including 12 captains. Almeida's body was recovered on the following day and buried on the spot where he fell.

See João de Barros, *Decadas da Asia*, ii (1553); Franz Hümmelich, *Die erste deutsche Handelsfahrt nach Indien, 1505-06*, Historische Bibliothek, Bd. 49 (1922). (R. A. SN.)

ALMEIDA, JOSÉ VALENTIM FIALHO DE (1857-1911), Portuguese short story writer and pamphleteer, was born on May 7, 1857, at Vila-de-Frades, Alentejo. After leaving the primary school, and not without financial sacrifices on the part of his parents, he went to Lisbon to take a course in pharmacy. Soon captivated by the literary and artistic life of Lisbon, he remained there even after the death of his father; and, intent on becoming a doctor, he registered as a student in the Escola Médico-Cirúrgica in 1878, finishing the course in 1885. He supported himself in Lisbon with difficulty, by contributing to newspapers and magazines. Meanwhile, in 1881, he published his *Contos* and in the following year, *A cidade do vicio*, which established him as one of the most forceful of Portuguese storytellers, despite the unevenness noted by critics. Almeida's efforts to achieve independence quickly wearied him, and, not meeting with any official patronage, perhaps because of his undisciplined and bohemian temperament, he gave vent to his rancour in a publication called *Os gatos* ("The Cats," 1889-94). Its pages included some great literature—*e.g.*, "O enterro de D. Luis" (on the burial of the king Don Luis); "O violinista Sérgio" (on the violinist Sérgio); "Tragédia de um homem de génio obscuro" (the tragedy of an unknown genius); "Descrição de uma manhã no Tejo" (description of a morning in the Tejo)—but there were many vehement attacks as well, especially on the political institutions of the country and on the persons of the royal family, including the king.

These attacks, which greatly contributed to the downfall of the monarchy, finally made him unacceptable in official circles and caused him, in 1893, to return to the Alentejo where he married a rich heiress who died shortly afterward. Almeida was left master of an important farmstead and devoted the greater part of his time to its administration, seldom going to Lisbon and only at long intervals writing for newspapers and magazines. In 1907 he accepted the dictatorship of João Franco and after the assassination of the king and the heir apparent he severely criticized the Republican party, thus making himself unacceptable to the republic which was formed in 1910. He died at Vila-de-Frades on March 4, 1911.

As well as the works already mentioned, Almeida wrote *Pasquinadas* (1890), *Lisboa galante* (1890), *Vida irdnica* (1892), *O país*

das uvas (1893) and *A esquina* (1903). Many of his articles were collected posthumously in such volumes as *Barbear, Pentear* (1911); *Saibam quantos* (1912); *Figuras de destaque* (1924); and *Vida errante* (1923).

The dramatic, poetic and fantastic aspects of Almeida's talent as a storyteller are exemplified in "A Ruiva" (Contos), "Madona do Campo Santo" (*A cidade do Vicio*), "O sineiro de Santa-Agata" (*Aves migradoras*) and "Ceifeiros" (*A esquina*). His liking for themes of social pathology is seen in "O roubo" (*A cidade do vicio*) and "Três cadáveres" (*O país das uvas*). His language suffers from excessive subordination to French influence and to the stylistic niceties of French realism introduced into Portugal by Eça de Queirós; and his independence of linguistic tradition is confirmed by his capacity to create new words, unequalled by any other 19th-century Portuguese writer.

ALMEIDA GARRETT, JOAO BAPTISTA DA SILVA

J. LEITAO, VISCONDE DE: see GARRETT, JOÃO BAPTISTA DA SILVA LEITAO DE ALMEIDA.

ALMELO, a town in Overijssel province, Neth., lies at the junction of the Overijssel canal and the branch of the Twente canal, 9 mi. N.W. of Hengelo. Pop. (1957 est.) 48,018 mun.

Among the chief buildings are the 17th-century Dutch Reformed church; the 16th-century town hall, now a tourist office; and the Weigh house, an art gallery. Almelo is on the main railway from

Amsterdam, Rotterdam and The Hague to the German border via Deventer. The town shared in the rapid development of the Twente district and has many modern buildings. Its chief manufactures are cotton and metal.

The lordship of Almelo belonged to the lords of Heeckeren, who acquired the barony of Rechteren by marriage in 1350 and the countship of Limpurg in 1711. A branch of the family still holds the seat. (H. F. HE.)

ALMERÍA, a city and seaport of southern Spain, capital of the province of the same name and in the region of Andalusia, lies 165 km. (103 mi.) S.E. of Granada by road (^{via} Guadix). Pop. (1960 est.) 73,715 (mun.). Facing south over the gulf of Almeria below steep mountains, the town has an architecture and a dazzling brightness which gives it a Moroccan rather than a European appearance. The streets of the shopping centre are wide and tree lined, with garden squares. The principal thoroughfares are the Paseo del Generalísimo Franco and the Calle de Reina Regente leading to the park of José Antonio, which extends along the shore of the bay. Among the chief buildings are the Gothic cathedral (1524-43), built in the form of a fortress, the bishop's palace and seminary and the Alcazaba (773), built by the amir of Córdoba Abd-al-Rahman I. The dismantled Castillo de San Cristóbal overlooks the city and harbour, which is sheltered and equipped with modern facilities. The town has an archaeological museum, an institute of historical research, an art school and the Francisco Villaespesa cultural institute, which houses the municipal library. The mild and sunny climate, which makes bathing possible all the year round, gives Almeria its claim to be the great city of the Costa del Sol. Almeria is the terminus of a railway from Linares and Madrid and lies on the coastal highway, with a branch road to Granada. There is manufacture of chemicals, metalworking, fish canning and salting. The port is especially busy from August to December because of the export of oranges and grapes.

Known to the Romans as Urce or Portus Magnus, Almeria was one of their chief harbours after 19 B.C. It received its name from the Moors, who held it, with one brief interlude, until its reconquest by Ferdinand V and Isabella in 1489.

ALMERÍA PROVINCE was formed in 1833. Pop. (1960 est.) 355,201; area 3,388 sq.mi. This most easterly part of Upper Andalusia is crossed by sierras in which terminate successive zones of the Sistema Penibético. The Sierra de Gádor and Sierra Alhamilla form part of, or continue, the Alpujarra system (see ALPUJARRAS, LAS); the Sierra de los Filabres continues the Nevada core of the cordillera, while the enveloping crystalline of the Málaga zone is represented in the Sierra de las Estancias. The intervening valleys of the rivers Adra, Andarax-Almeria and

Almanzora provide the only fertile land. The annual rainfall is below 8 in. in the east of the province, and the supply of water for irrigation is most irregular. Nevertheless, several important irrigation systems were inaugurated, resulting in a considerable increase in the area of land under cultivation. Fruitgrowing is the principal agricultural activity, and large quantities of the world famous oranges and white grapes are exported. Olive oil, cane and beet sugar, almonds and esparto are also produced. Livestock is raised, especially sheep. Almeria has important mineral resources, including deposits of iron, lead and gold, and fine marble is quarried in the Sierra Nevada. There is a flourishing ceramics industry at Nijar. The mountainous character of the area prevents good communications, but road improvements have been made. The province is served by the railway from Almeria to Madrid and by the coastal road westward toward Málaga and the highway from Murcia and the northeast. A road links Almeria with Granada and there are some minor roads. The port is well served by shipping services, and there is an airport. The principal towns (1950 mun. pop.) are Almeria, the capital (75,861), Adra (13,817), Berja (11,133), Cuevas de Vera (11,344), Huércal Overa (14,020), Nijar (10,557) and Garrucha (3,532). (J. S. CA.)

ALMOGÁVARES (from Arabic *al-Mughāwir*, "raider"), the historical name of a class of Spanish soldiers who came originally from the Pyrenees and were in later times recruited mainly in Navarre, Aragon and Catalonia. They were frontiersmen and professional foot soldiers who wore no armour, dressed in skins, were shod with brogues (abarcas) and carried the same arms as the Roman legionaries—two heavy javelins (Spanish azagaya, the Roman pilum), a short stabbing sword and a shield. In the war between the houses of Aragon and Anjou for the possession of Naples and Sicily after the Sicilian Vespers (1282), the Almogávares formed the most effective element of the Aragonese army. When the war ended in 1302 they went with their commander Roger di Flor (*q.v.*) to Constantinople as mercenaries, under the name of the Grand Catalan company, for the Byzantine emperor Andronicus II against the Turks. In 1304 they successfully relieved the Turkish siege of Philadelphia (modern Alasehir, Turk.), but their lust for plunder made them as dangerous to their Greek employers as to the Turks. The emperor recalled them to Europe after they had attacked the Byzantine town of Magnesia (modern Manisa, Turk.) and settled them at Gallipoli, but in April 1305 their leader Roger was assassinated at Adrianople and they embarked on a war of vengeance against the Greeks. They devastated Thrace for two years before marching into Macedonia. They pillaged the monasteries of Mt. Athos, but failed to take Thessalonica (1308) and made their way south into Thessaly. Engaged as mercenaries by the Frankish duke of Athens, Walter of Brienne, they turned against him and in March 1311 defeated and killed him in the battle of the Cephissus, by Lake Copais in Boeotia. Frankish rule in central Greece then gave place to the Catalan duchy of Athens, which in 1312 the Almogávares placed under the protection of the king of Sicily. Though Thebes, their first capital, fell to the Navarrese company in 1379, the duchy survived until 1388, when Athens was occupied by the Florentine lord of Corinth, Nerio Acciajuoli (see GREECE: *Postclassical and Medieval History*). The name Almogávares died out in the 16th century, but it was revived for a short time in the civil wars of the reign of Ferdinand VII.

See Ramon de Muntaner, *Chronicle*, Eng. trans. by Lady Goodenough (1920); K. M. Setton, *Catalan Domination of Athens, 1311-1388* (1948). (D. M. N.)

ALMOHADS (AL-MUWAHHIDIN, "the Unitarians") was the name taken by a Berber confederation which ruled at Marrakech in Morocco from 1147 to 1269. It was based on the Masmuda tribe from the High Atlas mountains and had its origin in a movement for religious reform inspired by Mohammed ibn Tumart, a Berber from the Anti-Atlas. It succeeded in founding the greatest empire known in the Muslim west.

Ibn Tumart, who had studied in the Muslim east, formulated a doctrine which demanded puritanical moral reform and at the same time presented a very strict concept of the unity of God. To this orthodox teaching, however, he added certain Shi'ite elements,

proclaiming himself mahdi and "sinless imam," absolute master in both spiritual and temporal spheres. He taught without much success in Tunisia and Algeria, gathering only a few faithful disciples, one of whom was a Zenati from the Tlemgen region, Abd-al-Mumin. In Morocco, for preaching against the Almoravid sultans, Ibn Tumart was forced to flee to the Atlas mountains. There he quickly roused his fellow tribesmen, the Masmuda, and, with Tinnel as its centre, founded a strange Berber state in the form of a confederation of tribes united by their Islamic beliefs. Ibn Tumart, who had failed in an attack on Marrakech, died in 1129. He was succeeded by Abd-al-Mumin, who after 18 years of bitter fighting conquered the hlaghreb from the Almoravids. Marrakech, which fell in 1147, was retained as capital by the Almohads, who made it more flourishing than ever before. In two campaigns (1151-52 and 1159) Abd-al-Mumin conquered North Africa as far east as Tripolitania and brought all the Berbers under one rule. With the title of caliph, he brought Berber Islam to its zenith. Though he defeated a coalition of Arab tribes at Setif in 1152, these tribes were later to prove themselves the dynasty's worst enemies. Abd-al-Mumin had to intervene in Spain where the Andalusian amirs had been independent since the fall of the Almoravids and the Christians were gaining ground, but it was his son Abu Yaqub Yusuf (1163-84) who succeeded in conquering the territories of Spanish Islam.

The Almohad empire kept its original tribal hierarchy as a political and social framework, the founders and their descendants forming a ruling aristocracy, but a Spanish form of central government was superimposed on this Berber organization. Abd-al-Mumin soon forgot the puritanical outlook of Tinnel. Like the Almoravids, he had costly monuments built by Andalusian artists, and the ornamentation of some of his mosques was of a truly classical elegance. His successors continued his patronage of the arts in all their domains.

Under the second and third caliphs the Almohad empire remained powerful, although throughout the reign of Abu Yusuf Yaqub al-Mansur (1184-99) serious Arab rebellions devastated the eastern provinces. In Spain the Christian threat remained despite Al-Mansur's brilliant victory at Alarcos (1196). The fourth caliph, however, Mohammed al-Nasir (1199-1213), suffered a shattering defeat by a Christian coalition at Las Navas de Tolosa (1212). Thereafter the fortunes of the Almohad dynasty declined, and their empire gradually broke up. The Hafsids seized power at Tunis (1236), the Abd-al-Wadids at Tlemgen (1239) and the Marinids, a Zenati dynasty, at Marrakech (1269).

The movement for religious reform did not survive. The Almohad kings did not restrain the great mystical movement which was revolutionizing the outlook of western Islam, and they protected the great philosophers of their time, Ibn Tufail and Averroës (*qq.v.*). In all their territories they were, like the Almoravids, the devoted servants of Spanish-Moorish civilization. See also ISLAM.

Terrasse, *Histoire du Maroc*, vol. i (1949). (H. L. E. T.)

ALMON, JOHN (1737-1805), English parliamentary reporter and political writer, who was keenly involved in the 18th-century struggle between press and parliament. He was born in Liverpool, Dec. 17, 1737. When he arrived in London (c. 1758), freedom of expression in political matters was in hazard. He became known for his *A Review of Mr. Pitt's Administration* (1761) and other pamphlets. He was a friend of John Wilkes (*q.v.*) and was himself one of the most industrious writers in the Whig cause. In 1763 he opened a bookseller's shop in Piccadilly, which became a centre for the dissemination of political publications. In 1765 he was unsuccessfully prosecuted for publishing *Juries and Libels* but in 1770 was fined for reprinting Junius's letter to George II in *The London Museum*. The result was the bitter letter of Junius to Lord Mansfield (see JUNIUS). The following year, believing that the country had the right to know what was going on in parliament,

he used his notes on proceedings in the commons in his paper the *London Evening Post*. Other papers followed this example and the failure of the action by the commons against eight newspapers marks the beginning of the tacit acknowledgment of the right to publish parliamentary proceedings. In Nov. 1774 he began publishing *The Parliamentary Register*, a monthly record of proceedings, which continued until July 1813. He had meanwhile become a marked man and in 1773 John Miller, the publisher of the *London Evening Post*, had been fined the crippling sum of £2,000 for publishing his article accusing the notorious earl of Sandwich of selling an office of trust. At one point Almon was imprisoned for libel and at another was forced to leave the country. It is not surprising that he once wrote that "A man had better make his son a tinker than a printer or a bookseller. The laws of tin he can understand, but the law of libel is unwritten, uncertain, and undefinable. It is one thing to-day and another to-morrow. No man can tell what it is." His publications include *Memoirs of John Almon, Bookseller in Piccadilly* (1790), *Anecdotes of William Pitt . . .* (1792), *Biographical, Literary and Political Anecdotes . . .* (1797), *The Correspondence of John Wilkes*, vol. iii (1805) and an edition of *The Letters of Junius . . .* (1806), wrongly identifying their author as Hugh Boyd. He died at Boxmoor, Hertfordshire, Dec. 12, 1805. (J. H. JA.)

ALMOND, the tree, nut or seed of *Prunus amygdalus*, an important food-producing species appearing to be native to south-western Asia. The nuts are of two distinct types, sweet and bitter. The sweet are the well-known edible almonds of the world's market. The kernels of the bitter almonds are as inedible as peach kernels. They contain about 50% of a fixed oil, which occurs also in the sweet almond, together with a ferment emulsin, which in the presence of water acts on the glucoside amygdalin, yielding (1) glucose, (2) prussic (hydrocyanic) acid and (3) the essential oil of bitter almond, benzaldehyde (*q.v.*). When freed from prussic acid, the oil of bitter almonds is used in the manufacture of flavouring extracts. The sweet almond is cultivated extensively in certain favoured regions between 28° and 48° N. and between 20° and 40° S. Sweet almonds are eaten as nuts, or are used in confectionary or as a source of almond oil or almond meal. Leading exporting countries of shelled almonds during the late 1950s were Italy (half the production from Sicily), Spain, the United States, Iran, Portugal and Morocco.

The almond tree greatly resembles the related peach (*q.v.*), with which it occasionally hybridizes. While dormant, it is nearly as hardy as the peach, but ordinarily flowers much earlier, from late January to early April north of the equator. This causes crops of nuts to be uncertain wherever frosts are likely to occur during flowering. Sweet almonds mature only occasionally in climates like that of southern England. Ridenhower and other hard-shelled varieties which are self-fertile and otherwise indicate peach hybrid ancestry in their foliage, nut shell grooves and poor kernel flavour, have matured fairly regularly in such areas as Illinois and Pennsylvania, but are of no commercial promise.

The almond tree grows somewhat larger than the peach and lives longer. It is strikingly beautiful when in flower. The growing fruit resembles the peach until it approaches maturity, but its outer flesh then does not enlarge and become sweet and edible as in the peach. In ripening, the leathery outer covering, called the hull, splits open along the suture line, curls outward and discharges the nut.

The old-world almond industry was characterized by small plantings; trees interplanted with other crops; great variability in age, condition and bearing capacity of individual trees; and hand labour, often with crude implements. To a great extent production was primarily for food to be used by the family, and exports represented small surpluses from many small plantings. Modern Italian and Spanish growers pay more attention than they once did to the asexual propagation of improved varieties. But sales are by type rather than by variety in the horticultural sense of a clone. Thus two of the best-known type names are Jordan and Valencia from Spain. Neither is a true variety, as each includes many clones producing nuts similar in appearance and general character. The kernels of both are excellent for certain

(LEFT) BY COURTESY OF CALIFORNIA ALMOND GROWERS' EXCHANGE, (RIGHT) J. HORACE MC-FARLAND CO

ALMOND (*PRUNUS AMYGDALUS*): FLOWERS AND FRUIT

purposes, particularly for making glacé almonds. However, the shells of both types are hard, the trees are light bearers, and neither has been found profitable to grow else here.

Almond growing in the United States is confined almost wholly to California, where interior valleys and hillsides are protected from cold Pacific air movement by mountains near the coast. Production is mainly from orchards, often several hundred acres in extent. The trees are of similar age throughout an orchard, and of carefully selected varieties of California origin. As cross-pollination is required, a few special pollinizing varieties are systematically placed in all plantings, and colonies of bees are placed in strategic positions while the trees are in flower. Among leading varieties are Drake, I. X. L., Ne Plus Ultra, Nonpareil, Peerless and Texas. Newer varieties with better combinations of late flowering and high kernel quality, obtained through controlled breeding, were introduced in the early 1960s.

Orchard heating and other protective measures are frequently employed when subfreezing temperatures appear imminent during still nights when California almonds are flowering. By use of such measures it is often possible to save the major portion of a crop which otherwise would be lost during one or more nights of frost. Special wind machines and sometimes helicopters are used to drive cold air from low levels and allow it to be replaced with warmer air from slightly higher levels. Irrigation water, either flooded or applied by sprinkler to the tree tops, also is frequently useful in preventing much freeze damage to flowers or small almond fruits, unless temperatures drop to excessively low levels. The California Almond Growers exchange maintains standards of size, appearance and general quality. (J. C. Mc D.)

ALMONER, originally an officer charged with the distribution of alms, primarily for a religious house. Almoners attached to the French court appear early, but the title of grand almoner of France first appears in 1486. The office, which acquired great importance through its control of preferments, was suppressed in 1790, revived by Napoleon I and again by Napoleon III, but was abolished in 1870. In England the offices of hereditary grand almoner (a sinecure held by the marquess of Exeter) and lord high almoner still exist. The latter, usually a bishop or other prelate, distributes the royal alms of silver pennies on Maundy Thursday (*q.v.*).

In modern times the word is used in Britain for a professionally trained social worker, usually a woman, qualified to work in a medical setting (the corresponding term in the United States is medical social worker). The almoner, co-operating with the doctor, helps the patient and his family to make constructive use of medical care. To do this she makes an appraisal of the social and other problems of a patient's illness, establishes a firm and trusting relationship with him and where indicated helps to make and carry through plans for the future. Almoners are employed by most hospitals and an increasing number of public health departments.

ALMORA is a town and district in Uttar Pradesh, India. The town lies about 170 mi. N.E. of Delhi on a ridge of the Himalayas,

5,494 ft. above sea level. Pop. (1951) 12,116; cantonment 641. There are road connections with Delhi via Moradabad. It has a degree-granting college affiliated to Agra university, named after Sir Henry Ramsay, and several schools.

Almora was captured in 1790 by the Gurkhas, who constructed a fort on the eastern extremity of the ridge. Another citadel, Ft. Moira, is situated 2 mi. away at the other end of the ridge. Almora is also celebrated as the scene of the British victory which terminated the war with Nepal in 1815.

ALMORA DISTRICT was constituted in 1891, together with Nainital, by a redistribution of the two former districts of Kumaon and the Tarai. Bordering Tibet on the north and Nepal on the east, it lies almost entirely within the Himalaya mountains and about one-third of it lies above the snow line. In the northern parts elevations reach to about 20,000 ft. and peaks of the Nandakot and Panchachuli group are noteworthy. The upper waters of the Ganges and the Kali, which flows along its eastern boundary, drain the slopes, which abound in oak, deodar and pine.

With an area of 2,721 sq.mi., it had a population of 631,108 in 1961. The only other town of any size is Ranikhet (pop. [1951] 8,937), 29 mi. W. of Almora. Because of its rugged topography, only about 15% of the area is cultivated. Rice, wheat and small millet (raggee) are the main cereals and tea is grown in small quantities. Magnetite deposits are found at Jakhera and large deposits of copper ore also occur. (S. S. BH.)

ALMORAVIDS (AL-MURABITUN, "the people of the ribat"), rulers of northwestern Africa and Muslim Spain in the 11th and 12th centuries, were a confederation of Saharan Berbers—Lamtuna, Goddala, Massufa—belonging to the Veiled Sanhaja, closely akin in their way of life to the modern Tuareg. They acquired about A.D. 1040 a new cohesion and strength when their leader Yahya ibn Ibrahim, returning from the pilgrimage to Mecca, brought back with him a Moroccan Berber scholar, Abdullah ibn Yasin, to improve their rather sketchy knowledge of Islamic doctrine. Onto this movement for religious reform, which had started in a Senegalese hermitage (ribat), a great military enterprise was grafted, and the Veiled Sanhaja under their amir Abu Bakr were thrown into the conquest of Morocco.

Abu Bakr was later replaced by his cousin Yusuf ibn Tashfin, amir from 1062 to 1106. He founded Marrakech, established the Almoravid movement in Morocco and continued the great enterprise.

The conquest of Morocco and western Algeria (1063–82) required strenuous efforts. Algiers was included in the Almoravids' African empire, but they halted before the kingdoms of the Sanhajan Zeirids and Hammadids who were of the same people as the Veiled Sanhaja. Ibn Tashfin did not assume the caliph's title *amir al-muminin* ("commander of the faithful") but that of *amir al-muslimin* ("commander of the Muslims") and paid homage to the Abbasid caliph in Baghdad.

In Spain, meanwhile, the provincial rulers who, at the beginning of the 11th century, had divided among themselves the territories of the old caliphate of Córdoba were retreating before the Christians. When Toledo was retaken by Alfonso VI of Castile and León in 1085, Ibn Tashfin was called in to help. At the battle of Zallaka or Salaca (Sacralias, north of Badajoz) in 1086 he halted a dangerous advance by the Castilians. Having established his position, he later extended his rule over the whole of Muslim Spain except the kingdom of Valencia, which retained its independence under Rodrigo Diaz (the Cid; *q.v.*) for some time.

A new situation thus developed. Spain and northwestern Africa (the Maghreb) became parts of the same empire, and with the help of the Almoravids the civilization of Andalusia took root in African towns. In the reign of Ibn Tashfin's successor, Ali ibn Yusuf (1106–42), the union between Spain and Africa was consolidated. The administrative machinery of the Almoravids was Spanish in pattern; writers and artists crossed the straits; and the great monuments raised by Ibn Yusuf in the Maghreb were triumphs of pure Andalusian art with all its richness and subtle beauty.

But the Almoravids, despite the courage of their leaders and their astonishing adaptability, suffered from one great weakness:

they were only a Berber clan at the head of a Spanish-African empire in which they were always a foreign minority. They tried to hold Spain with Berber troops and Maghreb with a strong Christian guard; but with the fall of Saragossa in 1118 the tide of Christian reconquest started to advance and in 1125 the rebellion of the Almohads (*q.v.*) broke out in the Atlas mountains. After 22 years of fighting the Almohads were victorious; Marrakech fell in 1147, and thereafter Almoravid leaders survived only for a time in Spain and the Balearics.

The achievements of the Almoravids, though incomplete, were of considerable importance. Their reign marked the political zenith of one of the great Berber clans, the Sanhaja. Moroccan territories were for the first time united under a single ruler and, although in matters of religion they followed the sterile Maliki school, the Almoravids were, especially in Africa, the devoted and efficient servants of Spanish-Moorish civilization.

ALMQVIST, CARL JONAS LOVE (1793–1866), Swedish writer, an interesting representative of mid-19th-century romanticism, was born at Stockholm on Nov. 28, 1793. After studying at Uppsala university he entered the department of ecclesiastical affairs in Stockholm. In 1823 he gave up his position and went to western Sweden to lead with a group of friends an idealized peasant existence. Two years later he returned to Stockholm and from 1829 to 1841 he was rector of an experimental secondary school. In 1851 he fled to the U.S. after being accused of fraud and attempted murder. He returned to Europe in 1865 and died at Bremen, Ger., on Sept. 26, 1866.

Almqvist was little known until the mid-1830s when he began to publish a stream of works in prose and verse. Most of these—novels, short stories, poems and verse dramas—were included in a series called *Törnrosens bok* ("The Book of the Briar Rose," 13 vol., 1832–40; vol. 14, 1851; 2nd series, 1839–50). Particularly important were *Amorina* (written c. 1821; pub. 1839) and *Drottningens juvelsmycke* ("The Queen's Diamond Ornament," 1834), a historical novel whose heroine, the mysterious, hermaphroditic Tintomara, is Almqvist's most fascinating character and a central symbol in his creative writings. *Det går an* ("It will do," 1839; Eng. trans., *Sara Videbeck*, 1919) is a brilliant, realistic story pleading for the emancipation of love and marriage. Almqvist was also a musician and set some of his short lyrics to music.

In both his life and his writings Almqvist showed an astonishing versatility. His vast literary output is a strange mixture of bizarre romanticism and bold realism. He attacked conventional matrimony, satirized the beliefs of the Lutheran Church (although he took orders in 1837) and as a radical journalist and in many of his creative writings fought for moral and social reform. But there were in his nature strong tendencies toward egocentric indifference and separatism, and the core of his personality remained dominated by Christian mysticism and Swedenborgian otherworldliness. Although uneven, his work contains brilliant passages and greatly influenced the development of Swedish literature.

An unfinished edition of his collected writings was published in 21 volumes (1920–38).

BIBLIOGRAPHY.—The literature on Almqvist is extensive. A standard modern work is Henry Olsson, *Carl Jonas Love Almqvist till 1836* (1937). See also Olsson's chapter on Almqvist in *Ny illustrerad svensk litteraturhistoria*, part 3, *Romantiken. Liberalismen* (1956), with a bibliographical survey. (G. STR.)

ALMUCANTAR (also written ALMACANTAR), an astronomical term for a small circle of the celestial sphere parallel to the horizon; when two stars are in the same almucantar, they have the same altitude. The term also refers to instruments of a pattern invented by S. C. Chandler to determine the latitude or the time by observing the times of transit of stars across a fixed almucantar.

ALMUCE (AMICE or AMESS), a hooded cape of fur, or fur lined, worn as a choir vestment; not to be confused with the amice worn by the priest when celebrating the Eucharist. It is known to have been worn as early as the 12th century, and by the 16th it had become definitely established as the distinctive choir vestment of canons, often being carried over the left arm as a symbol of office. See VESTMENTS. ECCLESIASTICAL.

ALNAGE or AULNAGE, a term describing the system for standardizing the size and quality of woolen cloth maintained by the English government for about 600 years. The word also denoted the fee charged by officials who measured cloth. This early state regulation of industry was designed, as a commission of 1622 put it, to prevent "the false and deceitful making, dyeing and dressing of our cloth and stuffs, which disgraceth it in foreign parts." It also protected English buyers from like deceit by foreign manufacturers whose cloth was sold in England.

The assize of cloth, first promulgated by Richard I in 1197, prescribed statutory dimensions for all salable cloth. It was reaffirmed in Magna Carta and by 1280 was enforced by special officers called aulnagers, who examined cloth for quality and dimensions, sealing what was sound and confiscating what was defective. The effort to enforce standard dimensions broke down during the 14th century through the increasing variety in overseas demand, but the drive for standard qualities continued. Aulnagers, however, often sealed cloth without scrutiny, only asking their fees.

An act of 1552 provided searchers to assist the aulnagers in every borough, a device extended to the counties by statutes of 1598 and 1601. In 1594 the finer fabrics made in England by refugees from the Spanish Netherlands were brought within the aulnage. By 1699, when it was abolished, the system was in evident decay. However, local efforts to regulate quality through searchers persisted in the Yorkshire woolen industry until 1765.

(G. Y. T.)

ALNWICK, a market town in Northumberland, Eng., lies 34 mi. N. of Newcastle by road. Pop. (1961) 7,482. Area 7.5 sq. mi. It is on the south bank of the river Aln, in undulating wooded country between the Cheviots and the sea. The town is dominated by the castle which, although extensively restored, occupies the same area as when founded in the 11th century; the shell-keep of Eustace Fitz-John (c. 1157) still forming its central building. In 1309 it was bought and enlarged by the Percy family and acquired great strategic importance during the Border wars. It has remained the principal seat of the earls and dukes of Northumberland (*q.v.*) ever since. After 1750 the first duke transformed it into a palace, Gothic outside and Italianate within, while the gardens were laid out by Lancelot "Capability" Brown (1765). The castle houses a museum and is open to visitors during the summer.

Ruins remain of St. Leonard's hospital (c. 1200) and, in Hulne park, of the Gatehouse of Alnwick abbey (1147) and parts of the Carmelite Hulne priory (1240). The church of St. Michael was rebuilt in Perpendicular Gothic about 1464, and from the 15th-century parts of the town wall (notably the Hotspur tower), the old grammar school and a chantry chapel still survive.

(M. G. C.)

ALODAE (ALOIDAE), Otus and Ephialtes, in ancient Greek legend, the twin sons of Xloeus or Poseidon, celebrated for their extraordinary stature and strength. According to the Odyssey, they made war upon the Olympian gods and endeavoured to pile Pelion upon Ossa in order to storm heaven itself, but Apollo destroyed them before they reached manhood. In the Iliad Ares is imprisoned by them but delivered by Hermes. They sought Artemis and Hera in marriage, whereupon Artemis appeared between them in the shape of a stag, which they endeavoured to kill, but slew each other.

ALOE, a genus of plants belonging to the family Liliaceae, with about 180 species growing in the dry parts of Africa, especially Cape Colony, and in the mountains of tropical Africa.

The plants are apparently stemless, bearing a rosette of large, thick, fleshy leaves, or have a shorter or longer (sometimes branched) stem, along which, or toward the end of which and its branches, the generally fleshy leaves are borne. They are

WILLIS PETERSON

ALOE VERA

AGAVE), belongs to a different family, viz., Amaryllidaceae.

Aloes is used medicinally as a purgative and produced from various species of aloe, such as *A. vera*, *A. barbadensis*, *succotrina*, *chinensis*, and *perryi*. Several kinds of aloes are distinguished in commerce—Barbadoes, Socotrine, hepatic, Indian and Cape aloes. The first two are those commonly used for medicinal purposes. When the leaves are cut the juice flows out and is collected and evaporated. From the juice active principles termed aloins are extracted by water.

The lign-aloes is quite different from the medicinal aloes. The word is used in the Bible (Num. xxiv, 6), but as the trees usually supposed to be meant by this word are not native in Syria, it has been suggested that the Septuagint reading in which the word does not occur is to be preferred. Lign-aloes is a corruption of the Lat. *lignum-aloe*, a wood, not a resin. Dioscorides refers to it as *agalochon*, a wood brought from Arabia or India, which was odoriferous but with an astringent and bitter taste. This may be *Aquilaria Agallocha*, a native of east India and China, which supplies the so-called eaglewood or aloeswood, which contains much resin and oil.

ALONSO, AMADO (1896–1952), Spanish philologist who applied to his native language several harmoniously fused methods of analysis. Was born in Lerin, on Sept. 13, 1896. Trained as a linguist in Madrid and Hamburg and variously associated with Madrid's Centro de Estudios Históricos, Alonso rose to fame as professor at the University of Buenos Aires and director of its Instituto de Filología (1927–46). Later he taught at Harvard university. Alonso was a brilliant lecturer, dynamic teacher, demanding editor (*Revista de filología hispánica*, 1939–46) and imaginative organizer. Noteworthy among his writings are the miscellaneous *Estudios lingüísticos* (1951–53), the essays included in vol. i of *Biblioteca de dialectología hispanoamericana* (7 vol., 1930–49), the torso of an inquiry into early modern Spanish pronunciation (1955–) and monographs on the historical novel (1942) and on P. Neruda's hermetic poetry (2d ed., 1955). Alonso died at Arlington, Mass., on May 26, 1952.

ALOR ISLANDS: see SOLOR AND ALOR ISLANDS.

ALPACA (*Lama pacos*), a fleece-bearing, cud-chewing mammal, one of four new world relatives of the camel. The alpaca and the llama (*q.v.*) are each distinct species probably saved from extinction through domestication by Indians in the lofty Andes. Two other *Lama* species (lamoids) exist more or less in the wild state, the vicuña and the guanaco (*q.v.*). Alpacas are readily distinguished from llamas (*Lama glama*) by their smaller size (about three feet high at the shoulders) and rounded, rather than squarish, body. Also the alpaca usually appresses its tail close to the body, whereas the llama usually holds its curled tail somewhat erect. The shaggy hair varies in colour from the usual black or brown through lighter shades to pale yellow and occasionally white. Rarely are alpacas multicoloured, and blotched individuals with alpacoid characteristics are mostly hybrids resulting from crosses with llamas. Present distribution is restricted to southern Peru, adjacent Bolivia

and northern Argentina. Alpacas are the most limited in range and the most specialized of the four lamoids, being adapted to marshy ground at altitudes from 4,000 to 16,000 ft. In adaptation to the reduced oxygen content of the air, red blood corpuscles are exceptionally numerous—20,000,000 per cubic millimeter, as against 6,000,000 to 8,000,000 per cubic millimeter in man at high altitudes. Alpacas are the most important of the lamoids for wool production. During the Inca civilization, alpaca and vicuña wools were reserved for the higher classes and royalty.

BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

ALPACA (LAMA PACOS)

Two breeds, the common and the suri, were developed in pre-Columbian time. If the hair of the suri breed is allowed to grow, it reaches the ground, making the animal look like an overgrown poodle. Hybrids between alpaca and llama are common, but they do not breed true and in time revert to the parental types.

Although the alpaca has been crossed with the vicuña since Inca time to establish a hybrid (paco-vicuña) with the exquisite silky wool of the vicuña and the high wool production of the alpaca, success has never been achieved. After the first shearing, the fleece of the paco-vicuña loses its fine quality and the coarse hairs increase. Furthermore, succeeding generations revert to alpaca or vicuña types. To hybridize the alpaca and vicuña, a baby male vicuña is disguised with the skin of a baby alpaca and given to a lactating alpaca. Only in this way will the foster mother accept the vicuña, and only a vicuña reared by an alpaca will be accepted by a female alpaca as a mate.

When an alpaca reaches its third year, the oldest hairs begin to shed individually at various times, not all at once during a particular period of each year, as in sheep. From the age of two years onward, an alpaca is sheared every other year. Hair growth in two years is about 12 in. in the common breed and 24 in. in the suri. When maximum yield is achieved at five years of age, each shearing yields about 6 lb. of wool. Individuals are considered old at about seven years, though longevity is much longer, and they are killed for meat.

The wool has excellent qualities in being remarkably light in weight, strong, lustrous, high in insulation value and resistant to rain and snow. It is used in parkas, sleeping bags and fine coat linings.

Peru leads in production with an estimated 2,000,000 alpacas producing annually over 3,000 tons of wool, most of which is marketed in Arequipa, where it is sorted into seven grades by Indian women. The Peruvian government has established a breeding station to improve the quality of the wool and increase production.

Although the fleece of alpaca has been used in making clothing since the Inca civilization, it was considered unworkable material for textiles until Sir Titus Salt (*q.v.*) developed ingenious techniques to enable successful manufacture of alpaca cloth for European use. See also TYLOPODA. (H. K. B.)

ALP ARSLAN, MOHAMMED IBN DA'UD (*c.* 1030–1073), whose Turkish name Alp Arslan means "the lion hero." was the second sultan of the Great Seljuk line (see SELJUKS). He succeeded his father Da'ud Chagri Beg as ruler of Khurasan *c.* 1060 and his uncle Togrul Beg as sultan in western Iran and Mesopotamia (1063), thus uniting under his rule the whole of the Seljuk empire except Kerman. Alp Arslan's fame rests mainly on his victories against the Byzantine empire. He invaded Armenia in 1064 (capturing Ani, the old capital) and Georgia in 1068. In 1071, while marching against Aleppo on his way to attack the Fatimids in Egypt, he was diverted by an attack of the Byzantine emperor Romanus IV Diogenes, who penetrated deep into Armenia. Alp Arslan was forced to turn back, and the armies met in the battle of Manzikert (*q.v.*) in Aug. 1071. The Byzantine army, deceived by the Turkish tactic of simulated flight, was to-

tally defeated and Romanus taken prisoner. As a result of the battle, the Byzantine army was rendered powerless and the Turkmans were enabled to effect a permanent settlement in Asia Minor, thus laying the foundations of modern Turkey.

Alp Arslan died in early Jan. 1073 at the hand of a prisoner captured during an expedition against the Qarakhanids of central Asia. Christian writers represent him as interested neither in administration, which he left in the hands of his great vizier, Nizam al-hulk, nor in intellectual life; yet it was for him that an anonymous author wrote the *Maliknameh*, the sole source of information on the origins of the Seljuk dynasty.

ALPES-MARITIMES, a *département* in the extreme south-east of France, formed in 1860 out of the county of Nice (till then a possession of the house of Savoy) with the addition of the districts of Grasse (formerly in the *département* of Var) and Menton (purchased from the prince of Monaco). A frontier strip (202 sq.mi.), ceded by Italy under the terms of the Franco-Italian peace treaty of 1947, was also acquired and extended the border northward along the crest of the Maritime Alps. It is bounded northeast by Italy, south by the Mediterranean sea and west by the *départements* of Var and Basses-Alpes. Pop. (1954) 515,484. Area 1,527 sq.mi. Alpes-Maritimes surrounds the rocky promontory of Monaco (*q.v.*) which, with Monte Carlo adjoining, forms an independent principality.

Most of the *département* consists of rugged limestone mountains, with peaks approaching 10,000 ft. inland. The mountains extend right to the coast in a succession of rocky headlands, such as Cap Ferrat and Cap d'Antibes. The former shelters the naval base of Villefranche (*q.v.*), and the ancient port of Nice (Gr. Nicea) also lies in the shelter of a limestone promontory. Most of the *département* lies within the basin of the Var river and its main tributaries, the Tinée and Vésubie, which often flow in deep gorges: there is little coastal lowland.

The coast itself, from Cannes in the west to the Italian frontier in the east, sheltered by the Alps and bathed in Mediterranean sunshine, has developed as a great tourist region, known as the Côte d'Azur or French Riviera. Along the coast is a succession of fashionable resorts, including Cannes, Antibes, Nice, Monte Carlo, Menton (*qq.v.*) and Juan-les-Pins (see also RIVIERA). Slightly inland is Grasse (*q.v.*), famous for its scent industry. Lavender cultivation, together with vineyards, olive groves and fruit orchards extend up the alpine valleys. Between the main urban areas the coastlands are dotted with innumerable villas and are served by good roads, including the Corniche system at three levels between Nice and the Italian frontier. They provide magnificent views of the coast and of ancient perched villages such as Èze and La Turbie.

The *département* is divided into the arrondissements of Nice and Grasse. It forms the bishopric of Nice, dating back to the 4th century. (AR. E. S.)

ALPHA AND OMEGA (Α and Ω), the first and last letters of the Greek alphabet used as the self-designation of God, denoting his eternity and infinitude, and of Christ. The New Testament references are Rev. i, 8; xxi. 6: and (of Christ) xxii. 13. The usage is based on passages such as Isa. xlv. 6 ("I am the first and I am the last") and Ps. xc. 2 ("from everlasting to everlasting thou art God"). In rabbinic literature the first and last letters of the Hebrew alphabet are similarly used. The word *Emeth* ("truth"), composed of the first, middle and last letters of the Hebrew alphabet, is the seal of God.

ALPHABET, strictly defined, indicates by written symbols a set of speech sounds. The alphabet was a Greek invention based upon North Semitic (proto-Canaanitic) writing which indicated only consonants, a procedure suitable enough for a Semitic language but not for an Indo-European one. The word itself is de-

rived from the names (of Semitic origin) of the first two letters of the Greek alphabet! alpha and beta, and the definition is of quite a general character, as is easily seen in the case of the first letter of the English alphabet, which represents different sounds in the words "father," "man" and "take." Even when a letter represents a single sound, it does so roughly, taking no account of intonation, stress or pronunciation, which vary not only between speakers but also within the speech of an individual according to the position of the sound in a word or phrase and the nature of the phrase.

An alphabet is a highly developed, artificial form of writing. The connection between sound and character is conventional and not essential. This is not the case with all forms of writing. Pictographs, ideographs and hieroglyphs bear an essential relationship to what they represent. Such methods constitute an earlier stage of writing than syllabaries and alphabets.

Alphabetic writing is the most convenient and adaptable form of writing. It is learned in childhood with ease, which is not the case with the Chinese script, for instance. The alphabet may also be passed from one language to another without difficulty. It has changed surprisingly little in nearly 3,000 years, despite the introduction of printing and the typewriter. (The history of writing, from its earliest forms to the development of the alphabet, is discussed in WRITING AND PALAEOGRAPHY. Nonalphabetic forms of writing and communication are treated in CUNEIFORM; HIEROGLYPHS; LOGOGRAM AND SYLLABARY; and PICTOGRAPHY.)

Origin. — The oldest known Greek inscriptions of the 2nd millennium B.C., found in Greece near Pylos, at Mycenae, and elsewhere, and in Crete, are written in a syllabary (see MINOAN LINEAR SCRIPTS). They are some centuries older than Greek inscriptions written in the Greek alphabet, which is now thought to be derived from a Canaanitish variety of North Semitic script that came to the Greeks through Phoenician traders as intermediaries.

The story of the alphabet from the time it is first found employed in Greek inscriptions is not hard to trace. It is its pre-Greek history that is still disputed. The Greek names for its letters, alpha, beta, gamma, delta, etc., demonstrate its Semitic origin, for though the names may not in every case have a Semitic etymology, they correspond closely with the Semitic names (*cf.* the Hebrew aleph, beth, gimel, dalet). Two questions have remained unanswered. How did the Greeks obtain it from the Semites? And what was its pre-Semitic history?

In 1929 an epoch-making discovery of cuneiform texts of the 15th century B.C. was made at Ras Shamra (ancient Ugarit) on the Syrian coast opposite Cyprus. This cuneiform script seems to have been derived from the North Semitic by people who were accustomed to the use of clay and stylus; since it combines the idea of an alphabet for consonantal writing with the use of wedge-shaped elements arranged in simple combinations. Other important documents, discovered at Byblos (now Jebeil, Lebanon) in 1929, 1933 and following years, are written in a pseudohieroglyphic syllabary; its symbols bear some resemblance to Egyptian hieroglyphs and may be of the 22nd century B.C.

Until the second decade of the 20th century the earliest known examples of the Semitic alphabet were found in the Moabite stone (an inscription of Mesha, king of Moab, dating from the 9th century B.C.) and in a votive inscription to Baal-Lebanon discovered in Cyprus. Various theories have been current as to the origin of the Semitic alphabet, the earliest being the view of Lenormant, published by De Rougé in 1874, that Egypt was its starting place. Others attempted to connect it with Babylonian cuneiform: with the Cyprian syllabary or with the Minoan writing of Crete. This was the view of Sir Arthur Evans; who, in his *Scripta Minoa*, developed the theory that the alphabet was taken from Crete to Palestine by the Philistines and from them borrowed by the Phoenicians. The Egyptian view was revived in 1916 by Alan Gardiner in a paper dealing with certain inscriptions discovered in 1906 by Sir W. Flinders Petrie in the Sinai peninsula, which exhibit a stage of writing intermediate between Egyptian hieroglyphs and the Semitic alphabet. The script appears to be alphabetic, and the date of the inscriptions is not later than 1500 B.C. These inscriptions have also been dealt with by Hans Bauer, who saw in the script a prototype of the Semitic alphabets, independent of Egypt.

Advocates of this view appeal to the evidence of the four South Semitic alphabets. These are known as Sabaeen, Lihyanic, Thamudenic and Safahitic. Inscriptions in these South Semitic alphabets were discovered in considerable numbers during the course of the 19th century. Those in the Sabaeen alphabet came from the district of Yemen in South Arabia, the Lihyanic from El-Ola in the north of the Hejaz. The Thamudenic inscriptions are from north-western Arabia, and the Safahitic inscriptions came from rocks in the district of Safah near Damascus. Most of the South Semitic inscriptions read from right to left but a few are written boustrophedon, *i.e.*, from right to left and left to right in alternate lines. There are 29 letters in the Sabaeen alphabet. The date of the earliest Sabaeen inscriptions appears to be about the 6th century B.C., and most of those who have noticed them are agreed that this alphabet descends not from that of the Moabite stone but from an older source common to both. Gardiner saw this source in the alphabet of the Sinai inscriptions. Two or three of the signs, notably that for *beth* □ in Sabaeen, for *phe* ◊ in Sabaeen and for *thau* † in Thamudenic and Safahitic, resemble symbols of the Sinai script. But there are strong objections to the theory, which is now generally abandoned.

ADAPTED FROM TABLE OF ALPHABETS, "CAMBRIDGE ANCIENT HISTORY," VOL III; CAMBRIDGE UNIVERSITY PRESS

FIG. 2. — COMPARATIVETABLE OF ALPHABETS. THE FIGURES IN COLUMNS 4 AND 5 INDICATE THE ORDER OF THE LETTERS IN MODERN ETHIOPIAN AND VAU (DIGAMMA)

A different view of the origin of both the Phoenician and Greek alphabets was offered by Flinders Petrie. He argued that both these alphabets, together with those of Asia Minor, the South Semitic, Cyprian and certain Egyptian scripts, developed from a series of conventional marks or signs employed for commercial purposes throughout the Mediterranean area from earliest times. But he was practically alone in supposing that the early marks to which he referred had any certain significance! and his theory of the development of various local alphabets from such marks has not found general acceptance. Too many links are missing in the chain of proof. The fact that identical alphabetical symbols occur in widely distant regions of the Mediterranean area, which he stressed, is capable of other explanations.

The most important fact ignored by any theory that would derive the Greek and Phoenician alphabets independently from a source older than either is that the names of the letters, as far as they have a known etymology or meaning, are Semitic. The Semitic names are all words in the Semitic languages. The Greek names are meaningless in Greek. It has indeed been argued that the Greek names were the original ones, meaningless, and taken in the first instance simply from the sounds represented by the letters; and that the Phoenicians took over the alphabet together with the names from the Greeks and adapted the names by the process known as folk etymology. But the Sinai inscriptions, discussed above, have rendered this theory untenable. If they do not represent a link between the hieroglyphic system of Egypt and the Phoenician alphabet, they represent a prototype of the latter, appearing at a date and at a place that render any theory of borrowing from Greek sources highly improbable. It is reasonably certain that the Greeks derived their alphabet from Semitic sources, taking over the names with the letters. The names are not identical. The Greek names end with a vowel—alpha for *aleph*, beta for *beth*, etc. The vocalization has been explained merely as being more in agreement with Greek morphology, and this is a very satisfactory explanation.

The Greek Alphabet. — The two forms of the Greek alphabet! Chalcidic and Ionic, generally known as western and eastern, represent two different borrowings, but the theory of any direct borrowing from Phoenician sources may probably be ruled out. The tradition that this was so came from Herodotus, who referred only to Boeotia, and it is probable that the name *Phoenices* was a vague term for eastern foreigners. The Achaeans were a naval power settled in the eastern Aegean in the 15th century B.C. There is therefore no difficulty in concluding that they borrowed the alphabet from peoples with whom they were in close contact in western and southern Asia Minor at a considerably earlier date than has generally been supposed; or that, independent as Greek states were, there were separate borrowings and separate adaptations.

The inscriptions of the Bronze Age discovered in Palestine in the third decade of the 20th century have simplified the problem considerably even though there is still no complete agreement. These texts, conveniently described as being in an early Canaanitish script, are thought to provide a transition between Sinaitic and those North Semitic forms which include early "Phoenician" forms that the oldest Greek alphabet resembles so closely as to make it commonly asserted that the Greek alphabet is of Phoenician origin. All authorities accept the relationship as proved beyond question. But the Phoenician is only one variety of North Semitic (i.e. ultimately Canaanitish) writing and the Greek alphabet therefore must be regarded as of North Semitic origin, probable as it is that the Phoenicians were the intermediaries through whom the Greeks obtained their alphabet.

The North Semitic varieties of writing concerned are shown on the accompanying chart.

The chief adaptations made by the Greeks were the allocation of certain of the 22 Semitic letters to vowel sounds and the addition of certain letters. The oldest extant inscriptions written in the Greek alphabet are those found in 1896 on the island of Thera, which date from the 8th, possibly even the 9th, century

ARABIC ALPHABETS GIVEN IN COLUMNS 22 AND 23. † (GAML. GIML);

B.C.; the inscriptions from Abu Simbel in upper Egypt, dating from the 7th century; a Corinthian and an Athenian inscription of the 6th century; and some vase inscriptions still older. In Thera the oldest inscriptions are written from right to left, others are boustrophedon, others still later read from left to right. In the Lydian alphabet known from inscriptions found at Sardis at the beginning of the 20th century, these symbols also represent vowels. Most Greek states developed local variations either in the forms of certain letters or in the representation of sounds not represented by any of the 22 letters taken over. The two main divisions, eastern and western, however, remained till the 4th century B.C., when, in the main, uniformity of alphabet (eastern) was attained throughout Greece. The early inscriptions from Thera show a remarkably close resemblance to the forms of the Semitic alphabet as represented on the Moabite stone or the Baal-Lebanon inscription from Cyprus. The alphabet of Abu Simbel was of the Ionic type. Alphabets derived from, or related to, the Greek (e.g., Carian, Iberian and Etruscan) sometimes show clear traces of syllabic, as distinguished from purely alphabetic, writing

The two main divisions, eastern and western, again subdivided into two, the cities of Asia Minor and the adjacent islands with their colonies using forms shoning in some cases slight differences from those in use in the Cyclades and in Attica. Again, the alphabets of Megara, Corinth, Sicyon, Phlius and western Argolis with their colonies differed from the rest, which included Euboea, Boeotia, Phocis, Locris, Thessaly and the remainder of the Peloponnese. Throughout all Greek alphabets the Semitic letters aleph, *he* and *ayin*, which represented breathings were adapted to represent vowels. Alpha (aleph) was consistent throughout. The letter corresponding to Semitic *he* (later epsilon) represented both the short and long vowel *e* in those cases where eta (H, η and ε from Φ) represented the rough breathing. Generally speaking, eta represented the vowel sound in the eastern alphabet, the breathing in the western. Thus in the west the symbol Ε or Ε was used for the two sounds represented in Attic by ε and η; in the east it

more usually represented the short vowel alone. In addition to this, however, it was occasionally used throughout to represent the long close ē (the long ē represented by eta was open), which in Attic was written ει, since this diphthong had become ē. The Corinthian alphabet was peculiar in using (up to the 6th century and later in outlying regions) the sign Β or Β to represent e, the long close vowel being written ΒΣ. Sicyon used a symbol with the form Σ. Semitic cheth (Greek eta) was used, as has been seen, in the east generally speaking as a vowel, in the west as the rough breathing. In the Thera inscriptions it occurs in both capacities. The semivowel *i* (resembling the sound of English initial y) had disappeared from the Greek language in prehistoric times, degenerating into a rough breathing, so that Semitic *yod* was adapted in Greek to represent the vowel *i* (iota). Koppa (Ϟ) had disappeared in the eastern alphabets by the 5th century B.C., its place being usurped by kappa (Κ), but it lingered in the west and was introduced into the Italic alphabets, as will be seen.

The digamma (Ϝ, representing the *w* sound) was of Semitic origin. *Vau*, the sixth letter of the Semitic alphabet, was taken by the Greeks for use as a vowel, exactly as they had taken *yod*, and placed at the end of the alphabet following tau. But whereas the consonantal *i* sound did not exist in Greek, the consonantal *u* sound (akin to *w*) survived till classical times in certain dialects and needed a symbol to represent it. But the digamma also kept both the place of *vau* in the order of the alphabet and the value of consonantal *u*, and its old numerical value ("six").

The treatment of the sibilants of the Semitic alphabet by the Greeks is complicated. *Zain* was taken over as zeta, though its

FIG. 4 — TABLE OF ITALIC ALPHABETS + INDICATES

pronunciation in early times is not certain and may have varied throughout the dialects between *dž*, *dz*, *ž* and *z*. The pronunciation of these and *s* or *sh* sounds was literally a shibboleth. The 15th letter of the Semitic alphabet was *samech*, the name of which through its Aramaic form *simcha* became in Greek by metathesis sigma. The name, however, was transposed to the 21st letter, which in Semitic was *san*. The letter itself was retained in the eastern or Ionic alphabet with the value *ks* ({}). In Thera, however, in early times it had the value of *ss*, while *x* or *ks* were expressed by **KM**. The usual manner of expressing this combination in the Aegean Islands was **XΣ**. The letter **X**, which often appeared in the west as **+**, may be a direct descendant of **Ξ** (*samech*) and quite independent of **X** or **+**, the 26th letter of the Greek alphabet, the origin of which is unknown. The sibilant *s* was expressed by two separate symbols, **M** and **Σ** or **Σ**, the one descended from Semitic *sade*, the other from Semitic *san*. Both did not appear in the same alphabet. **M** appeared in Crete, Thera and Melos, in Phocis in the 6th century and elsewhere only in the Peloponnese and its colonies. In two 5th-century inscriptions from Teos and Halicarnassus a form **T** appeared with the value *σσ*. The unvoiced velar aspirate was expressed by a form **X** or **+**, which became the 26th letter of the alphabet in practically all alphabets except in the western group. The same form was used in the west for the *x* sound, and here it was probably a descendant of Semitic *samech* &. In the west where **X** was used for the *x* sound and not for the unvoiced velar aspirate (*kh*, **X**), the latter was expressed by a symbol **ψ**. In Boeotia **ψ** was actually found used in combination with **Σ** to represent the *x* sound. A fact that suggests that there was some consciousness that it was used in the west as a substitute for eastern **X**. **ψ** was used singly to express the *x* sound in Thera and Melos. In the east, where **X** expressed the *kh* sound, **ψ** was used (sometimes with the form **Ψ**) to express the combination *ps*, a use in which it was later standardized by the spread of the Ionic alphabet.

Other symbols not derived from Semitic were: (1) **φ** (phi), used to express the unvoiced labial aspirate (*ph*); and (2) **Ω**, the last letter of the Greek alphabet, probably differentiated from **O**. In the west this symbol appeared very seldom. In the east it represented the long open *o*. In the Cyclades, by a phonetic change, it frequently expressed the close vowel, whether long or short (*o* or *ov*), while **O** represented the open sound.

The origin of the symbols **φ** and **ψ** is unknown. In the case of **X** or **+** it is probable that **X** derived from **Ξ** and standing for *x* should be differentiated from **X** standing for *kh*. The origin of the latter is, however, obscure. It is possible that these signs were adapted in Asia Minor from the Cypriote syllabary.

Various local alphabets that were parallel to the Greek were in use in Asia Minor. The Lydian alphabet for instance is known from inscriptions dating from the 4th century B.C. A few of these were discovered in the 19th century, 36 were found by a U.S. expedition in Sardis between 1910 and 1913, the rest by J. Keil and Von Premerstein and others in various parts of ancient Lydia since 1906. Another U.S. expedition began excavations in Sardis in the early 1960s.

The Lydian alphabet consisted of 26 symbols. The parallelism of the Greek and Semitic alphabets is clear but there are additional symbols the sound of some of which is uncertain in the absence of a completely certain interpretation of the language of the inscriptions. The most interesting fact about this alphabet is the identity of the symbol for *f*, which is **8**, with the Etruscan and Italic symbol for the same sound.

The Latin Alphabet. — The western Greek or Chalcidic alphabet was brought to Italian soil by the Etruscans and by the Greek colonies of Magna Graecia; it was once confidently held that the Latin alphabet was derived from this Chalcidic alphabet by contact with the Greek colonies of southern Italy. Too little was made of the influence of Etruria because too little was known of that country and its people. Over a dozen Italic alphabets are known. The Messapic is purely Greek in origin and was used by a people who were isolated in Calabria and spoke an Illyrian dialect.

RETROGRADE DIRECTION. THAT IS. RIGHT TO LEFT

The Umbrian, Oscan and various subalpine alphabets are derived from the Etruscan. The district in which the Umbrian alphabet was used was east of the Xpennines. The Oscan was in Campania. Thus the Latin and Faliscan alphabets were bounded on all three sides by the Etruscan and alphabets derived from it. In these circumstances Etruscan must have exercised a strong influence upon the Latin alphabet, following the impact of Etruscan civilization upon Roman in other directions.

The Etruscan alphabet is known from certain tomb inscriptions, from part of an Etruscan book that was used as the wrapping of a mummy and from several alphabets or abecedaria. It has **F** (digamma) and retains forms corresponding to all three Phoenician sibilants, *samech*, *san* and *sade*. It has **X** representing *ks*, **φ** for *ph* and **ψ** as *kh*. On one tomb inscription of the 8th century B.C., **θ** is found representing *f*, identical with the same character used for the same sound in the Lydian alphabet (see above). The view now usually held as to the origin of the Etruscan alphabet is that it was brought by its users to Italy when they migrated from Asia Minor probably in the 9th century B.C., and that they had received it while still in Asia Minor or in the Aegean Islands from Greek sources at a period prior to the division of the Greek alphabet into eastern and western. The Etruscan names for the letters of the alphabet are the same, in the main, as the Latin, which had borrowed them. There is nothing impossible, or even improbable, in the view of the derivation of the Etruscan alphabet from Greek sources in the Aegean at an early date since inscriptions found on the island of Lemnos show them in possession of it.

The oldest extant records of the Latin alphabet are first the inscription known as the Dvenos inscription (it begins **DVENOS MED FECE**), found in 1880 in Rome upon an earthenware vessel with three separate branches and dating from the first half of the 4th century B.C. In the second place is the Praeneste fibula, dating from the 6th or 5th century, the inscription upon which runs from right to left. It reads **MANIOS MED FHEFHAKED NUMASIOI** and is remarkable as illustrating the device of com-

binning the letters **F** (digamma) and **H** (aspirate) to represent the sound of *f* which was common in Latin but did not occur in Greek. In the Dvenos inscription **F** alone is used, a later development, for the Romans had the *w* sound in their language, but instead of using **F** to represent it, they rather clumsily allowed **V** to represent both this and the vowel sound *u*. The third instance of early Latin is an inscription upon a column, written boustrophedon, found in the Roman forum and dating probably from the 5th century. In it **K** is in ordinary use for *k*, and **Q** for *q* or *qu*; and the word **RECEI** occurs where **C** has still the force of *g*.

The third letter of the alphabet, **Γ**, **Λ** and **C**, which represented in Greek the voiced velar stop (the sound of *g*), came in Latin to represent the unvoiced stop. The reason for this is obscure, but Etruscan influence cannot have been absent for the voiced stops were unrepresented in the Etruscan language. Latin did not lose the voiced stop but adapted a symbol **Q** from **C** to represent it, which it placed in the position of **I** (zeta) for which it had no use. **C** thus took the place of **K**, which fell out of ordinary use, remaining only as the initial of archaic or official words. **C** also remained with the force of *g* in the initials of proper names. **F** (digamma) was used at first in combination with **H** to represent the *f* sound. Later the **H** was dropped, again probably under Etruscan influence. When after the conquest of Greece Greek words began to be borrowed by the Latin language, the symbols **Υ** and **Z** were adapted from Greek for use in such words and placed at the end of the alphabet. There were no sounds in Latin to correspond to the three aspirates. **Θ** (theta) was retained to represent the numeral 100 and became modified to **C** and identified with the initial letter of the number (centum). **Φ** (phi) written **(I)** was used to represent 1,000 and became identified with **M**, the initial letter of *mile*. **Ψ** (chi) became **L**, then **L**, and was used for 50.

The Latin alphabet of 23 letters (including **Υ** and **Z**) became extended during the course of the middle ages to the English alphabet of 26 by the division of **I** into *i* and *j* and the tripartite

division of **V** into *u*, *v* and *w*. **J** developed in the 15th century as an initial (more ornate) form of *i*, and as the consonantal sound occurred more at the beginning of words as well as in the middle, *j* became specialized to represent the consonant wherever it came in the word. The history of *u* and *v* is precisely similar except that it took place five centuries earlier. *W* arose, as its name implies, out of a combination *uu* or *vv*, which about the 11th century came to represent in Old English the *w* sound, previously represented by a 'rune'.

Other Alphabets.— The alphabets of India derive from two sources. Kharosthi and Brahmi. Though attempts have been made to show that the Brahmi alphabet was developed in India itself without connection with outside sources, this contention cannot be maintained. It has a manifest kinship with the Semitic alphabets. Its origin is obscure, but there seems little doubt that it derives from the South Semitic group of alphabets through contact with Sabataean traders. The Brahmi alphabet is the parent of all modern Indian alphabets. Kharosthi is an adaptation, to the needs of the Indian languages, of the Aramaic alphabet, in use in north-west India in the days of Persian rule. Inscriptions in it first appear in the 3rd century B.C. None has been found of a date subsequent to the 5th century A.D. By the 3rd century A.D. it had spread to Chinese Turkestan. It was superseded in all districts by Brahmi.

The alphabets in use in Persia, at least from the time of the Arsacid dynasty onward, are based upon the Aramaic. Cuneiform was the writing of the Achaemenidae empire, but after the Greek conquest Aramaic was introduced and became general. The Pahlavi is the alphabet of the Sassanid kings. The Xrsacid and Sassanian alphabets are found together in the liturgical inscription of Hadji-abad, as well as in the Paikuli inscriptions dating from about 300 B.C.

Modern Arabic writing has developed from a form of Aramaic used in the land of the Nabataeans, an Arabian people. The oldest record of it now extant is a stele from Tema, in northwest Arabia, dating from the 5th century B.C. or perhaps earlier. Distinctively Nabataean inscriptions are from a period beginning about the mid-

dle of the 1st century B.C.; the script was standardized in the early Christian era. The graffiti on the rocks of Mt. Sinai carry the record of the development of this alphabet down to the 3rd century A.D. In the early Islamic period two types of Arabic writing existed, known as the Kufic and the Naskhi. The former was discontinued except for formal purposes, where cursive writing could not be employed. The Naskhi is the parent of modern Arabic writing, in which many characters have become so similar owing to the degeneration of the cursive script that it is necessary to distinguish them by diacritical points.

Persian, Turkish (until recently) and a few other languages have used the Arabic alphabet. But there has been a marked trend in modern times to take over the Latin or Roman alphabet, as was done in Turkey in 1930. The Latin alphabet has also been adapted to some languages in the U.S.S.R., Africa and elsewhere.

The earliest records of Aramaic go back to about 800 B.C. and were found at Sindjirli in northern Syria. The alphabet at this time differed little from that of the Moabite stone. Aramaic became by far the most important and widespread of the North Semitic alphabets. It was used in Assyria as a cursive script side by side with cuneiform. It is marked by two distinct tendencies: (1) the opening of the heads of the letters, beth (𐤁) becoming 𐤂, daleth (𐤃) and resh (𐤄) 𐤅. O became U, then V; (2) angles became rounded and ligatures developed. These tendencies were completed during the Persian period and they are emphasized in the Aramaic writing on papyrus employed in Egypt between 500 and 200 B.C. Other developments of Aramaic are modern square Hebrew and the alphabet of Palmyra.

A group of alphabets arose in Asia Minor during the first half of the 1st millennium B.C. deriving from a common source, which was also akin to the source of the Greek alphabet. The Carian alphabet was one of these, the Lycian another. Both seem parallel to Greek, not offshoots of it. The Phrygian, on the other hand, seems to be derived from the Greek and from the western variety.

The Armenian alphabet owes its origin to Bishop Mesrob late in the 4th century A.D., who adapted it from Greek for the use of a rising Armenian Christian literature. A few Persian characteristics that appear are the influence of the dominating political power.

In all Germanic countries are found inscriptions in the alphabet known as runic (see RUNE). The affinities of this alphabet with the Greek are apparent, but there has been dispute whether or not it is derived directly from Greek or through an Italic alphabet. Comparison with subalpine alphabets (of Etruscan origin) and the fact that the oldest runes are found just north of the eastern end of the Alps supports the latter view.

The cryptographic Ogham writing was employed by Celtic peoples in Britain and Ireland (see OGHAM SCRIPT). In this the several letters of the alphabet were represented by strokes differing in number (from one to five) and in position on either side, or on both sides, of a straight horizontal line. The symbols are indicative of binary choices in origin. The bulk of the Ogham texts, both in Ireland and in Wales belong to the 3rd to 5th centuries A.D.

Finally must be mentioned the two Slavonic alphabets, Cyrillic and Glagolitic, both according to tradition the invention of Cyril, the missionary to the Slavs, in the 9th century. Each is taken from the Greek alphabet of that period, Glagolitic from the cursive writing, Cyrillic from uncial, when the value of **B** had become the spirant *v*, that of **H** *i*, of **Φ** *f* and of **Χ** the sound of Scotch *ch*. Several additional symbols were invented to express those sounds of the Slavonic language which could not be comprised within the compass of the Greek alphabet. Glagolitic survived in Croatia till the 17th century. Cyrillic has for long been the alphabet in which the Slavonic languages are normally expressed.

A.; J. W.H.)

ALPHA PARTICLES, also called a-rays, the positively charged particles that are ejected by certain radioactive substances. (See RADIOACTIVITY, ARTIFICIAL; RADIOACTIVITY, NATURAL.) They are the nuclei of helium atoms (*i.e.*, normal atoms of the isotope ${}^2\text{He}^4$), which, however, are without their usual complement of two exterior electrons (*i.e.*, doubly ionized helium-four, He^{4+}). (See ATOM; ELECTRON.) These may also be produced by an electric discharge through this gas. See also Index references under "Alpha Particles" in the Index volume. (H. B. L.M.)

ALPHEGE (AELFHEAH), **SAINT** (954-1012), English archbishop and martyr. His early life is obscure, but he was a monk at Deerhurst and later a hermit at Bath, where followers are said to have flocked to him, electing him abbot. He was a friend of St. Dunstan, through whose influence he was named bishop of Winchester in 984. In 1006 he succeeded Aelfric as archbishop of Canterbury. Alphege was captured by the Danes in the sack of Canterbury in 1011 and held for ransom for seven months. When he refused to pay he was stoned to death at Greenwich. He was first buried at St. Paul's but was removed to Canterbury in splendour in 1023. From the earliest years after his death he was venerated as a martyr. His feast day is April 19.

See J. P. Migne (ed.), *Patrologia Latina*, vol. cxxxix. (T. L. C.)

ALPHEUS (mod. Gr. ALFIOS), the chief river of Peloponnesus, Greece. The Alpheus proper is 68 mi. long and rises near Asea in central Arcadia (Arkadhia), but its passage there by subterranean channels from the Tegean plain, and its union with the Eurotas are probably mythical (W. Loring, *Journal of Hellenic Studies*, vol. xv, p. 67). The shallow and rapid stream occupies but a small part of its broad, stony bed. Leaving the plain of Megalopolis by a rugged gorge, it receives above Olympia two large tributaries, Erimanthos and Ladhon, from the northeast and empties into the Ionian sea. In late Tertiary times the plain of Megalopolis was occupied by a lake, and the lower Alpheus represents the overflow channel by which it was drained. Pliny states that it was navigable for six Roman miles from its mouth. Alpheus was recognized as the typical river god in the Peloponnesus, as was Achelous (*q.v.*) in northern Greece. His waters were said to pass beneath the sea and rise again in the fountain Arethusa at Syracuse. (W.M. C. B.)

ALPHONSE I (1103-1148), count of Toulouse, son of the crusading count Raymond IV by his third wife, Elvira of Castile, was born in the castle of Mont-Pèlerin at Tripoli in the Lebanon and was surnamed Jourdain, having been baptized in the Jordan. He was taken to France in 1107 and, on the death of his brother Bertrand (1112), succeeded to the whole countship of Toulouse and marquisate of Provence, which had been first divided between Bertrand and him. Dispossessed of the countship of Toulouse by William IX, duke of Aquitaine, in 1114, he recovered part of it in 1119 and the rest in 1123. He next fought against Raymond Berengar I (Ramón Berenguer III of Barcelona) for the sov-

erignty of Provence, and by a peace reached in Sept. 1125 became master of most of the country north of the Durance. He occupied Narbonne in 1134 and held it till 1143.

Alphonse did much to reduce his vassals to obedience and to protect the towns (charters of 1141 and 1147 to Toulouse); his great work was the founding of Montauban (1144). In Spain he arbitrated several times between princes. In 1141 he was attacked by Louis VII of France, who besieged Toulouse, on the pretext of rights due to his wife Eleanor of Aquitaine. After being twice excommunicated (in 1123 for interfering with the abbey of Saint-Gilles and in 1142 because of a dispute with Montpellier), he took the cross in 1146 at Vézelay and embarked for Palestine in Aug. 1147, reaching Acre in 1148. He was poisoned at Caesarea, Palestine, in April 1148, at the instigation either of Eleanor or of Melisande, mother of Baldwin III of Jerusalem.

ALPHONSE (1220-1271), count of Poitiers and of Toulouse, notable for his administration of Languedoc, was born on Nov. 11, 1220, the fifth son of Louis VIII of France, under whose mill he received Poitou and Auvergne in appanage. He married Joan, daughter of Raymond VII of Toulouse, in 1237. While he was in Egypt with his brother Louis IX of France, during the seventh crusade, he inherited the countship of Toulouse on Raymond's death (1249). Returning to France (1250), he was joint regent with Charles of Anjou from 1252 till Louis IX's return in 1254. In his lands in southern France he repaired some of the damage done in the Albigensian War, created and developed privileged settlements of the type known as *bastide* (*q.v.*) and tried to keep the peace between the various orders of society in the towns. By working through a large administrative staff in Paris he helped to prepare the way for the final reunion of the countship of Toulouse with the French crown. In 1270 he went to Tunis for the disastrous eighth crusade. On his way home he died in Italy, probably at Savona, on Aug. 21, 1271. There is an edition of his administrative correspondence by A. Molinier, 2 vol. (1884-1900).

ALPHONSINE TABLES, astronomical tables prepared in Toledo, Spain, about 1272 (for the epoch 1252), under the direction of King Alfonso X, by Judah ben Moses and Isaac ibn Sid. The Alphonsine tables superseded the Toledan tables prepared in the 11th century by al-Zarqali (Arzachel); they served the European astronomers for several centuries in several Latin versions. With the gradual introduction of the Copernican system and the publication of Reinhold's *Prutenicae tabulae* (1551) and of Kepler's *Tabulae Rudolphinae* (1627), tables based on the Ptolemaic system became useless.

See ASTRONOMY: *History of Astronomy*. (A. Po.)

ALPHONSO, an English form of a Christian name derived from the ancient Germanic Adalfuns (*adal*, "nobility," *funs*, "eager"). The French form is Alphonse, the Spanish (Castilian) Alfonso, the Portuguese Afonso. The widespread use of the name in Spain and Portugal seems to have originated in some association with that of the 7th-century archbishop of Toledo, St. Ildefonsus (Sp. Ildefonso), the latter name representing perhaps an old patronymic meaning "son of Adalfuns," Sp. *hi(jo) de Alfonso*. The name has been borne in the form Alfonso (*q.v.*) by 11 kings of Asturias, Castile and León, by 5 kings of Aragon the last of whom was also king of Naples, and by 2 kings of all Spain, as well as by another king of Naples alone; and in the form Afonso (*q.v.*) by 6 kings of Portugal.

ALPHORN (German, *Alpenhorn*), the wooden trumpet of Alpine herdsmen and villagers, sounded for intercommunication and at daily ceremonies and seasonal festivals. It is carved or bored in wood and overwound with birch bark. Some instruments are straight, reaching 12 ft. in length, with a curving bell; others, mainly in the eastern Alps, have the shape of a trumpet. The herdsmen's *Ranz des Vaches* (*Kuhreihen*): the melody played on the alphorn have been introduced into several musical works, notably Rossini's *William Tell*. The alphorn is much played in trios and quartets, with the same compass and notes as a natural French horn in F. Though first depicted in the 15th century the species may be considerably older, for herdsmen widespread across Europe make similar instruments, from Rumania (*bucium*) through Russia and the Baltic countries to Finland and Scandinavia

(*lur*), some of them entirely of birch bark.

See K. M. Klier, *Volkstümliche Musikinstrumente in den Alpen* (1956). (A. C. BA.)

ALPINI, PROSPERO (1553–1616), Italian physician and botanist, best known for his observations on the pollination of the date palm, was born at Marostica in the Veneto, on Nov. 25, 1553. He accompanied the Venetian consul, Giorgio Emo, to Egypt as medical adviser and made full use of his three years' stay there to study the flora. He stated that "the female date-trees or palms do not bear fruit unless the branches of the male and female plants are mixed together; or, as is generally done, unless the dust found in the male sheath or male flowers is sprinkled over the female flowers." He saw the coffee plant growing in Cairo and his account of it is said to be the first published in Europe. In 1593 he was appointed professor of botany at Padua (the oldest botanical chair in Europe) and cultivated many Egyptian plants in the university garden. He died at Padua on Nov. 23, 1616. His best-known work is *De plantis Aegypti* (1592). He also wrote *De Medicina Aegyptiorum* (1591) and *De Plantis exoticis* (1627), published by his son, ALPINO ALPINI (1592–1637), who succeeded to the chair in 1633, and died in 1637. (J. RM.)

ALPS, the collective name for one of the great mountain systems of Europe stretching from the Gulf of Genoa to Vienna, and rising between the plains of northern Italy and of southern Germany. The Alps do not present so continuous a barrier as the Himalayas, the Andes or even the Pyrenees. They are less extensive than the Urals or the Scandinavian highlands. They are formed of numerous ranges, divided by comparatively deep valleys. This mountain mass forms a broad band, convex toward the north, while most of the valleys lie between the directions

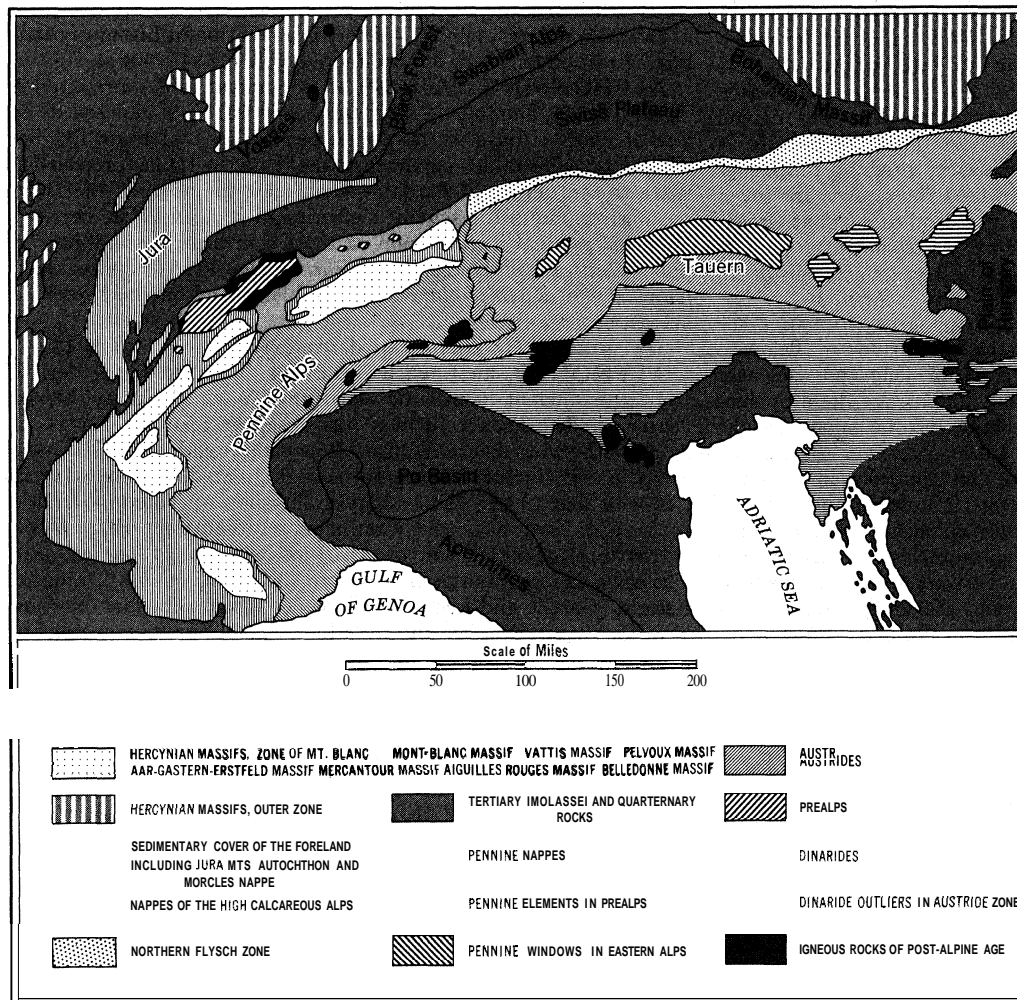

west to east and southwest to northeast. Many deep transverse valleys intersect the prevailing direction of the ridges and facilitate the passage of man, animals and plants, as well as of currents of air which mitigate the contrast that would otherwise be found between the climates of the opposite slopes. The derivation of the name alps is uncertain; in all parts of the great chain itself the term alp (or alm in the Eastern Alps) is strictly applied to the high mountain pastures, and not to the peaks and ridges of the chain. The name alps has been applied to other ranges in the world, notably the Australian Alps and Japanese Alps.

Limits of the Alps.—Merely to distinguish the Alps from minor ranges the best limits are on the west (strictly speaking, south), the Sella di Altare or Colle di Cadibona (1,427 ft.), leading from Turin to Savona and Genoa, Italy, and on the east the line of the railway over the Semmering pass (3,215 ft.) from Vienna, Austria, to Marlbor, Yugoslavia, in the Mur (Mura) valley, and on by Ljubljana, Yugoslavia, to Trieste. An Italian commission in 1926 placed the limit on the east at a line from Vienna through Graz to Rijeka, Yugoslavia. But if the term is confined to those parts where the height is sufficient to support perpetual snow, the limit to the west will be the Colle di Tenda (Col de Tende) (6,135 ft.), leading from Cuneo (Coni) to Ventimiglia, Italy, while on the east the line will be the route over the Radstadter Tauern (5,702 ft.) and the Katschberg (5,384 ft.) from Salzburg, Austria to Villach in Carinthia, and thence by Klagenfurt to Maribor and so past Ljubljana in Yugoslavia on to Trieste.

On the north side, the Alps (in either sense) are definitely bounded by the Rhine from Basel to Lake Constance, Switzerland, the plain of Bavaria and the low foothills from Salzburg to the neighbourhood of Vienna. The waters of the northern slope

of the Alps find their way either into the North sea through the Rhine, or into the Black sea by means of the Danube, none reaching the Baltic sea. On the south side the mountains from near Turin to near Trieste subside into the great plain of Piedmont, Lombardy and Venetia. The true west section of the Alps runs from near Turin to the Colle di Tenda, in a southerly direction, then bends east to the Sella di Altare, which divides it from the Apennines.

Divisions.—The Alps consist of a main chain, with ramifications, and of several minor chains. They form a single connected whole as contrasted with the plains at their base, the only breaks in them being mountain passes at high altitudes. For the sake of convenience the best marked passes have long been used to serve as limits within the chain, whether to distinguish several great divisions or to break up these into smaller ones. Coolidge's system of division considers only topographical aspects (see COOLIDGE, WILLIAM AUGUSTUS BREVOORT). The divisions given lie between the Colle di Tenda and the route over the Radstadter Tauern. Three main divisions are generally distinguished: the Western Alps, extending from the Colle di Tenda to the Simplon pass; the Central Alps from the Simplon pass to the Passo di Resia (Reschen Schei-

GEOLOGICAL FORMATION OF THE ALPS. SHOWING OUTCROPS OF CHIEF TECTONIC ELEMENTS

deckj; and the Eastern Xlps from the latter to the Radstadter Tauern route, with a bend outward toward the southeast in order to include the higher summits of the southeastern Alps. Assuming these divisions, it is found convenient to subdivide the whole mountain system into 18 smaller groups—5 in the Western Alps, 7 in the Central Alps and 6 in the Eastern Alps. These, with the limits of each subdivision, are as follows:—

Western Alps.—The Maritime Alps (from the Colle di Tenda to the Col de l'Argentière). The Cottian Xlps (from the Col de l'Argentière to the Mont Cenis pass and west to the Col du Galibier). The Dauphiné Alps (from the Col du Galibier, westward and southward). The Graian Alps (from the Mont Cenis to the Little St. Bernard pass). These are usually divided into three groups, the Central (the watershed between the two passes named); the Western or French, and the Eastern or Italian. The Pennine Alps (from the Little St. Bernard pass to the Simplon pass).

Central Alps.—The Bernese Alps (from Lake Geneva to the Furka pass, the Reuss valley and Lake Lucerne). The Lepontine Alps (from the Simplon to the Spliigen and south to the Furka and the Oberalp passes). The eastern portion of this range is sometimes named the Adula Alps (from the St. Gotthard to the Spliügen pass). The Todi range (from the Oberalp to the Klausen pass). The Glarus Alps (north of the Klausen pass). The Bernina Alps (from the Maloja to the Resia and the Giogo dello Stelvio, south and east of the Val Bregaglia and of the Engadine [*q.v.*] and north of the Valtellina [*q.v.*]). The Albula range (from the Spliigen to the Fluela pass: north and west of the Val Bregaglia and of the Engadine). The Silvretta and Rhatikon ranges (from the Fluela to the Passo di Resia and the Arlberg pass).

Eastern Alps.—The Alps of Bavaria. Vorarlberg and Salzburg (north of the Arlberg pass, Innsbruck, the Pinzgau and the Enns valley). The central Tirol Alps (from the Brenner to the Radstadter Tauern pass, north of the Drave valley and south of the Pinzgau and the Enns valley). This includes the Zillertal and the Tauern ranges. The Ortler (*q.v.*), Stubai and Ötztal (from the Passo di Resia and the Stelvio to the Brenner pass, south of the Inn valley, and north of the Tonale pass). The Lombard Xlps (from Lake Como to the Adige valley, south of the Valtellina and the Aprica and the Tonale passes). This division includes the Adamello, Presanella, Brenta and Bergamasque ranges. The Dolomites of south Tirol (from the Brenner to the Passo di Monte Croce Carnico, and south of the Pusterthal). The southeastern Alps (east of the Monte Croce Carnico). This division includes the Julian, Carnic and the Karawanken Xlps.

In 1926 an Italian commission considered the subdivision of the Alps and their suggestions embodied several modifications of the above. (See L. W. Freshfield, *Geogr. J.*, p. 37, Jan. 1928.)

Geology and Structure.—The Alps form but a small portion of a great zone of crumpling which stretches in a series of curves from the Rif mountains of Morocco to beyond the Himalayas. The whole group of mountains may be conveniently called the Alpine-Himalayan group. Within this zone the crust of the earth has been ridged up into a complex series of creases and folds, out of which the great mountain chains of southern Europe and Asia have been carved by agents of weathering and erosion. Superficially, the continuity of the zone is broken at intervals by gaps of greater or less extent; these are due in part at least to the subsidence of portions of the folded belt and their subsequent burial by more recent accumulations. Such a gap is that between the Alps and the Carpathians.

This mountain system, which stretches a quarter of the way across the globe, is formed not of a single fold of the crust but of a number of such, often parallel to one another and to the general direction (trend) of the chain. The mountains of southern Europe are an exception to the last statement, for there are five great mountain systems radiating from the Alps themselves. One arm stretches east through the Carpathians and another to the southeast through the Dinaric Alps. The latter passes through Candia and Rhodes into the Taurus mountains, where it is joined by the continuation of the Carpathian branch, and east into the Iran plateau and the Himalayas. This arm appears to cross southern

China while there is a loop to the south forming the Burmese-Malayan arc. The third arm stretches west from the mountains of Provence into the Pyrenees and the northern Spanish highlands; a fourth through Liguria, Corsica! Elba, the Apennines, Sicily, the Balearic Islands, the Baetic Cordillera (Cordillera Penibética), across the Strait of Gibraltar and into the Rif mountains of Morocco. This latter demarcation of the fourth arm is according to R. Staub, but L. Kober considers the Baetic Cordillera as part of the Provence-Pyrenees branch, and thinks that the Apennines branch continues by way of Sicily directly into the Rif mountains. A fifth narrow chain stretches from Grenoble into the Jura mountains. These several chains, forming one great mountain system, were uplifted during the same period of earth movement and by the same set of causes. Each branch is in a certain sense a separate unit but each is represented in the Xlps which is the narrowest portion of the whole mountain belt, and in consequence every aspect of the geology of the Alps is of paramount importance when the whole chain is considered.

Sedimentary rocks form a large part of the Xlps. These range from the Trias to the Miocene, but older rocks (Permian, Carboniferous, Devonian! Silurian and possibly Cambrian) also occur and are of considerable importance, especially in the Eastern Alps. Crystalline gneisses and schists and igneous rocks also occur. There are many rock types of local importance which need special mention. Here are found characteristic Tertiary rocks, Molasse, Nagelfluh and Flysch. The former consists of a remarkably uniform series which crops out along the northern border of the Alps in the Swiss plateau. To the south of this is the Flysch zone which attains more important dimensions in the east than in the west. Other types which have commanded universal interest are the Gossau beds, Verrucano and Schistes Lustrés.

The Alps stand upon the site of a geosyncline which, from late Carboniferous times, through the whole of the Mesozoic period until the Miocene period, existed between the Eurasian (Foreland) land mass to the north and the African (Hinterland) land mass to the south. The sea which occupied this depression was called by Eduard Suess (*q.v.*) and others the "Tethys." Great thicknesses of deposits were laid down in it, causing the floor to sink and thus enabling the sediments to be deposited at approximately the same depth below the sea level. P. Termier compared this geosyncline to a huge vice, the jaws of which moved slowly inward concurrently as deposition was taking place between them. The Hinterland moved northward toward the Foreland. E. Argand has suggested that, by this movement two geanticlines (arches) arose within the geosyncline, thus bringing about the following subdivision:—the Valais geosyncline (north), the Briançonnais geanticline, the Piedmont geosyncline, the Dolin geanticline and the Canavese geosyncline. The two geanticlines continued to increase in size as compression proceeded during the whole of the Mesozoic period until the culmination of the movement in the Miocene. The compression was so great that the geanticlines rose completely out of the Tethys and were driven northward on to the Foreland in the form of huge recumbent folds, to which the name of "nappes" was given. The geanticlines can now be identified in the Pennine Alps as the Great St. Bernard nappe and the Dent Blanche nappe. Further, the rise of these two structures also brought about the formation of other structures within the Alpine geosynclines; the Great St. Bernard nappe forcing upward and forward the three Simplon nappes which lie beneath it, and the Dent Blanche nappe similarly bringing into being the Monte Rosa nappe. There are thus in the Pennine Xlps six major tectonic elements which arose from the Alpine geosyncline.

Apart from these, the Foreland and the Hinterland both played important roles and large tracts of the mountains belong to these divisions. Sedimentary rocks were laid down in epicontinental seas upon the peneplained Hercynian surfaces of these continental masses and these rocks, as well as the fundamental crystalline rocks, were affected by the Alpine earth movements. The northward movement of the Hinterland was so great that portions of it were driven completely over the geosynclinal rocks on to the Foreland itself. Sedimentary rocks of the same age belong to the Foreland? the Hinterland and the Geosyncline, but there are dis-

tinct differences in facies between them as well as differences within each group. Recumbent folding and overthrusting are common throughout the whole of the Alps, but the particular type of structure found in any locality depends upon the nature of the rocks and their location in one or other of the main divisions.

From a geological point of view it is convenient to divide the Alps into Western Alps and Eastern Alps along the Rhine line (a north-south line through Lake Constance, Chur and the Septimer pass). The following is a summary of the chief tectonic divisions:—

Western Alps.—(1) The Jura mountains; (2) the Swiss plateau of Tertiary rocks; (3) the Prealps, with exotic Paleozoic, Mesozoic and Tertiary rocks; (4) the zone of the High Calcareous Alps of Switzerland (the Helvetic zone of R. Staub); (5) the zone of Mont Blanc in which are the crystalline Hercynian massifs. Mercantour, Pelvoux and Belledonne, Mont Blanc and the Aiguilles Rouges, Gotthard, Aar and Gastern-Erstfeld (the Autochthonous massifs of Heim); (6) the Pennine zone, in which occur the Pennine nappes (Pennides of R. Staub); (7) the zone of the "Inner Roots," containing the roots of the Pennine, Austride and Dinaride nappes.

Eastern Alps.—(1) The Swiss plateau with Tertiary rocks; (2) the northern Flysch zone (the East Alpine equivalent of the zone of the High Calcareous Alps); (3) the zone of the Eastern Alps; (a) the northern Limestone zone of Triassic, Jurassic and Cretaceous rocks; (b) the Greywacke zone of schists and limestones of Paleozoic Age; (c) the central zone, forming the chief mountain tracts of the Eastern Alps, and built up chiefly of Austride nappes; (d) the Pennine "windows" which occur within the central zone and in which Pennine nappes are found; (4) the Dinaride zone in which the Dinaride nappes occur and which is formed of Paleozoic and Mesozoic rocks and several plutonic intrusions.

Of these divisions the Jura mountains, the Swiss plateau, the zone of the High Calcareous Alps, the northern Flysch zone and the zone of Mont Blanc belong to the Foreland; the Pennine zone, the Pennine "windows" and part of the zone of the "Inner Roots" belong to the Alpine geosyncline, while the northern Limestone zone, the Greywacke zone, the central zone, the Prealps, part of the zone of the "Inner Roots" and the Dinaride zone belong to the Hinterland.

Although the Foreland acted as a single unit during the Alpine earth movements it did not possess a simple homogeneous structure. Some portions of it (*e.g.*, the central plateau of France, the Vosges, the Black Forest, the Bohemian mountains and the massifs of the zone of Mont Blanc) resisted the northward advance of the folds, and the effect of this is well seen in the trend of the chain. There were two sets of obstructions, an outer group comprising the Maures-Esterel massif, central plateau of France, Vosges-Black Forest and Bohemian massifs; and an inner group, the zone of Mont Blanc. The outer group, well within the Foreland, determined the trend of the chains of the Basses and Dauphiné Alps, the Jura mountains and Swabian Alps. The effect of the zone of Mont Blanc, nearer the southern edge of the Foreland, is seen in the Pennine and Eastern Alps. Here R. Staub has identified ten distinct arcs, five in the Eastern Alps and five in the Western Alps. The latter are more distinct than those east of the Rhine line, for the massifs of the zone of Mont Blanc all occur in the Western Alps, but the occurrence of arcs farther east indicates the presence of similar massifs buried beneath the Austrides. The presence of these is further indicated by the occurrence of culminations, which are portions of the true nappe mountains in which the lower elements have been forced to high altitudes, having been driven over elevated portions of the Foreland. Denudation, especially river action, has brought about the removal of much of these upper structures and has revealed different lower units in different districts. Vertical movement, during and since the orogenic period, has made this type of segmentation more marked. Between two culminations a tectonic depression occurs in which, owing to downward sagging, the uppermost tectonic elements have been preserved from denudation. Staub has identified eleven culminations and eleven depressions in the Alps, and in the Western Alps the culminations occur in each case directly behind the individual massifs

of the zone of Mont Blanc.

The massifs of the zone of Mont Blanc are, generally speaking, large granitic intrusions (batholiths), surrounded by crystalline schists and gneisses with sedimentary rocks more or less highly metamorphosed. In the Aar, Mont Blanc and Pelvoux massifs "fan" structure has been identified, the granitic rocks being subdivided longitudinally by steep-sided synclines of crystalline schists. The larger massifs of the zone, namely, the Aar-Gotthard, Mont Blanc, Pelvoux and Mercantour, form an inner arc, while the smaller ones, namely, the Gastern-Erstfeld, Aiguilles Rouges and Belledonne, form an outer arc. Both arcs are open to the south and adjacent massifs are separated by zones of sedimentary rocks, many of which have been so highly metamorphosed as to be reduced to paragneisses. The Lotschental zone (paragneisses), the Chamonix sedimentary zone and the zone between the Pelvoux and the Belledonne occur between the two arcs. In the two former zones and in the adjacent massifs the roots of the nappes of the High Calcareous Alps are located. The sedimentary cover of the Aiguilles Rouges and the Gastern massifs has been called the Autochthon. This term is also applied by some authorities to all that portion of the sedimentary cover of the Hercynian peneplained surface which has not suffered acute folding, such as is found in the zone of the High Calcareous Alps. A. Heim further calls the massifs of the zone of Mont Blanc the autochthonous massifs. The Autochthon (in its wider sense) has not suffered acute folding such as is found in the other parts of the Alps, but the rocks are in contact with the surface upon which they were originally deposited.

In the High Calcareous Alps six nappes have been identified. These are called the Helvetides by R. Staub, but simply the nappes of the High Calcareous Alps by L. Collet and others. They are named as follows (from the highest to the lowest):—(6) The Oberlauchhorn nappe, (5) the Mont Bonvin nappe, (4) the Plaine Morte nappe, (3) the Wildhorn nappe, (2) the Diablerets nappe, (1) the Morcles nappe.

The Morcles nappe lies as a great recumbent fold upon the Autochthon, and has its roots in the zone of Chamonix. It is composed of sediments ranging from the Trias to the Eocene. Above it lies the Diablerets nappe, the roots of which probably lie in the Mont Blanc massif. This nappe does not possess a reversed limb, this and much of the upper limb having been replaced by a "slide" (E. B. Bailey). The Wildhorn nappe is the greatest of this group and is characterized by a number of digitations in the front of the structure, by disharmonic folding, and a large "involution." Its roots probably occur on the south side of the Mont Blanc massif. The three higher nappes (the Ultra-Helvetic nappes of Heim) crop out in a belt 16 mi. long on the south side of the Wildhorn-Wildstrubel range, and again on the north side of the High Calcareous Alps in the zone of cols, where they form the Internal Prealps. In eastern Switzerland (*i.e.*, east of the Hasli-Tal) the following units occur:—The Santis-Drusberg unit, the Axen unit, the Glarner-Murtschen unit, the Parautochthonous nappes.

The upper unit (Santis-Drusberg) is an eastward extension of the Wildhorn nappe, the Glarner-Murtschen unit is homologous to the Diablerets nappe, and the Parautochthonous nappes rest upon the Autochthon and are homologous to the Morcles nappe. The Axen unit is not represented in west Switzerland. Three nappes, digitations of one structure, are distinguished in the Santis-Drusberg unit, four in the Axen unit and two in the Glarner-Murtschen unit.

With the exception of the Prealps, the Swiss plateau bounds the High Calcareous Alps on the north. The plateau is underlain by Tertiary rocks, covered by glacial, fluvio-glacial and alluvial deposits. It forms a wide syncline between the Jura mountains and the Western Alps, and in it are gentle flexures, the most important of which is a central anticline which passes from Lake Constance to Lake Geneva. The sedimentary rocks of the Jura mountains are continuous with those of the Autochthon beneath the Tertiary rocks of the great Swiss plateau, but they do not show the same facies. They have been folded into anticlines and synclines, the trend of which is parallel to that of the Alps, but

the folds are bunched together in the neighbourhood of the central plateau of France and the Vosges-Black Forest massifs. In the eastern part of the mountains the folding is complicated by block faulting. This portion is known as the Jura tableland while the remainder is called the Folded Juras. The folding has only a superficial character, for it dies out downward, the Anhydrite group (Middle Muschelkalk) not being folded. The beds of this latter horizon acted as a plane along which the folding took place, so producing a *décollement*. A study of the tectonics of the Jura mountains reveals a remarkable association between them and the Alps.

The Pennine nappes (Pennides of R. Staub), being great recumbent folds which arose out of the Alpine geosyncline, consist of Paleozoic rocks as crystalline cores, with envelopes of newer sedimentary rocks now highly metamorphosed and known as *schistes lustrés*. The evidence for the age of the *schistes lustrés* is sufficient to prove that they range from the Lower or Middle Trias to the Nummulitic limestone (Eocene). They occur in the synclinal structures between the crystalline cores of the nappes and also along the frontal archbends of the latter. The three Simplon nappes, Monte Leone (III), Lebendun (II), Xntigorio (I), crop out in the Ticino district, in the Lepontine culmination brought about by the obstacle of the Aar massif. (The figures I, II, etc., after the names of the nappes indicate the relative position of the structures, I to VI being Pennine nappes and VII-X Austrides.) The nappes pass round the culmination and are directly connected in the south with their roots. The *schistes lustrés* associated with them are not so thick as elsewhere in the Pennine Alps. The Great St. Bernard nappe (IV), which arose from the Briançonnais geanticline, occurs above the Simplon nappes, the latter being regarded as major digitations of the higher structure. The Great St. Bernard nappe is the most extensive of the Pennine units and stretches in an almost unbroken outcrop from the Gulf of Genoa to the Simplon pass. *Schistes lustrés* mark the front of it and also separate it from the crystalline core of the Monte Rosa (V) nappe, which forms the massifs of Monte Rosa, Grand Paradis, Ambin and Dora Maira and is in fact a major digitation of the highest Pennine nappe. The Dent Blanche (VI) nappe, which arose from the Dolin geanticline, has suffered considerable denudation and its main outcrop in the Dent Blanche-Weisshorn mountain mass is now isolated from the roots. Here the nappe is in contact with the Great St. Bernard nappe, for the Monte Rosa nappe does not reach so far north and the Great St. Bernard has suffered backward folding.

The country east of the Rhine line belongs principally to the Hinterland. In it are found several tectonic units, named the Austrides by R. Staub, who also recognizes two divisions in the group, the Upper (Tirolides) and the Lower (Grisonides), both so named because of the location of their main outcrops. This is R. Staub's scheme, but L. Kober uses the name East Alpine nappes for the Xustrides and recognizes in them four main divisions. The Austrides overlie the Pennine nappes in the Eastern Xlps, for where denudation has been great the lower structures are exposed beneath the Xustrides in what are known as "windows." In the Lower Engadine window, *schistes lustrés* occur surrounded by Grisonide elements, while in the Hohe Tauern window there are tectonic elements correlated by R. Staub with the Monte Rosa and the Dent Blanche nappes as well as *schistes lustrés*. (L. Kober considers that the lowest elements here are homologous with the higher Simplon nappes.) In the Semmering window, denudation has revealed the Grisonides beneath the Tirolides.

The Grisonides are divided into two major structures, the Campo (VIII) nappe and the Err-Bernina (VII) nappe, each of which has several digitations in its frontal portion. The lower of the two rests on the Margna (VI) nappe, which is homologous to the Dent Blanche nappe. The Grisonides consist of crystalline cores surrounded by sedimentary rocks, the latter being peculiar in age and facie: to each nappe. In the Rhätikon the Grisonides show *schuppen* structure (*i.e.*, slices overthrust one upon another) and parts of them exhibit interesting sedimentary types, which are important in a study of the Prealps. The Tirolides are similarly divided into two major structures, the Ötztal

(X) nappe and the Silvretta (IX) nappe. The latter nappe is the greatest East Alpine structure and, being the lower of the two Tirolide elements, will occur to the north of the Ötztal nappe in the root region, but the sedimentary cover of the latter has been driven over the Silvretta nappe and forms the northern Limestone zone. The main outcrop of the Ötztal nappe is in the Mur Alps of Styria, while the other forms the Silvretta mountain mass. The northern Limestone zone forms a wide belt from the Rhine line to Vienna and has the structure of a great pile of overthrust masses of rocks ranging from the Trias to Cretaceous, the dolomite of the Trias being the principal member of the group. North of this zone is the northern Flysch zone, which is the eastern representative of the High Calcareous Alps.

Austride elements occur west of the Rhine line, in the Prealps, which lie between the Swiss plateau and the High Calcareous Xlps and between the Arve river and the Lake Thun. The following tectonic elements have been identified in this region: the External Prealps forming the northern portion and being overthrust upon the Molasse of the Swiss plateau; and the Internal Prealps on the southern margin. The Internal and External Prealps are probably connected and completely underlie the basinlike structure filled by the higher elements of the Prealps. In these two zones the higher units of the High Calcareous Alps occur. Above the Internal Prealps is the Niesen nappe (chiefly sandstones and conglomerates), which shows Pennine affinities; while above the External zone there are similar sandstones, etc., forming the zone of Gurnigel which is considered by some to represent the Niesen nappe. The Median Prealps nappe occurs above the zones mentioned and forms the greater part of the Prealps. Above it are the Simme nappe and the Brèche nappe. These structures seem to show Austride affinities, and the association between them and the Austrides is further established by the occurrence of *Klippen* (*i.e.*, frontal portions of nappes isolated by erosion) which have the character of a connecting link, resting upon the Mesozoic rocks of the High Calcareous Alps in the central Swiss region. According to Argand the roots of the Simme nappe occur in the zone of Canavese, south of the Lepontine culmination. These also are west of the Rhine line, but they are continuous with the roots of the other Austride elements farther east. In the zone of Canavese the Dent Blanche nappe is rooted together with the Austrides, and in consequence of this Kober considers that this nappe must belong to the East Alpine group (Austrides) and not to the Pennine chain.

The roots of the Pennine nappes (the "inner roots") lie in a zone which stretches eastward from near Ivrea, through Locarno. The roots of the Austrides are in contact with these but on the south side of them. The nappes are vertical in this zone or even overturned toward the south. To the south again are the Dinaride nappes. The boundary between the Austrides and the Dinarides (the Dinaric boundary) passes from the neighbourhood of the Italian lakes to Merano, then east through the Drau range to the southeast end of Bacher mountains, where it disappears beneath the Hungarian plain. The tectonics of the Dinarides are comparatively simple. The term "nappes" is still used here by some authorities to designate the tectonic units; but the latter are very different from the nappes of other parts of the Alps, being essentially thrust masses. The extent of the thrusting is never very large. Moreover the units are not so strikingly different from one another in facies as is the case in other parts of the Alps. L. Kober recognizes four zones here, the Outer zone (Adriatic), the Lower Dinaric nappe, the Upper Dinaric nappe and the High Dinaric nappe. The stratigraphy of the Dinaric zone shows an important development of Upper Paleozoic rocks, Silurian, Devonian, Carboniferous, Permian and Trias, Jurassic, Cretaceous and Flysch are also important in some units. This southern belt of the Xlps is noted for its rich development of calcareous rocks. *Klippen* (outliers) of Dinaride elements occur resting upon the Ötztal nappe in the Mur Alps district. The tectonics of the structures south of the Dinaric boundary show a southward direction of movement. This reverse direction of movement probably indicates one of the latest phases of the Alpine movements. There has been considerable igneous activity in this region, but the in-

trusions are not all of the same age. The following are affected by Tertiary movements and must therefore belong to an earlier period:—the Kreuz, Iffinger, Brixen, and Riesenferner intrusions. The "Peri-Adriatic Intrusion zone" (W. Salomon) contains the following igneous bodies:—Ivrea, Baveno. Bergeller, Adamello, the tonalite of Eisenkappel and the granites of the Bacher mountains. These were not affected by Alpine movements and are, by many authorities, thought to be of slightly later date than those movements.

Main Chain.—Several important mountain groups are situated on one or other side of the watershed of the Alps and form almost independent ranges, connected with the main chain by a kind of isthmus: such are the Dauphiné Alps, the Eastern and Western Graians, the entire Bernese Oberland, etc. The Alps, therefore, are not composed of a single range but of a great "divide" flanked on either side by other important ranges.

Starting from the Col d'Altare or Colle di Cadibona (west of Savona), the main chain extends first southwest, then northwest to the Colle di Tenda, though nowhere rising much beyond the zone of coniferous trees. Beyond the Colle di Tenda the direction is first west then northwest to the Rocher des Trois Évêques (9,422 ft.), just south of the Mont Enchastraye (9,698 ft.), several peaks of about 10,000 ft. rising on the watershed, though the highest of all, the Punta Argentera (10,817 ft.) stands a little way to its north. From the Rocher des Trois Évêques the watershed runs due north; of the two loftiest peaks of this region, one, the Aiguille de Chambeyron (11,155 ft.), is just to the west and the other, the Monte Viso (12,602 ft.), to the east of the watershed. From the head of the Val Pellice the main chain runs northwest and diminishes much in average height till it reaches the Mont Thabor (10,453 ft.), which forms the apex of a salient, which the main chain here presents toward the west. Hence the main watershed extends east, culminating in the Aiguille de Scolette (11,500 ft.) but makes a great curve to the northwest and back to the southeast before rising in the Rochemelon (11,607 ft.), a re-entering angle in the great rampart by which Italy is guarded. Thence the direction taken is north as far as the east summit (11,873 ft.) of the Levanna, the watershed rising in a series of snowy peaks, though the loftiest point of the region, the Pointe de Charbonel (12,302 ft.), stands a little to the west. Once more the chain bends northwest rising in several lofty peaks (the highest is the Aiguille de la Grande Sassikre [12,323 ft.]), before attaining the considerable depression of the Little St. Bernard pass (7,178 ft.). Thence for a short way the direction is north to the Col de la Seigne (8,245 ft.), and then northeast along the crest of the Mont Blanc chain, which culminates in the peak of Mont Blanc (*q.v.*) (15,782 ft.), the loftiest in the Alps. A number of high peaks crown the watershed before it attains the Mont Dolent (12,342 ft.). Thence after a short dip southeast, the chain takes near the Great St. Bernard pass (8,111 ft.) the general easterly direction that it maintains throughout the Pennine Alps till it reaches Monte Rosa, whence it bends north, making one small dip to the east as far as the Simplon pass. In the Pennine Alps the main chain maintains a greater average height than in any other part, but, though it rises in a number of lofty peaks, such as the Mont Velan (12,251 ft.), the Matterhorn (*q.v.*) (14,690 ft.), the Lyskamm (14,691 ft.), the Nord End of Monte Rosa (15,131 ft.) and the Weissmies (13,119 ft.), yet many of the highest points such as the Grand Combin (14,164 ft.), the Dent Blanche (14,318 ft.), the Weisshorn (14,804 ft.), the true summit or Dufourspitze (15,203 ft.) of Monte Rosa itself, and the Dom (14,942 ft.) rise on its northern slope and not on the main watershed. The chain between the Great St. Bernard and the Simplon sinks at barely half a dozen points below a level of 10,000 ft. Eastward from the Simplon (6,592 ft.) through the Lepontine Alps so far as the St. Gotthard (6,918 ft.) the divide runs northeast, all the higher summits (including the Monte Leone, 11,653 ft., and the Pizzo Rotondo, 10,486 ft.) rising on it, a curious contrast to the long stretch just described. From the St. Gotthard to the Maloja (5,960 ft.) the watershed between the basins of the Rhine and Po runs east as a whole, though making two great dips toward the south first to near the Vogelberg (10,565 ft.) and again to near the Pizzo Gallegion (10,203 ft.), so that it presents a broken

and irregular appearance. Its highest point is the Rheinwaldhorn (11,161 ft.).

From the Maloja pass the main watershed dips southeast for a short distance, and then east and nearly over the highest summit of the Bernina group, the Piz Bernina (13,304 ft.) to the Bernina pass (7,645 ft.). Thence to the Passo di Resia (4,947 ft.) the main chain is ill-defined, though on it rises the Corno di Campo (10,833 ft.), beyond which it runs slightly northeast, past the sources of the Adda and the Frael pass (6,398 ft.), sinks to form the depression of the Ofen pass (7,523 ft.), soon bends north and rises once more in the Piz Sesvenna (10,568 ft.). The break in the continuity of the Alpine chain marked by the deep valley, the Vintschgau, of the upper Adige (*q.v.*) is one of the most remarkable features in the orography of the Alps. The chief source of the Adige is the little Reschen lake, which is only 13 ft. below the Passo di Resia (4,947 ft.) and but 5 mi. from the Inn valley. East of this pass the main chain runs northeast to the Brenner pass along the snowy crest of the Ötztal and Stubai Alps, the loftiest point on it being the Weisskugel (12,291 ft., Ötztal), for the highest summits both of the Ötztal and of the Stubai districts, the Wildspitze (12,380 ft.) and the Zuckerhiitl (11,539 ft.), stand a little to the north.

The Brenner (4,501 ft.) is almost the lowest of all the great motor road passes across the main chain, and has always been the chief means of road communication between Germany and Italy. For some way beyond it the watershed runs east over the Hochfeiler (11,516 ft.) the highest crest of the Zillertal Alps. A little farther, at the Dreiherrnspitze (11,480 ft.), we have to choose between following the watershed south, or keeping due east along the highest crest of the Greater Tauern Alps. (1) The latter course is adopted by many geographers. The watershed (though not the chief Alpine watershed) continues east through the Greater Tauern Alps, culminating in the Gross Venediger (12,008 ft.), for the Gross Glockner (12,461 ft.) rises to the south. The chain bends northeast near the Radstadter Tauern pass (5,702 ft.) and preserves that direction through the Lesser Tauern Alps to the Semmering pass (3,248 ft.). (2) On the other hand, from the Dreiherrnspitze the true main watershed of the Alpine chain dips south, passes over the Hochgall (11,270 ft.), the culmination of the Rieserferner group, and then sinks to the Sella di Dobbiaco (3,967 ft.) but a little east of the great Dolomite peak of the Drei Zinnen (9,839 ft.) it bends east again and rises in the Monte Cogliano (9,121 ft., the monarch of the Carnic Alps). Soon after the watershed makes a last bend to the southeast and culminates in the Triglav (9,393 ft.), the highest point of the Julian Alps, though the Grintovec (8,392 ft., the culmination of the Karawanken Alps) stands more to the east. Finally the watershed turns south and ends near the great limestone plateau of the Birnbaumerwald, between Ljubljana and Gorizia.

Principal Passes.—The Alps have never formed an impassable barrier. The spots at which they are crossed are the points at which the great chain sinks to form depressions. Hence the oldest name for such passes is *Mont* (still retained in cases of the Mont Cenis (*q.v.*) and the Monte Moro); it was long before this term was especially applied to the peaks of the Alps, which, with a few rare exceptions (*e.g.*, the Monte Viso was known to the Romans as Vesulus), were simply disregarded. The native inhabitants of the Alps were naturally the first to use the alpine passes, but to the outer world these passes first became known when the Romans traversed them in order to conquer the world beyond. For obvious reasons the Romans, having once found an easy pass did not trouble to seek for harder routes. The passes known to them were comparatively few: they are, in topographical order from west to east, the Col de l'Argentière, the Col de Genève (Montgenève pass), the two St. Bernard passes, the Splügen, the Septimer, the Brenner, the Radstadter Tauern, the Solkscharte, the Plocken (Croce Carnico) and the Pontebba (or Saifnitz). The Col de Genève and the Brenner were the most frequented, while it will be noticed that in the Central Alps only two passes (the Splügen and the Septimer) were certainly known to the Romans. The Simplon is first certainly mentioned in 1235, the St. Gotthard (without name) in 1236, the Lukmanier in 965, the San Bernardino

in 941. Even the Mont Cenis (from the 15th to the 19th century the favourite pass for travelers) is first heard of in 756 only. In the 13th century many hitherto unknown passes came into prominence, even some of the easy glacier passes. In the Western and Central Alps there is but one ridge to cross, to which access is gained by a deep-cut valley, though often it would be shorter to cross a second pass in order to gain the plains, *e.g.*, The Col de Genève, that is most directly reached by the Col du Lautaret. In the Eastern Alps it is generally necessary to cross three distinct ridges between the north and south plains, the central ridge being the highest and most difficult. The passes which crossed a single ridge, and did not involve too great a detour through a long valley of approach, became the most important and the most popular, *e.g.*, the Mont Cenis, the Great St. Bernard, the St. Gotthard, the Septimer and the Brenner. As time went on the travelers who used the great alpine passes could not put up any longer with the bad old mule paths. A few passes (*e.g.*, the Semmering, the Brenner, the Tenda and the Arlberg) can boast of carriage roads constructed before 1800, while those over the Umbrail and the Great St. Bernard were not completed till the early 20th century. Many of the carriage roads across the great alpine passes were constructed in the 19th century, largely due to the impetus given by Napoleon. As late as 1905, the highest pass over the main chain that had a carriage road was the Great St. Bernard (8,100 ft.). By mid-20th century railway lines had been carried over or through the chain—there being the Brenner and Pontebba lines, both over passes, and the Colle di Tenda, Mont Cenis, Simplon, St. Gotthard, Lotschen, Arlberg, Albula and Pyhrn through tunnels. Road tunnels were constructed (1960) under the Mont Blanc massif and under the Great St. Bernard pass.

See also separate articles on the ALBULA, BRENNER, LÖTSCHEN, MONT CENIS, SAINT BERNARD, SAINT GOTTHARD, SEMMERING, SIMPLON, SPLÜGEN and RESCHEN SCHEIDECK passes.

Glaciers.—Because the Alps were explored and studied earlier than the other mountain systems of the world, the type of glaciation found there has received the name "Alpine type." It is similar to that of parts of the Himalayas, Andes, Rockies and the mountains of New Zealand but is different from that of Spitzbergen, Greenland, Alaska and the Polar regions (see GLACIER). The main characteristics of the Alpine type consist of an elevated "catchment area" from which valleys pass down to lower altitudes. The highest peaks do not necessarily form the centres from which the largest glaciers radiate, but these latter arise where the topography of the mountain masses is that of numerous depressions and wide hollows separated by rounded snow-capped peaks, as Mont Blanc or by steep-sided frost-eaten peaks and ridges as the Aiguilles. Snow accumulates in these hollows and is compacted into ice which differs in appearance and internal structure from ice formed in the normal way by freezing. It is known as *névé* (Fr.) or firn (Ger.). This ice is forced downward by the weight of the accumulated snow above, or falls down as avalanches into the valley below, forming the valley glaciers characteristic of the Alps. The boundary between the *névé* and the valley glacier (the firn line) is marked by a change in the character of the surface of the ice. Above the *firn* line precipitation is greater than melting and so snow covers the surface, but below it the reverse is the case and the ice is exposed. In summer the firn line is quite distinct, but generally some hundreds of feet below the limit of perpetual snow.

It is estimated that there are 1,200 separate glaciers and *névé* fields in the Alps, but many are mere accumulations of snow in small hollows which really form part of larger basins. The largest glacier in the Alps is the Aletsch glacier which is 16 mi. long and with its *névé* and catchment area covers an area of over 50 sq.mi. The lowest point reached by glaciers varies considerably; it is as low as 3,200 ft. above sea level at Grindelwald, but the height is more often quite 1,000 ft. higher than this. The line of perpetual snow lies between 8,000 ft. and 9,500 ft. Its exact position varies locally; regions which rise above these limits form centres for the radiation of valley glaciers. The largest of such centres are in the Mont Blanc group, the Bernese Oberland (from Blumlisalp to the Wetterhorn) and in the Pennine Alps (from the Grand Combin

to the Mischabel). The main chain boasts of more glaciers and *névé* than the subsidiary chains. Nevertheless, the three longest glaciers of the Alps, the Greater Aletsch (16 mi.) and the Unteraar and the Viescher (each 10 mi.), are in the Bernese Oberland. The longest glaciers in the main chain are the Mer de Glace and the Gorner (each 9½ mi.).

During the Pleistocene Ice Age the whole chain was more than once covered by an ice sheet above which perhaps the main peaks stood out. A. Penck infers four ice maxima. One of the intervals, it is generally agreed, witnessed a return of warm temperate conditions. The final retreat of the Pleistocene Ice Sheet proceeded by stages, and it has been suggested there was a serious regrowth of glaciers in early centuries of the last millenium B.C. Each stage was marked by a continuous retreat of the ice front to higher altitudes, no movement or perhaps even a temporary advance occurring in the intervals. During historical times the movement of the fronts has not been very marked. In 1918 a general forward movement was noticed in most Alpine glaciers, the previous great advance commencing in 1818 and finishing in 1822. The smaller glaciers will, of course, show movement more quickly than the larger. This is illustrated in the case of the Aletsch glacier, which has maintained the same position of its front for many years. In 1823 this glacier suddenly dropped its level (for reasons not understood) causing the level of Lake Märjelen, which is formed by the glacier obstructing the mouth of a tributary stream, to fall.

Lakes and Water Power.—The lakes of the Alps are of several types. (*See* LAKE.) Lakes of the barrier type are formed in various ways, principally by terminal and lateral moraines, in rarer cases by land slides, alluvial fans or a glacier. Lake Ziirich (*q.v.*) shows interesting phases of damming by various moraines; Lake Mattmark is formed by a lateral moraine; Lake Märjelen is a classic example of a glacier acting as a dam. Examples of lakes of tectonic origin are Lake Joux, in the Jura region, which occurs in a syncline, and Lake Fahlen near Santis. Lakes formed by the solution of calcareous rocks are of two types: the "polje" and the "doline" types. Frequently the depressions occupied by these lakes were the sites of former glaciers, as proved by the lining of glacial clay which the lakes now possess. Lakes of these types are quite frequent in the limestone areas and examples are Lakes Dauben, Mutton and Seewli (the latter also being in a corrie). Lakes in depressions in water-bearing strata occur on moraines or on fluvio-glacial material. No rivers feed them and they have no visible effluents. Examples of the formation of two small lakes from a large one by a lacustrine delta are the lakes of Thun (*q.v.*) and Brienz and of Sils and Silvaplana.

By mid-20th century the Alps had become a most important source of hydroelectric power for industry, railway transport and lighting, and the amount of coal used is diminishing. Nowhere, even in the limestone districts! is the amount of water so small as to warrant the exclusive use of coal or other fuels. As the water is derived from melting snow and ice, there is no fear of summer shortage, but a winter stoppage may occur. Most of the great lakes of the subalpine region are used as sources of supply, as also are many of the smaller ones; in the latter cases the level of water is frequently raised by a dam. The water is drawn from the bottom of the lake in order to ensure a constant supply in winter. Reservoirs are also constructed in suitable places. The choice of site depends upon several factors, *e.g.*, the impermeable nature of the rocks forming the basin, an adequate supply of water, a minimum amount of deposition of sediment within the basin and the geographical position. Old lake basins have been transformed into reservoirs, *e.g.*, the Barbarine, and many deep gorges have been so utilized. Electric power and lighting are to be found in remote villages. Many of the valleys in the French Alps have become industrial districts as a result of the availability of electric power; bauxite is refined, and numerous electro-chemical and electro-metallurgical industries are active.

In the Alps are the sources of the great rivers of western Europe—the Po, Rhône, Rhine and Danube (the actual source of the latter is in the Black Forest, but its main tributaries rise in the Alps). These rivers drain the south, west, north and east slopes

respectively, and the Danube also drains the north slope. There exists a very close connection between the direction of the river valleys in the Alps and the geological structure. Most of the valleys are either parallel to or at right angles to the trend of the chains. Examples of the former are the Isère, the Upper Rhône and the Upper Rhine, and of the latter the rivers of the Pennine Alps. (J. I. P.; F. J. M.)

Minerals. — Mineral deposits in the Alps are generally small and scattered, and there were only a few mines of economic significance in the 1960s. The Swiss Alps provide no minerals of any commercial importance apart from minor deposits of lead, zinc and copper in Valais. Coal has in times of necessity been produced from Valais, but the quality is very poor. The principal minerals extracted from the Austrian Alps consist of iron ore (there are very large reserves of good quality in Styria), lignite, magnesite (the Veitch mines are the richest), salt (important in the Salzburg area), and some minor deposits of lead, zinc and copper. In the past, gold was mined in the Hohe Tauern. In the Italian section of the Alps some anthracite is obtained from the Aosta region, together with iron and copper pyrites; there is also a small production from scattered deposits of antimony, zinc, lead and manganese. The alluvium of several rivers was washed for gold, and numerous small gold mines opened in the past in the Monte Rosa area and elsewhere, but little gold is extracted. The principal mineral worked in the French Alps is bauxite, in the extreme south near Brignoles; this area produces about three-quarters of the total output of bauxite in France. Near La Mure (south of Grenoble), and elsewhere, there are some small coal deposits, but these supply less than 1% of France's coal production. Limestone is found widely in the Alps, and is quarried for cement. (C. EN.)

Climate. — It is well known that with the rise from the sea level into the upper regions of the atmosphere the temperature decreases. Mountain chains cause the prevailing winds to rise to higher altitudes, thus frequently bringing about the precipitation of snow or rain principally upon the windward side. The vast mass of snow, converted into glaciers, maintains a gradation of very different climates within the narrow space that intervenes between the foot of the mountains and their upper ridges; it cools the breezes that are wafted to the plains on either side, but its most important function is to regulate the water supply of the large region traversed by Alpine streams. Nearly all precipitation during six or seven months is in the form of snow, gradually released by melting in the course of the succeeding summer; even in the hottest and driest seasons the reserves accumulated in the form of glaciers maintain the regular flow of the greater streams. Nor is this all; the lakes that fill several main valleys on the south side are somewhat above the level of the Lombardy plain, and afford inexhaustible water for that system of irrigation to which it owes its proverbial fertility.

Six regions or zones, which are best distinguished by their characteristic vegetation, are found in the Alps. They are (1) the olive region; (2) the vine region; (3) the mountain region or the region of deciduous trees; (4) the subalpine region or the region of coniferous trees; (5) the Alpine region; (6) the glacial region. Local conditions of exposure to the sun, protection from cold winds or the reverse, as well as height above sea level, are of primary importance in determining the climate and the corresponding vegetation.

1. The great plain of Upper Italy is colder in winter than the British Isles which has mean winter temperature of about 40° F. The olive and the characteristic shrubs of the north Mediterranean coasts do not thrive in the open, but olives ripen in sheltered places at the foot of the mountains and along the deeper valleys and the lake shores. The evergreen oak grows wild around Lake Garda, and fruit is cultivated on a large scale, with partial protection in winter.

2. The vine is far more tolerant of cold than the olive, but to produce tolerable wine it demands, at the season of ripening, not much less warmth than the olive, about 68° F. average. These conditions are satisfied in the deeper valleys of the Alps, and up to a considerable height on slopes exposed to the sun. Winter snow covering helps the plant to resist severe and prolonged

frosts.

3. So many varieties of grain are grown under various climatic conditions that their limits of cultivation are less useful for determining zones than are those of the chief deciduous trees—oak, beech, ash and sycamore. These do not reach exactly to the same elevation, nor are they often found growing together; but their upper limit corresponds accurately enough to the change from a temperate to a colder climate. This limit lies about 4,000 ft. above sea level on the north side of the Alps, but on the southern slopes it often rises to 5,000 ft., sometimes even to 5,500 ft. The interference of man has in many districts almost extirpated these trees. Their place has been occupied by the Scotch pine and spruce, which suffer less from goats, the worst enemies of trees. The mean annual temperature differs little from that of the British Isles which is about 50° F.; but snow usually lies for several months, till it gives place to a spring and summer considerably warmer than the average of British seasons.

4. The subalpine is the region which mainly determines the manner of life of the farming population of the Alps. Of the space lying between the summits of the Alps and the low country on either side roughly one-quarter is available for cultivation of which about one-half may be vineyards and cornfields, while the remainder produces forage and grass. About another quarter is utterly barren, consisting of snow fields, glaciers, bare rock, lakes and the beds of streams. There remains about one-half, which is divided between forest and pasture, and it is the produce of this half which mainly supports the relatively large population. For a quarter of the year the flocks and herds are fed on the upper pastures; but the true limit of the wealth of a district is the number of animals that can be supported during the long winter, and while one part of the population is engaged in tending the beasts and in making cheese and butter, the remainder is busy cutting hay and storing up winter food for the cattle. The larger villages are mostly in the mountain region, but in many parts of the Alps the villages stand in the subalpine region at heights varying from 4,000 ft. to 5,500 ft. above sea level, more rarely extending to about 6,000 ft. Coniferous trees, where they have not been artificially kept down, form vast forests. They protect the valleys from destructive avalanches, and, retaining the superficial soil by their roots, they mitigate the destructive effects of heavy rains. On very steep slopes avalanches have frequently torn up the trees, leaving long avenues of varying width through the forests. In such places and in valleys where they have been rashly cut away, and the waters pour down the slopes unchecked, every tiny rivulet becomes a raging torrent, that carries away the soil and subsoil from the grassy slopes and devastates the floor of the valley, covering it with debris and gravel. The prevailing species are the common spruce, the silver fir, the larch and the Scotch pine. The Siberian fir is also found. In the northern Alps the pine forests rarely surpass the limit of 6,000 ft. above the sea, but on the south side they commonly attain 7,000 ft., while the larch, Siberian fir and mughus often extend above that elevation.

5. Throughout the Teutonic region of the Alps the word alp is used specifically for the upper pastures where cattle are fed in summer, but this region is held to include the whole space between the uppermost limit of trees and the first appearance of permanent snow. Here the characteristic vegetation of the Alps is developed in its full beauty and variety. Shrubs are not wanting. Three species of rhododendron give masses of red or pink flowers; the common juniper rises higher still, along with three species of bilberry; and several dwarf willows attain nearly to the utmost limit of vegetation, the so-called limit of perpetual snow.

6. On the higher parts of lofty mountains more snow falls in each year than is melted on the spot. A portion of this is carried away by the wind before it is consolidated; a larger portion accumulates in hollows of the surface, and, gradually converted into glacial ice, descends slowly into the deeper valleys, to swell perennial streams. As on a mountain the snow does not lie in beds of uniform thickness, and some parts are more exposed to the sun and warm winds than others, are commonly found beds of snow alternating with exposed slopes covered with brilliant vegetation; and to the observer near at hand there is no appearance in the

least corresponding to the term limit of perpetual snow, though the case is otherwise when a high mountain chain is viewed from a distance, for the level at which large snow beds show themselves along its flanks is approximately horizontal, in so far as conditions are similar. On the opposite sides of the same chain, exposure to sun or to warm winds may cause a wide difference in the level of permanent snow; but in some cases the increased fall of snow on the side exposed to moist winds may more than compensate increased influence of the sun's rays. Still, even with these reservations, the so-called line of perpetual snow is not fixed. In some parts of the Alps the limit may be set at about 8,000 ft. above the sea, while in others it cannot be placed much below 9,500 ft. As very little or no snow can rest on rocks that lie at an angle exceeding 60°, some steep masses of rock remain bare even near the summits of the highest peaks, but as almost every spot offering the least hold for vegetation is covered with snow, few flowering plants are seen above 11,000 ft. It is, however, want of soil rather than climatic conditions that checks the upward extension of the alpine flora. Increased direct effect of solar radiation compensates for the cold nights, and in the few spots where plants have been found in flower up to a height of 12,000 ft., nothing has indicated that the processes of vegetation were arrested by the severe cold which they must sometimes endure. The climate of the glacial region has often been compared to that of the polar regions, but they are widely different. Here, intense solar radiation by day, which gives the surface when dry a temperature approaching 80° F., alternates with severe night frost. There, a sun which never sets sends feeble rays that maintain a low equable temperature rarely rising more than a few degrees above the freezing point. Hence the upper region of the Alps sustains a far more varied and brilliant vegetation. (J. I. P.; F. J. M.)

Vegetation.—The alpine flora in general belongs essentially to the middle belt of the European high mountain flora, and contains numerous significant species common to all these mountains. The flora of the western parts of the Alps shows connections with that of the Pyrenees, while the flora of the eastern parts shows a closer relationship to that of the Carpathians. The Alps, however, have a considerable number of species that occur nowhere else, the so-called endemic species. It is difficult to find a border line within the Alps between the east and west, since the distribution of the vegetation does not correspond with the geographical borders between the eastern and western Alps. The differences in the two floras here mainly derived from the destruction of plants in the Ice Age and the postglacial plant migrations in the thickly glaciated middle part of the Alps. The easiest way to describe the present distribution is to divide the transverse mountain chains of the middle and eastern Alps (Helveto-Norican province, from Geneva to Vienna and Trieste) from the longitudinal ones of the southwestern Alps (Gallic province, from Geneva to the Riviera). The middle and eastern Alps with their great transverse valleys are characterized, among other things, by such outstanding communities as those of *Pinus mugo* (mountain pine) and *Rhododendron hirsutum* (alpine rose); the region of the southwestern Alps is characterized by *Hugueninia* (*Sisymbrium*) *tanacetifolia*, *Scutellaria alpina*, *Saxifraga diapensioides*, *Artemisia glacialis*, etc. The latter region, in contradiction to the former, is marked by great longitudinal valleys which allow the Mediterranean flora to intrude far into the inner parts of the Alps. In some respects the southern limestone Alps (from Lake Maggiore to the Karawanken), belonging to the transverse mountain chains but favoured by a very good climate, are similar to the Gallic province; therefore they are often designated as a region of their own within the Helveto-Norican province.

History.—The "old-oceanic" element is the most ancient representative of the recent alpine flora. It consists mainly of very ancient mosses of tropic-oceanic distribution (*Rhacomitrium* heaths, *Hookeria* and *Brotherella* in subalpine mixed woods). The presumably oldest flowering plants of the Alps are restricted to the lower situations (submontane region) such as ravines (*Phytezma comosum*, *Saxifraga paradoxa*), to mountain forests and the edges of woods, (*Wulfenia carinthiaca*, *Pedicularis acaulis*) and to the subalpine vegetation of tall perennial herbs (*Gentiana*

lutea, *Rhaponticum scariosum* [*Centaurea rhaponica*], *Sanguisorba dodecandra*). These forms which were already developed during the folding of the Alps apparently did not produce high alpine descendants; on the other hand the ancestors of the original high-alpine-flora (certain species of *Primula*, *Gentiana* and *Saxifraga*) which had been growing once in lower situations, died out long ago. The real alpine plants (oreophytes), making up the Tertiary stock, can be divided into two elements: the arctico-tertiary group of high Asiatic origin, only growing in a narrow climatic region (*Saxifraga*, *Primula*, *Androsace*, *Gentiana*, *Pedicularis*), and the Mediterranean. eurythermic group, adapted to a broad belt of different climates (*Campanula*, *Phyteuma*, *Achillea*, *Semprevivum*, *Viola*). During Tertiary times (and possibly caused by the periodic folding of the different parts of the Alps) many species were split into parallel species, vicariads, such as *Pinus mugo* and *P. uncinata* (*mugo* rostrata), *Gentiana clusii* and *G. kochiana*. The glacial periods obliterated many ancient Tertiary elements, mainly the subtropical ones of the lowlands and the rich, Tertiary deciduous forests; but the main part of the truly alpine elements succeeded in surviving in refuges on the unglaciated borders of the Alps. There are a great number of plants that have migrated to the Alps from the north during these periods of cold climate; among them are not only purely arctic species and those of northern Europe but a number of Asiatic species. Besides many plants of bogs and moors (*Juncus*, *Carex*, *Scirpus*), there are plants of the dry alpine meadows and rock heaths (altaic-alpine elements, alpine steppe: *Callianthemum*, *Hedysarum*, *Astragalus*, *Lloydia*, *Leontopodium*). Many of the alpine plants that seem to be characteristic (*e.g.*, the well-known edelweiss) have become inhabitants of the Alps only in relatively recent times. In the postglacial periods the re-afforestation of the Alps that took place led to the structure of vegetation that is found there now.

Vegetation Zones.—In the Alps the following zones of vegetation are usually distinguished: (1) colline zone (up to the upper limit of vine culture, 1,800–4,000 ft.); (2) montane zone (to the limit of the deciduous woods, 2,600–5,600 ft.); (3) subalpine zone (to the limit of the coniferous woods and the "fighting" zone, 5,200–7,900 ft.); (4) alpine zone (the region of the mountain pine, followed by dwarf shrubs and alpine meadows, 5,600–9,200 ft.); and (5) snow zone (above the climatic snow line, the region of pioneer-grass-heath communities, cushion plants and cryptogams). Over the whole range of the Alps the zones and the plant sequences within the several regions can be very different, depending on their geographical situation. Moreover, regional divisions in separate parts of the area can be recognized; for instance, in the forest region of Switzerland there is a northern zone of beech, a central zone of pine and a south alpine zone of chestnut; in the eastern Alps, to the north and to the south, a bordering zone of deciduous forest, a zone of mixed forest and an inner zone of coniferous forest are to be found. The most outstanding factor everywhere is the forest and tree limit (and between them the "fighting" zone); these limits are not only caused by low temperatures, but by the short growing season and by the lack of appropriate soils. In the oceanic marginal areas of the Alps the forest limit consists of spruce, but in the more continental areas of the central and parts of the southern Alps cembra pine and larch grow in the highest places. Above the tree limit there is the region of the true oreotrophes showing various adaptations to this special climate: the short growing period is overcome by perennial growth, evergreen foliage and early flowering; high transpiration, caused by intensive sunlight, is diminished by cushion growth, a dense cover of hairs and alterations in the structure of the leaves (leathery, needle-shaped or succulent leaves). Many alpine plants can bear freezing and melting; others, the less hardy ones, are found only in places where they are sheltered by snow during the winter. Another sharp separation is caused by the fact that many species are only able to grow on soil with a certain degree of acidity; a limestone substratum will not produce soils of very high acidity so the limestone floras (calcicole) are mostly very different from the silicate floras (calcifuge) of the acid soils of the crystalline rocks. The splitting into separate species, subspecies or varieties was often combined with their separation in calcicole and calcifuge

races (*Pulsatilla alpina* and *P. apiifolia*, *Rhododendron hirsutum* and *R. ferrugineum*).

Plant Associations.—The following is a list of the chief plant associations of perennial dicotyledons with examples found in each: rock crevices (*Potentilla caulescens*, *Androsace multiflora*), shale and gravel (*Thlaspi rotundifolium*, *Androsace alpina*), tall perennial herbs (Adenosfyles), late-snow-patches (*Salix herbacea*, *Arabis coerulea*); in all these cases there is a clear division into calcicole and calcifuge plants. There are also associations, mainly dominated by monocotyledons, chiefly sedges and grasses, of the shallow moors and transition moors (*Carex fusca* and *C. davaliana*), of the rich meadows and pastures (*Trisetum flavescens*, *Poa alpina*), of dry, rich grass heaths (Sesleria, *Elyna*) and of the sour, poor grass heaths (*Nardus*, *Carex curvula*). The tree- and shrub-associations can be divided into the following zones (excluding the associations of the deciduous trees, which are mostly restricted to the lowest zones): coniferous trees (spruce and fir), subalpine shrub-associations (*Pinus mugo*, *Alnus viridis*) and dwarf shrubs (*Rhododendron*, *Loiseleuria*, *Vaccinium*). (HE. M.)

Animal Life.—The fauna of the Alps includes both invertebrates and vertebrates. The invertebrates are geologically more ancient than the vertebrates and the details of their distribution markedly different. The birds and mammals, zoologically the most recent, have evolved rapidly and show a different distribution, one that can be more clearly distinguished as alpine.

In the mountains of the northern hemisphere generally may be found species of birds and mammals typical of the cold plains further north. As compared with the mountain ranges of Asia, those in Europe show a smaller number of species and the individuals of these species are most sparsely distributed. Some of these species represent relics of the Ice Age, left behind on "islands" as the glaciers retreated north. Others belong to species that enjoy a wide distribution elsewhere but have found a congenial habitat in the Alps also. Among birds, the chaffinch is an example of a species widely distributed that also lives in the Alps wherever there are trees. The skylark, typically an inhabitant of low-lying pastures, will be found on alpine pastures provided the slope is not too steep. The wheatear occurs locally in the Alps, and other mountainous regions, but is also found on shores, moors and heaths, wherever there are large stones or rocky outcrops.

When these and the other ubiquitous species, found in the lowlands, hilly country and mountains, are ignored, the birds of the Alps can be divided into three groups: (1) those belonging more properly to the coniferous forests of the Siberian taiga and its outliers further west; (2) those common to the Alps and to the mountain ranges of central Asia; and (3) those common to the Alps and the arctic tundra.

The species included under (1) are such as the capercaillie, black grouse and hazel hen, the black and the three-toed woodpecker, the nutcracker, the crossbill, Tengmalm's owl and the pigmy owl. These are all birds of the cold forests and although their distribution has been effected by climatic changes during the Pleistocene period they are not markedly separated from their main centre of distribution in the north, and are not therefore typically alpine.

The birds grouped under (2) are most distinctly mountain birds and represent a few of the species that have their main centre of distribution in the Tibetan mountains. These typically Asiatic species become more rare as one travels west, until in the Alps they are represented only by the lammergeier, rock partridge, alpine chough, water pipit, wall creeper, alpine accentor and snow finch. Mountains, being inaccessible, often serve as the last refuges from persecution by man. This has not saved the lammergeier or bearded vulture, which has been exterminated in the Swiss Alps and occurs there now only as a very rare vagrant, at the most. Like all the other birds listed under (2) it is adapted to a rocky biotope, nesting on precipices. The rock partridge flourishes in wooded rocky country, the alpine chough nests in rocky clefts, sometimes in ruins that simulate cliffs, always at great altitudes. The water pipit is a race of the rock pipit which breeds near the shore, but the water pipit breeds in mountainous areas, nesting in crevices. The wall creeper inhabits rocky ravines and earth cliffs, breeds in crevices on inland cliff faces, in rocks or, occasionally,

on buildings, from 6,000 ft. to the snow line. All these move down in winter to the rocky valleys and the foothills. The snow finch breeds on bare mountain tops above 6,000 ft. coming lower in winter.

Like the varying hare, the birds listed under (3) are distinctly isolated from their main area of distribution in the north. They constitute small islands of the arctic fauna, left behind by the retreating ice, and are characteristic elements of the glacial relict fauna. They include the ptarmigan and the dotterel, the latter being localized and of irregular occurrence in the Alps.

The mammals are less numerous than the birds, both in species and in populations. Only one of them represents a true relict of the glacial fauna. This is the varying hare, living at 4,500 to 9,000 ft. It is known in England under a variety of names: Scottish, blue, variable or mountain hare. It is intermediate in size between the common rabbit and the brown hare, and is unlike either of these in changing from a summer to a winter coat. There are other varying hares, all restricted to the northern regions except for this one isolated form in the Swiss Alps.

The beasts of prey are represented by the fox, weasel and stoat. So far as the fox is concerned there is some evidence that individuals living on mountains are slightly larger in size than the lowland foxes. This is to be expected, since the large bulk gives a relatively smaller surface area thus reducing the loss of body-heat, the usual response to living in a colder climate.

Two rodents are characteristic of the Alps. The marmot is a relative of the ground squirrels. There are several species, mostly mountain dwellers, in northern Europe: northern Asia and North America as far north as Alaska. The common marmot of the Swiss Alps, about two feet long, lives among piles of rocks. It exists elsewhere only in the Carpathians but has recently been introduced into the Pyrenees. The second rodent is the snow vole, with a curiously discontinuous distribution in the Alps. It is a large vole with a grey coat and is found on rocky islets protruding through the glaciers at 12,000 ft. It also occurs in suitable habitats down to sea level.

The alpine ibex, in the Alps of Switzerland, France, Italy and Austria, is a small animal less than three feet at the shoulder, with horns up to 35 in. It is believed to have been exterminated as a wild animal but has been re-introduced to many of the valleys where it interbreeds freely with the domestic goat, so that it is doubtful whether there is any pure blood left. The well-known chamois, one of the goat antelopes, lives in the Alps and in a few other mountain ranges in southern Europe as well as in Asia Minor. It is preserved as a sporting animal and is usually found at the upper edge of the tree line, going higher up into the mountains in summer. (MA. BU.)

The People.—The Alps have been inhabited since prehistoric times, but their population has never been a homogeneous one; the uniqueness of their surroundings has not produced any ethnic unity among the people. The races, languages and religions, with only slight modifications, are those of the European countries that share the Alpine chain. The Alps, therefore, so closely associated with the history of Europe, do not constitute a region apart.

The peopling of the Alps began during Paleolithic times with raids by hunters; it was completed in the Neolithic Age (when the last Quaternary glaciers melted) by cultivators and herdsmen. In the Iron Age the copper and iron workings of the Alps drew further numbers of people. Hallstatt (*q.v.*) where the first Iron Age was determined, lies in the calcareous Alps of Austria, southwest of Salzburg. Salt (from Salzkammergut, in Austria), and alpine pasture above the tree line were other sources of attraction. The people in the western Alps with the most distant origins are the Ligurians (see LIGURIA), who came from the shores of the Mediterranean, and in the central Alps the Raeti or Rhetæ (see RAETIA), who possibly originated in the Dinaric region. The Celts or Gauls mingled with both groups a short time before the Roman conquest. The Romans were the only people to unify the Alps under one system of administration, which depended on a network of roads and military posts. They created towns, notably Augusta Pretoria (Aosta), lying at the junction of the routes to the Great and Little St. Bernard. The Germanic invasions of the

first centuries of the Christian era—Burgundians in the west, Alemanni in the centre and Bavarians in the east—changed the population of the central and eastern Alps and penetrated as far as the Italian side. Slavonic peoples infiltrated the southwestern corner of the Alpine chain.

The languages spoken in the Alps are mainly German (Austria, Bavaria, eastern Switzerland), French (western Switzerland, France), Italian on the southern side and Croatian in the south-eastern corner. In the heart of the Alps, in the vast canton of Graubünden (Grisons). Ladin or Raeto-Romance, a Latinized form of the language of the ancient Raeti, is still used (see RAETO-ROMANCE DIALECTS). The linguistic boundaries do not correspond to those on the map; French is spoken on the Italian side, in the eastern Briançonnais part (which belonged to France until 1713) and in the Valle d'Aosta; German has been maintained in the southern Tirol (an Austrian possession until 1919), chiefly in the valley of the Alto Adige. Even the Swiss Valais is shared linguistically between German and French, the boundary passing through Sierre (Ger. Siders).

The boundary between Roman Catholics and Protestants in no way corresponds to linguistic boundaries. Protestants, very much in the minority, are predominant only in a few Swiss cantons (Bern, Glarus, Graubünden). The French and Piedmontese Alps, where the Waldenses were numerous, have now only small groups of Protestants. The French Alps, like the Italian Alps, Valais, Ticino, and the Bavarian and Austrian Alps, are Catholic.

The original customs and various types of culture of the inhabitants of the Alps are retreating before the invasion of modern civilization. The costumes, which are the modified and fossilized forms of the old costumes of the plains! are interesting only as relics of the past, except in Bavaria and the Tirol; the costumes of the women were often uncomfortable and heavy. The houses have remained more faithful to tradition. In the Germanic Alps of Bavaria, Austria and Switzerland (with the exception of a part of Graubünden) wood is used for building. Apart from a few places stone dwellings are preferred in the French, Italian and Croatian Alps. Quite often an attic of wood is built on top of a ground floor of stone and on the roofs corrugated iron, tiles and slate have replaced thatch and stone. In the French and Italian Alps houses are grouped into villages and hamlets, but are more widely dispersed in the Germanic Alps. In the case of the former this has been detrimental to property holding, land being split up into fragments following successive divisions. Forests and pasture land are generally owned by the community, the right of use being regulated by different customs. Direct ownership of the soil is very ancient except in the neighbourhood of the towns and convents. The mountain people often own vineyards at low altitudes; they move about in order to work their land at the different levels, going up to the pastures in the spring and summer and returning in the autumn to the village, where they spend the winter. They have several houses in which they live in turn. The problem of overpopulation was at one time dealt with by seasonal migrations (itinerant tradesmen, chimney sweeps, agricultural workers, cab drivers, etc.), but it is now taken care of by permanent emigration. The western Alps have lost a good part of their population, more so than the eastern Alps. Industry based on electrical power, timber, in some cases iron (Austria) and the tourist trade—at first in summer and then both in winter and summer—have changed conditions of life in much of the Alps. Tourism is one of the chief sources of income and many Alpine resorts such as Chamonix, St. Moritz, Davos, Garmisch-Partenkirchen, Cortina d'Ampezzo and Zermatt (*qq.v.*) are internationally known. Towns have grown up which are the regional centres of intellectual life and economic vitality. (P. V.E.)

Exploration of the **High Alps**.—About 20 glacier passes were certainly known before 1600, about 25 more before 1700 and another 20 before 1800. Though the attempt of P. A. Arnod (an official of the duchy of Xosta) in 1689 to "re-open" the Col du Géant may be counted as made by a non-native, no further cases of this kind occurred until the last quarter of the 18th century. Among the earliest recorded ascents of high peaks made by non-natives were those of the Rochemelon in 1358, in fulfilment of a

vow, and of the Mont Aiguille in 1492 by order of Charles VIII of France, in order to destroy its reputation for inaccessibility. In 1555 Konrad von Gesner (*q.v.*) climbed the lowest of the seven summits of Pilatus. The first two men who really explored the regions of ice and snow were Horace Benedict de Saussure (*q.v.*; 1740–99, the Pennine Alps), and the Benedictine monk of Disentis, Placidus à Spescha (1752–1833), most of whose ascents were made before 1806 in the valleys at the sources of the Rhine. The ascent of Mont Blanc in 1786 by M. G. Paccard (1757–1827) and Jacques Balmat (1762–1834) was the first great milestone in the development of the sport of mountaineering. In the early 19th century the Meyer family of Aarau conquered the Jungfrau (*q.v.*) (1811) and the Finsteraarhorn by deputy (1812, though this is disputed and the first ascent may not have been made until 1829) beside several glacier passes, all in the Bernese Oberland. Their work was continued by a number of Swiss, particularly Gottlieb Studer (1804–90) of Bern, and Edouard Desor (1811–82) of Neuchâtel. In 1877 Mark Beaufoy (1764–1827) made the first English ascent of Mont Blanc, a mountain to which his fellow countrymen devoted themselves rather exclusively, with notable exceptions such as J. D. Forbes (*q.v.*; 1809–68), A. T. Malkin (1803–88) and John Ball (*q.v.*; 1818–89). Around Monte Rosa the Vincent family, Josef Zumstein (1783–1861) and Giovanni Gnifetti (1801–67) explored in the period from 1778 to 1842, while in the Eastern Alps the Archduke John (1782–1859) and P. J. Thurwieser (1789–1865) were pioneers worthy of note. The spread of railways in Europe in the 1850s made access to the Alps much easier and British climbers became especially active. The second half of the century saw a systematic exploration of the Alps, in particular by F. F. Tuckett (1834–1913), W. A. B. Coolidge (*q.v.*; 1850–1926), Edward Whymper (*q.v.*; 1840–1911), W. M. Conway (1856–1937) and D. W. Freshfield (1845–1934). The English Alpine club was founded in the winter of 1857–58, followed in 1862 by the Austrian Alpine association, in 1863 by the Italian and Swiss Alpine clubs and in 1874 by the French Alpine club. In 1874 the Austrian Alpine association was fused with the German Alpine association, founded in 1869, but they were later separated. These clubs have explored the peaks, built huts, trained guides and published journals and guidebooks. (See also MOUNTAINEERING.)

The two subjoined lists give the dates of the initial conquest of about 50 of the greater peaks (apart from those already noticed) achieved before and after Jan. 1, 1858.

Before Jan. 1, 1858: Titlis (1744), Mont Vêlan (1779), Rheinwaldhorn (1798), Gross Glockner (1800), Ortler (1804), Todi (1824), Altels (1834), Gross Venediger (1841), Wetterhörner (1844–45), Mont Pelvoux (1848), Piz Bernina (1850), Fletschhorn (1854), Monte Rosa (1855), Laquinhorn, Allalinhorn (1856) and Pelmo (1857).

After Jan. 1, 1858: Dom, Eiger (1858), Aletschhorn, Bietschhorn, Rimpfischhorn, Grand Combin (1859), Grand Paradis, Grande Casse (1860), Weisshorn, Monte Viso, Gross Schreckhorn, Lyskamm (1861), Dent Blanche, Monte Della Disgrazia, Täschhorn (1862), Dent d'Hérens (1863), Presanella, Barre des Écrins, Mont Dolent, Zinal Rothorn (1864), Matterhorn, Ober-Gabelhorn, Aiguille Verte, Piz Roseg (1865), Grandes Jorasses (1868), Langkofel (1869), Cimon della Pala, Ailefroide (1870), Aiguille de Blaitière, Rosengartenspitze (1874), Monte di Scerscen, Aiguille Noire de Peuterey, Meije (1877), Aiguille du Dru (1878), Aiguille du Grépon (1881), Aiguille du Géant (1882), and Aiguille Blanche de Peuterey (1885).

ALPS, AUSTRALIAN: see AUSTRALIAN ALPS.

ALPS, ROMAN PROVINCES OF THE, small provinces established in the Western Alps under the Roman empire occupying areas in modern France, Italy and Switzerland. Around most of the Alpine barrier Italy was regarded as extending to the mountain summit and the defense of the passes could be provided by the adjoining military provinces. Pannonia, Noricum and Raetia (*qq.v.*). Rut Gaul was by the time of the empire practically demilitarized, and the vital passes from the Great St. Bernard to the coast needed special treatment.

1. The Alpes Maritimae were made a province, administered by a procurator, probably in 14 B.C., and included Pedo (Borgo San Dalmazzo in Piedmont) in the Italian foothills as well as Cemnelum (Cimiez, adjoining Nice) on the Gallic side of the summit. The coastal towns were still regarded as Italian, but the procurator's main duty was clearly to protect the Via Julia Augusta (the Riviera road on which they lay).

2. Adjoining the Alpes Maritimae near the Col de l'Argentière was the province of the Alpes Cottiae, with its capital at Segusio (Susa in Piedmont) and extending west to take in Ebrodunum (Embrun). Cottius, king of this region, had kept his tribes loyal to Augustus and was left in charge of them as prefect (*praefectus civitatum*), though both he and his son are sometimes called rex. The son died about A.D. 65 and was replaced by a procurator.

3. Further north was a province in Savoy, called variously Alpes Graiae or Xtrectianae or Ceutronicae, with capital at Forum Claudi Ceutronum (Aime). There the province was wholly on the transalpine side of the Little St. Bernard (Alpis Graia), since in Italy the colony of Augusta Praetoria Salassorum (Aosta) had already been founded in 23 B.C. with a territory extending to the passes. Similarly the Great St. Bernard (Alpis Poenina) was the frontier of Italy: beyond it the Vallis Poenina (the Swiss canton of Valais) was first grouped with Raetia, but in the 2nd century A.D. was detached and added to the Alpes Graiae. All these border areas contained cities which attained Latin rights, a status formally accorded to the whole of the Alpes Maritimae in A.D. 63.

See D. Gribaudi, *Il Piemonte nell' antichità classica* (1928); G. E. F. Chilver, *Cisalpine Gaul* (1941). (G. E. F. C.)

ALPUJARRAS, LAS, a district of southern Spain in the provinces of Granada and Almería, stretches northward from the towns of Motril and Almería to the foothills of the Sierra Nevada. It is in fact a trough between the coastal mountains—the Sierra la Contraviesa and the Sierra de Gádor—and the Sierra Nevada. The rivers Guadalfeo to the west and Andarax to the east, as well as smaller streams, have cut gorges and flow through beautiful fertile; secluded valleys. Frequently the villages are on ledges over-

hanging the gorges and it is to these villages exclusively that the name Alpujarras is often applied.

A centre of repeated Moorish rebellions, the inhabitants of Moorish descent were finally evacuated in 1570 and were replaced by colonists from Extremadura and Galicia; however, not all of the 165 Moorish villages were repopulated. Although they n-ere little experienced in irrigation the new colonists cleared much of the land for dry cereal cultivation, but because of the steep slopes erosion was severe. In consequence, new deltas have appeared on the coast, notably at Adra.

The district has a range of vegetation unparalleled in Europe: from sugar cane and palm on the coast, it extends through belts of citrus, vine, olive, chestnut and oak to alpine flora on the heights. Densely populated, with more than 100,000 inhabitants, this poverty-stricken region was first developed by the fruit and vegetable industry and in the mid-20th century it was further developed by new roads. Lanjarón (pop. 1950, 5,314) has become a notable mineral spa.

See J. Sermet, "Le relief de la Sierra Contraviesa," *Bol. Soc. esp. Hist. nat.* (1934), "Un cas de morphologie littorale héritée sur la côte de Grenade" (1954). (J. M. Ho.)

ALSACE (Ger. ELSASS), a region of Europe, corresponding to the modern French *départements* of Haut-Rhin and Bas-Rhin and Territoire de Belfort (*qq.v.*) bounded by the Vosges mountains and the historic Lorraine on the west, the German Land Rhineland-Palatinate on the north, the middle Rhine river on the east and Snitzerland on the south.

Alsace is an area in which many races have come into collision and many civilizations met. Occupied by the Romans during Julius Caesar's conquest of Gaul in the 1st century B.C., it had been profoundly romanized by the time of the invasion of the Alamanni (*q.v.*) in the 5th century A.D. The Alamanni, however, were soon conquered by the Franks under Clovis. In the Frankish duchy of Alsace Christianity prospered, and many ecclesiastical foundations were made. Incorporated in Lotharingia (see LORRAINE) by the treaty of Verdun in 843, Alsace was united with the German territories of the Carolingians by the treaty of Mersen (870) and so remained part of the Holy Roman empire for 800 years. During that period its territory was divided into a number of ecclesiastical or secular lordships and municipalities, whose boundaries varied in the course of time but whose influence persisted until the French Revolution. The period was also marked by the growing importance of the cities, as these, with the support of the emperors, were able to emancipate themselves from their feudal overlords. The burghers of Strasbourg, for example, expelled their prince-bishop after their victory at Oberhausbergen (1262), and many cities in upper Alsace freed themselves from the control of Habsburg princes. Ten Alsatian cities, Haguenau, Landau, Colmar, Sélestat, Wissembourg, Obernai, Rosheim, Kaisersberg, Turkheim and Munster, formed a union (decapolis) in 1354, under the protection of the Holy Roman emperor, who appointed a *Landvogt* (resident) with his seat at Haguenau. This lasted till Louis XIV's time and did much to give unity to the country.

The Reformation transformed Alsace profoundly, its political mosaic being complicated by a religious one. Strasbourg, where the reformer Martin Bucer came into especial prominence, became in a may the capital of Alsatian Protestantism, and the *Gymnasium* of Strasbourg was a centre of humanist learning for the Rhineland. Strasbourg's Protestantism, however, was countered by the resolute Catholicism of the Habsburgs, who after suppressing the Peasants' War (1525) eradicated heresy in upper Alsace.

French influence began to be felt in Alsace later in the 16th century, during the Wars of Religion (Calvin moreover spent two years in Strasbourg before returning to Geneva in 1541). This influence became stronger during the Thirty Years' War, when the Alsatian cities, seeing both their political and religious freedom threatened by Austrian Catholicism and by Swedish Protestantism alike; appealed to the king of France for help. The war left Alsace exhausted, but the peace of Westphalia (1648) made the French king, in rather ambiguous terms, either the sovereign or the protector of the Alsatian lands.

Under the French Bourbon monarchy, from 1633 to 1789, the

territorial unit of Alsace was further consolidated. The policy of *chambres de réunion*, whereby cities on the frontier declared themselves reunited with France, culminated in the French occupation of Strasbourg (1681), which then became the capital of Alsace, its cathedral being restored to the Catholics. The administration of justice, police and finance passed into the hands of intendants and Colmar was made the seat of a *conseil supérieur*. In the peaceful years of the 18th century the population of Alsace increased and its economy prospered, chiefly the result of the transit trade (Alsace remaining outside the French customs system), agricultural development and increased exploitation of the textile and metallurgical industries. The people continued to speak a German dialect, but French spread among the upper classes.

The French Revolution and the Napoleonic era brought further changes to Alsace. The Protestants, who had been insecure though never persecuted under the kingdom, enjoyed complete freedom, the peasants were released from the arbitrary domination of the local territorial lords, and the towns exploited the increased facilities for trade up and down the Rhine. Alsace was included in the French customs area, enterprising *préfets* (as, for instance, Adrien Lezay-Marnézia) took the place of the intendants, a court of appeal was set up at Colmar, and the two *départements* of Haut-Rhin and Bas-Rhin, into which the country was divided, were both included for ecclesiastical purposes within the diocese of Strasbourg. The administrative reorganization was followed by a road-building program and increased industrialization. Neither the merchants of Bas-Rhin nor the manufacturers of Haut-Rhin, however, took much interest in acquiring large estates, so the number of peasant proprietors grew. The first teachers' college was founded in Strasbourg in 1810.

From 1815 to 1870 Alsace actively participated in the French national life. The introduction of universal suffrage (1848), the building of railways and the development of other communications and information services all contributed to bind France and its eastern frontier province more closely together. These links, however, were shattered at the end of the Franco-German War when Alsace was detached from France and annexed to the German empire. For its subsequent history see ALSACE-LORRAINE.

(G. LI.)

ALSACE-LORRAINE (Ger. ELSASS-LOTHRINGEN), the name given to the 5,607 sq.mi. of territory ceded by France to Germany in 1871 after the Franco-German War, retroceded to France in 1919 after World War I, ceded again to Germany in 1940 during World War II and again retroceded to France in 1945. It comprised the French *départements* of Haut-Rhin and Bas-Rhin, namely the former province of Alsace (*q.v.*), together with two *arrondissements* (Château-Salins and Sarrebourg) from the former *département* of Meurthe and five (Metz, Thionville, Boulay, Forbach and Sarreguemines) from the original *département* of Moselle, the two latter *départements* having been part of the ancient Lorraine (*q.v.*). As the French had formed the *département* of Meurthe-et-Moselle from what was left to France of Meurthe and of Moselle in 1871, the modern *département* of Moselle was formed to comprise all the parts of Lorraine retroceded in 1919.

The population of the area is predominantly Roman Catholic. Pop. (1954) 1,986,969. The majority speak German or dialects of German as well as French, a minority German alone. (See BAS-RHIN; HAUT-RHIN; MOSELLE.)

History. — Annexed to the newly founded German empire by the treaty of Frankfurt in May 1871 after the Franco-German War (*q.v.*), Alsace-Lorraine was constituted as a *Reichsland* or condominium of all the states of the empire, instead of being attached to Prussia or to any of the states individually. The population, however, was enthusiastic for the new French republic and had sent a delegation to the French national assembly to protest against the transfer to Germany. Its first delegation to the German *Reichstag*, in 1874, likewise carried a protest, and until 1890 practically every such delegation was unanimously opposed to the German regime. Many irreconcilables left the region and went to France or other countries. The German chancellor, Prince Otto von Bismarck, seems to have had high hopes for an early assimilation of the German-speaking majority, but under the circumstances

he was practically compelled to govern Alsace-Lorraine as a conquered province. A local consultative committee (*Landesausschuss*) was granted in 1874 and in 1877 was given some power to initiate legislation, but in 1879 a *Statthalter* or resident representing the chancellor was appointed, with powers to declare martial law whenever he thought fit. Consequently there could be no effective self-government until 1902, when these special powers were withdrawn from the *Statthalter*. From the time of the Dreyfus case onward, however, the French government pursued an increasingly anticlerical policy that alienated many of the inhabitants of Alsace-Lorraine. By 1905 the anticlerical legislation had been passed in France and the clerical party, the strongest single party in Alsace-Lorraine, sought a new orientation. Bismarck (despite his *Kulturkampf*) and the German statesmen who succeeded him after 1890 never interfered with the functioning in Alsace-Lorraine of the concordat of 1801 between France and the papacy. The eventual German compromise with the church appealed to the clericals more than French anticlericalism. After 1900 the clericals in Alsace-Lorraine looked forward to an autonomous Alsace-Lorraine within the German empire.

By 1911 a new constitution was granted which opened the way for the *Reichsland* to become an equal among the members of the empire. Provision was made for a bicameral *Landtag* and a vote in the imperial federal council. There was much dissatisfaction, but the first election seemed to indicate that the government party had the majority. Feelings of sympathy for Germany, however, were soon counteracted by a new trend of events. After the fall of Bismarck, German statesmen had moved in the direction of pan-Germanism and imperialism. The new policy called for a tremendous increase in the military and naval budgets and these were opposed by the members of the *Reichstag* from Alsace-Lorraine. The inhabitants of the region saw nothing to be gained and much to be risked by war. As an exposed part of the empire, they were heavily garrisoned. Clashes between the civilians and the military authorities were inevitable. The most notorious was the incident at Saverne (Zabern) in Nov.-Dec. 1913, when a German lieutenant provoked a riot by insulting Alsatian recruits (29 people were arrested). The local diet, under the presidency of Eugen Ricklin, a leading autonomist, placed the blame for this directly on the military authorities. Such incidents caused the tide to turn against the German regime although it was not until 1916, two years after the outbreak of World War I, that the majority were against the government. To meet this situation it was proposed to dismember the province and partition it among several German states, but the course of the war led to the abandonment of this project. Instead the Germans decided that Alsace-Lorraine was to have a more autonomous government. The local politicians, however, were too shrewd to attempt to form a cabinet.

The treaty of Versailles in 1919 recognized "the moral obligation to redress the wrong done by Germany in 1871 both to the rights of France and to the wishes of the population . . ." but little consideration was given to the extent to which these wishes might have changed since 1871, especially with regard to the Alsatian areas. The tumultuous welcome given to the French (Nov. 1918) was the result, in a measure at least, of war weariness. French officers had made it clear that traditions and liberties would be respected, but French officials almost immediately began to speak of assimilating the reconquered provinces to France. A commissioner-general for Alsace-Lorraine was appointed with one commissioner for each of the three resurrected *départements*, but no sovereign power was recognized except the central government of France. Even the functions of the transitional commissariat-general were transferred to Paris in 1925. Then Edouard Herriot's ministry (1924-25) declared for the introduction of "the whole of the republican legislation" into Alsace-Lorraine, and the implication that the status of the confessional schools was to be changed was seen as a threat of the concordat of 1801.

At that stage, Eugen Ricklin founded a newspaper and the *Heimatbund* ("League for Home Rule") calling for complete autonomy "within the French state." The issue was between centralization and particularism. The French premier Raymond Poincaré in 1926 resorted to drastic action, suppressing newspapers

on the ground that they were in a foreign tongue, although German was the written language of 75% of the population, and on Christmas Eve 1927 wholesale searches, seizures and arrests were made. Two of those held were elected to the chamber of deputies before their trial, but were denied the right to their seats on their being convicted, whereupon a second election gave the voters the opportunity to elect two other autonomists. These events induced the French government to adopt a more conciliatory policy; which, however, did not cause the autonomists to disband.

In World War II the collapse of France in 1930 was followed by the annexation of Alsace-Lorraine to Germany. Part of the territory was then incorporated in Baden, part in the Westmark, and about 18,000 Alsatians perished in the German armies on the eastern front, but attempts to germanize Alsace-Lorraine were a failure.

In 1945 Alsace-Lorraine became French again. Problems subsequently became much less acute. The local legislation and particularly the concordat remained in force. The autonomist movement disappeared. If most of the people would still call themselves Alsatian, few, if any, would accept being labeled Germans. By the wish of the majority, some German was reintroduced in the elementary schools, but basic teaching was given in French. See also Index references under "Alsace Lorraine" in the Index volume.

ALSBERG, CARL LUCAS (1877–1940), U.S. biochemist, who specialized in food chemistry, was born in New York city on April 2, 1877. He graduated from Columbia university in 1896 and from the College of Physicians and Surgeons in 1900. Following study in Germany in 1900–03, he was an assistant and instructor at Harvard university until 1908. From 1908 to 1912 he was chemical biologist in the bureau of plant industry and was chief of the bureau of chemistry in the U.S. department of agriculture from 1912–21.

In 1920 Alsberg was made director of the Food Research institute, Stanford university, Stanford, Calif., and in 1937 director of the Giannini Foundation of Agricultural Economics, University of California, Berkeley.

Alsberg's research included investigations on pure foods and drugs, the biology and toxicology of molds, cyanogenesis in plants, poisonous plants, phosphoric acid, metabolism, nucleic acids, proteins, cystinuria and enzymes. He also studied problems of population growth and food supply.

Alsberg died on Nov. 1, 1940, at Berkeley, Calif.

ALSIKE CLOVER, the common name of *Trifolium hybridum*. It is of agricultural importance for hay, pasture and soil improvement in cool humid climates of North America and Europe. Botanically, alsike clover is a perennial, but under many agricultural conditions it behaves as a biennial. The flower colour is white or pinkish white. A native of Europe or Asia Minor, alsike clover has become widely naturalized in the United States, since the first known seed introductions in 1839. It is probable that it had been previously introduced by chance.

ALSOP, VINCENT (c. 1630–1703), English Nonconformist minister, a leader of those ejected under the Act of Uniformity of 1662. He was born in Northamptonshire about 1630, and after being ordained deacon, became a schoolmaster, but was converted from his "rollicking ways" and reordained by the presbyters. Ejected from Wilby, Northamptonshire, in 1662, he was licensed as a Congregational teacher, preaching privately and gaining fame as a hard-hitting and witty pamphleteer, particularly by his *Antisozzo* (1675), a defense of Nonconformist theology against William Sherlock's attacks. He became minister of the Presbyterian congregation in Tothill street, Westminster, in 1677 and was subsequently appointed to several lectureships. He was a leader in the so-called "happy union" of Presbyterians and Congregationalists (1691). He gained some favour with James II, who pardoned his son's "treasonable practises," and he continued to write and preach with undiminished vigour until his death in London, May 8, 1703.

ALSTON, JOSEPH (c. 1779–1816), U.S. lawyer and gover-

nor of South Carolina during the War of 1812. The precise date and place of his birth are not known. As a rice planter in South Carolina he lived at "The Oaks" on Waccamaw river; adjoining "Brookgreen" plantation of William Alston and his son Washington, the celebrated painter. Alston was educated at Princeton, but left in his senior year to study law under Edward Rutledge. Elected to the state legislature in 1802, he served until 1812, being speaker from 1805 to 1809. In 1801 he married Theodosia Burr (*q.v.*), brilliant daughter of Aaron Burr (*q.v.*), thereby becoming involved in the Burr conspiracy. How much he knew of Burr's plans is uncertain, but he assisted with funds and personal participation, and he defended Burr during his trial in Richmond. These activities did not promote Alston's political fortunes, yet he was elected governor in 1812 and vigorously supported the war against England. During this year his only son died, and in 1813 Theodosia was lost at sea. Three years later, on Sept. 10, 1816, Alston died and was interred at his plantation. (T. P. A.)

ALT, ALBRECHT GEORG (1883–1956), one of the most important Old Testament scholars of the first half of the 20th century. was born on Sept. 20, 1883, in Stiibach, Bavaria. He was *Privatdocent* and professor in Greifswald from 1909 to 1914, then professor in Basel (1914–21), Halle (1921–22) and Leipzig (1922–56). He was also head of the Deutsches Evangelisches Institut für Altertumswissenschaft des Heiligen Landes (German Evangelical Institute for Archaeology of the Holy Land) in Jerusalem from 1921 to 1923 and remained thereafter its spiritual and organizational leader. He died in Leipzig on April 24, 1956.

His chief field of study was Palestinian history and archaeology and the history of ancient Israel in its relationship to the history of the near east. He specialized in the legal and political institutions of ancient Israel, and also shed light on the religion and worship which lie behind the Old Testament traditions. His most important papers are *Die Landnahme der Israeliten in Palastina* (1925), *Die Staatenbildung der Israeliten in Palastina* (1930), *Der Gott der Väter* (1929) and *Die Ursprünge des israelitischen Rechts* (1934). He laid the foundation for a new and soon widely accepted view of the history of Israel and decisively influenced Old Testament studies throughout the world.

BIBLIOGRAPHY.—Collected edition of most of Alt's writings in *Kleine Schriften zur Geschichte des Volkes Israel*, vol. 1–3 (1953–59); list of 243 of his works in his *Festschrift, Geschichte und Altes Testament* (1953); M. Noth, memoir in *Zeitschrift des deutschen Palästina-Vereins*, vol. 72, pp. 1–8 (1956). (M. N.)

ALTAI, a complex mountain system of central Asia, at the junction of the boundaries of the Union of Soviet Socialist Republics, Outer Mongolia and China. The Altai, which means "gold" in Mongolian, extends from 48° to 53° N. latitude and from 81° to 90° E. longitude. Most of the mountain system is situated within the Gorno-Altai autonomous *oblast* of the U.S.S.R., with the outer slopes extending into the Tuva autonomous *oblast* and the Khakass autonomous *oblast* in the northeast, the Altai *krai* in the northwest, the East Kazakhstan *oblast* in the west, China's Sinkiang Uigur autonomous region in the south and the western portion of Outer Mongolia in the southeast. The mountain system of the Altai may be divided into four subranges fanning out from the mountain hub of Kuiten (15,266 ft.), the highest peak, situated near the junction of the Soviet, Chinese and Mongolian borders. These four major subranges or groups of ranges are the south Altai, extending to the west, the central Altai, to the northwest, the east Altai, to the northeast, and the Mongolian Altai, to the southeast. The south Altai, which forms the watershed between the upper Irtysh and Bukhtarma rivers, is known as the Naryn range at its western end. The south Altai reaches an elevation of 12,700 ft. in its highest point. Mountain spurs on its southern slope enclose the lake Marka Kul. The central Altai, which consists of parallel elongated ranges extending to the northwest, contains snow-capped mountains known in Russian as *belki*. The most important of these ranges, the Katun, reaches 14,783 ft. in Mount Belukha, the highest point in the Soviet section of the Altai. The east Altai forms the watershed between the Ob and Yenisei river systems. It begins at the Tabun Bogdo hub as the Saylyugem range (13,291 ft.) and continues northward as the Shapshal range before linking up with the mountain systems

of the west Sayans and the Kuznestk Ala-tau. The picturesque Teletskoye mountain lake (1,066 ft. deep) lies on the western slopes of the east Altai subrange. The Mongolian Altai extends about 900 mi. southeast into Outer Mongolia (Mongolian People's Republic), where it gradually breaks up into lower ranges that disappear in the Gobi desert. The Mongolian Altai reaches an elevation of 13,881 ft. in the Munku-Khayrkan.

Geology.—From the point of view of historical geology, the Altai system is divided into two parts: the Altai proper, which includes the larger northeastern portion of the system, and the so-called Rudny (or mineralized) Altai in the southwest. The Rudny Altai emerged during the Upper Paleozoic (Variscan) period of mountain forming, while the Altai proper was subjected to the most intense folding during the Lower Paleozoic (Caledonian) revolution. The Altai proper consists of Paleozoic rocks extending to the Upper Devonian period, when the last marine transgression took place. In the Rudny Altai, on the other hand, marine sediments have been found through the Lower Carboniferous period. The long duration of the continental phase, which began in the Lower Carboniferous and in many places even earlier, led to the wearing away by erosion of the entire Altai, which did not exist as a mountain system during the Tertiary period. At the end of the Tertiary and the start of the Quaternary, extensive faulting took place, creating the configuration of the present Altai. This is characterized by the predominance of plateaus of varying elevations, sometimes half worn away by erosion. Many of these watershed plateaus are quite flat and allow poor drainage. Streams drain at first with a barely perceptible gradient, then cut deep gorges at the points where they empty into the main rivers. Such are the upper courses of the Katun and Biya rivers, the two headstreams of the Ob. Other rivers rising in the Altai are the Bukhtarma, a tributary of the Irtysh, and the Kobdo in Outer Mongolia. Most of these rivers rise in small glaciers, but glaciation is relatively limited in the Altai. The total glacier area is 230 sq.mi., far less than in the Tien Shan.

Climate.—The Altai is situated near the centre of Asia far from the moderating influence of the sea and its climate is sharply continental. Dry south and southwest winds prevail in winter, and moist northwest and west winds in summer. Most of the annual precipitation of about 40 in. occurs in July and August. The western Altai, directly in the path of the moisture-laden winds from the Atlantic ocean, receives most of the precipitation. Valleys on the leeward side of the ranges are quite dry. On moist slopes the snow line lies at an elevation of about 8,000 ft.; on dry slopes at 10,000 ft.

Vegetation.—The steppes that adjoin the Altai are suitable for agriculture, which can be carried on up to an elevation of about 3,500 ft. The forest zone, which extends in places to 8,000 ft., consists mainly of conifers, such as the larch, stone pine, fir and spruce. Deciduous stands (birch, aspen, mountain ash) are of secondary importance. After a transitional zone of stunted shrubs, such as the dwarf arctic birch and dwarf willows, the alpine meadows begin.

Settlement and Economy.—The indigenous Altaic tribes (formerly called Oirat) are of mixed Mongol-Tungus descent. In ancient times they developed a well-rounded economy, including agriculture, stock raising and metal working. However, when the first Russian settlers reached the foothills of the Altai in the 17th century, they found the Altaic peoples engaged only in hunting and primitive stock raising. Under Russian rule, the Altai passed through an early silver-mining phase, which lasted from the early 18th century until the second half of the 19th. This was followed by more intensive agricultural settlement of the Altai piedmont in the late 19th and early 20th centuries. Under Soviet rule, the Altai has played an important role both as a mining region and a piedmont farming area (wheat, sunflowers, sugar beets). Mining is carried on primarily in the mineralized section of the Altai (Rudny Altai), which corresponds to the East Kazakhstan *oblast* of the Kazakh Soviet Socialist Republic. This area is one of the Soviet Union's most important lead and zinc producers, with mines and smelters at Leninogorsk, Ust-Kamenogorsk and Zyrvanovsk.

Other minerals mined in Altai include tungsten, tin, copper and mercury. Railroad spurs of the Soviet rail system serve both the rich wheat lands of the Altai piedmont and the mining area of Kazakhstan. In the mountains themselves, transportation relies on motor highways, such as the Chuya valley road, which connects the Soviet Union with Outer Mongolia. (T. SD)

ALTAIC PEOPLES, on the basis of their linguistic affinity, comprise the Turks, the Mongols and the Manchu-Tungus. These peoples have been grouped on a linguistic basis since 1730, when F. J. von Strahlenberg first proposed the genetic relationship of these languages. He further suggested their inclusion in a larger family of Ural-Altai languages (*q.v.*), including the Finnic, Hungarian, Samoyedic and other peoples. The Ural-Altai relationship was accepted more or less through the 19th century, came under sharp attack during the first part of the 20th century, and today is the subject of careful consideration by scholars. This article deals only with the Turkic, Mongolic and Manchu-Tungusic peoples.

The largest of the three divisions of Altaic peoples is the Turkic. There are about 50,000,000 Turkic-speaking peoples in the countries of Asia and Europe. Turkic-speaking peoples of the Soviet Union number about 20,000,000; about 1,000,000 live in eastern Europe; 18,000,000 live in Turkey; about 4,000,000 live in China; and the remainder live in Iran, Afghanistan and neighbouring countries (northern Iraq and Syria). The Turkic peoples are divided into four main subdivisions: (1) *Northwest*: Kazakh, Kirghiz and Kara-Kalpak in central Asia; Nogai, Karachai, Balkar and Kumyk in the north Caucasus; Tatar, Mishar, Tepter, Bashkir in European Russia; Karaim in Poland; Siberian Tatar; (2) *North-east*: Tuvian (Soyot, Urianghai) in Tuva and southern Siberia; Karagas; Shori. Khakass and lesser languages of the Sayan mountains; Saryg Uighur of China; Altai mountain Turkic; Baraba dialects; (3) *Southeast*: Uighur or Turki of Chinese and Russian Turkestan; Uzbek of Russian Turkestan and Afghanistan; and (4) *Southwest*: Turkish and related Anatolian dialects of Turkey; Azerbaijani of the Soviet Caucasus and Iran; Turkmen of Russian Turkestan, Iran and Afghanistan; Gashgai, and Ainalu of southwest Iran; Balkan Turkish of Yugoslavia, Greece, Bulgaria and Rumania (Gagauz); Crimean Tatar. Two distantly related Turkic languages are Chuvash of European Russia and Yakut of northeast Siberia. Yakut has a general relationship to the Siberian Turkic dialects, including the Dolgans, a group of Tungus who have become Yakutized.

The Mongols are classified into three subdivisions, the eastern, western and northern. The eastern Mongols include the Mongols of Outer Mongolia (Khalkha Mongol) and Inner Mongolia (Ordos, Urat, Tumut, Kharchin, Chahar, Chipchin). Rfonguor of Kansu (China) and Dagur of the Amur basin are separately classified. Western Mongol includes Mogol of Afghanistan. Oirat of Sinkiang and western Mongolia, Volga Kalmyk (including Sart Kalmyk of Kirgizia). The northern Mongols include the Buryats.

The largest number of Mongols live in China (1,500,000 in 1953); of these the majority live in Inner Mongolia (1,100,000) the remainder are distributed in north and northwest China. The Mongols of Outer Mongolia number about 750,000. The Buryats number 253,000, the Kalmyks 106,000 (1959). The remainder of the Mongol groups are fewer in number. A small number of Kalmyks settled in the United States after World War II. The total of all Mongols in the world is 2,500,000 to 3,000,000.

The Manchu-Tungusic peoples live in China proper, Manchuria and eastern Siberia. A small number are settled in Inner and Outer Mongolia and Sinkiang. The most powerful group were the Manchus who conquered all of China in the 17th century; since then many Manchus have been absorbed into Chinese culture. The census of mainland China of 1953 counted 2,400,000 Manchus. However, many of these are only nominally Manchus and live scattered among the Chinese. The Manchu-Tungusic peoples are divided into a northern and southern branch. The northern branch includes the eastern Siberian Tungus proper (Evenki or reindeer Tungus and Lamut or coastal Tungus), and Negidal of the Amur region. The southern branch includes the Manchus proper; and the river tribes of Manchuria: Nanai or Gold, Ulchi, Orochi, Ude

and Oroki. These tribes number only a few thousand. The largest of the Manchu-Tungusic peoples other than the Manchus are the Evenki, who number 24,000 (1959).

The Turks and Mongols live in a zone of aridity: desert, steppe desert and steppe. The traditional economy of the earliest of these peoples, the Huns (Hiung-nu), Juan-Juan, Sien-pi and Avars, was nomadic pastoralism; that is the raising of stock and pasturing them in a fixed round of annual movement. Today, Mongols of Inner and Outer Mongolia and the Turks of Iran and Afghanistan still nomadize in the traditional fashion. Most of the other Turks and Mongols, once nomads, have become sedentarized.

The traditional habitat of the Manchu-Tungusic peoples is the Siberian forest and the Amur drainage to the south. They are pastoralists of a simpler type: they raise but one animal. The Evenki raise reindeer, as do many Turk-speaking peoples of Siberia, the Yakut, Dolgan and Sayan mountain Turks. Some Tungus and Manchus raise pigs. The remainder hunt and fish.

The Turks and Mongols were called Tatars in the olden sources of the Chinese and Russians. The nomad Tatars lived in a complex interrelationship of raiding, trading and tribute exchange with their sedentary neighbours, at times erupting into great conquests (Jenghiz Khan, Timur [Tamerlane], Ottomans). These conquests succeeded when the indigenous sedentary dynasties of China and interior Asia were weakened internally. See also TATARS; MONGOLS; TUNGUSES; TURKS OR TURKIC PEOPLES.

ALTAI KRAI, a territory of the Russian Soviet Federated Socialist Republic, U.S.S.R., covers an area of 101,042 sq.mi., almost wholly in the basin of the upper Ob (*q.v.*) and its headstreams, the Biya and the Katun. The northern and northwestern parts consist of rolling plain and mountain foreland with steppe and forest-steppe vegetation. The southern part, which forms the Gorno-Altai Autonomous *oblast* within the *krai*, consists of mountain ranges and high plateaus, with wide intermontane basins and deeply incised valleys. The mountains and plateaus are forested, the basins are under steppe vegetation. The 1959 population was 2,685,000, of whom 880,000 were urban. The chief towns are Barnaul, the capital (320,000), Bisk (146,000) (*qq.v.*), Rubtsovsk (111,000), Slavgorod and Gorno-Altai (27,000). Of the 159,000 inhabitants of the Gorno-Altai Autonomous *oblast*, about one-fourth were Altai, a Turkic people related to the Tuvinians.

The *krai* is one of the most important areas in western Siberia, both agriculturally and industrially, lying close to the Kuznetsk basin. The northern steppes are almost entirely under cultivation, with wheat, oats and maize (corn) the chief crops, together with sunflowers: flax, hemp and sugar beet. In the mountains there are large herds of cattle and sheep. Nonferrous ores, copper, zinc, lead, silver, mercury, barium, tungsten and gold are mined, chiefly around Zmeinogorsk, and salts are obtained from the lakes of the Kulunda steppe. Light engineering, mostly agricultural machinery, chemical industry and timber working are developed in the main towns. The north is served by a railway net focussed on Barnaul, while the Bisk-Mongolia highway crosses the mountains.

Once part of the khanate of Dzungaria (*q.v.*), the *krai* was colonized by the Russians from the 18th century, following the overthrow of the khanate. Its early importance lay in silver-mining, but with the coming of the Turksib railway the lower north was opened up to agriculture. (R. A. F.)

ALTAIR, the brightest star in the constellation Aquila (*q.v.*), and, because of this, also known as α : Aquilae. It is the middle member of the group β , α , γ in the constellation, and is of the first magnitude, being one of the nearest and brightest stars. Its distance from the solar system is about 16 light-years. It is a

white star having a size somewhat greater than that of our sun and giving out about ten times as much light.

ALTAMIRA CAVE, famous for its magnificent prehistoric paintings and engravings, is situated 2 km. (1 mi.) from Santillana-del-Mar, a small town 30 km. (19 mi.) W. of Santander in northern Spain. The opening of the cave, at the summit of a limestone cliff, was discovered by a hunter in 1868. In 1875 it was visited by Marcelino de Sautuola, an engineer from Santander, who found animal bones and flint implements there. He returned in the summer of 1879, and on one visit was accompanied by his little daughter Ilaria; it was she who, looking at the roof, noticed paintings of "bulls." With Vilanova y Piera, professor of geology of Madrid university) they went back to the cave, and the geologist examined the finds, which included bones engraved with animal figures. Both men were convinced of the antiquity of the paintings. As early as 1880 Sautuola reproduced them in his booklet *Breves apuntes sobre algunos objetos prehistóricos de la provincia de Santander*, and in the same year Vilanova y Piera made them known to an international congress held in Lisbon. Both Spanish and foreign experts reacted unfavourably; the paintings were dismissed as recent forgeries or as the work of Roman soldiers taking part in the Cantabrian war of 26 B.C. to 19 B.C. Sautuola died in 1888 and Vilanova in 1893. Shortly after, the repeated discoveries of small carved objects created a more favourable atmosphere, and the engravings which came to light in the cave at La hlouthe (Dordogne) in 1895 prepared the way for the acceptance of Altamira. Finally, the discovery in 1901 of paintings in the caves of Combarelles and Font-de-Gaume (Les Eyzies, Dordogne) made the truth manifest. The French scholar Émile Cartailhac thereupon wrote his famous article *Mea culpa d'un sceptique* (1902) and went to Altamira with the abbé Henri Breuil, who made copies of the paintings. These were published by the Institut de Paléontologie Humaine in 1908. A second edition, in English and Spanish and with new copies, was brought out by the Real Academia de la Historia in 1935.

The Altamira cave is 270 m. long. In the vestibule numerous archaeological remains belonging to the Aurignacian (Perigordian), upper Solutrian and lower or middle Magdalenian periods (*i.e.*, between approximately 30,000 B.C. and 10,000 B.C.) were found, including ceremonial staves and engraved animal shoulder blades. At some time after the middle Magdalenian a rock fall closed the cave, around which Abbevillian, Acheulian and Mousterian tools have been discovered. The great lateral chamber which contains most of the paintings measures 18 m. by 9 m., the height of the vault varying from 1.15 m. to 2.65 m.

The roof of the chamber is covered with paintings, chiefly of bison! executed in a magnificent, vivid polychrome of red, black and violet tones. The animals are in various positions, protuberances of the rock having been utilized to assist in rendering their poses. There are in addition two wild boars, some horses, a hind 2.25 m. in length and some other figures in a simpler style (*e.g.*, a perfectly executed hull's head in black); also eight engraved anthropomorphic figures and various hand prints and hand outlines. The other galleries contain numerous black-painted or engraved figures, especially of horses, deer, wild cattle and goats; tectiforms (wedge-shaped markings resembling a sloping roof) and other signs which are indecipherable; finger-drawn lines and bear tracks. In the last gallery there are an engraved antelope and a figure which may represent a wolf. At the very back of the cave is a row of six engraved heads of hinds. The number of figures discerned totals 150.

Abbé Breuil and H. Obermaier assign them to various periods of culture as follows: the silhouettes, hands, tectiforms and other markings to the Aurignacian; the monochromes in semi-relief to the lower Magdalenian; the beautiful polychromes to the upper Magdalenian. Spanish authorities are dubious of this scheme; they prefer to allot the light silhouettes and monochromes to the Solutrian period, preceding the Magdalenian. Steps have been taken to preserve this magnificent assemblage which Joseph Déchelette called the Sistine chapel of Quaternary art. (L. P. G.)

ALTAMURA, a city of southeast Italy in the region of Puglia, and the province of Bari, is situated on the side of the Murge

Salentine hills at 1,543 ft. above sea level 27 mi, by road S.S.W. of Bari. Pop. (1957 est.) 43,178 (commune). The town is elliptical in shape and surrounded by a high medieval wall from which it takes its name. The Romanesque cathedral of the Assumption, begun in 1232 by Frederic II of Swabia, has been restored several times. Its façade, flanked by two Romanesque belfries, has a beautiful central rose window; the west door rests on two marble lions. The Pulo d'Altamura, about 4 mi. away, is a large limestone abyss, 1,640 ft. across and 236 ft. deep. Cattle and cereals are the chief products from the district and almonds and vines are cultivated. There is a wool market in the town. Altamura was founded about 1200 by Frederick II who created several new towns in Apulia, attracting Saracens and Jews with privileges to help him in his struggle against the barons. In World War II Altamura was captured by the Allies in Sept. 1943.

(M. T. A. N.)

ALTAR is the name given to a surface at or on which sacrifice is offered. In primitive religious observances, a natural rock, a stone or heap of stones; or a mound of earth probably sufficed for this purpose. With the development of the institution of sacrifice in sanctuaries and temples, more elaborate structures were built of stone or brick on which the victim was killed and its blood channeled off or its flesh burned. A trench or pit often was used for offerings to the dead, to chthonian divinities and to the heroes, as, for example, in Greek temples; or the altar might take the form of a table on which food was placed for the deity. In some religions no altars are used, the sacrifice being simply placed on the ground, thrown into water, etc. Where an altar is used it is set apart as holy, and regarded as a place of contact with the deity, whether it serves as a table of sacrifice to him, a hearth for burnt offerings or a grave ditch where oblations are made to the dead.

NON-CHRISTIAN RELIGIONS

Egypt.—A bowl, tray or censer sometimes stood on a pillow-shaped upright stand of stone or wood for offerings of incense. Oblong tables (hotep) with a spout in front were a development of the mat on which the sacrificial gifts were laid for the gods or the deceased. The great rectangular altars occasionally found in solar temples are rare, and those approached by a flight of steps, as in the temple of Hatshepsut at Dayr al Bahri, belong to the New Kingdom.

Mesopotamia.—The archaic altars depicted on Babylonian seals are small portable constructions carved out of stone or built of large flat bricks or stones placed one upon another triangular in shape, with a fire pan on the top. Others are of clay in the form of houses, hollow and approached by steps, and ornamented with doves, lions and serpents, or of hourglasses, candlesticks and stands for flower vases. Tables of offerings frequently are depicted; in Assyria these were fashioned in bronze with molded legs joined to one another by horizontal bars.

Syria and Palestine.—Banks of earth or heaps of unhewn stones were piled up to represent mountains on which sacrifices were offered. In a sanctuary an unhewn stone pillar (*mazzebah*) was erected on which oil was poured sacrificially as in the story of Jacob at Bethel (Gen xxviii. 17 ff.), the pillar being regarded as the abode of the indwelling deity. The simplest artificial constructions apart from these mounds, cairns and menhirs were rock-cut altars, often rounded at the top, with a square base and steps cut in the stone at the corners or, as at Petra, approached by a flight of steps on the east side. Such altars had a hollow, used as a fire pan, on the top, and conduits through which the blood was carried into basins. Natural rocks containing depressions for this purpose are still used as altars by Arabs.

Hebrew Altars.—When the Hebrews occupied Palestine they continued the Canaanite practice of erecting altars of earth and of unhewn stone (Ex xx, 24–26). After the centralization of worship at Jerusalem, Solomon is alleged to have incorporated a bronze altar (II Chron. iv. 1; II Kings xvi, 14) on three levels (Ezek xlili 13–17) like the Babylonian temple tiers, perhaps under the influence of Mesopotamian cosmic ideas transmitted from Phoenicia. That the normal equipment of the earlier Semitic

sanctuaries, or "high places," survived during the monarchy in Israel is shown by the efforts of Hezekiah and Josiah to destroy the *mazzebah* (I Kings xiv, 23; II Kings xvii, 10). (See HIGH PLACE.) The old Canaanite sites, such as Taanach, Gezer, Shechem and Megiddo, with their altars, standing stones, sockets for the sacred poles and remains of infant victims which have survived to the present day, were still places of sacrifice as late as the 8th century B.C. Indeed, it was not until after the exile 200 years later, when the Priestly document was compiled (see PENTATEUCH), that altars were erected in the post-exilic temple on what was alleged to have been the pattern of the tabernacle in the wilderness though, as they were required for burnt offerings, they could hardly have been made of acacia wood overlaid with bronze and gold, as is asserted (Ex. xxvii). This seems to have been a fanciful correlation on the part of the priestly writers. The earlier sanctuaries were brought within the tradition of Israel, for instance by assigning Bethel to Jacob (Gen. xxviii, 17 ff.), the altar on Mt. Ebal to Joshua (Josh. viii, 30), and representing the altar set up by the tribes of Reuben, Gad and the east Jordan group of Manasseh as a witness of their solidarity with the rest of Israel and not as a place for sacrifice (Josh. xxii, 9–34). Thus, the altar, reinterpreted, was preserved as a legitimate centre of worship. Similarly, in the second temple (I Macc. iv, 47) and in Herod's temple the altar was again constructed after the same model and dimensions as the original. According to Josephus' book on the Jewish war, the altar in Herod's temple was 15 cubits high and 50 cubits square with corners like horns and approached by a slight slope, to evade the prohibition of steps in Ex. xx, 26; the Talmudic tractate of Middoth gives rather different measurements. Use of iron tools in construction of the altar was strictly forbidden in order to preserve its archaic character. The altar had "horns" (protuberances) at the four corners (Ex. xxvii, 2); these were later regarded as its holiest part, so that any one clinging to them was immune from molestation (cf. I Kings i, 50, 51; ii, 28).

Before the veil separating the holy of holies from the holy place stood an altar overlaid with gold, perhaps a so-called altar of incense (Ex. xxx) used for burning incense or fat, though no description is given of its form (I Kings vi, 22; vii, 48). It was removed from the temple at Jerusalem by Antiochus Epiphanes and subsequently restored (or rebuilt) by Judas Maccabaeus (I Macc. i, 21–23; iv, 35–49). A table, made of acacia wood overlaid with gold (Ex. xxv, 23–30), on which the shewbread was laid, stood in the holy place; but it was not an altar.

Greece and Rome.—The Greeks had both domestic altars for family use and public altars such as the city altar on which fire continually burned and the temple altar dedicated to the god concerned. Altars varied greatly in shape and size, but were generally made of stone and often decorated with relief work. Roman altars were very similar to those of the Greeks. Usually they were rectangular, though some of the older ones were round or oval like the earth mounds on which they were modeled. In Hellenistic times small circular altars used for burning incense and for libations and gifts of fruit and flowers were common. Larger altars for animal sacrifice were erected on terraces approached by steps. The altar of Zeus at Olympia is said by Pausanias to have been 22 ft. high, 125 ft. in circumference on its lowest platform and 32 ft. on the altar proper. That at Pergamum had a platform of 20-ft. circumference and a total height of 40 ft. These lofty structures were particularly suitable for sky gods such as Zeus (Jupiter); for the earth and for domestic deities such as Vesta, Demeter and the Erinyes low altars were more suitable. But Roman temples usually stood on eminences with steps in front of which were altars, often decorated with allegorical and ceremonial scenes in the form of reliefs and with naturalistic garlands carved in the marble.

In the home, since the hearth was the centre of the domestic cultus and the kitchen the principal room, the shrine frequently was located near the kitchen hearth, as at Pompeii. But sometimes a special room was provided for the altar. When the temple of Vesta became the hearth of the city, with its vestal virgins continually in attendance upon the sacred fire, the divine personification of the hearth fire was worshiped by the senate in the *atrium*

Vesfae on the forum. Small altars were placed in the streets in niches with pictures of the gods to whom they were dedicated; such altars served as places of refuge for suppliants who were under the protection of the god to whom the altar belonged.

Iran and India. — Altars are not mentioned in the Avesta or in Zoroastrian inscriptions, but in Iran during the Achaemenian period the sacred fire burned continually in urns on altars supported by pedestals and set upon mountains and eminences; later the altar was surmounted by a baldachin with four arches. Portable altars containing the fire were carried in processions. From Sassanian times (3rd century A.D.) animal sacrifices have been strictly forbidden, but the Parsees of India, among whom the religion of Zoroaster survives, continue to use the fire altars, priests performing before them the prescribed rites.

Behind this reverence for fire lies the very ancient cult of Agni (*q.v.*) in the Indo-Iranian background of Zoroastrianism. It is found also in Hinduism, in which the building of the fire altar in seven layers in the form of a falcon representing the body of Agni was a repetition of creation. In the midst of the construction a fire pan was fashioned as a ritual act by which the creation of the universe was reproduced, and the sacred flame rekindled by the fire sticks of the priests recreated the life pervading the universe. Each type of offering had its own distinctive altar, constructed according to carefully prescribed dimensions, symbolizing in its form and manner of building its specific purposes and significance.

China. — From early times the Chinese offered burnt sacrifices to the god of heaven on mountaintops. In the Ming period (A.D. 1368–1644) a magnificent marble altar dedicated to Heaven was erected on three circular terraces in a park on the south side of Peking; the enclosure occupied over a square mile and was approached by flights of steps located at the four points of the compass. The lowest terrace was 210 ft. in diameter, the second 150 ft. and the third 90 ft. At this altar the emperor offered the sacrifice to imperial Heaven at the winter solstice each year until the fall of the empire in 1911. At midsummer he repaired to the altar of Earth in the northern suburb to sacrifice for the purpose of inducing the earth to produce "the balmy wind and sweet rain." This altar was smaller, consisting of two terraces, but the rite performed on it was almost identical with that at the altar of Heaven. Local sacrifices to the earth were offered on mounds about five feet square and a foot high. In both Confucian and Buddhist temples stands a rectangular stone table, used as an ancestral altar, on which are two candlesticks, a censer and sometimes a pair of bronze porcelain or stone vases. Sacrifices have been offered biennially to the spirits of the dead on altars in front of tombs, and most private houses have contained miniature altars where food offerings and incense have been presented to deceased relatives or to a particular minor divinity.

Ancient America. — Altars were in common use among the Indian tribes of North America. In the chief village of the Natchez of Louisiana stood a large temple in the centre of which a fire burned perpetually on an altar; behind the altar was a raised platform on which were laid baskets containing the bones of some of the "suns" who formed the governing caste (see NATCHEZ). This practice was adopted by the surrounding tribes. In the mounds area east of the Mississippi altars of clay, or very occasionally of stone, in various shapes and sizes, were situated near the centre of the mound, seldom more than a few inches above the ground (see MOUND BUILDERS). Basin-shaped hollows filled with ashes have been found at the tops of these mounds, and on one mound an oval altar six feet in length with charcoal and fragments of charred human bones was found, suggesting that it was used for burnt offerings or mortuary rites.

The most elaborate Indian altars, however, are those built by the Hopis and other Pueblo tribes in New Mexico, constructed of sand to resemble animals (*e.g.*, snake or antelope). Behind the sand altars are reredoses made of wooden slats placed horizontally and vertically, decorated with symbolic pictures of rain and cloud. The Zuni in western New Mexico have similar altars composed of a picture on the floor in coloured earths with reredoses of carved and painted symbolic slats.

In Central America every home had its domestic altar, but it

was in the temples that human sacrifice was practised. Thus, in the great temple of Huitzilopochtli, the Aztec warrior god, in Mexico city, the heart of the sacrifice was extracted on a jasper stone. The ancient Mayans and Guatemalans had sculptured altars of similar shape and proportions with grooves at the top to receive the blood. Sometimes they were erected on the graves of the dead, but generally they were placed at a considerable elevation on a pyramid.

CHRISTIAN RELIGION

The central act of Christian worship is the Eucharist (*q.v.*), which requires a table on which to place the bread and the wine. Before the building of churches for worship, when Christianity was still a persecuted sect, the Eucharist was celebrated in private houses on tables used as altars and at the tombs of the martyrs. In the catacomb of St. Calixtus a fresco dating from the latter part of the 2nd century shows a three-legged table, similar in form to the tables used for domestic purposes, bearing the eucharistic elements. At first probably such tables were made of wood, but the practice of celebrating the Eucharist on tombs led to the introduction of stone altars in which martyrs' relics were enclosed. By the 4th century some altars were made of precious metals. Wooden altars still survive in Orthodox churches, but in Roman Catholic churches permanent altars must be of stone.

During the early period the altar was placed at the chord of the apse (*q.v.*), since the Eucharist was celebrated behind the altar, the celebrant facing the congregation. When this practice was reversed, the altar was pushed back, even as far as the rear wall. In modern times in some western churches there is a movement to place the celebrant facing the congregation once more, and altars are again being erected well away from the wall of the chancel (*q.v.*) and even toward the centre of the church. If the church is oriented, the altar is at the east end; if the church looks west (as in St. Peter's, Rome, and the early Roman basilicas), the altar is at the west.

Altars have been consecrated in the east since the 4th century and in the west since the 6th century. Consecration includes the anointing with oil of five Greek crosses, one at each corner and one in the middle of the upper surface of the altar. Originally each church had only one altar, as is still the case in the Orthodox churches. In the west, however, by the 6th century, side altars were erected in addition to the main or high altar. Altars are generally raised on steps behind a railing, at which communicants kneel to receive Holy Communion. In Orthodox churches, where the altar frequently is called the holy table, it is concealed behind a tall screen covered with icons known as the iconostasis (*q.v.*). The whole space behind the iconostasis is the bema (*q.v.*).

Altar Furnishings and Accessories. — The earliest references to altar coverings come from the 4th century. The simplest is a white cloth, but coverings of precious stones also were known in the 4th century. By the 9th century in the west the custom had arisen of having three altar cloths over a cerecloth waxed on one side to avoid possible contact of the consecrated elements with the altar stone. In the east one of these, called the antimension, takes the place of the altar stone or a portable altar in the west. It is itself consecrated, and relics are sewn into it. From the 9th century in the west, relics and a pyx (*q.v.*) or tabernacle containing the reserved sacrament began to be placed on the altar during the celebration of the Eucharist, and then kept there permanently. Somewhat later a cross was added, then a candlestick on either side. These were increased to six or seven (one being placed behind the cross) when a bishop celebrated in his own cathedral, as in modern times. The chalice or cup for the wine and the paten or plate for the bread, both usually made of precious metal, are not part of the altar furnishings, being placed on the altar only during the relevant part of the Eucharist.

Altars are sometimes covered by a canopied structure, surmounted by a cross and supported by four pillars, called a baldachin (*q.v.*) or ciborium. The earliest surviving examples are of the 8th century, but they are known to have existed before this date. A well-known Renaissance example is Bernini's baldachin on twisted columns in St. Peter's, Rome. In the Western Church

Model of an Egyptian copper altar table (*hotep*) from Abydos; 6th Dynasty, c. 2300 B.C. The top is in the shape of two loaves of bread on a reed mat; hieroglyphs on the front represent the priest's name and titles

Hebrew limestone horned altar from Megiddo; period of the Israelite monarchy, 10th–9th centuries B.C.

Part of a triangular bronze fire altar, probably from Mesopotamia; 1st–2nd centuries A.D.

Neolithic limestone altar slab, originally painted red, from Hagar Qim, Malta

Pre-Islamic incense altar, probably of limestone, with goats and astral symbols carved in relief around the top; from southern Arabia

Altar 'Q' at Copán, Honduras, an ancient Mayan altar with carved figures of representatives from 16 Maya centres. The date inscribed on top of the altar corresponds to A.D. 776

Remains of the lower part of the Bactrian fire altar of the south temple at Surkh-Kotal, site of worshipers of Mazdak, Afghanistan; 1st–2nd centuries A.D.

Ruins of a large rectangular Hellenistic sacrificial altar in the Athenian Agora; 4th century B.C.

ALTARPIECES

a covering is required over every altar. Frequently there is a reredos (*q.v.*), or decorated background, behind and above the altar. At first the wall against which the altar stood was adorned with paintings, but in the middle ages a separate decoration in the form of a rich cloth, a picture or a carving of wood, stone or metalwork came to use. These became very elaborate and ornate, as illustrated by the lofty stone structures covered with sculptured figures of saints that mask the whole height of the wall behind the altar in the chapels of New college and All Souls at Oxford. The *pala d'oro* behind the high altar at St. Mark's, Venice, a splendid example of Byzantine metalwork made of gold studded with jewels, shows Christ surrounded by angels, prophets and saints. The reredos was often in the form of a triptych or polyptych, either carved or painted, as the "Adoration of the Lamb" by Jan van Eyck which is in the cathedra: at Ghent, though no longer as a reredos. (See also ALTARPIECE.)

Reformed Churches.—The repudiation of the doctrine of the eucharistic sacrifice by the continental reformers meant that the altar as such ceased to have any rightful place in their public worship. It was replaced, save in Lutheran Germany and Scandinavia, by the pulpit or rostrum from which the minister conducts the services. The movable wooden table, not called an altar, on which the bread and wine are placed and blessed at the administration of the Lord's Supper has a strictly utilitarian purpose, devoid of any sacred or sacrificial significance and of symbolic or aesthetic qualities calling for veneration or adornment.

In England this practice was adopted under the influence of the continental Reformers, and the terms "table" and "God's board" were substituted for "altar" in the second Prayer Book of Edward VI (1552). The name "altar," however, though retained only in the coronation rite and in the canons of 1640, has been commonly used in the Church of England since the Restoration. Archbishop William Laud restored the altar to its former position at the east end of the church, and since the Oxford movement permanent stone altars have not incurred serious opposition although the law requiring altars in parish churches to be of wood and movable has never been rescinded. Similarly the accessories presupposed by the ornaments rubric inserted in the Prayer Book of 1559 are in general use in Anglican churches (*e.g.*, a cross or crucifix with one or more candles on either side: and vases of flowers).

ALTARPIECE. The altarpiece, or retable, is a structure above the altar table, adorned with holy personages, saints and biblical subjects. The term "reredos" (*q.v.*) is used for structures not directly attached to the altar table but affixed to the wall behind it. The predella is a low, decorated strip intended to raise the main part of the altarpiece to a height where it is readily visible from a distance. A diptych is an altarpiece consisting of two panels; the triptych consists of three panels; and the polyptych of still a greater number of panels. A winged altarpiece is one equipped with wings which can be opened and closed over a fixed central part. It allows various representations to be exposed.

Painting, relief and sculpture in the round have been used in altarpieces, either separately or in various combinations. The art work cannot be fully understood divorced from its original context. The structure connecting the altarpiece with the altar proper may be a simple picture frame or it may consist of the most elaborate architectural elements.

Painted altarpieces were originally in tempera on wooden panels.

In the 11th century oil became the more widely used technique, and in the 16th century canvas became the preferred surface. Some early, relatively small altarpieces were made in low relief of gold, silver or gilded copper over wooden cores, and decorated with precious stones. Reliefs, as well as figures in the round, were carved in stone. Carvings in wood, usually coloured and gilded, were very popular in 15th-century Germany. Bronze was rarely used before the 17th century. Coloured and gilded stucco became a favoured material in the 18th century in Germany and Austria.

The architectural framework for painted panels or wood sculptures was carved in wood and gilded. The simpler frames for large Renaissance paintings were done in the same technique. Where stone sculpture was used, the architectural parts were also in stone. The baroque, with its large, stagelike structures: used a good deal of stucco with imitation marble effects for some of the architectural parts.

Middle Ages.—The practice of erecting a structure above the altar and adorning it with paintings and sculptures reaches back at least to the 11th century. The earlier custom of having a hanging or an image on the wall behind the altar was very likely one of the sources of this development. The new devotional spirit of the Gothic and the improved social and economic conditions of the medieval city-states also contributed. The reversal of the position of the priest in relation to the congregation was still another factor. In the early church the priest stood behind the altar and faced the congregation. The introduction of the altarpiece necessitated a change of the position of the celebrating priest who would otherwise have been covered by the altarpiece. This change took place in the 12th or 13th century but was never canonized. It is for this reason that a return to the original position of the priest has become possible today. (See below.)

The earliest altarpieces were rather small and often were not permanently connected with the altar. They were made of precious materials and this is one reason so few have survived. The *pala d'oro* of St. Mark's, Venice, whose earliest parts are from the 10th century, is a good example.

One of the oldest known painted panels is the triptych of the "Savior Between the Virgin and St. John" in the Cathedral of Tivoli, Italy, which is possibly of the 11th century. This piece was painted in the so-called Byzantine tradition of Italy which lasted through the 13th century. Many important pieces painted in this manner are now in museums (*e.g.*, "St. Magdalen," late 13th century. Accademia delle Belle Arti, Florence). These works, many of which were by anonymous masters, attest to the widespread use of painted altarpieces in Italy by this time.

Outside Italy, painted altarpieces seem to have been rare before the 15th century. After the great achievements of Gothic sculpture in the 13th century, sculpture was more popular in the north. Among the early large altarpieces in sculpture is that in the church of Unserer Lieben Frauen (1308) in Oberwesel, Ger. Numerous saints appear in individual niches in an elaborate Gothic structure. More restrained in the over-all composition, even if profuse in the movements of the single figures, is the marble altar at Lucca by the Italian Jacopo della Quercia, of 1424. Mention should also be made of the free-standing sculptures created by Donatello for the high altar of the Santo in Padua (1450).

The greatest carved altars are those of the German school, marking the end of the middle ages in the 15th century. Outstanding are the violently expressive forms of the "Altar of Mary" (1477-89), by Veit Stoss, in Cracow, Pol., and the more quietly moving figures of the "Blood Altar" in Rothenburg-ob-der-Tauber, by Tilman Riemenschneider, which was finished in 1505.

Renaissance.—In all of Europe except Germany, sculpture was overshadowed by painting until the baroque period. In 14th-century Italy two contrasting tendencies developed side by side. In the first, which was strongly influenced by the Gothic and centred in Siena and Venice, the architectural framework was very elaborate and polyptychs were quite frequent (*e.g.*, the triptych of the "Annunciation" (1333), by Simone Martini, Uffizi, Florence). The second, which centred in Florence and favoured single, monumental paintings with simple frames, represented the more progressive tendencies of the Renaissance; an outstanding example

of this truly great style is Giotto's "Madonna" in the Uffizi, Florence, of the early 14th century.

In 15th-century Italy, altar painting was simply a branch of the general development of painting. An outstanding example is Piero della Francesca's "Nativity" in the National gallery, London. A characteristic transformation of the Gothic triptych with elaborate architectural framework is Giovanni Bellini's altar (1488), in the Frari church in Venice. The intricately carved frame represents the arched nave of a church with one bay on each side. The perspective of the painting continues the architecture of the frame into the depth of the picture.

Outside Italy, altar painting began only in the early 15th century, with its centre in the Netherlands. The famous polyptych with movable wings (1432), by the Van Eyck brothers, is the outstanding example of this group. Some of its panels are no longer conceived as individual representations or scenes. In the "Annunciation" for instance, four panels are drawn together to represent the room where the event takes place; the partitions of the frame are like windows through which one can look into space. Retarded in style but often very expressive and refined are the great polyptychs of the 15th century in Germany; e.g., the "Altar of Mary" by Konrad of Soest, in Dortmund.

In Renaissance Italy, the polyptych had been all but eliminated in favour of large single paintings. The elaborate architectural framework of the Gothic was replaced by a relatively narrow gilded frame, the prototype of the frame that remained an integral part of all easel painting until the 20th century. Characteristically, the increased importance of the picture, as against the frame, was particularly favoured by the great painters of Venice. The paintings themselves had become very large; for instance, Titian's "Assumption" in the Frari church, Venice, is over 22 ft. high. Michelangelo's huge fresco of the "Last Judgment" (1534-41), in the Sistine chapel, even though technically not an altarpiece, should not be omitted in this context. For all practical purposes it functions as a reredos. The last great altarpieces in which painting was the dominant factor were by 17th-century masters such as Caravaggio and Rubens.

The end of the middle ages in Germany witnessed a splendid combination of sculpture and painting. Painted wings closed over boxlike cores with elaborate sculptures carved in wood, gilded and coloured. The greatest work of this type is Matthias Grünewald's "Isenheim Altar" (about 1516).

Baroque.— Gothic altars mere still essentially pieces of church furniture, whether they were freestanding or attached to a wall. During the Italian Renaissance, on the other hand, there was an increasing tendency to integrate the whole altarpiece with the architecture of the church. This aim, however, was hardly ever accomplished because the church and its interior equipment were rarely planned and executed together during the short period of the High Renaissance. It was only with the baroque that a complete integration of the various components was accomplished. The essential distinction between the architecture of the church, the architecture of the altarpiece, and the sculptural and painted portions disappeared. However, with some notable exceptions: the artistic quality of painting and sculpture declined in connection with this change. Interest in the ensemble overshadowed interest in the components. Even the altar proper became more and more an adjunct to the altarpiece, and lost much of its original, independent significance.

As a consequence of this tendency to merge all the arts, the baroque excelled in large stagelike ensembles. The great architect-sculptor Bernini made the most creative contributions toward this development. His "Cathedral Petri Altar" (1657-66), in St. Peter's, Rome, is an outstanding example. This altar is no longer a piece of church furniture; its components are a direct extension of the architecture, integrating even the sources of light into the general composition. Bernini's "Altar of St. Teresa" became the prototype of German 18th-century altarpieces in which the design of building and altar originated together. The high altar of the church of the Monastery in Weltenburg, Bavaria, by the brothers Asam is an outstanding example. The altar proper, populated with many painted sculptures, is simply an extension of the

architecture of the nave. It opens into an arched stage with the figures of St. George and the Dragon indirectly lighted by an unseen window. The background of this stage is taken up by a painting which blends with the colours of the sculptural and architectural parts in front.

A Spanish variant of the baroque altarpiece was transplanted to the Americas in the 18th century. It is of the reredos type, which, in Spain, was already favoured during the Gothic period.

19th and 20th-Century.— In the 19th century, following the use of various historical styles in church architecture, the design of altarpieces degenerated into pure eclecticism. Interesting attempts to revive the altarpiece were made in the 20th century. Examples by such great contemporaries as Matisse and Bonnard are in the church of Assy, France. A reredos in the form of a huge stained glass window by Emil Frei is in St. Ann's church, Normandy, Mo. The general tendency of the 20th century, however, seemed to be toward the reintroduction of the unadorned altar table combined with a return to the early position of the priest behind the altar.

ALTA VERAPAZ, a department in north-central Guatemala. Its area is 3,354 sq.mi., and its population (1957 est.) was 234,229. Its capital is Cobán. Most of the inhabitants are in the highlands east of the Rio Chixoy where there are coffee plantations. Other crops include maize, beans, sugar cane, cacao; much of the land is used for beef cattle. From the forests of the north come chicle, vanilla and wood. The main route of access is by road and rail to the Rio Polochic and Lago de Izabal to the port of Livingston. (P. E. J.)

ALTAZIMUTH, an astronomical telescope of a pattern similar to a theodolite but on a much larger scale. It is used principally to observe positions of the moon before first quarter and after last quarter, when the moon passes across the meridian in daylight. In order to secure more favourable nocturnal observations at such times it is necessary to have an instrument which can be turned out of the meridian but in other respects is used similarly to a meridian circle.

ALTDORF, the capital of Uri canton, Switz., is on the Reuss river where it is joined by the Schachen torrent, 490 m. (1,607 ft) above sea level, 74 km. (46 mi.) by road south of Zürich. Pop. (1960) 7,477, mostly Roman Catholic and German-speaking. In the centre of Altdorf a bronze statue of William Tell by Richard Kissling of Zürich stands on the spot where, according to tradition, Tell shot the apple from his son's head. In 1899 a theatre was opened for the performance of Schiller's play *Wilhelm Tell*. Near Altdorf is Biirglen, where Tell is said to have been born and later drowned. In the village is a Tell museum in an ancient tower. The town is on the Saint Gotthard railway from Ziirich and Lucerne to Lugano and Italy. The main road from north to south also passes it, the part to the north, the famous Axenstrasse, being partly in tunnel cut out of the mountainside above Lake Lucerne. There are rubber and cable works and an ammunition factory. Altdorf was burned down four times, completely in 1400 and 1799 and half of it in 1488 and 1692, with loss of historical documents. (HA. GA.)

ALTDORFER, ALBRECHT (?1480-1538), German painter, engraver and architect, among the earliest European artists to stress the romantic aspects of landscape, became a citizen of Regensburg in 1505 and remained there all his life, aside from occasional visits to Austria. In later years, he was official architect of the city and held a seat in its inner council. Altdorfer was the guiding spirit of the Danube school. He was the first European painter to probe the mysteries of impenetrable forests ("St. George," 1510, Munich), of sunset moods ("Danube Landscape Without Figures," Munich), and of picturesque ruins in twilight ("Nativity," Berlin). For Altdorfer, man was part of a strange symphony of trees, plants, rocks, mountains and clouds, and often resembled their weird, primeval forms. He disregarded the Italian concepts of rational organization which occupied his great con-

temporary, Albrecht Dürer. Of the masterful altar panels in St. Florian near Linz (1518), depicting the Passion of Christ and the martyrdom of St. Sebastian, several are night scenes illuminated by torches or a distant twilight—a new venture then. His masterpiece in dramatic illumination is the "Battle of Alexander at Issus" (1529, Munich).

The fantastic element appears most unrestrained in his drawings, most of which are in black and white lines on brown or blue-gray tinted papers. His engravings and woodcuts are generally of miniature size, but their playful imaginativeness distinguishes them from the more pedantic production of the "Little Masters" of engraving. His most important woodcuts are the 40 plates called "The Fall and Redemption of Man." About 1530, he used the new medium of etching in nine exquisite landscapes as well as a series of fanciful tankards, intended as work models for goldsmiths.

ALTENBURG, a town in the Leipzig district of Germany, lies on the southern edge of the central German brown coal deposits about 30 mi. S. of Leipzig. Pop. (1959 est.) 47,060. The town is known as the birthplace of the card game skat (*q.v.*). The former ducal castle, built in the 10th century and several times destroyed, was restored in the 19th century and contains a playing-card museum. The fountain is decorated with sculptures of skat players. The Lindenau museum contains a large collection of art objects. Altenburg is noted for its manufacture of playing cards, and the nationally owned playing-card factory exports all over the world. Sewing machines (also a nationally owned enterprise) are exported and hats are made. Altenburg has the only drum-skin tannery in east Germany, a private concern with an extensive export program. A teachers' training school and schools for papermakers and railwaymen are located there.

The town arose in 1130 as a trading centre. It served the emperor Frederick Barbarossa as a royal residence and he founded an Augustinian monastery there. Altenburg was a principality from 1603 to 1672, and from 1826 to 1918 it was the residence of the dukes of Saxe-Altensburg.

ALTERNATING CURRENT, electric current which grows to a maximum value, decreases, changes its direction (with respect to a datum line), reaches a maximum value in the new direction (which is equivalent to a minimum value for the original direction), and returns to its original value, whence it repeats this cycle an indefinite number of times. The interval between the attainment of a definite value on two successive occasions is called the period, and the number of cycles or periods per second is the frequency of the alternating current. High frequency currents have several thousand cycles per second. The amplitude is the deviation of the maximum (or of the minimum) from the datum line. See **ELECTRICITY: Direct-Current Circuits**; see also **Index** references under "Alternating Current" in the **Index** volume.

ALTGELD, JOHN PETER (1847-1902), governor of Illinois in the 1890s, famous for his pardon of convicted Haymarket rioters. He was born in Prussia, Dec. 30, 1847, and as a child was brought by his parents to a farm near Mansfield, O. He had little formal education. At the age of 16 he served for a short time in an Ohio volunteer regiment during the Civil War. After the war he moved west and studied law. In 1869 he went to Savannah, Mo., where in 1874 he won his first political race and became county prosecuting attorney. He resigned this office the next year and moved to Chicago. He entered politics again in 1884, running as Democratic candidate for congress, but he was not elected. The same year he published a book, *Our Penal Machinery and Its Victims*, which reflected his deep resentment against injustice. From 1886 to 1891 he was superior court judge in Chicago. Meanwhile he had accumulated a fortune in real estate. In 1892 he won his party's nomination for governor and was elected by farm and labour votes, the first Democratic governor of the state since the Civil War.

As governor he promoted reform programs, especially social

legislation. Early in his term as governor he was urged by Clarence Darrow, labour leaders and others to pardon three of the men convicted of complicity in the Haymarket riot (see **CHICAGO: History**) that had occurred in Chicago in 1886. He signed the pardons in June 1893, and at the same time released a statement charging that the men had not been given a fair trial. The anticipated storm then broke. Altgeld was denounced by the press and employers as the friend of anarchists. A year later, Altgeld's protest to President Cleveland against the use of federal troops during the Pullman strike produced further attacks, and in 1896 he was defeated for re-election. He became an advocate of free silver and supported Bryan in 1896 and 1900.

Altgeld had published a book entitled *Live Questions* in 1890; an expanded edition appeared in 1899. Another book, *Cost of Something for Nothing*, was published posthumously in 1901. He died on March 12, 1902.

See: Harry Barnard, *Eagle Forgotten; Life of John Peter Altgeld* (1938); Raymond Ginger, *Altgeld's America* (1958); Henry M. Christman (ed.), *The Mind and Spirit of John Peter Altgeld* (1960). (H. F. Tr.)

ALTHING, the legislative assembly of Iceland (*q.v.*).

ALTICHIERO (ALDIGHERO) DA ZEVIO (c. 1330-after 1390), Italian painter, was the effective founder of the Veronese school. He was born, according to Vasari, at Zevio, a village near Verona. Nothing is known of his early work in Verona. He migrated to Padua about 1370, perhaps at the invitation of Francesco I Carrara, painting frescoes (destroyed) in the Sala dei Giganti and, with Guariento, in the Palazzo del Capitano del Popolo. His main surviving works are two fresco cycles; one, with the "Crucifixion" and "Scenes from the Legend of St. James" in the chapel of S. Felice in the basilica of S. Antonio (completed 1379), and the other, with "Scenes from the Legends of St. George and other Saints" (c. 1384), in the Cappella di S. Giorgio nearby. In the latter cycle Altichiero was assisted by an associate, Jacopo Avanzo: the respective shares of the two artists in the work have not been satisfactorily ascertained. Altichiero returned to Verona, probably about 1390, executing (before 1396) a votive fresco over the Cavalli monument in Sta. Anastasia.

Altichiero's frescoes, in which elements deriving from Giotto are combined with a courtly style that anticipates Pisanello, had a profound influence on Veronese painting in the early 15th century.

(J. W. P.-H.)

ALTIMETRY. Altimetry is the process of determining the altitude above mean sea level of a point in the atmosphere, usually by measurement of the air pressure with an aneroid barometer. The relationship between pressure and altitude varies in space and time with varying weather conditions and is determined at known elevations on the surface of the earth with mercurial barometers. However, for points above the surface of the earth it must usually be calculated by assuming the hydrostatic equation, which expresses the fact that the rate of decrease of pressure with altitude is such that the difference in pressure on the bottom and top of a unit volume of air is equal to its weight. The weight of the air depends on its pressure, temperature and water-vapour content, the values of which are measured in the upper air with radiosondes or aeroplanes. The hydrostatic equation can be expected to be in error by less than 0.1% except in extreme weather conditions such as hurricanes or thunderstorms. Meteorological charts are used to interpolate the pressure-height relationship between observation points and for making forecasts of future conditions. (See **METEOROLOGY**.)

Altimeters, which are aneroid barometers used for altimetry, are marked in terms of a special pressure parameter, the pressure altitude, which is the height in a standard atmosphere at which a given pressure occurs. As an example, the U.S. standard atmosphere is defined as one in which the pressure at sea level is 760 mm. of mercury and in which the temperature is 15° C. at sea level and decreases with altitude at the rate of 6.5° C. per kilometre until it becomes equal to -55° C., above which point the temperature remains constant. The standard atmospheres have been chosen to represent average atmospheric conditions so that the numerical pressure indications are approximately equal

to the altitude. The difference between the actual altitude of a point and the pressure altitude at that point is called the altimeter correction and thus varies in both space and time. The maximum spatial variations of the altimeter corrections are observed to be about plus or minus 2,000 ft., while the time variations at a given point during periods of a few days are usually considerably less than this amount.

In order to obtain direct indications of altitude most altimeters are constructed so that the pressure-measuring apparatus can be adjusted with respect to a separate altitude scale in such a way that the appropriate altimeter correction is mechanically added to the measured pressure altitude. The amount of adjustment is usually indicated by an altimeter setting scale. The altimeter setting is defined as being the pressure corresponding to that pressure altitude which is equal to the negative of the altimeter correction.

From 1938 radio altimeters had been developed which measure the height of an aircraft above the surface of the earth by measuring the time for a radio signal generated in the aircraft to be reflected from the earth's surface back to the aircraft. With such instruments the altitude above mean sea level can be determined directly without a knowledge of the pressure distribution when flying over oceans. However, when flying over land, rapidly varying altitude of the underlying terrain, the elevation of which many times cannot conveniently be determined from the aircraft, limits the usefulness of these instruments for determining altitudes above mean sea level. (J. C. By.)

ALTITUDE AND AZIMUTH, two readings useful in astronomy, navigation, gunnery and other fields for describing the position of an object above the earth. Altitude in this usage is defined as the distance of the object above the ground or sea level and usually is expressed as the angular elevation (up to 90°) above the horizon. Azimuth (or bearing) is the number of degrees (up to 360°) clockwise from north, or (up to either 90° or 180°) east or west of a north-south base line. Altitude and

OBJECT WITH AZIMUTH OF 40° EAST OF NORTH AND ALTITUDE OF 30°

azimuth readings can be made with radar or with special telescopic devices such as the theodolite (*q.v.*) or altazimuth (*q.v.*).

For purposes such as aerial gunnery in which exact position is needed, a third factor must be known—the range, or distance from the object to the observer. See diagram for the position of an object with an azimuth of 40° east of north and an altitude of 30° .

See also **ALTIMETRY**; **COMPASS**: Azimuth Instruments; **SEXANTANT**; **SURVEYING**: Angular and Directional Measurement.

ALTMAN, BENJAMIN (1840–1913), C.S. merchant, art collector and philanthropist, established one of the world's great department stores. Born on New York city's lower east side on July 12, 1840, he had little formal schooling, but at the age of 25 he was able to open his first dry goods store, and in 1906 moved it to the uptown section, pioneering the movement of business there. With additions in 1913–14, the store occupied the entire block bounded by Madison and Fifth avenues and 34th and 35th streets. Known for his organizing ability and his promotion of medical service, rest and other benefits for his employees, he set up a foundation for their welfare and for other philanthropic purposes.

An astute art collector, Altman also built up a valuable art library. He had extensive collections of Chinese porcelains, crystals, rugs and other objects of art. Among his paintings were 13 Rembrandts and canvasses by Botticelli, Holbein and Filippo Lippi. The entire collection, appraised at \$20,000,000, was bequeathed, with \$150,000 for its care, to the Metropolitan Museum of Art.

Altman's estate of \$35,000,000 included a substantial gift to

the National Academy of Design to encourage American painting. He died in New York city Oct. 7, 1913.

ALTO, a musical term meaning "high" (Ital., from Lat. *altus*) and used of certain types of voice—the countertenor in men and the contralto in women (see **VOICE**; **SINGING**). It is also the term in Italian and French for the viola which used to take the highest part in works for strings (see **VIOLIN FAMILY**), and is used as part of a compound (*e.g.*, alto trombone) for instruments of high pitch.

ALTO ALENTEJO, a province of southern Portugal, was created in 1933 to include the two districts of Évora and Portalegre. Pop. (1950) 394,789. Area 5,128 sq.mi. It comprises a series of high plateaus at 600–1300 ft. forming the watershed between the Tagus (Port. Tejo) and Guadiana rivers. The province is divided naturally into four regions: the Évora plateau to the south, the Campo de Benavila drained by the Sado river to the west, the Elvas-Estremoz plateau on the east and the Sierra de S. Mamede (3,350 ft.) to the northeast. Most of the land consists of ancient crystalline rocks with poor soils. The province is sparsely populated and in summer is exposed to the rays of a torrid sun. Extensive stock raising and cereal production on large properties of 100 to 1,000 ac. are typical, and rich cereal lands are found where the diorite weathers into deep, black soils around Elvas, Campo Maior and Alter do Chão, and especially where the soils of syenite origin occur around Évora. There are famous olive groves and fruit orchards in the Elvas and Estremoz districts.

Bvora (*q.v.*), the capital, has much fine architecture dating from the 17th century. Elvas (10,748), Estremoz (6,929) and Portalegre (10,486) are noted agricultural centres but, apart from food processing and marble quarries, there is little industry.

(J. M. Ho.)

ALTON, an urban district and market town of Hampshire, Eng., lies among the downs on the river Wey, 18 mi. N.E. of Winchester by road and 20 mi. by rail. Pop. (1961) 9,158. In the church of St. Lawrence, which is Perpendicular with a Norman tower, fierce fighting took place between parliamentarians and royalists in 1643. Eggar's grammar school was founded in 1642 and there are many Georgian buildings. William Curtis, the botanist, was born at Alton in 1746 and the Curtis museum was founded in 1855. Within the urban district are the Lord Mayor Treloar Orthopaedic hospital, the 20th-century abbey of the Order of St. Paul and the village of Holybourne, where Mrs. Elizabeth Gaskell died in 1865. During 1809–17 Jane Austen lived at Chawton, 1 mi. S., and in 1588 George Wither was born at Bentworth, $3\frac{1}{2}$ mi. N.W. The village of Selborne (*q.v.*), where Gilbert White lived, lies 4 mi. E.S.E. Alton was granted an annual fair by Edward II; it is now biannual. Hops are grown in the district and the chief industries are brewing and the making of artificial limbs.

ALTON, a city of Madison county, Ill., U.S., on the Mississippi river, about 5 mi. above the mouth of the Missouri and 25 mi. N. of St. Louis, Mo. (For comparative population figures see table in **ILLINOIS**: *Population*.)

Named after Alton R. Easton, a son of the St. Louis lawyer politician who platted the townsite in 1817, it was organized as a town in 1833 and in 1837, when the population was about 4,000, it was incorporated as a city.

While Alton never realized its early ambition of commercial greatness, it enjoyed steady economic development as a part of the industrial arc that reaches down the Mississippi to East St. Louis. Locally, glass, paper, metal and canvas products, building materials, cereal foods and oil refining industries are important. Alton is divided by bluffs, some of which rise abruptly to a height of more than 200 ft. In the lower town, industrial establishments fill the river plain. Residential Alton lies away from the river on the bluffs. In some sections the wide, brick-paved streets and architectural styles convey the flavour of the 19th century.

Shurtleff college (Baptist) founded at Alton in 1827, and Monticello seminary for girls, founded in 1835 at the village of Godfrey, 5 mi. N., were among the earliest educational institutions in the Mississippi valley. Southern Illinois university operates a campus

on the site of Shurtleff college. Historical monuments commemorate abolitionist newspaper editor Elijah P. Lovejoy, who was killed by a pro-slavery mob in 1837, and the scene of the last Lincoln-Douglas debate in 1858.

(R. E. M.)

ALTONA, a suburb of Hamburg, in the north of Germany, is situated on the right bank of the Elbe. Until 1938 it was administered as a separate town, with a charter dating from 1664. Altona is built on cliffs above the Elbe and lies 5 km. (3 mi.) *it.* of the centre of Hamburg, with which it is connected by railway and buses. The industries are similar to those of Hamburg. The name may have come originally from *allzu-nah* ("all too near") which was the Hamburger's designation for an inn which lay too close to their territory, and which for a long time was the only building. Altona was a small fishing village called *Altwasser* when captured by the Danes in 1640 but soon became a formidable rival to Hamburg. It passed to Prussia in 1866. See **HAMBURG**.

ALTOONA, a city of Blair county, Pa., U.S., 99 mi. E. by N. of Pittsburgh. It is located in the rugged terrain of central Pennsylvania, on the eastern slopes of the Allegheny front which separates the Atlantic from the Mississippi valley watersheds. The city was named for Altona, an important river port in Schleswig-Holstein, Ger.

The Altoona region has always functioned as a transportation and communication centre between the eastern and western states. The first settlements in the area were made before the American Revolution. Fort Roberdau was established in the region in 1778 to protect lead deposits used by the patriot army. In 1787 the Frankstown trail (connecting the Susquehanna and Ohio river systems) was surveyed. Shortly after 1800 that highway was extended to Pittsburgh. During the canal building boom of the 1830s the most spectacular of all canal links, the Portage railroad, was developed to span the 36-mi. divide between the Juniata and Conemaugh rivers. Using railroad flat cars, the canal barges were hauled up a series of inclined planes and lowered by similar stages down the western slopes.

The city of Altoona proper was founded in 1839 by the Pennsylvania Railroad company. It soon became the major centre for the construction and repair of railroad rolling stock, still the city's chief occupation after mid-20th century. The city's population declined from a peak of 82,053 in 1930, to 80,214 in 1940, to 77,177 in 1950 and to 69,407 in 1960, largely as a result of the conversion from steam to diesel locomotives and a general decline in railroad activity.

The population of the standard metropolitan statistical area (Blair county) was 137,270 in 1960. (For comparative population figures see table in **PENNSYLVANIA: Population.**)

Pennsylvania State university has an undergraduate centre at Altoona. Nearby points of interest include surviving portions of the Portage railroad and Horseshoe Curve park. (R. L. L.E.)

ALTO PARANA, the easternmost department of Paraguay, was named after the river which bounds it for 150 mi. and separates it from Brazilian Paraná and Argentine Misiones. Area 7,817 sq.mi. It forms part of the Paraguayan extension of the Brazilian plateau, dissected by eastward-flowing tributaries of the Paraná. In the northeastern corner occur the Guaira (Sete Quedas) falls. Although as large as Wales, its population was estimated at only 13,745 in 1960, mainly recent European immigrants. Its economic development was awaiting transport links, the first of which would be a trunk road connecting Asuncion with Foz de Iguacú in Brazil. The only significant settlement is Hernandarias, the capital, previously named Tacurupuch.

(G. J. B.)

ALTO-RILIEVO: see **RELIEF**.

ALTRINCHAM, a municipal borough of Cheshire, Eng. lies 8 mi. S.W. of Manchester. Pop. (1961) 41,104. About 1290 Altrincham was granted by chartkr of Hamon de Massey a court leet, market and annual fair, the latter being replaced from 1319 to 1895 by the "Sanjam" held on the eve, fast and morron of St. James's day. The court leet regulated the tonn's affairs, appointing officials such as constables, market lookers and dog muzzlers, until the middle of the 19th century. The town was incorporated in 1937 and the market is now biweekly. The 18th-century Dun-

ham Massey hall, seat of the earl of Stamford, stands in a fine deer park. The old town hall, built by the 7th earl in 1849, now forms part of a hotel; the new town hall was opened in 1901. The Stamford hall serves as a social centre. Altrincham's commercial expansion began with the construction of the Bridgewater canal, started in 1760. In the mid-19th century the spinning of linen thread and bobbin turning were its two industries, and market gardening the chief occupation of its inhabitants, but early in the 20th century engineering of various kinds became the main local industry, and many residents travel daily to work in Manchester. Manchester airport is situated at Ringway, 3½ mi. S.E.

ALTRUISM, a philosophical term used in ethics (*q.v.*) for the theory of conduct which regards the good of others as the end of moral action. It was invented by Auguste Comte and adopted generally as a convenient antithesis to egoism. As a theory of conduct, its adequacy depends on the interpretation given to the term good. If the good is taken to be pleasure and the absence of pain, altruism would seem a reasonable principle. Most men would agree that a moral agent has an obligation to further the pleasures and alleviate the pains of other people, while it would seem contrary to ordinary usage to say that a man has a duty to further his own pleasure or to spare himself pain or is to be blamed for not doing either of these things. The same arguments hold if happiness is taken as the end of life. But if good is used more widely to include knowledge, aesthetic experience, virtue of character and personal holiness, then altruism fails as a complete theory of morals, for a moral agent has a duty of self-improvement in these fields, as well as his duties to others.

Some utilitarians (*e.g.*, Herbert Spencer and Sir Leslie Stephen; see **UTILITARIANISM**) held that these distinctions between self and others were unsatisfactory. Both egoism and altruism conceived society as an aggregate of units. The true moral aim was the welfare neither of others nor of self but of society (the social organism). This view claimed the support of evolutionary theory. Society was thought of as preserved and developed by the harmonious co-operation of the individuals composing it, just as an organism is by the harmonious interaction of the cells of which it is made up. This analogy was dangerous for two reasons: it does not seem possible to speak of the good of a society except in terms of the goods of its individual members; and these theories do not make clear whether the society to which individual actions are referred is one society or many. In ordinary usage there are many societies, each with its own members, but it is not an adequate theory of morals to limit the moral agent's duties to actions serving the particular society to which he belongs.

The principle of altruism recalls the Christian maxim "Do unto others as you would they would do unto you." But "others" in this maxim means not "other Englishmen" or "other Christians" but "other men regardless of the particular societies to which they happen to belong." (J. D. M.)

ALUDEL, a pear-shaped pot generally made of fire clay and open at both ends. The aludels are arranged in series, the neck of one fitting into the base of the next, to form a condenser. They were used by the early chemists in sublimation, and, at Almaden in Spain, the aludel or bustamente furnace has long been employed for the extraction of mercury from its ores.

(J. B. Ps.)

ALUM is the name commonly applied to a hydrated double salt, usually consisting of aluminum sulfate, water of hydration and the sulfate of another element. In more specific chemical terminology, alum refers to a whole series of hydrated double salts resulting from the hydration of the sulfate of any one of a number of triple-valence (+3) ions, including aluminum, and the sulfate of a single-valence (+1) ion.

The alums collectively have many important uses, including the production of medicines, textiles, sugar, paper, paints, matches and deodorants. They also are used in baking powder: styptic pencils, fire extinguishers, as a mordant (binder) in dyeing, as a flocculating agent in water purification and for waterproofing paper. The alum of greatest commercial importance is aluminum potassium sulfate, also known as potassium alum or potash alum.

Aluminum sulfate also can form alums with the sulfates of the singly charged (valence of 1) ions of sodium, ammonia, cesium, silver, rubidium, thallium, hydrazine, hydroxylamine, many organic amines and possibly lithium. These sulfates of singly charged ions, in addition to combining with aluminum sulfate, also can form alums with the sulfates of trivalent iron, chromium, manganese, cobalt, gallium, titanium, vanadium, iridium, rhodium, indium and others. Many of the alums theoretically possible have not yet been prepared.

Alums generally are produced by precipitating them from solution. For instance, in producing aluminum potassium sulfate, aluminum sulfate ($\text{Al}_2[\text{SO}_4]_3$) and potassium sulfate (K_2SO_4) are dissolved in water and then on evaporation the alum is caused to crystallize out of solution. The formation of each formula weight of alum requires one formula weight of aluminum sulfate, one formula weight of potassium sulfate and 24 molecules of water. The resulting hydrated double salt can be written either as $\text{K}_2\text{SO}_4 \cdot \text{Al}_2(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$ or as $\text{KAl}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$. In general, the ease of alum formation increases (i. e., the solubility decreases) as the size of the singly charged ion increases and that of the trivalent ion decreases. Thus, the largest of the singly charged metal ions, cesium, forms alums with all the triply charged ions listed, while for the smallest, lithium, only the aluminum alum has been reported and the supporting evidence for it has been questioned.

The list of alums is considerably extended by substituting selenate ion for part or all of the sulfate ion. Similar compounds have been prepared in which sulfate has been replaced by fluoroberyllate (BeF_4^{2-}) or chlorozincate (ZnCl_4^{2-}).

Nature of Alum Crystals. — The alums crystallize in the regular system, usually in octahedra; however, from a basic solution of ordinary alum, the cube tends to predominate. An octahedral crystal immersed in a slightly basic solution at room temperature will gradually be converted to the cubic form, the composition remaining unaltered. Owing to the symmetry of the crystal form, perfect single octahedra of large size may be obtained by slow crystallization at room temperature. A crystal weighing 125 lb. has been grown in this way in a period of about two years.

Studies of alum crystals by X-ray analysis have shown that the triply charged ion is in union with six water molecules, which occupy the corners of an octahedron, with the metal ion at the centre. The other six molecules of water serve to link these octahedra to the ions of the singly charged ion and the sulfate ions. Because the various singly charged ions differ markedly in size, the ions do not pack together in quite the same way in crystals of different alums. This gives rise to three distinct types of alums, which show different crystal shapes and can often be distinguished by outward appearance. The alums containing medium-sized singly charged ions have a structure designated as α , those of large ions as β , and those of small ions as γ . For aluminum alums, sodium forms the γ modification; ammonium, potassium and rubidium, the α ; and cesium, the β . Some alums can be induced to crystallize in more than one form, but in general the classes are not isomorphous and do not combine to form mixed crystals. Consequently, fractional crystallization furnishes a means of separating rubidium (α alum) from cesium (β alum). The nature of the triply charged ion also has some influence on determining the type of alum formed, as is shown by X-ray studies of chromium alums. The rubidium alum of this series forms β crystals rather than the α type formed in the aluminum series. Of the other chromium alums studied, potassium and ammonium are α , while cesium, thallium, and methyl ammonium are β .

Properties. — Potash alum, as is true of most alums, has an astringent and acid taste. It is colourless, odourless and exists as hard, transparent crystals or white crystalline powder. Potassium and ammonium aluminum alums are stable in air, but the sodium salt effloresces and disintegrates. The alums melt in their water of hydration between about 37°C . for thallose ferric alum and 117°C for cesium aluminum alum. By careful heating in a current of air, ordinary alum can be dehydrated at 100°C . If heated rapidly, it snells and forms a light bulky mass of "burnt alum." When ammonium alum is heated at much higher tempera-

tures, it yields pure aluminum oxide.

The solubilities of alums in water vary widely. The quantities (parts) of some of the aluminum alums dissolved by 100 parts of water (15°C .) are as follows: cesium alum, 0.35; potassium alum, 9.59; ammonium alum, 12.66; sodium alum, 51 (16°C .). Water dissolves several times its own weight of potassium alum at 90°C . The aqueous solutions act as weak acids.

Mixtures of chromium and aluminum alum are used to produce and measure the lowest temperatures yet achieved. In this application, the alum is cooled with liquid helium, magnetized with a strong magnetic field, then insulated from its surroundings, and the magnetic field removed. Work is done by the alum during its spontaneous demagnetization and the energy required is obtained at the expense of heat energy, so that the temperature falls. By this method, temperatures are obtained well within a tenth of a centigrade degree of the theoretical lower limit of temperature (absolute zero).

Manufacture. — The early history of the manufacture of alum is unknown. Potassium alum, aluminum sulfate and iron sulfates occur native in varying degrees of admixture and purity, and the *alumen* mentioned by Pliny in chapter 15, book 35 of *Natural History* would appear to include a number of salts and mixtures. In the 15th century, the Turkish Mediterranean trade in dyed fabrics and wool, in which alum was employed as mordant, amounted to a considerable sum. About 1460, John di Castro, after learning the alum manufacturing process at Constantinople, began to make alum at Tolfa, Italy, from a local deposit of alunite (a basic sulfate of aluminum and potassium) that was still being used in the 20th century. The introduction of the manufacture of alum into Italy (where it shortly afterward became a papal monopoly) was announced as a victory over the Turks. In England, preparation of alum from the schists of Yorkshire was begun about 1600.

Manufacture of alum from both alunite and alum schists was carried on without addition of sulfuric acid, the production of which did not assume importance until about 1800. In 1845, the manufacture of alum in England was radically altered by the substitution of aluminous shales for the schists. These shales contained more aluminum and less iron, and after being heated were reasonably soluble in sulfuric acid, from which alum could be crystallized. With the change to shales, the weight of aluminous material required to produce a ton of alum was reduced from about 100 tons to two-thirds of a ton; the time required also was greatly shortened and so the old process was gradually abandoned.

Potassium alum is largely obtained from the Italian mineral, leucite, a double silicate of aluminum and potassium or sodium. After crushing, grading, and an electromagnetic separation of gangue, the leucite meal is treated with sulfuric acid. The resulting solution contains aluminum and potassium in almost equimolar mixture, and the alum can be crystallized out and purified. In the United States alum is obtained by treatment of bauxite or clay with sulfuric acid, followed by addition of potassium sulfate to the solution. The alum crystallizes when the solution cools. Iron alum (ferric ammonium sulfate) is manufactured to a small extent, but the only other alum of commercial importance is the chromium potassium sulfate obtained as a by-product from the reduction of potassium dichromate in the manufacture of alizarin.

ALUMBRADOS (Sp. "enlightened"), the name given to followers of a pseudo-mystical movement current in Spain during the 16th and 17th centuries. Its adherents, who began to attract the attention of the Inquisition, especially in Andalusia, at the end of the 15th and beginning of the 16th centuries, claimed that the human soul, having attained a certain degree of perfection, was permitted a vision of the divine and could enter into direct communication with the Holy Spirit. From this state the soul could neither advance nor regress; consequently intercession of the saints, good works and observance of the exterior forms of religious life were unnecessary for those who had received the "light." The *Alumbrados* came especially from among the re-

formed Franciscans and the Jesuits (St. Ignatius Loyola was charged in 1527 with sympathizing with them); the extravagant claims made for their visions and revelations caused them to be relentlessly persecuted. The Inquisition issued edicts against them on three separate occasions (1568, 1574 and 1623), and it is principally from these that knowledge of the beliefs of the *Alumbrados* is derived. See also ILLUMINATI.

ALUMINA, the oxide of aluminum, occurs as corundum which is a hard crystalline mineral. The dark variety of corundum contains magnetite and is known as emery (*q.v.*); clear transparent crystals, tinted by other metallic oxides, are gem stones such as ruby and sapphire. Alumina may be prepared by the ignition of aluminum hydroxide, ammonium alum, etc., and from the various natural hydrated oxides of aluminum which occur in the minerals bauxite and gibbsite. Alumina is used in the manufacture of metallic aluminum, in the manufacture of synthetic gems, as an abrasive, and in the manufacture of refractory materials. It is polymorphous, existing in a number of crystalline forms, is close to the diamond in hardness and has the chemical formula Al_2O_3 . See ABRASIVE; ALUMINUM; CORUNDUM; CORUNDUM, ARTIFICIAL; GEM; see also Index references under "Alumina" in the Index volume.

ALUMINUM or ALUMINIUM is the most modern of the common metals, having been first isolated in 1825 and introduced to the public in 1855 at the Paris exposition. Its name is derived from the Latin *alumen*—a naturally occurring aluminous sulfate, probably a crude potash alum. Crude salts of this sort were used as astringents and mordants at least as early as the 5th century B.C. In the 13th century, men began to purify these crude salts into crystalline alum. The first mention of the production of alum from clay occurred in the 17th century, and in the 18th century its earthy base was differentiated from lime, shown to exist in clay, and given a name (*terre argilleuse*). It was suspected that it had a metallic base, but this was unproved until Sir Humphry Davy showed, in 1809, that an aluminum-iron alloy could be produced by the electrolysis of fused alumina in a hydrogen atmosphere, and that, on dissolving this alloy, aluminum oxide could be recovered from the solution. Davy suggested the name aluminum for this metal, a name which has been retained in North America but modified to aluminium in England and in most European countries. Its chemical symbol is Al, atomic weight 26.98 and atomic number 13.

Occurrence and Ores.—Because of its chemical activity, aluminum never occurs in the metallic form in nature, but its compounds are present to a greater or less extent in almost all rocks, vegetation and animals. In fact, aluminum is the third most abundant element on the earth's surface, being exceeded in amount only by oxygen and silicon. It is estimated that the outer ten miles of the earth's crust contain about 8% by weight of aluminum, or about 15% of aluminum oxide (alumina). The aluminum present in the original igneous rocks on the earth's surface (chiefly as feldspar and mica in the granites, basalts, etc.) is relatively insoluble in the weathering process by which soil has been formed out of these rocks. Therefore, it largely remains in this soil in the form of an aluminum silicate (clay), or when the weathering was more extensive much of the silica of the aluminum silicate was also dissolved by the percolating water, and the alumina and most of the oxides of iron and titanium present in the rock were deposited in the hydrated form as laterites or bauxites. (See BAUXITE; BOEHMITE; CLAY AND CLAY MINERALS.) These may contain up to 60% or even 70% of aluminum oxide, and are the principal commercial sources of aluminum and its compounds. In a few igneous rocks, deposits of crystalline alumina (corundum or emery) occur, and are mined for the production of natural abrasives. In some places aluminum sulfate, alum or alunite (*q.v.*) have been formed in weathered aluminous rock under the influence of sulfur-bearing gases or solutions. Cryolite (*q.v.*), the double fluoride of sodium and aluminum, oc-

curs in a great dike in Greenland, and is of commercial importance.

PRODUCTION OF THE METAL

Unlike the other common industrial metals (iron, copper, zinc, lead) pure aluminum is not produced by the direct smelting of its ores. In the first place, its affinity for oxygen is so much greater than that of the principal metallic impurities in the ore (iron, silicon, titanium) that their oxides are more readily reduced to the metallic state than is alumina. Therefore, if smelting conditions were chosen which would reduce the alumina, the other oxides would also be reduced and the resulting alloy would be too impure for use. In the second place, the temperature at which pure aluminum oxide is reduced by smelting with carbon is so very high that the greater part of the aluminum produced is lost, mostly as vapour with the gaseous carbon monoxide, unless there is considerable less-volatile metal such as iron or copper present to absorb it, or enough excess carbon to convert it into aluminum carbide. The production of alloys of aluminum with iron, copper and silicon has, however, been carried out commercially by such electrothermal smelting processes.

The earliest methods of producing metallic aluminum involved chemical reactions between purified aluminum compounds and metallic sodium or potassium. Hans Christian Oersted was the first to produce the metal (in 1825) by causing dilute potassium amalgam to react with an excess of anhydrous aluminum chloride. By distilling the mercury away from the resulting aluminum amalgam, a residue of slightly impure aluminum was obtained. In 1827, Friedrich Wöhler described the production of aluminum as a powder by the direct reaction of potassium upon anhydrous aluminum chloride. In 1845, he was able to make slightly larger amounts of the metal (some of the particles being as large as big pinheads) and determine some of its physical properties, such as specific gravity, ductility, colour, etc. In 1854, H. Sainte-Claire Deville improved Wöhler's method by using the cheaper sodium instead of potassium, forming a fusible double salt ($NaCl \cdot AlCl_3$) flux, which allowed the aluminum globules to coalesce. This developed into a successful (but expensive) commercial process which was practised in France and several other countries until the advent of the cheaper electrolytic process.

Aluminum cannot be produced by the electrolysis of aqueous solutions of its salts, hydrogen and aluminum hydroxide being formed at the cathode instead of aluminum. In 1854, Robert Wilhelm von Bunsen showed that the metal could be produced by the electrolysis of molten anhydrous sodium aluminum chloride, but as batteries were the only available source of electricity, the development of this process was impractical.

The modern electrolytic method of producing aluminum was discovered almost simultaneously by Charles Martin Hall, in the United States, and Paul L. T. Héroult, in France, in 1886. The development of the dynamo had then reached the point where currents of several hundred amperes were commercially available, thus making electrolytic methods of production practical.

The essentials of the Hall and Héroult processes were identical and are the basis of the modern aluminum industry. Purified alumina (Al_2O_3) is dissolved in molten cryolite and electrolyzed with direct current. The mixture is contained in a carbon-lined steel box which acts as the cathode (negative pole) while carbon rods or blocks dipping into the molten bath form the anode or positive pole. Under the influence of the current, the oxygen of the Al_2O_3 is deposited upon the anode, which is thereby burned, while the molten aluminum is deposited on the carbon lining of the cell (cathode). Since molten aluminum is slightly heavier than molten cryolite at the operating temperature (about 950° C.) the metal accumulates in the bottom of the cell. Additional alumina is stirred into the electrolyte from time to time and the molten metal removed. Most commercial cells for the production of aluminum use currents of 50,000 to 100,000 amp. Since each cell requires only five to six volts, it is customary to connect a large number (often 100 or more) of such cells in series, and supply the necessary power from a group of rotary converters,

mercury arc rectifiers or large direct current generators. In many plants, large Soderberg self-baking electrodes (one or two per cell) are used instead of the numerous smaller prebaked carbon anode blocks or rods which are employed in the older plants.

The steel box for 50,000-amp. cells may be 20 ft. long, 6 ft. wide and about 3 ft. deep, made of steel about 0.5 in. thick. Such cells are arranged in a line or several lines in suitable buildings (often 700 ft. or more in length) supplied with equipment to remove and collect the fumes and minimize the effect of the radiated heat. The gross power consumption may be 8–10 kw.hr. and the gross carbon consumption 0.6–0.8 lb. per pound of metal produced. Aluminum fluoride is added to the molten electrolyte from time to time to neutralize the soda in the alumina (derived from the Bayer process), and some cryolite is added to make up for the absorption by the cell lining, losses caused by spillage, etc. The total of such additions is usually less than 0.1 lb. per pound of metal produced, while the alumina required is somewhat more than 1.9 lb. per pound of metal.

An upward trend in world production of aluminum, which began in 1947, continued into the second half of the 20th century, with world capacity reaching about 5,000,000 short tons by 1960. The United States and Canada produce more than half the world total.

ALLOYS AND USES

In general, small to moderate amounts of aluminum may be added to certain other metals to improve their properties for special uses (*e.g.*, in the case of aluminum bronzes and most magnesium base alloys), or small to moderate amounts of other metals and silicon can be added to aluminum to form the so-called aluminum-base alloys, which because of their improved castability and higher strength, are better adapted than pure aluminum for most industrial applications.

Strictly speaking, ordinary commercial aluminum (99.0%–99.6% pure) should be considered as an alloy of pure aluminum with small amounts of iron and silicon. These definitely change the properties of the pure metal, markedly increasing its strength and decreasing its resistance to corrosion. For practical reasons, iron is generally considered as an impurity to be controlled, while silicon may be either an impurity or a major alloying ingredient. The other major alloying ingredients are copper, magnesium, manganese, zinc and nickel. Moderate amounts of tin, cadmium, lead, bismuth and cobalt may be used in special alloys; small amounts of chromium and titanium (usually less than 0.3%) and still smaller amounts of vanadium, zirconium, boron, beryllium and sodium are also sometimes used for special purposes, such as grain refinement (see ALLOYS).

Casting Alloys.—Pure aluminum, like most pure metals, can only be made into commercial castings with considerable difficulty. A pure molten metal freezes quite sharply at a definite temperature, and consequently it is difficult to arrange "risers" and other devices to feed molten metal into the casting during freezing, and make up for the solidification shrinkage. The alloys used for making castings, on the other hand, freeze through a considerable range of temperature, passing through a mushy stage in which the crystals of more or less pure aluminum are mixed with the still-liquid concentrated alloy. This permits the metal from the gates and risers to flow into the casting until the solidification (and therefore the shrinkage) is nearly complete and minimizes the formation of shrinkage cavities, which are objectionable in the finished castings. One of the advantages of the presence of a considerable percentage (5%–20%) of silicon in aluminum-base casting alloys is that silicon actually expands on freezing or crystallizing out of molten aluminum, and consequently tends to counteract the solidification shrinkage of the aluminum itself.

In the early days of the industry, up to about the outbreak of World War I, the alloys used in the United States were of the aluminum-copper type, while those used in England and in Europe were largely of the aluminum-zinc type, but often contained some copper. Shortly after the war, the aluminum-silicon alloys were introduced and became quite popular. The 12% silicon alloy (containing a small amount of sodium to "modify" the silicon)

largely displaced the aluminum-zinc alloy in England and Europe, while a 5% silicon alloy became popular in the United States for architectural and other castings, where good casting properties and high resistance to corrosion were important and high strength was not required. Alloys containing about 10% copper were used quite largely throughout the world after World War I, to make pistons for internal combustion engines, being generally cast for this purpose in iron molds (so-called permanent molds). Most of the aluminum alloy castings made in the United States up to the time of World War II continued to be made of alloys containing 7%–10% copper, although heat treated alloys containing about 4.5% copper or 10% magnesium were extensively employed where higher strength and ductility were required.

The heat treatment of castings requires a relatively long heating (6–24 hr.) at temperatures of 700°–1,000° F.—the exact temperature and time depending on the alloy composition and type of casting (sand or permanent mold). This is followed by "quenching" the casting in hot or cold water or oil, with subsequent aging at either room temperature or a temperature somewhat above the boiling point of water. The purpose of the "solution heat treatment" at 700°–1,000° F. is to put into "solid solution" as much as possible of the alloying elements, particularly copper, magnesium and zinc.

The reason for the long time of heat treatment is inherent in the structure of the castings. When a casting is made from an aluminum-base alloy containing copper, for example, the crystals which form first during the freezing process are nearly pure aluminum. Most of the copper remains in the liquid phase, and as the crystals grow the concentration of the copper in the liquid increases, although small amounts of it are deposited in the outer layers of the crystal. Since increasing the proportion of copper in aluminum lowers its freezing point, this process continues as the casting cools, until the temperature is reached at which the eutectic (lowest melting mixture) of aluminum and copper (containing 33% copper) freezes. Meantime: however, the crystals have grown until they almost touch one another, so that when the eutectic freezes it fills the small intergranular spaces and acts as a cement between the crystals. Aluminum can hold approximately 4.3% of copper in solid solution at the heat treating temperature (about 950° F.) but only a small fraction of this is actually in solid solution "as cast"; the rest being in the intergranular eutectic. In order to obtain a nearly saturated solid solution in the aluminum, it is necessary to hold the casting at high temperatures long enough for the copper to diffuse from the grain boundaries and distribute itself throughout the grains or crystals. Naturally, the larger the grains the longer this takes. Consequently, fine-grained castings (such as those cast in permanent molds) require a shorter heat treating time than coarse-grained castings, and wrought material (where the eutectic has been broken up and mechanically dispersed) a much shorter time. (See also HEAT TREATMENT.)

If the article is now suddenly cooled or quenched to room temperature, we have a supersaturated solid solution, since the solid solubility of copper in aluminum at room temperature is about 0.25%. Unless some accelerating metal, such as magnesium, is present, this solid supersaturated solution only changes and precipitates slowly through a long period of storage at room temperature. However, if the temperature is raised to the boiling point of water or higher, the mobility of the atoms of copper in the alloy is sufficiently increased so they are able to get together in a few hours and apparently precipitate in the form of submicroscopic particles of the compound CuAl_2 . With longer heating and at higher temperatures, these particles may grow large enough to become visible under the microscope upon a polished and properly etched surface of the alloy. They are found to be arranged in quite definite patterns along certain planes in the individual crystals. Apparently the effect of these minute particles of hard constituent is to "key" these slip planes, just as a stack of sheets of paper would be keyed against a sidewise thrust by particles of fine sand between each sheet and the next. The precipitation process thus increases the tensile strength and yield strength of the alloy but decreases its ductility. In the

presence of 0.5% magnesium, this precipitation occurs spontaneously in a few days at room temperature. Such precipitation at room temperature is spoken of as "natural aging," while precipitation induced by heating at elevated temperatures is spoken of as "artificial aging."

In the binary aluminum-magnesium alloys the solid solubility of magnesium at the heat treating temperature and at lower temperatures is considerably greater than that of copper, but the phenomena of heat treating, quenching and aging are similar. The solubility of silicon varies little with temperature, so that a solution heat treatment of a binary aluminum-silicon alloy has little effect on its properties. However, if magnesium is present, a magnesium silicide (Mg_2Si) is formed which has an appreciable solid solubility at heat treating temperature, and precipitates by natural aging after quenching. A heat treatable casting alloy of this type may contain about 5% silicon, 0.5% magnesium and 1–1.5% copper. Its tensile properties are lower than those of the heat treated copper or magnesium alloys, but it has much better casting properties, and is used for difficult castings.

The physical properties of castings vary greatly, depending not only upon the composition but also on the casting conditions. Thin sections generally show a somewhat higher tensile strength in pounds per square inch than do thick sections. Heat treated alloys generally show higher strength and ductility than those not heat treated. Typical strengths for ordinary sand cast alloys are in the range 19,000–30,000 lbs. per square inch (p.s.i.), while heat treated alloys may show 30,000–45,000 p.s.i. As a general rule, an alloy cast in permanent (metal) molds will show tensile strengths 5,000–10,000 p.s.i. higher than when sand cast.

Wrought Alloys.—Contrary to the situation in the casting field, the pure metal is the easiest form of aluminum to use in producing wrought articles. This is because of its softness and high ductility, which permit it to be rolled, forged, drawn, extruded, etc., with a maximum of ease and a minimum of scrap. Alloying elements cause the pure metal to become stronger, harder and less ductile, although these increases are not necessarily directly proportional to the amount of the added alloying ingredients. The higher strength naturally imposes a greater burden upon the fabricating machinery, and the lower ductility increases the tendency of the metal to crack or tear when worked severely.

The first step in the production of wrought articles is the casting of the ingot which is to be worked. Because of the tendency of pure aluminum to crystallize out first and leave the liquid portion enriched in the alloying ingredients (as explained above) the tendency of some of the alloying metals to segregate into certain areas during the freezing of the ingot is increasingly troublesome as the amounts of alloying ingredients increase. Rather elaborate special mechanical arrangements are therefore required to produce satisfactory ingots of such alloys. The basic principle of such ingot production is to chill the metal vigorously and cause it to freeze rapidly, preferably from the bottom up, so that the primary grains may be as small as possible and the distribution of the eutectic (which solidifies last) may be as uniform as possible throughout the whole ingot.

As indicated, commercial aluminum may be considered to be an alloy of pure aluminum with small amounts of iron plus silicon and traces of other elements, particularly copper and manganese. As the simplest of the aluminum alloys, it stands next to pure aluminum in ease of working. Ordinary commercial "pure aluminum" sheet contains 99.0%–99.4% aluminum. Foil is generally made of somewhat higher purity material, ranging up to 99.99% for foil used in electrolytic condensers. Ordinary pure aluminum tubing has about the same composition as sheet aluminum, but the so-called "collapsible tubes," made as containers for tooth paste, shaving cream, etc., are usually made of 99.5%–99.8% aluminum to reduce their stiffness. Wire for electrical conductors is usually 99.5%–99.7% aluminum. With this purity of metal, the conductivity is 60%–62% of the international annealed copper standard.

In the manufacture of wrought aluminum articles, maximum ductility and minimum strength are produced by annealing the cold worked article, usually by heating for some time at a tem-

perature of about 650° F.

The hardening and strengthening effect of even small amounts of alloying ingredients is clearly seen on comparing the typical properties of commercial annealed aluminum sheet with those of similar sheet made of 99.99% aluminum. The typical tensile strength of about 7,000 p.s.i. for 99.99% metal increases to 13,000 p.s.i. for commercial aluminum sheet, while the yield strength increases from 1,800 p.s.i. to 5,000 p.s.i. (The yield strength of aluminum is defined as the load in p.s.i. which produces a permanent elongation or "set" of 0.2% in 2 in.). At the same time the elongation in 2 in. is reduced from about 50% to 35%. Cold working (rolling, forging, drawing through dies, etc., at ordinary temperatures) hardens the metal, increasing both tensile and yield strength. This effect increases with the amount of cold work. The magnitude of the changes involved is seen from the fact that a typical tensile strength for hard rolled commercial aluminum sheet would be 24,000 p.s.i. with a corresponding yield strength of 21,000 p.s.i. and an elongation of only 5% in 2 in. Intermediate amounts of cold working produce intermediate tempers designated as quarter-, half-, and three-quarters hard. In general, annealed or quarter-hard sheet is chosen as the starting point for such operations as the production of cooking utensils by drawing or spinning, and the production of other drawn articles. Aluminum electrical conductors, on the other hand, are practically always delivered in the full-hard condition, because high strength is desired.

Next to commercial aluminum, the simplest wrought aluminum alloy is the one made by adding about 1.25% of manganese to commercially pure aluminum. This alloy has been widely employed under various designations, both in Europe and in the United States, for uses such as the manufacture of cooking utensils, where a somewhat higher strength than that of commercial aluminum is desired. It is slightly more difficult to work (draw, spin, etc.) than commercial aluminum, as would be expected from its higher strength.

Another group of relatively simple aluminum-base alloys includes those in which magnesium (2%–9%) is added to commercial aluminum, with or without small amounts of chromium, manganese or zinc. The most common type contains about 2.5%–3.5% magnesium and either about 0.5% manganese or 0.2% chromium. It has a considerably higher strength in the annealed and cold worked conditions than the manganese alloy, together with excellent resistance to sea water corrosion. An alloy containing 2.5% magnesium and 0.25% chromium would have typical tensile and yield strengths in the annealed condition of 29,000 and 12,000 p.s.i., and in the hard rolled condition of 41,000 and 36,000 p.s.i., with elongations of 25% and 7% respectively. With 5.2% magnesium and 0.1% each of manganese and chromium, these figures become 42,000 and 20,000 p.s.i. respectively, in the annealed condition, and 58,000 and 48,000 p.s.i. in the hard worked condition. Somewhat higher physical properties may be obtained by further increasing the magnesium and manganese contents, at the risk of producing alloys which may be subject to a marked acceleration of their rate of corrosion under the influence of stresses, particularly in the hard worked condition.

The heat treated strong alloys of aluminum form an important and characteristic group. Their importance may be seen from the fact that after 1938 substantially all the structural parts of military and larger civilian airplanes were made of them. The earliest and most important group of these is popularly known as duralumin (*g.v.*) and contains 4%–5% copper, 0.6%–1.2% magnesium and 0.6%–1.2% manganese. Their heat treatment has been discussed above, under casting alloys.

The important copper-free heat treatable alloys containing magnesium silicide (Mg_2Si) with a slight excess of silicon were first developed and commercially exploited in the United States in the early 1920s. Their somewhat inferior strength, compared with the duralumin type alloy, was offset by greater workability, both hot and cold, and consequently lower fabricating cost. The use of these alloys gradually spread to other lands, where they were given distinctive local designations.

Great difficulty was found in the early days in producing satisfactory forgings of the duralumin type alloys, because of their high strength and tendency to crack under the hammer. Along with the magnesium silicide type alloys, therefore, there was developed and commercialized in the United States a special forging alloy which differed from duralumin in omitting the magnesium. This facilitated fabrication, and the resulting forgings, after solution heat treatment and quenching, could be artificially aged to substantially the properties of duralumin. This made it practical to produce commercially aluminum propellers for the multitude of aircraft which were needed in World War II, and most of the metal propellers used before and during this war were forged out of this alloy.

After the obstacles to the fabrication of the standard duralumin had been overcome, intensive research and development work in both Germany and the United States brought forth a stronger variety of this alloy in which the copper and magnesium were both increased appreciably, and yet the composition was so adjusted that it was still possible to fabricate it commercially into sheet and other forms. This variety (first commercialized in the United States and known throughout the English-speaking world as 24S or 2024) had, roughly, 10% higher tensile and yield strengths than its predecessor.

A further increase in physical properties was accomplished near the end of World War II, by the practical introduction of aluminum base alloys in which the magnesium-zinc compound $MgZn_2$ was the principal hardening agent. These alloys had been originally developed and patented in Germany in the early 1920s, but their practical use had been prevented because of their susceptibility to stress corrosion. After many years of work, the modifying effects of copper and small amounts of chromium, vanadium and other elements on this sensitiveness to stress corrosion were worked out and commercially stable alloys developed. The alloy of this type commercialized in the United States in 1944 contained about 5.75% zinc, 2.5% magnesium, 1.6% copper and a little chromium. Heat treated extrusions of this alloy showed a typical strength of 88,000 p.s.i. and a yield strength of 80,000 p.s.i., with an elongation of 10% in 2 in. It was also used in what is known as the "alclad" sheet form, where its tensile properties were somewhat reduced by the presence of a thin layer of a weaker alloy on each surface of the sheet. Even then, in the heat treated state the tensile strength was typically 76,000 p.s.i. and yield strength 66,000 p.s.i., with 11% elongation.

The problem of protecting alloys of the duralumin type from corrosion is not serious when only relatively thick pieces are involved, but when the aircraft industry began to require large quantities of very thin sheet (0.01–0.02 in. thick) it became apparent that even slight superficial corrosion might be serious and must be prevented. The advantage of protecting the surfaces of such sheet with a thin integral coating of pure aluminum (which not only mechanically protected the surface from corrosion, but also electrolytically protected the cut edges, just as zinc does in the case of galvanized iron) was first demonstrated and a practical method for producing such sheet worked out in 1926, in the United States. The production and use of such alclad sheet spread throughout the aluminum-producing countries of the world during the next ten years, and the use of such sheet for wing covering and other purposes on airplanes became substantially standard for civilian planes and most military planes by the beginning of World War II. Pure aluminum is satisfactory as a cladding layer for alloys of the duralumin type, but in some countries (and for other types of alloys) alloys containing small amounts of magnesium silicide or zinc, with or without manganese, are preferred.

Standard specifications for the various types of wrought and cast aluminum alloys have been developed and published by official and semiofficial bodies in the United States, England, Germany, France and Italy, and should be referred to in connection with the literature of the producers for specific information as to alloys available in the different countries.

Other Uses.—High thermal and electrical conductivity, together with light weight and excellent resistance to corrosion, were

the basis of most of the early tonnage uses of aluminum, as in the field of cooking utensils and electrical conductors. In cooking utensils, high thermal conductivity of the metal is especially important in conducting the heat laterally and spreading it uniformly over the bottom of the utensil which is in contact with the flame or other source of heat, thus avoiding local hot spots which might cause the food to burn.

Although considerably weaker than hard-drawn copper conductors, pure aluminum wire was made to compete economically for transmitting electric power at high voltages over long distances by stranding it about a strong galvanized steel wire core to make "aluminum cable steel reinforced." The use of aluminum bar, cable and wire for secondary electrical distribution systems employing moderate voltages, and for motor, generator and transformer windings, became important about 1950.

With the development of stronger and better cast and wrought alloys in the period between World War I and World War II, aluminum became increasingly important as a structural material, particularly in the transportation industry. The original and most important early use of the wrought alloys of the duralumin type was in the framework of the Zeppelin airships which were used by the Germans in World War I. Aluminum castings were used in airplane engines in that war, and the Germans made a beginning in the use of duralumin type alloys in the structural parts of the planes themselves. In the period between World War I and World War II, wood (which had been the principal structural material for planes prior to that time) was almost completely replaced by metal (chiefly strong aluminum alloys of the duralumin type) in the form of sheet, extrusions and tubing. At the same time increased experience and the reduction in cost of producing and fabricating such alloys resulted in their rapid introduction in many other industrial fields where strength was required but light weight was advantageous. Buses and trucks used for long distance hauling were increasingly provided with aluminum bodies, crankcases and other parts. Aluminum tank trucks and trailers for hauling gasoline and milk were found to be economically advantageous, and railway tank cars were constructed of aluminum for the shipment of hydrogen peroxide, high strength (95 + %) nitric acid, organic solvents and other special materials. Deluxe high speed trains were built of aluminum alloys, and considerable aluminum was used in the construction of passenger automobiles.

The light weight, attractive appearance and resistance to atmospheric influences displayed by aluminum accounted for its introduction and popularity in the architectural industry, beginning about 1926. Aluminum spandrels, windows, doors, ornamental railings and grillwork, roofing, store fronts and miscellaneous hardware became increasingly popular both before and after World War II. Exterior walls of aluminum sheet, backed with light concrete, fashioned in attractive patterns, either anodically oxidized (and often coloured) or enameled, became popular for large buildings about 1954. By 1960 the building and construction industry had become the largest consumer of aluminum.

Because of its resistance to many rather corrosive chemicals, and the colourless and nontoxic character of its corrosion products, aluminum has been extensively used in the chemical and allied industries for tanks, piping, reaction vessels and miscellaneous equipment. Its use is particularly important in the synthetic acetic and nitric acid industries and in the manufacture of formaldehyde, hydrogen peroxide and various organic chemicals. For similar reasons, it has been widely used in the brewing industry for brewing kettles, storage tanks, fermenters and other equipment, and for beer barrels. The use of light aluminum drums was an important and successful application during World War II for the shipment of aviation gasoline by air from India to bases in China.

In this war, the use of aluminum for military and naval purposes other than aviation was limited as strictly as possible because the tremendous demands of the aircraft industry taxed the producing and fabricating capacity. It was, however, extensively used for mess kits, canteens and other articles carried by the men, and for various parts of the superstructure and furniture of naval

vessels. Similar uses in merchant vessels were extensive after the war.

An aluminum powder, used as a pigment for paint and ink, is produced by a stamping or grinding operation. It has the form of minute thin flakes, coated with a little stearic acid which makes the flakes "leaf" or come to the surface of the paint coat. This phenomenon and the complete opacity of the metal flakes protect the dried and hardened vehicle in the paint layer from deterioration caused by sunlight, air and rain, giving the paint a long life, even in the tropics, and a good reflecting power for radiant heat from the sun. A similar powder, compacted into ingots and fabricated by extrusion or rolling, gives a product (called SAP or APMP) which retains its strength exceptionally well, for aluminum, at elevated temperatures. Its commercial use began about 1955.

Because of its higher strength and lower cost, aluminum foil largely replaced tin foil as a wrapping material for chocolate bars and other candies, cheese and other foodstuffs. Laminated with thermoplastic resins, it became widely used during World War II in the manufacture of small "heat sealed" packages for foodstuffs, medicines, etc. Large tonnages of aluminum foil are also used for electrical condensers in radio and radar equipment, and small strips of foil were scattered from aeroplanes to confuse enemy radar. Aluminum foil and thin aluminum sheet have been used to a large extent in the manufacture of closures for milk bottles and other bottles containing foods and drinks.

Aluminum castings have been used for a great variety of applications, the largest being probably in connection with internal combustion engines (pistons, crankcases, cylinder heads, etc.) and domestic appliances such as washing machines and vacuum cleaners. They are made by techniques similar to those employed with other nonferrous metals.

Extrusions are made by forcing the solid metal (hot or cold) through a suitable die under heavy pressure. Collapsible tubes for toothpaste and the like are made by "impact extrusion" in which a blank of cold metal placed in a suitable die is struck a sudden blow by a plunger in a press. The diameter of the plunger is just a little less than the diameter of the hole in the die, so that the metal is forced back up as a thin tube between the plunger and the die, while a part of the metal remains in the die to form the head of the tube. Most extrusions are, however, made by using hot ingots (700°–950° F.) 6–18 in. in diameter and of suitable length, placed in a hydraulic "extrusion press." They are then subjected to high pressures and forced through dies, from which they emerge in the desired form as rods, structural shapes, heavy walled tube "blooms," special moldings for window frames and other construction, etc. These extrusions may be of pure aluminum or of any of the aluminum alloys. Most of the extrusions used in the aircraft industry are made of high strength aluminum alloys and heat treated. Tube "blooms" are reduced to tubing by cold drawing.

Forgings are made with air or steam hammers or suitable forging presses, from "forging stock," which is usually a rod or bar of high strength aluminum alloy. Tremendous numbers of such forgings have been used in aircraft, several hundred being used on each large plane. The manufacturing technique resembles that employed in forging steel articles of similar size.

Joining Aluminum.— In building aluminum structures such as buses, cars, aircraft and the like, and in many simpler articles, it is necessary to join together various pieces of aluminum, with or without pieces of other metal. As in steel structures, riveting may be employed. Untold millions of small, strong aluminum alloy rivets were used in the construction of aircraft in World War I. During that war, however, electric spot welding and seam welding made marked progress and were increasingly used, particularly with alclad sheet. Torch welding, with a suitable welding flux, has been extensively used since before World War I for joining articles of pure aluminum or nonheat treated alloys, and was supplemented just before World War II by arc welding, with either metallic or carbon electrodes. Later, argon or helium arc welding became common practice. Aluminum may

also be soldered, but the joint should usually be protected against moisture.

While many improvements have been made in solders, the demand for this type of joint has largely been met by the brazing process, in which the metal used for uniting the two aluminum surfaces is an aluminum base alloy (generally containing silicon) melting at a convenient interval below the melting point of the articles to be joined. By the use of a suitable flux, articles may thus be joined by the use of a torch or by passing them through a furnace at a controlled temperature. More intricate assemblies (such as an intercooler for an airplane) may be brazed by immersing the article for a few minutes in a bath of molten flux maintained at the proper temperature. Brazing is often facilitated by using sheet metal having a thin layer of brazing alloy on one or both sides, similar to the protective layer in the alclad strong alloy sheet. Brazing became of commercial importance at about the beginning of World War II. Braze joints are in general as resistant to corrosion as the rest of the article. Inserts of copper, brass or iron may be united with aluminum by the brazing process.

PROPERTIES

Physical.— Aluminum is a silvery ductile metal which is one of the lightest of those used structurally, being only about one-third as heavy as an equal volume of iron, brass or copper. The table shows many of its physical properties. It crystallizes in the cubic system (face centred cubic lattice) and when it is deformed by working (rolling, forging, drawing, etc.) slip within the crystals occurs predominantly on the octahedral planes. Upon melting, the solid metal expands about 7% in volume, the solidification shrinkage being 6.6% of the liquid volume.

Physical Properties of Aluminum

Density (g./c.c.) at 20° C. (68° F.)	2.70
Melting point (° C.)	660.2
Melting point (° F.)	1,220.4
Boiling point (° C.)	2,477 ± 50
Boiling point (° F.)	4,491 ± 90
Specific heat at 100° C., cal./g.	0.2241
Latent heat of fusion cal./g.	96.4
Heat of combustion (2Al+3O=Al ₂ O ₃) kg. cal.	400.0
Heat of vaporization at b.p., B.Th.U. per pound.	4,670
Thermal expansivity 20–100° C., per degree	23.86 × 10 ⁻⁶
Thermal expansivity 20–200° C., per degree	24.58 × 10 ⁻⁶
Thermal expansivity 20–300° C., per degree	25.45 × 10 ⁻⁶
Thermal expansivity 20–400° C., per degree	26.49 × 10 ⁻⁶
Thermal expansivity 20–500° C., per degree	27.68 × 10 ⁻⁶
Thermal expansivity 20–600° C., per degree	28.6 × 10 ⁻⁶
Electrical resistivity (vol.) at 20° C., microhm-cm.	2.6548
Electrical conductivity (vol.) at 20° C., percent of international annealed copper standard	64.94
Temperature coefficient of resistance at 20° C.	0.00429
Thermal conductivity—cal./sec./sq.cm./cm. ² C.	0.5
Thermal emissivity at 100° F., percent	3
Reflectivity for light, tungsten filament, percent	90
Reflectivity for radiation at 2,500 Å.U.	85
Reflectivity for radiation at 10,000 Å.U.	95
Magnetic susceptibility, c.g.s. units.	0.61 × 10 ⁻⁶
Atomic radius, Å.U.	1.431
Ionization potential, volts.	5.98, 18.8, 28.5
Oxidation-reduction potential (calc.), volts	1.67
Electron structure	1s ² , 2s ² , 2p ⁶ , 3s ² , 3p ¹
Radioactive isotopes (mass numbers)	24, 25, 26, 26*, 28, 29

The strength of aluminum depends upon its purity and the thermal and mechanical treatment to which it has been subjected. Pure aluminum (99.996%) is quite soft and weak in the cast or annealed condition, with a tensile strength of only about 7,000 p.s.i. By alloying and proper thermal and mechanical treatment, however, tensile strengths as high as 100,000 p.s.i. may be obtained. Silicon and most of the common metals (copper, iron, zinc, tin, manganese, magnesium) readily dissolve in molten aluminum, but sodium and potassium are almost completely insoluble and the solubility of titanium, vanadium, boron and chromium is low. Hydrogen is about the only gas which is appreciably soluble in molten aluminum: its solubility increases with temperature but becomes nearly zero when the metal freezes.

Chemical.— Ordinarily aluminum is trivalent, although there is evidence that it may be monovalent and possibly bivalent at elevated temperatures under some conditions. Its oxide, Al₂O₃, is amphoteric; *i.e.*, it may act as a base to form salts with acids, or as a weak acid to form salts with strong alkalis. Its heat

of formation is high (400,000 cal. per gram molecule) and aluminum is therefore able to reduce most metallic oxides, in the thermit process (*q.v.*). A freshly cut surface of metallic aluminum is immediately oxidized and covered with a thin, transparent coating of Al_2O_3 , about 0.00000025 in. thick, which protects it from further oxidation and reaction, except with substances which can dissolve the oxide. The surface of molten aluminum is also covered with a similar oxide coating which protects it from burning. However, finely divided metallic aluminum is rather easily inflammable and, when mixed with air and ignited, will produce a violent explosion. Protective coatings of aluminum oxide may be produced by anodic oxidation of aluminum in certain electrolytes such as dilute sulfuric or chromic acids. These coatings are adsorbent and may be impregnated with dyes or mineral pigments to produce pleasing finishes, or with salts of chromic acid to improve their protection against corrosion. Thinner, impervious coatings of Al_2O_3 , produced anodically in boric or phosphoric acid or their salts, are important in aluminum condensers and electrolytic rectifiers.

Aluminum is slowly attacked by most dilute acids, especially the mineral acids. Concentrated hydrochloric acid dissolves it rapidly, $2\text{Al} + 6\text{HCl} = 2\text{AlCl}_3 + 3\text{H}_2$. On the other hand, concentrated nitric acid (95%–100%) has so little effect on it that aluminum drums and tank cars are used for shipping this chemical. Strictly anhydrous organic acids often attack aluminum vigorously, but the presence of a few tenths of a percent of water will greatly retard this reaction. The rate of attack by dilute acids is largely reduced as the purity of the aluminum is increased, and is slow for metal with a purity more than 99.95%. Alkalies, on the other hand, attack it rather vigorously irrespective of its purity; sodium and potassium hydroxide dissolve it rapidly with the formation of the corresponding aluminates, $2\text{Al} + 2\text{OH}^- + 2\text{H}_2\text{O} = 2\text{AlO}_2^- + 3\text{H}_2$. Sodium carbonate solution attacks and corrodes it more slowly, and this reaction may be largely prevented by the addition of a suitable amount of sodium silicate. Lime also corrodes it. Distilled water at ordinary temperatures has almost no action on aluminum, but water containing dissolved salts (especially common salt) allowed to stand for a long time in contact with commercial aluminum, may gradually attack and corrode it to an extent depending upon both the kind and amount of salts present and upon the kind and amount of alloying elements or metallic impurities present in the aluminum. High purity aluminum and certain aluminum-magnesium alloys are, however, resistant to corrosion, even by sea water, for many years.

Because of its great affinity for oxygen, finely divided aluminum, if ignited, will burn in carbon monoxide or carbon dioxide with the formation of a mixture of aluminum oxide and carbide; it will also burn in nitrogen to form the nitride (AlN). The carbide (Al_4C_3) is substantially insoluble in molten aluminum, so that only a superficial film of it is formed when the molten metal stands in contact with carbon. It is easily formed by the electrothermal reduction of the oxide in the presence of an excess of carbon at temperatures above about 1,800° C. Aluminum combines vigorously with the halogens at slightly elevated temperatures but is inert to sulfur at temperatures up to red heat. Phosphorus does not react with aluminum at ordinary temperatures, and aluminum phosphide is substantially insoluble in molten or solid aluminum.

Most of the metals which are soluble in molten aluminum form compounds with it, which crystallize out when the metal freezes, and can be identified under the microscope on a polished surface, particularly after etching. Silicon alone forms no binary compound with aluminum, and crystallizes out as such upon cooling the binary aluminum-silicon alloy. It does, however, form ternary compounds with aluminum and iron or manganese, when they are present. The study and identification of these constituents and their behaviour in the aluminum alloys is an important part of the metallography of aluminum. In addition to the amount of alloying metal which combines with the aluminum to form the precipitated compounds, a certain amount remains in "solid solution" in the solid aluminum. The solid solubility of some of these

metals (copper, zinc, magnesium) may be considerable at elevated temperatures, but is markedly lower at room temperature.

Physiological.—Metallic aluminum and its oxide and hydroxide are completely nontoxic, and generally inert as far as living organisms are concerned. Thus, in contrast to copper and iron, the metal has no bactericidal effect. Animal experiments have shown that small amounts of aluminum dust inhaled with silica dust into the lungs prevent the development of the typical lesions of silicosis (*q.v.*) by coating the silica particles with a thin layer of aluminum hydroxide, which apparently makes them inert. Inhalation of small amounts of aluminum dust has also been reported to have a beneficial effect in allaying some of the symptoms of human silicosis. Colloidal aluminum hydroxide, administered as a nasal drip or by mouth, has been found to exert a marked healing effect in cases of stomach ulcer. Water soluble aluminum salts (such as the chloride and sulfate) are used in medicine and in cosmetics as astringents.

CHEMICAL COMPOUNDS

Aluminum Oxide and its Hydrates.—Aluminum oxide exists in several different crystallographic forms. The one which occurs in nature (corundum, *q.v.*) is designated as the alpha form, and is characterized by a high specific gravity (4.0), a high melting point (about 2,015° C. or 3,660° F.) and great insolubility. Its high hardness (hard enough to scratch glass) makes it one of the most useful of natural or artificial abrasives (*q.v.*). Commercially pure aluminum oxide is made by calcining the purified hydrate at temperatures about 2,000° F. and is chiefly used as a raw material for the production of the metal. Its principal impurities are soda (0.1%–0.6%), iron oxide and silica (usually less than 0.03% each). It is an important raw material for the manufacture of certain articles such as insulators and spark plugs, "Alundum" laboratory ware (tubes, crucibles, etc.) and pure fused alumina for certain types of abrasive wheels. Rubies and sapphires are crystalline, nearly pure varieties of alpha alumina, the colours being the result of small amounts of impurities. Synthetic rubies and sapphires are made on a commercial scale by fusing a mixture of high purity Al_2O_3 with traces of the necessary colouring agents, in an oxyhydrogen blowpipe flame (*see GEM: Synthetic Gems*). Most of the material thus produced is cut up into jewels for watches and other precision instruments.

When the alumina hydrates are heated to gradually increasing temperatures up to about 1,000° F., they are decomposed and lose most of their water. The aluminum oxide formed goes through a series of physical changes as the temperature increases, and some of the products are interesting and commercially important. At the lower temperatures, water is driven out without appreciable shrinkage of the granules; so that the result is a porous structure. The area exposed in the pores when the water has been driven out can be measured by physicochemical means, and may be as high as several hundred square metres per gram. This surface is extremely active and has the power of adsorbing water vapour and some other gaseous molecules upon it. The product (commercially known as activated alumina) is important in drying gases and some liquids, and as a catalyst carrier in certain reactions such as the production of toluene from the vapours of other hydrocarbons at high temperatures. The affinity of the alumina surface for water vapour is such that air may be dried by it as completely as with phosphorus pentoxide.

The hydrous forms of alumina (often called alumina hydrates) may contain either one (monohydrate) or three (trihydrate) molecules of water per molecule of Al_2O_3 . Each is known in two distinct modifications (alpha and beta). In both cases the alpha variety is the more common one. The alpha trihydrate (gibbsite or hydrargillite) is the principal constituent of the bauxites found in North and South America, and in the East Indies. The alpha monohydrate (boehmite) is the principal constituent of European bauxites. The beta monohydrate occurs in nature as the mineral diasore.

Alpha trihydrate is the variety sold commercially as hydrated alumina. It is the raw material out of which commercial alumina is prepared by calcination, and is produced by the Bayer process.

The first step in this process involves dissolving the alumina hydrate out of bauxite or laterite in superheated caustic soda (sodium hydroxide) solution under pressures of 60–200 p.s.i. The solution is then filtered from the residue (red mud) containing the impurities. The filtered solution (sodium aluminate) is cooled to a little above room temperature and becomes supersaturated with respect to alumina hydrate. Upon now agitating this solution with "seed" of the finely divided crystalline trihydrate, the excess (about two-thirds of the total) of the alumina crystallizes out. The solution, after some evaporation, is used to extract more alumina from a new charge of bauxite. The precipitated hydrate is mashed and dried, or else calcined if the oxide is to be the finished product. This trihydrate is a fine crystalline powder (specific gravity about 2.4), soluble only to the extent of less than one part per million in water but readily soluble in dilute mineral acids, sodium hydroxide or potassium hydroxide. Aside from the production of the various forms of alumina, its principal use is for the production of pure aluminum sulfate and alums (*q.v.*).

Beta alumina trihydrate may be made by neutralizing sodium aluminate solution with carbon dioxide under certain carefully controlled conditions. It is unstable, rather readily converted to the alpha monohydrate by heating in water.

The alpha monohydrate may be produced from the trihydrate by heating it cautiously in air or under pressure with water containing some sodium hydroxide. It is less easily dissolved in dilute acid and alkalis than the trihydrate; consequently monohydrate bauxites are not as suitable for the manufacture of alum, and require a higher temperature and a higher sodium hydroxide concentration than the trihydrate bauxites in the Bayer process.

Salts.—Various sulfates and double sulfates are the commonest of the aluminum salts. Alums (*q.v.*) are soluble double sulfates of aluminum with potassium, sodium or ammonium. Alunite (*q.v.*) is an insoluble basic alum. The normal aluminum sulfates are quite soluble in water, and are discussed under sulfuric acid (*q.v.*).

Aluminum chloride and aluminum nitrate are also soluble, and are discussed under the corresponding acids.

Edwards, *Aluminum Paint and Powder* (1936); Aluminum Company of America, *Structural Aluminum Handbook* (1945). For a discussion of the economics of the industry, see N. H. Engle, H. E. Gregory and R. Mossé, *Aluminum, an Industrial Marketing Appraisal* (1945).

Current statistics on world production and prices are summarized annually in the *Britannica Book of the Year*. (F. C. F.)

ALUMINUM BRONZE, the name given to copper-base alloys containing aluminum as the main alloying constituent. They have strength comparable with mild steel, and good resistance to oxidation at high temperatures and to corrosion, particularly by dilute acids.

Alloys with up to about 8% aluminum have a simple homogeneous structure and can be cold-rolled into sheet or drawn into tubes. Such alloys, which may also contain small amounts of iron, nickel and manganese, are used in chemical plants, oil refineries, etc., for pressure vessels and heat exchangers.

Alloys containing more than 8% aluminum are capable of only limited cold working, although they can be readily hot-rolled, extruded or forged. Iron is an essential constituent and manganese is also usually added. The strongest and most corrosion-resistant alloy of the group contains nickel and has the nominal composition

80% copper, 10% aluminum, 5% nickel, 5% iron. Typical properties for forgings are: 0.1% proof stress, 25 tons per square inch; tensile strength, 45 tons per square inch; elongation, 15%. This alloy has good resistance to creep up to 250° C. (in lightly stressed parts it can be used at much higher temperatures) and to fatigue and corrosion-fatigue, and has been used for gas turbine compressor blades. The alloys containing about 10% aluminum have excellent casting characteristics, although special running systems must be used to avoid entrapment of the tenacious oxide film present on the molten metal. They are used for gravity die-casting small high-strength components such as gear selector forks as well as for sand casting. Many marine castings, including large ships' propellers, are made from an aluminum-nickel bronze.
