EDITORS' PREFACE

THE preface to the first edition of *Encyclopedia Britannica*, 1768, stated that utility is the "principal intention of every publication." The *Britannica's* progressive history since that date has been one of expansion and enlargement, and the problem has been to hold the developing amount of information to a convenient and usable form. Times change, fresh information demands inclusion, and supplementary volumes added to old ones offer no adequate solution of the problem of keeping the reader abreast of the times; nor, indeed, do completely reset new editions solve the problem. Such editions in the past have taken many years to make, and material in one volume was old before the next volume was made.

The matured plan of continuous revision of the *Britannica* obviates these editorial difficulties.

By 1771 the *Encyclopedia Britannica* consisted of three volumes containing 3,000,000 words. Today the *Britannica* comprises twenty-four volumes with 38,000,000 words and the annually issued *Book of the Year*.

Experience through the years indicates that much of the material in an encyclopaedia needs changing only at fairly long intervals. Other material requires more frequent revision, some every year, some every two years, some every three years and so on. Under the *Britannica* plan of continuous revision, all the material in the set is scheduled in classifications for more extensive annual revisions than have ever before been possible in the history of encyclopaedias. The result is that, within the obvious limitations set by the structure and manufacture of an encyclopaedia of 38,000,000 words, the *Britannica* is never old. The second unit of the plan is the annual *Book of the Year*, which keeps the information of the *Britannica* owner current. It is itself an encyclopaedia of more than 1,000,000 words covering the significant events of each succeeding year.

The present *Encyclopædia Britannica* is a modern informational instrument in a changing and complex world. It is not the work of a few authors or of the authors of any one country. It is the result of the cordial co-operation of more than 9,000 authorities from most of the countries of the world. Without their help no good work of reference, covering information on every essential subject, could be made.

The reader can contribute much toward the economical use of the great quantity of material in this reference set by first turning to the Index volume when in search of information. The Index is the direct guide to the many thousands of topics in the more than 38,000 entries, and the way to use it is described on pages v–viii in the Index volume.

Turn to the next page in order to understand the rules for the alphabetization of articles in the set.

HARRY S. ASHMORE, *Editor in Chief*
JOHN V. DODGE, *Executive Editor*
HOWARD E. KASCH, *Managing Editor*

HOW ENCYCLOPÆDIA BRITANNICA'S ARTICLES ARE ARRANGED— ALPHABETICALLY AND SYSTEMATICALLY

IN ORDER to make each of the 38,000 articles in the *Encyclopædia Britannica* easily accessible to the reader, the articles have all been placed in strictly alphabetical order throughout the set, regardless of the specialized fields to which they apply. An alphabetical listing on so large a scale requires clear and consistent methods for dealing with various details. The rules adopted by the editors of the *Encyclopædia Britannica* were designed on the basis of long experience for maximum usefulness to the reader, and a few minutes spent in becoming acquainted with them will amply repay every user of the set.

First, it is important to note that titles of articles are in strict alphabetical order regardless of whether the title contains one, two or more words. Thus ARTILLERY precedes ART INSTITUTE OF CHICAGO. Separate words are alphabetized as if they were one word and this system continues up to the punctuation mark. Words in parentheses are not generally considered as part of the heading for purposes of alphabetization. Names beginning with Mc or M', St. or SS. are alphabetized as though they were spelled out; *i.e.*, Mac, Saint or Saints.

The position of articles which have the same name is determined by the order: (1) persons; (2) places; and (3) things. When there are a number of biographical entries for persons bearing the same name, they are arranged in the order: saints, popes, emperors, kings, nobility in order of preference, persons other than the above bearing the one name only, and persons bearing the name as a surname. Thus JOHN, SAINT, THE APOSTLE, precedes JOHN I, Byzantine emperor; JOHN, duke of Burgundy, precedes JOHN OF ASIA, who in turn precedes JOHN, AUGUSTUS EDWIN.

Popes of the same name are included in one article. Within the article, the popes are listed in order by number. Kings of the same name are alphabetized by the name of their realms, and numbered kings of the same name and realm are arranged by number. Thus JOHN II, king of Aragon, precedes JOHN I, king of Castile. Others whose names include numbers, such as emperors, are also arranged by number.

Territorial designations and sobriquets (ROBERT OF GLOUCESTER; HOLBEIN, HANS, THE YOUNGER)

are not considered in alphabetizing unless there are two or more entries with titles which are otherwise the same. These entries are then alphabetized by the first principal word of the subsidiary designation, the "of" or "the" being disregarded. Thus JOHN, SAINT, THE APOSTLE, precedes JOHN, SAINT, OF THE CROSS; JOHN OF ASIA precedes JOHN OF SALISBURY.

Persons with the same family name are arranged in relation to each other by alphabetizing the given name. Persons with the same family and given name are arranged by date of birth, the earliest coming first. Titles such as "Sir" or "Dame" are not considered in alphabetizing. Unused portions of given names, when they precede the name that is used, are enclosed in parentheses and are also disregarded in alphabetizing. CHAMBERLAIN, SIR (JOSEPH) AUSTEN thus precedes CHAMBERLAIN, (ARTHUR) NEVILLE.

Names with connectives such as "de," "von," etc., are generally alphabetized under the main part of the name—GOGH, VINCENT WILLEM VAN—except where the European form has been anglicized, as in DE QUINCEY and DU PONT.

Places of the same name are arranged in the order: (1) countries; (2) subordinate divisions, such as *département*, province or state; (3) cities; and (4) geographic features, such as islands, mountains, lakes and rivers. Cities of the same name are alphabetized, in relation to each other, by the names of their countries: ALBANY in Australia precedes ALBANY in New York, U.S. Cities of the same name and country are arranged by alphabetizing the territorial unit next below the country: ALBANY, Georgia, U.S., precedes ALBANY, New York, U.S.

In addition to the main articles, there are thousands of cross references throughout the *Britannica*. These appear as boldface entries in alphabetical position in the text (*e.g.*, DISRAELI, BENJAMIN: see BEACONSFIELD, BENJAMIN DISRAELI, EARL OF); the "see" and "see also" references to other titles in the body or at the end of articles; and the parenthetical *q.v.* (*quod vide* "which see") references, which indicate that separate articles under the titles cited will be found in the *Britannica*.

It is important to read also the introductory sections of the *Index* volume, which explain how the articles are indexed alphabetically by subject matter.

A NEW SURVEY OF UNIVERSAL KNOWLEDGE

ENCYCLOPÆDIA BRITANNICA

Volume

1

A TO ANTARAH

A THIS letter has stood at the head of the alphabet (*q.v.*) during the whole of the period through which it can be traced historically. The name of the letter in the Phœnician period resembled the Hebrew name *aleph* meaning "ox"; the form is thought to derive from an early symbol resembling the head of an ox. The letter was taken over by the Greeks in the form of *alpha*. In the Phœnician alphabet the letter stood for a species of breathing, since vowels were not represented in the Semitic alphabets.

Throughout its history variations have occurred in the form of the letter. The Phœnician form was . In the Lydian alphabet of the 5th century B.C. it appeared as , in the Carian alphabet *A'* or *Δ*. In the early Greek alphabet from the island of Thera, which may possibly be dated as far back as the 8th century B.C., its form was *A* or *Α*. In the Greek alphabet of classical times its form was usually *Δ*. Early Italic and Latin forms were *Δ* and *Α*. As early as the middle of the 2nd century A.D. *λ* is found as a form of *A*, and this is the ancestor of the present minuscule printed *a* by way of uncial *λ* (4th century) and *λ* (8th century), uncial writing being the name given to the round hand which in late Roman times superseded the square capitals that had been suitable for inscription in stone. Under the influence of the uncial hand this form was adopted into Carolingian minuscules. The rounded minuscule *a* derives from Latin cursive, in which in the

5th century A.D. appeared the astonishing form . This was a hastily written majuscule *A* distorted by its apex having fallen to the left. In the 6th century the cursive form was , and from this in the 7th century developed the form  from which the rounded form of the Irish and early English hands grew. The rounded capital *a* that sometimes appeared in handwriting was the minuscule letter written large.

The sound for which the letter consistently stood in Greek and Latin was the open low back vowel, sometimes known in modern English as continental *a*. There are of course countless slight variations in the method of pronouncing this sound. In English the sound has undergone far-reaching changes during and since the Middle English period. These are due to *fronting*, that is to say, pronouncing the sound more toward the front of the mouth, or to *rounding*, slightly rounding the lips, which has the effect of causing the sound to be pronounced higher in the mouth. At the present time the letter represents six principal vowel sounds: (1) its original value, the low back vowel, as in *father*; (2) an intermediate vowel, as in *man*; (3) a closer vowel, further fronted, as in *hare*, occurring only before the liquid *r*; (4) a diphthong (*ei*) as in *take*, *spade*. This is the sound that the letter now normally represents when the vowel is long.

(3) Represents a stage in the development of the sound on its way from (1) to (4) which was arrested at this point when the

word was followed by *r*. A similar fronting of this sound took place in the Ionic-Attic dialects of Greek, where sounds derived from the *a*-sound and represented in other dialects by *a* are represented by *η*.

The two remaining developments of the sound are due to rounding: (5) the vowel of water and (6) the vowel of was. This development is due to the influence of the preceding bilabial spirant *w*.
(B. F. C. A.; J. W. P.)

In music, A is the name of the first note of the musical alphabet and constitutes the 6th degree of the scale of C. In respect of pitch A is equal to 440 vibrations per second, this being the standard pitch.

A is the note always given to orchestral players, usually by the oboe, for tuning purposes.

See PITCH, MUSICAL.

AA, the name of many small European rivers. The word is derived from the Old High German *aha*, cognate to the Latin *aqua*, "water" (cf. Ger. *-ach*; Scand. *á, aa*, pronounced *ō*). Among the streams of this name are: two rivers in western U.S.S.R., entering the Gulf of Riga with Riga lying between their mouths; a river in northern France flowing through St. Omer and Gravelines; and a river of Switzerland, in the cantons of Lucerne and Xargau, which carries the waters of the "finger" lakes of Baldegger and Hallwiler into the Aar (Aare). In Germany there are the Westphalian Aa, joining the Werre at Herford, the Munster Aa, a tributary of the Ems, and others.
(A. F. A. M.)

AABENRAA-SONDERBORG (officially *ÅBENRÅ-SØNDERBORG*) is a county district of Denmark comprising the separate county council districts (amtsraadskredse) of Aabenraa and Sønderborg.

Aabenraa has an area of 305 sq.mi. and a population (1955) of 48,676 and its boundaries extend in an arc from Genner fiord to Flensborg fiord. It is centred on the town of Aabenraa (pop. [1955] 13,793), a port at the head of Aabenraa fiord (an arm of the Little Belt) which has a good harbour and a large import trade. Graasten (pop. [1955] 2,629) is another centre.

The county of Sønderborg embraces the island of Als and the adjacent Sundeved peninsula of southeast Jutland; area 170 sq.mi.; pop. (1955) 49,604. Hummocky moraine prevails in the east: and the fertile clay loams support wheat, barley, oats, roots, dairy cattle and pigs. In the west, poorer soils cover the outwash sands and gravels. The principal town is Sønderborg (pop. [1955] 18,418), a port and seaside resort on the southwest coast of Als Island, connected with the mainland by a double-bascule bridge (built 1925–30). Sønderborg castle, dating from medieval times, houses a museum. Textiles, machinery, margarine and beer are manufactured. The town has existed since the mid-13th century and was burned down in 1864 during the assault by the Prussians on the Diippler trenches. With the whole district it then passed to Germany, but was restored to Denmark by the plebiscite of 1920. Dybbøl Mill, the scene of the heroic Danish resistance in 1864, is now a symbol of national unity.
(H. A. T.)

AACHEN (Fr. *AIX-LA-CHAPELLE*; Dutch *AKEN*), an ancient city and spa of Germany, Land of North Rhine-Westphalia, Federal Republic of Germany, is situated under the northern slopes of the Ardennes, 70 km. (43.5 mi.) S.W. of Cologne by road. Pop. (1950) 129,811. Its municipal boundaries coincide on the west with the frontiers of Belgium and the Netherlands. The hot sulfur springs have been celebrated for centuries. In appearance it is a prosperous, modern commercial town but it is full of medieval associations. The outer town is mainly new, while the ramparts of the old inner town are now promenades, with two ancient gates. Ponttor and Marschiertor, remaining. The conspicuous cluster of buildings in the centre of the city includes the cathedral and the Rathaus (town hall), a Gothic structure (1353–70) built on the ruins of Charlemagne's palace, which contains the magnificent coronation hall of the emperors (143 ft. by 61 ft.) where 32 Holy Roman emperors and kings have been crowned. The two original towers, Granusturm and Glockenturm, were all but destroyed by fire in 1883; their restoration was completed in 1902. Near the Rathaus is the Grashauss, restored in 1889 to contain the municipal archives. The cathedral has two distinct styles:

the Octagon is Carolingian Romanesque and the choir is Gothic. The Octagon, begun about 796, was modeled on San Vitale at Ravenna and consecrated by Pope Leo III in 805. It is the finest extant building in that style. It suffered damage at the hands of the Normans in 881 and was later restored on the original lines. It is surrounded on the first story by a gallery (the Hochmünster) with antique marble and granite columns, of various sizes, brought from Rome, Ravenna and Trier. The columns were removed by Napoleon to Paris, but mere in part returned after 1815. The mosaic representing Christ surrounded by "the four-and-twenty elders," which originally lined the cupola, was executed in 1881 from a 17th-century copy of the ancient originals. The bronze west doors date from 804. Underneath the dome, tradition places the tomb of Charlemagne, said to have been opened by Otto III in 1000 and to have shown the emperor's body on a marble chair which was removed and long used for coronations. It is now in the gallery. The site of the tomb is marked by a stone slab, with the inscription *Carlo Magno*, and above it hangs the famous bronze chandelier presented by the emperor Frederick I (Barbarossa) in 1168. In the Hungarian chapel, to the southwest, is the rich cathedral treasury, with fine medieval work such as the 13th-century gold casket containing the relics of Charlemagne. The Gothic choir was added during the 14th and 15th centuries and contains the tomb of the emperor Otto III. The pulpit, a gift of emperor Henry II, dates from c. 1020. The cathedral possesses many relics, the more sacred of which are exhibited only once every seven years, when they attract large crowds.

The churches of St. Foillan (founded in the 12th century, but twice rebuilt, in the 15th and 17th centuries, and restored 1883–88) and St. Paul, with its beautiful stained-glass windows, are interesting. The Suermondt museum contains good pictures by early German, Dutch and Flemish masters. There are many fine streets, squares and public monuments. The fountain in the market square is surmounted by a statue of Charlemagne. In the principal square, Friedrich-Wilhelmplatz, is the Elisenbrunnen, with its colonnade and garden, the chief resort of visitors taking the baths and waters. Educational institutions include the Rheinisch-M'estphalische Technische Hochschule, a polytechnic founded in 1870.

Aachen is on the main line from Cologne to Brussels. Since the working of extensive coal fields in the district almost every branch of iron industry has been carried on. Cloth, glass, needles and pins are important products. The suburb of Burtscheid, incorporated with Xachen in 1897, has old established manufactures of cloth and needles and contains, among frequented thermal springs, the Schwertbad-Quelle (171° F.), the warmest spring in Germany.

History.—The ancient city and watering place of Aachen represents the Aquisgranum of the Romans, named after Apollo Granus, who was worshiped in connection with hot springs. As early as A.D. 765 King Pepin III had a palace there, in which it is probable that Charlemagne was born. The greatness of Aachen was attributable to the latter, who between 777 and 786 built a magnificent palace, raised the place to the rank of the second city of the empire, and made it for a while the centre of western culture and learning. From the coronation of Louis the Pious in 813 until that of Ferdinand I in 1531 the sacrificing of the German kings took place at Aachen. Late in the 12th century (1172–76) the city was surrounded with walls by order of the emperor Frederick I, to whom (in 1166) and to whose grandson Frederick II (in 1215) it owed its first important civic rights. In the 16th century Aachen began to decline. It lay too near the French frontier to be safe, and too remote from the centre of Germany to be convenient as a capital; and in 1562 the election and coronation of Maximilian II took place at Frankfurt am Main, a precedent followed till the extinction of the empire. Aachen was the scene of several important peace conferences, notably the treaty of 1668 that ended the War of Devolution, and the peace of 1748 ending the War of Austrian Succession. The city was occupied by French troops in 1794 and was annexed in 1801 by France, who held it until the congress of Vienna (1814–15), after which it was given to Prussia. The Aachen congress, sealed in 1818, regulated the affairs of Europe after the Napoleonic wars. In Nov. 1918, at the conclusion of World War I, Aachen was occupied for a period by Belgian

troops. During World War II it was bombed many times and was captured on Oct. 20, 1944, the first large city on German soil to fall to the Allies.

AANMES: see **AHMOSE**.

AAL (A'L, ACH or AICH), the Hindustani names for the *Morinda tinctoria* and *M. citrifolia*, plants extensively cultivated in India because of the reddish dyestuff which their roots contain. The name is also applied to the dye, but the common trade name is *suranji*. Its properties are a result of the presence of a glucoside known as morindin.

AALBORG (officially **ALBORG**), a seaport in northern Jutland, Den., and capital of the *amt* (county) of Aalborg, lies on the south side of Limfjord, with its suburbs of Hasseris, Norresundby and Sundby-Hvorup extending on both sides of the fiord. Pop. (1955) 83,210; greater Aalborg 91,997. Area 52 sq km. (20 sq.mi.). Founded in 1342, and one of the oldest towns in Denmark. Aalborg has many buildings of interest including the Holy Ghost monastery (1431), the cathedral of St. Botolph, Aalborg castle (1539) and several old merchant houses. There is a modern town hall and a theatre, as well as several schools and colleges, and six parks, fine zoological gardens and a racecourse. In the museum and art gallery some of the relics from the Viking village of Lindholm Hoje are preserved. Aalborg has an international airport with flights direct to Norway and Copenhagen. The port has considerable overseas trade and the town manufactures cement, tobacco, chemicals and spirits. It is also an important shipbuilding centre.

The county of Aalborg, bounded in the south by the Mariager fiord and in the north by the Geraa river, has an area of 1,125 sq.mi. Pop. (1955) 232,855. It has poor quality soil and there are two large areas of moorland. (P. E. JE.)

AALSMEER, a village in the province of North Holland, Neth., lies about 10 mi. S.W. of Amsterdam. Pop. (1957 est.) 13,861 (mun.). It is an important flower-growing centre with nearly 1,000 nurseries. The older part is on peaty soil at about sea level surrounded by polders with loamy soil, 9–15 ft. below sea level. The principal products are carnations (approximately 119,000,000 a year), cut roses (88,000,000), lilacs (9,000,000), freesias (45,000,000), chrysanthemums and potted plants such as cyclamens and begonias. About half the flowers are exported and there is a big trade in seeds and nursery plants. There are two flower auctions and an experimental station for floriculture. The Resteinder lake is popular for sailing. (JA. W.)

AALST (Fr. **ALOST**), an industrial town of Belgium in the province of East Flanders, lies on the Dender river where the undulating countryside of mid-Belgium levels out to the coastal plain. 26 km. (16 mi.) by road west-northwest of Brussels. Pop. (1955 est.) 43,537. The town hall, begun between 1200 and 1225, is the oldest in Belgium and contains a 43-bell carillon. The town archives include 12th-century manuscripts. The large, but unfinished, church of St. Martin has a transept containing remarkable furnishings, sculptures and a Rubens painting. Aalst is on the railway from Brussels to Ghent, and the E5 motorway from Brussels to Ostend skirts the town. The manufacture of textiles, from the linen thread to the finished cloth, and the making of clothing and textile machinery are the chief industries. Hops provide malt for flourishing breweries. The first printing shop in the Low Countries was established at Aalst by Thierry Martens (later a professor at the University of Louvain) in 1473. Marshal Turenne took the town after a four-day siege in 1667 during the War of Devolution that gave southern Flanders to France. During World War I the town was in German hands from Sept. 1914 until Nov. 1918. In World War II the Germans occupied Aalst from May 1940 until Sept. 1944. (R. M. AN.)

AALTO, ALVAR (1898–), Finnish architect, designer and planner, whose works have influenced modern design throughout the world, especially for their sensitive treatment of natural materials, was born in Kuortane, on Feb. 3, 1898, and studied at the Helsinki Institute of Technology. His sanatorium at Paimio (1923–33), the library at Viipuri (1927–33, destroyed) and other buildings helped introduce modern architecture into Finland and Scandinavia. Featuring native materials, brick and timber, as

well as concrete, his works range from private dwellings, like the Gullichsen house (1938–39), to the Sunila Cellulose Products factory (1937–39) and community buildings at Sanyatsala (1951–52). He built the Finnish pavilion at the New York World's fair (1939) and the Massachusetts Institute of Technology senior dormitory (1947–49). Aalto also designed influential standardized plywood furniture. He was ably assisted by his architect-wife Aino (1894–1949).

See Sigfried Giedion, *Space, Time and Architecture*, 3rd ed. (1954); Eduard and Claudia Neuwander, *Finnish Architecture and Alvar Aalto* (1954). (A. K. P.)

AARDVARK, "earth-pig," the Dutch name for an exclusively African termite-eating mammal of the genus *Orycteropus*, comprising the order Tubulidentata (*q.v.*). It is a curious looking animal, of unknown relationships, having a stout piglike body, long snout, donkeylike ears and powerful short, thick legs armed with strong, blunt claws. The body averages four feet in length, with the tail an additional two feet. In colour the Cape aardvark is pale sandy to yellow, the hair being scanty and allowing the skin to show; the northern form has a still thinner coat, a shorter tail and longer head and ears; the western has the fullest coat, a glossy black fur.

BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

AARDVARK (*ORYCTEROPUS AFER*), NATIVE OF AFRICA

The arddvark lives in both forest and plains country, wherever their insect food is plentiful. This highly specialized digger excavates large burrows in which it rests by day, venturing out at night to forage. After digging into and demolishing a large termite hill, the aardvark rapidly laps up the routed insects with its sticky, foot-long tongue.

Aardvarks are not aggressive, but when attacked, usually by larger carnivores such as lions and leopards, they roll over and use their powerful claws to good effect. A single young is born in summer. Besides keeping termites in check, the aardvark is also important in the native economy for its edible flesh and its teeth, prized as amulets to ward off evil.

AARDWOLF (*Proteles cristatus*), a mammal superficially resembling a small striped hyena and about 30 in. long, of which the tail accounts for 8 in. It has front legs longer than the hind, large ears and a pointed muzzle. The colour is buffish-gray with dark vertical stripes, dark muzzle and forefeet. A long, coarse-haired erectile mane runs the length of the back. Aardwolves live in the drier parts, but not the forests, of eastern and southern Africa and are usually nocturnal. They inhabit burrows, feed largely on termites, are usually solitary but sometimes forage in small packs. The litter averages three. They are mild, harmless animals whose only defense is to emit a musky smelling fluid and run away. See also **CARNIVORE**. (L. H. M.)

AARE or **AAR**, the longest river entirely within Switzerland, is 295.2 km. (183 mi.) long and the area of its basin is 17,779 sq km. (6,864 sq.mi.). It rises in the Aare glacier in the canton of Bern, below the Finsteraarhorn and west of the Grimsel pass. Near there an artificial lake, 7 mi. long, was created behind two dams which control the flow of water to the Grimsel underground power station. Below the Handegg falls, the Aare drains the Oberhaslital and there a power station was built in the Aare gorge at Innetkirchen above Meiringen. The Aare expands into the glacial lake of Brienz, on the southern shore of which the spectacular Giessbach falls occur. The river then crosses the lake delta of the Bodeli at Interlaken as a canalized river, before expanding into the similarly formed lake of Thun, at the lower end of which is the medieval castle town of Thun. Flowing northwest in a deeply entrenched valley, the Aare almost encircles the peninsula on which the medieval core of the city of Bern (*q.v.*) lies, then turns west and finally north to Aarberg, where it is diverted west by the Hagneck canal into the lake of Biel (Bienne). It subsequently flows northeastward parallel to the foot of the Jura, past

AARGAU—AARON

the castle towns of Solothurn, Olten and Aarau. The chief right bank tributaries in this section are the Grosse Emme, Wigger, Suhr and Aa. Below Brugg, first the Reuss and then the Limmat converge on the Aare. The combined rivers turn north to join the Rhine at Coblenz. (A. F. A. M.)

AARGAU (Fr. ARGOVIE), a canton of northern Switzerland, takes in the lower course of the Aare river (*q.v.*), whence its name. The capital is Aarau and the total area of the canton is 1,403.5 sq.km. (542 sq.mi.). It forms the northeastern section of the great Swiss plateau between the Alps and the Jura. Its fertile valleys alternate with pleasantly wooded hills.

In 1415 the Aargau region, previously the centre of the Habsburgs, was taken from them by the Swiss Confederates. Bern kept the southwestern portion. In 1798 the Bernese part became the canton of Aargau of the Helvetic republic and the remainder of the Aargau region formed the canton of Baden. In 1803 the two halves (plus the Frick glen, ceded in 1802 by Austria to the Helvetic republic) were united under the name of Canton Aargau and admitted to membership of the Swiss confederation.

The population in 1950 was 300,782 and in 1957 was 340,753, almost exclusively German-speaking with Protestants predominating. The canton is governed by an executive council of five members who are elected by direct vote, and it sends 13 members (on the basis of the 1957 census) to the federal *Nationalrat*. The principal industries are agriculture, dairying and fruit growing, straw-plaiting, electrical engineering, the making of precision instruments, cement and cigars, and the mining and refining of salt. The canton has much to offer the tourist in its beautiful landscape, its ancient castles and its museums with their artistic treasures. Baden (*q.v.*), an important city in the canton, has a tourist industry based on hot sulfur springs.

AARAU, capital of the canton, had a population (1950) of 14,280. At the southern foot of the Jura, it is built in terraces on the right bank of the Aare and is 50 mi. by rail N.E. of Bern and 31 mi. W. of Zürich. In the newer parts industries have grown up, the most important of which produce footwear and precision instruments.

Once an ancient fortress, it was taken by the Bernese in 1415, and in 1798 became for a time the capital of the Helvetic republic. The cantonal library has a fine collection of books and manuscripts, and the art gallery an important collection of pictures. Eight miles by rail northeast of Aarau is Schinznach Bad whose famous sulfur waters have been used for medicinal purposes since the end of the 17th century. Near Schinznach Bad is the ruined castle of Habsburg, or Habichtsburg (hawk's castle), the original home of the Habsburg family.

BIBLIOGRAPHY.—*Biographisches Lexikon des Kantons Aargau* (1957); Nold Halder, *Geschichte des Kantons Aargau 1803-1953*; Charles Schopp, *Heimatkunde des Kantons Aargau* (1960).

AARHUS (officially ÅRHUS), a seaport, the capital of Aarhus amt (county), and the second town in Denmark, lies on the east coast of Jutland on Aarhus bay. Area 20.5 sq.km. (7.9 sq.mi.) (including suburbs, 114.2 sq.km. [44.1 sq.mi.]). Pop. (1955) 118,943 (including suburbs, 165,522).

The oldest buildings in the town are the 11th-century crypt of St. Nicholas under the Church of Our Lady and the 13th-century cathedral. The town hall built in 1941 by A. Jacobsen and E. Möller and the university (1932) by C. F. Moller are fine examples of modern Danish architecture. There is an art gallery, a prehistoric museum and Den Gamle By, a unique open-air museum of an early Danish town. Aarhus has a botanical garden and several other parks. In addition to the university (opened 1928) there are training establishments for dentists, journalists and technicians; a merchant high school; and four teachers' training colleges.

Aarhus is the centre of both transport and commerce in Jutland. The harbour, with a maximum depth of 33 ft., has eight docks. Daily services are maintained from Aarhus to Kalundborg; Copenhagen; Halmstad, Swed.; and Oslo, Nor. From the Tirstrup airfield, 37 km. (23 mi.) N.E., there are daily flights to Copenhagen. The major industries of Aarhus are metals and chemicals.

Though the origin of the town is unknown, it became an episco-

pal residence as early as 948. The oldest existing charter dates from 1441 and refers to a still earlier one. Since the beginning of the 19th century Aarhus has expanded rapidly.

Aarhus county (area 311 sq.mi., pop. [1955] 210,409) is low-lying, fertile farming country with a large amount of woodland. (J. JE.)

AARON, the traditional founder and head of the Jewish priesthood, who, in company with Moses, led the Israelites out of Egypt (see EXODUS; MOSES). He is described as a son of Amram and Jochebed of the tribe of Levi, and as three years older than his brother Moses (Ex. vi, 20; vii, 7). He acted together with his brother in the desperate situation of the Israelites in Egypt (Ex. iv ff.), and took an active part in the exodus. While Moses was the actual leader, Aaron acted as his "mouth" (Ex. iv, 16). The two brothers went to Pharaoh together, and Aaron told the king to let the people of Israel go (Ex. vii). He used his magic rod in order to show the might of Yahweh. When Pharaoh finally decided to let the people go, Yahweh gave the important ordinance of the Passover to Aaron and Moses (Ex. xii, 43 ff.). But Moses alone went up on to Mt. Sinai, and he only was allowed to come near to Yahweh (Ex. xxiv, 2). Moses later was ordered to "bring near" Aaron and his sons with him, to serve as priests (Ex. xxviii, 1). They should be brought to the tent of meeting, washed with water and have the priestly garments put on them. Aaron received a coat and the robe of the ephod, the breastpiece, the turban and the holy crown upon the turban. He and his sons were anointed and consecrated to be priests "by a perpetual statute" (Ex. xxix). Aaron's sons were to take over the holy garments after him.

Aaron is not represented as wholly blameless. When Moses was delayed on Mt. Sinai, the people gathered and asked Aaron to make them gods. Aaron told them to bring their gold rings, and with them he made a golden calf, upon which the people declared: "These are your gods, O Israel, who brought you up out of the land of Egypt." Aaron was then reproached by Moses, and the people were punished (Ex. xxxii).

Only once a year, on the Day of Atonement, Aaron was allowed to come into the Holy Place within the veil, bringing his offering (Lev. xvi). He was solemnly installed as the leader of the Levites, who were consecrated to minister at the temple. Aaron and his sons were given monopoly as priests (Num. iii). Together with his sister Miriam, Aaron spoke against Moses because he had married a foreigner (a Cushite woman), but as in the episode of the golden calf the narrative in Num. xii tells how Aaron was merely reproved, though Miriam was punished, for the offense. In the rebellion of Korah the Levite, however, Aaron stood firmly at the side of Moses (Num. xvi). Aaron died on the top of Mt. Hor at the age of 123 (Num. xxxiii, 39). In Deut. x, 6, which represents another tradition, Aaron is said to have died in Moserah and was buried there, while Deut. xxxii, 50 has the same tradition as Num. xx.

Aaron is a central figure in the traditions about the exodus, though his role varies in importance. At the beginning he seems to be co-equal with Moses (cj. also Mic. vi, 4), but after the march out of Egypt he is only a shadow at the side of Moses. Moses is obviously the leading person in the tradition, but it is also clear that he is pictured as delegating his authority in all priestly and cult matters to Aaron and "his sons."

Aaron and the Biblical Critics.—Scholars have long been aware that the figure of Aaron as it is now found in the Pentateuch (*q.v.*) is built up from several sources or layers of traditions. According to J. Wellhausen and his followers the Yahwistic source was the oldest one, with the Elohist one following next, then later the Deuteronomist and finally the Priestly Codex. Scholars have distributed the passages about Aaron to one or the other of these sources. Although their results differ, they do agree in ascribing about 90% of the material about Aaron to the Priestly source, which was written after the exile, and which is also the source that can be most easily traced. According to Wellhausen, Aaron was not mentioned at all in the early (Yahwistic) narrative, but he may have been inserted by later redactors. It was Moses who was the hero of the priests before the exile (Ex. iv, 17; xxiv),

and it was Joshua, not Aaron, who officiated in the tabernacle (Ex. xxxiii, 7-11).

Other scholars, such as S. Mowinckel, are of the opinion that the narrative about the golden calf, which presents Aaron in an unfavourable light, was part of the ancient traditions in the Yahwistic work, being the only passage in the latter where Aaron was mentioned. This narrative, according to these scholars, originally came from the northern kingdom of Israel and described Aaron as the ancestor of the priests in northern Israel, but it was later rewritten in a way defamatory to Aaron. But there are also features in the narrative which may indicate that a later source (or traditionist), the Elohist, tried to excuse Aaron and to put the main responsibility on the people. The Elohist narrator was credited with making Aaron the brother and helper of Moses (Ex. iv, 14-17, 27-30), who stood at the side of Moses under the conflict with Pharaoh (Ex. v, vii-x) and assisted Moses as a leader in battles (Ex. xvii, 7-13) and in the cult (Ex. xviii, 12). It may also be the Elohist who provides the unfavourable story about Aaron's objection to Moses' wife (Num. xii). On the other hand it seems to be the same narrator who mentions Aaron at the side of Moses in the revolt at Meribah (Num. xx), but here also Aaron, together with Moses, is actually reproached. There is reason to believe that Aaron was not mentioned in the Deuteronomistic work by the original author, but that his name has been added by a redactor. For instance in Deut. ix, 20, x, 6 and xxxii, 50. The main bulk of the traditions about Aaron, and the frequent addition of "and Aaron" after the mention of Moses, are found in the Priestly source, which was written at a time when the priests had a more dominating position in Judah than they had before the exile. By then Moses had ceased to be the hero of the priests, and Aaron had taken over that role.

Many modern scholars prefer to speak of traditions and layers of traditions where their predecessors spoke of sources, but apart from this terminology the view concerning Aaron has not greatly changed. There have been new attempts, however, to see the contrasting figures of Moses and Aaron in new light. It has been suggested that the traditions about Moses represent a southern, Judean tradition, while the old traditions about Moses originated in the northern kingdom. It has also been indicated that the traditions about Moses are primarily concerned with a prophet, while those about Aaron are connected with priesthood. There may be a kernel of truth in all these suggestions, as also in the theory of I. Engnell that Moses represents the royal ideology while Aaron stands for priesthood, and priesthood alone. The standing struggle between the king and the leading priests is reflected both in the laws and in the narratives of the historical books. The descriptions of the relationship between Aaron and Moses—priest and king—are coloured by this struggle, for instance in Lev. xvi, Ezek. xlv, II Chron. xxvi, 16 ff. In the long run the priests were victorious, but Moses at the same time won an authority that could not be shaken.

Aaron in Later Jewish Thought.—Aaron continued to live as a symbol in Jewish religion and traditions. The position of the priests was strengthened after the exile, a fact which can be seen in Ezek. xl ff., Chronicles and Ezra. Also in the Qumran sect Aaron was a symbol for a strong priesthood, as can be seen from the Dead sea scrolls. At the end of time men of the community should be set apart, as a house of holiness for Aaron. Only the sons of Aaron should "administer judgement and wealth," and according to the *Manual of Discipline* two Messiahs were expected, one of Aaron, the priestly one, and one of Israel. According to a fragment found near Qumran the priest would have the first seat in the banquets in the last days and bless the bread before the Messiah of Israel. Here "the sons of Aaron" have the highest position.

In Midrash and Talmud Aaron is seen not so much as a symbol as the leading personality at the side of Moses. The relationship between the two brothers is painted as prototypical in the Haggadah. Rabbi Hillel praised Aaron as peace-loving, a man of good will, who wanted to teach his fellow men the Law (*see* Talmud: Aboth 1. 13). In the Haggadah his rod also played a role (cf. Num. xvii, 16-26). In Jewish exegesis little is said about him,

though he is mentioned as a man who created peace among men. Many attempts have been made to explain the episode of the golden calf. According to some exegetes Aaron had to make the calf in order to avoid being killed. Gersonides (1288-1344) explained that this would have been fatal, not only for Aaron, but even more for the people. Ibn Ezra (c. 1090-1164) underlined that here was no apostasy, and Rashi (1040-1105) contended that the calf was a symbol for the leader, Moses, who was at that time on the mountain. The relationship between Moses and Aaron also is discussed in the Talmud. Some traditionists have wondered why Aaron and not Moses was appointed high priest. The answer has been found in an indication that Moses was rejected because of his original unwillingness when he was called by Yahweh (*see* Talmud: *Zebahim* 102 a). It also seems to have been hard for some traditionists to accept that Aaron was described as older than his brother Moses (*see* Talmud: *Sota* 12 b). The death of Aaron is described in the Midrash Petirat *Aharon*.

Aaron in Christian Symbolism.—The first Christian communities admitted that Aaron, "the sons of Aaron" or "the order of Aaron" were symbols of the highest priesthood. But from the Epistle to the Hebrews (iv ff.), where Christ is described as a High Priest according to the order of Melchizedek, which was set over against "the order of Aaron" (Heb. vii), it can be seen that this caused problems. Of the church fathers, Cyril of Alexandria in his *De adoratione* i, 11 says that Aaron was divinely called to a priesthood in spirit and in truth, and that he was a type of Christ. Cyril also goes into the symbolism of Aaron's garments and their ornaments. Gregory the Great in his 33rd homily translates the name Aaron as "mountain of strength," and sees in him a redeemer, who mediated between God and man. Isidore of Seville in his 60th scriptural allegory takes Aaron as a sacrificer, representing Christ who effaced the sin of the world through his blood. Alcuin in his commentary on Ps. cxxxiii saw in Aaron the type of Christ, who penetrated into the Holy of Holies, not with the blood of others but with his own blood, to intercede for the world with the Father.

AARON'S-ROD, the popular name given to various tall flowering plants, such as garden orpine (*Sedum telephium*) or live-forever, great mullein (*Verbascum thapsus*) and goldenrod (*Solidago*).

AASEN, IVAR ANDREAS (1813-1896), Norwegian philologist, who constructed one of the two official languages of Norway, was born at Aasen i Orsten, in Sondmore, Aug. 5, 1813. His first publication was a small collection of folk songs in the Sondmore dialect (1843). The Grammar of the Norwegian Dialects (1848) and the Dictionary of the Norwegian Dialects (1850) prepared the way for the wide cultivation of the popular language in Norwegian. With certain modifications, the language Aasen constructed, which is now called nynorsk, rapidly assumed an importance comparable to that of Dano-Norwegian. Aasen composed poems and plays in the composite dialect and continued to enlarge and improve his grammars and his dictionary. Quite early in his career (1842) he had begun to receive a stipend to enable him to give his entire attention to his philological investigations. Aasen died in Christiania (now Oslo), Sept. 23, 1896.

ABA, a town of Eastern region of Nigeria, Africa, lies on the west bank of the Aba river, about 40 mi. N. of Port Harcourt, in the heart of the tropical rain forest but high enough above sea level to be clear of mangrove and fresh-water swamps. Pop. (1952-53) 57,787, (1959 est.) 62,500. Area about 13 sq.km. (5 sq.mi.).

The town came into existence with the gradual pacification of the village communities of the area in the early years of the 20th century. Its development was hastened by the arrival in 1915 of the railway from Port Harcourt, extended to Enugu in 1916, and the subsequent construction of roads. By 1933 Aba was a settled urban area and a principal centre of trade. The town was laid

ABACÁ—ABACUS

out on modern lines around the main street, Asa road. There is a government school, a technical engineering school, Roman Catholic and Qua Iboe missions, a golf course and a prison.

Aba is the centre of a palm oil and palm kernel producing district and contains large and well-equipped soap factories. Other industries established or projected include furniture, textiles, concrete, aluminum ware and a brewery. The town is linked by road as well as by rail to Port Harcourt and Enugu (150 mi), capital of Eastern region, and by road to the federal capital, Lagos (510 mi.). It is within reach of the airport at Port Harcourt.

(W. H. I.)

ABACÁ FIBRE (MANILA HEMP), one of the most valuable of all fibres for cordage, is the product of *Musa textilis*, a plant of the banana family (Musaceae). This fibre is also known in the trade as manila and manila hemp, but abaci is a hard fibre and is entirely different from true hemp, which is a soft fibre and is the product of *Cannabis sativa*.

SHELL
STRIPPING, OR "TUXYING," STALK OF ABACÁ (*MUSA TEXTILIS*). STRIPS ARE CLEANED AND DRIED, AFTER WHICH THEY ARE GRADED AND BALED FOR USE IN MAKING CORDAGE

The abacá plant, which resembles in appearance the banana and plantain, which it is closely related, is a perennial. Numerous suckers grow from the rootstocks, forming a cluster of stalks 10 to 25 ft. in height. These stalks, formed by the overlapping leaf stems, bear at the top a crown of large, undivided leaves. The point of growth is at the base. The flower stalk is pushed up through the centre of the plant, bearing at the top flowers that are followed by fruits similar to small bananas but filled with black seeds. Abaci plants grown

from seeds do not come true to type, so the plant is propagated from suckers or from rootstocks.

The abaci plant flowers when about two years old, at which stage it is in the most favourable condition for the production of fibre. The stalk is cut down, and the outer fibre-bearing layer of each successive leaf stem is stripped off in the form of ribbons known as "tuxies." The tuxies are scraped to remove the pulp and other waste material, leaving the cleaned fibre, which is then hung up to dry in the open air. Formerly, most of the processing was done by hand; more recently various machines, called decorticators, have been used. Without further treatment the fibre is graded and baled for shipment.

The outer sheaths of the abacá stalk contain a rather short, strong but discoloured fibre; the middle sheaths produce a fibre of medium colour and good strength; the sheaths near the centre of the stalk have a very white, fine fibre of medium strength. Delay and carelessness in drying affect both the colour and the strength of the fibre.

The exceptional strength of abaci fibre and its quality of resistance to the action of salt water make it particularly suitable for marine cordage. It is also largely used for well-drilling cables: hoisting ropes and various other types of rope where strength and durability are required. Henequen and sisal have largely replaced abaci as a binder twine fibre. In the Philippines the superior grades of abaci are used for textile fabrics, hats, slippers, rugs and various other articles. In Japan large quantities of abaci fibre, particularly the waste products, are used for the manufacture of paper. From the old and disintegrated ropes is made the well-known manila paper.

The abaci plant has been introduced into many different tropical regions, including Indonesia, India, the Andaman Islands, the West Indies and Central America; formerly the commercial production of this fibre was confined to the Philippine Islands. About 1921 shipments of abaci rootstocks were made from the Philippine Islands to Sumatra, where fairly large plantings were made. Despite some expansion of the industry there, it remained relatively unimportant. Small abaci plantings were also made in North Borneo.

In 1925 a shipment of propagating material of the superior varieties of abaci was brought from the Philippine Islands to the republic of Panamá by the United States department of agriculture. It was determined by experimental plantings that the climatic and soil conditions of this region are suitable for the abaci plant; that this plant is resistant to the more serious diseases of the banana plant, and that abaci fibre of excellent quality can be produced in tropical America. Little attention was given the Central American plantings until 1942 when the war cut off abaci supplies from the Philippines. At that time production of the fibre started in earnest in Costa Rica, Guatemala, Panamá and other countries of Central America.

In the early 1960s world production of abacá fibre exceeded 100,000 long tons, of which total the Philippines contributed over 90%. (H. T. Es.; X.)

ABACUS, a calculating device of ancient origin still used in parts of the orient and middle east. The first abacus probably was a slab or board on which a Babylonian spread sand so he could trace letters. The word "abacus" is believed to be derived from the Phoenician *abak*, describing sand strewn on a surface for writing. As the abacus came to be used solely for counting and computing, its form was changed and improved. Wax-covered boards were introduced, and later a counter abacus was devised in which loose counters of bone, glass or metallic disks or rods were placed on a ruled table drawn on the board. In a still later form, the one used in some parts of the world today the counters slide in grooves or on wires or strings.

The table of the early counter abacus was composed of lines representing units, tens, hundreds, etc., or units of value, such as shillings, pence, pounds. Addition on an abacus of this type probably was performed as represented in fig. 1, which shows the steps in adding 64 and 239. Subtraction was simply the process of taking away counters: multiplication was considered as repeated addition, and division as repeated subtraction. This type of abacus was known in the Mediterranean countries, and Herodotus (c. 450 B.C.) is authority for the statement that the Egyptians wrote

FROM D. SMITH, HISTORY OF MATHEMATICS
FIG. 1.—ADDITION ON ABACUS AS PRACTISED IN ANCIENT MEDITERRANEAN COUNTRIES

Lines represent hundreds, tens and units. The computation represented is: $239 + 64 = 29[13] = 2[10]3 = 303$

their figures and reckoned with pebbles "bringing the hand from right to left," while the Greeks proceeded in the opposite direction.

There are several references to the abacus in Roman literature, and what is apparently a Greek computing table was found in the 19th century on the island of Salamis.

Latin writers tell of three types of abacus in use in Rome, namely: (1) the sand board or wax tablet; (2) a marked table for counters; and (3) a table with grooves in which the counters were free to slide. Fig. 2 shows a late Roman abacus now in the British museum, each upper button representing five units of the order in

FIG. 2.—LATE ROMAN ABACUS

Bronze table with each upper button representing five units and each lower button representing one unit of the order in which the column stands

which the column stands and each lower button representing one unit of the same order. Cicero speaks of the counters as *aera* ("bronzes") but the common name was *calculi* ("pebbles") or *abaculi*. The pieces were stone, ivory, metal or coloured glass.

The earliest type of abacus in China seems to have been the bamboo rods that served instead of counters. These were known as early as the 6th century B.C. and they survived in Korea until the close of the 19th century. They found their way into Japan

about the year 600 and were known as *sangi* or *sanchu*. Until recent times they were used to represent algebraic coefficients, being placed on a ruled board. Since the 12th century the *suàn-pán* ("computing tray"; see fig. 3) has been generally used throughout China. The chief difference between this and the Roman abacus lies in the fact that the latter has one less bead in each section. In the 16th century this type, slightly changed and bearing the kindred name of *soroban*, found its way into Japan, where it is still in use. An abacus differing considerably from the Roman or oriental types is found in the middle eastern countries. The Turks call it the *coulba*; the Armenians, the *choreb*; and the Russians, the *s'choty*. As in the case of the *suàn-pán* and the *soroban*, this permits rapid computation and serves a purpose similar to that of the modern calculating machine.

FIG. 3.—CHINESE SUAN-PAN
Each upper bead represents five units and each lower bead represents one unit of the order in which the column stands. The number represented is 7230189

A type of abacus called the line abacus appeared in Europe in the middle ages. It consisted of a table ruled with horizontal lines representing the successive powers of ten, each space between lines representing half the value of the line immediately above it. This type was used well into the 18th century.

Abacus disks used in computing were known in Great Britain as counters; in the Latin books as projectiles (*pro*, "forward," + *jacere*, "to throw"), being thrown or cast upon the counting board, or as *denarii supputarii* ("computing pennies"); and in France as *jetons* (from *jacere*, "to throw"). In Germany a counter was called a *Rechenpfennig* or *Zahlpfennig* ("number penny"). Such later expressions as "cast an account," "borrow one," "carry two" and possibly "lay a wager" have their origin in this kind of computation. The countinghouse, billiard counters! poker chips and various games trace their origin to the counting board.

By medieval times the counter abacus was being used in most regions of the known world, but it gradually was abandoned as the Arabic notation of nine figures and zero replaced the Roman numeral system in calculating. The abacus was last generally used in Spain and Italy in the 15th century, in France in the 16th century and in England and Germany in the 17th century.

ABACUS, in architecture, the upper member of a capital (*q.v.*) whose function is to provide a supporting surface for the structure above. In Egyptian capitals it is smaller than the parts below and in the late work it has great height. In the Greek Doric order it is a plain square slab, but in the Roman Doric it is usually crowned by a molding. In the Greek Ionic order it is at first rectangular, to cap the projection of the volutes, but later becomes square, except at corner capitals where it is curved out over the angle volutes. In both Greek and Roman Corinthian orders and in the composite and four-sided or Scainozzi Ionic order it is molded with concave sides and usually the corners are cut off slightly. In Romanesque architecture the abacus usually is square, with sides splayed or molded, and in the Gothic, outside of England, it is square or octagonal and richly molded. In English Gothic, however circular forms are frequent especially in 13th-century work. The diminutive, *abaculus*, is applied to the squares of tile, or tessera. See also ORDER.

ABADAN, a city of the sixth province or *ostan* (Khuzistan) of Iran, lies on an island of the same name off the eastern bank

of the Shatt-al-Arab, 33 mi. from its mouth on the Persian gulf. The island, 42 mi. long and from 2 to 12 mi. wide and known to the Arabs as Jazirat al-Khidr (from the tomb of a saint of that name), is bounded on the east by the Khowr-e Bahmanshir, a branch of the Karun river. The population of Abadan city in 1932 was about 40,000 and by 1956 had reached 226,103, with a further 57,522 in the area, mostly date-palm growers. The climate is extremely hot and often very humid for seven months of the year.

Abadan Island was referred to in the 13th century by the historian Nasir Khosrow as the southernmost settlement of Iraq. Its possession was long in dispute between Persia and Turkey but was awarded to Persia by the treaty of Erzurum (1847); the Turks retained control of the Shatt-al-Arab, while ensuring freedom of navigation to the Persians.

In 1909 the Anglo-Persian Oil company, by agreement with the sheik of Mohammerah, established its pipeline terminus and refinery there. Once the largest in the world, with a daily capacity of 500,000 bbl., it is served by 1,880 mi. of pipelines from the oilfields in the foothills of the Zagros range. The port has deep-water jetties for the loading of tankers and the discharge of other goods. A 590-mi. pipeline to Teheran was completed in 1959. Asphalted roads connect Abadan with the port of Khorramshahr (formerly Mohammerah) and with the oilfields. There is a separate crude oil port at Bandar-e Ma'shur, 55 mi. to the east.

The city is among the best equipped in Iran and consists mainly of a series of compounds for the company's staff and its labour force, which is recruited from all over the gulf and from the Bakhtiari tribes. There is a lively bazaar and poor housing quarters for unemployed immigrants.

The nationalization of the oil industry by the Iranian government in 1951 led to a virtual cessation of operations. Three years later an agreement to resume production was made between the government and a consortium of eight foreign oil companies, but it was not until 1959 that full production was restored.

(H. Bo.)

ABAE, an ancient town in Greece, in the northeastern corner of Phocis, north of Lake Copais and west of modern Topolia, famous for its oracle of Apollo, one of those consulted by Croesus. Its rich treasures were sacked in 480 B.C. by the Persians; who burned the temple. The oracle was, however, still consulted; *e.g.*, by the Thebans before the battle of Leuctra in 371 B.C. The temple, burned again during the Sacred War of 355–347 B.C., was very dilapidated when seen by Pausanias in the middle of the 2nd century A.D., although some restoration had been undertaken by Hadrian. Privileges due to the sanctity of the shrine were confirmed to the people of Abae by the Romans. The polygonal walls of the acropolis may still be seen, with one gateway and traces of town walls below.

ABAILARD: see ABÉLARD, PETER.

ABAKAN, the capital of the Khakass autonomous oblast, Russian Soviet Federated Socialist Republic. U.S.S.R., was created a town in 1931 and stands on the left bank of the Abakan river at its confluence with the Yenisei. Pop. (1959) 56,000. It is the terminus of the branch railway from Achinsk on the Trans-Siberian; a line from Abakan to Stalinsk in the Kuzbas mas under construction in the 1960s. X branch links Xbakan with the coal-mining town of Chernogorsk, 10 mi. N. X motor road from Abakan crosses the Yenisei to Minusinsk and runs on over the western Sayan mountains to Kyzyl, capital of the Tuva autonomous oblast. The town is a centre of metal-working and saw-milling, and of food-processing based on agricultural products of the fertile Minusinsk basin. It has a pedagogical institute.

(R. A. F.)

ABALONE, a common name of Spanish derivation, applied in California to various species of marine snails of the genus *Haliotis*. They are widely distributed and are called perlemeon in South Africa, ormer or ormier in the Channel Islands and France, paua in New Zealand and ear shells in Australia. The single flattened shell is earlike with the large body whorl perforated on the left side by a single row of small openings that become filled progressively during growth; the last five to nine remain open to serve as outlets for waste products. Depending

ABANDONMENT — ABBADIDS

on the species, abalones range from a few inches to ten inches across and up to three inches in depth. The lustrous, pearly interior of the shell (see MOTHER-OF-PEARL) is commonly iridescent and is utilized in the manufacture of attractive ornaments such as buttons and inlaying.

The large muscular foot of these snails was a popular food of primitive man and is still regarded as a delicacy in many countries. Commercial fisheries exist in California, Mexico, Japan, South Africa and the Channel Islands off England. The west American species inhabit algal covered rocky bottoms from the tidal zone to depths of more than 100 ft. and are sought by skin divers and commercial fishermen using diving equipment. Of the eight Californian abalones, the red (*Haliotis rufescens*), pink (*H. corrugata*) and green (*H. fulgens*) are the commercially important ones. See also SNAIL.

See "Review of the Abalone in California," *Calif. Fish Game*, 46:381-406 (1960). (W. K. E.)

ABANDONMENT, a legal term denoting the relinquishment of an interest, claim or privilege by the owner. The conduct sufficient to manifest an intention to abandon and the consequences of such conduct vary according to the branch of law under which the issue arises. Thus, while the benefit of an easement may be abandoned by the owner of the dominant estate, mere nonuser for a period of time is usually not sufficient to manifest an intention to abandon (see EASEMENT). On the other hand, no matter how clear the intention to abandon an estate in land is expressed, such abandonment is not possible since this would leave the ownership vacant (see REAL PROPERTY AND CONVEYANCING, LAWS OF).

For abandonment of children, see CHILDREN, LAWS CONCERNING; for abandonment of domicile, see DOMICILE AND RESIDENCE. (A. DM.)

ABARBANEL: see ABRABANEL, ISAAC.

ABAS, the name of several characters in classical literature and mythology.

1. Abas, son of Lynceus and Hypermetra (daughter of Danaus), was the 12th king of Argos and founder of Abae in Phocis. He was noted for his shield, which had been consecrated by Danaus to Hera but was given to Abas by his father on his report of Danaus' death. The gift was apparently the explanation of the prize given at an Argive festival, a shield rather than a crown.

2. Three persons by this name appear in Ovid's *Metamorphoses*: a centaur, a friend of Perseus and a companion of Diomedes who was turned into a swanlike bird by Aphrodite. (T. V. B.)

ABATEMENT, in law, the interruption of a legal proceeding upon the pleading by a defendant of matter which prevents the plaintiff from going forward with the action at that time or in that form. Pleas in abatement raise such matters as objections to the place, mode or time of the plaintiff's action, lack of proper parties to the action or lack of jurisdiction in the court to entertain it, without questioning the justice of the plaintiff's claim. In earlier procedures, abatement of proceedings in equity differed from abatement at law in that the former merely suspended the action, subject to revival when the defect was cured, while the latter entirely terminated it, although the plaintiff could start anew. The latter is now the more usual usage. (C. E. CL.)

ABATTOIR: see SLAUGHTERHOUSE.

ABAUZIT, FIRMIN (1679-1767), French theologian, remembered both for the extent of his learning and for his great kindness and modesty, was born of Huguenot parents at Uzès in Languedoc in Nov. 1679. His mother contrived his escape to Geneva in 1689 from enforced Catholicism in France. In 1698 he began to travel, visiting Germany, the Netherlands and England and making the acquaintance of learned and literary men, Pierre

BY COURTESY OF AMERICAN MUSEUM OF NATURAL HISTORY

SHELL OF BLACK ABALONE (*HALIOTIS CRACHERODII*), SHOWING BREATHING HOLES

Bayle and Sir Isaac Newton among them. He declined William III's offer of domicile in England and also the offer (1723) of the professorship of philosophy at Geneva. but in 1727 he was granted citizenship of Geneva and accepted an honorary post as librarian there. He collaborated on a new French version of the New Testament (1726) and wrote the article "Apocalypse" for Diderot's encyclopaedia, but his vast scholarship, which he was more inclined to share with others than to turn to his own profit, extended far beyond Christian doctrine. His theology was of a liberal type. J. J. Rousseau praises him enthusiastically in *La Nouvelle Héloïse*. Abauzit died in Geneva on March 20, 1767.

BIBLIOGRAPHY.—*Oeuvres de feu M. Abauzit* (1770); *Oeuvres diverses de M. Abauzit*, 2 vol. (1770-73; Eng. trans., *Miscellanies*, 1774). See also A. Gibert, *Abauzit et sa théologie* (1865); E. Stroehlin, *Firmin Abauzit* (1894).

ABBADIDS, a Muslim dynasty which arose in Andalusia on the downfall of the caliphate of Cordoba (*q.v.*).

ABBAD I (Abu'l-Qasim Mohammed) (d. 1042) was the qadi of Seville who, in 1023, with aristocratic support, declared his city independent from Cordoba. Before his death he had enlarged his territory at the expense of neighbouring kinglets by a mixture of political chicanery and indiscriminate border warfare.

ABBAD II, known as al-Mu'tadid (d. 1069), continued this policy of aggrandizement far more successfully by leading Muslims of Arab and native Spanish descent against the Berbers of eastern Andalusia and even aimed at taking Córdoba and restoring the caliphate. He failed in this mainly because of family defections and the opposition of the Castilian king Ferdinand I, whom he later appeased by becoming his tributary. A "vengeful, suspicious and bloody" character, poet and patron of poets, wine drinker and skeptic, he is said to have killed a rebellious son with his own hand and disposed of certain Berber chiefs of Ronda by smothering them in a steam bath in the Alcazar of Seville. Even more sadistically picturesque was his flower garden, planted over the skulls of his enemies, which he "contemplated with ecstasy."

ABBAD III (1040-1095), his son, generally known as al-Mu'tamid, the last ruling member of the dynasty, epitomizes the chivalrous, extravagant and tragic virtuosity of medieval Andalusia. Remembered as the poet-king of Seville, whose example and patronage made the city a brilliant centre of Spanish Muslim culture, he appointed as his vizier his fellow poet Ibn Ammar, and took as his queen a Sevillian slave girl, I'timad al-Rumaykiyah, who had capped one of his improvised couplets. Though he was a less ruthless character than his father, his political life, was equally turbulent and scarred by repeated tragedies and failures. His son and namesake was killed in early youth during a struggle with the ruler of Toledo for possession of Córdoba. His alliance with the Catalans for the conquest of Murcia was destroyed by an unforeseeable mishap, and the conquest of that city by his troops led to a breach with Ibn Ammar, who lampooned his master so stubbornly that he had him strangled in jail. Al-Mu'tamid's downfall was precipitated by the outbreak of hostilities against the Castilian king Alfonso VI, whose Jewish envoy had accused al-Mu'tamid of debasing the tribute money. Al-Mu'tamid had him crucified, and in revenge Alfonso made a fruitless incursion into Andalusia. Christian progress in Aragon and Valencia and the fall of Toledo in 1085, together with pressure from religious enthusiasts at home, forced al-Mu'tamid to seek alliance with the Almoravid amir Yusuf ibn Tashfin (see ALMORAVIDS). Although the Sevillian had distinguished himself for generalship and personal valour in their joint victory in 1086 over the Castilians in the battle of Zallaka or Zalaca (Sacralias, north of Badajoz), the Almoravid later turned against his ally and besieged Seville. The city was betrayed by Muslim zealots after a heroic defense by al-Mu'tamid, who was taken prisoner (1091). Some of the elegies he wrote in his five-year captivity in north Africa won him popular sympathy, and for more than two centuries his tomb was a centre of pilgrimage.

(K. GA.)

ABBADIE, ANTOINE THOMSON D' (1810–1897), and **ARNAUD MICHEL D'** (1815–1893), geographers and travelers in north Africa who were born in Dublin, Ire., of a French father and an Irish mother. Their parents moved to France in 1818. In 1835 the French Academy sent Antoine on a scientific mission to Brazil, the results being published in 1873 under the title of *Observations Relatives à la Physique du globe faites au Brésil et en Éthiopie*. Arnaud spent some time in Algeria before the two brothers started for Abyssinia in 1837, landing at Massawa in Feb. 1838. After collecting much information on the geography, geology, archaeology and natural history of Abyssinia, the brothers returned to France in 1848. Arnaud then paid another visit to Abyssinia in 1853.

Meanwhile Antoine had become involved in various controversies relating to both his geographical results and his political activities in Abyssinia. Time and the investigations of subsequent explorers have shown that he was quite trustworthy as to his facts, though wrong in his contention that the Blue Nile was the main stream. The topographical results of his explorations were published in Paris in 1860–73 in *Géodésie de l'Éthiopie*. Of the *Géographie de l'Éthiopie* (1890) only one volume has been published. *Un Catalogue raisonné de manuscrits éthiopiens* (1859) contains a description of 234 Ethiopian manuscripts collected by Antoine. He published numerous papers dealing with the geography of Abyssinia, Ethiopian coins and ancient inscriptions. His *Reconnaissances magnétiques* (1890) is an account of the magnetic observations made by him in journeys to the Red sea and the Levant.

The general account of the travels of the two brothers was published by Arnaud in 1868 under the title of *Douze ans dans la Haute-Éthiopie*. Antoine died in 1897 and bequeathed an estate in the Pyrenees, yielding 40,000 francs a year, to the Academy of Sciences, on the condition that it produce a catalogue of 50,000 stars within 50 years. His brother Arnaud died in 1893.

ABBA MARI (ABBA MARI BEN MOSES BEN JOSEPH), French rabbi, was born at Lunel, near Montpellier, toward the end of the 13th century. He is also known as Yarhi from his birthplace (Heb. *Yerah*; i.e., "moon," *lune*), and he further took the name Astruc, Don Astruc or En Astruc of Lunel. In Montpellier, where he lived from 1303 to 1306, he was much distressed by the prevalence of Aristotelian rationalism, which, through the medium of the works of Maimonides, threatened the authority of the Old Testament, obedience to the law, and the belief in miracles and revelation. He, therefore, in a series of letters (afterward collected under the title *Minhat Kenaot*; "Jealousy Offering") called upon the famous rabbi Solomon ben Adret of Barcelona to come to the aid of orthodoxy. Ben Adret, with the approval of other prominent Spanish rabbis, sent a letter to the community at Montpellier proposing to forbid the study of philosophy to those who were less than 30 years of age, and, in spite of keen opposition from the liberal section, a decree in this sense was issued by Ben Adret in 1305. The result was a great schism among the Jews of Spain and southern France, and a new impulse was given to the study of philosophy by the unauthorized interference of the Spanish rabbis. On the expulsion of the Jews from France by Philip IV in 1306, Abba Mari settled at Perpignan, where he published the letters connected with the controversy.

ABBAS I (1571–1629), shah of Persia from 1587 to 1629, is known as Abbas the Great. His brutal uncle Isma'il II ordered his execution when he was a child, but he was saved by Isma'il's death in 1577. Four years later he was proclaimed ruler of the great province of Khurasan. He became shah of Persia on the abdication of his father, Mohammed Khudabanda, in 1587. His prospects seemed gloomy, as he was confronted with anarchy in Persia due to the insubordination of the Turkmen tribal leaders, and with invasion by the Ottoman Turks on the west and by the Uzbeks on the northeast.

Faced with such odds, Abbas was forced to make peace with the Turks on unfavourable terms in 1599, but he was then able to subdue the rebels in his own country and to crush the Uzbeks and

drive them out of Persia. He reopened hostilities with Turkey in 1603 and in a series of campaigns regained the territory that had been surrendered in 1599; the war against the Turks continued, with intervals, until the end of his reign. In 1621 his forces regained Kandahar, which the Mogul emperor Akbar had seized 30 years earlier. In the following year, with naval aid furnished by the English East India company, Abbas expelled the Portuguese from the island of Hormuz; much of the trade from there was diverted to Gombrun on the mainland, which was renamed Bandar 'Abbas after the shah. In gratitude for the East India company's assistance against the Portuguese, the shah gave the company valuable privileges at Bandar 'Abbas.

Abbas' military successes were largely the result of his thorough reorganization of the army. In place of the tribal levies, whose loyalties were primarily to their own chiefs, he created a regular force, which gained both in reliability and in efficiency. In this he owed much to the help of an English adventurer, Sir Robert Shirley (Sherley), who also assisted him in the creation of an artillery corps. Abbas' reign was distinguished by military successes and administrative efficiency, also by the magnificence of his court and by his zeal as a builder. He largely replanned and rebuilt Isfahan, which he had made his capital in 1598; many of the architectural glories of that city date from his reign. He fostered trade and industry by constructing highways, bridges and caravanseries and also by granting privileges to his Armenian subjects (many of whom he had forcibly moved from their homes in the north and settled in a suburb of Isfahan). He also encouraged the English and Dutch East India companies to trade in Persia. He was tolerant in religious matters and allowed foreign monastic orders to establish missions in Persia.

Abbas' fame, however, was tarnished by some terrible deeds of cruelty. At his orders Queen Ketevan of Kakhétia was tortured and put to death. He blinded and imprisoned his father and two brothers and had his own son Mohammed Baqir Mirza executed and another son, Imam Quli, blinded. Although he had made Persia a great power once again, he was nevertheless partially responsible for its subsequent decline by reason of his inauguration, for reasons of security, of the practice of immuring the heir apparent (as well as the other royal princes) in the harem until the moment came for his accession to the throne.

ABBAS I (1813–1854), pasha and viceroy of Egypt, a grandson of Mohammed Ali (q.v.), came to power in 1849, nine months after the death of his uncle Ibrahim Pasha. Abbas was by nature cautious and secretive. His years of office were marked by reaction against the westernizing tendencies of Mohammed Ali; he curtailed the scope of government activity, reduced the fighting services, closed factories and abolished, though only partially in the Sudan, the state trading monopoly imposed by his grandfather in defiance of Ottoman treaties with the Powers. He distrusted western, especially French, thought and ways and dismissed many European experts, while Egyptian intellectuals influenced by European culture, such as Rifa'a Bey al-Raf'i, were banished to the Sudan. Nevertheless his retrenchment in government spending lightened taxation and restored the Egyptian finances, strained by Mohammed Ali's wars and economic experiments. Abbas permitted the construction of the Alexandria-Cairo railway by Robert Stephenson (1852–56). His loyalty to the Ottoman empire was expressed by the dispatch of an Egyptian contingent in 1853 to support the Turks against the Russians (see CRIMEAN WAR). On July 13, 1854, he was murdered at Benha. (R. L. HL.)

ABBAS II (ABBAS HILMI PASHA) (1874–1944), last khedive of Egypt, was born in Cairo on July 14, 1874, the eldest son of Mohammed Tewfik (Tawfiq) Pasha, whom he succeeded in the khedivate in 1892. His relations with the British occupying power were invidious. With studied indiscretion at a parade of troops at Wadi Halfa during a tour of the frontier garrisons in 1894, he publicly criticized the military efficiency of the British officers

serving in the Egyptian army, an incident which caused the fall of the Riyad ministry and brought no gain to his prestige in any quarter. His dealings with the Egyptian nationalists were equally unfortunate. So long as nationalist criticism was confined to agitation against the British occupation, he discreetly supported the nationalist cause and in 1904 procured from the sultan the grade of pasha for the nationalist leader Mustafa Kamil, who for a time pursued a pan-Islamic and pro-Ottoman policy. When, however, partly as a result of the Anglo-French settlement of 1904, the nationalists began to advocate a more liberal regime for Egypt, their relations with the khedive became estranged.

Abbas showed a lively interest in the social and economic welfare of Egypt and the Sudan. He visited Berber and Khartoum in 1901–02 and opened the new harbour at Port Sudan in 1909. While on a visit to Constantinople he was shot and wounded by an Egyptian student in July 1914. He was still in Turkey when the Ottoman empire entered World War I; his return to Egypt was forbidden by the British, who declared a protectorate over Egypt and, on Dec. 19, 1914, deposed him in favour of his uncle, Husain Kamil Pasha, who assumed the title of sultan. Abbas passed the rest of his life in exile, chiefly in Switzerland, and died at Geneva on Dec. 21, 1944. He wrote *A Few Words on the Anglo-Egyptian Settlement* (1930).

See Evelyn Baring, earl of Cromer, *Abbas II* (1915); A. A. H. Beaman, *The Deposition of the Khedive*, ed., with introduction, by J. M. Robinson (1929). (R. L. H.L.)

ABBAS, FERHAT (1899–), Algerian political leader of the Front of National Liberation (F.L.N.) in the Algerian rebellion against French rule, was born at a village near Djidjelli in the Constantine department. Son of a caid, he was educated at Philippeville and later at Algiers university. Entirely French-educated, he never spoke Arabic well. After two years' service with the French army, he became a pharmacist at Sétif and later a member of the *conseil général* of Constantine. In his first period of political activity Abbas stood for the emancipation of the Algerian Muslims as French citizens. "Algeria is French soil," he wrote in 1931, "and we are French Moslems." As late as 1936 he declared that he had interrogated the living and the dead and found no one who mentioned an Algerian nation. Bitterly disillusioned by the subsequent French rejection of the proposals in the Blum-Violette plan, he yet served as a volunteer with the French forces in World War II from 1939 until the fall of France in 1940. Later he promoted the "Algerian manifesto" which was presented to the allied leaders in Algeria in 1942 and, in a modified form, accepted for discussion by the French authorities in 1943. In its final form this envisaged an Algerian state at the end of the war, with a constitution to be worked out by a constituent assembly elected by universal suffrage; meanwhile a government should be formed with Muslim and European members in equal numbers and parity be established in all assemblies. As leader of the Union Démocratique du Manifeste Algérien and member of the French constituent assembly, he submitted in Aug. 1946 a project for the recognition of Algeria as a state federated with France. This, however, was not considered by the assembly. On the outbreak of the rising in 1954, he appeared at first taken aback and issued an appeal for calm. Later, however, with other former moderates of various tendencies, he escaped to Cairo and joined the Front of National Liberation (April 1956). On Sept. 19, 1958, the formation of a provisional government of the Algerian republic was announced in Cairo, with Ferhat Abbas as prime minister. (N. B.A.)

ABBASIDS, the second of the two great dynasties of the Moslem Arab empire (see CALIPHATE). The name is derived from Mohammed's uncle, al-Abbas (566–652), of the Hashemite clan of the tribe of Quraysh in Mecca. From c. 718 some of the family of al-Abbas were planning to gain supreme power. By skillful propaganda their agents won much support, especially from Arabs and Persians in Khurasan. Open revolt in 747 under Abu Muslim led in 750 to the defeat of the Omayyad dynasty and the proclamation of the first Abbasid caliph, Abu'l-Abbas.

Iraq became the centre of the caliphate instead of Syria, Baghdad being founded as capital c. 762. Much of the support of the

Abbasids came from Persian converts, and it was therefore natural for them to take over much of the Persian (Sassanian) tradition of government. Support by pious Muslims likewise led them to acknowledge publicly the embryonic Islamic law and to profess to base their rule on the religion of Islam. Under them commerce and the liberal arts expanded. The reigns of Harun al-Rashid (786–809) and al-Ma'mun (813–33) were periods of splendour.

Gradually Abbasid power decayed. First in the east, then elsewhere, provincial governors made themselves independent though still nominally receiving appointment from the caliph. In the 10th century, real power even at the centre passed into the hands of dynasties of military leaders, such as the Buyids and the Seljuks (*q.v.*). The caliph retained the nominal power of making appointments while these rulers had titles such as sultan. This nominal power was ended in 1258. A branch of the family held formal, religious powers in Cairo until the death in 1538 of al-Mutawakkil III who had been moved to Istanbul in 1517. See also Index references under "Abbasids" in the Index volume. (W. M. W.T.)

ABBE, ERNST (1840–1905), German physicist, is best known for his invention of the Abbe refractometer and his many improvements in microscopic and photographic lenses. He was born in Eisenach, Thuringia, Jan. 23, 1840. He was educated at Gottingen and Jena. In 1863 he became an instructor, and in 1870 was made a professor, in the University of Jena, at which in 1878 he was appointed director of the astronomical and meteorological observatories. In 1866 he became connected with the optical works of Carl Zeiss, was made a partner in 1875, and contributed in a very large degree through his experiments to the excellence of the instruments and lenses made by the firm.

In 1884, with Zeiss and Otto Schott, he established important works for the production of technical glass. Upon the death of Zeiss in 1888 he became the sole owner of the Zeiss optical works, which he reorganized as a co-operative establishment; the officials, the workmen and the university participated in its profits. His collected works were published in 1903–06. He died in Jena, Jan. 14, 1905.

ABBESS: see ABBOT.

ABBEVILLIAN (formerly known as CHELLEAN [*q.v.*]), the oldest Stone Age industry with hand axes, named after Abbeville in the Somme valley, France, where it occurs in terrace gravels believed to date from the first warm interval in the Pleistocene Ice Age, *i.e.*, more than 300,000 years old. These simple tools, also called *bifaces* or *coups de poing*, consist of a lump of flint or other suitable stone flaked to a tongue-shaped form with a margin for cutting, and may be pointed or oval. Abbevillian hand axes are coarsely flaked (probably with hammerstone) and have a thick, largely unworked butt. Lower Paleolithic hand-ax culture spread throughout Africa, western Europe and southwestern Asia. The development of hand axes from roughly chipped pebbles has been traced in Oldoway (Olduvai) gorge in Tanganyika. The Abbevillian type was superseded by the more regularly flaked Acheulian hand axes, associated with Ternifine and Swanscombe man. See also ARCHAEOLOGY. (K. P. O.)

ABBEY, EDWIN AUSTIN (1852–1911), U.S. painter, one of the foremost illustrators of his day, was born in Philadelphia, Pa., April 1, 1852. After studying at the Pennsylvania Academy of Fine Arts, he became in 1871 an illustrator for the publishing house of Harper and Brothers in New York. Harper's, because of his success, was persuaded to send him to England in 1878 to gather material for illustrations of the poems of Robert Herrick. These drawings, published in 1882, and followed by illustrations for Oliver Goldsmith's *She Stoops to Conquer* (1887), *Old Songs* (1889), and the comedies of Shakespeare, among others, established his reputation in England and America. His water colours and pastels were no less successful, and he was elected a member of the Royal Institute of Painters in Water-Colours in 1883. He first exhibited an oil painting at the Royal Academy in London in 1890; he was elected an associate (A.R.A.) in 1896, academician (R.A.) in 1898, and to the National academy in 1902.

In his later years he created several large decorative schemes, including murals in the Boston public library and in the state capitol at Harrisburg, Pa. He painted the official picture of the

coronation of Edward VII in 1902 and supervised the decoration of the peers' corridor of the houses of parliament just before his death. Aug. 1, 1911. His work, especially his perceptive drawings, water colours and sketches, was of consistently high academic quality. At his finest he achieved a degree of spontaneity and life seldom attained by artists of this persuasion. He is represented by works at the Metropolitan Museum of Art, New York; the Boston Museum of Fine Arts; Carnegie institute, Pittsburgh; and the Tate gallery, London. The Yale University Art gallery, New Haven, Conn., possesses a large collection of his work.

ABBEY THEATRE, the national theatre of Ireland, began in 1902 when the Irish Literary theatre's work in Dublin was taken over by W. G. Fay's Irish National dramatic company, which presented Irish plays with Irish actors. In 1903 it became the Irish National Theatre society. This brought W. B. Yeats, J. M. Synge, Lady Gregory, George William Russell (A?) and others into contact with the group of amateur actors which the brothers Frank and William Fay had been building up since 1891.

In 1904 an Englishwoman, bliss A. E. F. Horniman (*q.v.*), paid for the conversion of an old theatre and adjoining buildings into the Abbey theatre. Its early years were tempestuous. Synge's *The Playboy of the Western World* (1907) was greeted with almost riotous disorder. Tension and quarrels with the directors caused the resignation of the Fays later the same year—the chief but not the only schism of the early period. Two years later Miss Horniman withdrew her subsidy, by which time the company was strong enough to carry on. Lennox Robinson (*q.v.*) joined the management in 1910. He was active as dramatist, manager and director for more than 40 years and next to Lady Gregory (*q.v.*) did most to keep the Abbey going from 1916 to 1924, when the government subsidy was first given. Sean O'Casey brought a change in luck, and his plays, produced between 1923 and 1926, gave a splendid opportunity to a new generation of actors. George Shiels wrote plays from 1921 until his death in 1949, and Brinsley MacNamara, Paul Vincent Carroll and Denis Johnston made important contributions in the 1930s.

The Abbey's contribution to the world theatre is divided between a school of playwrights and a style of acting which abolished the "stage Irishman." Its plays are presented mainly in English but a few are in Irish. After a fire in 1951 the company moved to the Queen's theatre nearby. Plans were published (1958) for a larger theatre on the original site.

ABBON, SAINT, OF FLEURY (ABBO) (c. 930-1004), French Benedictine monk and scholar, who led a vigorous movement for monastic reform, was born near Orleans. In 985 he was invited to England to establish the monastery school at Ramsey. After his return to France, Abbon was elected abbot of Fleury on the Loire (988). He played a leading role at the synod of St. Basle where Archbishop Arnolf was tried for treason and deposed. At the monastery of La Réole in Gascony, he tried to re-establish strict Benedictinism by bringing in a group of his own reform monks. The original group at the monastery revolted against

the reformers, and Abbon was killed during the ensuing fracas. His feast day is Nov. 13.

Abbon's life, written by his friend and disciple, Aimoin of Fleury (and reprinted in J. P. Migne, *Patrologia Latina*, vol. cxxxix, pp. 375-414), is an important source for the reign of Robert II of France.

See Dom Patrice Cousin, *Abbon de Fleury-sur-Loire* (1954). (E. G. R.N.)

ABBOT, EZRA (1819-1884), U.S. biblical scholar, whose studies were chiefly in oriental languages and the textual criticism of the New Testament, though he was a remarkable bibliographer, was born at Jackson, Me., April 28, 1819. He graduated at Bowdoin college in 1840, and, after being principal of a public school in Cambridge, became assistant librarian of Harvard university. From 1872 until his death, on March 21, 1884, he was Bussey professor of New Testament criticism and interpretation in the Harvard divinity school.

Abbot's publications were largely dispersed in the pages of reviews and other publications. but to the enlarged American edition of Smith's *Dictionary of the Bible* (1867-70) he contributed more than 400 articles, besides greatly improving the bibliographical completeness of the work. His principal single production, representing his scholarly method and conservative conclusions, was *The Authorship of the Fourth Gospel* (1880; second edition, by J. H. Thayer, with other essays, 1889), up to that time probably the ablest defense, based on external evidence, of the Johannine authorship, and certainly the most complete treatment of the relation of Justin Martyr to this gospel. Abbot also was one of the original members of the American New Testament Revision company in charge of the Revised Version of the Bible.

See S. J. Barrows, *Ezra Abbot* (1884).

ABBOT, GEORGE (1562-1633), archbishop of Canterbury and the recognized leader of the Calvinists during the early years of the 17th century, was born on Oct. 19, 1562, at Guildford, Surrey, the son of a clothworker. Educated at Balliol college, Oxford, he became master of Gnivarsity college (1597) and dean of Winchester (1600). He was vice-chancellor of the university of Oxford at different times between 1600 and 1605, when his theological views brought him into conflict with Laud. He wrote *A Briefe Description of the Whole Worlde* (1599), *An Exposition upon the Prophet Jonah* (1600), and helped to prepare the Authorized Version of the New Testament (1611). James I sent him to Scotland in 1608 to arrange for the establishment of episcopacy there. In 1609 he became bishop of Lichfield and Coventry, in 1610 of London and in 1611 archbishop of Canterbury. He promoted the marriage between the elector palatine and Princess Elizabeth and resisted the proposal for the marriage of the prince of Wales to the Spanish infanta. In 1621 he accidentally shot a keeper while hunting. The question whether the homicide, though accidental, disqualified him from office was referred to a commission, on which King James exercised the casting vote in his favour. Under Charles I he was suspended from his functions as primate for refusing to license the assize sermon of Robert Sibthorp at Northampton (Feb. 22, 1627) advocating non-resistance to the royal demands, however arbitrary. He died at Croydon, Aug. 4, 1633. (G. H.U.)

ABBOT, WILLIAM (1789-1843), English actor, of whom William Hazlitt said, "he never acts ill," was born in Chelsea, London, and made his first appearance on the stage at Bath in 1806, and his first London appearance in 1808. He created the parts of Appius Claudius in Sheridan Knowles's *Virginus* (1820) and of Modus in his *Hunchback* (1832). In 1827 he organized the company, including William Charles Macready and Harriet Constance Smithson, which played Shakespeare in Paris. Abbot's two melodramas, *The Youthful Days of Frederick the Great* (1817) and *Swedish Patriotism* (1819), were produced at Covent Garden. He died in poverty in Baltimore, Md., on June 6, 1843.

(W. J. M.-P.)

ABBOT, is the official title of the superior of a monastic community that follows the Rule of St. Benedict (Benedictines [*q.v.*], Cistercians, Camaldolese, Trappists) and of certain orders of canons regular (Premonstratensians, Canons Regular of the

W. SUSCHITZKY
THE ABBEY THEATRE, DUBLIN, IRE.,
DESTROYED BY FIRE JULY 18, 1951

Lateran). The word derives from the Aramaic *ab, aba* ("father," "my father"), which in the Septuagint and Yew Testament Greek was written *abbas*. In early Egyptian monastic history, monks renowned for age and sanctity were called *abbas* by their disciples. The word signified the spiritual fatherhood which, according to the Scriptures of both Testaments, he exercises who teaches divine wisdom (e.g., I Cor. iv, 15). This father-son relationship between Christian teacher and disciple was also recognized in nonmonastic circles—e.g., by Irenaeus, Clement of Alexandria, Origen, etc.—and led to the term "Father" being applied subsequently to important early Christian writers. Originally, therefore, the title did not have the connotation of authoritative ruling. When monasticism in the east became more organized, under Pachomius and Basil, and more stress was correspondingly laid on the power of jurisdiction, the superiors of such monasteries were called not *abbas* but *proestos*; i.e., "he who rules." Its Latin equivalent, *praepositus*, was adopted in western monasticism by Cassian.

It was Benedict, in his "Rule for Monks," who restored the word *abbas*, the abbot being regarded as the representative of Christ in the monastery, who teaches and instructs in Christ's name. To this earliest concept of spiritual fatherhood through teaching, connoted by the word *abbot*, Benedict added the concept of *patria potestas*, the authority wielded by a father according to Roman law. The abbot has the fullness of authority to rule the monastery in temporal as well as spiritual matters; and the monks, his sons, owe him the typically Roman virtues of reverence, obedience and filial piety. The abbot's rule may therefore rightly be called monarchic. Yet it is also clearly constitutional, for the abbot himself is bound by the Rule, details of which, however, he may adapt according to changing needs. In the course of the centuries the Rule was supplemented by decrees of popes and councils, and more recently by the Code of Canon Law. Yet the supremacy of the abbot and his government of the monastery has never been seriously weakened.

Abbots at first were laymen, but beginning about the 5th century in the east, and, under the influence of that example, in the 7th century in the west, only an ordained priest was normally elected abbot. This became mandatory through a council of Rome in 826.

The Rule of St. Benedict stipulates that the abbot be elected by the monks of the monastery. As the monasteries became more and more influential, however, bishops and secular rulers often interfered and claimed the right to name abbots, or appointed abbots *in commendam*; i.e., persons who were granted the temporal revenues of the monastery. This latter abuse continued in some countries into the 18th century. It was so entrenched that every ecclesiastic of any standing possessed an abbey or two in *commendam*, and was therefore a commendatory "abbot." Hence it became customary to presume this honour in all ecclesiastics, and, in France, to address every priest as *Monsieur l'Abbé*.

As a protection against such encroachment, abbeys secured from Rome exemption from the jurisdiction of the local bishops, and also united in so-called "congregations." Such congregations become the norm in the 14th century, but the autonomy of the individual abbey, and correspondingly the authority of the abbot, were nonetheless jealously guarded, especially among the "black monks," the Benedictines. In 1893 Pope Leo XIII united all the Benedictine congregations into a federation presided over by an abbot primate who resides in Rome and has certain supervisory rights over the discipline of the abbeys. By the *Lex Propria* of 1947, the abbot primate's privileges and obligations were more closely defined. The Reformed Cistercians, or Trappists, were similarly federated under an abbot general in 1892.

According to law, an abbot is elected by the chapter of the monastery in secret ballot. He must be at least 30 years old, of legitimate birth, professed at least ten years and an ordained priest. An abbot is elected for life except in the English congregation, where by special dispensation he is elected for a term of 8–12 years. The election must be confirmed by the Holy See or by some other designated authority. The bishop of the diocese in which the monastery is situated confers the abbatial blessing, assisted by two abbots. This solemn rite, found in the Roman

Pontifical and dating back in part to the 8th century, strikingly resembles the consecration (*q.v.*) of a bishop, including a laying on of hands. Though not a sacrament, it is regarded as one of the most important sacramentals of the Roman Catholic Church because of the privileges and powers it confers. Chief among these are the power to administer tonsure and the four minor orders on his own subjects, and the right to celebrate Mass according to pontifical rite, to give many of the blessings normally reserved to a bishop, and to use the pontifical insignia of mitre, crosier, pectoral cross and ring.

Some abbots have ordinary jurisdiction over a given territory and govern it as a bishop does his diocese. They may administer confirmation, but, unless in episcopal orders, may not confer the major orders. Such an abbot is called *abbas nullius* (diocese); i.e., abbot belonging to no diocese. Archabbot is a title borne by abbots of certain distinguished monasteries.

In eastern monasticism, the superior of a community of cenobite monks is called archimandrite (*q.v.*) or hegumen. Idiorhythmic (i.e., "self-governing") monasteries, which made their appearance in the 14th century, are ruled by several elder monks whose leader is given the name of abbot. The election of a monastic superior is confirmed by the diocesan bishop, who also officiates at the blessing. Abbatial insignia include the *mandyas* (similar to the western *cappa magna*) and the *pateritsa*, the pastoral staff.

Abbess is the title given to the superior of certain communities of nuns following the Benedictine Rule, of convents of the Second Franciscan order (Poor Clares) and of certain communities of canonesses. The name is met with for the first time on a Roman inscription of 514. To be elected, an abbess must be at least 40 years old and a professed nun at least ten years. She is solemnly blessed by the diocesan bishop in a rite resembling that of the blessing of abbots. Her blessing gives her the right to specified pontifical insignia: the ring and, sometimes, the crosier. In medieval times, abbesses occasionally ruled double monasteries, of monks and nuns, and enjoyed various privileges and honours.

ABBOTSFORD, the country seat of Sir Walter Scott (*q.v.*) from 1812 till his death in 1832, lies 3 mi. W. of Melrose. Roxburghshire, Scot. Scott bought, in 1811, from the Rev. Robert Douglas of Galashiels, a farm of 110 ac. on the right bank of the river Tweed opposite Galashiels. He renamed the land Abbotsford. By successive purchases he enlarged it to 1,200 ac., much of which he planted with trees. To the original farmhouse he built (1817–19) a Gothic addition which he extended (1822–25) over the site of the old house, which was pulled down. Although he consulted Edward Blore, Daniel Terry and others, he himself superintended the planning and building of the house, employing as architect William Atkinson. In 1823 Scott installed a gas plant to light the house with oil gas. James Hope-Scott added a south wing in 1855. The house, still owned and occupied by Scott's direct descendants, is furnished substantially as it was in Scott's day and contains a valuable collection of books and historic relics. It is open to the public from March to October. (J. C. Co.)

ABBOTT, GRACE (1878–1939), U.S. social worker and reformer, influenced public opinion in favour of the child-labour amendment and related social legislation. She was born in Grand Island, Neb., Nov. 17, 1878, and educated at Grand Island college and The University of Chicago. In 1908 she went to Hull House, Chicago, as director of the newly formed Immigrants' Protective league. She exposed the exploitation of immigrants in a series of weekly articles ("Within the City's Gates") in the Chicago Evening Post (1909–10), in articles in the *Journal of Criminal Law and Criminology* (1911 and 1915) and in her book

The Immigrant and the Community (1917). As director of the child-labour division, U.S. Children's bureau (1917-19), she administered the first federal child-labour law. As chief of the bureau (1921-34) she administered the Maternity and Infancy act (1922-29). She was U.S. delegate to the International Labour organization in 1935 and 1937. While serving as professor of public welfare at The University of Chicago (1934-39) she edited the *Social Service Review* and published *The Child and the State*, 2 vol. (1938). Some of her papers were published posthumously under the title *From Relief to Social Security* (1940). She died in Chicago on June 19, 1939.

Her sister, Edith Abbott (1876-1957), was dean of The University of Chicago school of social service administration from 1924 to 1942. She died in Grand Island, July 28, 1957. (A. W. M.)

ABBOTT, JACOB (1803-1879), U.S. teacher and writer, was best known for his many books for young readers, including the "Rollo" series. Born at Hallowell, Me., on Nov. 14, 1803, he and his four brothers all attended Hallowell academy and Bowdoin college (Brunswick, Me.), studied at Andover Theological seminary (Andover, Mass.), and became teachers and ministers. After teaching at Amherst college (Amherst, Mass.), Abbott, in 1829, moved to Boston where he founded and was the first principal of the Mount Vernon school, a secondary school for girls. *The Teacher* (1833), which pioneered in advocating an appeal to students' honour and conscience in place of traditional disciplinary methods, was widely used as a textbook in early teacher-training institutions. In 1833 Abbott left Boston for suburban Roxbury, where his third son, Lyman Abbott (*q.v.*), was born. He devoted his time chiefly to writing. Later he established a home at Farmington, Me., where he died on Oct. 31, 1879.

He was sole author of 180 books, and co-author or editor of 31 others, notably the "Rollo" series (28 vol.). To accompany the earlier books (*Rollo at Work, Rollo at Play*), Abbott wrote a volume for teachers, *The Rollo Code of Morals, or the Rules of Duty for Children, Arranged With Questions for the Use of Schools* (1841). In following Rollo's travels about the world, with his all-knowing Uncle George, the young reader could improve himself with information on ethics, geography, science and history. Abbott also wrote 22 volumes of biographical histories and the *Francia Stories* (10 vol.).

BIBLIOGRAPHY.—The memorial edition of *The Young Christian* (1882) contains a biographical sketch by his son Edward Abbott; Lyman Abbott, *Silhouettes of My Contemporaries* (1921); Carl J. Weber, *Bibliography of Jacob Abbott* (1948).

ABBOTT, LYMAN (1835-1922), U.S. Congregationalist minister, was editor for almost half a century of the *Outlook*, and influential as a leading exponent of the Social Gospel. He was born at Roxbury, Mass., on Dec. 18, 1835, the son of Jacob Abbott (*q.v.*). He graduated from New York university in 1853, studied law and was admitted to the bar in 1856, left the practice of law to study theology and was ordained a minister in 1860. After serving in two pastorates he became associate editor of *Harper's Magazine* and in 1870 editor of the *Illustrated Christian Weekly*. In 1876 he joined Henry Ward Beecher as associate editor of the *Christian Union*, an undenominational religious weekly founded by Beecher, and in 1881 became editor in chief. After Beecher's death, he succeeded in 1888 to his pulpit in the Plymouth Congregational church, Brooklyn, where he served until resigning in 1899.

Abbott early became interested in industrial problems. Under his editorship the *Outlook* (as the *Christian Union* was renamed in 1893) became the first leading religious journal to enter into a discussion of labour problems, both editorially and through the contributions of such economists as Elp and such ministers as Washington Gladden (*q.v.*). With Gladden and Walter Rauschen-

busch (*q.v.*), Abbott was a leader in presenting the Social Gospel, which sought to interpret Christianity in terms of practical applications to industrial and social problems. His *Christianity and Social Problems* (1897), *The Rights of Man* (1901), *Industrial Problems* (1905), *The Spirit of Democracy* (1910) and *America in the Making* (1911) present his sociological views, which were middle-of-the-road, opposed both to socialism and to *laissez-faire* economics (see CHRISTIAN SOCIALISM).

On other problems Abbott led in presenting the viewpoint of liberal evangelical Protestantism. He sought to interpret rather than condemn the impact of the theory of evolution on religion. Abbott also popularized the point of view of "higher criticism." Among several popular devotional books, *The Other Room* (1903) and *The Great Companion* (1904) are notable. He published *Reminiscences* (1915; new ed. 1923). As editor he supported Theodore Roosevelt's presidential campaign of 1912, and early recognized as inevitable the entrance of the U.S. into World War I.

Abbott died in New York city, Oct. 22, 1922.

BIBLIOGRAPHY.—Character sketches and tributes in the *Outlook* (Nov. 8, 1922); Ira V. Brown, *Lyman Abbott, Christian Evolutionist: A Study in Religious Liberalism* (1953), containing extensive bibliography; C. H. Hopkins, *The Rise of the Social Gospel in American Protestantism 1865-1915* (1940).

ABBOTTABAD, headquarters of Hazara district and a military cantonment, lies 38 mi. N.N.E. of Rawalpindi. Pop. (1951) 27,617, including 14,163 in cantonment. Total area 7 sq mi. Abbottabad lies 4,120 ft. above sea level on a saucer-shaped plateau at the southern corner of the Rash or Orash plain with the snow-covered Kagan and Bhogarmang to the north and the wooded hills of Thandiani and the Galis to the east. It contains a men's and a women's college affiliated with Peshawar university and two public parks. It is the chief market town for the surrounding countryside and lies on the main road running from the Indus plainlands of Campbellpur district northeastward to the Kagan valley and Srinagar (Kashmir). The railroad is Havelian (10 mi. S.); the end of a branch line from Taxila on the Lahore-Rawalpindi-Peshawar main line. At Kakul (5 mi. N.E.) is the Pakistan military academy. Abbottabad was founded in 1853 and named after Maj. James Abbott, the first British deputy commissioner of Hazara. (K. S. Ad.)

ABBREVIATION. Strictly a shortening, the word abbreviation commonly refers to a letter or group of letters taken from a word or words and employed to represent it or them for the sake of brevity. Abbreviations, both of single words and of phrases, having a meaning more or less fixed and recognized, were common in ancient writings and inscriptions (see PALAEOGRAPHY). A common form of abbreviation is the substitution for a word of its initial letter, but one or more of the other letters are frequently added. Letters are often doubled to indicate a plural or a superlative. The list below gives a selection of common abbreviations with their meanings. Geographical names (for which see the list of abbreviations in vol. 24) are omitted; so are abbreviations for Christian names, weeks and months, points of the compass, and those which have passed into common usage as ordinary words, like Benelux, Cominform and gestapo. For symbols of the chemical elements, see ELEMENTS, CHEMICAL; for colloquial expressions (for example, O.K.) see AMERICAN ENGLISH and SLANG.

No universally accepted rule as to the use of periods in abbreviations has been followed. The method used in this article is to place periods after the initials of all organizations except U.S. government and United Nations agencies, and some, but not all, organizations whose letters form pronounceable words (called acronyms) such as WAVES. In cases where the abbreviation has multiple meanings, only the most common are given.

A.B.C. POWERS, a term used to denote the three leading nations of southern South America, Argentina, Brazil and Chile. The term refers particularly to their informal association, including the exchange of friendly speeches and official visits, which began about 1905 and was formalized in a five-year treaty in 1915. The treaty pledged the A.B.C. states not to war on each other without first attempting a neutral investigation of the causes of the conflict, but it was never implemented and had no lasting effect.

The most significant accomplishment of the A.B.C. countries was their joint mediation between the United States and Mexico in 1914. The mediation effort followed the U.S. bombardment of the port of Veracruz, Mex. (April 21–22, 1914). The mediation conference was held from May to August of that year at Niagara Falls, Ont. The good offices of the A.B.C. mediators contributed to a solution of the immediate dispute between Mexico and the United States if only by providing time for further diplomatic negotiations and, as it happened, for a change of presidents in revolutionary Mexico which worked to the advantage of the policy being pursued by Pres. Woodrow Wilson.

The importance of this South American "triple entente" lies in the indication it provided of the sensitivity of even remote Latin American nations to United States intervention south of the Rio Grande, and in the wider reputation it gave those nations as active partners in hemispheric affairs. (T. F. McG.)

ABD-AL-MALIK (‘ABD-AL-MALIK IBN MARWAN) (c. 647–705), Omayyad caliph from 685 to 705 and reorganizer of the Arab Muslim empire after the civil war of 680–692, was born at Medina in Arabia and lived there until 683. His father, Marwan I, was proclaimed caliph in Damascus in June 684 but was assassinated in April 685. Abd-al-Malik succeeded him, but was at first recognized only in Syria and Egypt. Several years were spent in recovering the empire. The rival claimant, Abdullah ibn al-Zubair, of Mecca, who was at first acknowledged in Iraq also, was defeated in 692 by Abd-al-Malik's able general al-Hajjaj. There were also bands of Kharijite and other rebels to be subdued and the Byzantines to be held in check. Eventually control was reasserted and the closing years of the reign were prosperous. Frontier campaigns recovered lost territories (as in central Asia) or prepared for further advances (as by establishing a firm base at Kairouan in Tunisia). Important internal changes were also made. Arabic became the official language in the financial offices instead of Greek or Persian. The first Islamic gold dinars were minted. To al-Hajjaj were due both the founding of a new garrison city for Iraq at Wasit, and the edition of the text of the Koran with vowels. Abd-al-Malik died in Damascus in Oct. 705. See CALIPHATE (W. M. Wt.)

ABD-AL-RAHMAN, the name of five Omayyad rulers, amirs and caliphs of Cordoba in Muslim Spain. (See CORDOBA, CALIPHATE OF)

ABD-AL-RAHMAN I (Abd-al-Rahman ibn Mu'awiya ibn Hisham) (reigned 756–788) escaped the massacre when the Abbasids overthrew the Omayyad caliphate in Syria in 750 (see CALIPHATE). Abd-al-Rahman after adventurous wanderings accepted an invitation to intervene between two warring Muslim factions in Spain. His energy, generalship and political vision enabled him to master a bewildering situation and to found, in 756, an independent emirate centred on Córdoba. With a standing army of mercenaries he temporarily repressed the rivalries of the Arab aristocracy and the anarchic tribalism of the Berbers in Spain, while defending his territories against invasions organized by the Abbasid caliph of Baghdad and the ruler of Meknès. His internal reforms, which included the formation of a council of state, the reorganization of the judiciary under a senior *cadi* and the division of Spain into six military provinces, together with his embellishment of Córdoba (where he constructed the famous mosque with its schools and hospitals) and his clemency to the Christians, have led historians to treat him as the equal of Charlemagne, the defeat of whose army in 778 at Roncesvalles (*q.v.*) by the Navarrese marked the end of a Frankish invasion of Abd-al-Rahman's domains.

ABD-AL-RAHMAN II (reigned 822–852), son of the amir al-Hakam I, was the fourth Omayyad amir of Córdoba. In spite of internal troubles, increasing seditiousness on the part of his Chris-

tian subjects and wars with the Franks, his reign was noted for the cultivation of the arts and sciences and for the enlightened encouragement of commerce and public works.

ABD-AL-RAHMAN III (Abd-al-Rahman ibn Mohammed ibn Abdullah) (reigned 912–961), the eighth and perhaps the greatest Omayyad ruler of Cordoba, was the first to use the title of caliph in Spain (Jan. 16, 929). He succeeded to the throne at the age of 22, when Omayyad rule was crippled by tribal warfare among the Arabs and by strife between them and Muslims of Spanish descent, while the greater part of Andalusia had seceded under the leadership of Ibn Hafsun. The first ten years of his reign were spent in restoring central authority, the rest in defending his northern borders against the inroads of the Leonese and in stemming the westward advance in north Africa of the Fatimids, who also claimed the caliphate. For a time his navy mastered the western Mediterranean, and he maintained diplomatic relations with the Byzantine emperor and with the princes of southern Europe. Under his rule Cordoba, with 500,000 inhabitants, was the largest and most civilized city of Europe. The seat of Europe's first academy of medicine, a centre for geographers, architects, craftsmen, artists and scholars of every kind, it rivaled for a brief period the splendour of Alexandria in the 4th century B.C.

ABD-AL-RAHMAN IV, styled al-Murtada (reigned 1018–1023), and **ABD-AL-RAHMAN V**, styled al-hlustazhir (reigned 1023–1024), succeeded to the caliphate in the death agony of the Omayyad dynasty. Both were puppets of factions which soon deserted them. The first was killed while fleeing from a battle in which his troops were victorious, while the second was dismembered, two months after his proclamation, by a revolutionary mob headed by his cousin.

See R. Altamira, "The Western Caliphate," *Cambridge Mediaeval History*, vol. iii (1922); P. K. Hitti, *History of the Arabs*, 5th ed. (1951). (K. G. A.)

ABD-AL-WADID DYNASTY (ZEIYANIDS OF BENI ZEYAN), a dynasty which ruled at Tlemcen (*q.v.*) in northwestern Africa from 1239 to 1554. In 1239, when the empire of the Almohads (*q.v.*) was breaking up, the amir Yaghmorasen, of the Abd-al-Wadid section of the Berber Zenata tribe, set up a new kingdom at Tlemcen, with the support of other Berber tribes and of immigrant Arab groups. This kingdom, however, had neither geographical unity nor fixed frontiers, being peopled mainly by Zenata tribesmen and equally nomad Arabs, and its internal life was much disturbed. The amirs, being unable to find enough Berbers for their armies, were forced to recruit from the unreliable Arab tribes, and their best troops were used for the suppression of internal rebellions. Attempts at expansion eastward and westward failed, and twice during the 14th century the kingdom was annexed by the Marinids of Fez. More than once also the Abd-al-Wadids acknowledged the Hafsid of Tunis as suzerains.

Tlemcen, on the trade route between the Mediterranean ports and Saharan oases, was long prosperous, and the Abd-al-Wadid amirs encouraged the growth there of Andalusian civilization. Several masterpieces of Spanish-Moorish art still bear witness to the city's past splendour. The Abd-al-Wadid kingdom, which had been declining since the 15th century, was overwhelmed by Ottoman Turkish troops from Algiers in 1554.

ABD-EL-AZIZ IV (ABD-AL-AZIZ IBN AL-HASAN) (1878–1943), sultan of Morocco from 1894 to 1908, whose reign was marked by the failure of the sherifian empire to modernize itself by its own efforts. When Abd-el-Aziz succeeded his father Mulay el-Hasan at the age of 16, the government was carried on for six years, on traditional lines, by his late father's chamberlain, Si Ahmed ben Musa, who acted as regent. On the latter's death in 1900 the young ruler, whose mother was a Circassian and who was glad to seek European advice, attempted to modernize the country and in particular to reform the methods of taxation. These

well-meant endeavours, defeated because of the complete lack of administrators trained on modern lines, caused great resentment among influential notables of the old school. This was further accentuated by the sultan's indulgence in childish and often fantastically expensive hobbies. The Anglo-French agreement of 1904, which deprived him of the hope of British aid to resist French encroachments, was a further blow. Nor did the German-sponsored conference of Algeciras (1906) help him in view of the increasing internal anarchy. A pretender, known as Bu Hamara, who claimed to be the sultan's elder brother, headed a rising and all but captured Fez. Though driven back he maintained himself in the eastern provinces. In 1907, the sultan's brother Mulay Abd-el-Hafidh raised the standard of revolt in the southern capital, Marrakesh. After seeking a loan in France, Abd-el-Aziz marched on Marrakesh in July 1908. His forces were however routed (Aug. 19, 1908) and he himself took refuge with the French troops established near Casablanca. Later pensioned by his brother, he spent the rest of his life at Tangier. See MOROCCO: *History*.

(N. BA.)

ABD-EL-KADER (ABD-AL-KADIR) (1808–1883), Algerian national leader, was born near Mascara in northwestern Algeria on Sept. 6, 1808, the third son of Mahi-ed-Din, head of the Kadria Muslim sect. Inured to hardship from early childhood, he became a fine horseman. He also received a sound education and grew up to be very devout. He made the pilgrimage to Mecca in 1827. In 1832, before the death of Mahi-ed-Din, who in 1832 had declared a holy war against the French in Algeria, Abd-el-Kader was proclaimed amir of Mascara. He built up his power astutely, taking advantage of the mistakes of the French and, when the French negotiated with him in 1834, making it clear to the Muslims that the French regarded him as the Muslims' leader.

Success, however, eluded him, and although he won a victory at La Macta (June 28, 1835) he could not prevent Gen. Bertrand Clauzel from sacking Mascara in December and was defeated by Gen. T. R. Bugeaud at Sikkah (July 6, 1836). Resourceful in adversity, he entered into negotiations, and the treaty of Tafna (May 30, 1837) saved his prestige just when the tribes were going to desert him. He still had difficulty, however, in establishing his authority over the tribesmen because of the rivalries of the different Muslim brotherhoods.

In 1839 Abd-el-Kader declared that the French by uniting Constantine and Algiers had broken the Tafna treaty, and holy war was again proclaimed. He laid waste the Mitidja and harried the French troops. In 1840, however, the French decided to compensate themselves in Algeria for the loss of prestige they had suffered over the Eastern Question and Bugeaud was given command of a reinforced army of 106,000 men. Abd-el-Kader lost Tlemcen in 1842, his Moroccan ally was defeated at Isly in Aug. 1844, and his success at Sidi Brahim (Sept. 1845) served only to postpone the French victory. He finally surrendered on Dec. 23, 1847, his only condition being a safe-conduct to the east for himself and his family. Although this was agreed, he was arrested and imprisoned in France first at Toulon, then at Pau and at Amboise (1848–52). He wrote at this time a philosophical treatise which was translated as *Rappel à l'intelligent, avis à l'indifférent*. Finally, on Oct. 16, 1852, he was released and, after a stay of nearly three years in Bursa in Turkey, he settled in Damascus (1855). There in 1860 he saved 12,000 Christians from a crowd of fanatical Muslims (for this he was awarded the *grand cordon* of the *Légion d'Honneur*). On a last visit to Paris (1863–65) he tried in vain to influence Napoleon III's Algerian policy. He died in Damascus during the night of May 25–26, 1883. See ALGERIA: *History*.

See Gen. Paul Azan, *L'Émir Abd-el-Kader, 1808–1883* (1925); P. d'Estaille-Chantereine, *Abd-el-Kader: l'Europe et l'Islam au XIX^{ème} siècle* (1947). (L. G.)

ABD-EL-KRIM (MOHAMMED ABD-AL-KARIM AL-KHAT-TABI) (1881–) achieved fame as leader of the resistance in the Moroccan Rif mountains to the implantation of the Spanish protectorate. His father, a caid of the Berber tribe of Ait Wariyagher, or Beni Uriaghel, gave him a Spanish education and he became *qadi al-qudat* ("chief Muslim judge") at Melilla and

editor of the *Telegrama del Rif*. First known as friendly to the Spaniards, he took offense at a slight offered him by a Spanish officer, was imprisoned, then fled to Ajdir near Alhucemas and organized armed resistance among the Beni Uriaghel. In 1921 he achieved a tremendous success by completely routing a Spanish force of 20,000 men under Gen. M. F. Silvestre and pursuing them into the suburbs of Melilla. He then organized the whole of the Rif and much of the country to the east into a rudimentary state under his own leadership. The Spanish withdrew from the interior and maintained themselves only in Tetuan. In 1925, however, the French advanced from the south into the valley of the Wargla, from which Abd-el-Krim had drawn supplies. He thereupon attacked them also and in the first onslaught almost reached Fez. This produced a combined Franco-Spanish reaction. The Spanish dictator, Primo de Rivera, organized a successful landing at Alhucemas, in the immediate neighbourhood of Abd-el-Krim's capital, Ajdir; while Marshal Pétain took charge of a French army of 160,000 men and attacked from the south. Soon the end was no longer in doubt; in May 1926 Abd-el-Krim surrendered to the French forces and was sent into exile on the island of Réunion. In his heroic struggle he had displayed great qualities, both military and administrative. If the technical disparity between Morocco and Europe had been no greater than it was in earlier ages he might well have succeeded in driving out the foreigners. But times had changed, and there was no possibility of restoring Moroccan independence until a new generation had grown up, educated in modern schools and methods. While himself a Berber, Abd-el-Krim was a good Arabic scholar and the administration which he introduced was essentially Arab.

After he had spent 21 years in exile on Réunion, the French government in 1947 authorized his residence in the south of France. While passing through the Suez canal he was persuaded by north African emissaries to accept from King Farouk an offer of refuge in Egypt. In Cairo, he presided over the organization known as the Maghrib office. He was, however, out of sympathy with nationalist leaders of the new school and, while disapproving of terrorism, was in other respects entirely intransigent. After the restoration of Moroccan independence, Sultan Mohammed V invited him to return to Morocco. This he refused to do as long as foreign troops remained on north African soil.

See W. B. Harris, *France, Spain and the Rif* (1927). (N. BA.)

ABDERA (modern AVDIRA in the *nomos* of Xanthi in Greece), an ancient town on the coast of Thrace, near the mouth of the Nestos river, almost opposite the island of Thasos. An attempt in the 7th century B.C. by Greek colonists from Clazomenae to occupy the site failed; but the people of Teos, evacuating their homes when the Persians under Cyrus overran Ionia (c. 540 B.C.), succeeded in establishing a colony there, which developed a brisk trade with the Thracian interior. Abdera was a prosperous member of the Delian league in the 5th century but was crippled early in the 4th century B.C. by the incursions of Thracian marauders and declined sharply in importance. The air of Abdera was proverbial in causing stupidity, but among its citizens were the philosophers Protagoras and Democritus. The ruins both of the ancient town and of a medieval settlement survive in the neighbourhood of Avdira.

ABDIAS, PROPHECY OF: see OBADIAH.

ABDICATION, the renouncing of office and of power before the end of the term for which it was assumed. In ancient Roman law *abdicare* meant primarily "to disown," as when a father disowned a son, who was thereby disinherited; but the word was also used in Latin as meaning "to renounce." In modern usage the word "abdication" is generally confined to signifying the renunciation of supreme power in a state. When it is said that a potentate abdicated, it may be implied that he did so voluntarily. But in many cases where abdication is alleged there is an obvious element of constraint, a show of willingness being put forward in order to avoid the consequences of what would otherwise have to be called deposition. Even so, in arguing that James II of Great Britain "abdicated" by his desertion of the kingdom, the Whigs of 1689 seemed to be straining the sense of the word.

Celebrated voluntary abdications include those of Sulla, of

Diocletian and of the emperor Charles V. The abdication of Edward VIII (*q.v.*) of Great Britain was the result of conflict between personal and political interests. Abdications in the face of military disaster, revolution or the threat of revolution include those of Napoleon I in 1814 and in 1815; of the French, Bavarian and Austrian sovereigns in 1848; of Tsar Nicholas II of Russia in 1917; of the German emperor William II and of the rulers of Bavaria, of Saxony, of Baden and of Wiirttemberg, as also of the tsar of Bulgaria, after World War I; of Kings Victor Emmanuel III of Italy, Leopold III of Belgium and Michael of Rumania after World War II and during the Communist subjugation of eastern Europe; and of King Farouk of Egypt in 1952.

ABDOMEN, the belly, the body cavity lying between the chest or thorax above and the pelvis below. The diaphragm is its upper boundary. There is no wall or clear-cut boundary between it and the pelvis. It contains organs of digestion and the spleen, which are surrounded by a serous membrane, the peritoneum. See ANATOMY, GROSS; GASTROINTESTINAL TRACT.

ABDOMEN, SURGERY OF. The diseases of this region are dealt with generally in the article GASTROINTESTINAL TRACT, DISEASES OF, and under their own names (*e.g.*, APPENDICITIS).

The main barriers to be overcome in the advancement of abdominal surgery were pain and infections. The first was overcome by the introduction of ether in 1846 and chloroform in 1847. Prevention or reduction of infection became possible after the introduction of antiseptic drugs in surgery in 1867, and was further advanced in the latter half of the 19th century through the development of aseptic techniques. With further improvement in the selection of anesthetic and analgesic drugs and in methods of administration, the length of surgical operations could be increased without danger to the life of the patient. Proper preparation of the patient before the operation and adequate care afterward still further increased the safety of surgery, even when it involved extensive surgical procedures. (See also ANESTHESIA AND ANESTHETICS.)

Discovery of the therapeutic value of sulfa drugs and antibiotics greatly diminished the incidence of postoperative infection and further decreased the danger of abdominal surgery. (See also ANTIBIOTICS; SULFONAMIDES.)

Types of Operations.—Operations on the abdomen may be elective or emergency. The former are those planned beforehand and executed at a deliberately chosen time. Emergency surgery is that which has to be performed at once or within a very short time. In some cases the nature of a contemplated operation is envisioned beforehand; in others it is determined only after the abdomen is opened, that is, after exploratory laparotomy.

Gastrointestinal Surgery.—The stomach and the small and large bowel are the major organs in this category.

The commonest stomach operations are those performed for cancer or ulcer. The stomach may be removed in *toto* (total gastrectomy) or a portion may be removed (partial gastrectomy). In the operation called gastrojejunostomy an artificial communication is made between the stomach and a loop of small bowel (jejunum) in order to bypass a duodenal ulcer or a benign pyloric stricture.

Gastrostomy is an operation employed on the stomach of patients suffering from constriction of the esophagus. It consists of making an opening in the stomach with an outlet on the anterior abdominal wall. Food is introduced into the stomach through this opening.

Operations on parts of the small bowel such as the duodenum, jejunum or ileum are employed when parts become gangrenous, as in intestinal obstruction or mesenteric thrombosis, or when they are invaded by malignant tumours. These conditions necessitate resection (removal) of the affected portion of the bowel. Among affections of the large bowel are appendicitis and cancer. Cancer may affect any part, but the rectum and the sigmoid are most often attacked. If cancer is detected early—that is, before there is involvement of other structures—it is possible to remove the diseased portion with the hope of a cure or of five-year survival.

Strangulation of loops of the bowel by a muscular ring of the abdominal wall (external hernia) or by peritoneal bands within

the abdominal cavity (internal hernia) requires immediate surgical intervention, ranging from mere cutting of the ring or band to resection of a loop of bowel if gangrene has developed.

Glands of the Digestive System.—Glands include the liver (with the gall bladder and extrahepatic biliary passages) and the pancreas. Resection of a portion of the liver was done occasionally in the second half of the 19th century for wounds or for removal of echinococcus cyst or carcinomatous growth. With the development of the control of hemorrhage by electro-surgery and particularly by suture methods, operations upon the liver ceased to be a rarity. Partial liver resection now is performed not only for the conditions mentioned above but also, for example, to expose branches of the biliary ducts and utilize them for establishment of anastomosis with a loop of jejunum.

Operations upon the gall bladder include several procedures—cholecystostomy, cholecystectomy, cholecystogastrostomy and cholecystenterostomy.

Cholecystostomy implies the formation of a fistula between the gall bladder and the exterior surface of the abdomen. It is done occasionally after the removal of gallstones by inserting one end of a rubber tube into the gall-bladder cavity and bringing the other end outside, thus allowing bile to flow outside the body.

Cholecystectomy denotes removal of the gall bladder. It is usually performed for chronic diseases of the gall bladder or after gallstones have been cleared. Cholecystogastrostomy consists of making an artificial communication between the gall bladder and the stomach. In cholecystenterostomy such a communication is made between the gall bladder and a loop of small bowel, usually the jejunum. These operations are performed to sidetrack the common bile duct when the latter is obstructed and there is no possibility of removing the obstruction, as for instance when the duct is compressed by a malignant tumour from the outside.

Cholecystojejunostomy or choledochojejunostomy is one of the surgical steps in removal of the pancreas with a portion of the duodenum, an operation known as pancreatoduodenectomy.

Although some comparatively simple operations on the pancreas were performed in the last quarter of the 19th century, it was not until the 20th century that the more complicated operative procedures, such as removal of stones and resection of part or even the entire pancreas, were attempted.

An operation is employed in which an artificial communication is established between the vena cava inferior and the vena porta (Eck's fistula), for relief of ascites or of hemorrhages from the veins of the lower esophagus, caused by cirrhosis of the liver.

Other Procedures.—These include sympathectomy, removal of the sympathetic nerves for spasm of the blood vessels in the legs; vagotomy, or division of the vagus nerves to the stomach to decrease the secretion of acid gastric juice; removal of the spleen for a variety of hematologic conditions; and replacement of the aorta with grafts for aneurysm or arteriosclerotic obstruction.

(J. L. SK.; P. V. H.)

'**ABDUH, MOHAMMED** (1849?–1905), a pioneer of modern Islamic thought in Egypt, whose legacy of personal character and educational leadership has become formative in Arab history. After a traditional mosque-school education, he became a devotee of Sufi discipline according to the Shadhili order, until he encountered Jamal al-Din al-Afghani, tireless advocate of Pan-Islamic revival, under whose powerful influence he was stimulated into fervent political and journalistic activity. Exiled to Syria in 1882, he traveled in France, Tunis and Lebanon. Returning to Egypt in 1888, he became convinced that the future called for a more Fabian approach. Thus he set himself to instigate wide legal and legislative reforms, to improve student conditions in al-Azhar university and to develop worthier standards among the sheikhs. But inertia and obscurantist hostility finally robbed him of any substantial fulfillment of his aspirations. He died on July 11, 1905.

It was this apathetic spirit of taqlid, or blind appeal to book-authorities, that 'Abduh sought by his writings to banish. His most significant works were an unfinished Koranic commentary and a treatise on divine unity (*Risalat al-Tawhid*) in which he set out his conviction of the essential rationality of Islam. He pre-

supposed the corpus of orthodox theology, aiming only to rid it of this incubus of traditionalism—a negative but urgent task in his day. On the positive side, he tended to a placid concept of faith, "in the knowledge that every sound speculation leads to a belief in God as he is described in the Koran" (*Risalat*, p.10). Holding this harmony between sound natural reason and revealed theology, he did not examine further his assumption that Islam was the religion of reason and the finally perfect faith, or delve into attendant problems. In these terms of attained ultimacy, he interpreted the familiar phrase describing Mohammed as "the seal of the prophets."

'Abduh's greatest achievement lay in the reforming range and vigour of his official *fatwas* as grand mufti of Egypt and in the devotion his personality evoked among his disciples, notably Rashid Rida, Taha Husayn and Mustafa Abd al-Raziq.

See C. C. Adams, *Islam and Modernism in Egypt* (1933).
(A. K. Cr.)

ABDUL-AZIZ (1830–1876), Ottoman sultan of Turkey, second son of the sultan Mahmud II, was born in Istanbul on Feb. 9, 1830, and succeeded his brother Abdul-Mejid I as sultan on June 25, 1861. He belonged to the Mevlevi sect (dancing dervishes) and loved music, painting and wrestling. Between 1861 and 1871 Abdul-Aziz cultivated good relations with Great Britain and France, with whose collaboration the troubles in Syria, the Balkans and Crete were settled. He was the first Ottoman sultan to visit Egypt (1863) and western Europe (1867). At the same time he continued his predecessors' policy of westernizing Ottoman institutions. On the suggestion of the French government, a council of state was established; an imperial college was opened for both Muslims and non-Muslims; and the first Ottoman civil code was promulgated. Abdul-Aziz enriched himself through the constant issue of state loans but squandered money extravagantly. He also received valuable gifts from Ismail Pasha, the khedive of Egypt, for making the succession to the khedivate hereditary from father to son in direct line and for extending the khedive's prerogatives.

After the French defeat in the Franco-German War, Abdul-Aziz deprived the grand vizier of his prerogatives and made himself an absolute monarch. Abandoning western ideas, he turned to Russia for friendship. In 1870 he signed the firman creating an exarchate in Bulgaria. Finally, however, insurrections in Bosnia and Herzegovina (1875) and in Bulgaria (1876) caused an outbreak of Muslim discontent in Turkey itself and of fanaticism against Russia and the sultan. Abdul-Aziz was deposed on May 29, 1876, and his death in Istanbul four days later is attributed to suicide.

(E. Z. K.)

ABDULHAK HAMID (1852–1937), Turkish poet and playwright, who introduced western influences into Turkish poetry, was born in Istanbul, Jan. 2, 1852, and educated in Paris and Teheran where his father, Hayrullah Efendi, a famous historian, was ambassador. He held diplomatic posts in Paris and Bombay, where his wife became mortally ill. Deeply affected, he wrote his poetic masterpiece *Makber* (1885). Later, when counselor in London (1885–1908), he remarried, and subsequently became ambassador in Brussels, senator (1914) and, finally, member of parliament in Ankara. He died in Istanbul, April 12, 1937.

A follower of the Tanzimat school of literature which developed from the movement for political reform, he was strongly influenced by Shinasi, Ziya Pasha and especially Namik Kemal. He soon broke with classical tradition, introducing western genres, techniques and ideas into poetry. Shakespeare and Victor Hugo greatly influenced him. His poems, mainly romantic and contemplative, are obsessed by ideas of death and human destiny. His best dramas (*Tarik*, *Tezer*, *Eshber*, *Ibn-i Musa*, *Abdullahüsagır*, etc.), written between 1876 and 1885, are inspired by Muslim history, though *Finten* (1887), his own favourite, portrays London society.

His powerful influence completely changed literary taste in Turkey, and paved the way for the more radical reforms of Tevfik Fikret and his successors.

See E. Rossi, "In morte del poeta turco Abd ul-haqq Hamid," in *Oriente Moderno* 17 (1937); A. Fischer, *Abdülhaqq Hamids dramatische*

Ruhlar, text with German trans. (1941).

(F. I.)

ABDUL-HAMID I (1725–1789), Ottoman sultan of Turkey, succeeded his brother Mustafa III on Jan. 21, 1774. He was a practical man, but at the same time superstitious, believing in his own sanctity. During his reign, the decline of Turkey became more pronounced: the disastrous treaty of Kuchuk Kainarji (1774) was concluded with Russia; Bukovina was ceded to Austria (1775); and the Russian annexation of the Crimea was recognized (1784). In order to prevent Russian schemes for the partition of his territories, the sultan in Aug. 1787 declared war on Russia and Austria, in accord with the Russian plans, joined in the war against Turkey the next year. Abdul-Hamid tried to reorganize his army with the help of French experts, but his efforts were frustrated by fanatics. He died on April 7, 1789, before the end of the war.

(E. Z. K.)

ABDUL-HAMID II (1842–1918), Ottoman sultan of Turkey from 1876 to 1909, was born in Istanbul on Sept. 21, 1842. A son of the sultan Abdul-Mejid I, he succeeded to the throne, at the deposition of his brother Murad V, on Aug. 31, 1876. Brought to power by a group of liberals led by Midhat Pasha (*q.v.*), he proclaimed the first Ottoman constitution on Dec. 23, 1876.

Circumstances, however, were ill-suited for liberal developments. Indignation had been aroused throughout Europe by the savage repression of the Bulgarian rising of May 1876; peace had not yet been ratified with Serbia; and the treasury was empty. Then, early in 1877, the disastrous war with Russia began (see **RUSSE-TURKISH WARS**). Though the hard terms of the treaty of San Stefano (*q.v.*) were mitigated mainly through British efforts at the congress of Berlin (*q.v.*), it became clear to the sultan that he could expect little more help from the western powers whose pressing requests for further reforms he was obstinately resisting. The first Turkish parliament, which had met in March 1877, was dismissed and the constitution suspended in Feb. 1878. Midhat Pasha was exiled in 1881 and died by violence in 1883. Thenceforward until 1908 the sultan's rule was absolute.

After the French had occupied Tunisia (1881) and the British had consolidated their hold over Egypt by overthrowing Arabi Pasha (1882), the sultan turned more and more to Germany for support. Germans were employed to re-organize his finances (by a decree of Dec. 1881 many of the imperial revenues had been handed over to the public debt administration for the satisfaction of bondholders) and to train the Turkish army. In return for this help, concessions had from time to time to be made to Germany, culminating in 1899 in permission to construct the Baghdad railway (*q.v.*).

Though he resented the Bulgarian occupation of eastern Rumelia in 1885, Abdul-Hamid was able to maintain toward Bulgaria an attitude astutely calculated to suit both German and Russian wishes. In Armenia, however, there was agitation from 1890 onward for the reforms promised at the congress of Berlin, and in 1894 a serious rebellion broke out. When this was ruthlessly suppressed, the European powers demanded reforms. The granting of these (autumn 1895) was followed by massacres of Armenians both in Armenia itself and also in Constantinople (mod. Istanbul), and the reforms came to nothing.

Meanwhile Crete had been constantly in turmoil, and Greek support for the Cretans led in 1897 to war. In this the Turks were easily successful (see **GRÆCO-TURKISH WAR**, 1897) and gained a small rectification of the frontier from Greece, but a few months later Crete was taken in trust by Great Britain, Russia, France and Italy who appointed Prince George of Greece as their mandatory. Germany and Austria did not participate in this, and in 1898 the sultan received the visit of the German emperor William II.

In his opposition to European pressure, Abdul-Hamid had always insisted on his role as the champion of Islam against Christian aggression. Pan-Islamic propaganda was encouraged; the privileges of foreigners in the Ottoman empire were curtailed; the Hejaz railway was pushed on toward the Muslim holy places in Arabia; and emissaries were sent far afield to preach Islam and the caliph's supremacy. This appeal to Muslim sentiment, however, failed to prevail over the disaffection caused by Turkish misgovernment. In Mesopotamia and Yemen disturbances were endemic,

and in the nearer parts of the empire the loyalty of the army and the people could only be maintained by a police system of espionage and delation. Obsessed by the fear of assassination, Abdul-Hamid kept himself in fortified seclusion in the palace of Yildiz.

These conditions, together with fresh resentment at Turkish humiliations in the Balkans, led at last to the military revolution of the Young Turks (*see* TURKEY: *History*) in 1908. Abdul-Hamid capitulated, and on July 24, 1908, the restoration of the suspended constitution of 1876 was announced. The sultan, however, despite his correct behaviour, was suspected of intriguing with the reactionary elements in the empire, and this suspicion was confirmed by his acquiescence to the counterrevolution of April 13, 1909, when the new regime was temporarily overthrown. When the Young Turks' army from Salonika restored the new regime, Abdul-Hamid was deposed and his brother was proclaimed sultan as Mohammed V (April 27). Confined at first in Salonika, Abdul-Hamid was in 1912 brought back to Constantinople. He died in the palace of Beylerbeyi on the Bosphorus on Feb. 10, 1918.

Abdul-Hamid had a great capacity for work: before his accession, unlike any other Ottoman prince, he had managed a farm. His system of personal rule, however, though apparently successful for many years, was an anachronism. An opportunist, he was not vindictive, but he had no friends and was so mistrustful of other people that he used to extract his own teeth and prepare his own medicines.

See Sir E. Pears, *Life of Abdul-Hamid* (1917); Joan Haslip, *The Sultan: the Life of Abdul Hamid* (1958). (E. Z. K.)

ABD-UL-ILAH (1913–1958), regent of Iraq from 1939 to 1953 and crown prince thereafter, was born at Taif, the son of Ali ibn Husain who for a few months was king of the Hejaz. He accompanied his father thence to Baghdad in 1926 after the loss of the Hashemite family's throne and position in peninsular Arabia. Educated at Victoria college, Alexandria, interested in racing and polo, society and travel and possessing an attractive, intelligent personality, the amir Abd-ul-Ilah was called unexpectedly to act as regent for his cousin and nephew Faisal II when the latter, a child of four, succeeded to the throne of Iraq as a result of the death by accident of the boy's father, King Ghazi (April 4, 1939).

Abd-ul-Ilah showed throughout his regency an admirable loyalty and affection to the boy-king and resolutely upheld, with gifts and powers which steadily developed, the position of the throne. Compelled to leave Iraq for some weeks in 1941 on the seizure of power by Rashid Ali, he returned with British assistance; and thereafter, in close collaboration with Nuri as-Sa'id and other moderate statesmen, he opposed the more violent forms and personalities of local nationalism and saw Iraq's advantage in a policy of collaboration with the west. He paid numerous state visits to foreign capitals between 1945 and 1953 and, without unconstitutional action, played a considerable, indeed a central, part in Iraqi politics. Relinquishing his functions to Faisal II in 1953, Abd-ul-Ilah remained the king's constant adviser and supporter. He was assassinated with the king in the revolutionary uprising in Baghdad on July 14, 1958. *See* IRAQ: *History*. (S. H. Lo.)

ABDULLAH IBN HUSAIN (1882–1951), amir of Transjordan from 1921 to 1946 and king of Jordan from 1946 to 1951, may be said to have created that country. Born in Mecca, the second son of the sharif Husain (*q.v.*; later king of the Hejaz), he was educated in Turkey and became a member for Mecca in the Ottoman parliament. He played an outstanding role in preparing the Arab revolt against Turkey in World War I and in 1920 boldly occupied Transjordan, where he was recognized as amir by Great Britain, the mandatory power, in March 1921. He ruled as a benevolent autocrat, guided by British advisers, adroitly establishing Transjordan as an entity separate from Palestine by exacting a pledge from the British that Jews should not settle there. His Hashemite blood and typically Arab attributes — piety, courage, prowess as a marksman and love of poetry and laughter — endeared him to his people. But his unconcealed ambition to extend his rule to Syria and to form with Syria and Iraq a dominant Hashemite bloc embittered the long-standing feud between the Hashemites and the Wahhabi dynasty of Saudi Arabia. In World War II he sent his army, the Arab legion, to assist British troops

in Iraq and Syria. Rewarded in 1946 by the grant of full independence, he retained a treaty with Great Britain, renamed his country Jordan and became king.

When in 1947 the United Nations resolved to partition Palestine, Abdullah was the only Arab head of state to accept the plan. But, on failing to win his Arab neighbours to his view, he joined them in fighting the Jews in Palestine, where his army captured Old Jerusalem and played a decisive part in holding central Palestine for the Arabs. In 1950 he annexed these Arab-held territories to Jordan, thereby incurring the anger of the Egyptian, Saudi Arabian and Syrian governments, which considered that Arab Palestine should constitute a separate state under the control of Haj Amin al-Husaini, former mufti of Jerusalem. Thereafter Abdullah's problems increased. While his country was desperately impoverished by the arrival of thousands of refugees from Palestine, his new Palestinian subjects clamoured for a more democratic constitution. His enemies multiplied, and a plot to murder him was brought to fruition on July 20, 1951, when he was shot in the Aqsa mosque in Jerusalem by a young Palestinian Arab, a supporter of Haj Amin al-Husaini.

ABDUL-MEJID I (1823–1861), Ottoman sultan of Turkey, was born in Istanbul on April 23, 1823, and succeeded his father Mahmud II, on July 2, 1839, at the age of 16. Well-educated and able to speak French, Abdul Mejid was also liberal-minded and receptive of western ideas. He came to terms with Mohammed Ali (*q.v.*), the rebel Egyptian viceroy, and then attempted to carry through the program of reforms which he had inherited from his father. On Nov. 3, 1839, he issued an edict, known as the *Hattı-sherif* ("handwriting") of Gulhane, which contained some provisions regarding human rights. The lives and property of all Ottoman subjects, irrespective of race or creed, were safeguarded, and their right to justice guaranteed; and the incidence of taxation was determined and its collection regulated. A regular system of recruiting was introduced. These regulations heralded a new era known as the *tanzimat*, which was applauded by the liberals of Europe. Abdul-Mejid refused to surrender the Hungarians who had fled to Turkey after the rising in 1849. His liberal dispositions helped to secure for him the support of Great Britain, France and Sardinia in the Crimean War (*q.v.*) against Russia. In 1856, Abdul-Mejid issued a new regulation by which he accorded civil and political rights to his Christian subjects and opened the door to foreign capital. The later years of his life, however, were troubled by a financial crisis and by a conspiracy against him. He died in Istanbul on June 25, 1861. (E. Z. K.)

ABDUL-MEJID II (1868–1944), the last caliph and crown prince of the Ottoman dynasty of Turkey, was born on May 30, 1868, in Istanbul, the son of the sultan Abdul-Aziz and Hayranidil Kadın. Although confined to the palace until he was 40, Abdul-Mejid was considered to be better-informed than other Ottoman princes of the time, but his inconsistencies and his behaviour created a general impression that he was psychologically affected like his father and his elder brother. In 1918, when Mohammed V died and Vahid-ed-Din ascended the throne as Mohammed VI, Abdul-Mejid became crown prince, but he lost this title when Mohammed VI fled the country (1922) and the sultanate came to an end. He was then chosen caliph, but, four months after the proclamation of the republic, the caliphate was abolished (March 3, 1924) and members of the Ottoman dynasty were expelled. Abdul-Mejid died in Paris on Aug. 23, 1944. (M. P. P.)

ABDULRAHMAN (TUANKU ABDULRAHMAN) (1895–1960), the first king (*Yang di-pertuan Agong*) of the Federation of Malaya, was born at Sri Menanti, on Aug. 24, 1895, the son of Tuanku Mohammed, the ruler (*Yang di-pertuan Besar*) of Negri Sembilan. He accompanied his father to England in 1925 and remained to study law, being called to the bar from the Inner Temple in Nov. 1928. Returning to Malaya he held a variety of posts in the civil service. After his father's death he was, on Aug. 3, 1933, elected ruler of Negri Sembilan. A retiring but kindly man who

had inherited from his father a deep respect for constitutional law and a profound sympathy for his people, Tuanku Abdulrahman was admirably fitted to be Malaya's first king when, on Aug. 31, 1957, it became independent. He died at Kuala Lumpur on April 1, 1960. (R. O. WT.)

ABDULRAHMAN, TENGKU (1903–), first prime minister of Malaya, was born at Alor Star, Kedah, on Feb. 8, 1903, a son of Abdulhamid Halim Shah, sultan of Kedah, and a Thai mother. After a long period in England (from 1920), he returned to Malaya in 1931 to enter the Kedah civil service. He remained in Kedah throughout the Japanese occupation in World War II. Thereafter he again went to England and was called to the bar in 1949. On his return to Malaya he took a prominent part in politics as a leader of the United Malays' National organization (U.M.N.O.), succeeding Dato Onn bin Ja'afar as president in 1951. His great achievement as president was to effect the alliance of U.M.N.O. with the Malayan Chinese association. This was not easy, since before Malaya's first general election (1955) many members of U.M.N.O. would have restricted the number of Chinese candidates, and Malay religious leaders would have wanted Muslims to vote only for Muslims, *i.e.*, Malays. Tengku Abdulrahman resisted both these communal demands, and his alliance swept the poll, losing only one seat. In Jan. 1956, as chief minister, he headed a *merdeheka* ("freedom") mission to London, when the British government decided to grant Malaya self-government at once and independence by Aug. 31, 1957. He then became independent Malaya's first prime minister, and the success of that independence was largely due to his unselfish zeal, ability and winning personality. In Jan. 1961 he was made a companion of honour. (R. O. WT.)

ABDURRAHMAN KHAN (1844–1901), amir of Afghanistan from 1880 to 1901, was born in Kabul, the son of Afzal Khan and the grandson of Dost Mohammed Khan, the founder of the Mohammedzai (or Barakzai) dynasty. When his father was appointed governor of the northern province of Mazar, Abdurrahman, then about ten years old, went with him. Thereafter his youth was spent mainly in shooting, riding and military training.

Dost Mohammed died in 1863 and was succeeded by his third son Sher Ali Khan, whose elder brothers Afzal Khan and Azam Khan, with Abdurrahman's support, then rose in revolt. For several years civil war was waged with fluctuating fortune. When Sher Ali was finally victorious Abdurrahman Khan took refuge in Russian Turkistan. Warmly received by the governor, he lived at Samarkand from 1870 to 1880, profiting by his study of the Russian administrative system.

After the outbreak of war between the British and the Afghans (1878), which was followed by the death of Sher Ali and the deportation of his son Yakub Khan to India, Abdurrahman in 1880 returned to Afghanistan where he was heartily welcomed by the people. At a conference held at Kabul on July 22, 1880, the British, then in possession of Kabul and Kandahar, formally proclaimed him amir. All British troops were withdrawn from Afghanistan after Lieut. Gen. Frederick Roberts (later Earl Roberts) had relieved the siege of Kandahar, which Ayub Khan, Yakub's brother, had been besieging. Abdurrahman then set to work with great energy and determination to pacify the country and to consolidate his authority. His methods may have been grim and cruel but, as he himself confessed, he had to rule an iron people with a rod of iron. Ayub, who for a time was able to maintain himself in Herat, gave trouble intermittently till his final defeat in 1887.

After establishing law and order Abdurrahman turned his attention to the settlement of border disputes with his powerful neighbours. In 1887 agreement was reached on the demarcation of Afghanistan's northwestern border with Russia. At the end of a series of talks held near Kabul in Oct.–Nov. 1893 with a British delegation led by Sir Mortimer Durand, Abdurrahman was constrained to accept the Durand line as his frontier, relinquishing some of his hereditary rights over the tribes on the eastern border of the country.

In spite of these preoccupations Abdurrahman found time to reorganize the administrative system of the country and to initiate

internal reforms. He brought foreign specialists and experts in and imported machinery for making guns, rifles and cartridges; factories were established for the manufacture of boots, soap and candles; distilling apparatus and new agricultural tools were successfully introduced; the first modern hospital was established; and mines were successfully opened.

Abdurrahman Khan died in Kabul on Oct. 1, 1901.

ABEL, the second son of Adam and Eve (*q.v.*), portrayed in the fourth chapter of Genesis. He was a shepherd and offered the first born of his flock to the Lord, comparable to a faithful Israelite in the nomadic tradition. In a jealous rage, Cain, his brother, slew him, thus committing the "first murder." Cain was a farmer, and many interpreters feel that the story constitutes a polemic against agriculture. Its major concern, however, is the guilt incurred by shedding innocent blood. Cain must become a fugitive because his brother's blood, spilled on the soil and unavenged, puts a curse on him. Matt. xxiii, 35 and Luke xi, 51 cite the blood of Abel as an example of the vengeance of violated innocence. In Heb. xi, 4 and xii, 24 the blood of Abel becomes a type of the blood of Jesus. *See also* CAIN. (J. C. RY.)

ABEL, JOHN JACOB (1857–1938), U.S. pharmacologist and physiological chemist, was a specialist in the chemistry of the ductless glands. He was born on May 19, 1857, in Cleveland, O. After attending the University of Michigan, Ann Arbor (1876–79), he was principal of the high school and superintendent of the public schools of La Porte, Ind. (1879–80; 1880–82), receiving his Ph.B. in 1883. After a year of study at Johns Hopkins, Baltimore, Md., he studied chemistry and medicine at several European universities, receiving his M.D. from the University of Strasbourg in 1888. He was lecturer and professor of materia medica at the University of Michigan (1890–93); in 1893 he became professor of pharmacology at Johns Hopkins, and, in 1932, director of the Laboratory for Endocrine Research. From 1909 to 1932 he edited the *Journal of Pharmacology and Experimental Therapeutics*.

Abel isolated adrenaline (epinephrine), the blood-pressure raising constituent of the adrenal glands, in the form of a benzoyl derivative. He also isolated insulin in crystal form. He became internationally known through these discoveries and through his many studies on the chemical composition of animal tissue and fluids, albumoses in the tissues, the action of pthaleins, the poisons of mushrooms, hydrolytic products of proteids, carbamic acid and histamin. He died on May 26, 1938, in Baltimore, Md.

ABEL, KARL FRIEDRICH (1723–1787), German musician, one of the last great players of the viola da gamba, and a notable symphonist of the preclassical school, was born at Cöthen, Dec. 22, 1723. He played from 1748 to 1758 under J. A. Hasse in the famous Dresden court orchestra, and, going to England in 1759, became chamber musician to Queen Charlotte.

When J. C. Bach arrived in London in 1762 they became friends and later established a famous series of concerts, known as the Bach and Abel concerts, one of which, in 1775, inaugurated the celebrated Hanover Square rooms. At these concerts, Haydn's symphonies were first publicly performed in England. Abel himself was not only a fine performer on the viola da gamba, but a gifted instrumental composer; his first set of symphonies was published *c.* 1761 and achieved great success. He wrote about 40 symphonies, most of which were published: one was long attributed wrongly to the youthful Mozart (the so-called K. 18). Abel also published several sets of quartets and trio-sonatas, and a set of harpsichord concertos.

After the death of J. C. Bach (1782), he allowed his weakness for alcohol to gain hold upon him, and the last part of his life was clouded by this failing. He died in London, June 20, 1787. Some of his music has been reprinted; it has formal neatness and balance, and considerable melodic facility. His technical knowledge was highly regarded, and he was esteemed as a teacher, one of his most famous pupils being J. B. Cramer, who published some of his adagios (1820).

See S. M. Helm, *Carl Friedrich Abel, Symphonist* (1953).
(Cs. Ch.)

ABEL, NIELS HENRIK (1802–1829), Norwegian mathematician, a pioneer in the development of modern mathematics, was born on Aug. 5, 1802, on the island of Finnøy, near Stavanger, Nor., where his father was a minister. Shortly after Abel's birth, his father was transferred to the parish of Gjerstad, near the town of Risør (southeast Norway), and there the boy grew up, the second of six children. His mathematical talent was recognized, while he was a student at the Cathedral school in Oslo, by a young teacher, B. M. Holmboe (who edited the first edition of Abel's work, in 1839). While still in school he believed he had found a solution of the general quintic equation, but he discovered an error before publication.

In 1820 Abel's father died, mainly from drink, and left the family in poverty. The boy was able to enter the University of Oslo in 1821, sponsored by personal contributions of several of the professors. His first papers were published in 1823 in the new periodical *Magazin for Naturvidenskabene*. The topics were functional equations, integrals and the first instance of the solution of an integral equation. At this time Abel received a small stipend from the mathematics professor Rasmussen, which enabled him to take a trip to Copenhagen to make the acquaintance of the Danish mathematicians. Upon his return Abel found the proof for the result that the general quintic equation or higher had no solution in radical expressions; it was published in a small pamphlet at his own expense. In 1824 he received a government fellowship for mathematical studies in Oslo and abroad. The winter of 1825–26 he spent in Berlin with Norwegian friends, mainly geologists. He had the good fortune of making the acquaintance of A. L. Crelle, who became his close friend and protector. Inspired by Abel, Crelle founded the important *Journal für die reine und angewandte Mathematik*, the first volume of which is filled with papers by Abel. They concern such topics as equation theory, functional equations, integration in finite form, problems from theoretical mechanics and others.

Abel's early mathematical training had been in the formal calculating school typified by Euler. In Berlin he came into contact with the new direction represented by C. F. Gauss and A. L. Cauchy, requiring a much stronger degree of logical stringency. Under this influence he wrote a study of the binomial series, considered to be one of the classics in function theory. It contains the principles of convergent series with special applications to power series (Ostwald's *Klassiker der exakten Wissenschaften*, no. 71).

During the spring of 1826 Abel undertook a journey with his Norwegian friends through Prague, Vienna, northern Italy and Switzerland to Paris. Upon his arrival there he completed his *Mémoire sur une propriété générale d'une classe très-étendue de fonctions transcendentes*, which he himself considered his masterpiece. In this he gives a theory of integrals of algebraic functions—in particular, the result known as Abel's theorem, that there is a finite number, the genus, of independent integrals of this nature. This forms the basis for the later theory of Abelian integrals and Abelian functions. The paper was submitted to the French institute Oct. 30, 1826. Abel had hoped that it would open the door to the French mathematicians, but he waited in vain until his money gave out and he had to return to Berlin. There he completed his first long article on elliptic functions, a topic he had worked on in his student days. Abel returned to Norway heavily in debt. He subsisted by tutoring and a small grant from the university; beginning tuberculosis of the lungs aggravated his situation. In 1828 he received a substitute teaching position. His poverty and ill-health had little influence, however, on Abel's scientific production. He poured forth a great number of papers, principally on equation theory and elliptic functions. Among them are found the theory of the Abelian equations with Abelian groups. The theory of elliptic functions was developed with great rapidity in competition with K. G. J. Jacobi.

By this time Abel's fame had spread to all mathematical centres, and strong efforts were made to secure a suitable position for him. Bernadotte, the king of Norway-Sweden, was addressed directly by a group of members of the French Academy; Abel's friend Crelle

worked feverishly to secure a professorship for him in Berlin. But in the fall of 1828 Abel became seriously ill, and his condition deteriorated on a several-day sled trip at Christmas time to visit his fiancée at Froland. He died there on April 6, 1829, at the age of 26. The appointment to Berlin had just been made; posthumously he was awarded, together with Jacobi, the Grand Prix of the French academy for 1830.

Crelle stated in his obituary: "One may say that he was able to penetrate all obstacles down to the very foundation of the problems, with a force which appeared irresistible. . . . He distinguished himself equally by the purity and nobility of his character and by a rare modesty which made his person cherished to the same unusual degree as was his genius."

(O. OE.)

ABELARD, PETER (Lat. PETRUS ABÆLARDUS; Fr. PIERRE ABAILARD or ABÉLARD) (1079–1142), theologian and philosopher, was the son of the lord of Le Pallet in Brittany south of the Loire. Between c. 1094 and c. 1106 he studied logic at Loches and in Paris under Roscelin and Guillaume de Champeaux and taught it at Melun and at Corbeil. After one or two years in Brittany he returned to Guillaume's school; but the violent polemics with his master, whom he forced to change views on the nature of universals, made his stay in Paris difficult. He went again to Melun but was soon back in Paris as a teacher on the Mont Ste. Geneviève. After another interval in Brittany he attended Anselm of Laon's theological school (c. 1114) but alienated his masters by sharp criticism of their scholarship and went back to Paris as a teacher of logic and theology at Notre Dame. Fulbert, a canon there, entrusted him with the education of his brilliant niece Heloise. Abelard's love for her led to the birth of a child and to a secret marriage; Fulbert took his revenge by having Abelard emasculated; whereupon Heloise became a nun and Abelard a monk (c. 1118). In the monastery of St. Denis, he made himself unpopular by denouncing the worldliness prevailing there; and his success as a theologian prompted other theologians to probe his views on the Trinity. The council of Soissons (1121) ordered his first theological book to be burned and its author to retire to St. Médard. After returning to St. Denis, he fled to Provins because of the storm which he aroused by claiming that the traditional identification of St. Denis with Dionysius Areopagiticus was wrong. Soon he was allowed to found the community of the Paraclete (Le Paraclet, in the vicinity of Nogent-sur-Seine), which was later given to Heloise and her nuns. As abbot of St. Gildas de Ruys in Brittany (1125–c. 1132), he struggled to rule over corrupted monks, who even tried to murder him. In 1136 John of Salisbury was his pupil on the Mont Ste. Geneviève. In 1140 or 1141 he was faced with a new and stronger attack, led by St. Bernard of Clairvaux (*q.v.*), against his theological doctrines. The council of Sens and the pope condemned him. He decided to appeal to Rome, but on his way there was persuaded by Peter of Cluny to submit to the verdict of the council and make peace with Bernard. From Cluny he passed to the priory of St. Marcel near Chalon-sur-Saône, where he died on April 21, 1142.

The mainspring of Abelard's thought and teaching was his optimism concerning the power of human reason to achieve true knowledge in the natural and supernatural spheres; unaided reason would not lead to "comprehension" of all truth accessible to man, but would "understand" much which is more directly and more completely available through faith. Thus pagan philosophers knew something about God's Trinity; and ancient philosophy (which Abelard knew almost exclusively through the evidence of the Fathers and from Cicero, Aristotle's *Categories* and *De Interpretatione*, a section of Plato's *Timæus*, Porphyry's *Isagoge* and Boethius) provided sufficient evidence that God had also revealed himself, to some extent, outside Scripture, the incarnation and the church. Reason, philosophy and logic can still walk side by side with faith in the province of theology. The written words of Scripture and of the Fathers must be subjected to the scrutiny of reason; Scripture is God's work, produced through fallible

men, transmitted by fallible scribes, interpreted by fallible apologists; language is liable to innumerable ambiguities and changeable. A healthy skepticism is a steppingstone to knowledge. Should the mind, however, find itself on the verge of an insoluble conflict, Abelard would rather reject Aristotle than St. Paul. The aim of his teaching and writing was to give a more logically argued foundation to Christian doctrine and thus to defeat the contemporary heresies or dangerous views of such thinkers as Roscelin and Gilbert de la Porrée, but St. Bernard, among others, saw in those methods the very source of heresy.

As a philosopher Abelard excelled in his study of the nature of abstraction and in his search for the source of responsibility in human actions. His inquiries into the problem of universals, far from crystallizing in a moderate nominalism or intellectualism, ranged from a critical survey of the opinions of other philosophers to an analysis of the functions—logical and grammatical—of universal words, to a research into the various levels of knowledge and to a metaphysical discussion on the similarities of things and on the relationship between God and universality in created things. His inquest into the components and aspects of human action made him conclude that intention is what makes an action good or bad, independently of its being performed or not.

A man enthusiastically devoted to the search for truth, intellectually self-centred, impetuous and uncompromising, Abelard stimulated and inspired large numbers of pupils, angered—and was feared by—many of his elders and provoked equally stubborn opponents, foremost of all St. Bernard, to fight him. The direct influence of his writings was limited; the indirect influence of his teaching has yet to be assessed. No other works of the early 12th century give as clear a picture as do Abelard's of that deep concern with a vast range of problems or of that critical attitude toward past and contemporary solutions which characterized the period. In his poetical compositions, particularly in his *Planctus*, Abelard also left a mark in the history of Latin metric.

Abelard's extant works may be divided among five groups: (1) theological writings; (2) philosophico-theological writings; (3) logical treatises; (4) letters; and (5) poetical compositions. To the first group belong the successive elaborations of his *Theologium*, namely, the *Theologia "Summi Boni"* (of which the so-called *De Unitate et Trinitate* is an incomplete text), the *Theologia Christiana* and the *Theologia "Scholarium"* (of which the so-called *Introductio ad Theologiam* is one of the five known recensions); the incomplete *Apologia; Sic et non* (a collection of apparently contrasting passages from the Fathers on various theological topics); the *Expositio in Hexaemeron* and the *Expositio in Epistolam ad Romanos*; the *Sermons*; and some shorter treatises. The second group comprises the *Scito te ipsum* (the *Ethica*) and the incomplete *Dialogus inter Philosophum, Judaeum et Christianum*. The logical treatises include short commentaries on some works by Aristotle, Porphyry and Boethius; longer commentaries (*Logica "Ingredientibus"* and *Logica "Nostrorum petitioni"*); the *Dialectics*; and possibly the *De intellectibus* and the *Sententiae*. The letters comprise his autobiography down to 1132 (*Historia Calamitatum*), five letters to Heloise, a letter to St. Bernard and six other letters. The poetical compositions comprise hymns, sequences, the *Planctus* and the *Ad Astralabium filium*.

No complete edition of Abelard's works exists, and a few texts are unpublished. Collected works were edited by F. d'Amboise and A. Duchesne (1616); by Victor Cousin, *Ozivrages inkdits* (1836), and, with Charles Jourdain, *Opera hactenus seorsim edita* (1849–59); and by J. P. Migne, in *Patrologia Latina*, clxxviii (1855). Editions of separate works include those of the *De Unitate et Trinitate* by R. Stolze (1891); of the *Theologia "Summi Boni"* by H. Ostlender (1939); of the *Apologia* by P. Ruf and M. Grabmann, in *Sitzungsberichte der Bayerischen Akademie der Wissenschaften: Philos.-hist. Abt.* (1930); of *Sic et non* by E. L. T. Henke and G. S. Linderkohl (1851); of the *Logica "Ingredientibus"* (incompletely) and of the *Logica "Nostrorum petitioni,"* under the title *Peter Abelards philosophische Schriften*, by B. Geyer (1919–33); of the short commentaries and of the commentary on Boethius' *De Differentiis Topicis*, under the title *Scritti filosofici*, by M. Dal Pra (1954); of the *Dialectica* by

L. M. de Rijk (1956); of the *Historia Calamitatum* and other letters by J. T. Muckle, in *Mediaeval Studies*, xii, xv and xvii (1950–55); of the *Hymnarius* by G. M. Dreves (1891; also in *Analecta Liturgica Medii Aevi*, xlvi, 1905); of the *Planctus* by G. Vecchi (1951); and of the poem *Ad Astralabium* by B. Hauréau in *Notices et extraits*, xxxiv, 2, pp. 153–154 (1895). There are English translations of the *Ethics* by J. R. McCallum (1935); of the *Letters to Heloise* by C. K. Scott Moncrieff (1925; 1926); and of the *Historia Calamitatum* by J. T. Muckle (1954).

ABELL, SIR WESTCOTT STILE (1877–1961), British naval architect and engineer who did much to maintain the standards of British mercantile shipbuilding during and after World War I, was born on Jan. 16, 1877. After professional training at the Royal Naval colleges of Keyham and Greenwich and service in the admiralty as naval constructor, he was in 1910 appointed the first professor of naval architecture at Liverpool university, where he inaugurated a new course in that subject. From 1914 to 1928 he was chief ship surveyor, Lloyd's Register of Shipping, and greatly assisted the government's merchant shipbuilding program during World War I. Sir Westcott was created knight of the British Empire in 1920. Between 1928 and 1941, while professor of naval architecture at Armstrong college, Newcastle upon Tyne, he designed the Dover-Dunkirk ferry steamers. He was the author of several works on shipbuilding. He died on July 29, 1961.

ABENCERRAGES, a family or faction said to have been prominent in palace intrigues in the Moorish kingdom of Granada in the 15th century. The name seems to be derived from that of Yusuf ibn Serragh, head of the tribe under Mohammed VIII of Granada. Ginés Pérez de Hita's romance, *Guerras civiles de Granada*, originally entitled *Historia de los bandos de los zegríes y Abencerrajes* (1595), celebrates the family's feud with the Zegrís. A hall in the Alhambra (*q.v.*) is the reputed scene of the massacre of the family (*c.* 1485?). Chateaubriand's *Aventures du dernier Abencérage* (1826; new ed. with historical notes by P. Hazard and M. J. Durry, 1926) also has done much to preserve the name.

ABEOKUTA, town and capital of the province of that name of Western Region, Nigeria, Africa, lies on the east bank of the Ogun river, about 65 mi. N. of Lagos and 48 mi. W. of Ibadan, around a group of rocky outcrops about 600 ft. above sea level. The surrounding country is savanna. Pop. (1952–53) 84,451, (1959 est.) 95,000. Area about 5 sq.mi. The inhabitants are of the Egba branch of the Yoruba (*q.v.*) and have four chiefs of whom the *alake* (king) of Abeokuta is *primus inter pares* ("first among equals").

In spite of the abundance of local stone from the the Aro quarries south of the town, which have supplied granite for much of the new building in Nigeria, the majority of the houses of Abeokuta are of pounded laterite mud with pan (metal) roofs. The more notable buildings include the Ake (residence of the *alake*), the Anglican church, the Centenary hall (1930) and Abeokuta grammar school.

There are six secondary schools, among them the Blaize memorial institute for handicraft training, founded in the early part of the 20th century.

Farming is the main occupation of the inhabitants and the town is a centre for palm kernels and cocoa. A traditional craft is the dyeing of cloth in Yoruba patterns and colours (especially blue). The women of the tom-n have a strong organization for retail trade,

of which they have a virtual monopoly.

Abeokuta is on the main railway from Lagos to the north and on the older trunk road from Lagos to Ibadan, now replaced for through traffic by the shorter road through Shagamu.

According to local tradition Abeokuta ("under stone") was first settled about 1830 by people from townships in Egba forest in the Ibadan area who fled when their homes were destroyed by slave raiders. Their association with the British crown developed after the arrival of Christian missionaries in 1842 (Abeokuta was for a long time the headquarters of the Yoruba mission), through one of whom in 1850 Queen Victoria presented them with two Bibles, in English and Arabic (since twice replaced by British sovereigns). They gave their co-operation in suppressing the slave trade which still persisted along the coast; and in 1893, through the intervention of the governor of the colony of Lagos, a united Egba government was formed to end local rivalries, and a treaty of friendship and commerce was concluded between the alake and the British sovereign. In 1914 the Egba kingdom came formally under British protection on the amalgamation of Northern and Southern Nigeria. See also NIGERIA. (W. H. I.)

ABERCORN, EARLS AND DUKES OF. The 1st earl of Abercorn, JAMES HAMILTON (c. 1575–1618), the eldest son of Claud Hamilton, Lord Paisley, and grandson of James, 2nd earl of Arran (*q.v.*), was probably born on Aug. 12, 1575. He gained favour with James VI of Scotland, who appointed him privy councillor (1598) and hereditary sheriff of Linlithgow (1600). He was created Lord Abercorn (1603), and in recognition of his support of a proposed union between Scotland and England was created earl of Xbercorn, lord of Paisley, Hamilton, Mountcastle and Kilpatrick (1606). Later King James made him a privy councillor for Ireland (1615) and granted him estates in the barony of Strabane. He died at Monkton on March 23, 1618, and was succeeded by his eldest son JAMES (c. 1604–c. 1670), the 2nd earl.

The title of Abercorn, held by the head of the Hamilton family, became a marquise in 1790 and a dukedom in 1868. JAMES (1811–1885), the 1st duke, was born in London on Jan. 21, 1811, and succeeded his grandfather JOHN JAMES (1756–1818), the 1st marquess. In the house of lords he consistently supported Tory policies and was by Conservative prime ministers appointed lord lieutenant of Ireland (1866–68 and 1874–76). He held strong views on Irish land problems and forced upon the Liberal government several amendments to the Irish land act of 1880. He also laboured to end religious discrimination in education and became in 1879 the first chancellor of the Royal University of Ireland. He died at Baronscourt, County Tyrone, on Oct. 31, 1885.

His son JAMES (1838–1913), the 2nd duke, was born at Brighton on Aug. 24, 1838. He became a member of the household of the prince of Wales (afterward Edward VII) and accompanied him on a visit to Russia in 1866. He was president of the Irish landlords' convention (1888) and opposed land purchase, although this was a Conservative policy; nevertheless after George Wyndham's act (1903) he was among the first to sell land to his tenants. He was a stalwart Unionist and opposed the Home Rule bill of 1912. He died in London on Jan. 3, 1913.

JAMES ALBERT EDWARD (1869–1953), the 3rd duke, was born on Nov. 30, 1869. Like his father and grandfather he supported the Unionist interest. After the passage of the Government of Ireland act (1921) he became a senator of Northern Ireland and served as governor from 1922 to 1945. He died in London on Sept. 12, 1953, and was succeeded by JAMES EDWARD (1904–), the 4th duke.

ABERCROMBIE, LASCELLES (1881–1938), English poet and critic whose work is distinguished by clarity, intellectual power and keen interest in structure and form. Born at Ashton-upon-Mersey, Cheshire, Jan. 9, 1881, he was educated at Malvern college and studied science at Manchester, 1900–02. He then became a journalist and began to write poetry. His first book, *Interludes and Poems* (1908), was followed by *Mary and the Bramble* (1910), a dramatic poem—Deborak—and *Emblems of Love* (1912) and prose *Speculative Dialogues* (1913). A leading member of the Georgian group of poets, he collaborated with John Drinkwater, Rupert Brooke and Wilfrid Gibson in the periodical *New Numbers* (1914). His chosen metres, the irregular choric ode

and blank verse, reflected his feeling for classical poetry, especially Greek, as did his increasing concern to establish a philosophy of poetry and his interest in prosody.

After World War I, Abercrombie began an academic career with his appointment to the first lectureship in poetry at Liverpool university. There, as professor of English literature at Leeds (1922–29) and London (1929–35), and as reader in English literature at Oxford (1935–38), he showed keen critical and philosophical powers. His critical works include *Thomas Hardy* (1912), *An Essay Towards a Theory of Art* (1922), *The Theory of Poetry* (1924) and *Poetry, Its Music and Meaning* (1932). His most mature poetic work, *The Sale of St. Thomas*, a poetic drama the first act of which appeared in 1911, was published in 1931. He died in London, Oct. 27, 1938.

Abercrombie's *Collected Poems* were published in 1930. A collection of lectures, *The Idea of Great Poetry* appeared in 1925. See also O. Elton, *Lascelles Abercrombie* (1939).

ABERCROMBY, SIR RALPH (1734–1801). British soldier, whose command restored discipline and prestige to the British army after the disastrous campaigns in the Low Countries between 1793 and 1799, and who prepared the way for the successful campaign against Napoleon in Egypt, was born on Oct. 7, 1734, at Tullibody, Clackmannanshire, Scot. He was educated at Rugby school and at Edinburgh and Leipzig universities, where he studied law. Preferring a military career, he entered the army as cornet in the 3rd dragoon guards in 1756, served in the Seven Years' War and was schooled in the methods of Frederick the Great. In 1774 he was elected member of parliament for Clackmannanshire in the Whig interest. His opposition to the American war impeded his professional advancement and, disgusted with politics, he went out of parliament in 1780. On the outbreak of war with France in 1793 he returned to the army and was appointed to the command of a brigade under the duke of York, for service in Flanders. Commanding the rear column, he had to protect the army in its retreat from Holland in the winter of 1794–95. Returning home, he was made a knight of the Bath and appointed to the command of the British forces in the West Indies, in which capacity he seized the French sugar islands. During his absence there he was re-elected to parliament for Clackmannanshire without a contest (1796), but resigned his seat in 1798. He commanded the troops in Ireland in 1797–98 but, finding all his efforts to tighten military discipline and to end the excesses of the militia were thwarted by the Irish government, he resigned the command and was at once appointed commander in chief in Scotland. He served under the duke of York in the second expedition to the Netherlands in 1799. In 1800 he was given the command of the troops in the Mediterranean. After the failure of a descent on Cadiz, he was ordered to Egypt to expel or destroy the army which Napoleon had left there in 1799. Landing at Abukir bay on March 8, 1801, he advanced toward Alexandria. A French attack before daybreak on March 21 was beaten back with heavy loss, but Abercromby was mortally wounded in the hour of victory. He died on board the flagship "Foudroyant" on March 28 and was buried at Malta. His widow was created Baroness Abercromby of Tullibody and Abukir Bay. Major General Hutchinson, who succeeded him in the command and quickly completed the reconquest of Egypt, wrote of him and his troops: "It was my fate to succeed such a man, who created such a spirit and established such discipline among them that little has been left for me to perform, except to follow his maxims and to endeavour to imitate his conduct."

See Lord Dunfermline, *Sir Ralph Abercromby* K. B. 1793–1801, a memoir published by Abercromby's third son (1861); Sir John Fortescue, *A History of the British Army*, vol. iv. part ii (1906). (A. AL.)

ABERDARE, HENRY AUSTIN BRUCE, 1ST BARON (1815–1895), British statesman, who was home secretary from 1868 to 1873 and lord president of the council from 1873 to 1874, was born at Duffryn, Aberdare, Glamorganshire, Wales, on April 16, 1815. Coal discovered on the Duffryn and Aberdare estates of the family made him a rich man, always prominent in Welsh affairs. Entering politics as a Liberal, Bruce represented Merthyr Tydfil from 1852 to 1868, and Renfrewshire from 1869 to 1873, when he became a peer. Efficient and conciliatory, he served under

Lord Palmerston and Lord John Russell, gaining a high reputation as undersecretary at the home office (1862–64) and vice-president of the council for education (1864–66). Until his death Aberdare took an active interest in social and economic questions. He presided over several royal commissions and was first chancellor of the University of Wales. From 1882, when he became chairman of the National African company (later the Royal Niger company), he was associated with developments in west Africa.

He was a lifelong ardent admirer of W. E. Gladstone who described him as "a heaven-born Home Secretary"; yet Gladstone's first administration was much damaged by Bruce's policies. The trade union legislation of 1871 was contradictory and generally unpopular. Bruce, a sincere churchman, came to be regarded by both Anglicans and Dissenters as evasive in ecclesiastical matters. Above all, his regulation of liquor licensing in 1872, an attempted compromise on a controversial topic, contributed significantly to the defeat of the Liberals, "borne down in a torrent of gin and beer," at the general election of 1874. Now a liability to his party, Aberdare retired from politics. He died in London on Feb. 25, 1895. (A. F. T.)

ABERDARE (ABERDÂR), an urban district in the Aberdare parliamentary division of Glamorgan, Wales, at the confluence of the Dar and Cynon (the latter being a tributary of the Taff), 23 mi. N.N.W. of Cardiff by road. Pop. (1961) 39,044. Area 23 7/8 sq. mi. The neighbouring moorlands show evidence of occupation in pre-Roman times. The parish church of St. John the Baptist dates from the 12th century. Aberdare has a fine public park.

The town remained but a small nucleus among the scattered farms of the moorlands until the beginning of the 19th century when it grew rapidly because of the abundance of its coal and iron ore, and the population of the whole parish (which was 1,486 in 1801) increased tenfold during the first half of the century. Ironworks were established at Llwydcoed and Xbernant in 1799 and 1800 respectively, followed by others at Gadlys and Aberaman in 1827 and 1847. The building of the Glamorgan canal in 1811 connected these ironworks with the coast, but the railways superseded the canals and at the same time gave an impetus to the iron trade between 1820 and 1870. Previous to 1836 most of the coal mined in the parish was consumed locally, chiefly in the ironworks, but in that year the mining of steam coal for export was begun, pits were sunk in rapid succession and the coal trade, which at least since 1875 had been the chief support of the town, soon replaced the ironworks. Aberdare was severely affected by the depression of the 1930s. Some mines were abandoned, but others were modernized, while new fields and opencast sites were developed after 1945. There are several brickworks and breweries. After World War II many light industries were established in the vicinity, especially at Hirwaun. Cables, metal tubes and washing machines are made and a patent smokeless fuel is produced. A college of further education was opened at Cwmdare in 1955.

ABERDEEN, GEORGE HAMILTON-GORDON, 4TH EARL OF (1784–1860), British statesman, who was prime minister of the coalition government in office at the outbreak of the Crimean War, was born at Edinburgh, Scot., on Jan. 28, 1784. His parents both died before he was 12; his grandfather, the 3rd earl, who died in 1801, cared little for him and he was brought up by his guardians William Pitt and Henry Dundas (later Viscount Melville). He was educated at Harrow and St. John's college, Cambridge. He traveled in southern Europe and the Levant during 1802–04, and made useful excavations at Ephesus and Athens (hence Byron's reference to "The travell'd Thane! Athenian Aberdeen"). In 1805 he married Catherine, daughter of the 1st marquess of Abercorn; they were ideally happy together, but she died of consumption in 1812, and none of her children lived to come of age. He wore mourning for her for the rest of his life.

In 1813 Viscount Castlereagh, then foreign secretary, appointed him special ambassador to Austria. For nine months Aberdeen was one of the central figures in European diplomacy, helping to form and to hold together the coalition that crushed Napoleon's power. He signed the treaty of Toplitz (Sept. 1813), was present at the battle of Leipzig (October) and at the congress of Châtillon, and signed the treaty of Paris on May 30, 1814. Castlereagh, who

thought him too lenient to the French, then took over all the principal negotiations himself, and Aberdeen retired. One of his brothers, Sir Alexander Gordon, aide-de-camp to the duke of Wellington, was killed at Waterloo. In July 1815 Aberdeen was remarried, to his first wife's sister-in-law Harriet, dowager viscountess Hamilton, who bore him five children and died in 1833.

Aberdeen devoted much time, thought and money to his large estates round Haddo house, Aberdeenshire; he planted numerous trees there and greatly improved his tenants' conditions. In 1825 he persuaded parliament to pass the liberalizing Entail (Scotland) act. At Wellington's request, he became chancellor of the duchy of Lancaster in Jan. 1828, and in June took over the foreign secretaryship. He helped to settle the question of Greek independence, maintained neutrality in Portuguese affairs, and opposed France's designs on Algeria. Resigning in Nov. 1830, he did not again hold office for over a decade, except as secretary for war and the colonies in Sir Robert Peel's brief administration in 1834–35. Scottish church affairs much occupied him, and he strove without success to avert the disruption of 1843 (see SCOTLAND, CHURCH OF).

From Sept. 1841 to July 1846 he was again foreign secretary under Peel. The queen had confidence in him; his friendships with Metternich and Guizot, who became French foreign minister in Oct. 1840, and his pacific inclinations, helped him to do well. He established an effective entente with France, which survived a sharp quarrel over Tahiti in 1844, but not his own retirement. More importantly, he composed two long-standing boundary disputes with the United States, by the Webster-Ashburton treaty of 1842 and the Oregon treaty of 1846. He supported Peel in his corn law policy and resigned with him. On Peel's accidental death in 1850 he was acclaimed the leader of the Peelites.

They agreed with him in deploring Lord John Russell's Ecclesiastical Titles bill, introduced early in 1851, which forbade Roman Catholic bishops to use their territorial titles; but the measure was momentarily so popular that it prevented Aberdeen from accepting the queen's invitation to form a government on Russell's resignation that spring. In April he received Gladstone's ardent protests at the iniquities of the Bourbon regime in Naples, and took the matter up privately with Vienna; but the answer took so long to come that Gladstone published his *Letters* to him before it arrived, in July.

In Dec. 1852 Aberdeen succeeded in forming a coalition cabinet, composed of six Whigs, six Peelites and one Radical. The cabinet's harmony was almost entire, except for occasional notes of discord from Russell, who wanted to head it himself; and with Gladstone's celebrated first budget it had a successful year at home. Yet, during 1853, difficulties over the eastern question became so acute that war with Russia was unavoidable by the end of it. Public opinion in London forced war on a largely reluctant government. The prime minister, usually firm, upset Lord Clarendon, his foreign secretary, by vacillating. The two of them took a fatal step on Sept. 23; without consulting their colleagues, they ordered the fleet to Constantinople. The cabinet agreed, three months later, to send it into the Black sea; and the declaration of war that necessarily followed came in March 1854. At the time, Aberdeen could see no other step he could have taken; but in retrospect he felt himself responsible for the war. He never repaired a tumbledown church near Haddo; I Chronicles xxii, 7–8, David's account of his unwillingness to build the Temple, provided his reason. Aberdeen was ill-informed by the soldiers on the spot in the Crimea, but he was constitutionally responsible for their mistakes, and was driven from office by a strongly adverse vote of the commons in Jan. 1855. The queen created him a knight of the Garter on retirement. He lived on, an elder statesman and a Scottish patriarch, till his death in London on Dec. 14, 1860.

Though dour and stiff at first meeting, Aberdeen was a quick-witted man of great gentleness and sweetness of temper. Of singular uprightness and probity, he was almost too straightforward and naive to tackle the diplomats and politicians of his day. He was a sincere lover of peace; the cries of the wounded at Leipzig never ceased to ring in his ears.

Of his sons, the eldest, George John James (1816–64), became the 5th earl, and the youngest, Arthur (1829–1912), a successful

colonial governor, was created Lord Stanmore in 1893. His grandson, the 7th earl, was created marquess of Aberdeen and Temair in 1915.

BIBLIOGRAPHY.—Lord Stanmore, *The Earl of Aberdeen* (1893); Lady Frances Balfour, *Life*, 2 vol. (1923); H. W. V. Temperley, *England and the Near East: the Crimea* (1936). Aberdeen's papers (320 vol.) are in the British Museum. (M. R. D. F.)

ABERDEEN, a royal burgh, city and county of a city and the capital of Aberdeenshire (*q.v.*), Scot., is situated on a bay of the North sea between the rivers Dee and Don, 130½ mi. N.E. of Edinburgh by rail and 118 mi. by road and ferry. Pop. (1961) 185,379. It is the third city in Scotland and the chief seaport of the north of Scotland.

The City.—Aberdeen (Gaelic *Aber*, "mouth"; *deen*, "of the Dee") is called "the Granite city" from the gray granite of which it is largely built and which, gleaming in the sunshine, justifies the other popular name of "the Silver City by the Sea." The old market place (Castlegate), lying at the base of the Castle hill (this recalls the castle, which was demolished in the 14th century), has been a focal point of the burgh's activities since earliest times. Nearby are the oldest streets, dating from the 13th and 14th centuries. Union street, the principal thoroughfare (nearly a mile long) and King street, which were constructed early in the 19th century, form with Holburn street a main artery, 5 mi. in length, linking the Dee with the Don.

In the Castlegate stands the market cross (1686), an open-arched hexagonal structure, considered to be the most handsome of old crosses in Scotland. In the neighbourhood are three 17th-century houses, Wallace tower, Provost Skene's house (now a museum of local history) and Provost Ross's house. Behind a dignified granite façade in Union street stand the twin churches of St. Nicholas (the West, and the North and East), which occupy a building that until 1596, when it was divided, was the old parish church dedicated to the burgh's patron saint. The oldest parts of the structure are the transepts, which separate the two churches, and a small vaulted chapel (St. Mary's) built about 1430. The steeple above the transepts houses a carillon of 48 bells, the largest in Great Britain. The existing West church dates from 1755 (a famous Aberdeen architect, James Gibbs, was the designer) and its neighbour from 1838 (the work of another eminent Aberdonian, Archibald Simpson). In Old Aberdeen stand two pre-Reformation structures. One is the cathedral of St. Machar, built, partly of granite, between c. 1366 and 1530. Its heraldic ceiling is an interesting feature. The other is the chapel of King's college with its stately Crown tower (1505). Within the chapel are exquisite examples of oak carving on stalls and choir screen, and there (as also in the cathedral) are to be seen beautiful stained-glass windows by Douglas Strachan, a native of the city. Two old bridges survive in Aberdeen: the Brig o' Balgownie, spanning the Don and built, it is said, by order of King Robert I about 1320; and the old Bridge of Dee, completed in 1527.

There are many handsome new granite buildings in the city, in both traditional and modern design. At the east end of Union street stand the imposing municipal buildings (with a main tower 200 ft. in height), which assumed their present form in 1868–74. In the charter room is a valuable collection of documents and relics. No other burgh in Scotland possesses so complete a record of its past. The council's records cover the burgh's activities from 1398 to date, with one break: vol. iii (1414–33) is missing. In Union street also are Trinity hall, the home since 1847 of the incorporated trades, the Music hall with a well-proportioned Grecian portico and, dominating the west end, Christ church (Divinity hall). In Broad street, on a site once occupied by Grey Friars: stands Marischal college, the largest granite building in Great Britain. Part of the existing structure was erected in 1844 (to the design of Archibald Simpson), and in 1893–1906 considerable alterations and additions were made, including a magnificent granite frontage (400 ft. in length) and the Mitchell hall with a lofty tower (235 ft.) named after the donor, an alumnus of the university. The Roman Catholic cathedral of St. Mary is in Huntly street. In an attractive setting in a residential district called Foresterhill are Aberdeen's main infirmary build-

ings, completed in 1936. The parks, recreational grounds and open spaces in the city total 2,185 ac.

History.—Aberdeen's recorded history goes back to the 12th century. The oldest extant charter is one granted by William the Lion (c. 1179) conferring trade privileges on the burghesses. The burgh supported Robert Bruce during his struggle for Scotland's freedom. By a charter dated 1319 he handed over to the burghesses (for a small yearly feu duty) the royal burgh itself and extensive lands adjoining it, but a large part of this valuable gift was alienated in the 16th century. The burgh was burned by the English in 1336. In 1638 Charles I acknowledged the support given to his religious policy in Aberdeen by granting a "Great Charter" amply confirming the burgh's ancient rights. In the wars of the 17th century between royalists and parliamentarians Aberdeen suffered severely, particularly in an attack on the city in Sept. 1644 by the marquis of Montrose, fighting then on the king's side. In 1715 and again in 1745 the Jacobite pretender to the throne was proclaimed king by his adherents at the market cross, but while in 1715 there was displayed in the city a measure of enthusiasm for the Stewart cause this had waned 30 years later. From the early 19th century Aberdeen grew in size and importance, and in 1891 large adjoining areas, including the two burghs of Woodside and Old Aberdeen, were incorporated in it.

The history of Old Aberdeen is bound up with that of the cathedral. Legend tells that St. Machar, a disciple of St. Columba, was instructed to build a church in the northeast of Scotland at a spot where a river took the form of a shepherd's crook. Not far from the sea the Don river assumed such a form and, in a tiny hamlet nearby, the church of St. Machar was built. In the 12th century the status of this Christian settlement was radically altered when it became the seat of the bishopric of Aberdeen founded by David I. Thereafter the cathedral of St. Machar dominated the life of what in old documents was called Aberdon, but later became known as Old Aberdeen (or Aulton). Charters granted by James IV in 1489 and 1498 created it "a free Burgh of Barony for ever," with the church as its superior. The administrative control of the church continued till some time after the Reformation. Till 1891 Old Aberdeen had its own council, provost, trade guilds, etc. Recalling its former independence there remain the old town house and, nearby, a fragment of the market cross.

From early times Aberdeen was prominent in cultural and other achievements. It claims as its son Scotland's first poet, John Barbour (*q.v.*), author of *The Brus*. The earliest mention of a "play" in Scotland is to be found in Aberdeen's records—a performance of *Halybluid* in 1440. George Jamesone (c. 1587–1644), the first Scottish painter of whom there is any record, was a native of the city. Among a large number of others whose fame spread far beyond their birthplace were Alexander Cruden (*q.v.*), author of the *Concordance of the Holy Scriptures* (1737), John Hill Burton (*q.v.*), the historian, William Dyce (*q.v.*), the painter, Mary Slessor (1848–1915), missionary in Africa, Sir George Reid (1841–1913), president of the Royal Scottish academy, and Sir Arthur Keith (*q.v.*), the anthropologist.

Education.—For more than 260 years there were two separate, autonomous universities in the northeast of Scotland within a mile of each other. Through the efforts of Bishop William Elphinstone (*q.v.*), Pope Alexander VI authorized, by a bull dated Feb. 10, 1494, the foundation of a university in Old Aberdeen, and King's college was built. From the beginning King's offered a course in medicine—the first recognition of this subject by a university in what was later to become Great Britain. The second university was Marischal college in the main burgh, founded in 1593 by George Keith, 5th earl marischal, as an essentially Protestant institution to offset the Catholicism that persisted at King's, which was under the influence of the staunch Roman Catholic, George, 6th earl of Huntly. From 1641 to 1661 King's and Marischal were united under the name of King Charles's university, but the union was merely formal (virtually no change took place in administration or policy) and it was not until 1860 that a complete union was effected. Other institutions of higher education are the Robert Gordon's technical college, the training college

for teachers and (just outside the city) the North of Scotland College of Agriculture. Research work is carried out by the Marine laboratory and Torry station (fisheries), the Macaulay institute (soil) and (near the city) the Rowett institute (animal nutrition).

Of secondary schools the oldest is the grammar school, founded as the medieval burgh school. It occupies a handsome building in Scottish baronial style, opened in 1863. In the front quadrangle stands a statue of Lord Byron, who was a pupil there for a time. The only other old school is Robert Gordon's college, opened in 1750 as a "hospital" for the maintenance and education of "sons or grandsons of decayed Burgesses of Guild" of Aberdeen. The founder was an Aberdeen trader, Robert Gordon, who left his fortune of £10,000 to endow the institution. In 1881 the old "hospital" came to an end, its place being taken by the college, primarily a day school.

Communications, Commerce and Industries.—Not only has Aberdeen a good harbour and, at Dyce, 6 mi. N.N.W., its own airport, but it is also an important junction for rail and road communications between north and south. It is in fact the commercial capital of a large part of northern Scotland and, with its rich agricultural hinterland, is one of Scotland's largest livestock-selling centres.

The estuary of the Dee formed Aberdeen's first natural harbour, which was gradually improved in the course of the years. The construction of the North pier (1,200 ft.) in 1780 (on the advice of John Smeaton), the extending of this in the following century (after consultation with Thomas Telford), the completion of the South breakwater in 1878, etc., lessened the hazards of the navigation channel, while the building of quays, docks and warehouses and the diversion of the Dee into a new bed vastly improved the harbour facilities. The harbour can accommodate vessels drawing up to 27 ft. of water and is well provided with modern equipment. A dock bridge, opened in 1953, is of interest since it was the first aluminum-alloy bascule bridge to be constructed in Scotland. The harbour estate, administered by a board of commissioners, extends to 370 ac., of which 199 ac. comprise the water area. One valuable asset is the fish market (nearly half a mile in length with an average width of 52 ft.), which was opened in 1889 and considerably enlarged and modernized in the late 1920s. The trade of the port is extensive and links Aberdeen not only with other ports in Great Britain but also with the mainland of Europe (particularly Scandinavian, Baltic and Mediterranean countries), North and South America, Australia, etc.

Aberdeen owes its importance as the premier fishing port of Scotland and the third in Great Britain to the development of the steam-trawling industry. This was started in 1882 but is now being superseded by diesel-trawling. Linked with the fishing industry are ancillary trades, such as curing and ice manufacture. In the 19th century Aberdeen became famous for the construction of fast tea clippers (the best-known was probably the "Thermopylae") and, since iron replaced wood, its shipyards have launched trawlers, cargo vessels and tugs.

Since the middle of the 18th century granite has been quarried in Aberdeen (Rubislaw quarry is the main source) and, with other quarries in Aberdeenshire furnishing a plentiful supply of the stone, the city has become the largest centre of granite working in the United Kingdom, providing not only building material but also monumental work, sets for road paving, etc. Other industries include textile manufacturing (wool and linen), papermaking, engineering, the making of agricultural implements, plastics, paint, chemicals and fertilizers. Aberdeen has also become a popular holiday resort and it is the depot of the Highland brigade.

Administration.—The city returns two members to parliament. For local government it is divided into 12 wards, each returning 3 members to the council, on which also sits the dean of guild. The chairman of the council (and civic head) is designated lord provost.

ABERDEEN, a city of South Dakota, U.S., seat of Brown county, is located in the northeastern part of the state about 270 mi. W. by N. of Minneapolis, Minn. With more than 50 wholesale concerns in the city it is the financial and trading centre for a large wheat, corn, cattle and hog producing area extending into North Dakota.

Aberdeen's first settlers arrived in 1880 and the city, which was incorporated in 1882, has grown steadily since that time, exceeding 20,000 after mid-20th century. (For comparative population figures, see table in SOUTH DAKOTA: *Population*.) The state's early settlers were, for the most part, young men from the wooded areas of the east and, in smaller numbers, Scandinavians, Germans and Russians.

Northern State Teachers college, a four-year liberal arts and teacher-training college, was founded in Aberdeen in 1901. The largest teacher-training college in the state, it had an enrollment of more than 1,000 after mid-20th century. Presentation junior college, a Catholic school for girls, was founded there in 1951.

(M. G. Co.)

ABERDEEN, the largest city in Grays Harbor county, Wash., U.S., is located about 48 mi. W. of Olympia and Puget sound on the estuaries of the Chehalis. Wishkah and Hoquiam rivers which together make Grays harbour. It combines with its neighbouring communities of Hoquiam and Cosmopolis to form a single area of settlement.

Aberdeen is located just south of the wild areas of the Olympic peninsula and Olympic National park. The recreation facilities in the Olympic mountains, the Quinault Indian reservation and the nearby ocean beaches bring visitors from every state in the union. The foggy climate and heavy rainfall on the western slopes of the Olympics to the north promote the growth of vast stands of cedar, hemlock and Douglas fir. Although fishing is an important resource, Aberdeen's basic industry has always been lumbering. Many of its inhabitants are descendants of Finnish and Swedish immigrants who came to the region to work in the lumber camps and mills.

The site of Aberdeen was first visited by Capt. Robert Gray who came on the "Columbia" May 7, 1792. Gray named the bay Bulfinch harbour. Samuel Benn, a Scottish immigrant, established a cannery there in 1878 and platted the townsite in 1883. The population reached a peak of about 20,000 in 1930 and remained constant for the next three decades while that of the rest of the state increased about 81%. (For comparative population figures see table in WASHINGTON: *Population*.) Aberdeen is the home of Grays Harbor college, founded in 1930. (K. A. M.)

ABERDEENSHIRE, the sixth largest county in Scotland with a land area of 1971.4 sq.mi., projects shoulderlike into the North sea, bounded on the west by Banffshire and Inverness-shire, on the south by Perthshire, Angus and Kincardineshire. Pop. (1961) 298,503.

Physical Features.—Although the county lies north of the Highland boundary fault, it consists essentially of an agricultural lowland drained by rivers which flow generally in an easterly direction. This low coastal plateau rarely rises more than 400–600 ft. above sea level except where it is surmounted by resistant rock formations such as the quartzites of the Hill of Mormond in the northeast of Buchan or the outliers of the Highlands. Elsewhere it is a rolling countryside, wind-swept and almost devoid of trees except in sheltered situations. The gentle slopes are mantled with glacial debris and dissected by the melt-water channels of the ice sheets which converged from the Grampians, the Moray firth and Strathmore. Marshy wastes, peat bogs, lochans

and infertile, often stony moorlands, penetrated by haughs or riverine lands along the Dee, Don, Deveron, Ugie and Ythan which were, and still are, liable to flooding, have been transformed by the plow and drainage to make the essentially agricultural landscape of today. Fertile raised beaches fringed with expanses of sand dunes alternate with magnificent cliffs cut in metamorphic and igneous rocks or Old Red Sandstone along the North sea and Moray firth to give an exposed coast broken only by small estuaries of which two, the Dee and Ythan, are navigable for a short distance inland.

The lonland of Buchan, and its southerly continuation in Formartine and Mar, terminates abruptly against the steep slopes of the Grampians (*q.v.*), which form a mountainous or upland rim to the west and south. From these heather-covered or cold stony wind-swept plateaus dissected by corries, which culminate in Ben Macdhui (4,296 ft) and other peaks such as Braeriach, fingers of the Highlands spread north and east back into the lowlands while the valleys of Dee and Don and their tributaries bring lowland conditions far into the highland zone. These cultivated glens, straths or wider basins, such as the Howe of Cromar, Strathbogie, the Howe of Alford and the Garioch, offer a sharp contrast with the uninhabited peaty flat upland surfaces of the Hill of Fare, or the steep rocky slopes of Bennachie. Only at the southeastern and northwestern extremities is there easy connection with adjacent regions, although in the historical period the southern upland rim or Mounth was frequently crossed by glen and moorland routes which penetrate it from Strathmore in the south and from the Dee valley in the north.

The Old Red Sandstone rocks which probably once covered the whole area have been almost completely stripped away, except where preserved by down faulting, as in Strathbogie and in a belt between Turriff and the north coast, to reveal the underlying complex of igneous and metamorphic rocks. Although mainly composed of closely folded and faulted metamorphic rocks of the Dalradian series, with a Caledonian or north-northeast to south-southwest trend, the continuity is broken by masses of plutonic and hypabyssal intrusions, so that wide areas of gabbro and granite rocks occupy large parts of Aberdeenshire. These granites were formed both prior and subsequent to the folding of the main metamorphic rocks, and the Newer Granites such as the salmon pink variety from Peterhead, the gray of Aberdeen and the light-coloured rock from Kemnay have given rise to the important quarrying and polishing industries of the country. Over most of the lowlands and in the highland valleys, the solid geology is effectively masked by the deposits of the ice streams which invaded the district from the Cairngorms, the Moray firth and Strathmore, the latter leaving a characteristic belt of red clays and moraines with marginal channels along the coast as far north as Peterhead, covered in places by deposits of the valley glacier of the Dee. The salmon- and trout-bearing Dee, Don and other rivers have been diverted in many places, while lochs have been impounded by moraines as at Loch Kinord and Loch Davan on the Muir of Dinnet on Deeside.

Situated on the east of Scotland in the rain shadow of the Grampians, the climate of Aberdeenshire is generally dry with parts of the coastal strip receiving less than 25 in. of rain annually, but cold sea mists occasionally cover a narrow belt along the littoral and penetrate farther inland along the river valleys. Temperatures are warm for the latitude but exposure to cold winds from the north and east gives a somewhat harsh winter climate. High-level hill roads have been blocked with snow in June.

The subalpine vegetation on the highest summits and plateaus gives way at lower levels to heather moors, which are found also on the unreclaimed sections of the lowlands and on the older dunes along the coast. Elsewhere the natural vegetation of the lowlands has been modified by cultivation, except, for instance, on the sandy outwash deposits of the Dee valley which are still under forest. The fauna ranges from the eider ducks and waders of the nature reserve of Forvie, at the mouth of the muddy Ythan estuary, to the deer, mountain hares, golden eagles, grouse and snow buntings of the high Cairngorms. On the lowlands the development of agriculture has encouraged the growth of a vege-

tarian population, including hares and rabbits. (K. W.)

History.—some of the coastal stretches of the county and parts of lower Deeside have been occupied since Mesolithic times. One or two long cairns of the Neolithic period survive; but the effective colonization of the area dates from the settlement of the Beaker folk, coming direct from Holland at the commencement of the Bronze Age, about 2000–1800 B.C. To the latter part of this period belong the stone circles and round cairns in which the shire is so rich. A special type of stone circle, marked by a recumbent stone in the southwestern sector, is almost restricted to the area between Dee and Spey. The Iron Age is represented by numerous earth houses and a group of massive stone hill-forts—two of which, on Dunnideer and Tap o' Noth, are vitrified. At the dawn of history the county was occupied by Celtic tribes whom Ptolemy called Taixali. Later, Aberdeenshire formed part of the territories of the Northern Picts. Roman marching camps exist at Culter, Kintore and Ythan Wells. Christianity was introduced at an early period, and there were Celtic monasteries at various places, notably Old Deer and Monymusk. Early Christian sculptured stones of high artistic merit, many showing the mysterious Pictish symbolism, abound. Though the coast was exposed to Viking raids, definite traces of Scandinavian colonization are lacking; but with the advent of Anglo-Norman feudalism, sponsored by the Canmore dynasty, colonies of Flemings were introduced, by whom the wool trade was developed. Royal burghs were built at Aberdeen, Kintore and Inverurie, and were peopled mainly by English settlers. The great Celtic mormaorships of Mar and Buchan were in due course transformed into feudal earldoms (see MAR, EARLDOM OF; BUCHAN, EARLS OF). Gradually the old Celtic tongue became restricted to the upper parts of Deeside and Don-side, and in the 20th century it became extinct in the county.

Aberdeenshire played its part in the long struggle between the rival houses of Canmore and Macbeth. It was at Lumphanan on Deeside that Macbeth (*q.v.*) fell in 1057, and his stepson Lulach, who continued the struggle, was killed next year at Essie in Strathbogie. During the Anglo-Norman penetration great families such as the Balliols, the Bruces and the Comyns obtained a footing in the shire. When the contested succession between these three houses resulted in the Scottish War of Independence, Edward I twice traversed the county, in 1296 and 1303; and a famous event was the heroic defence of Kildrummy castle in 1306. Robert Bruce's victory next year near Inverurie may be regarded as a turning point in the struggle, and was followed by the savage harshep or wasting of the Comyn earldom of Buchan (see ROBERT I, "THE BRUCE"). Another turning point was the victory of the nationalists at Culblean on Deeside in 1335. The triumph of Bruce resulted in the settlement of new families, among whom the Forbeses and the Gordons emerged as the principal rivals in the period of feudal strife during the 14th and 15th centuries. A deep mark was left upon the memory of after generations by the bloody battle of Harlaw (1411), in which Donald, lord of the Isles, seeking to enforce his claim to the earldom of Ross against the earl of Buchan, was defeated by Alexander Stewart, earl of Mar. Sir Alexander Forbes and Sir Alexander Seton of Gordon were created Baron Forbes and earl of Huntly respectively in 1445; and the struggle for power between these two families fills up the history of the next two centuries. Its bitterness was intensified by the fact that, in the main, the Forbeses accepted the Reformation, while the Gordons adhered to the ancient faith. Huntly castle, the chief seat of the Gordons, became in effect the Scottish headquarters of the counter-Reformation. A notable event in the struggle was the victory of the royal forces over the earl of Huntly at Corrichie on the Hill of Fare (1562) (see GORDON; HUNTLY [EARLS AND MARQUESES OF]). During the Civil War of the 17th century Aberdeenshire emerged as a stronghold of royalism and episcopacy. The very first action of that war was known as the Trot of Turriff (1639). Inevitably the county was the scene of much fighting, notably the marquess of Montrose's victories in the royal cause at Aberdeen and Fyvie (1644) and Alford (1645). Aberdeenshire also witnessed some of the most agile marches and countermarches of John Graham of Claverhouse and Hugh Hlackay during the Jacobite rising of 1689.

Meanwhile, trade with the low counties, the Hanseatic league, Prussia and Poland had flourished, and in the 17th century this laid the foundations of a new wealth among some of the ancient county families. The progress of learning is marked by the founding of three universities—King's college in Old Aberdeen (1494), Marischal college in the new town (1593) and the short-lived University of Fraserburgh (1597). The episcopacy of the northeast, more favourable to culture than was Calvinism, reached its fine flowering in the celebrated school of scholars known as the "Aberdeen Doctors"—scattered by the "club law" of the Covenant.

From 1690, after the Revolution settlement, more tranquil conditions prevailed. Yet local devotion to Jacobitism and episcopacy persisted and found vent in the risings of 1715 and 1745. It was at Braemar (*q.v.*) that the Stewart standard was raised in 1715, and later in that year James, the Old Pretender, landed at Peterhead. A brisk event in the 1745 rebellion was the Jacobite victory at Inverurie. Upon the collapse of this rebellion the penal laws destroyed the ascendancy of episcopalianism and the feudal power of the landowners, and paved the way for the ensuing era of agricultural and industrial progress.

The castles of Aberdeenshire range from Norman earthworks, like the Bass of Inverurie, the Peel of Lumphanan and the Doune of Invernochty, through the splendid royal stronghold of Kildrummy, to such fine Renaissance buildings as Huntly, Craigievar, Castle Fraser and Fyvie. Ecclesiastical architecture includes the Norman church of Monymusk and the remains of the Cistercian abbey of Deer. There are fine 16th-century sacrament houses, of a type peculiar to the northeast, at Kintore, Kinkell and Auchindoir. (W. D. S.)

Population and Administration.—The population in 1961 was 298,503, of whom 161,125 were in the Aberdeenshire portion of the city of Aberdeen (the small portion of the city south of the Dee is, for census purposes only, in Kincardineshire). The figures for the county were the lowest at any census since 1851 because of continued rural depopulation. The bulk of the rural population is found on the lowlands, where the larger towns such as Peterhead (12,497), Fraserburgh (10,462), Inverurie (5,152), Huntly (3,952) and Turriff (2,686) (*qq.v.*) are also situated. The supreme court of judiciary sits in Aberdeen to try cases from the counties of Aberdeen, Banff and Kincardine, while Aberdeenshire and Kincardineshire together return three members to parliament.

Agriculture, Industries and Communications.—The favourable environment of the lowlands has been intensively exploited since the re-organization of the economy and agricultural techniques which has been completed by about 1850. Emphasis was laid on the rearing of beef cattle, especially the famous Aberdeen Angus (see CATTLE), in association with arable farming to provide fodder, with sheep also important in both highland and lowland areas. The cattle industry gathered momentum as communications with London and the industrial markets improved. Oats are the predominant crop, with turnips, swedes, potatoes, barley and sown grasses on the remaining cultivated acreage, which extends to an altitude of about 800 ft., varying locally with the degree of exposure. Dairying and pig and poultry keeping are increasing in importance with the establishment of a surplus milk conversion unit, a bacon factory and egg-grading stations. About two-thirds of the population depend on farming, practised principally on small farms and crofts, while the fishing industry is the second most important occupation.

The steam trawler, which caused the eclipse of numerous small fishing ports and gave the county town of Aberdeen pre-eminence as the Scottish centre for trawling and great-line fishing, making it the chief port for white fish, is itself on the decline. Its place is being taken by diesel trawlers which, although fewer in number, are much more efficient. Fresh fish is taken increasingly to the southern markets by road rather than by rail, while new techniques, such as fish freezing at the port, are being intensively employed. Fraserburgh and Peterhead, formerly most important as seasonal herring ports, now give increasing attention to white fishing using dual-purpose seine-net vessels. Stake nets for salmon fishing are found along many sections of the coast.

Auxiliary industries such as boxmaking, curing and kippering are important in each of the fishing ports and the food- and fish-canning factory at Peterhead is of especial interest. Shipbuilding is prominent in Aberdeen, where large coastal, ocean-going and fishing vessels are built, while smaller, principally wooden, fishing vessels are produced at Peterhead and Fraserburgh.

Although there are precision industries at Peterhead and Fraserburgh, where twist drills and pneumatic tools, respectively, are manufactured and give much-needed diversification of employment, industry is concentrated principally in Aberdeen and its vicinity and steps are being taken to increase industrial employment there. Papermaking is important along the lower reaches of the Don, newsprint and high-quality papers being produced from imported pulp, esparto grass and rags. Granite working, using local and imported stone, is concentrated in many small yards where monumental polished masonry, granite facings and blocks for constructional work are prepared. Engineering workshops, linen- and canvas-weaving factories, and paint, chemical and fertilizer industries are also found in Aberdeen, which acts as a market and distributing centre for most of the north of Scotland. Elsewhere in the county industries include distilling and forestry and a railway repair workshop at Inverurie.

J. ALLAN CASH
PASTURE LAND OF UPPER DEESIDE, ABERDEENSHIRE, WITH BALMORAL CASTLE IN THE BACKGROUND

The attractions of the coastal and mountain scenery bring increasing numbers of tourists while the association of the royal family with Balmoral castle (*q.v.*) and upper Deeside is well known. Winter sports in the Cairngorms are being encouraged by the construction of ski tows and huts, and hotels which formerly closed in the winter now remain open all the year round.

Guided by the relief features, the main road and rail communications enter the county at the southeastern and northwestern corners, and although there are roads through and over the mountain rim these are liable to be blocked by snow in the winter. Some local railway lines have been closed, but a system of bus routes connects rural districts with their market centres and with Aberdeen. Air services from Dyce airport near Aberdeen connect with all parts of the United Kingdom, including the Shetland and Orkney islands, while regular steamer services for passengers, freight and livestock operate from Aberdeen to the northern isles and the southern ports.

ABERDOVEY (ABERDYFI, "mouth of the Dovey"), a small seaside town on the north side of the Dovey estuary, Merionethshire, Wales, lies 28 mi. N. of Aberystwyth. Pop. (1931) 1,262.

Its site has associations in Welsh folklore with coastal submergence (see CARDIGANSHIRE), and the song and legend of "The Bells of Aberdovey" are supposed to commemorate the inundation of the Lowland Hundred or Cantre'r Gwaelod (c. 520). During the 17th, 18th and 19th centuries Aberdovey had a considerable coasting and fishing trade and subsequently became a popular resort, because of its mild climate and pleasant scenery. It has a beach of firm sand which affords safe bathing, and there are excellent facilities for boating, fishing, golfing and rough shooting. The first Outward Bound Sea school for boys was established there in 1941.

ABERGAVENTNY, a municipal borough and market town of Monmouthshire, Eng., lies at the confluence of the Gavenny with the Usk, 15 mi. W. of Monmouth and 19 mi. W.N.W. of Merthyr Tydfil by road. Pop. (1961) 9,625. Area 3.7 sq.mi. Situated at the entrance of the pass between the Black mountains and the Brecon beacons, it is a popular tourist centre and a nodal point for roads joining England and Wales. It also lies on the main Newport-Hereford railway line.

Abergavenny (*Aber*, "mouth of river") was the Roman Gobannium, a legionary fortress guarding the road up the Usk. It grew under the Norman lords of Abergavenny and there are remains of its medieval walls and of the 11th-century castle built by Hamelin de Ballon or Baludin. He also founded the Benedictine mitred priory of St. Mary, the chapel of which later became the parish church. The town was frequently embroiled in the border warfare of the 12th and 13th centuries and was burned by Owen Glendower in 1404. At the dissolution of the priory part of its endowment went toward a free grammar school, founded in 1542, when the town received its first royal charter. Abergavenny showed strong royalist tendencies during the Civil War, when it suffered badly at the hands of Thomas Fairfax (1646), and in 1689 it lost its charter because of its Jacobite sympathies. The market was of consequence as early as 1200, but with the better roads and greater movement of the 18th and 19th centuries cattle and horse fairs became more important. Today trade is still largely agricultural, the cattle market being one of the largest in the south Wales area. In the 18th century Abergavenny was famous for its wigs and Welsh flannel; its present industries include iron founding, printing and the manufacture of machines and sweets (candies). Abergavenny was reincorporated in 1899 and its boundaries were extended in 1935.

ABERRATION (OF LIGHT). This is an astronomical phenomenon depending on the fact that light is not propagated instantaneously. Observations of the heavenly bodies are made from the earth, a planet whose speed of motion is not incomparably smaller than that of light; the result is that the apparent position of a star in the sky does not correspond to its true direction from the earth. It is customary to assume intuitively that a body is "where it is seen to be"; or, since the distance cannot always be judged, that at any rate it is in the direction in which it is seen. But actually vision gives only an indirect acquaintance with its position. That which affects the observer's eyes is the light which has traveled to him from the object; the circumstances of propagation of the light must therefore be taken into consideration. It is well known that a light ray changes direction in passing from one transparent medium to another. *e.g.*, water to air, and that its course is curved in a medium of varying density such as the earth's atmosphere; an object seen by these dislocated or curved rays is displaced from its correct position, and the corresponding correction for refraction by the earth's atmosphere is highly important in determining the positions of stars. The correction for aberration is also concerned with the propagation of light; it arises from the fact that an observer's actual judgment of the direction of a ray involves a combination of the earth's motion and the motion of the light.

The most elementary explanation can be given in terms of the old corpuscular theory of light—which was the theory accepted at the time aberration was discovered. If the ray of light be thought of as a stream of missiles proceeding from the star with a speed of 156,000 mi. per second, it is clear that the apparent direction from which the missiles come will be affected by the earth's

own velocity if that is not too insignificant in comparison. A common illustration is that of a man walking through a rainstorm with the drops falling vertically; the faster he walks, the more inclined is the position in which he must hold his umbrella to shield off the "missiles." The argument can be restated in terms of the wave theory of light without essential alteration; but reference should be made to an account of that theory for an explanation of the signification of "rays of light."

A rough way of aligning the direction of a star is to point a long, narrow tube so that the star can be seen through it. The alignment is given by the two apertures at the ends of the tube, which must be such that the small pencil of rays admitted through the one can make an exit through the other and thus reach the observer's eye (see diagram). The upper part of the diagram shows the raps of light coming from a star; the upper aperture E admits a narrow beam which continues in the original direction, so that F is the position in which the exit aperture has to be placed. Suppose that while the light travels the distance EF the earth moves through a distance GF; then the required direction of the tube is GE. It will then admit the light at E, and, by the time the light has traveled down the tube, the lower aperture will have reached the position F and the light will pass out. It will be seen that the tube GE does not point in the true direction of the star FE. The same principle applies when the tube is furnished with lenses, as in a telescope.

The alignment is the same whether the tube is long or short, and the relative proportions can be appreciated conveniently if EF is taken to be 186,000 mi. The light then takes 1 second to pass from E to F; and in 1 second the earth travels in its orbit $18\frac{1}{2}$ mi., represented by GF. Thus GF is $\frac{1}{10,000}$ of EF. The greatest possible angle between the observed direction and the true direction is $\frac{1}{10,000}$ of a radian, or more accurately 20.49"; this is called the constant of aberration. (For comparison the apparent radius of Jupiter is about 20"; so that [when the aberration is at maximum] the observer sees the centre of Jupiter when actually looking toward the edge of its disk.) As the direction of the earth's motion changes throughout the year so the direction of the aberration displacement of a star changes; the star is always displaced toward the "apex of the earth's way," *i.e.*, the point of the sky toward which the earth's motion is directed, which is a point on the ecliptic 90° behind the sun in longitude. The star apparently moves in an ellipse around its true position as centre, making a circuit once a year. For a star at the pole of the ecliptic this ellipse is a circle of radius 20.49"; for other parts of the sky the path may be regarded as a parallel circle which is projected into an ellipse by foreshortening. The major axis of the ellipse is always 40.94", but the minor axis depends on the latitude (*i.e.*, distance from ecliptic) of the star.

Discovery of Aberration.—The discovery of the aberration of light in 1725 by James Bradley (1693–1762) is one of the most important in the whole domain of astronomy; and in pure physics it has provoked a succession of investigations culminating in the theory of relativity. It was entirely unexpected, and it was only by extraordinary perseverance and perspicuity that Bradley was able to explain the phenomenon in 1729. The discovery arose in the course of an attempt to discover whether the stars had appreciable parallaxes. The first authentic parallax was not measured until a century later, and it is now known that stellar parallaxes are less than a second of arc. Many observers had, however, claimed to have discovered such parallaxes. In 1680 Jean Picard in his *Voyage d'Uraniborg* stated, as the result of ten years' observations, that the pole star exhibited variations of position amounting to 40" annually; some astronomers endeavoured to explain this by parallax, but the motion was at variance with that which parallax would occasion. John Flamsteed, from measurements in 1689 and succeeding years with his mural quadrant, concluded that the declination of the pole star was 40" less in March than in September. Robert Hooke in 1674 concluded from his observations that γ Draconis was 23" more northerly in July than in October.

When James Bradley and Samuel Molyneux entered this area of astronomical research in 1725 there was much uncertainty as to whether genuine stellar parallaxes had been detected or not; and

it was with the intention of answering this question definitely that they erected a large telescope in Molyneux's house at Kern. They determined to reinvestigate γ Draconis, a star selected because it passed almost through the zenith in the latitude of London; its position would not therefore be affected by troublesome and uncertain corrections for refraction. The telescope constructed by George Graham (1673-1751), a celebrated instrument maker, was affixed to a vertical chimney stack; the eyepiece could be moved a little laterally by means of a screw so as to measure deviation from the vertical, which was fixed by a plumb line. The first observations were made on Dec. 3, 5, 11, and 12, 1725. On Dec. 17 Bradley found the star to be moving southward and confirmed this on Dec. 20. (The change of position in the north-south direction through aberration at this time of the year is rapid and amounts to about 3.2" in ten days.) γ Draconis was found to continue its southerly course until March when it was about 20" south of the December position. By the middle of April it was apparent that it was returning north again. In September it reached its northerly limit, the extreme range between March and September being 40".

Although the observers were seeking an apparent shift of the star, they immediately realized that what they had found could not be attributed to parallax. The maximum range of parallactic shift for γ Draconis should be between June and December. Aberration and parallax are easily distinguished by this three months' difference of phase; the displacement of a star due to aberration is always at right angles to that due to parallax. Bradley and Molyneux discussed several hypotheses in the hope of arriving at an explanation. One hypothesis was that the direction of the earth's axis and therefore of the plumb line varied, causing an apparent displacement of the star when its position was measured with respect to the plumb line. Observations were therefore made of another star on the opposite side of the pole; from a comparison of its displacements with those of γ Draconis it was found that they could not be explained by a shift of the earth's axis. (The precaution, however, was fruitful, for by long-continued observation Bradley ultimately established that shifts due to a change of the earth's axis actually occurred; and he was led to his second famous discovery—nutations.) Bradley realized that observations of many more stars were required in order to determine the laws governing this mysterious effect of aberration. He therefore set up a more convenient telescope at the rectory at Wanstead, the residence of the widow of his uncle, James Pound, who had guided him in his early astronomical work. This telescope, erected in Aug. 1727, had a range of $6\frac{1}{4}^\circ$ on each side of the zenith and thus covered a much larger area of the sky than the Kew instrument. Fifty stars were kept under close observation. Bradley disentangled from these observations the conclusion that a star had its extreme declinations at the times of the year when it passed through the zenith at 6 A.M. or 6 P.M.

The true theory of aberration was discovered by an accident reminiscent of the more apocryphal story of Newton and the apple tree. Sailing on the Thames, Bradley noticed the shifting of the vane on the mast as the boat altered its course; the shift was not due to unsteadiness of the wind but to the combining of the changing motion of the boat with the steady velocity of the wind. This suggested that the changing direction of the light ray from the star was the result of the combination of the changing motion of the earth with the steady velocity of the starlight. The finite velocity of light had been discovered by the Danish astronomer Ole Roemer 50 years earlier; Bradley's discovery enabled him to give a greatly improved value for this velocity.

Astronomical Effects.—In modern astronomy the aberration due to the earth's orbital motion is included along with precession

DETERMINING THE DIRECTION OF LIGHT FROM A STAR (see TEXT)

and nutation as part of the "star correction" applied to reduce from apparent to mean place. A small correction is also applied for diurnal aberration arising from the motion of the observer caused by the diurnal rotation of the earth. For planets and comets a different procedure is adopted. It must be remembered that, even after allowing for the aberration, the body is seen not where it is now but where it was when the light left it (see fig.). Thus the corrected direction FE joins the position of the earth at the instant of observation of a planet to the position of the planet some minutes or hours before. Using the figure with a new connotation let E be the planet when the light left it, and let F be the position of the earth when the light arrives. While the light travels from E to F the earth travels from G to F, so that the apparent direction of the planet GE is the actual direction joining the positions of the earth and planet at the time when the light left the planet. Accordingly there is no need to trouble about the hybrid direction FE. GE is accepted uncorrected, but a correction is applied to the time of observation, antedating it by the light time. This simple procedure is inapplicable to the stars whose light time is many years, because it assumes that the earth's velocity has been constant throughout the interval. But it answers a question often raised—whether a correction ought not to be applied on account of the aberration due to the motion of the whole solar system through space toward a point in the constellation Hercules. This motion, being uniform, admits of the above treatment; and the answer is that no correction is required provided it is understood that the observation relates to the state of things when the light left the star; the aberration rather helpfully "puts back the sun" to the earlier date which must in any case pertain to the star.

Since the velocity of light is known with great accuracy the observed value of the constant of aberration determines the earth's orbital velocity. This can also be calculated: when the radius of the earth's orbit is known, from observations of the solar parallax. There has long been a rivalry between the constant of aberration and the solar parallax as to which shall provide the more accurate determination; at present the degrees of accuracy seem to be about equal, and the two methods are in satisfactory accord.

Aberration, Ether and Relativity.—In the explanation of aberration, light was pictured as traveling in a straight line from the star uninfluenced by the motion of the earth carrying the observer. In the 19th-century picture of light as a wave train through a rarefied medium called the "ether," this would not be true if the ether in the earth's neighbourhood were carried along with it; for when the light reaches this moving region of the ether its course will be disturbed, the motion of the ether (if the phrase has any literal meaning) being superposed on the ordinary velocity of the light traversing it. According to the modern idea of the atom introduced by Ernest Rutherford (later Lord Rutherford) in 1911, the electrons and atomic nuclei are so minute that the ether can slip through the void interior of the atom as easily as through the solar system, and there is no longer any reason to anticipate a convection; but in the 19th century it seemed almost contrary to reason to imagine solid matter pushing its way through the ethereal medium without serious disturbance. Apart from this prejudice, experimental evidence in the 19th century suggested that the ether in the lower part of the atmosphere was traveling with the earth, and, further, that moving matter such as a stream of water partially dragged the ether with it. Thus in 1818 the French scientist François Arago pointed out that the refraction by a prism (depending on the ratio of the velocities of light in air and glass) ought to be altered by the motion of the prism through the ether; since no such alteration was observed he concluded that the surrounding ether shared the motion of the prism. His co-worker A. J. Fresnel explained this effect by a "dragging coefficient," his hypothesis being that the "condensed" ether carrying the light inside the prism did not have the full motion of the prism but was only partially dragged in the same direction. This was apparently verified by A. H. L. Fizeau in 1851; he sent light in opposite directions around a circulating stream of water and thus studied its velocity with and against the current. In 1871 Sir George Airy performed his water-telescope experiment (originally

suggested by the Italian Jesuit physicist Ruggiero Giuseppe Boscovich), in which he measured the constant of aberration with a telescope that had its tube filled with water. According to crude reasoning, the aberration should have been increased, since the velocity of light is less in water than in air; but the normal value was obtained. Fresnel had already predicted that there would be a compensation when account was taken of the alteration of refraction at the surface of the moving liquid.

When Fresnel's theory was taken into account, the conclusion seemed to emerge that the ether-drag was limited to the interior of the moving bodies, and that its effects were compensated by changes of refraction at the surface of the bodies, except when (as in Fizeau's experiment) differential motions were concerned. Thus the ether just outside the solid earth would be stagnant as the theory of aberration requires. But in 1887 the American physicists A. A. Michelson and E. W. Morley made a much more delicate attempt to detect the difference of velocity of the earth and surrounding ether (*see RELATIVITY: Special Theory of Relativity*); this seemed to decide that the ether was carried with the earth. Thus the conflict between stagnant and convected ether was brought to a head, the former being demanded by astronomical aberration and the latter by the Michelson-Morley experiment and certain later experiments involving similar principles. A reconciliation was ultimately effected by the theoretical investigations of the Dutch physicist H. A. Lorentz and Sir Joseph Larmor. Their work showed that the electrical structure of matter involves an alteration of length of all material objects in the direction of their velocity through the ether, which would compensate the effect looked for in the Michelson-Morley experiment—confirming a suggestion originally made by George FitzGerald. When allowance is made for this contraction, none of the numerous experiments are capable of testing the relative motion of the earth and ether. The position just prior to 1905 could be summed up as follows: The earth moves through the stagnant ether without disturbing it, as the original explanation of astronomical aberration demands. The objection that bodies carried on the earth show no effects of this relative motion is of no value because in all experiments the effects are precisely compensated.

A more radical view of aberration—eliminating the ether from physical theory altogether—was put forward by Albert Einstein in 1905 in the special theory of relativity (*see RELATIVITY: Special Theory of Relativity*), which asserts that the laws of nature, and the value of the speed of light in a vacuum, are the same for all observers in uniform relative motion. Einstein deduced from this that two such observers would measure slightly different time intervals and spatial distances along the direction of their relative motion, and that these time intervals and distances would be related by the Lorentz transformation. In the same paper, Einstein gave the relativistic theory of aberration, which leads to the same formula as the older theory provided that the velocities involved are much smaller than that of light; but with the essential difference from the older theory that only relative motions between observers are involved. The two observers in this case are terrestrial astronomers measuring the angular position of a particular star from the earth at two different points of the latter's annual orbit around the sun; the measured position of the star undergoes a shift in the direction of the relative motion between the terrestrial observers at different times of year. The resulting annual change in the star's apparent position in the sky is of exactly the same character, and for practical purposes of the same amount, as is given by the classical explanation discovered by Bradley. However, the change in direction is due to fundamental relationships between distances and times measured by observers in mutual relative motion, and is thus virtually unaffected by the presence of small local amounts of refracting material; *e.g.*, in Airy's water-filled telescope.

The constant relative motion between the solar system and individual stars naturally leads to no observable change in any angular position in relativity theory. However, an important effect still does arise when very high velocities are involved (as in the case of remote galaxies). Aberration necessitates a correction to the apparent brightnesses of the galaxies, because the angle

subtended at the source of light by the light-receiving surface (such as the observer's eye or a telescope) appears smaller to an observer moving with the source than to one stationed on the earth; without this correction, the intrinsic brightness of a rapidly receding light source would be underestimated.

At the present time, the special theory of relativity has received such abundant confirmation from laboratory experiments that there is no longer any doubt that aberration is due to relative velocity, or rather to the differences in the earth's velocity at different times of year. According to current ideas, there is no all-pervading physical medium, such as the ether, which would transmit light rays at a certain velocity and thus make uniform motion through the medium detectable. In this connection it is of some interest to note that astronomical observations have shown that aberration is equal for observatories at sea level and at the tops of mountains, contrary to what could be expected if there were an ether which was, in addition, dragged along at the earth's surface, but was stagnant at greater heights. However, laboratory experiments showing the validity of the Lorentz transformation for the masses and lifetimes of atomic particles now provide much more accurate and detailed verifications of special relativity than the above astronomical observations.

Whittaker, *A History of the Theories of Aether and Electricity* (1910), rev. ed., 3 vol. (1953); W. H. McCrea, *Relativity Physics* (1950). The astronomical application of aberration is treated in all textbooks on spherical astronomy.

(A. S. E.; B. E. J. P.)

ABERRATION IN OPTICAL SYSTEMS, the deviation of light rays from certain points through which they should pass in order to satisfy the conditions necessary for distinct focus. Spherical aberration results in distortion of the image, and chromatic aberration produces coloured fringes around an otherwise white image. *See OPTICS; MICROSCOPE: Simple Microscope.*

ABERTILLERY, an urban district in the Abertillery parliamentary division of Monmouthshire, Eng.. 22 mi. N.N.E. of Cardiff by road. Pop. (1951) 27,620. Area 10.1 sq.mi. It is a coal-mining town, with five collieries in the area, lying in the Ebbw Fach valley that runs south to Newport between two spurs of mountains. Formerly known for its stone quarries, it developed rapidly after the middle of the 19th century, the first coal mine being sunk at Cwmtillery about 1850, at which time the tin-plate works were already established.

Following the depression of the 1930s, a joint industrial development committee with the neighbouring towns of Brynmawr (Brecon), Nantyglo and Blaina (Monmouthshire) was formed and many factories were built in the valley.

ABERT RIM, a striking rock formation in south central Oregon, U.S., is one of the largest fault scarps in the world. (*See also FAULT.*) The rim runs along the eastern edge of Abert lake for 19 mi., rising about 2,000 ft. above the lake, and has an 800-ft. lava cap ending in a sheer precipice.

Lieut. John Charles Frémont and his men discovered Abert rim and lake in Dec. 1843. Legend says that a party of Indians chased a wagon train of white people across the level plateau which slopes gradually from the east up to the summit of the rim, and drove them over the cliff. In the vicinity of Abert lake are found crude pictographs on rocks, rock foundations of dwellings of prehistoric people, arrowheads and skeletons.

Rhinoceros and camel fossil remains and those of many other animals have been found nearby.

ABERYSTWYTH, a municipal borough, seaside resort, university town and the county town of Cardiganshire, Wales: in the Cardigan parliamentary division. It stands on the shores of Cardigan bay, backed by hills, at the mouth of the artificially united Rheidol and Ystwyth rivers, 111 mi. N.N.W. of Cardiff by road. Pop. (1961) 10,318. Area 1.8 sq.mi. On Pen Dinas hill, south of the town, is one of the largest hilltop earthworks in central Wales. With the clearing of the lowland, Pen Dinas was superseded by Llanbadarn Fawr. Castell Aberystwyth—the most interesting of three Norman motte and bailey castles in the neighbourhood—stands above the bend of the Ystwyth and gave its name (*Aber*,

"mouth of river") to the stone castle built about 1277-89 near the fishing village that grew up at the river mouths. The history of the castle was a troublesome one. It was finally captured by the English in 1407-08 and during the Civil War a mint was established there which was moved to Shrewsbury in 1642. In 1646 the castle surrendered to the parliamentarians and was destroyed. Restoration work was done on it in the 20th century. After about 1555 the fishing village of Llanbader was called Aberystwyth. Traces of the medieval town walls are still to be seen.

Aberystwyth shared in the mining (lead), agricultural and sea trade movements of the early 19th century and seems to have become at this time the social centre for the surrounding area. It has since gained favour as a summer holiday resort with its wide beaches of sand and shingle. The coming of the railways killed the coastal trade and the harbour is now little used. There are boatbuilding, brewing and mineral water works and the town is the centre for a large agricultural district. There is a plant-breeding station there. Aberystwyth became the site of the founder college of the University of Wales, founded in 1872 and incorporated by charter in 1889, and of the National Library of Wales, begun in 1911 and completed in 1955. The library, standing on a hill, has more than 1,000,000 books and thousands of manuscripts. In 1906 the Theological College of the Presbyterian Church of Wales was moved there from Trefecca.

Aberystmyth, whose first charter was granted in 1277, was incorporated in 1877. The Michaelmas fair (now called the November fair) and the Monday market (now for cattle), granted by the first charter, are still held.

ABETTOR, a law term implying one who is present, actually or constructively, and aids and abets another to commit an offense. An abettor differs from an accessory (*q.v.*) in that he must be present at the commission of the crime; all abettors (with certain exceptions) are principals in the second degree, and, in the absence of specific statutory provisions to the contrary, are punishable to the same extent as the actual perpetrator of the offense. See CRIMINAL LAW.

ABEYANCE, in law, is a state of expectancy with respect to property or title when ascertainment of the owner of a right must await the happening of some future event such as marriage or birth. If the next taker of an interest was unascertained at the time of the creation of the interest, strict common law rules required ascertainment prior to termination of a prior estate (*see* ESTATES, ADMINISTRATION OF); otherwise the title or seisin was in abeyance and the conveyance void (*see* REAL PROPERTY AND CONVEYANCING, LAWS OF). The term was also used in connection with offices and titles (*see* PEERAGE). (A. DM.)

ABGAR, the name of several kings of a dynasty that reigned in Osroene (*q.v.*) in Mesopotamia, with their capital at Edessa. According to legend, Abgar V. Ukkama ("the Black"), (4 B.C.—A.D. 50), afflicted with leprosy, had heard of Jesus' miracles, and wrote to Jesus acknowledging his divine mission, asking to be cured and inviting him to Edessa. Jesus wrote to him in reply that after the completion of his earthly mission he would send one of his disciples to heal the king. In its oldest form this legend emerges in Eusebius (*Ecclesiastical History*, i, 13), who claims that it had come into his possession from the archives of Edessa. A developed form of it exists in the *Doctrine of Addai*, a Syriac document that seems to contain some reflections of the primitive Christianity in Edessa. Jesus' reply to Abgar has long been used in the Syrian and Egyptian orient as a magic amulet.

It has been thought that the legend is an echo of the beginnings of Edessene Christianity, under Abgar IX (179-214). The view, however, that Abgar IX received the Christian faith, though popular, is doubtful. *The Book of the Laws of the Nations*, the earliest monument of Syriac literature, emanating from the traditions of Bardesanes (*q.v.*), says that when this Abgar became a believer he forbade castration. However, the words "became a believer" appear to be an interpolation caused by the Abgar legend. Eusebius quotes the same source *in extenso*, but these words do not appear in the text he used. See also EDESSA: *Edessene Christianity*.

ABHDISHO BAR BERIKHA (EBEDJESUS; OF NISIBIS; d. 1318), was the last important writer among the Nestorians (*q.v.*). Abhdisho ("servant of Jesus") became bishop of Shiggar and Beth-Arbaye about 1285, and by 1291 was metropolitan of Nisibis and Armenia. Though few details of his life are known, a complete list of his writings prepared by Abhdisho himself is preserved. This includes some works no longer extant, such as his biblical commentary; 12 treatises on science, ecclesiastical decisions and canons, and another against heresies; and a commentary on a letter dealing with alchemy addressed to Alexander the Great allegedly from Aristotle. Among those extant are his *Marganitha* ("Pearl"), a theological treatise written in 1298 in five sections on God, the creation, the Christian life, the sacraments and the signs of the world to come, a work which may be regarded as a statement of Nestorian doctrine toward the end of its development. Parts of an Arabic translation of it made by Abhdisho in 1312 are cited by the historian 'Amr ibn Matta. The *Collection of Synodical Canons* or *Nomocanon* dealing with civil and ecclesiastical law depicts the organization of the Nestorian church in his day. His *Paradise of Eden*, 50 homilies published in 1291, is a metrical tour de force. The most cited of his works is his *Catalogue*, written in 1316, a list of titles covering the books of the Bible, Syriac translations of Greek fathers and works of Syrian fathers, chiefly Nestorian. It gives no information about dates or contents, but it does mention works otherwise unknown.

See A. Baumstark, *Geschichte der Syrischen Literatur*, pp. 323-325 (1922); J. B. Chabot, *Littérature syriaque*, pp. 139-141 (1934). (W. D. McH.)

ABHINAVAGUPTA (fl. A.D. 1014), an outstanding Indian philosopher, ascetic and writer on aesthetic theory, was a Rashmiri Brahman and a spiritual descendant of the 9th-century Kashmiri Somananda, founder of the "recognition" (*pratyabhijna*) school of Kashmiri Sivaist monism. Together with Somananda's disciple, Utpaladeva, he is the most important representative of this school. He conceived Siva, the I or consciousness, and the All as synonymous; and multiplicity or objectivity as an expression of the freedom and strength of the I which through it affirms and realizes itself precisely as I, consciousness or freedom. This concept of freedom (*svatantrya*) is one of the principal achievements of Kashmiri Sivaist thought. Abhinavagupta's chief philosophical works are the *Isvara-pratyabhijna-vimarsini* and the fuller *Isvara-pratyabhijna-vivriti-vimarsini*. The extensive *Tantra-aloka*, summarized by him in the *Tantra-sara*, is one of the most important works on Tantrism. A most beautiful and profound philosophico-religious work is his commentary on *Para-trimsika*. His most notable works upon aesthetics are his commentaries on the *Natyasastra* of Bharata, and on the *Dhvani-aloka* of Anandavardhana.

Soc.*, pp. 718-747 (1910). (R. GN.)

ABIATHAR, in the Old Testament, son of Ahimelech, priest of Nob. He alone escaped from the massacre carried out by Doeg. Fleeing to David, he remained with him throughout his wanderings and his reign. He was loyal through the rebellion of Absalom, but supported Adonijah against Solomon and was banished to Anathoth. He probably represents an early rival house to that of Zadok, the official priestly family of Jerusalem down to the exile. (*See* especially I Sam. xxii *et seq.*; II Sam. xv, xx; I Kings i, ii. iv.) See also SOLOMON.

ABIDJAN, capital of the Ivory Coast, west Africa, stands on a promontory of the mainland shore, overlooking Ebrié lagoon and linked by bridge to its southern quarter on the island of Little Bassam. Pop. (1955) 127,585. A village in 1898, the town became capital of the colony in 1933. Its wide, shady avenues and garden squares are flanked by modern buildings for the town

hall, government offices, law courts, consulates and other public and private purposes. There are a *lycée*, a technical college, a theatre, and also a library and museum of ancient art under the direction of the Institut Français d'Afrique Noire. The town has an average temperature of 79.7° F. The beach, the forest of Banco, and the botanical gardens at the old capital of Bingerville to the east are popular resorts; there are three stadiums and two swimming pools.

Abidjan has been a rail terminus since 1904 but lacked port facilities, depending on the inadequate Port Bouet on the ocean shore of the sand bar south of the lagoon. But a long-cherished project of cutting the sand bar and linking the capital itself to the sea was consummated when the seaport of Abidjan was opened in 1951. The Houphouët-Boigny road-rail bridge, joining the mainland to Little Bassam, was opened to traffic in May 1958 and is a notable engineering achievement. The airport near Port Bouet, 10½ mi. from the capital, is served by French and other airlines. Motorable roads run to Upper Volta, Guinea and Ghana.

Abidjan is a trading and commercial centre; its local industries include soap manufacture, canning, sawmills and breweries. Exports are coffee, cocoa, timber and bananas; imports include textiles, machinery, petroleum and food products. (P. DU P.)

ABIETIC ACID is a constituent of the exudate (oleoresin) flowing from the incised trunks of conifers. Various species of pine may serve as a source, among them *Pinus abies* and *Pinus palustris*. Distillation of the exudate gives the volatile oil of turpentine, consisting largely of the monoterpene α -pinene and a residual resin known as rosin or colophony. This is rich in abietic acid, partly because of the oleoresin's original content and partly because other resin acids change to abietic acid during heat treatment. Abietic acid, a diterpenoid, is purified through the diamylamine salt and has the following formula:

If fresh oleoresin is allowed to stand at low temperatures, a crystalline mass of mixed acids known as galipot is formed. From this mixture some of the less stable resin acids can be obtained. Rosin is one of the cheapest large sources of organic acids. The sodium salt, a low-grade soap, is used as an emulsifying agent and as a size in paper-making. Since the rosin acids are highly susceptible to air oxidation, some of their heavy metal salts are used as driers for paints and varnishes. Rosin esters also are used in the paint industry. See also RESINS: Oil-Soluble *Resins*; ROSIN. (P. DE M.)

ABIGAIL (ABIGAL), in the Old Testament, the wife of Nabal the Carmelite of southern Judah, on whose death she became one of the earlier wives of David (I Sam. xxv). By her David had a son, whose name appears in the Hebrew of II Sam. iii, 3 as Chileab, in the Septuagint as Daluyah and in I Chron. iii, 1 as Daniel. The name Abigail also was borne by a sister of David's (I Chron. ii, 16 ff.). From the former (self-styled "handmaid"; I Sam. xxv, 25 ff.) is derived the 16th- and 17th-century colloquial use of the term for a waiting woman.

ABIJAN (Heb. ABIYAH and ABIYAHU, "Yah is father"), a name borne by nine different persons mentioned in the Old Testament, of whom the most noteworthy are the following. (1) The son and successor of Rehoboam, king of Judah (II Chron. xii, 16; xiii), reigned about two years (918-915 B.C.). The accounts of him in the books of Kings and Chronicles are very conflicting. The Chronicler says that he has drawn his facts from the Midrash (commentary) of the prophet Iddo. This is perhaps sufficient to explain the character of the narrative. (2) The second son of Samuel (I Sam. viii, 2; I Chron. vi, 28). He and his brother Joel judged at Beersheba. Their misconduct was made by the elders of Israel a pretext for demanding a king (I Sam. viii, 4). (3) A son of Jeroboam I, king of Israel; he died young (I Kings xiv,

1 ff., 17). (4) Head of the eighth order of priests (I Chron. xxiv, 10), the order to which Zacharias, the father of John the Baptist, belonged (Luke i, 5).

ABILDGAARD, NIKOLAJ ABRAHAM (1743-1809), Danish painter, was born in Copenhagen, Sept. 11, 1743, and studied in Rome during 1772-77. His style was classical, though with a romantic trend, and he had a remarkable sense of colour. He enjoyed great fame in his lifetime and taught at the Danish Royal Academy of Fine Arts, of which he became director in 1789. He died at Frederiksdal, Den., on June 4, 1809. Bertel Thorvaldsen was his pupil. (S. Sz.)

ABILENE, a city of Kansas, U.S., located about 95 mi. W. of Topeka, was settled on the Smoky Hill river in 1858, and became the seat of Dickinson county in 1861.

In 1939 Abilene adopted a commission-manager form of city government. (For comparative population figures see table in KANSAS: *Population*.) Joseph McCoy (1837-1915), a cattle entrepreneur and later mayor of Abilene, selected Abilene for the northern terminus of the Texas cattle drives in 1867, the year the Kansas-Pacific railroad reached this point. The biggest year of cattle drives to Abilene over the Chisholm trail was 1870 when more than 5,000 cowboys driving 700,000 cows arrived at the yards. The appearance of homesteaders and fenced ranges discouraged the Texas cattle trade, much of which was diverted to Wichita. There is still a considerable trade in cattle, however, and grain and poultry markets are centred in the city. Flour and milk products are also important to the city's economy. The Eisenhower museum was opened in 1954 in Abilene, the boyhood home of the 34th president of the United States. (D. P. G.)

ABILENE, a city of Texas, U.S., about 150 mi. W. of Fort Worth almost at the geographical centre of the state, is the seat of Taylor county. Named after Abilene, Kan., its site was determined by the route of the Texas and Pacific railway. On March 16, 1881, the first sale of building lots was held for the city of Abilene. The city adopted a council-manager form of government in 1947. The population in 1960 was 90,368. (For comparative population figures see table in TEXAS: *Population*.)

Abilene is the distributing centre for a farming and stock-raising region. Outside the city are many producing petroleum pools; natural gas is abundant. Abilene has more than 100 wholesale concerns and is headquarters for many oil companies and oil-well supply firms. Cottonseed and peanut products, feeds, pressed brick, dairy products, clothing, oil-field equipment, soap and watches are manufactured. The West Texas fair is held there. There are three denominational institutions of higher learning: Hardin-Simmons university (Baptist) founded in 1891, Abilene Christian college (Church of Christ) founded in 1906 and McMurry college (Methodist) founded in 1922. The Abilene state school cares for and trains pupils of retarded mental development. Dpress air force base is located there. (R. N. R.)

ABIMELECH (Hebrew for "the [divine] Father is Icing"), the name of two well-known Old Testament personalities, and a common west Semitic name known in various forms from extra-biblical documents.

1. ABIMELECH was a king of Gerar in south Palestine with whom Isaac had relations (Gen. xxvi). Isaac's dealings with Abimelech were a part of the common struggle over grazing and water rights during the period. The story of Isaac's representing his wife Rebekah to be his sister in order to facilitate his relations with Abimelech has its parallel in the story of Abraham's having declared Sarah to be his sister (Gen. xx); another close parallel appears in Gen. xii, telling of the pharaoh's having taken Sarah as his wife, believing her to be Abraham's sister. These stories are chiefly designed to show how God protected the people of the promise even when they lacked courage and faith. In the first two of these accounts, the foreigner Abimelech is represented to be more upright and ethically sensitive than are Isaac and Abraham.

2. ABIMELECH, a son of Jerubbaal or Gideon (*q.v.*) by his Shechemite concubine (Judg. viii, 31; ix). On the death of Gideon, Abimelech set himself to assert the authority which his father had earned, and through the influence of his mother's family won over the citizens of Shechem. Furnished with money from the treasury

of the temple of Baal-berith, he hired a band of followers and slew 70 (*cf.* II Kings x, 7) of his brethren at Ophrah, his father's home. Abimelech thus became king, and extended his authority over central Palestine. But his success was short-lived, and the subsequent discord between Abimelech and the Shechemites was regarded as a just reward for his atrocious massacre. Jotham, the only surviving son of Gideon, is reported to have denounced Abimelech to the Shechemites in a fable of the trees who desired a king to rule over them. Not one of the trees was willing to rule, but the bramble gladly accepted.

It has been supposed that this sharply negative attitude toward kingship belongs to a later period of Israelite life, after the prophetic denunciations of the kings of Israel and Judah. More probably, it represents a basic distrust of kingship characteristic of the 12-tribe system of Israel which, for a time, had its centre at or near the old Canaanite city of Shechem. The story of Abimelech's disastrous attempt to establish a kingship over Israel, culminating in his death at Thebez, reveals the importance of Shechem for the life of early Israel; it also indicates that the tribal confederation, despite its political weaknesses and disadvantages, would not yield easily to the monarchical system characteristic of Israel's neighbours. (W. HA.)

ABINGDON, a municipal borough of Berkshire, Eng., lies 7 mi. S. of Oxford and 20 mi. N. of Newbury, in the flat Thames valley where the small river Ock, draining the Vale of the White Horse, joins the Thames. Pop. (1961) 14,283. Area 2.7 sq.mi. The town grew up round a Benedictine abbey founded in 675 which, after being twice destroyed by the Danes, acquired great wealth and importance. The abbot controlled the town and despite serious riots in 1327 the townspeople did not gain local government until 1556 when, the abbey having been dissolved by Henry VIII, Mary I granted Abingdon its first charter, establishing it as a free borough corporate. Holders of the office of high steward have included Queen Elizabeth I's favourite, the earl of Leicester, and Edward Hyde, 1st earl of Clarendon, but after 1709 it became customary to appoint the successive earls of Lindsey and Abingdon. Abingdon was the county town from Tudor times until 1870.

Remains of the abbey comprise a beautiful Perpendicular gateway (the gatehouse now forms part of the guildhall); the Checker (*i.e.*, exchequer) with a vaulted undercroft and a rare chimney; the Long gallery, believed to have been a guesthouse; and the restored Checker hall, now used as an Elizabethan-style theatre. The arched bridge over the Thames (1416, widened 1929) gives fine views toward the old part of the town and the Early English tower and Perpendicular spire of St. Helen's church. This, having five aisles, is wider than it is long. In the churchyard are three sets of almshouses, the oldest erected in 1446. The guildhall (1440, with later additions), which has some fine portraits and plate, includes the Roysse schoolroom built in 1563. The county hall (1677) was for 200 years the assize hall of Berkshire and now houses a museum collection. Opposite is St. Nicholas' church, whose west front was built in 1180. Schools include Abingdon (Roysse's) school, which is one of the oldest public schools (*q.v.*) in England. Radley college (1847), two girls' boarding schools and a technical high school.

A Thames-side resort, with parks and other amenities, Abingdon is also a residential area for nearby establishments for research into atomic energy (Harwell) and petroleum. Its manufactures include automobiles, prestressed concrete, scientific instruments and leather products. There are also a large brewery and a substantial agricultural trade, a cattle market being held every Monday. The corporation owns, uniquely, fisheries in the Thames. Ancient customs still maintained are the great Michaelmas fair in the main streets (on the Monday and Tuesday before Oct. 11), the Morris-dance (*q.v.*) along Ock street (on the Saturday nearest June 19) and, on royal occasions, the throwing of 2,500 buns into the market place by the mayor and council from the roof of the county hall. (E. W. J. N.)

ABINGTON, FRANCES (FANNY) (née BARTON) (1737–1815), English actress, daughter of a private soldier named Barton, was first a flower girl (hence her later nickname, Nosegay Fan) and

street singer. Employment by a French milliner gave her taste in dress and a knowledge of French that later stood her in good stead. She first appeared on the stage at the Haymarket in 1755 as Miranda in *The Busybody*. In 1756 she joined the Drury Lane company but was overshadowed by Hannah Pritchard and Kitty Clive. After an unlucky marriage with her music master in 1759, she was known as Mrs. Abington. She spent five successful years in Ireland and was then invited by David Garrick to rejoin Drury Lane. There she remained for 18 years, creating many important roles, among which was Lady Teazle in the *School for Scandal* (1777). She was equally successful in drama, tragedy and comedy. In 1782 Mrs. Abington left Drury Lane and went to Covent Garden. She left the stage in 1790, returning for two years in 1797. Despite her humble origin, her wit, cleverness and ambition won her a place in society. She was a leader of fashion, and a head-dress of hers called the "Abington cap" was very widely worn. She died on March 4, 1815. (W. J. M.-P.)

ABIOGENESIS: see BIOLOGY: *History: Biogenesis Versus Abiogene pis.*

ABIPON, a South American tribe of the Guaycuruan (*q.v.*) language family, which lived on the lower Bermejo river, in the Argentine Chaco. The Abipones acquired fame in anthropological literature because of the much-quoted description of their culture by a Jesuit missionary, Father Martin Dobrizhoffer (pub. in 1784; Eng. trans., *An Account of the Abipones, an Equestrian People of Paraguay*, 1822). These Indians—whose seminomadic bands lived on hunting, fishing, food-gathering and limited agriculture obtained the horse in the 17th century and became the scourge of the Spanish settlements that they raided from the foothills of the Andes to the Paraná river. Their social structure combined the democratic features of primitive bands with incipient forms of a military aristocracy. Conjurament of spirits and spectacular recapture of lost souls by influential medicine men were the salient features of their simple ritualism. The Abipones were settled on various missions by the Jesuits in 1748 (the modern cities of Reconquista and Resistencia in the Argentine were former Abipón missions). Originally perhaps 5,000 strong, they vanished altogether as distinct people in the 19th century. (A. Mx.)

ABISHAG, in the Old Testament, the Shunammite nurse of David (*q.v.*) and last addition to David's harem. References to her occur in narratives relative to the close of David's reign, the coronation of Solomon and Solomon's establishment of his position as king (I Kings i, 3, 15–31; ii, 17, 21–22). Found as the result of a search for a beautiful young virgin, Abishag was brought to David's court to serve as nurse and bed mate for the aged king. In the latter role her function was to impart heat to the king's body and to restore his sexual potency. In the counterplot to have Solomon displace Adonijah, Abishag witnessed David's promise to Bathsheba that Solomon would succeed him. Abishag appears lastly as the favourite member of the harem that Solomon inherited from David. Abishag was requested as wife by Adonijah, who engaged Bathsheba to present his request to Solomon, whereupon Solomon had Adonijah murdered.

See Edith Deen, *All of the Women of the Bible* (1955). (C. B. Co.)

ABITIBI, a lake and river in Ontario, Canada. The name is an Algonkian Indian word descriptive of the lake's central location on an old canoe route halfway between Ottawa valley and Hudson bay. The lake, on the Ontario-Quebec boundary, is 55 mi. long and has an area of 350 sq.mi. It is shallow, island studded and a popular tourist area.

The river, which flows northward 200 mi. to Moose river, is roughly paralleled by the Ontario Northland railway (Canadian National railways). It has a total length of 340 mi. The forested Abitibi valley is the location of an important pulp and paper industry. Pomer plants at Abitibi canyon, Island falls, Iroquois falls and Twin falls provide 376,000 h.p. for northern mining developments. (F. A. CK.)

ABKHAZ AUTONOMOUS SOVIET SOCIALIST REPUBLIC (ABKHAZIA) occupies the northwestern corner of the Georgian S.S.R., U.S.S.R., between the Black sea and the crest of the greater Caucasus range (Bolshoi Kavkaz). Along the coast is a narrow lowland, broken by mountain spurs reaching almost to

the sea, and widening to the southeast. Behind this lowland is a hilly foreland zone of eroded sea and river terraces, backed in turn by the steep slopes of the Caucasus, which rise to 13,254 ft. in Mt. Dombai-Ulgen. The sharp relief in close proximity to the sea gives Abkhazia a distinctive climate, the wettest in the U.S.S.R., with annual rainfalls of from 48 to 55 in. on the lowland to 80 in. on the slopes, where up to 120 in. have been recorded. Conditions on the lowland are subtropical and this is one of the few areas of the U.S.S.R. where January average temperatures remain above freezing point. The heavy rainfall gives rise to a large number of rivers, flowing usually in a southwesterly direction and subject to frequent floods during thawing and heavy downpours, while the subtropical climate leads to the formation of subtropical soils, yellow earths and terra rossa, bearing a luxuriant vegetation of more than 1,500 species. The forests of oak, beech and hornbeam which once covered all Abkhazia have been cleared from wide areas of the lowland and foreland zones. Higher up, the trees are mainly coniferous, giving way to meadow. At about 9,000 ft. the snow line occurs. Abkhazia, once the home of the Abkhaz tribe (in Abkhaz *Apsua*; in Greek *Abasgoi*) and part of the Roman empire, became Christian under Justinian (c. 550). In the 8th century, Leo, duke of the Abasgoi, formed the kingdom of Abasgia, independent of Byzantium and later part of Georgia. In 1463 the duchy became independent of Georgia only to come under the Ottoman empire in the 16th century when Islam replaced Christianity. In 1810 George I Sharvashidze, prince of Abkhazia, signed a treaty with Russia acknowledging a protectorate and in 1864 Abkhazia was annexed by Russia. The country proclaimed its autonomy in 1919 and was formed into an A.S.S.R. in 1921. The population of Abkhazia in 1959 was 400,000, of which approximately 37% (or 147,000) were urban dwellers. Most of the people are concentrated in the coastal lowland where the larger settlements are located—Sukhumi (q.v.), the capital, Ochamchire and a chain of resorts such as Gagra and Novy Afon (New Athos). The one large exception to a coastal location is the coal-mining town of Tkvarcheli in the Galidzga valley, which in 30 years has grown from a village of about 500 to a town of more than 28,000 inhabitants.

The agricultural economy of the country, thanks to the subtropical conditions, has an importance in the U.S.S.R. out of all proportion to its area. There is grown the best tobacco of the Soviet Union, particularly in the foreland zone, while the coastal zone is a major tea-producing region. There are 11 tea-processing plants. Other crops of importance are citrus fruits, although, since these have suffered greatly from the abnormal frosts of 1950 and the following years, special precautions are now taken, such as the use of gauze covers in winter. The tung tree, the nut of which is used for oil, is widely grown, while plantations of eucalyptus and bamboo add a characteristic element to the Abkhazian landscape. Orchards are numerous, not only of apples, pears, plums and cherries, but also of figs, medlars, quince and olives. The vine has been cultivated since ancient times, although the quality of the wine is not high. Silk is obtained in the lowland. Inland, on the higher areas, timber production is the major occupation, especially in the Bzyb and Kodori valleys. Beech and pine are the most common timbers. Coal was discovered at the end of the 19th century, but only since 1935 has it been mined, centred on Tkvarcheli. In the late 1950s nearly 1,500,000 tons were being produced annually, partly by the opencast process. The rivers are well suited to the production of hydroelectric power and several plants were built, the largest being at Sukhumi. The coastal resorts and the lovely Lake Ritsa are popular holiday and convalescent centres for people from all over the Soviet Union. The main line of communication is the railway along the coast, linking the major towns, with an electrified branch line to Tkvarcheli. Roads lead inland to Lake Ritsa and along the Kodori valley.

(R. A. F.)

ABLUTION, a religiously prescribed washing of part or all of the human body, or of possessions such as clothing or ceremonial objects, with the intent of purification or dedication (Lat. *ablutio*, from *abluerē*, "to wash off"). Water, or water with salt or some other traditional ingredient, is most commonly used,

but washing with blood is not uncommon in the history of religions, and urine of the sacred cow has been used in India. The devout Shintoist rinses his hands and mouth with water before he approaches a shrine (*haiden*) and prepares to clap his hands to draw the attention of the divine (*kami*) to his devotions. The monk of the southern Buddhist (Theravada) tradition washes himself in the monastery pool as he prepares to honour in his meditations an enshrined relic or image of the Buddha. The upper-caste Hindu bathes ceremonially in water before performing his daily morning worship (*pūja*) in his home. The Jewish family that does not have a separate set of ritual dishes and glassware for the Passover meal (*Seder*) may take the traditional course of preparing such dishes by dipping in boiling water; at the same meal the family uses pitcher and towel for hand ablutions. The Roman Catholic priest (and priests of some Orthodox churches) celebrating the Mass prepares himself by ritual washing of his hands in the *lavabo* (a ceremonial basin); after the offertory of the sacred elements there is a ritual washing of the fingers. Seven days after baptism those newly baptized in Eastern Orthodox churches often go through a ceremony in which holy oil is washed from the forehead. In some of the Brethren sects in rural United States ceremonial foot washing is performed on stated occasions, continuing in Protestant life what was centuries ago common in Christian piety as a response to the gospel story of Jesus' washing his disciples' feet (John xiii, 1–15) and to the Pastoral epistle's description of upright widows as having "washed the feet of the saints" (1 Tim. v, 10). In Muslim piety it is required that the devout wash their hands, feet and face before each of the five daily prayers; however, in keeping with the koranic claim that God does not desire needless suffering for believers, the use of sand is permitted in place of water where desert conditions make water difficult or impossible of access.

The Jewish Torah (Mosaic law, embodied in the Pentateuch) contains numerous examples of ablution. At this period of history ablution is only one of many methods for catharsis (see PURIFICATION) of the dangerous "charge" that was felt by Semitic peoples—as by the Greeks, Romans, Babylonians, Egyptians, Chinese and many primitive peoples—to be associated with death and corpses, women in childbirth, menstruating women, male nocturnal emissions, violent acts and booty of battle, certain diseases, initiation to high office, performance of priestly rites, etc.

Like most ritual acts, ablution may carry a wide range of meanings to those who perform it. The stain of ritual uncleanness may be felt to be as real as contamination with unseen germs is for the medically minded, and as productive of suffering and misfortune; or the act of cleansing may be only a gesture, symbolic of desired purity of soul, as Thomas Aquinas thought of ablution in the Mass. Probably both objective and subjective referents are often fused in the act, as C. G. Jung and others have suggested in studies of unconscious elements in religious symbolism. The cleansing often is sought in a perfunctory way. But it may also be sought as a matter of gripping holy (numinous) concern, as Rudolf Otto suggested in his analysis of such ritual elements as chants, art and sacrifices. Such concern, compounded of inarticulate awe and adoration, may have no ethical or rational content, as any review of the varieties of ablution will confirm. Yet, as Otto and others have shown, the irrational sense of the holy in such acts as ablution often serves as a vital background upon which worship may develop its profoundest rational and ethical content.

ABNAKI (*ABENAKI*) designates a confederacy of Algonkian-speaking Indian tribes in northeast North America, which was organized to furnish resistance and protection against the warring encroachments of members of the Iroquois league of northern New York state, especially the Mohawk. In its earliest organization

it consisted of tribes east and northeast of New York: Maliseet (Malecite) in New Brunswick; Passamaquoddy, a segment from the Maliseet; Penobscot in Maine; and tribes in Vermont and New Hampshire. Later it included some eastern tribes as far south as the Delaware tribe. Some agriculture was practised throughout the coastal region, more intensively from north to south. In the northern portion the typical dwelling was the birch-bark covered wigwam. The birch-bark canoe was in general use. Game was taken in snares and traps and by bow and arrow. Each tribe consisted of small bands under a head man or chief who had little compulsory authority. There was institutionalized comradeship with mutual responsibility, which united two men for life. Belief in a culture hero who will return to help the people in time of great need persists to the present. The 1959 population, including so-called Abenaki groups in Canada, was about 3,300.

See "Abnaki" in Bureau of American Ethnology, *Handbook of American Indians North of Mexico*, vol. i, pp. 2-6. Bulletin 30 (1907). (W. D. W4)

ABNER, in the Old Testament, Saul's cousin and commander in chief, comes into prominence only after the crushing defeat of Israel at Mt. Gilboa. This battle placed the Philistines in control of the whole of central Palestine, and the weakness of Israel was enhanced by the division into two parties, that of the south, which followed David, and that of Trans-Jordan which remained faithful to Ishbosheth, the son who succeeded Saul. Ishbosheth himself, however, was a weak character, and the whole strength of the party was concentrated in Abner. The struggle between the two parties was continuous, and in the battle of Gibeon Abner killed Asahel, brother of Joab, thus exposing himself to the blood-revenge of the dead man's whole family. It seems that Abner aspired to become the sole leader of his party and, as a step in the achievement of his aim, married Rizpah, one of the concubines of Saul. For this he was reproved by Ishbosheth and thereupon deserted to the opposite party. An agreement was made between David and Abner, by which David had restored to him Michal, daughter of Saul, thus establishing a claim on Saul's throne, and Abner was received into favour. Joab, however, in obedience to the binding law of blood-revenge, took an opportunity of putting Abner to death, and his disappearance practically brought to an end the resistance of the eastern party. David, of course, was not implicated in Abner's death, and his short dirge over the body, like that over Saul and Jonathan, is an exquisite specimen of the early poetry of Israel. See chiefly II Sam. ii. iii. iv.

ABNEY, SIR WILLIAM DE WIVELESIE (1843-1920), English chemist, is best known for research on colour measurement and mixture and on photographic processes. He was born in Derby, July 24, 1843. He was educated at Rossall school and in 1861 obtained a commission in the royal engineers through the Royal Military academy. He was appointed instructor in chemistry and photography at the school of military engineering at Chatham and in 1874 was placed in charge when the department was made a separate school. In 1877 he entered the science and art department at South Kensington where he was appointed director in 1893. In 1899 he was made principal assistant secretary to the board of education. After his retirement from this position in 1903, he served as scientific adviser to the board.

Abney invented gelatino-chloride, or printing-out paper, and discovered the developing power of hydroquinone and the "failure of the reciprocity law." He made the earliest measurements of the relation of the transparency of a photographic image to the exposure and prepared red-sensitive plates, with which he made many observations in the red and infrared regions of the spectrum.

In 1900 he was made knight commander of the Bath. He was elected fellow of the Royal society in 1876. In 1882 the Royal society awarded him the Rumford medal for his work on spectrum analysis. He was president of the Royal Astronomical society from 1893 to 1895, of the Physical society from 1895 to 1897, of the Royal Photographic society from 1892 to 1894, in 1896, and for 1903 to 1905. He received the Royal Photographic society's progress medal in 1878 and 1890. Abney died in Folkestone, Kent, Dec. 3, 1920. (C. E. K. M.)

ABODE: see DOMICILE AND RESIDENCE.

ABOLITIONIST, an advocate of the abolition of slavery. The term as used in the United States referred specifically to those persons who, during the years 1830-61, made it their mission to advocate the immediate abolition of Negro slavery. In spite of riots, assaults and persecutions of every kind, they carried on their task by means of the press, tracts, lectures and petitions to congress. Among the outstanding leaders of the abolitionist movement were William Lloyd Garrison, Wendell Phillips, Lucretia Mott and John Brown. See SLAVERY.

ABOLITION MOVEMENT, a movement primarily in Britain, the United States and western Europe, between about 1783 and 1888, to abolish the international slave trade and the institution of chattel slavery.

After Roman slavery was gradually converted into serfdom, slavery was virtually unknown in western Europe until 1442, when the Portuguese began to bring back Negro slaves from their explorations along the west coast of Africa. Soon after, the need for labour in the colonies of North and South America created an immense market for slaves. Consequently, a vast trade sprang up and flourished for more than three centuries, being dominated in turn by Portugal, Spain, Holland, France and England. Altogether probably more than 15,000,000 slaves were transported, and prior to 1800 far more African slaves than English or European colonists crossed the Atlantic—mostly to the West Indies and South America.

Despite its severity and inhumanity, the slave system aroused little protest until the 16th century. Rational thinkers of the Enlightenment then began to criticize it for its violation of the rights of man, and pietistic or evangelical religious groups condemned it for its unchristian and brutal qualities. In Britain and America, the Quakers, who began their criticism in 1671, were the first significant opponents of slavery, and the dynamics of the antislavery movement were largely religious throughout. Consequently the leaders were always more concerned with ending the sin of slavery than with finding a constructive social policy for the slaves. In France, where the Société des Amis des Noirs was founded in 1788, the rational factor was stronger than the evangelical.

By the late 18th century moral disapproval of slavery was widespread and antislavery reformers gained a number of deceptively easy victories. In Britain, Granville Sharp, working almost alone, secured a decision in the Somerset case (1772) that West Indian planters could not hold slaves in England, since slavery was contrary to English law. In America leading figures of the revolutionary period, such as Washington, Jefferson and Franklin, condemned slavery unequivocally. Between 1777 and 1801 all of the states north of Maryland abolished it—some by gradual, others by immediate action. Meanwhile, in the south, numerous and vigorous antislavery societies enjoyed considerable success in persuading owners to manumit their slaves voluntarily.

These victories, however, had little effect upon the centres of slavery, the great plantations of the deep south, the West Indies and South America. The antislavery movement, therefore, slowly turned to the problem of slavery in these areas, and as it did so, it passed through three major phases.

The first phase involved British and American efforts to prohibit the importation of African slaves into the British colonies and the United States. English Quakers began actively to campaign for such a prohibition in 1783. In 1787 the Abolition society, consisting mostly of Quakers, was formed. Under William Wilberforce (*q.v.*), who led the movement in parliament, and Thomas Clarkson (*q.v.*), who devoted many years to the tireless collection of evidence concerning the evils of the trade, the antislavery forces waged an unremitting contest against extremely powerful opposition. After two decades the trade to the British colonies was abolished in 1807.

Meanwhile in the United States: the Constitutional Convention in 1787 had considered placing in the constitution a prohibition of the trade, but in order to conciliate southern interests which opposed immediate action the convention agreed to a provision that

Congress might prohibit the trade after 20 years. Accordingly, in 1807 the United States also prohibited it.

Antislavery men had hoped that when the supply of new slaves was stopped, slavery itself would gradually wither away. But this did not follow, and in its second phase abolitionism concentrated upon the emancipation of populations already in slavery. In Britain antislavery leaders organized the Anti-Slavery Society in 1823, made Thomas Fowell Buxton (*q.v.*) their parliamentary leader in place of the aging Wilberforce and, after another prolonged and dramatic contest, finally succeeded in 1833 in passing a law to free all slaves in the British colonies after a six-year period of apprenticeship, with compensation to their owners. In 1838 France also abolished slavery in its West Indian colonies. This was France's second attempt, for the French revolutionists in 1794 had proclaimed emancipation but the internal struggle over this question in Haiti had led to bloody and violent uprisings. During a vain attempt to restore French control of the island, Napoleon re-established slavery (1802), and it continued in other French colonies until 1848.

The British abolition movement had a deep influence in the United States. As the cotton economy developed, slavery gained new vigour and the south began to defend slavery in positive terms. Discouraged by these developments and disappointed by the limited results of their appeals to gradualism and persuasion and their attempts to colonize free Negroes in Liberia, U.S. antislavery men turned, about 1830, to a more militant policy. Denouncing all slaveholders, they demanded immediate abolition by law. In this aggressive program the most conspicuous and most extreme leader was William Lloyd Garrison (*q.v.*), editor of the *Liberator* (1831) and founder of the American Anti-Slavery Society (1833). But Garrison's actual following was small, and it is quite possible that a greater influence was exercised by the burning evangelist Theodore Dwight Weld, who with his "Seventy apostles" carried the gospel of antislavery to pulpits throughout the north. Also, the activity of free Negroes, of whom Frederick Douglass (*q.v.*) was the most important, is not to be underestimated.

U.S. abolitionism laboured under the handicap that it threatened the harmony of north and south in the union, and it ran counter to the constitution, which left the question of slavery to the individual states. Therefore the northern public remained unwilling to adopt abolitionist policy and distrustful of abolitionist extremism, as illustrated by John Brown's raid at Harpers Ferry (1859). Even when convinced of the evil of slavery as they were by Harriet Beecher Stowe's *Uncle Tom's Cabin* (1852), most northerners rejected abolitionism. But they were prepared to resist the spread of slavery into new territories. The election of Abraham Lincoln as president on this issue in 1860 led to the secession of the southern states and to the Civil War (1861–65). The war, in turn, led Lincoln, who had never been an abolitionist, to emancipate the slaves in areas in rebellion (1863), and led further to the freeing of all other slaves by the 13th amendment to the constitution in 1865.

Meanwhile, the third phase of the abolition movement had already begun as Britain took the lead in efforts to break up the remaining slave trade. All leading countries, by this time, had enacted laws against the trade, but smuggling was extensive and open. In fact, the closing of U.S. and British markets had merely deflected the trade to Cuba, Brazil and elsewhere! and as late as 1850 more than 50,000 slaves a year were being transported. A new organization, the British and Foreign Anti-Slavery Society, was therefore formed in 1839 under the leadership of Joseph Sturge. While this society kept up a public agitation, the British government sought to obtain international agreements to stop the trade by means of an effective naval patrol, but the profitability of the trade and jealousy of British naval power both stood in the way. In 1862, however, the United States signed a treaty conceding the right of search, which was necessary for effective enforcement. After this treaty, the slave trade was quickly reduced to a trickle. Later, the world-wide reaction against slavery led to abolition in Cuba, between 1880 and 1886, and in Brazil, between 1883 and 1888. Some slavery, of a rather different kind, still prevailed in parts of Africa and Asia and was still the target

of reformers' activities. But the system of African slavery as a western phenomenon, after shaping the destiny of three continents and dominating the history of three centuries, had ceased to exist. See also SLAVERY. (D. PR.)

ABOMINABLE SNOWMAN, a mythical monster supposed to inhabit the Himalayas at about the level of the snow line. No one has ever seen an Abominable Snowman, or Yeti, alive or dead, but certain marks found in the snow have been attributed to it. Where these have not been caused by lumps of snow or stones falling from higher regions and bouncing across the lower slopes, they have probably been produced by bears: at certain gaits bears place the hind foot partly over the imprint of the forefoot, thus making a very large imprint that looks deceitfully like an enormous human footprint traveling in the opposite direction. Credulity is strengthened by the legends current among the Sherpa natives of the neighbouring regions about the Yeti, the local bogyman. Specimens of hair alleged to have come from the Abominable Snowman have proved on scientific examination to be hairs of bears, yaks or other well-known animals. One such specimen, a dried scalp, preserved in a monastery of Tibetan lamas, is the skin, molded to shape during drying, from the back of a serow, a goatlike mountain antelope. (L. H. M.)

ABOMINATION, anything regarded with aversion as things contrary to omen (Lat. *ab*, "from," *omino*, "I forebode"); in the Old Testament, evil doctrines, impure ceremonial practices and heathen idols. The Hebrew words *thoava* and *shikkuz* became *bdelygma* in the Septuagint (Greek version of the Bible) and *abominatio* in the Vulgate (Latin version), the latter term passing into modern European languages. The gospel expression translated in the Authorized Version as "abomination of desolation" (Matt xxiv, 15; Mark xiii, 14; "desolating sacrilege" in the Revised Standard Version) derives from Dan. xi, 31 and xii, 11 ("the abomination that makes desolate"), where it refers to a statue of Zeus Hypsistos (Semitic Baal Shamaim, "Lord of Heaven") erected in 167 B.C. by the Seleucid king Antiochus IV Epiphanes in the temple at Jerusalem. (J. T. M.)

ABOR, an Assam tribe inhabiting hills north of the Brahmaputra river in northeastern India, subdivided into Minyong, Galong, Padam and other groups. They fall into patrilineal exogamous sects or clans with traces of dual organization. A cross division exists into Mishing and Mipak—pure and impure, the latter condition being hereditary and contagious as a result of sexual intercourse: though exogamy is not affected by it. The dead are buried; monogamy prevails, but the Galongs practise the levirate (*q.v.*) and polyandry within the family circle; slavery, tattooing and segregation of the unmarried obtain. Public affairs are managed by elders and offenders are fined by the random confiscation of property. Weapons used include long swords, crossbows, bows, poisoned arrows and spears. Men wear bark loin cloths with tails, women a string of small circular metal plates.

ABOR HILLS: see SIANG FRONTIER DIVISION.

ABORIGINES, the inhabitants found in a country at its first discovery. The aborigines were a mythical people of central Italy, supposed to have descended from near Reate (an ancient Sabine town) upon Latium, whence they expelled the Siceli and settled down as Latini under a King Latinus. The etymology of the name (*ab origine*) makes them the original inhabitants (Gr. *autochones*) of the country, but is inconsistent with the fact that the oldest authorities (*e.g.*, Cato in his *Origines*) regarded them as Hellenic immigrants, not as a native Italian people. Other explanations suggested are *arborigines*, "tree-born," and *aberrigines*, "nomads." See RACES OF MANKIND.

ABORTION may be defined as the termination of pregnancy before independent viability of the fetus has been attained. It is one form of human reproductive wastage, the general descriptive term for loss of embryonal and fetal lives in reproduction. Wastage may occur throughout pregnancy, during the birth process and in the first days following delivery. Very few fetuses weighing less than 1,000 g. (2 lb. 3½ oz.) and born earlier than 24 weeks after conception survive, and pregnancies terminated prior to this period are generally considered abortions. Expulsion of a dead fetus later in pregnancy is called stillbirth, and birth of a living infant

before term is called premature birth. Miscarriage is a folk term for spontaneous abortion.

The distinction between abortion and stillbirth is not agreed upon by all persons and all governments, and the World Health organization in 1950 recommended that neither term be used, suggesting instead that when a fetus is born dead it be classified in one of four groups: group I, early fetal death—pregnancy of less than 20 weeks; group II, intermediate fetal death—pregnancy from 20 to 28 weeks; group III, late fetal death—pregnancy of more than 28 weeks; group IV, fetal death with length of pregnancy unknown.

It has been estimated that 10% to 12% of all pregnancies terminate as abortions. Early abortion may occur before the young pregnancy has obtained a secure attachment to the uterine lining. Many such early abortions are not recognized by the patient or her physician because they induce no recognizable symptoms.

The failure of a baby to survive pregnancy may be the result of a number of factors, among them physical impairment of the mother; a complication of pregnancy; or abnormal condition of the baby or its environment. Abnormalities of the developing embryo and chorionic sac which contains it are the result of intrinsic defects in the germ cells (that is, of defects existing in the egg or sperm before conception took place); uterine lining poorly prepared because of insufficient hormones; or gross alteration of the environment by tumours of the uterus, infections, or congenital or acquired defects. The ovarian hormones estrogens and progesterone are necessary for the establishment and normal progress of early pregnancy, and inadequate secretion of them may result in abortion. Psychogenic factors also are probably responsible in some cases. A mother who has acquired diabetes during childhood or adolescence may experience a fetal death or give birth to an excessively large child who may fail to overcome the results of the abnormal environment provided by its diabetic mother. The mother who has Rh-negative blood married to a husband who is Rh-positive may become immunized in her first or subsequent pregnancies and the baby may develop a serious anemia and succumb in the uterus or (rarely these days) after birth. A mother may have high blood pressure or kidney disease which become aggravated during pregnancy. The inadequate circulation to the uterus under such circumstances may interfere with the development of a normal placenta, or this important structure may undergo early senile changes, so that the baby is deprived of an adequate blood supply and it dies in the uterus or its growth and development are retarded.

A fetal death may result when a baby who moves freely in the uterus becomes entangled in its umbilical cord, cutting off its oxygen supply. The placenta may become partially separated from its uterine attachment, likewise interfering with oxygenation and occasionally initiating early labour. A baby may develop major malformations, resulting in its death during pregnancy or immediately after its birth. Infections of the baby can occur in late pregnancy, particularly if the fetal sac ruptures some time prior to the onset of labour, or in the early days following birth. Some of these infections are due to staphylococcus organisms which may be resistant to antibiotic therapy.

A few women, designated as habitual aborters, have repeated abortions. In these women some recurrent factor or factors predispose to the early termination of pregnancy. Complete and careful diagnostic study and proper therapy will prevent the recurrence of abortion in most of these women.

The course of an abortion varies. The embryo may die and its expulsion from the uterus may be delayed for several weeks or even several months. The abortion process may begin with lower abdominal pains, resembling menstrual cramps, and slight bleeding. At this stage damage to the gestation may be slight, and proper treatment may result in continuation of the pregnancy and a healthy child. In other cases the abortion process starts with profuse bleeding and severe cramps, indicating a rapid separation of the gestational sac from its uterine attachment and its expulsion from the cavity of the uterus. The physician will usually complete such an abortion surgically and make certain that no remnants of the pregnancy remain in the uterus.

In most countries medical ethics and the law permit the deliberate termination of pregnancy (therapeutic abortion) when the mother's health, life or reason are seriously jeopardized by the continuation of the pregnancy and when grossly defective offspring may surely be expected. The frequency of therapeutic terminations of pregnancy is decreasing rapidly with the advances of medical knowledge. In many parts of the world a person who willfully causes an abortion, as well as anyone who contributes to the act in the absence of medical indications, is liable to conviction of crime. The frequency of such criminal abortions is unknown, but they contribute to much invalidism and death. Infection is a common complication and may result in the inability to have children.

ABORTION, CONTAGIOUS; see BRUCELLOSIS.

ABOUT, EDMOND FRANÇOIS VALENTIN (1828–1885), French novelist and journalist, a vigorous polemist who effectively introduced a mordant humour into the most serious subjects, was born on Feb. 14, 1828, at Dieuze, in Lorraine. After a period at the École Normale he went to Greece with a grant from the French school at Athens. On his return he published *La Grèce contemporaine* (1854), a biting satirical and occasionally unfair account of his personal impressions. Turning to novel writing, he published the whimsical *Le Roi des montagnes* (1856), showing an individual humour later echoed by Daudet, and attempted realism in *Tolla* (1855), *Germaine* (1857) and *Madelon* (1863). About resumed his humorous style with *Le Cas de Monsieur Guérin*, *L'Homme à l'oreille cassée* and *Le Nez d'un notaire* (all 1862), his best works.

Under Napoleon III, About proclaimed his liberal views in *La Question romaine* (1861) and *Le Progrès* (1864). Following the establishment of the Third Republic he founded in 1871 a periodical, the *XIX^e Siècle*, in which he showed himself a brilliant journalist and controversialist, with a formidable wit. A convinced anticlerical, he campaigned for the secularization of French education. Elected to the Académie Française in 1884, About died in Paris on Jan. 16, 1885.

See M. Thiébaud, *Edmond About* (1936).

(R. DL.)

ABOYNE, a village of Aberdeenshire, Scot., lies on the river Dee. 31 mi. W. of Aberdeen by road. Pop. (1961) 1,544. It is a picturesque village with a large green where the Aboyne Highland games are held every September. To the north is Aboyne castle, for centuries the seat of the marquises of Huntly. At Aboyne the Dee is crossed by a fine bridge (leading to Glen Tanar), and nearby is the Queen's loch. Local industries are farming and saw-milling, and there is a fortnightly market for cattle and sheep. Michael fair is a well-known sheep sale held every autumn.

(Jo. F.)

ABRA, interior province in northwestern Luzon, Republic of the Philippines. Area 1,471 sq.mi. Pop. (1960) 116,700. Hilly and mountainous, it is drained by the Abra river, whose flood plain is the principal level terrain. The main crop is rice, with tobacco and corn of secondary and lumbering of minor importance. Bangued, the capital, is the chief settlement and commercial centre. The inhabitants are principally Ilocanos, and secondly Igorots (mountain people).

(AN. C.)

ABRABANEL (ABRAVANEL OF ABARBANEL), **ISAAC** (1437–1508), Jewish statesman, philosopher, theologian and commentator, was born at Lisbon, Port., of an ancient family which claimed descent from the royal house of David. Like many of the Spanish Jews he united scholarly tastes with political ability. He was a favourite of King Alfonso V, who entrusted him with important state business, but after the king's death in 1481 Abrabanel was compelled to flee to Spain, where for eight years (1484–92) he held the post of a minister of state under Ferdinand and Isabella. After the expulsion of the Jews from Spain in 1492 Abrabanel resided at Naples, Corfu and Monopoli, and in 1503 moved to

Venice, where he was a minister of state until his death in 1508.

Abrahanel was one of the first to see that for biblical exegesis it was necessary to reconstruct the social environment of olden times, and he applied his practical knowledge of statecraft to the elucidation of the books of Samuel and Kings.

BIBLIOGRAPHY. — J. S. Minkin, *Abarbanel, and the Expulsion of the Jews From Spain* (1938); J. Sarachek, *Don Isaac Abravanel* (1938); B. Netanyahu, *Don Isaac Abrahanel, Statesman and Philosopher* (1953).

ABRACADABRA, a word analogous to *abraxas* (*q.v.*), used as a magical formula by the Gnostics of the sect of Basilides (*q.v.*) in invoking the aid of beneficent spirits against disease and misfortune. It is found on *abraxas* stones, which were worn as amulets. The Gnostic physician Serenus Sammonicus gave precise instructions as to its mystical use in averting or curing agues and fevers generally. Subsequently its use spread beyond the Gnostics, and in modern times it is applied contemptuously to complicated, unscientific hypotheses.

ABRAHAM, the first of the Hebrew patriarchs, stands at the fountainhead of the history of redemption in the Bible.

Traditions About Abraham in Genesis. — In the prologue to the tradition about Abraham in Gen. xi the origin of Abraham, at first called Abram, is traced to Harran in northern Syria and to Ur of the Chaldees in the lower Mesopotamia valley. The prologue connects the history of Abraham (Gen. xi, 26–xxv. 10) with the primeval history of Gen. i, 1–xi, 9. Therein Abraham is a symbol of God's plan of redemption for the world.

In Gen. xii Abraham's story proper begins. His call is described briefly (xii, 1 ff., part of the "J" tradition; see **PENTATEUCH**). God commands him to break away from his environment and to go out to a new land. The promise of progeny and of material felicity is given to him. Furthermore, he is to act as intermediary for this blessing to "all the families of the earth" (xii, 3).

The theological importance of these opening verses cannot be overemphasized. Abraham is from now on to live on God's word (God's providence) alone, but in a hostile world (xii, 6). Abraham's unhesitating acceptance of his call is described in a single word in the Hebrew ("so [he] went"; xii, 4). The meaning of the story lies in Abraham's obedience to God, his severing of his ties with his former life and his achieving of a new existence based on one single thing: God's promise.

The journeyings of Abraham are related in the subsequent material. He comes to Shechem, builds an altar there and receives the divine promise that his descendants will inherit the land (xii, 7). On his way south through the central mountain ridge of Canaan, he pauses at Bethel, where he builds another altar and worships, and then comes to the Negev, where he settles close to Hebron (xii, 9; xiii, 18). It is in this southern area that the traditions about Abraham most probably belong, and the body of the tradition actually begins to develop at this point (xii, 10). When Abraham journeys from Hebron down to Egypt for better grazing grounds, which is normal nomadic practice, the story for the first time takes on flesh and colour, reporting incidents and describing people. Because of the beauty of his wife Sarah, he meets trouble in the land of Egypt, but he is saved by his presence of mind and the power of Yahweh (xii, 11 ff.; cf. xx, 12, where Sarah is reported to be Abraham's half sister).

The narrative moves from the story of Lot in ch. xiii (continued in ch. xix) and the puzzling ch. xiv on toward the important event of God's covenant with Abraham in ch. xv. Ch. xiv is somehow intrusive in the story, and it is strangely foreign to the traditions about Abraham. In it Abraham appears as a warrior who, in order to help Lot, his captured kinsman, campaigns against four foreign kings who had made war on Bera, king of Sodom, and his four allies. (The names of these Canaanite allies do not occur in other sources, and scholars have not identified any of them with certainty.)

The campaign incident in ch. xiv connects Melchizedek, king of Salem (Jerusalem), with Abraham. He blesses Abraham who, in his turn, swears to Melchizedek's God, El Elyon ("God most high"). Here, then, the continuity between Abraham's God and native Canaanite worship is expressed. Thus too, Abraham is

linked with Jerusalem, the later throne of David, and Melchizedek becomes a symbol of the promises to David (Ps. cx, 4).

Ch. xv contains the account of God's covenant with Abraham—material of unmistakable historical value for the understanding of Abraham and his religion. In several ways the chapter is comparable with the narrative of his call in ch. xii, and it has been suggested that in the oral stage of the tradition this account stood originally at the beginning of the story of Abraham in Canaan.

The chapter falls into two sections, xv, 1–6 and xv, 7–21, relating first the promise to Abraham and second the covenant with him. These two are inseparable and belong almost entirely to "J," the oldest literary tradition of the Pentateuch. In the first section Abraham receives God's promise of progeny in a vision. He was concerned about his childlessness and the possibility that his slave Eliezer would succeed him. (This point is clarified by comparison with the customary law of the 2nd millennium B.C. regarding adoption, as exemplified in tablets found at Nuzi, southeast of Nineveh. A childless man would adopt a son who would serve him in his old age. Should a son be born to the man, the adopted son's status as an heir would be changed.)

This section is highly theological; it brings together the themes of God's promise and man's doubt (xv, 2–4). The tension between the two is resolved only by Abraham's quiet and submissive acceptance and trust (*i.e.*, his faith), which is the occasion for the famous statement "And he believed the Lord; and he reckoned it to him as righteousness" (xv, 6).

The second section, xv, 7–21, is an account of the covenant (xv, 13–16, 19–21 are a later interpolation). During a sacrificial rite, in a "deep sleep" and in "dread and great darkness," Abraham perceives God as a flaming torch passing between the portions of the offering. Here, a covenant rite is easily recognizable (the "passing between" was a part of the ritual). The psychological mystery is expressed through the "deep sleep" during which Abraham's perceptive powers are heightened. Once more the promise given to Abraham concerns the land which his seed is to inherit (xv, 18). Through this account of the covenant, we are given an authentic glimpse into Abraham's cultic experience of the transcendent God who speaks into a human situation.

Abraham's concubine Hagar and her son Ishmael are introduced in the following chapter. In accordance with a type of marriage contract known from the 2nd millennium, Sarah, being childless, had provided her husband with a concubine, who bore him a son. The story of Hagar is resumed in ch. xxii, where Abraham is reluctant to "cast out this slave woman with her son" (xxii, 10 ff.) because of Sarah's jealousy. (Nuzi law forbade the expulsion of the slave wife in such cases.)

A second account, ch. xvii, of the covenant with Abraham (from the so-called Priestly tradition), although differing considerably in detail and in theological concern from its parallel in ch. xv, 7–18, is in essentials the same: God establishes a covenant with Abraham and gives him a promise of land and offspring. God reveals himself here as El Shaddai ("God Almighty"; xvii, 1), another form of revelation for Yahweh, as explained in Ex. vi, 3 (also from the Priestly source, "P"). Here, God announces that Abraham is to change his name from Abram to Abraham, showing that he is to become the father (Heb. *ab*) of a multitude of nations. This is probably a popular etymology. The name Abraham is a longer form of the shorter Abram with the same meaning: "The father [the deity] is exalted." In xvii, 9–14 the rite of circumcision is introduced as the sign by which Abraham's descendants shall be distinguished.

In the following section, also from "P," Abraham is promised a son (xvii, 15–27). The promise is repeated in xviii, 10 (from "J") when God appears in the form of three men whom Abraham entertains to a meal. Later, "at the appointed time," the child, Isaac, is born (xxi, 2; xviii, 14).

At this point a climax has been reached in the narrative. The promise of descendants has materialized at the birth of Isaac. This climax, however, is soon to be countered by the command to sacrifice the boy in ch. xxii.

In the meantime, other material is brought in before and after the birth of Isaac, some of which had belonged originally to inde-

pendent cycles of traditions, such as the story of Lot's escape from Sodom in xix, continuing xiii, 5–13. Abraham journeys in Gerar (ch. xx), is in danger on account of Sarah (xx, 1 ff., a doublet to xii, 10 ff.), makes a treaty with Abimelech of Gerar (xxi, 22–32) and founds the cult of El Olam in Beersheba (xxi, 33).

The great testing point in Abraham's life is then described (ch. xx). God tests his obedience (it is stated explicitly in xxii, 1) by ordering him to offer up his only son, Isaac, as a burnt offering. Abraham leaves Beersheba in obedience and journeys to the land of Moriah (unknown; traditionally Jerusalem). The great scene, holding all the tension of tragedy, is, in true Hebrew narrative style, painted with few but bold strokes. There had been built up in the preceding chapters (xii; xvi; xviii) a climactic account of God's promises and their fulfillment in the birth of Isaac. All this is now to be nullified at one stroke. "The story tells of something far more terrible than human sacrifice: namely of being forsaken by God" (G. von Rad).

At the last moment, God releases Abraham from the terrible injunction. The story, then, finds its denouement in the redemptive word, the command not to harm the boy (xxii, 12), and the accompanying event, the finding of a ram which Abraham offers up in Isaac's place.

The tradition about Abraham in its present form ends with the death of Sarah and the purchase of the patriarchal burial chamber in Hebron (ch. xxiii), the death of Abraham himself and the burial of them both (xxv, 7–10).

Figure of Abraham Elsewhere in the Old Testament.—There is little doubt that David took up the tradition about Abraham to consolidate the religious authority of Jerusalem (Gen. xiv, 19 ff.; Ps. cx, 4). Abraham is the active symbol of the blessing and the promises of the covenant (Ex. vi, 8; Deut. i, 8; II Kings xiii, 23), and as such he is the symbol of the meaning of the nation's history. In Isa. li, 2 he is called the father of Israel, and in Isa. xli, 8 Israel is called "the offspring of Abraham" and Abraham the friend of God.

Abraham in Judaism and in the New Testament.—In rabbinic tradition Abraham occupies a position of eminence. His faith atones for the sins of Israel, and he was even the rock upon which God built and established the world. In the New Testament, allusions are made to this role of Abraham; e.g., in Matt. viii, 11 and Luke xiii, 28–29, where Abraham is an eschatological figure, represented as the host at the heavenly banquet (cf. Luke xvi, 22). The promises to Abraham are recognized as giving the Jews a special prerogative (Rom. ix, 8; xi, 1 ff.). Yet, being children of Abraham has a spiritual, rather than a national, meaning (Rom. ix, 7 ff.; cf. Gal. iii, 9). The true children of Abraham are "children of the promise" (Rom. ix, 8), and that promise is fulfilled in Christ (Gal. iii, 14). Thus Abraham becomes a precursor of Christ. In Him the promises to Abraham are fulfilled (Gal. iii, 25–29; cf. Heb. vii), and Christians, even the gentile ones, partake in the blessing in Abraham (Gal. iii, 8 ff.; cf. Gen. xii, 3). Paul seizes upon Abraham's righteousness by faith (Gen. xv, 6) in order to expound his central thesis that righteousness is granted through faith rather than through works (Rom. iv, 1 ff.; Gal. iii, 6 ff.). In the epistle to the Hebrews, Abraham is an example of the faith that receives God's promise and responds to it in obedience (Heb. xi, 8 ff.).

Abraham as a Historical Figure.—The traditions about Abraham in the Bible are derived from oral traditions in epic form. Successive generations retold the stories and applied them to the needs and concerns of their own particular cultic and social institutions. Some of the narratives were probably told in order to substantiate ancient blood ties between clans. Furthermore, the tradition about Abraham is involved with those of Isaac and Jacob in a simple manner, making of the whole a well-rounded story. Behind this simplicity, there undoubtedly lies a vastly complex picture of Hebrew origins in the pre-Mosaic era.

How much can be stated about Abraham as a historical person? Abraham and the other patriarchs have sometimes been considered to be personifications of clans or even figures of myth. This opinion has been proved erroneous. To be sure, the story of Abraham in the Bible is not a biography in the modern sense of

the word. The ancients told stories of persons in order to illuminate the meaning of the clan's or the nation's life. Yet, there can be no doubt that Abraham existed. On the other hand, it is not possible to be specific either about when he lived or about the details of his life.

Excavations at Mari on the Euphrates, at Nuzi and elsewhere have yielded texts which illuminate customs, names and tribal history in the first half of the 2nd millennium B.C.; it has become evident that the narratives about Abraham in the Bible authentically reflect that age (or perhaps the middle of the millennium). Abraham was a seminomad who belonged perhaps to a social stratum called Habiru (cf. the word "Hebrew," possibly from the same root, in Gen. xiv, 13).

The religion of Abraham has now been shown, by Old Assyrian inscriptions from the 20th century B.C. and by material of a later period, to belong to a type of high-god religion, which fits the picture given in Genesis. The "God of the Fathers" was a type of deity intimately connected with the clan, whose "patriarch" consciously chose the God and became the founder of the clan's cult. Abraham was such a cult founder (cf. "the God of Abraham," Gen. xxvi, 24).

The literary history of the traditions about Abraham is uncertain in many points because an extremely complex tradition-history has been compressed into a relatively short cycle. As in other histories of the same type, groups of stories have been connected with a particular locality such as Beersheba and Mamre-Hebron. In some cases, the name of the locality has not been preserved, such as the scene of the covenant in Gen. xv. The stories of Lot in xix and of the courtship on Isaac's behalf in xxiv are but loosely tied to the traditions about Abraham. The stories connected with the terebinth grove in Mamre (xviii, 1 ff.) and the cave of Machpelah (xxiii, 19; xxv, 9) locate Abraham in Hebron, where his home probably was. The chronological framework and the ties between independent cycles come from the "P" tradition (xi, 10–27, 31, 32; xvi, 3, 15, 16; xvii; xxi, 3–5, 23; xxv, 7–10). Some of the material assigned to this source, such as the Machpelah story (xxiii), is among the oldest of the traditions about Abraham.

Abraham's Religious Significance.—The story of Abraham centres in three themes: God's call; Abraham's response, in obedience and faith, to God's call; and God's promise to Abraham and its fulfillment. These themes constitute the significance which Abraham had for religious thought in the Bible. The implications of faith for social responsibility were not spelled out until later, in the covenant theology of Moses and his followers (see COVENANT and MOSES), but Abraham, as a figure in history, furnished the directive principles for the life of God's people: faith in God's promise and obedience to God's call.

See APOCALYPTIC LITERATURE for the Apocalypse of Abraham and the Testament of Abraham.

ABRAHAM, THE PLAINS OF, a plateau to the southwest of the city of Quebec, the scene of the historic battle between the French under Louis Joseph Montcalm (*q.v.*) and the English under James Wolfe on Sept. 13, 1759.

ABRAHAM ECHELLENSIS: see ECHELLENSIS, ABRAHAM.

ABRAHAM IBN DAUD (c. 1110–c. 1180), Jewish historiographer and philosopher of Toledo, Spain. His historical work was the Book of Tradition (*Sepher ha-Qabbalah*), a chronicle to the year 1161 (Latin trans. by Gilbert Générard in *Hebraeorum breve chronicon*, 1572). His philosophy was expounded in an Arabic work better known under its Hebrew title *'Emunah Ramah* ("Sublime Faith," Ger. trans. by S. Weil, 1852). Ibn Daud was

one of the first Jewish scholastics to adopt the Aristotelian system. His work was, however, soon eclipsed by that of Maimonides and failed to exercise much influence.

ABRAHAM-MAN, the nickname for a vagrant who wandered in England in Tudor times. The phrase is as old as 1561, and was due to these beggars' pretending that they were patients discharged from the Abraham ward at Bedlam insane asylum in London; on his discharge the genuine Bedlamite, provided he wore a badge, was allowed to roam the country, soliciting alms. This privilege was grossly abused, and thus gave rise to the slang phrase "to sham Abraham"—meaning to feign illness.

ABRAHAMS, ISRAEL (1858–1925), the first native-born Anglo-Jewish Hebraist to enjoy a European reputation, was born on Nov. 26, 1858, into a rabbinical family in London. In 1902, after teaching for several years at Jews' college, London, he was appointed reader in Talmudic at Cambridge, where he remained until his death on Oct. 6, 1925. He was distinguished both for the range of his interests and for the lightness of his touch. His *Jewish Life in the Middle Ages* (1896; rev. ed. by C. Roth, 1932), a highly readable social history, was his first major book. His other works include several monographs on medieval Jewish literature and *Studies in Pharisaism and the Gospels* (1917; 2nd series, 1924). From 1889 to 1908 he was co-editor of the *Jewish Quarterly Review*, and he was a leading member of the Jewish Historical Society of England. Orthodox by upbringing, he was later among the founders of the Liberal Jewish movement in England.

(C. R.)

ABRASIVE, relatively hard material used to grind or polish materials softer than itself. Grinding wheels, oil stones and sandpaper are common examples of abrasives. The high precision and fine surface finish of many modern machine tools are obtainable only with the use of abrasive grinding operations. Most household cleansers use a mild abrasive to help the soap or detergent do its work.

Primitive man used abrasives to help shape his stone tools by rubbing them against harder stones. Drawings in ancient Egyptian tombs show the polishing of jewelry and vases with abrasives. In later historical times, craftsmen used natural abrasive stones shaped into wheels, such as grindstones and mill wheels, and into blocks for use by hand for sharpening scythes, knives, axes and woodworking tools. Powdered abrasives were used for polishing in much the same manner as they were used by the Egyptians.

It was not until late in the 19th century, when it became necessary to work with harder metals and to closer tolerances, that abrasives assumed a major role in the manufacturing industry. Synthetic abrasives were developed with improved and more uniform characteristics, and new machines were designed to use these abrasives to best advantage. Natural abrasives are still widely used in some applications, but in industrial grinding they have been largely replaced by synthetics.

Natural Abrasives.—Diamonds are the hardest of all abrasives. The small and imperfect diamonds are crushed and the abrasive powder obtained is graded and used in many grinding and polishing operations, especially on carbide tools, which are difficult to form by any other method. (See **DIAMOND**.)

Corundum (*q.v.*) is a crystalline form of aluminum oxide (Al_2O_3) mined principally in South Africa. It is quite high in cost but among natural abrasives is second only to diamond in hardness.

Emery (*q.v.*) is a mixture of corundum and magnetite (black iron oxide, $FeO \cdot Fe_2O_3$), which has been mined for several centuries on Cape Emery on the island of Naxos in the Greek archipelago. For many years it was the standard industrial abrasive, being formed into emery wheels and emery stones and used to coat cloth. It has now been largely supplanted by synthetic abrasives such as silicon carbide and synthetic aluminum oxide.

Garnet is a silicate of iron and aluminum mined in the eastern United States and in Spain. It is used for making coated abrasive paper and cloth.

Quartz is among the commonest of all minerals and occurs in many forms. Quartz sand is used for making sandpaper and for sandblasting. Sandstone, of which quartz is the main constituent, is used for making grindstones and for sharpening stones. Some

compact forms of quartz, such as Arkansas and Washita stone, make the finest oil stones for sharpening knives and other edge tools.

Pumice is the frothy part of lava. It is a relatively soft abrasive used in cleaning and scouring compounds. Other soft abrasives such as diatomite, tripoli, rouge and crocus are used primarily for buffing and polishing operations.

Synthetic Abrasives.—Carborundum, or silicon carbide (SiC), initially prepared in 1891, was the first important synthetic abrasive. It is made by fusing coke and sand at high temperature in an electric furnace. Silicon carbide is harder and stronger than corundum, but inferior to synthetic diamonds and boron carbide in hardness. It is second only to aluminum oxide in its importance as an industrial abrasive and is used for grinding cast iron, tungsten carbide and other hard materials. (See **SILICON CARBIDE**.) Other important synthetic abrasives, in order of hardness, are discussed in the following paragraphs.

Synthetic diamonds are produced commercially and are competing with the natural product. Their greater uniformity justifies their higher cost in some applications.

Boron carbide (B_4C) is, next to diamond, the hardest of all abrasives. It is used for grinding very hard materials such as tungsten carbide, which is widely used in dies and cutting tools.

Artificial aluminum oxide (Al_2O_3), or artificial corundum, is not so hard as silicon carbide but is stronger and is preferred for grinding the common grades of carbon and alloy steel. (See **CORUNDUM, ARTIFICIAL**.)

Iron and steel are sometimes used as abrasives in the form of shot and grit for air blasting and in the form of steel wool for rubbing and polishing.

Industrial Techniques.—Abrasives for industrial use are crushed into a powder which is graded according to size from the coarsest, #6, to the finest, #600. In some polishing and cutting operations these powders are mixed with a liquid or paste and rubbed against the work. Abrasive grains are also cemented or applied as a paste to soft polishing wheels of cloth, felt or leather which are used for buffing or polishing metal or plastic parts to impart a fine finish or as a preparation for electroplating. Most of this buffing is done by hand; however, some operations, such as the polishing of stainless steel sheets, are done in large automatic machines.

In most applications the abrasive grains are pressed into wheels or blocks, using various binders, or are glued to the surface of paper or cloth to form coated abrasives. The wheels may be used in simple hand grinders or in high precision machines for grinding of flat surfaces, for internal and external cylindrical grinding or for the grinding of screw threads or cutting tools. The abrasive blocks may be used as oil stones for the hand sharpening of knives and other edge tools or in honing machines for imparting a fine finish to such parts as automobile cylinders and crankshafts. Coated abrasives include sheets of sandpaper and emery cloth, which have been used for many years for hand finishing of woodwork and metal parts, and synthetic abrasive belts, which are used in belt grinding machines for finishing many metal surfaces.

In sandblasting, the abrasive grains are blown by air pressure or impelled by centrifugal force against the surface of metal castings or other materials for removing rust or scale or smoothing irregularities, or for imparting a slightly rough or matte finish, such as in ground glass. (See **BLAST CLEANING AND SHOT PEENING**.) Ultrasonic machining uses a liquid abrasive mixture flowing under a shaped tool of brass or soft steel which is caused to vibrate at a high frequency. The tool, working in combination with the abrasive, penetrates rapidly even the hardest materials such as ceramics, glass and carbides, leaving a smooth and accurate hole. See **HARDNESS TESTING**; see also Index references under "Abrasive" in the Index volume.

ABRAUM SALTS (Ger. *Abraum-salze*, "salts to be removed"), a mixed deposit of salts originally regarded as rubble or waste material, including chlorides and sulfates of sodium, potas-

sium and magnesium, found in association with rock salt at Stassfurt, Ger. They are a principal source of potassium (*q.v.*).

ABRAXAS (ABRASAX), a word probably first used by the Basilidians (*see* BASILIDES) and engraved on certain stones, called on that account abraxas stones. The Greek letters *abraxas* make up the number 365, and the Basilidians gave the name to the 365 orders of spirits which emanated in succession from the supreme being. These orders were supposed to occupy 365 heavens, each fashioned like but inferior to that above it, the lowest being the abode of the spirits who formed the earth and its inhabitants, to whom was committed the administration of its affairs. In addition to the word abraxas the stones often have cabalistic figures engraved on them.

ABRAXAS STONE

ABREU, JOÃO CAPISTRANO DE (1853–1927). Brazilian historian, was born near Maranguape, Ceará, Oct. 23, 1853. In Rio de Janeiro after 1875, he was a journalist, teacher and member of the National Library staff. From 1883 to 1899 he was professor of Brazilian history at the Colégio Dom Pedro II. Distinguished as an editor and essayist, he was initially influenced by Auguste Comte (*q.v.*) but soon embraced the German school of historical realism. His critical editing of chronicles and of the historian Francisco Adolfo de Varnhagen assured him of high rank among Brazil's historians but his *Caminhos antigos e o povoamento* (1899; 1924) and *Capítulos de História Colonial* (1907) give him first place. The former work, often compared to Frederick Jackson Turner's frontier thesis, stressed the importance of the previously neglected backlands. The *Capítulos* reinterpreted and enlarged the scope of Brazilian historiography and became the guide for subsequent historical research and writing. He died in Rio, Aug. 13, 1927. (G. C. A. B.)

ABRON, a west African people, known also as Brong, numbering about 20,000 who live in the Bondoukou region of the Ivory Coast and north of the Ashanti in Ghana. In 1921 the 416 villages in the Abron kingdom included about 30% Brong and 70% Kulango, Agni, Dyula and other nearby peoples. Political and judicial representation are made through the family head (the eldest male) to the village chief, the chief of the province and the king. Descent is patrilineal but inheritance passes normally to the eldest younger brother, or if there are no brothers, to the eldest sister's eldest son. The son of the deceased inherits only if there are no brothers and no sisters' sons. The Abron practise neither circumcision nor clitoridectomy.

The Abron are sedentary farmers who grow bananas, manioc and taro. They recognize a sky god whom they identify with Allah, an earth god and deities of local rivers: they also sacrifice to their ancestors. (Wt. B.)

ABRUZZI, DUKE OF THE (LUIGI AMEDEO) (1873–1933), Italian vice-admiral, mountaineer and explorer, born at Madrid on Jan. 29, 1873 (the son of the duke of Aosta, who was then king of Spain as Amadeo), was the first to ascend Mt. St. Elias in Alaska (1897). In 1899 he organized an arctic expedition part of which reached latitude 86° 34' N., at that time the record of northern exploration. In 1906 he was the first to ascend the Ruwenzori in east Africa, reaching the twin summits which he named Margherita and Alexandra. He also made the first detailed map of the Ruwenzori. In 1909 he ascended K-2 in the Himalayas to an altitude of over 20,000 ft. and on July 17 Bride peak to 24,600 ft. During World War I he commanded the naval forces in the Adriatic, but he resigned in 1917 owing to disagreements with Adm. Thaon di Revel, his chief of staff, and retired from the service. Afterward he undertook a colonization scheme on the lower Webi Shebeli in Italian Somaliland, and explored and mapped the river. He died in Somaliland on March 18, 1933.

English translations of his works are *The Ascent of Mount St. Elias* (1900); *Ruwenzori* (1909).

ABRUZZI E MOLISE, a region of south central Italy, comprising the provinces of L'Aquila, Campobasso, Chieti, Pescara and Teramo, with a total area of 5,881 sq.mi. and a population of 1,684,030 in 1951. Most of the region is mountainous or hilly, except for intermontane basins such as those of L'Aquila, Sulmona and the Fucino. The Apennines cover the greater part of the region, consisting of three chains with a northwest-southeast trend. The easternmost of these is the highest, including such peaks as the Gran Sasso d'Italia (9,560 ft.) and the Maiella (9,170 ft.); the central group is lower, with Mt. Velino (8,159 ft.); while the western group, comprising the Sabini and Simbruini mountains, does not exceed 7,000 ft. The Apennines are chiefly of limestone, and karstic phenomena (dolinas, caves, underground drainage) are common. In the east, toward the Adriatic, the hills descend gradually to the sea and are of sand or clay. The southernmost part of the region is the rolling plateau of Molise. The coast lacks good harbours for its entire length and fishing does not play an appreciable part in the economy. The principal rivers draining toward the Adriatic (Tronto, Pescara, Sangro, Trigno, Biferno) provide water for irrigation in their fertile lower valleys. The water level in these streams varies greatly according to seasons; and floods, due in large part to indiscriminate felling of timber on the higher slopes, are frequent. Cutting of the forests also contributes to the ever-present danger of landslides endangering roads and railroads. Agriculture does not thrive on the shallow soils of most of the region and crop averages are low. Wheat is the main cereal crop; grapes and, toward the Adriatic, olives and fruit are grown, while among industrial crops tobacco, sugar beet and saffron are of importance. Animal husbandry has long been the mainstay of a large part of the population, and migratory herding (transhumance) of sheep, from mountain pastures in the Abruzzi to the lowland winter pastures of the Foggia plain and of the Roman region, is still a feature of the economy. Pigs are raised in large numbers, and hams and sausages of the Xbruzzi are well known. Industrial development has been negligible except for food industries and artisan work on a small scale. The main rail artery is the Rome-Pescara line, crossing the central part of the region, connecting Rome with the Abruzzi and with the Adriatic. Lines of local importance include those connecting Sulmona with L'Aquila and Terni to the north, with Venafrò and Campobasso to the south, as well as the lines from Campobasso to Benevento and to Termoli on the Adriatic. Important cities are the provincial capitals L'Aquila, Campobasso, Chieti, Pescara and Teramo.

The region had long resisted conquest and retained its own character even after Roman rule was imposed on it. During the early middle ages all of it came under the Lombards, the Abruzzi being controlled by the duchy of Spoleto, and Molise by the duchy of Benevento. The Normans established themselves in the Xbruzzi during the 12th century, and the region sided with the Hohenstaufens during their long struggle with the papacy. After the fall of the Hohenstaufens, the region came under the Angevin, Spanish and Bourbon rulers of the kingdom of Naples (divided as Abruzzo Ulteriore I, Abruzzo Ulteriore II, Abruzzo Citeriore and Molise) and became part of the united Italian kingdom in 1860. Among the natives of the region are two of the great writers of modern Italy, Gabriele D'Annunzio and Ignazio Silone. In the field of the fine arts, while the Abruzzi retain a few Roman monuments, their period of greatest development was the 12th–14th centuries, and cathedrals, churches and abbeys bear witness to the flowering of Romanesque and Gothic architecture and sculpture. (G. KH.)

ABSALOM, the third son of David (*q.v.*) and his father's favourite. The picture presented in II Sam. xiii–xix (which deals mainly with his life) suggests that he was the Alcibiades of the Old Testament, alike in his personal attractiveness, his lawless insolence and his tragic fate. He is first mentioned as murdering his half brother Amnon, David's eldest son, in revenge for the rape of his full sister Tamar. For this deed he was driven into banishment, but he was eventually restored to favour through the good offices of Joab. Later, when some uncertainty seems to have

arisen as to the succession, Absalom organized a revolt. For a time he seemed to be completely successful; David with a few followers and his personal guard fled across the Jordan, leaving to Absalom Jerusalem and the main portion of the kingdom. The usurper pursued the fugitives with his forces but was completely defeated in "the forest of Ephraim" (apparently west of Jordan) and killed by Joab, who found him caught by the hair in an oak tree. To the affectionate chivalrous heart of David, the loss of his son, worthless and treacherous as he was, brought grief which more than outweighed his own safety and restoration.

ABSALON (c. 1128–1201), Danish archbishop and statesman prominent in public affairs under Kings Valdemar I and Canute VI (*q.v.*), was a younger son of Valdemar's foster-father Asser Rig and belonged to the powerful Hvide family of Zealand. After studying in Paris, he returned to Denmark in 1156 and sided with Valdemar in his struggle for the kingdom. After Valdemar's victory at Grathehede (1157), Absalon in 1158 was made bishop of Roskilde. Thereafter he was the king's closest adviser. In opposition to Archbishop Eskil (*q.v.*), he approved the king's support of the emperor Frederick I Barbarossa in his dispute with Pope Alexander III and also Valdemar's oath of fealty to the emperor. By 1167, however, Absalon and the king were reconciled to the pope and were aiming at independence from the emperor.

Absalon directed the building of the fortress of Havn (Copenhagen) and campaigned vigorously against the pagan Wends of the north German coast, whose base on Rigen was captured in 1169. Its incorporation, with papal permission, into Absalon's diocese marked the beginning of Danish supremacy in northern Germany.

Valdemar's claim to rule by divine right received papal sanction in 1170 when his father, Canute Lavard, was canonized and his son Canute VI was crowned as joint king, and Absalon was undoubtedly the author of this policy. Elected archbishop of Lund in succession to Eskil in 1177, Absalon combined Lund with Roskilde till 1192. His zeal for discipline, however, provoked a rising in Skaane when he became archbishop. As guardian of Canute VI, he prevented the renewal of the oath of fealty to the emperor after Valdemar's death (1182) and in 1184 won a decisive victory over a German fleet. He founded many churches in Skaane and Zealand, generously endowed his family's abbey at Soro and, during his last years, tried to unify Danish ecclesiastical procedure. He died at Soro in 1201. Saxo Grammaticus (*q.v.*), whose patron Absalon was, glorifies him as a hero, but modern historians tend to estimate Absalon's achievement less highly.

ABSAROKA, a range of mountains immediately to the east of Yellowstone National park in northwestern Wyoming. The range extends about 170 mi. in a northwest-southeast direction and has a width of 84 mi. Mid-Tertiary volcanic action built up a great plateau in the area. This volcanic accumulation was then uplifted and streams cut deep canyons into the plateau surface. Mountain glaciers have scoured the eroded surface and the resulting features are most spectacular. The upland surfaces (10,000–12,000 ft. above sea level) rise from 2,000 to 4,000 ft. above Yellowstone park and 5,000–6,000 ft. above the Bighorn basin to the east. (H. B. HA.)

ABSCESS, a localized collection of pus in tissue spaces, hollow organs or body cavities. It is formed as the result of infection with pus-forming (pyogenic) organisms; there is local heat, redness, swelling and pain. The cells die and the centre of the inflammatory mass liquefies to form pus, which may break through the wall of the abscess or be emptied by incision. Various names are applied according to the location and the causative organism. The term "cold abscess" designates a localized collection of pus caused by the bacillus of tuberculosis. See BACTERIAL AND INFECTIOUS DISEASES; INFLAMMATION. (F. L. A.)

ABSCISSA. In Cartesian co-ordinates (see ANALYTIC GEOMETRY) the abscissa of a point (P) is the part (OP') of the X axis lying between the origin (O) and the point (P') where a line (PP') parallel to the Y axis cuts the X axis. In each of the two figures, the line segment P'P is also called the abscissa of P. The axis of

X (OX) is called the axis of abscissas.

ABSENTEE OWNERSHIP, a term originally used to describe the ownership of land by proprietors who did not reside on the land or cultivate it personally but enjoyed income from it. The term "absentee ownership" has come to have a social con-

notation not inherent in its literal meaning, based on the assumption that absentee owners lack the personal interest in and knowledge of their lands and tenants.

The fact of absentee ownership has been a social and political issue for centuries in many parts of the world. It was an important criticism directed at the absentee owners among the court nobility in prerevolutionary France, and it was a prominent issue in the debates concerning the alleged exploitation of Irish tenants by English absentee owners in the 19th century. It remains an issue in the numerous programs for land reform in many countries.

Early in the 20th century, Thorstein Veblen, the U.S. economist, also applied the term to owners of huge industrial combinations. He argued that, through their control of vast enterprises, they exercised control over industrial prices and output while not themselves engaging in industrial pursuits.

See T. Veblen, *Absentee Ownership and Business Enterprise in Recent Times* (1923); E. Roll, *A History of Economic Thought*, rev. ed. (1942). (FK. L. K)

ABSENTEE VOTING. A system designed to permit the use of their vote to persons unable to appear at the polling place where they are registered by reason of their state of health, occupation, etc. Special administrative safeguards are necessary to assure the secrecy and legitimacy of absentee ballots; in practice, these keep some eligible persons from voting and have, in certain instances, involved some discrimination along party lines. The basic provisions are few, although arrangements vary in detail from country to country. (X.)

United States.—Absentee voting in the United States was first provided for by state legislation during the Civil War, when 11 Union states permitted men serving in the Union army to vote in the federal election by absentee ballot or by proxy. There were then about 2,000,000 men under arms, of whom about 150,000 voted. But although more than three-fourths of the soldiers voted for the re-election of their commander in chief, Pres. Abraham Lincoln, their total vote scarcely affected the general outcome. There was relatively little interest in the soldier vote during the Spanish-American War or World War I. During the latter, some legislation was discussed, but no action was taken and the war department announced that there would be no voting overseas. It did, however, co-operate with those states which provided machinery for absentee voting within the U.S.

The first use of the absentee ballot by civilians was authorized by a Vermont law passed in 1896, and five years later a similar measure was adopted in Kansas.

Between 1917 and 1942 the number of states which extended this privilege to their citizens increased from 28 to 45. By the 1960s all states had established a system of absentee voting. Military personnel were permitted to vote by absentee ballot by all states, but, except for this common characteristic, great diversity existed in state absentee voting laws. Some states permitted any absent qualified voter to cast an absentee ballot. Others restricted the privilege to those engaged in certain duties, businesses or occupations. Some variation existed, too, in the types of elections in which absentee voting was authorized. The most restrictive laws limited the exercise of the privilege to elections for national office. At the other extreme, some states allowed it in all elections.

The trend has been toward extension and liberalization of the privilege of absentee voting. Many states have authorized the use of an absentee ballot by the physically incapacitated, whether they are located within or outside the state.

World War II experience showed the inadequacy of arrangements for absentee voting in time of war. Late in 1942 a Soldiers

Vote law was passed by congress to facilitate voting, but under its provisions only 28,051 votes were cast for members of congress in that off-year election. For the presidential election of 1944 the law was revised to provide a federal ballot for citizens of such states as approved its use, and then only if the serviceman had applied for a regular state absentee ballot by Sept. 1 and had not received it by Oct. 1. Twenty states approved the use of this ballot. About 2,800,000 servicemen, an estimated 30% of the total number of voting age, cast absentee ballots, state or federal, in this election.

The federal legislation and many of the state laws facilitating absentee voting by service personnel were temporary measures, which expired when peace was restored after World War II. As the presidential election of 1952 approached, with millions of Americans again in uniform, Pres. Harry S. Truman recommended that state laws be revised to remove obstacles to voting by absent military personnel. The president further recommended that a federal ballot be made available to servicemen from states which failed to make adequate provision for absentee voting, but congress failed to act on these recommendations. The defense department estimated that only 15% of the servicemen of voting age voted by absentee ballot in that election.

In the national election of 1956, by contrast, 35% of servicemen of voting age voted, although among the civilian population a smaller percentage of potential voters cast ballots in 1956 than in 1952. Instrumental in bringing about this change were the enactment of the Federal Voting Assistance act of 1955 by the congress and a general revision of state laws on the subject to enlarge the opportunities for absentee voting by removing such obstacles as tardy mailing of ballots to voters, the requirements of personal registration and payment of poll tax. (W. B. Pr.)

Great Britain, the Commonwealth and Europe.—The British Labour government's Representation of the People act of 1948 made eligible for a postal vote: (1) persons certified by a doctor as too ill to appear at a polling booth; (2) persons who would otherwise have to make a journey by sea or by air to reach a polling station; (3) persons who have moved from one electoral registration district to another since the register was compiled; (4) persons away from their place of voting on polling day by reason of their occupation. A proxy vote was allowed to servicemen, government employees and their dependents if they were outside Britain on election day. Few persons have claimed proxy votes, except at the 1918 and 1945 general elections. British law does not make provision for persons who are absent from their electoral district on vacation. It also discriminates against persons who have moved distances of up to 15 mi. within large cities; although they may have changed their constituency, they cannot have a postal vote since large cities are technically single registration districts.

Applicants for the postal vote in Great Britain must file their claim with the election officials for their place of registration at least nine working days before the election; often they do so at the behest of party canvassers. A postal ballot is then issued to them, along with a ballot-paper envelope (bearing on the outside the number of the ballot paper) and an identity form which must be countersigned by someone personally acquainted with the voter. Ballots must be returned by polling day; the election officials verify that the identity forms and the ballot-paper envelopes bear the same numbers and are properly filled out. The two are separated, the ballot envelopes opened and the postal votes then counted. Proxy voting requires an intending voter to nominate a proxy on an official form; the nominee then appears at the polling station with a certificate issued by the registration officer to substantiate his claim to cast a proxy vote.

The largest postal vote in Britain up to mid-20th century was in 1951 when 2.6% (742,000) of the total vote was so cast. In the 1959 election 692,000 postal ballots were issued of which 612,000 were returned; of these, 13,000 were invalidated, usually for lack of a witness's signature. The number of such votes varied from a minimum of 113 to a maximum of 4,069 in individual constituencies; it was usually higher in sprawling rural seats, and lower in compact urban ones.

In close elections the postal vote has been of considerable political importance, because in almost every constituency the Conservatives have obtained well over half of it. Since postal voting figures are not officially announced, one must rely upon the estimates of people present at the count. The authors of *The British General Election of 1959* (see Bibliography) calculate that at that election, if the postal vote be reckoned at three to one in favour of the Conservatives it may be deemed to have won them 11 seats. At a minimum, with the vote divided only six to four in the Conservatives' favour, it accounted for five of their victories. The Labour party's special effort to increase its postal vote at this election apparently had little success. Observers attribute the Conservatives' advantage partly to their superior political organization and partly to the fact that the postal vote seems to be more readily claimed by educated persons and that such are more likely to vote Conservative. Similarly, in the general election of 1957 in the German Federal Republic the party of the better educated, the Christian Democratic Union, secured 60.3% of the 1,537,000 postal votes, although it obtained only 49.6% of the votes cast in person.

Because the proper use of absentee voting facilities is related to education, in parts of the commonwealth where illiteracy is fairly widespread absentee voting is either not allowed, as in Nigeria and Uganda, or allowed only on a severely restricted basis, as in India, Malaya and Jamaica. But in highly literate Australia, where voting is compulsory, generous provisions are made for the casting of absentee votes; there is also an election officer in London to aid Australians in the United Kingdom to vote in Australian federal elections. Where qualifications for electors are not primarily geographical, the postal vote may be the normal form of voting. Such is the case in the voting for the university representatives in the house of commons of Northern Ireland and for the university seats in the senate of the Republic of Ireland. In some European countries where elections are held on Sundays, persons traveling for pleasure are permitted to cast their votes at polling places other than those where they are registered, provided that they have first obtained a certificate from the election officials. Normally the voter, even though voting away from home, must cast his ballot for candidates in his constituency of registration.

Smith, *Elections in Developing Countries* (R. Ro.)

ABSINTHE is a flavoured spirit and not, strictly speaking, a liqueur. It is yellowish-green in colour, dry and bitter, and of very high alcoholic strength, being 68% alcohol by volume. Its predominating ingredient is wormwood (*Artemisia absinthium*), but hyssop, fennel, aniseed, liquorice, angelica root, sweet flag, dittany leaves and star-anise fruit are also used. These herbs are found in the Val de Travers in the Swiss Jura.

Henri Louis Pernod first made absinthe commercially in 1797, after he had bought the recipe from Dr. Ordinaire of Couvet, Switz., but because of the danger to public health its manufacture was prohibited in Switzerland in 1908, in France in 1915 and, later, in other countries including the United States. Wormwood is habit-forming and can cause delirium, hallucinations and even permanent mental deterioration. In 1918 Pernod Fils (Sons) built a factory at Tarragona, Spain, where they imported the necessary herbs, but this was closed down at the time of the Spanish Civil War (1936-39). Since then only imitation absinthe has been obtainable; it is usually made out of aniseed and contains no wormwood. (C. C. H. F.)

ABSOLUTE. The term has two chief uses: as an adjective it is used in contrast with relative, comparative or conditioned; as a noun it is used by philosophers to denote the universe conceived as a single whole or system.

Absolute v. Relative, etc.—1. Sometimes the contrast is between what stands in a certain relation and what does not. Thus the term teacher is described by traditional logic as relative be-

cause its meaning involves relation to a pupil; similarly, pupil is relative because it involves the relation to a teacher. But table and boulder are absolute terms because they do not refer to their objects as standing in any special relation. It has proved difficult at times to be sure whether a term is absolute in this sense or not. For example, are space, time and motion absolute or relative? Newton maintained that they were both. The space, time and motion of ordinary perception were relative, since the position of everything for it was determined by relations to other things; but there were also an absolute space, time and motion in which, for example, a thing would have a position even if there were no other thing in the universe. This absolute view was rejected by Albert Einstein, who held that when we speak of a position, a moment or a motion, relations to other things enter into the very meaning of the term; and this view has come to prevail.

2. Sometimes the term absolute refers to what has reached the extreme limit within its own kind, so that no further improvement or advance is possible. Thus the propositions of mathematics are said to be absolutely true, while most other propositions are conceded only varying degrees of truth or probability; and absolute zero is the temperature at which the motion of particles which constitutes heat would reach complete rest; a more intense physical cold is inconceivable.

3. Closely connected with this usage is a third, in which absolute means that which is without conditions or reservations. Thus absolute monarchy is a government in which the power of the monarch is subject to no conditions or limitations. In ethics an action such as truth-telling is called absolutely right, or an attitude such as love absolutely good, to indicate that the rightness or goodness does not depend on the conditions of any particular society, but holds independently and universally.

The Absolute.—Among philosophers the notion of an Absolute has been common since the time of Plato, but the term is chiefly associated with the German school of Absolute Idealism, whose leading members were Johann Fichte, Friedrich Schelling and Hegel. The simplest way of arriving at the notion of the Absolute is as follows: start with any object or event and ask what are its causes. Repeat the question about the causes themselves and again about their causes. One finds that one is carried in thought along a set of radiating paths, all of which lead out into infinity. Philosophers have been led through such reflections to the notion of a being with the following characteristics: (1) It is all-comprehensive; there could not, even in theory, be anything outside it; to suppose there could only shows that me have not been thinking of the whole. This ultimate whole is the Absolute. (2) Furthermore, it is conceived as an intelligible whole, which implies that if enough is known about it, it is not a mere aggregate of parts, but it is seen that every part is necessarily connected with every other. (3) From this it is held to follow that ordinary beliefs are not wholly true, nor the things of common experience wholly real. Just as one cannot understand what a stomach or a heart is until seen in its place in the organism as a whole, so one cannot see what anything finally is until seen in its place in the Absolute whole. Only the Absolute is fully real. (4) It is timeless or eternal. All time is included within it, but it is not itself subject to change. (5) It is *causa sui*, self-caused; for there can be no cause or ground outside itself. (6) By its leading exponent, Hegel, it was conceived as a conscious whole or mind, consisting throughout of experience, though whether it was to be regarded also as personal and to be identified with God was a matter of dispute. Some philosophers, for example, Josiah Royce, have maintained the Absolute to be morally good; others have followed Spinoza in holding it to be above all distinctions of value. Again, for some who have accepted the notion, such as Plotinus and F. H. Bradley, the Absolute was a seamless whole, above relations and distinctions of any kind, and hence could be grasped only by a superrational or mystical insight, while for others, of whom Plato was apparently one, its parts were related very much as are the propositions in a system of geometry.

Critics of the notion of an Absolute have taken various lines. Many have pointed out that history could hardly be, as Hegel held,

a progressive realization of the Absolute if there were no real time or change and if the goal of the process were realized already. Others, such as Bertrand Russell, have insisted that not all present knowledge can be regarded as illusory appearance; if it is, this insight itself would have to be regarded as illusion. Others again have argued, with William James, that the world is a perfect whole neither logically nor morally and that belief in the Absolute is merely a "tender-minded" faith that the world is more rational than in fact it is.

See histories of philosophy by Wilhelm Windelband, Harald Hoffding, etc. Spinoza's *Ethics*, Hegel's *Phenomenology of Mind* and Bradley's *Appearance and Reality* develop the idea of an absolute in different ways; G. W. Cunningham, *The Idealistic Argument in Recent British and American Philosophy* (1933), considers the evidence pro and con. (B. Bd.)

ABSOLUTE DIFFERENTIAL CALCULUS: see VECTOR AND TENSOR ANALYSIS.

ABSOLUTE PITCH: see PITCH, MUSICAL.

ABSOLUTE TEMPERATURE SCALE, the scale of temperature based on thermodynamics, also called the Kelvin scale after Lord Kelvin (*q.v.*). The temperature scale derived from the law of expansion of a perfect gas is identical with this thermodynamical scale. The usual abbreviations for absolute scale are abs., A. or K. Comparing it (approximately) with the centigrade scale, $0^{\circ}\text{C.} = 273^{\circ}\text{A.}$, $100^{\circ}\text{C.} = 373^{\circ}\text{A.}$, thus absolute zero is equivalent to -273°C. See THERMODYNAMICS: *Thermodynamics and Physical Chemistry*; THERMOMETRY: *Modern Thermometry From 1920*.

ABSOLUTE UNITS, units of measurement of a physical quantity in terms of fundamental (arbitrary) units of length, mass and time. The implication of the word "absolute" is taken to mean that none of these units depends on variable factors that cannot be ruled out by the terms of their definition. The three absolute systems most commonly used are set forth in Table I for purposes of comparison.

TABLE I.—*Absolute Systems of Units, in Terms of Fundamental Units*

System	Abbreviation	Fundamental Units			Force	Conversion factor
		Length	Mass	Time		
Metric	c.g.s.	Centimetre	Gram	Second	Dyne	
Metric	m.k.s.*	Metre	Kilogram	Second	Newton	10^5 dynes
British	f.p.s.	Foot	Pound	Second	Poundal	1.38×10^4 dynes

*This system of units, because of its advantages in electrical measurements, came into increasing scientific use in the U.S.

Engineers frequently use systems of units in which weight replaces mass; *i.e.*, the force of the earth's gravitational attraction for an object instead of the object's inherent inertia. Since the weight of an object depends on its position because of the variation of gravitational attraction over the surface of the earth as well as everywhere in space, these engineering systems, according to the above criteria of invariance of the fundamental units, are not entitled to the name of absolute systems. For comparison with the above, however, these units and conversion factors are shown in Table II.

TABLE II.—*Engineering Systems**

System	Length	Force	Time	Mass	Conversion factor
English	1 foot	1 pound-weight	1 second	Slug	32.174 poundals
Engineering metric	1 centimetre	1 gram-weight	1 second	Metric slug	980.665 dynes

*If, and only if, by agreement, weight is defined as being measured where the acceleration of gravity is $980.665\text{ cm./sec.}^2$ can the above engineering systems be arbitrarily regarded as absolute, as indeed they often are

See also MECHANICS: *Newton's Laws; Physical Units; Weights and Measures.* (H. B. LM.)

ABSOLUTION, in religion, is the pronouncement of remission to the penitent. Interpretations of absolution in the several Christian traditions vary in relation to two issues, the designation of penance as a sacrament and the designation of the ministry as a priesthood (see MINISTRY, THE CHRISTIAN). In Roman

Catholicism, where penance is a sacrament and the minister is a priest, absolution grants release from the guilt of sin to the sinner who is truly contrite over his sin, confesses his sin to a priest and promises to perform satisfaction to God for the offense. The doctrine of absolution is similar in Eastern Orthodox teaching; but in place of the Western formula, "I absolve thee from thy sins in the name of the Father and of the Son and of the Holy Ghost," Eastern churches generally employ some such formula as "May God, through me, a sinner, forgive thee. . . ." In Anglican and in Lutheran usage, formulas of absolution have ranged from the declaratory "I forgive you all your sins" or "I forgive thee" in the Visitation of the Sick, to the precatory "Almighty God, have mercy upon you, and forgive you all your sins." Some Anglican writers distinguish three forms of absolution in the usage of that communion: declaratory, intercessory and judicial. In keeping with their doctrines of the ministry and of the sacraments, other Christian traditions have confined absolution to prayers for forgiveness and the announcement of God's willingness to forgive all those who truly repent of their sins; hence absolution is neither a judicial act nor a means by which the forgiveness of sins is conferred, but a statement of divine judgment and divine forgiveness. Nevertheless, some formula for the public confession of sins and the public pronouncement of forgiveness is included somewhere in the liturgies of most Christian groups, even of those that avoid the term absolution altogether. See also CONFESSION.

(J. J. PN.)

ABSOLUTISM, POLITICAL. In its general sense, absolutism means a governmental system in which power is wholly concentrated in a single ruling agency, typically a single individual. The essence of such a system is that the ruling power is not subject to regularized challenge or check by any other agency, be it judicial, legislative, religious, economic or electoral. Louis XIV, who ruled France during the late 17th and early 18th centuries, furnished the most familiar assertion of absolutism when he said, "L'état, c'est moi" ("I am the state"). Fascist, nazi and communist dictatorships provide more recent examples. In fact, all governmental systems described as dictatorial, despotic, autocratic, authoritarian or totalitarian are absolutist in their concentration of political power. By the middle of the 20th century, absolutism came to mean the opposite of western democracy, in which government is limited by free elections and often by other means of distributing power.

Varying in form, political absolutism has prevailed in much of the world over long periods of time. However, the form originating early in modern European history became the prototype. Its character was definitely monarchical, based on the strong individual leaders of new nation-states created at the breakup of the medieval order. The power of these states was closely associated with the power of their kings, and to strengthen both it was necessary to curtail the restraints on centralized government which had been exercised by the church, feudal lords and medieval customs generally. By claiming the absolute authority of the state against such former restraints, the monarch as head of state claimed his own absolute authority as well.

By the 16th century monarchical absolutism was coming to prevail in much of western Europe, and it was widespread in the 17th and 18th centuries. Besides France, whose absolutism was epitomized by Louis XIV, well-known illustrations may be drawn from Spain, Prussia and Tudor England.

Ideological Basis.—In defense of monarchical absolutism, the simplest argument was that kings derived their authority from God. This view could justify even tyrannical rule as divinely ordained punishment, administered by rulers, for man's sinfulness. In its origins, the divine right theory may be traced to the medieval conception of God's award of temporal power to the political ruler while spiritual power was given to the head of the church. However, the new national monarchs asserted their authority in all matters, and tended to become heads of church as well as state. Their power was absolute in a way that was impossible for medieval monarchs confronted by a church that was essentially a rival centre of authority.

More pragmatic arguments than that of divine right were also

advanced in behalf of absolute monarchy. Complete obedience to a single will was said to be essential to order and security. The alternative was the chaos believed to flow from challenging or dividing political power. Efficiency in protecting life and property required absolutism. In so justifying submission by subjects on the ground of self-interest, the most elaborate statement was made in the 17th-century work the *Leviathan* by Thomas Hobbes. Technically Hobbes's theory allowed the absolute sovereign to be a representative assembly instead of a monarch, but he regarded an individual ruler as more convenient. In this respect, Hobbes resembles other defenders of absolutism. The single will to which they assign all authority ordinarily turns out to be that of a single man or of a very small group. The same has often tended to be the case even with those theorists who have started with the premise that there is a "general will" of the whole community whose authority is absolute when expressed by a majority. Although Jean Jacques Rousseau, the 18th-century French writer who developed the conception of the general will, apparently meant its absolute authority to be exercised by the people themselves, it has readily been converted into a justification for strong leadership ruling absolutely in the name of the people.

20th-Century Forms.—The 20th-century forms of absolutism appear no different in this important respect. Although non-monarchical in leadership, fascist, nazi and communist systems strongly personalized the absolute power claimed for the state or for the sociopolitical movement dominating the state. Concentration of power thus approximated that of the older absolutist forms, but the 20th-century dictatorships were innovative in that they made absolute political authority virtually synonymous with society and accordingly more pervasive, or totalitarian, in its impact on the lives of individuals. Along with this went a much broader effort to manufacture popular support for absolute rulers than had been characteristic of the earlier monarchies.

Absolutism, especially in its later forms, is most clearly distinguished from democracy by contrasting the unlimited power claimed for dictators with the constitutional practices of democratic systems. The difference rests on more than the degree of popular support for governmental decisions. What is always absent in absolutism is restraint on the exercise of political power. No constitutional machinery exists to impose limits on what rulers may do. Not only are they unchecked by an electorate free to choose an alternative set of rulers, but they are conceived to be under no law or custom higher than their own will. Although absolutists are, in practice, likely to take some of their subjects' desires into account, if only as a means to maintain power, it is still true that law is a product of the will of the rulers alone. Furthermore this law of the rulers exhausts the meaning of justice in the absolutist state. No higher standard of right and wrong can be applied.

Nevertheless it is possible, and indeed frequent, for absolute rulers to claim that law as they make it is really based on some higher standard than that of their own will. From kings asserting that they represented God's will on earth to 20th-century leaders speaking in the name of a national, racial or class destiny, political absolutism cloaks itself in the language of philosophical absolutism.

The monopoly of political power is justified by a knowledge of absolute truth. Neither the sharing of power nor limits on its exercise appear valid to those who believe that they know, and know absolutely, what is right. See MONARCHY; see also Index references under "Absolutism, Political" in the Index volume.

ABSTRACT AND ABSTRACTION. A number of things may be found to have some property or relation in common, to which an appropriate designation is then given. This procedure is commonly known as a process of abstraction. Thus, when it was discovered that certain bodies allow electricity to

flow through them, they came to be known as conductors, and the common property was called conductivity. The word "conductivity" is said to be an abstract term; and conductivity itself is said to be an abstraction. Some writers also call the concept of conductivity an abstract idea. Abstraction may also occur when observation of a single thing leads to detection of some property or relation which can be shared with other things. In this way, the discovery that a man's blood fails to clot might lead to the introduction of the abstract term "hemophilia."

"Abstract" is contrasted with "concrete" (though there is no corresponding opposite for the word "abstraction"). A word or expression is said to be concrete if it refers to a particular thing. Thus the expression "World War I" is concrete, while the word "war" is abstract.

It is hard to give a satisfactory definition of "abstraction," since its use generally presupposes an oversimple conception of how thinking proceeds. It might be said that abstraction is a process in which consideration is given to some aspect or feature of a complex whole to the neglect of the remainder; but this statement is both too vague and too restrictive to cover all the cases in which abstraction is commonly said to occur.

In modern logic, the word "abstraction" has several more exact senses. For example, suppose a given relation R is transitive, symmetric and reflexive. And consider a class of objects, every two of which are connected by the relation R . Then to each such class there may be made to correspond a symbol, S_i . Each S_i can then be said to have been given a "definition by abstraction." This sense was introduced by Giuseppe Peano, who used it in defining cardinal numbers.

"Functional abstraction" is used for the process of obtaining a function from a given formula containing a free variable. If A is a formula, the notation " $Ax [A]$ " is employed for the function obtained from A by abstraction relative to A ; " Ax " is called an *abstraction operator*. (The foregoing is Alonzo Church's notation, for which see bibliography; other logicians use different but equivalent notations.)

Other abstraction operators have been found useful. By prefixing the symbol " \hat{x} " to a propositional form containing a free variable " x ," we can refer to the class of things satisfying that propositional form. The symbol " \hat{x} " is called the *class abstraction operator*. Again, by prefixing the symbol " \hat{xy} " to a propositional form with the two variables, " x " and " y ," we can refer to the relation in extension corresponding to the propositional form in question; " \hat{xy} " is the *relational abstraction operator*. The above technical devices can be regarded as instruments for sharpening the vague notions discussed at the beginning of this article.

ABSTRACT ART defines the nonfigurative painting and sculpture of the 20th century. The trends of modern art toward a diminished importance of the subject gave significant emphasis to the purely abstract qualities of form, colour, line and surface, and abstract art is based on the proposition that these formal attributes have an intrinsic and sufficient beauty and expressiveness. Deliberately avoiding the use or concealing the identity of any recognizable form of reality, abstract art is a complete rejection of subject, a total reliance on aesthetic elements.

The exploitation of colour by Fauvism and of form by Cubism (*qq.v.*) gave impetus to the early experiments of Wassily Kandinsky. Working with the Blue Rider group in Germany, he produced his first nonrepresentational picture ("Abstract Watercolour") in 1910. In 1912 he published *Über das Geistige in der Kunst insbesondere in der Malerei* (*The Art of Spiritual Harmony*), interpreting painting as an abstract art, analogous to music, capable of expressing and conveying emotion. In 1913 Kazimir Malevich launched Suprematism, a movement based on the creative manipulation of squares, circles, triangles and crosses, from which Naum Gabo and Antoine Pevsner developed Constructivism, an experimental form of nonfigurative sculpture. In 1917, Piet Mondrian and Theo van Doesburg founded the Dutch periodical *De Stijl* to

promulgate the theory of Neoplasticism, a derivative of Cubism. Mondrian, its chief exponent, using right angles, three primary colours and black, gray and white, evolved a compelling and distinctive art.

Between World Wars I and II nonfigurative art progressed hesitantly in uneasy partnership with Surrealism. but the wide appreciation of Mondrian's work, coupled with the influential teaching of Kandinsky, Paul Klee and László Moholy-Nagy at the Bauhaus (*q.v.*), had a marked effect on architectural and industrial design. After World War II abstraction spread and confirmed its importance as a persistent, characteristic tendency of modern art. During the postwar years, prominent names linked with abstract art were Jean Arp, Alexander Calder, Hans Hartung, Franz Kline, Alberto Magnelli, Ben Nicholson, Jean Paul Riopelle, Jackson Pollock and Nicholas de Stael. See also PAINTING: 20th Century.

ABSTRACT OF TITLE, a chronological summary of the essential portions of all documents such as deeds, mortgages, releases, bankruptcies, judgments, probates, tax liens and other records which affect the title to a parcel of land. In England the summary of the chain of title from a remote grantor is made from an examination of the original documents passed from grantor to grantee but in the United States it is obtained by a search of the public records (see TITLE TO LAND). This summary, usually prepared by a professional abstractor who may or may not be a lawyer, does not of itself disclose the state of the title but summarizes the evidence from which a title-examining attorney may draw legal conclusions. In large urban areas, abstracts of title have been superseded by title insurance (see TITLE INSURANCE COMPANY). (A. DM.)

ABSTRACTS. An abstract is a complete citation and condensation or summary of essential facts, theories and opinions presented in an article or book. It is frequently published at the beginning of an article or in an abstracting journal. The ideal abstracting journal is noncritical, covers its field completely, maintains a high quality in its abstracts, is prompt in its publication of the summaries and prints good annual and collective indexes. The cumulative index covering several years is a great time-saver for the busy researcher.

Almost every field of knowledge has its abstract journal. There is a list of these in the *Index Bibliographicus*, compiled by Theodore Besterman. UNESCO, 2 vol. (1951-52). The latest edition of *Ulrich's Periodicals Directory* also has a list of over 175 titles.

The first abstracting journal, the *Pharmaceutisches Centralblatt* (later the *Chemisches Zentralblatt*), started in 1830, is still being published. This was followed by the *Quarterly Journal of the Chemical Society*, now the *British Chemical Abstracts*. Abstracts appeared in it in 1871. Since then there have been many abstracting periodicals, mostly in the scientific fields. *The Zoological Record* began in 1864; the famous *Chemical Abstracts* in 1907; *Biological Abstracts* in 1926; *Psychological Abstracts* in 1927; *Nutrition Abstracts* in 1931; *Gas Abstracts* in 1945; *Fuel Abstracts* in 1947; and *Nuclear-Science Abstracts* in 1948.

Chemical Abstracts is one of the best known of the scientific abstracts. Started in 1907 by the American Chemical Society to replace the *Review of American Chemical Research* (1895-1906), it describes and indexes about 75,000 articles and 10,000 patents annually. About 1,500 part-time abstracters prepare most of the abstracts. There are 7,000 journals entered in the *List of Sources Searched for Abstracts* (1956). Decennial indexes have been published since 1906.

In the early 1950s the social sciences put forth some abstracting journals, such as the *International Social Science Bulletin* (1949-), under the direction of UNESCO; the *International Political Science Abstracts* (1951-), edited by the International Political Science association; *Sociological Abstracts* (1952-), published in New York; and *Economic Abstracts* (1953-

), published at The Hague.

A large amount of scientific research is published in foreign languages. Abstracts are usually written in English, so that the reader may know easily whether he needs the article in the original language or in translation. Complete copies of the article may be read in the larger scientific libraries, or photostatic or microfilm copies may be secured from the Library of Congress or other large libraries.

The Special Libraries association sponsors a translation centre, located in the John Crerar library in Chicago, which serves as a depository for translations contributed or loaned by government agencies, scientific societies, industrial concerns, universities or other similar organizations.

At mid-20th century, scholars and librarians felt there was too much overlapping among abstracting and indexing services. There was also considerable interest in the possibilities of machine searching for information, which resulted in several conferences, starting with the Royal Society Scientific conference of 1948 which discussed at length the problem of abstracts.

See also LAW REPORTS; ABSTRACT OF TITLE.

See S. C. Bradford, *Documentation*, 2nd ed. (1953). (W. V. N.)

ABU, MOUNT, a mountain near a town of the same name, is just within the southern border of Rajasthan, India, 110 mi. N. of Ahmedabad. It is an isolated feature of the Aravalli range, detached from the chain by a valley seven miles across, in which flows the Western Banas. It rises from the surrounding plains like a precipitous granite island, its several peaks ranging in height from 4,000 to 5,650 ft. The hill has been a place of pilgrimage for at least 2,000 years, and is mentioned as such in the *Mahabharata* where it appears as Arbuda. The elevations and platforms of the mountain are covered with elaborately sculptured Jain shrines, temples and tombs. On the top is a small round platform containing a cavern, with a block of granite bearing the footprints of Data-Bhrigu, an incarnation of Vishnu. The two principal temples, at Dilwara, about the middle of the mountain, are built of white marble and are pre-eminent both for their beauty and as examples of the culminating baroque phase of Gujarat architecture.

The more modern of the two, the Tejpal temple, was built by two brothers, rich merchants, between 1197 and 1247, and for delicacy and richness of carving and minute beauty of detail, especially of the elaborately worked underside of its famous dome, it stands almost unrivaled. The other was built by Vimala, a local governor of the Solanki monarch, apparently about A.D. 1032; simpler and bolder in style, it is one of the oldest, as well as one of the most complete, examples of Jain architecture known. The principal object within the temple is a cell lighted only from the door, containing a seated figure of Parswanath, the 23rd *tirthankara*, or sage, of the Jain faith. The portico is composed of 48 pillars, the whole enclosed in an oblong courtyard about 140 ft. by 90 ft., surrounded by a double colonnade of smaller pillars, forming porticos to a range of 52 cells, each of which is occupied by an image of Parswanath. According to legend the Agni Kula (Fire-group) Rajputs originated in a fire pit around Mount Abu. This seems to represent a purgation rite by which the taint of foreign extraction of these Rajput clans was removed.

The town of MOUNT ABU (pop. 1951, 4,439), a much frequented hill resort, was the headquarters of the Rajputana states agency under British rule.

See C. E. Luard, *Notes on the Dilwara Temples and Other Antiquities of the Sacred Mount of Arbuda (Abu)* (1913).

ABU-AL-ALA AL-MAARRI (Arab. ABU-AL-'ALA' AL-MA-'ARRI) (973-1057), Arab poet and man of letters whose two famous collections of poems. *Saqt al-Zand* ("The Tinder Spark") and the *Luzumiyyat*, place him in the first rank of Arab poets. He belonged to the south Arabian tribe Tanukh, a section of which had migrated to Syria before the time of Islam. Born at Ma'arrat al-Nu'man in north Syria, he was blind from early infancy as a result of smallpox. In 1007 he visited Baghdad and made the acquaintance of literary circles, but returned in 1009 to Ma'arra, where he spent the rest of his days, until his death in 1057, in teaching and writing.

Apart from poetry, he wrote a volume of epistles on various

literary and social subjects (*Mukatabat*), another of literary homilies, *al-Fusul wal-Ghayat* ("Chapters and Aims"), and a work on literary criticism in the unusual form of a description of a celestial journey, entitled *Risalat al-Ghufran* ("Epistle of Pardon"). The second collection of his poems, known as *Luzum ma lam yalzam* or the *Luzumiyyat* (a word meaning literally "necessities," descriptive of their complicated rhyming system), contains the more original, mature and pessimistic thoughts of the author in contemplating human life and death. Much interest has been shown in the author and his works by 20th-century scholars.

BIBLIOGRAPHY.—R. A. Nicholson, *Studies in Islamic Poetry*, with Eng. trans. of more than 300 poems from the *Luzumiyyat* (1921), his summary, with a partial Eng. trans., of the *Risalat-al-Ghufran* is in the *Journal of the Royal Asiatic Society* (1900 and 1902); A. Rihani, *The Luzumiyyat of Abu'l-'Ala'*, Eng. trans. (1920); D. S. Margoliouth, *The Letters of Abu'l-'Ala' oi Ma'arrat Al-'Nu'man*, with Eng. trans. and biography (1898), and "Abu-al-'Ala' al-Ma'arri's Correspondence on Vegetarianism" in *Journal of the Royal Asiatic Society* (1902); Ibrahim al-Arabi, Arabic ed. of the *Luzumiyyat* (1952); Taha Hussain and Ibrahim al-Abyari, *Sharh Luzum ma lam Galzam*, a commentary (1954). The *Saqt al-Zand* and *Risalat al-Ghufran* were published in Arabic in 1924 and 1950 respectively.

See also C. Brockelmann, *Geschichte der arabischen Literatur*, suppl. vol. i (1937).

ABU-AL-ATAHIYAH (ABU'L-ATAHIYA; Arab. ABU ISHAQ ISMA'IL IBN QASIM AL-'ANAZI) (748-828) was the first Arab poet of note to break with the conventions of the older poetry of the desert, and to adopt the simpler and freer language of the towns. Born at 'Ain al-Tamr on the Euphrates in 745, he was descended from clients (*i.e.*, loosely attached members) of the tribe of Anaza. His life was spent in Kufa and Baghdad, where he died in 828, during the reign of al-Ma'mun. In earlier life he wrote love lyrics, but his fame rests on the ascetic poems of his later years, the *Zuhdiyyat* (German translation by O. Rescher, *Der Diwan des Abu'l Atahija: Teil 1. Die Zuhdiyyat*, 1928), most of which are concerned with the observation of common life and mortality and are generally pessimistic in tone. In spite of this, and of suggestions of heresy in his verse, he was a favourite at the court of Harun al-Rashid. His poems were collected in part and published in Arabic (1887; reissued 1909).

On his position in Arabic literature see W. Ahlwardt, *Diwan des Abu Nawas* (1861); R. A. Nicholson, *Literary History of the Arabs* (1907; reissued 1953).

ABU-AL-FARAJ AL-ISFAHANI (ABU'L FARAJ; Arab. ABU-AL-FARAJ 'ALI IBN AL-HUSAIN AL-ISFAHANI) (897-967), Arab scholar, was the author of *Kitab al-Aghani* ("Book of Songs"), which gives an account of the chief Arabic songs known in his day, with the stories of the composers and singers. Born in Isfahan in 897, he was a member of the tribe of the Quraish (Koreish) and a direct descendant of Marwan, the last of the Omayyad caliphs who ruled at Damascus and were deposed and succeeded by the Abbasid caliphs in 750. He was thus connected with the Omayyad rulers in Spain, and seems to have kept up a correspondence with them and to have sent them some of his works. He spent his youth and made his early studies in Baghdad (the capital of the Abbasids), becoming famous for his knowledge of early Arabian antiquities. His later life was spent in Aleppo with Saif-al-Dawla (to whom he dedicated the *Kitab al-Aghani*), in Rai with the Buyid vizier Ibn Abbad, and in other cities in Moslem Arabia. In religion he was a Shiite and wrote a book on the martyrdom of the house of 'Ali, *Maqatil al-Talibiyyin*, but his fame rests on the *Kitab al-Aghani* which contains a mass of information as to the life and customs of the early Arabs, and is the most valuable authority for their pre-Islamic and early Moslem days. In the last years of his life he lost his reason. He died at Baghdad in 967.

The text of the *Kitab al-Aghani* was published in 21 vol. (1905-06). See also *Tables alphabétiques du Kitab-al-Aghani*, a volume of elaborate indexes edited by I. Guidi (1900).

For his life see M'G. de Slane's French trans. of Ibn Khallikan's biographical dictionary (1843-71).

ABU BAKR (c. 573-634): later known as al-Siddik (the truthful, the upright, or the one who counts true), was the first Muslim caliph, reigning from 632 to 634. Of the Taim clan of the

tribe of Quraish at Mecca, he was a merchant, probably in a small way, when he became a friend of Mohammed before the latter's call to preach. He is usually said to have been the first male convert to Islam; but this may only reflect his later position. Before the Hegira (Mohammed's migration from Mecca to Medina, A.D. 622), he was clearly marked out as second to Mohammed by the latter's betrothal to his young daughter 'A'isha and by Abu Bakr's being Mohammed's companion on the journey to Medina. He had spent most of his wealth to promote Islam by ransoming believing slaves and in other ways. From 622 to 632 he was Mohammed's chief adviser, but had no prominent public functions except that he conducted the pilgrimage to Mecca in 631 and led the public prayers in Medina during Mohammed's last illness.

On Mohammed's death (June 8, 632), Abu Bakr succeeded to his political functions by the choice of the Muslims of Medina, with the title of *khalifat rasul-Allah* ("deputy or successor of the Messenger of God," or caliph). His caliphate was occupied with suppressing the risings in various parts of Arabia known as the *rida* ("apostasy"), in which, despite the religious description, politics were probably uppermost. His chief opponent, Musalima, was killed at a battle in eastern Nejd in May 633. While clearing operations went on, Abu Bakr began to direct expansionist moves from Arabia into Iraq and Syria. The Muslim conquests had thus begun before his death (Aug. 23, 634). The ascription to him of the first "collecting" or writing down of the Koran is probably mistaken. See CALIPHATE. (W. M. WT.)

ABUKIR: see ABU QIR.

ABU 'L-FARAJ (13th century): see BAR-HEBRAEUS.

ABU'L-FAZL 'ALLAMI (1551-1602), secretary, historiographer, general and, in religion, tutelary genius of the great Mogul emperor Akbar. Born at Agra on Jan. 14, 1551, the second son of Shaykh Mubarak Nagauri and younger brother of the poet Fayzi, Abu'l-Fazl was presented to Akbar in 1574. A mystic and scholar, critical of the orthodox Moslem religious teachers, he assisted in the development of Akbar's eclectic *Din-i-Ilahi* ("The Divine Faith"). Appointed a military commander in the Deccan in 1599, Abu'l-Fazl distinguished himself there as a soldier and an administrator. He was assassinated at the jealous instigation of Akbar's eldest son, Salim (afterward the emperor Jahangir), on Aug. 22, 1602.

In Mogul Persian literature Abu'l-Fazl is famed for his *Akbar-nama* ("Book of Akbar"), a history of Akbar's reign to 1601 supplemented by the *A'in-i-Akbari* ("Akbar's Institutes"), a "gazetteer" of the administrative and military organization and the social and religious life of Akbar's empire. Two collections of Abu'l-Fazl's letters are also extant.

See C. A. Storey, *Persian Literature: a Bio-bibliographical Survey*, vol. i, pt. ii (1954). (P. H.)

ABULFEDA (ABULFIDA; Arab. ABU-AL-FIDA' ISMA 'IL IBN 'ALI 'IMAD-AL-DIN) (1273-1331), Arab prince, historian and geographer, best known for his *Mukhtasar Tarikh al-Bashar* ("Abridgement of the History of the Human Race"), extending from the Creation to 1329. He was born in 1273 at Damascus, whither his father, Malik al-Afdal, brother of the prince of Hamah, had fled from the Mongols. He was a descendant of Ayyub, the father of Saladin. In 1285 he was present at the assault of a stronghold of the Knights of St. John, and he took part in the sieges of Tripoli, Acre and Qal'at al-Rum. In 1310 he was appointed governor of Hamah by the Mameluke sultan Malik al-Nasir. In 1312 he became prince with the title Malik al-Salih, and in 1320 received the hereditary rank of sultan with the title Malik al-Mu'ayyad. For more than 20 years he reigned in tranquillity and splendour, devoting himself to the duties of government and to the completion of the works to which he is chiefly indebted for his fame. *Taqwim al-Buldan* ("Geography of Countries") was founded on the works of his predecessors, and so ultimately on the work of Ptolemy. Parts of the work were published and translated as early as 1650. He was a munificent patron of men of letters, who came in large numbers to his court. He died at Hamah in 1331.

The text of *Mukhtasar Tarikh al-Bashar* was published in 1869. There are translations of parts into Latin, French and English.

The *Taqwim al-Buldan* was edited by M'G. de Slane and M. Reinaud (1840), and translated into French, with introduction by M. Reinaud and S. Guyard (1848-83).

See C. Brockelmann, *Geschichte der arabischen Literatur*, vol. ii, (1902).

ABUL KASIM (Arab. ABU-AL-QASIM KHALAF IBN-ABBAS AL-ZAHRAWI; Lat. ALBUCASIS) (c. 936-c. 1013), a distinguished Arabo-Spanish physician, was born of Spanish parents about 936 at El-Zahra near Córdoba. His medical reputation was brought to the attention of Caliph Abd-ar-Rahman III (912-961), who named him as his court physician. He died about 1013.

Abul Kasim's magnum opus was his *Altasrif*, a comprehensive work devoted to medicine and surgery and divided into 30 parts. His surgical tract, which was translated into Latin by Gerard of Cremona, was the leading textbook on surgery in Europe for about 500 years. The material of the *Altasrif* was borrowed from the *Epitome* of Paul of Aegina (q.v.), but it eclipsed the *Epitome* and also the *Kitab al-Mansuri* of Rhazes because of its lucid descriptions and its remarkable illustrations of surgical instruments. Abul Kasim was not followed to any great extent by the Arab physicians, who favoured Rhazes and Avicenna (q.v.) as medical teachers. His chief influence was in Latin Europe, where his lucidity and method of presentation were preferred even over Galen. More than anyone else, Abul Kasim helped raise the status of surgery in Christian Europe.

ABU'L QASIM MANSUR: see FIRDAUSI.

ABUL WEFA (ABUL WAFI) (940-997/998), Persian astronomer and one of the greatest Moslem mathematicians, was born in Buzjan (now Buzdschan), Quhistan (now Khurasan), in 940, and flourished in Baghdad where he died in 997 or 998. He translated and commented on the works of the Greek mathematicians and made an exhaustive commentary on Diophantus, but these writings are lost; a book of applied geometry is probably the work of a pupil. He did not, as is sometimes claimed, discover the inequality in the moon's motion later called variation. He contributed much to the development of trigonometry, being probably the first to prove the generality of the sine theorem for spherical triangles; devised a new method for calculating sine tables; studied the tangent, drew up a table of tangents, and introduced the secant and cosecant.

See F. Woepcke in *Journal Asiatique* (1855); G. Sarton, *Introduction to the History of Science*, vol. i (1945). (D. McK.)

ABUNÁ, a river in Bolivia, rising east of the Cordillera Vilcabamba and flowing northeast for about 200 mi. to join the Madeira. Rubber, Brazil nuts, quinine and other forest products are the principal items of commerce in the densely forested and sparsely inhabited Abuná region. The Abuná constitutes the northern boundary between Bolivia and Brazil. (J. L. TR.)

ABUNDANTIA, Roman goddess, the personification of prosperity and good fortune. She appears holding a horn of plenty and distributing grain and money, or, in the aspect of Annona or Felicitas, almost exclusively on the coins, as representative of the personal power of the Roman emperor to induce prosperity. The numismatic representation occurs as early as Nerva and was especially popular under Antoninus Pius, Marcus Aurelius and Commodus. Because of the peculiarly single significance of the goddess she seems to have had no cult, unlike some other deified abstractions (e.g., Clementia). Abundantia may be compared with Domina Abundia (O. Fr., Dame Habonde, Notre Dame d'Abondance), a beneficent fairy who brought plenty to those whom she visited (Grimm, *Teutonic Mythology*). (T. V. B.)

ABU NUWAS (ABU-AL-HASAN IBN HANI' AL-HAKAMI) (c. 756-810), who is recognized as the greatest Arab poet of his time, was born about 756 in al-Ahwaz, Persia, of a Persian mother. His father was a native of Damascus and a soldier. He is said to have spent a year with the Arabs in the desert to gain purity of language. He settled in Baghdad, where he enjoyed the favour of

the caliphs Harun al-Rashid and al-Amin, and died there in 810. Genial. cynical. immoral. Abu Nuwas drew on all the varied life of his time for the material of his poems. In his formal odes he followed on the whole the old Arab tradition, though with greater freedom than his predecessors, but his native genius probably found its best expression in the *Khamriyyat*, a famous collection of wine songs.

Abu Nuwas' collected poems were edited by M K Farid, *Diwan Abu Nuwas* (1932) The *Khamriyyat* was edited by W. Ahlwardt. *Diwan des Abu Nowas*, i. Die *Weinlieder* (1861).

See R A Nicholson, *Literary History of the Arabs*, pp. 292-296 (1907; reissued 1953).

ABU QIR (ABUKIR; ABOUKIR), a fishing village and summer resort on the Mediterranean coast of Egypt, 14½ mi. N.E. of Alexandria by rail. Pop. (1957) 10,224. The name means "Father Cyrus," who was a Coptic saint. From the protected anchorage the bay of Abu Qir sneeps eastward about 30 mi to the Rosetta mouth of the Nile. Behind this coast line lies the lagoon of Lake Idku, a former embayment of the sea. A fish-smoking plant operates there and a paper mill, making wrapping paper from rice straw. In the bay on Aug. 1. 1798, Horatio Nelson defeated the French fleet in the battle of the Nile, and near Abu Qir on March 8. 1801. a British army commanded by Sir R. Abercromby landed in the face of strenuous opposition from a French force entrenched on the beach. The site of the ancient city of Canopus (*q.v.*) is about 2 mi. from the village. (A. B. M.)

ABU SIMBEL (IPSAMBUL), the name of a group of temples of Ramses II (c. 1250 B.C.) in Aswan province of Egypt (ancient Nubia), on the west bank of the Nile, 56 mi. S. of Korosko by river. The temples are hewn in the sandstone cliffs at the river-side, and are three in number. The principal one, probably the greatest and most imposing of all rock-hewn monuments, was discovered by J. Burckhardt in 1812 and opened by G. B. Belzoni in 1817; the front was cleared several times, but the sand pressed forward from the north end. The hillside was recessed to form the façade, backed against which four immense seated colossi of the king, in pairs on either side of the entrance rise from a platform or forecourt reached from the river by a flight of steps. Of nobly placid design, the colossi are 65 ft. in height and are accompanied by smaller figures of Ramses' queen and their sons and daughters; behind and over them is the cornice, surmounted by a long row of apes, standing in adoration of the rising sun. Large hieroglyphs just below the cornice give the titulary of Ramses II, who built the temple primarily for the solar gods Amon-Ra of Thebes and Ra-Horakhti of Heliopolis, the true sun-god; it is oriented to the east so that the rays of the sun in the early morning penetrate the whole length of two great halls to the innermost sanctuary and fall upon the central figures of Amon-Ra and Ramses, which are there enthroned with Ptah of Memphis and Ra-Horakhti on either side. The interior of the temple consists of a series of halls, penetrating for 185 ft. into the solid rock and decorated with coloured sculpture of fine workmanship and in a good state of preservation; some of the scenes are of religious import (among them Ramses as king making offerings to himself as god), others illustrate war in Syria, Libya and Nubia; another series depicts the events of the famous battle with the Hittites and their allies at Kadesh, in which Ramses saved the Egyptian camp and army by his personal valour. Not the least important feature of the temple belongs to a later age when some Greek, Carian and Phoenician soldiers of one of the kings named Psamtik (apparently I. 663-609 B.C.) inscribed their names upon the two southern colossi, doubtless the only ones then clear of sand. These graffiti are of the highest value for the early history of the alphabet, and as proof of the presence of Greek mercenaries in the Egyptian armies of the period. The upper part of the second colossus (from the south) has fallen; the third was repaired by Seti II not many years after the completion of the temple. A small temple, immediately to the south of the first, consists of a single rock-cut chamber originally preceded by an exterior antechamber. The scenes on the inner walls indicate that the temple served as a repository for divine barks that were carried in procession. The third and northernmost temple, separated from the others by a ravine, is on a large scale;

the colossi of the façade are six in number and 33 ft. high, representing Ramses and his queen Nefertari, to whom he dedicated the temple for the worship of the goddess Hathor.

Among the Nubian monuments that are in danger of being completely submerged by 1968 in the gigantic reservoir of water created by the erection of a high dam at Aswan, the Abu Simbel temples are the most important because they are architecturally unique. In 1955 an internationally composed team of Egyptologists began to record the scenes and inscriptions at Abu Simbel, and in 1960 UNESCO launched a world-wide appeal in an effort to obtain funds to preserve the major monuments in Nubia from complete inundation. In the case of Abu Simbel an oval-shaped cofferdam was planned to be erected around the two temples to hold back the waters. (E. F. W.)

ABU TAMMAM (Arab. ABU TAMMAM HABIB IBN AWS) (c. 800-c. 845), Arab poet, best known as the compiler of the anthology of early Arabic poems known as the *Hamasah* (*q.v.*). He was born about 800 either in Jasim (Josem) or near Manbij (Hierapolis), and he died in Mosul about 845. Two other similar collections are ascribed to him. His own poetry has been variously judged by Arab critics, some of whom regard him as the greatest of the poets of the Abbasid era.

For his collected poems see the critical edition by Muhammad 'Abduh 'Xzzam (1951-).

For his life see Ibn Khallikan's biographical dictionary, in Eng. trans. by M'G. de Slane, vol. i, pp. 338 ff. (1842); and *Kitab al-Aghani* ("Book of Songs") of Abulfaraj, vol. xv, pp. 100-108 (1905-06).

ABUTILON, a genus of more than 100 species of tropical shrubs or herbs (rarely trees) of the mallow family (Malvaceae), including such greenhouse favourites as the flowering maple (*Abutilon hybridum*), which is often used as a summer bedding plant. Abutilons have alternate leaves, often showy bell-shaped flowers and dry, beaked fruits. Some have beautifully variegated leaves and there are many horticultural forms. All should be grown in a cool greenhouse, in reasonably rich potting soil. They are easily propagated by cuttings of young twigs inserted in moist sand. Abutilon is found throughout the world, except on the European continent, and one weedy species (*Abutilon theophrasti*), the velvetleaf (*q.v.*), yields China jute, a bast fibre used for cordage. Besides the flowering maple, more than 15 ornamental species are cultivated in England, usually in the greenhouse; among them is *Abutilon esculentum*, the cooked flowers of which are eaten by Brazilians, under the name Bencao de Dios. (N. TR.)

ABUTMENT: see BUTTRESS.

ABYDOS, an ancient town of Mysia, the site of which lies just northeast of the modern Turkish town of Canakkale on the east side of the Dardanelles (Hellespont) at the narrowest point of the straits. Probably originally a Thracian town, it was colonized about 670 B.C. by the Milesians. There Xerxes crossed the strait on his bridge of boats when he invaded Greece in 480 B.C. Abydos is celebrated for its vigorous resistance to Philip V of Macedon (200 B.C.) and for the legend of Hero and Leander. It survived until late Byzantine times as the toll station of the Hellespont.

ABYDOS (Egyptian ABDU, Coptic EBOT), one of the most sacred cities of ancient Egypt. The site, now called al-'Arabat al-Madfunah, is in the low desert west of the Nile, near al-Balyana, about 100 mi. N. of Luxor. Abydos was the necropolis city for nearby Thinis, capital city of the eighth nome of upper Egypt.

The history of Abydos is intimately associated with the political and religious development of Egypt itself and goes back to the beginnings of Egyptian history (see EGYPT). There, in two low mounds composed of votive potsherds of all ages, close to the foot of the cliffs, E. Amélineau late in the 19th century discovered a series of pit tombs, proclaimed by their contents and by the steles with royal names found above them to have been those of kings of the first two dynasties of Egypt. The full excavation and description of these tombs by Sir Flinders Petrie gave much information about the earliest dynastic culture of Egypt, although they had been extensively plundered. Doubt has subsequently been raised as to whether these tombs were the actual burial places

of the pharaohs whose names they bore: in Saqqara, a series of mastaba tombs found by W. B. Emery contained objects bearing the same royal names, and the far greater size of these mastabas and the richness of their contents and decoration have led many scholars to suppose that these are the real resting places of the early kings and that the custom of constructing a sham burial, or cenotaph, at Abydos was practised as early as the archaic period. Some of the 2nd-dynasty pharaohs, however, may in fact have been buried at Abydos, and they built imposing brick fortresses at the northwestern end of the necropolis area; one, Shunet ez Zebib, covers nearly two acres.

The tutelary deity of the necropolis city was the jackal-god, in the Old Kingdom called Khenti-amentiu. By the 5th dynasty a new deity, the god Osiris, whose cult spread from Busiris (Djedu) in the delta, had become associated with Abydos. The city soon became the focal point of the cult of Osiris, which gradually absorbed that of Khenti-amentiu. Various places mentioned in the Osiris legend were located in and around Abydos, and one of the early tombs most revered by later generations, that of King Djer, was eventually selected as the authentic tomb in which the dismembered god's head was thought to be buried. The city became known as Abdu ("hill of the reliquary"); Abydos is the Greek form. At least as early as the 12th dynasty a sacred drama or mystery play dealing with the death and resurrection of Osiris came to be enacted at Abydos.

Abydos became a place of pilgrimage for pious Egyptians, who desired above all else to be buried as close as possible to the tomb of Osiris. If burial in the sacred precinct was not attainable—and few could afford the expense involved—it was possible to set up a stone in the necropolis inscribed with the dead man's name and titles and a prayer to the god. Thousands of these steles have been found in the cemeteries. Over the mound where the early tombs were known to be, the mound of votive pots grew, and the site is now known to the Arabs as Umm el-Ga'ab ("mother of pots").

The pharaohs, though they were now buried near their residence city, encouraged the cult of the deified king at Abydos and took especial care to embellish and enlarge the temple of Osiris, erected on the site of an older temple of Khenti-amentiu. It was entirely rebuilt by Pepi I, of the 6th dynasty, and much enlarged by the pharaohs of the 12th. In the 18th dynasty Ahmose I built a chapel and Thutmose III a far larger temple (about 130 by 200 ft.). Thutmose also made a processional way from the temple to the cemetery, with a granite gateway. Ramses III added a large building and Ahmose II (Amasis) in the Saite period rebuilt the temple once more and placed in it a large monolithic shrine.

Some pharaohs had a cenotaph or a mortuary temple at Abydos. The temple of Seti (Sethos) I, first excavated by A. Mariette in 1859, is one of the most beautiful of all the temples of antiquity. Its plan is unique, for it has no fewer than seven sanctuaries, approached through two broad hypostyle halls. The sanctuaries are dedicated to the king and the principal gods of Egypt. Behind lie halls devoted to Osiris, Isis and Horus, and to the south, at right angles to the axis, are other halls dedicated to the god of the underworld, Sokaris, and to Nefertum. In a long gallery leading to these halls is a relief showing Seti and his son Ramses making offerings to the cartouches of 76 of their dead predecessors beginning with Menes. This is the so-called Abydos list of kings (see CHRONOLOGY: Egyptian). The reliefs decorating the walls of this temple are of particular delicacy and beauty. Nearby is a smaller temple, built by Ramses II.

Only 26 ft. behind the temple of Seti I is a remarkable structure known as the Osireion, but probably in reality Seti's cenotaph. This curious monument, completed by the pharaoh Merenptah, is an underground vaulted hall containing a central platform with ten monolithic pillars surrounded by a channel of water. Perhaps the whole was an allegory in stone, a cosmological symbol of the primeval hill amid the waters of the deep.

Around and between the temples is a vast complex of cemeteries of every period of ancient Egyptian history, from the prehistoric age to Ptolemaic and Roman times. Abydos is one of the most important archaeological sites in Egypt.

Moss, *Topographical Bibliography*, vol. v, p. 38 (1937). (M. S. DR.)

ABYSS, any deep place (Gr. *a*, "not"; *byssos*, "bottom"), a bottomless depth. In general, the abyss is regarded vaguely as a place of indefinite extent, the abode of mystery and sorrow.

In the Greek version of the Old Testament the word represents the original chaos (Gen. i, 2) or the Hebrew *tehom*, which is used also in apocalyptic literature and in the New Testament for hell. In the Septuagint cosmography the word is applied to the waters under the earth, from which the springs and rivers are supplied, and to the waters of the firmament, which were regarded as closely connected with those below. Derivatively it acquired the meaning of the place of the dead. In Revelation it is the prison of evil spirits, from which they may occasionally be let loose, and where Satan is doomed to spend 1,000 years.

In rabbinical cosmography the abyss is a region of Gehenna situated below the ocean bed and divided into three or seven parts imposed one above the other. In the cabala the abyss as the opening into the lower world is the abode of evil spirits, and corresponds to the opening of the abyss to the world above.

The adjective *abyssal* is used to describe deep regions of the sea. In heraldry the abyss is the middle of an escutcheon.

ABYSSINIA: see ETHIOPIA.

ACACIA, a large genus of trees and shrubs belonging to the pea family (Leguminosae); the genus comprises a group of several hundred species widely distributed over the warmer regions of the world, but particularly abundant in Australia and Africa. The leaves are usually twice compounded (bipinnate); in some instances, notably with Australian species native to arid localities, the leaflets are suppressed, their stalks (petioles) then becoming flattened and acquiring the physiological functions of leaves. These stalks are commonly vertically arranged, an orientation which precludes the inception of intense sunlight, thus apparently preventing injury through the retardation of excessive surface evaporation.

The small, frequently fragrant flowers are arranged in rounded or elongated clusters. The several seeded podlike fruits are either flattened or cylindrical, often with constrictions between the seeds. Sharp spines arm the branchlets of many forms.

True gum arabic is the product of *Acacia senegal*, a native of both east and west tropical Africa (see GUMS, PLANT). The Indian *A. arabica* yields a similar gum, but of inferior quality. Catechu (*q.v.*) or cutch is procured from *A. catechu* and several other species. Extractions from finely divided wood of this tree are employed in dyeing khaki cloth. The barks of most acacias are rich in tannin. Babul or babool, derived from *A. arabica*, is used in India for tanning. The Australian acacias, often called wattle barks, are important sources of tannin; especially valuable are golden wattle (*A. pycnantha*), green wattle (*A. decurrens*) and silver wattle (*A. d. dealbata*). The golden wattle is the Australian national tree and flower.

A few acacias are productive of valuable timber. Australian blackwood (*A. melanoxylon*) is a highly figured wood used in cabinetry. *A. homalophylla*, also Australian, yields a fragrant, decorative wood. Koa (*A. koa*), a native of the Hawaiian Islands, produces a handsomely figured wood used in the manufacture of

A. W. KERR
FLOWERING BRANCH OF SILVER
WATTLE (ACACIA RECURRENS
DEALBATA)

ukeles. *A. heterophylla* from Mauritius and Bourbon is another excellent timber tree. The biblical shittah tree (*A. seyal*) is also a member of this group. Species noted for their heavily developed spines include the Australian kangaroo thorn (*A. armata*), the giraffe acacia or African camel's-thorn (*A. giraffae*) and the Central American *A. sphaerocephala* and *A. spadicigera*. The large thorn-like stipules of the two last-mentioned acacias are hollow and provide shelter for ants that feed on leafstalk secretions and curious food bodies at the tips of leaflets.

Sweet acacia (*A. farnesiana*) of the southwestern United States has been introduced into India and southern Europe. Its fragrant, yellow flowers are used in making perfume. The term acacia has been erroneously applied to species of the genus *Robinia*, also a member of the Leguminosae. The American black locust (*Robinia pseudoacacia*) is the false acacia so widely cultivated in milder parts of Great Britain. (E. S. HR.; X.)

ACADEMIC FREEDOM embraces freedom in teaching and freedom in learning, or *lehrfreiheit* and *lernfreiheit* in the language of Germany where the modern conception of academic freedom took form in the 19th century. It is that freedom of members of the academic community, assembled in universities and colleges, which underlies the effective performance of their functions. In modern understanding it embraces intellectual freedom, which is necessary to the acquisition and exchange of knowledge and to inquiry into the unknown, and freedom of creative activity in those arts which are practised in colleges and universities or in which training is offered: it includes also certain personal freedoms in relation to conduct outside of their institutions, which are deemed essential to faculty members and students as such. All of these freedoms exist elsewhere in society as well; but in higher education they occur in a specific institutional context which renders academic freedom distinctive.

Because of the social role of ideas, struggles over academic freedom between the academic community and other interests in society have taken place in all ages and in many circumstances. The nature and outcome of those struggles have been influenced by the forms of organization of academic institutions and the varieties of external authority over them. European universities began as self-constituted communities of scholars; but since these scholars were mainly ecclesiastics, the institutions they founded came under the sponsorship of the medieval church. Before the 18th century the Roman Catholic Church and in some areas its Protestant successors at times exerted a censorship with which the universities or members of their faculties found it necessary to contend. In the 18th and 19th centuries the political state became in many instances the supervising power. Aided by a tradition of faculty government within the institutions, relationships developed in most of the countries of western Europe which (with occasional lapses, notably in the Nazi period in Germany and in other dictatorships) eliminated external control over thought and teaching as an incident to the support and sponsorship of higher education. Faculty members were also left free of institutional control in their teaching and research. Students, similarly left largely free, were subject to the completion of examination and thesis requirements. In England, however, the relation of the established church to Oxford and Cambridge resulted in the maintenance of religious tests for university personnel of these institutions into the 19th century.

In the United States, in the absence of self-constituted communities of scholars, colleges and universities were established by religious or private nonsectarian groups and by states and, occasionally, cities for instruction and, later, for research and development of the arts and professions. Faculty members were hired. Representatives of the founders and their successors, established as boards of control, have remained vested with full legal authority over the institutions they head and have delegated much of it to academic administrators. The faculties usually lack legally secure authority to share in institutional government. Academic tradition and the professional status of faculty members have, nevertheless, served to establish a high degree of independence of the individual in teaching and research, and there has developed considerable faculty participation in college and uni-

versity government. Students in the United States have been subjected to a rather paternalistic relationship which imposes significant curricular requirements and controls over conduct. Developments in the overseas countries of the British Commonwealth have been similar in various respects to those in both England and the United States.

The academic profession in the United States has formulated principles relating to academic freedom and to a correlative, academic tenure, which has grown up, for the purpose of clarifying academic freedom and of safeguarding it by protecting the faculty member against unwarranted loss of his position or dismissal without a hearing. Originally set forth by the American Association of University Professors in 1915, these principles were supported by other organizations as well and became incorporated into the bylaws of many universities and colleges. Because they are of varying legal effect, their observance rests largely on academic and public opinion, sometimes called into play by investigations of alleged violations and publication of reports upon them. Clearly stated religious limits to academic freedom when the aims of an institution require them are recognized as permissible, but are generally regarded as qualifications to freedom rather than as consistent with it.

Academic freedom in the United States has been strongly influenced by court interpretations of the constitutional freedoms of speech, press and assembly and is itself included to some extent in the protection these freedoms receive against governmental impairment. State requirement of military training of students in state institutions, exclusion of students and faculty from public institutions on account of race, the power of legislative investigators to inquire into educational affairs, and the validity of requiring political oaths of academic personnel have come under judicial scrutiny. The constitutional freedoms of faculty members outside their institutions, which may be vindicated in court, have also been brought within the protections accorded to academic freedom by professional action; for in a democratic society, in which scholarship often is directed consciously to the service of specific social interests, the scholar demands liberty of action in public affairs as a professional as well as a personal right.

Academic freedom on the part of faculty members is accompanied by recognized obligations: the obligation to preserve scholarly objectivity; to refrain from using the classroom for extraneous purposes; and to distinguish the individual's personal role from his institutional or academic capacity. Observance of these obligations is enjoined upon members of the academic profession in the United States by the nationally recognized principles of freedom and tenure.

(R. F. Fu.)

ACADEMIES. The term "academy" is derived from the Greek *Academia*, originally an olive grove of a local hero, situated two miles from Athens. There Plato started his school, which became known by the same name (see ACADEMY, GREEK). Gradually the term acquired a general meaning of a higher school and in that sense it was used by Ptolemy I in Alexandria, by Spanish Muslim caliphs, by Charlemagne, by Alfred the Great and others. It is still used for some secondary schools and higher teaching in-

stitutions in many countries. The Calvinists in France, Switzerland and the Netherlands called their higher institutions "academies" until the 18th century, when the term "university" was generally adopted. In England both the dissenting and private institutions imparting secondary or higher learning were also called "academies," especially in the 18th century. In modern times many institutions for higher learning in special subjects such as naval, military, agricultural, fine arts, music or commerce have been called "academies." From the Renaissance the term was associated with learned societies which were not schools in the ordinary sense, and in this use "academy" may be defined as a society or institution for the cultivation and promotion of literature, of arts and sciences or of some particular art or science.

The beginning of such societies can be traced to the 13th and 14th centuries. Thus Brunetto Latini started a speculative society (*Accademia*) in Florence in 1270. The French troubadours started gatherings in Toulouse in 1323 for the promotion of poetry. In 1694 Louis XIV incorporated these gatherings as the *Académie des Jeux Floraux*. Most numerous and flourishing were these societies in Italy, where the movement started in 1439 in Florence subsequent to a Greco-Roman church congress. Two eminent Greek scholars, Gemistus Pletho and Johannes Bessarion, were present, and, influenced by the former, Cosimo de' Medici founded in 1442 the *Accademia Platonica* in Florence for the study of Plato's philosophy and Greek literature. Bessarion went to Rome where he became a cardinal and the promoter of the *Accademia Romana di Storia e di Archeologia*, incorporated in 1498. Another early academy, the *Accademia Pontaniana*, was founded in Naples in 1442 under the patronage of Alfonso V of Aragon.

The first scientific academies belong to the 16th century. In 1560 Giambattista della Porta founded the *Accademia Secretorum Naturae*, and in 1624, with G. B. Manso, the *Accademia degli Oziosi*, both in Naples. In 1575 Philip II of Spain founded in Madrid the *Accademia de Ciencias Matematicas*. The famous *Accademia dei Lincei* in Rome, to which Galileo belonged, was founded in 1603 by Federigo Cesi, but closed on his death. In 1870 it was resuscitated as the *Reale Accademia Nazionale dei Lincei*. In 1657 Leopold de' Medici founded in Florence the *Accademia del Cimento*, of which the physicist Torricelli was a member. (See also ITALY: Education: Academies.)

In Germany the first academy was *Die Fruchtbringende Gesellschaft*, founded at Weimar in 1617 for the purification of the language and the promotion of literature. The first German scientific academy was the *Societas Ereunitica*, founded at Rostock in 1622. In 1652 the physician J. L. Bausch founded at Schweinfurt an academy for research in medicine and connected sciences, called the *Accademia Naturae Curiosorum*. It published in 1670 the first German scientific periodical, *Miscellanea Curiosa*. In 1687, in honour of the emperor Leopold I, it was renamed *Accademia Caesarea Leopoldina*; later it became known as the *Leopoldinisch-Karolinische Deutsche Akademie der Naturforscher*, with its seat in Halle. It was also in the 17th century that the two pre-eminent scientific academies were founded. Both the English Royal society (*q.v.*) and the French *Académie des Sciences* began as informal gatherings of famous men. The "invisible college" of London and Oxford had its first meetings in 1645. It was incorporated as the Royal society in 1662. In Paris a group of men including Descartes, Pascal, P. Gassendi and M. Mersenne started private meetings almost at the same time. In 1666 they were invited by Colbert to meet in the royal library. In 1699 the society was transferred to the Louvre under the name of *Académie des Sciences*. The *Académie Française* also started as a private society of men of letters some five years before its incorporation in 1635 under the patronage of Richelieu. Another famous French academy, known as the *Petite Académie*, began as a committee of the *Académie Française* in 1663 for the study of ancient monuments, inscriptions and medals. In 1716 it became the *Académie Royale des Inscriptions et Belles-Lettres*.

In the 18th century the fame and achievements of the Royal society and of the *Académie des Sciences* were internationally recognized and many European countries started to found their own national academies of sciences. The chief promoter of this

European movement was Leibniz. As early as 1676 he urged the establishment of an imperial academy of sciences at Vienna. He prompted Frederick I of Prussia to found in 1700 in Berlin the *Societas Regia Scientiarum*, renamed in 1711 the *Preussische* (later *Deutsche*) *Akademie der Wissenschaften zu Berlin*. In 1703 he presented a memorandum for the foundation of the academy of sciences at Dresden. During 1708–11 he wrote plans for a similar academy at St. Petersburg for Peter the Great. These and other plans were all realized and at the end of the period of enlightenment most European countries had their academies of sciences.

The academies of the 16th and 17th centuries were either scientific or literary. During the 18th century the rise of academies of the fine arts took place. As a rule they were societies closely connected with a higher teaching institution and thus differed from the earlier societies. The foundation of academies continued throughout the 19th century and in the 20th century national centres of sciences, literature and the fine arts were established in most of the new European and non-European countries.

Academies often have included by invitation distinguished foreigners among their members and so have helped to foster the international character of science and scholarship.

SCIENTIFIC ACADEMIES

Austria.— In 1786 I. von Born founded an international Society of Mining, but the *Österreichische Akademie der Wissenschaften* in Vienna originally planned by Leibniz was founded only in 1847 by the emperor Ferdinand I.

Belgium.— The *Académie Royale des Sciences, des Lettres et des Beaux-Arts de Belgique* acquired its present title in 1845. It originated in 1769 as a literary society of which one of the founders was the English naturalist J. T. Needham.

Czechoslovakia.— The *Prager Gelehrte Privatgesellschaft* was founded by I. von Born in 1771. In 1784 it became *Societas Regia Scientiarum Bohemica* and in 1952 was re-founded as the Czechoslovak Academy of Sciences (*Ceskoslovenska Akademie Ved*).

Denmark.— The Royal Danish Academy of Sciences and Letters (*Det kongelige danske videnskabernes selskab*) was founded at Copenhagen in 1742 by Christian VI.

France.— The old *Académie des Sciences*, together with all French academies, was suppressed in 1793 by decree of the Convention. In 1795 its functions were assumed by a branch of the newly formed Institut National. In 1816 the former name was restored to this branch, which became one of the five academies of the Institut de France.

Germany.— The Leibnizian academy was reconstituted in 1743 by Frederick II, who appointed the French scientist Maupertuis as president. The *Bayerische Akademie der Wissenschaften* in Munich was founded in 1759. Maximilian I entrusted it with the organization and supervision of public education. The *Akademie der Wissenschaften* at Göttingen was founded in 1751 by Albrecht von Haller. It was reorganized in 1897. The *Akademie der Wissenschaften* at Mannheim was founded in 1755 by the elector palatine. Scientific academies were founded at Leipzig in 1846 and at Mainz in 1949.

Hungary.— The Hungarian Academy of Sciences (*Magyar Tudományos Akadémia*) was founded in 1825 by Count István Széchenyi.

Italy.— Scientific societies existed in many towns, but the beginnings of a well-established and permanent academy of sciences belong to Turin. In 1757 G. B. Beccaria, J. L. Lagrange and others founded a private scientific society called *Philosophico-Matematica Società Privata Taurinensis*. In 1761 it became *Società Reale* and in 1783 *Regia Accademia delle Scienze*. The second in importance of Italian academies of the 18th century was the *Accademia delle Scienze e Belle Lettere* at Naples (1779), promoted by Tanucci. One of its prominent members was Gaetano Filangieri. The *Accademia dei Ricovrati* of Venice was also founded in 1779.

Netherlands.— The first scientific society, the *Hollandsche Maatschappij der Wetenschappen*, was founded in 1752. In 1774 a special section was added devoted to agriculture, industry and commerce. The Royal Institute of the Low Countries was founded

by King Louis Bonaparte at Amsterdam in 1808. It was reorganized in 1851 and in 1855 became the Koninklijke Nederlandse Akademie van Wetenschappen.

Norway.—J. E. Gunnerus, the botanist, founded a scientific society at Trondheim in 1760. The Norske Videnskaps Akedemi at Oslo was founded in 1857.

Poland.—The first scientific society was founded in Warsaw in 1800 under the name of Towarzystwo Przyjaciół Nauk (Society of Friends of Science). The Cracow branch, opened in 1816, was reconstituted by the Austrian government in 1872 as an academy and in 1919 it was renamed Polska Akademia Umiejętności. In 1951 it was transferred to Warsaw as Polska Akademia Nauk.

Portugal.—The Academia Real das Ciências was founded in 1779 by the duke of Lafões and Correa da Serra, both members of the Royal society. In 1851 it was reorganized into two sections of sciences and literature and social sciences.

Spain.—Although scientific societies were founded in 1575 and 1657, the academy of sciences dates back only to 1774. In 1847 it became the Real Academia de Ciencias Exactas, Físicas y Naturales.

Sweden.—Archbishop Erik Benzelius, Emanuel Swedenborg and C. Polhem founded a private scientific society at Uppsala in 1710. In 1728 it received the title Kungliga Vetenskaps Societeten. Linnæus was one of the founders, in 1739, of a society in Stockholm incorporated in 1741 as Kungliga Svenska Vetenskapsakademien.

Switzerland.—Several cantons have their own scientific societies. The oldest is the Société pour l'Avancement des Arts in Geneva, started as a private society by H. B. de Saussure. It was approved by the Geneva government in 1776. The Schweizerische Naturforschende Gesellschaft in Zurich, founded in 1815 on a national basis, has enjoyed the rank of an academy of sciences since 1931.

U.S.S.R.—The academy of sciences was founded by Peter the Great in St. Petersburg in 1724 and was opened by his widow, Catherine I, in 1725 as Rossiyskaya Akademia Nauk. The first Russian member was the scientist and poet M. V. Lomonosov. In 1934 the academy was transferred to Moscow. At Kiev the Academy of Sciences of the Ukrainian S.S.R. was founded in 1918 and reorganized in 1919. The academies of other republics of the Soviet Union are of recent origin.

Yugoslavia.—Under Italian influence academies were flourishing in Dalmatia and Istria as early as the 16th century, for instance the Accademia dei Concordi at Dubrovnik. In Slovenia the Societas Unitorum at Ljubljana dates back to 1688. A society founded at Zagreb in 1848 by Bishop Strossmayer became in 1861 the Jugoslavenska Akademija Znanosti i Umjetnosti (Yugoslav Academy of Sciences and Arts). In Serbia the first society was founded in 1841. In 1864 it was named Srbsko Ucenje Druzstvo (Serbian Learned society) and in 1886 it became the Srbska Akademija Nauka (Serbian Academy of Sciences) in Belgrade. The Slovenska Akademija Znanosti in Umetnosti (Slovene Academy of Sciences and Arts) was formed in 1937 from a society founded at Ljubljana in 1921.

English-speaking Countries.—The relations between state and society in the English-speaking countries differed from those in continental Europe. Culture, including religion, science, literature and the fine arts, was considered a prerogative of society and private initiative. Reflecting this attitude Great Britain, the commonwealth countries, Ireland and the United States have no state-established academies of sciences. They have, however, scientific societies which rival European academies in fame and importance.

Great Britain.—The oldest and best-known English scientific societies are the Royal society, the Gentlemen's Society of Spalding (1710), the Royal Society of Arts (1754), the Lunar society (1768) and the Royal Institution of Great Britain (1799). In Scotland the Royal Society of Edinburgh originated in 1739 as a philosophical society. In Ireland the Royal Dublin society was founded in 1731.

United States.—The most influential scientific society was founded by Benjamin Franklin in 1743. It was incorporated in 1780 under the name of American Philosophical Society Held at

Philadelphia for Promoting Useful Knowledge and became recognized abroad as the national centre of scientific activities. In 1779 a group of Harvard graduates established a rival society in Boston, incorporated in 1780 as the American Academy of Arts and Sciences. The aims and organization were similar to those of Franklin's society and claims to represent the United States nationally were put forward. The New York lyceum, founded in 1817, was renamed the New York Academy of Science in 1876. The St. Louis Academy of Sciences was founded in 1856. The National Academy of Sciences was founded in 1863 in Washington, D.C. The Academy of Natural Sciences of Philadelphia was established in 1812. (See also ASTRONOMY, SOCIETIES OF; CHEMISTRY, SOCIETIES OF; HORTICULTURE AND BOTANY, SOCIETIES OF; ZOOLOGICAL SOCIETIES.)

LITERARY ACADEMIES

The Renaissance was not only the rebirth of classical literature and science, it also promoted national languages and literatures. Literary societies or academies were founded everywhere, but Italy was the source and model of this movement. In the 16th century the number of Italian academies approached 700. The most famous of Italian literary academies was the Accademia della Crusca, founded in Florence by A. F. Grazzini in 1582. Its *Vocabolario della Crusca*, published in Venice in 1612, stabilized the Italian literary language on the basis of Tuscan speech. In France the institution of this group is the Académie Française. The old academy of Richelieu was dissolved in 1793 and reconstituted as the third class of the Institut National in 1795. Napoleon, by abolishing the class of moral and political sciences, promoted it to the second class. In 1816 it was reconstituted under its old name. In Spain a similar role was played by the Real Academia Española, founded in Madrid by the duke of Escalona in 1713. The Russian Academy founded in 1783 became the eighth department of the Academy of Sciences of the U.S.S.R. The British Academy in London was founded in 1901. Its aim is defined in its charter as "the promotion of historical, philosophical and philological studies," or more precisely "the promotion of the study of the moral and political sciences, including history, philosophy, law, politics and economics, archaeology and philology." It will thus be seen that the British Academy combines literary and social studies.

In Latin America academies belonging to this group include the Academia Hispano-Colombiana de la Lengua founded in Bogotá, Colombia, in 1871, the Academia Chilena de la Lengua in Santiago, Chile, founded in 1885, and the Academia Venezolana de la Lengua, founded in Caracas, Venez., in 1882. (See also LITERARY, HISTORICAL AND ARCHAEOLOGICAL SOCIETIES.)

ACADEMIES OF SOCIAL SCIENCES

The two oldest academies of this group were founded in Portugal and Spain in the 18th century. They are the Academia Portuguesa da História (1720) and the Real Academia de la Historia (1738). The French Académie des Sciences Morales et Politiques can trace its origins to the Club de l'Entresol, known as the Académie Politique, which was influential until its closure by Cardinal Fleury in 1731. As the second division of the Institut National created in 1795 it was suppressed by Napoleon in 1803 as potentially subversive. In 1832 it was restored as one of the five academies of the Institut de France. The Academy of Social Sciences in Moscow, founded in 1956, is attached to the central committee of the Communist party. In the United States, the American Academy of Political and Social Science was founded in Philadelphia in 1889.

ACADEMIES OF FINE ARTS

The first academies of fine arts were in Italy. The Accademia di Belle Arti was founded at Perugia in 1546. It was followed by the Accademia di Disegno at Florence (1563), the Accademia di San Luca at Rome (1577) and the Accademia Albertina di Belle Arti at Turin (1652). The Akademie der Bildenden Künste in Vienna was started as a school in 1692 but was not incorporated as an academy until 1770. The French Académie Royale de Peinture et de Sculpture had its beginnings in 1648. It was reconstituted

as the Académie des Beaux-Arts in 1795. In Denmark, Det Kongelige Akademi for de skønne Kunster (the Royal Academy of Fine Arts) was founded in Copenhagen in 1754. In the U.S.S.R., the academy founded in St. Petersburg in 1757 by Count Shuvalov was re-established as the Academy of Fine Arts of the U.S.S.R. in Moscow in 1921. The Royal Academy of Arts in London, founded in 1768, is described in a separate article. (See ACADEMY, ROYAL.)

In the Americas, the first academies of fine arts were the Academia das Belas Artes, founded in Rio de Janeiro, Braz., in 1816, and the National Academy of Design founded in New York in 1825, whose first president was S. F. B. Morse, later the inventor of the electric telegraph. (See also ART, SOCIETIES OF.)

MUSICAL ACADEMIES

Musical academies were started in Italy and grew from societies of musicians and poets in the 16th century. The Accademia della Fama in Venice was founded in 1558 by the musicians G. Zarlino, A. Gabrieli and others. The Accademia degli Arcadi in Rome, of which the composers A. Corelli, A. Scarlatti and B. Marcello were members, was founded in 1690. The Accademia Filarmonica of Bologna, founded in 1666, numbered Mozart among its members in the 18th century. In France, the Académie de Musique, also known as the Théâtre National de l'Opéra, originated in 1669. The Austrian Akademie für Musik und darstellende Kunst was founded in Vienna in 1817. The first musical academy in England was the Academy of Ancient Music, founded in London in 1710. A Royal Academy of Music, under the direction of Handel, existed in London from 1720 until 1728, but the present institution was founded in 1822 and incorporated in 1830. (See also MUSICAL SOCIETIES AND INSTITUTIONS.)

MEDICAL AND OTHER ACADEMIES

The Académie Royale de Chirurgie founded in Paris in 1731 was suppressed in 1793 and reopened in 1820 as the Académie de Médecine. Since 1871 it has been called the Académie Nationale de Médecine. The Russian Military-Medical Academy was founded in 1799. Other medical academies are of the 20th century.

The first mining academy, the Bergakademie at Freiberg in Saxony, eastern Germany, was founded in 1765. In 1914 a mining academy was founded in Cracow, Pol. The first agricultural academy was founded in Venice in 1790. The Royal Swedish Academy of Agriculture and Forestry (Kungliga Skogs- och Lantbruksakademien) was founded in Stockholm in 1811. The Timiryazev Academy of Agriculture and the V. I. Lenin All-Union Academy of Agricultural Sciences in Moscow, founded in 1865 and 1929 respectively, and the Bulgarian agricultural academy founded in Sofia in 1948, are higher educational institutions with the title of "academy." Commercial academies, all 20th-century foundations, exist in the U.S.S.R., Poland, Rumania and other countries. See also MEDICAL AND SURGICAL SOCIETIES; MILITARY, NAVAL AND AIR ACADEMIES. (N. H.)

ACADEMY, GREEK. The Greek school of philosophy known as the Academy took its name from Academia (Akademeia), a locality in the northwestern outskirts of Athens, where Plato acquired property c. 387 B.C. and used to teach; the designation, however, is most usually applied not to Plato's immediate circle but to his successors down to Cicero's time. Legally, the school was a corporate body organized for the worship of the muses, the scholar (or head of it) being elected for life by a majority vote of the members. Most scholars infer, mainly from Plato's writings, that instruction in the Academy originally included mathematics, dialectics, natural science and preparation for statesmanship. The Academy continued in existence until A.D. 529, when the emperor Justinian closed it, together with the other pagan schools. The problem of its intellectual unity has always been controversial, particularly if its post-Ciceronian phase is included. Major differences concern its dogmatism and antidogmatism; its exclusiveness (syncretism); the primacy of speculation or of ethics; its religious ("mystical") or its secular ("rational") character. If these points are borne in mind, it seems reasonable to consider the Academy in five phases as follows:

1. The Old Academy (4th century B.C.), with Speusippus, Xenocrates, Polemo and Crates as successive scholarchs and with Philippos of Opus, Heraclides Ponticus (who had strong supranaturalist leanings), Eudoxus of Cnidus (outstanding as an astronomer) and Crantor as outstanding members, seems to have devoted itself mainly to the dissection of reality into spheres such as numbers, geometricals, soul, down to sensibles; or into spheres of knowledge, of opinion, of sensation. These appear to have been derived from one another or from a set or sets of ultimate principles, called "the one" and "the indeterminate dyad" or by analogous expressions. Discussion of the nature of "the one" and its relation to the good on the one hand and of the nature of the other principle and its relation to matter and evil on the other was combined with number-speculations in Pythagorean style, sometimes also with theology and demonology. In many respects the Old Academy was closer to what Aristotle presented as Plato's "system" than to Plato's works. Especially characteristic is the displacing of ideas in favour of numbers.

In what sense we should consider Aristotle a member of the Academy is a moot point.

2. The Middle (or New) Academy (3rd–2nd centuries B.C.) was the result of developments under Arcesilaus, when the school, with an obvious preference for Plato's early dialogues and in accordance with his criticism of sensation, turned antidogmatic — this tendency reaching its climax under Carneades about a century later (on the meantime we know almost nothing). Whereas Arcesilaus had mainly refuted all claims to infallibility put forward by the Stoics for certain sense-presentations, Carneades extended this refutation to all types of knowledge and criticized specific Stoic doctrines; e.g., their teleology, theodicy, astrology and theology. The key word of this antidogmatism is *epoche*, the withholding of assent. On the other hand, Carneades developed a doctrine of degrees of probability (of particular importance in matters of conduct). In ethics he professed or at least defended the doctrine that the goal of life and happiness consists in the fruition of "natural" things such as the integrity of one's own body and mind, to secure which man is instinctively driven. The text and the canon of Plato's work were probably established by the Academy early in this period.

3. In the 1st century B.C. a neodogmatic turn started with Philo of Larissa and reached its climax with Antiochus of Ascalon. The latter asserted that Academicism and Peripatetics originally were simply two branches of Platonism; and he traced Stoic doctrines (particularly their derivation of the standard of conduct from nature and their concept of *oikeiosis*, that is, the "propriety" of certain things to our nature and their "appropriation" as a foundation of morality) back to the Academy, with Polemo as key figure. This historical interpretation (the correctness of which is controversial) provided the justification for his syncretism. He accepted the division of philosophy into ethics, physics and logic (in order of decreasing importance) and distinguished goods of the mind and of the body and external goods, the last-named being essential for a life if it was to be not only happy, but consummately so (*vita beata, beatissima*). The reconstruction of additional doctrines of Antiochus (he has, for example, been credited with being the first to identify Plato's ideas with thoughts of God) and the tracing of their influence has been the object of much controversy.

Plato and Aristotle being excepted, not a single writing of any Academic mentioned hitherto has been preserved in its integrity. Some writings ascribed to Plato might, however, be Academic (on the *Epinomis*, see PLATO).

Cicero (*q.v.*), strongly influenced by Philo and Antiochus, combined a noncommittal attitude in matters of speculation with the conviction that, as the result of experiences (he says: innate ideas) common to all men, there is universal consensus in all matters relevant to conduct and religion.

4. Of the Academy after the time of Cicero we know little. In the 2nd century A.D., Calvisius Taurus was one of its scholarchs, and Atticus, a violent critic of Aristotle, perhaps another. With Eudorus, Albinus, Apuleius, Maximus of Tyre, Plutarch of Chaeronea, etc., they represent the so-called Middle Platonism, out of

which Neoplatonism developed.

5. In the 5th century A.D., when Platonism had already turned into Neoplatonism (since the 3rd century A.D.), the Academy becomes visible again. Within the Neoplatonic movement it constitutes the so-called Athenian school, distinct, for instance, from the Alexandrian in that it remained closer to the spirit of Plotinus (who had literary contacts with Eubulus, scholar of the Academy), of Porphyry and of Iamblichus and was devoted to polytheism. Other scholars were Plutarch of Athens, Syrianus, Proclus and Damascius, the last of them; and Simplicius was a famous member. Neoplatonism professed to be genuine Platonism but assimilated many doctrines belonging to other schools and to Greek and oriental religions. It teaches an ineffable deity, absolutely transcendent and yet the source out of which, in a nontemporal process, everything "flows," "dispersing" and thus decreasing in reality but longing to return to its origin; this return in man taking place in "ecstasy," an act of nondiscursive knowledge.

M.)

ACADEMY, ROYAL. The foundation of the Royal Academy of Arts in London in 1768 was the outcome of a memorial to George III presented by a group of the leading painters, sculptors and architects then in Great Britain, seeking his interest in setting up "a Society for promoting the Arts of Design" of which the two principal objects were to be the establishment of "a well regulated School . . . and an Annual Exhibition." The king signed the instrument of foundation on Dec. 10 of that year and graciously declared himself therein to be the Academy's "patron, protector and supporter." It decreed that there should be 40 academicians and it named the first 34; it defined the society's activities, the functions of the council and general assembly, the offices to be filled and the manner of electing new members.

The main terms of the instrument have always been observed and form the basis of the laws in force today, the sovereign's approval being necessary for any amendment and for the appointment of the president and other officers. There are still 40 royal academicians who serve in rotation on the council and on the selection and hanging committees of the annual exhibitions. Two major changes have been made, in 1769 and in 1918. The former instituted a class of associates (not less than 30 and not more than 35 in number) who are represented on various committees and from whom the academicians are elected. The latter change inaugurated the terms "senior academicians" and "senior associates" for members reaching the age of 75. They are then no longer eligible to serve in any office or committee although they retain their vote in general assembly and other rights. The vacancies thus created in the active lists, together with those caused by death or other reasons, are filled by election among all members. New royal academicians are each required to present to the Academy a specimen of their art before receiving their diplomas signed by

the sovereign.

From small temporary quarters in Pall Mall and old Somerset house, the Royal Academy moved in 1780 into the Strand block of the present Somerset house where it remained for 57 years. From 1837 to 1868 it was housed in the eastern half of the building on the north side of Trafalgar square (subsequently entirely occupied by the National gallery) and finally, on attaining its centenary, took possession of Burlington house in Piccadilly and built the main galleries and schools at its own expense on part of the gardens. The house itself was adapted for the library, offices and meeting rooms, and a third story was added to accommodate the diploma works.

The annual exhibition, by which the academy is perhaps best known to the public, has been held every summer without a break since 1769. Each member is allowed to send in not more than six paintings, drawings, engravings, pieces of sculpture or architectural designs, and any other person, of whatever nationality or domicile, may submit three. Over 10,000 items are received every year and an exhibition of some 1,500 is formed. No commission is deducted from the prices of the many works which are sold.

The winter exhibitions in the main galleries, usually of the works of old masters, were started in 1870 and have included large-scale displays of the highest international importance. Since 1952 the diploma galleries also have been used for special loan exhibitions from time to time throughout the year.

Entrance to the Royal Academy schools has always been "free to all students who shall be qualified to receive advantage from such studies." Successful candidates for the schools of painting and sculpture are admitted for a period of three months and thereafter, if approved, for a studentship of four years. The school of architecture was run on similar lines till 1947 when it was reconstituted as a postgraduate course of one year.

The Royal Academy has never received any subsidy from the state and except for the first 11 years of its existence, when the deficits were reimbursed from the king's privy purse, it has been financially self-supporting. The maintenance of its premises and the general administrative costs, together with the provision of free training in the schools, have all been paid for from the public's support of the exhibitions. In addition the Academy has been enabled, through the receipt of certain trust funds, to give scholarships and prizes to its students, to award annuities and grants to artists in distress, and to purchase works of art under terms designed to encourage artists living in Great Britain.

ACADIAN, a descendant of the French settlers in Acadie or Acadia, the French colony on the Atlantic coast of North America in what is now eastern Canada. The area, visited by Champlain (1603) and by De Monts (1604) and colonized by the French, was long a bone of contention in the wars between France and England. By the treaty of Utrecht (1713) Acadia became English. In 1755 the imminence of war with France, the vexed question of the neutrality of the Acadians and the possibility of revolt led to their forcible deportation—the theme of Longfellow's *Evangeline*. They were distributed among the English colonies, and one group made its way to Bayou Teche, La., where George Washington Cable (*q.v.*) described their subsequent life. After the treaty of Paris (1763) left the British in undisputed possession of Canada, and Acadia had ceased to exist as a political unit, a number of Acadians found their way back to Nova Scotia and New Brunswick. In many cases their descendants continued to form a distinctive part of the population. See NOVA SCOTIA: *History*.

See G. P. Bible, *An Historical Sketch of the Acadians* (1892); A. Doughty, *The Canadian Exiles* (1914); Grace Dean McLeod, *Stories of the Land of Evangeline* (1891).

ACANTHACEAE, containing about 240 genera and more than 2,200 described species, is a largely tropical family of plants allied to the Gesneriaceae and Bignoniaceae. They are perennial herbs, armed or unarmed shrubs, or rarely trees or vines. A few

genera are cultivated as ornamentals. Chief among these, and probably the best known because of the use of the leaf pattern in the design on the Corinthian columns, is *Acanthus* (*q.v.*). Other genera grown in greenhouses or out of doors in warm climates are *Ruellia*, *Pseuderanthemum*, *Aphelandra*, *Thunbergia*, *Fittonia*, *Jacobinia* and *Justicia*. The family can be recognized botanically by the following combination of characters: the opposite, usually large and thin leaves, commonly provided on the surfaces with minute whitish lines (cystoliths); the absence of stipules; the usually compound inflorescences; the presence of persistent, often conspicuous, floral bracts; the irregular, tubular, two-lipped, often highly coloured (red, purple or yellow) corollas; the four (or sometimes two) stamens inserted on the corolla tube; the free two-celled ovary; and the often club-shaped capsule, opening elastically from the apex downward.

(EY. C. L.)

ACANTHOCEPHALA, the spiny-headed worms, a phylum of parasites characterized by an anterior attachment organ (the proboscis) covered with rows of recurved hooks. These elongate worms as adults are found only in the intestine of vertebrates, and no free-living stage is present in any phase of their life histories. They vary in length from about $\frac{1}{8}$ in. to over 1 ft.

The Acanthocephala exhibit many of the aspects of "degeneracy" usually associated with parasitism. There is not the slightest trace of a digestive system in any stage of their development, and the relatively few sense organs, when they are present, are small and inconspicuous. The "brain" consists of a small cluster of cells located in an anterior muscular sac, the proboscis receptacle, into which the proboscis is retractable. Only a few species have any excretory system.

MALE ACANTHOCEPHALUS RANAE. A PARASITIC WORM THAT LIVES IN THE INTESTINES OF FROGS AND NEWTS

Natural History.— The spiny-headed worms undergo a two-host life history: the definitive host for the adult parasite is always a vertebrate, most commonly a fish or bird, and the intermediate host is always an arthropod such as an insect or crustacean. (Sometimes a "transport host" is interpolated between the intermediate and definitive hosts. It is not clear how necessary such transport hosts are for the completion of the life history.)

The arthropod host ingests the infective embryo which then hatches into the first larval stage, the acanthor. After penetrating the gut, the acanthor enters the body cavity of the host, where it successively develops into an acanthella and finally into a later larval stage, the cystacanth. Vertebrates are infected by feeding on arthropods containing infective cystacanths. Upon ingestion the cystacanth begins development to the adult stage. After anchoring itself, by means of its burrlike proboscis, to the intestinal lining of the host, the worm absorbs nourishment directly through its thin body covering.

Because of their method of attachment, the spiny-headed worms are relatively destructive parasites. Heavy infections, frequently fatal, have been reported among fish, birds and monkeys. Lighter infections produce significant damage to the intestinal wall.

Structure and Function.— The acanthocephalan body is divided into two structural units: The presoma and the trunk. The presoma consists of the proboscis, neck, proboscis receptacle, brain and two internal fingerlike projections (lemnisci) in the neck region. The proboscis varies from globular to elongate-cylindrical in shape and is armed with a varying number of hooks, usually arranged in a definite pattern and relatively constant in size and num-

ber for each species. Inside the proboscis a pair of muscles, the invertors, connect the tip of the proboscis to the posterior portion of the receptacle. Contraction of these muscles causes the inversion of the proboscis into the receptacle. The neck region extends from the basal row of hooks to the beginning of the trunk and is devoid of hooks and spines. It is usually quite short but in some forms, for example *Pomphorhynchus*, is remarkably elongated and specialized. The lemnisci are structurally and functionally connected to the subcuticula layer (*see below*) of the proboscis. Lemnisci are found in no other group of the animal kingdom and their function is unknown. Both the lemnisci and the proboscis receptacle project posteriorly into the trunk.

The trunk, the main part of the body, has a covering composed of a thin cuticula under which lies a thick, complex subcuticula. In many forms the cuticula is covered with spines which are primarily, if not entirely, limited to the anterior region of the trunk. The subcuticula is syncytial (lacking cell boundaries) and contains a rudimentary circulatory system, the lacunar system. The organs of the reproductive system are located in the trunk. In the male they consist of two testes, a variable number of cement glands and a muscular, copulatory bursa, within which is the penis. In the female, the ovary breaks up into "germ balls," where the eggs are produced, fertilized by the male's sperm and started on their development. After a period of maturation in the body cavity the embryonated eggs are passed into the anterior end of the female reproductive system, the uterine bell. From there a selective apparatus either passes the embryos on through the female ducts and out the genital pore or returns them to the body cavity for further development.

Classification.— There are approximately 400 species in about 85 genera. These are divided among at least three major groups.

1. The Archiacanthocephala are primarily parasites of terrestrial hosts. Examples include: *Macracanthorhynchus*, infecting beetle grubs and hogs; *Moniliformis* of roaches and rats; and *Mediorhynchus* of grasshoppers and birds.

2. The Palaeacanthocephala are parasites of aquatic and marine hosts. Examples include: *Polymorphus* of amphipods and ducks; *Eclzinorhynchus* of amphipods and fish; and *Corynosoma* of amphipods and ducks or seals, with fish serving to transport the parasite from amphipod to seal.

3. The Eoacanthocephala are primitive forms found almost entirely in fishes. Examples are: *Neoechinorhynchus* and *Octospinifer* of ostracods and marine or fresh-water fish.

Superficially, the Acanthocephala bear certain resemblances to the nematodes, and more basic characters suggest similarities with the flatworms. However, nearly all authorities agree in recognizing Acanthocephala as a separate phylum.

See also PARASITIC DISEASES: *Acanthocephala*.

See L. H. Hyman, *The Invertebrates*, vol. 3, *Acanthocephala, Aschelminthes, and Entoprocta* (1951). (W. L. BU.)

ACANTHODIAN, a small armour-plated fish, among the oldest jawed vertebrates, of the extinct group Acanthodii, often misleadingly called "spiny sharks." *See* PLACODERM.

ACANTHUS, a genus of plants of the acanthus family (Acanthaceae [*q.v.*]), embracing about 20 species, mainly perennial herbs and small shrubs, native to the Mediterranean region and the warmer parts of Asia and Africa. They are bold, vigorous, handsome plants, with mostly broad, much divided, often spiny-toothed leaves. The erect stems bear stately spikes of showy white, purple or red flowers, surrounded by sharp-pointed, sometimes highly coloured bracts.

Several species are grown as ornamentals. These are mostly thistlelike plants, with stems three feet to four feet high. The best known is the bears' breech or brankursine (*A. mollis*), common in Mediterranean countries, with deeply cut, hairy, shining leaves, which are without spines, and whitish or rose-coloured flowers in spikes $1\frac{1}{2}$ ft. long.

The spiny acanthus (*A. spinosus*), native to southern Europe, is so named because of its very spiny leaves. *A. perringii*, a native of Asiatic Turkey, with red flowers, is suitable for rock gardens. *A. montanus*, native to Greece, with roseate flowers, is grown in greenhouses.

H. D'ESPOUY, "FRAGMENTS D'ARCHITECTURE ANTIQUE" (CH. MASSIN ET CIE)

ARCHITECTURAL USES OF THE ACANTHUS DESIGN

In architectural decoration the acanthus was first reproduced in metal and subsequently carved in stone by the Greeks. It was afterward, with various changes, adopted in all succeeding styles of architecture as a basis for ornamental decoration.

There are two types: that found in the *Acanthus spinosus*, which seems to have been followed by the Greeks; and that in the *Acanthus mollis*, which seems to have been preferred by the Romans.

ACAPULCO, a resort city and port of Mexico, at sea level on the Pacific coast in the state of Guerrero, 288 mi. by road S.S.W. of Mexico City. Pop. (1950) 28,512; (1958 est.) 35,000, plus many transients. Acapulco has the best harbour on the Pacific coast of Mexico and one of the finest natural anchorages in the world; it is situated on a deep, semicircular bay, nearly landlocked and accessible by land. Acapulco was a main depot for Spanish colonial fleets plying between Mexico, the Philippines and the orient, and continued to be a port of call for steamship lines between Panamá and San Francisco as well as coastwise trading vessels. The town lies on a narrow strip of land between the bay and steeply rising mountains which encircle it. From May to November the climate is hot and humid, but from December through April it is warm and pleasant; February, March and April are almost rainless. Long a regional economic centre, Acapulco exports hides, cedar and fruit, as well as cotton, tobacco, cacao, sugar cane, Indian corn and coffee grown in the adjacent district of Tabares. No railways connect to Acapulco but a spreading network of highways and frequent air service make it accessible to visitors. Acapulco became "The Riviera of Mexico."

Many luxurious hotels attract tourists, and its principal beaches, Caleta and Los Hornos, offer excellent bathing facilities. Its deep-sea fishing is famous. A traditional tourist attraction is a spectacular dive into the sea from a high cliff by young men for whose benefit a collection is taken up by the spectators.

A main highway, passing through Taxco and Cuernavaca, runs to Mexico City, (R. B. McCk.)

ACARAI, SERRA (AKARAI MOUNTAINS), a range of low mountains on the border between Brazil and British Guiana, forming the watershed between the Rio Trombetas, which joins the Amazon just upstream from Óbidos, and the Oronoque river, which joins the Courantyne river on the border between British Guiana and Surinam. The underlying rocks are crystalline. On either side of the Serra Acarai there is a gently rolling crystalline hilly upland. At the headwaters, however, there is an erosion remnant, preserving a surface, developed during an earlier erosion cycle, that stands at an elevation of about 1,600 ft. above sea level with steep sides and a flattish top. The whole area is covered with a dense tropical rain forest and is little explored. The range extends for about 80 mi. east and nest on the southeasternmost part of the British Guiana border. To the east, the same surface feature runs along the border between Brazil and Surinam, where it is called the Tumuc-Humac mountains. The Serra Acarai was formerly spelled Acarahy; in British Guiana the range is known as the Akarai mountains. (P. E. J.)

ACARINA (ACARI) the scientific name for the order of small arthropods comprising the mites and ticks. Many are parasites and become important for health and economic reasons when they attack man and animals and cause dermatitis or transmit diseases. See MITE; TICKS.

ACARNANIA (AKARNANIA), a district of ancient Greece, bounded by the Ionian sea, the Ambracian gulf, Mt. Thyamus (Petalas) and the Achelous river; its most populous region was the fertile plain of the lower Achelous. The inhabitants emerged late from barbarism (Thucydides noted that in the 5th century B.C. they still carried arms in everyday life), but in the 7th century Corinthian colonists had already settled the coastal areas. The Athenians later helped the Acarnanians to repel attacks by these colonists (perhaps in 437 B.C.) and by the Spartans (429–426); but in 390 they were overcome by Agesilaus and fell successively under the sway of Sparta, Athens and Thebes. They joined the resistance against Philip II of Macedonia but after the battle of Chaeronea (338 B.C.) submitted to Macedonian control. In 314 they established a confederation of newly founded cities; but frontier disputes with Aetolia culminated in the partition of their country between Aetolia and Epirus (c. 243). The Epirote part of Acarnania recovered its independence after 230 and was closely allied with Philip V of Macedonia in his Roman wars. In 167 it lost its new federal capital of Leucas and was forced to send hostages to Rome; but the confederacy with its capital at Thyrrheum survived until the time of the Roman principate, when Augustus incorporated many Acarnanians into his new city Nicopolis Actia, and the rest were included in the province of Achaea. Acarnania took a prominent part in the Greek national uprising of 1821. In modern Greece it is linked with Aetolia in the prefecture (nomos) Aitolia kai Akarnania, with its administrative centre at Missolonghi.

Oost, *Roman Policy in Epirus and Acarnania in the Age of the Roman Conquest of Greece* (1954).

(F. W. WA.)

ACASTUS, in Greek mythology, son of Pelias and brother of Alcestis, but the friend of Jason; he took part in the Calydonian boar hunt and the Argonautic expedition. After his father had been murdered by Medea (who persuaded his daughters that if he were cut up and boiled he could be revived with renewed youth) he instituted splendid funeral games in honour of Pelias, having succeeded to the throne of Iolcus. His wife Astydameia (so named according to Apollodorus, but called Hippolyte in Horace's Odes and in Pindar) fell in love with Peleus (*q.v.*), who had taken refuge at Iolcus, and accused him falsely to her husband (see BELLEROPHON; HIPPOLYTUS). Acastus thereupon left Peleus asleep on Mt. Pelion, having first hidden his famous sword. On awaking, Peleus was attacked by the Centaurs but saved by Cheiron. Having recovered his sword he returned to Iolcus and slew Acastus and Astydameia. (T. V. B.)

ACCADIAN LANGUAGE: see AKKADIAN LANGUAGE.

ACCA LARENTIA (LARENTINA), a Roman goddess whose festival, the Larentalia, fell on Dec. 23. Her original functions and the nature of her cult remain obscure because her legend was humanized and rationalized by writers such as Livy, Ovid and Plutarch, the main literary sources. One tradition described her as a prostitute who, in the early regal period, was won by Hercules at dice, married a wealthy Etruscan, Tarutius, and bequeathed her husband's property to the Roman people. In another account she was the wife of Faustulus, the herdsman who rescued Romulus and Remus (see ROMULUS), and the original *fratres Arvales* were her sons (see ARVAL BROTHERS). Sometimes, as Romulus' foster mother, she was equated with the she-wolf (*lupa* can mean "prostitute"). Modern scholars suggest that she was mother of the Lares (*q.v.*) and symbolized the earth's fertility, but the evidence is inconclusive.

See T. Mommsen, "Die echte und die falsche Acca Larentia" in *Römische Forschungen*, vol. ii (1879). (D. E. W. W.)

ACCELERATION, as used in mechanics, denotes the rate of change, with time, in the velocity of a moving object or of some purely geometrical concept; *i.e.*, a point. Since velocity itself is by definition the time (*t*) rate of change of the distance (*s*) traversed by a moving object ($v = s/t$), this quotient is constant for uniform motion, or represents the average velocity during the interval *t* for nonuniform motion; measured in centimetres per

second (cm. sec.⁻¹). Likewise acceleration ($a = v/t$) is constant for uniform acceleration, or represents the average during the interval t for variable acceleration. This is measured as a rate of change of velocity (cm. sec.⁻¹) per second; *i.e.*, cm. sec.⁻². The term velocity is of a vector character, involving both magnitude (speed) and direction. A velocity may change in either or in both characteristics. Therefore, the idea of acceleration possesses vector characteristics. Near the surface of the earth and in *vacuo*, falling objects show slightly variable accelerations, depending on their location. The direction is approximately toward the centre of the earth and their rate of increase of speed is approximately 980.5 cm., or 32.2 ft. per second every second. See also MECHANICS.

See Index references under "Acceleration" in the Index volume. (H. B. L.M.)

ACCELERATORS, PARTICLE. In 1919 Sir Ernest Rutherford observed the disintegration of atomic nuclei under the impact of alpha particles emitted from a naturally occurring radioactive substance; this may be considered the beginning of nuclear physics as an experimental (rather than an observational) science. It was immediately apparent that a wider range of experiments could be performed if stronger and more flexible sources of fast nuclear particles could be made, and a great deal of effort during the next few years led to the development of several ways for producing such sources. In 1932 J. D. Cockcroft and E. T. S. Walton first observed the disintegration of a nucleus by artificially accelerated particles. Thereafter, the importance of particle accelerators in nuclear research became comparable to that of telescopes in astronomy or microscopes in bacteriology. The particles accelerated are usually the nuclei of light atoms, such as the proton or deuteron from light or heavy hydrogen, respectively, or the alpha particle from helium; heavier nuclei may also be used, or electrons, which are lighter than any nucleus. Since each kind of particle produces its own characteristic effects on nuclei, research with all kinds is desirable. In the simplest general type of accelerator the particle, which bears an electric charge, is pulled along by a steady electric field, just as a falling rock is accelerated by the force of gravity. The particle acquires a kinetic energy equal to its charge multiplied by the difference in electric potential through which it falls. This concept leads to a unit of energy, the electron volt (ev), based on the electronic charge and the volt as a unit of potential; the abbreviation Mev (million electron volts) represents 1,000,000 of these units. An accelerator of this type would comprise an ion source, in which the charged particles are produced (for example, protons from hydrogen gas by the action of an electric arc); an evacuated tube, in which they can travel freely while acted on by the electric field; and some means for providing the required electrical potential. Of greatest importance are machines using potential sources of the kinds first used in this connection by Cockcroft and Walton and by R. J. Van de Graaff; these are suitable for energies up to about 1 Mev and 8 Mev, respectively.

Resonance Accelerators.— The practical limitation on particle energies obtainable in the above way is imposed by the difficulty of preventing electrical breakdown at high voltages. This difficulty can be avoided if the particle is accelerated in steps by the

FIG. 1.— SCHEMATIC DIAGRAM OF SIMPLEST RESONANCE ACCELERATOR. Hollow cylinder *b* has an alternating potential with respect to *a* and *c*. If a positive ion enters the gap *ab* at a time when *b* is negative, it is attracted to *b* and thereby accelerated. The frequency of alternation is chosen so that when the particle reaches the gap *bc* the polarity has reversed and the particle, now being repelled by *b*, is accelerated again.

repeated application of a relatively small voltage, as in the general category of machines that can be called resonance accelerators. (The induction accelerator, representing another way around the difficulty, is discussed below under Betatrons.) The first resonance accelerator, built by R. Wideröe in 1927, is illustrated in fig. 1. This device served to introduce the idea to a scientific world that was eagerly searching for ways of producing high-energy particles. It led in two directions. One was the simple

FIG. 2.— ELEMENTS OF A CYCLOTRON SHOWING (RIGHT) PLAN VIEW AND (LEFT) SECTIONAL VIEW AA

Ions from the source *a* are attracted by one of the hollow electrodes, called "dees" because of their shape. The magnetic field forces them to follow a circular path. When they reach the point *b*, the polarity of the electric field between the dees has reversed, and they are now repelled by the same dee that formerly attracted them. If the frequency of alternation is properly chosen, acceleration occurs also at points *c*, *d*, *e*, etc. The increasing energy causes the circular orbit to expand, resulting in a spiral path. When the ions reach the outer edge of the dees, they emerge through a channel not shown.

extension to more and successive stages of acceleration, giving rise to the family of linear accelerators. The other was a basic modification, the cyclotron, proposed by E. O. Lawrence of the University of California, Berkeley.

In the cyclotron the particles are forced to move in a circular path by the action of a magnetic field. A particle of charge e (in absolute electromagnetic units) moving with velocity v (in centimetres per second) in a magnetic field of strength B (in gauss) is known to suffer a transverse force equal to Bev (in dynes). If the radius of the circular orbit is r , the centripetal acceleration is v^2/r and the radial force needed to keep the particle in the orbit is mv^2/r , where m is the mass in grams. Setting this equal to the magnetic force Bev and solving for r , we get

$$r = \frac{mv}{eB}$$

The important thing to notice about (1) is that, since the size of the orbit is proportional to the velocity, the time per rotation is a constant. The frequency f (number of times per second around the orbit) is simply the velocity divided by the circumference, or

$$2\pi f = \frac{eB}{m} \quad (2)$$

For a deuteron in a field of 13,000 gauss, f turns out to be 10,000,000 cycles per second; these values of field and frequency are easily attainable. Fig. 2 shows how the periodic electric impulses are applied to the particles as they travel around their orbit between the poles of a magnet. In the hands of Lawrence and others, the cyclotron quickly developed into a very powerful tool for nuclear research. For example, the 60-in. cyclotron completed at Berkeley in 1939 can deliver a current of more than 50 microamperes (μ amp.) of 20-Mev deuterons.

There is, however, a practical limit to the energy obtainable from a cyclotron, first pointed out by H. A. Bethe and M. E. Rose in 1937. According to the principle of relativity, the mass of a particle increases as its energy increases; in equation (2) the mass m varies as:

$$m = m_0 + \frac{W}{c^2} \quad (3)$$

where W is the kinetic energy in ergs, c is the velocity of light in centimetres per second and m_0 is the rest mass of the particle.

To illustrate the magnitudes involved, the mass of a proton is doubled when its kinetic energy is 938 Mev; for an electron the corresponding figure is 0.51 Mev. Thus relativistic effects become important for electrons at much lower energies than for protons and other heavier ions. The effect on cyclotron operation is obvious: as the energy increases, the frequency of rotation decreases and the particle falls out of step with the applied high-frequency accelerating potential. Another fact to be noted is that, in a practical cyclotron, the magnetic field B must be weaker at the edge of the pole than in the centre, since this sort of field distribution serves to keep the orbits in their proper position, as explained in the section headed *Cyclotrons and Synchrocyclotrons*. Therefore one cannot compensate for the mass increase by using a field in which B increases with the radius.

Synchrotron and Related Machines.—A practical way for removing the relativistic limit from machines operating on the cyclotron principle was pointed out by V. I. Veksler in the U.S.S.R. and, independently, by E. M. McMillan in the United States in 1945. This is based primarily on the recognition of a property inherent in cyclotron operation, which has been called phase stability. Fig 3 illustrates how this property comes about. The curve shows how the potential difference across an accelerating gap varies with time; and t_1 and t_3 are two successive times at which a particle is supposed to cross the gap, the energy gain at these times being such as to keep the particle at the required rate of acceleration. If the particle has less energy than it should have, according to equations (2) and (3), it will complete the orbit sooner than it should, and the second crossing of the gap will occur at a time such as t_2 . The particle will therefore gain energy at an increased rate, tending to restore the initial deficit in energy. Similarly, an excess in rate is corrected by a motion of the time toward t_4 . A more detailed analysis shows that the energy tends to oscillate about the correct value; the stability breaks down if a rate of energy gain greater than the peak of the curve is required. The stability in phase causes the motion of the ions to "lock in" to the applied radio frequency; or, in other words, the particles tend to seek out a state of motion in which equation (2) is satisfied, with f equal to the applied frequency. Thus a given set of

FIG. 3.— THE PRINCIPLE OF PHASE STABILITY

values of f and B determine a value of m and therefore, by (3), of the energy W .

Acceleration is achieved if f or B (or both) is made to vary slowly in time during the flight of the particle. At the start, f and B have values corresponding to the initial energy of the particles; a decrease in f or an increase in B will lead to an increase in particle energy. Machines in which B is constant in time belong to the general category of cyclotrons; if the frequency is modulated they are called synchrocyclotrons or simply FM cyclotrons. The general term synchrotron is now applied to machines in which B varies with time. This is technically more difficult than variation of f , and is done only when the mass varies by a large factor, as in the acceleration of electrons, or of protons to extremely high energies. Some practical realizations of these possibilities are described in later sections. See also ATOM; ELECTRICITY; ELECTRON; MAGNETISM; NUCLEUS; PARTICLES; ELEMENTARY: RADIOACTIVITY. (E. M. MC.)

VAN DE GRAAFF ACCELERATORS AND COCKCROFT-WALTON GENERATORS

Van de Graaff Accelerator.— This is an accelerator in which

power at high voltage is supplied by means of an insulating belt which carries charge from ground to the high-voltage terminal.

As pointed out by Van de Graaff in an early publication, a high-voltage machine utilizing a charge-carrying belt was first proposed by Lord Kelvin. Van de Graaff, while a Rhodes scholar at Oxford university, recognized the need for a steady, high voltage for particle acceleration and saw the possibilities of this device. After his return to Princeton university, Princeton, N.J., he built the first successful model in 1929.

In this device an electrical charge is deposited on a belt of insulating fabric. The charge is carried into a smooth, well-rounded metal shell. Here it is removed from the belt; it passes to the metal shell, and the shell will increase in potential until electrical breakdown occurs or until the charging current is balanced by load current.

FIG. 4.— SCHEMATIC DRAWING OF A VAN DE GRAAFF ACCELERATOR

To charge the belt a corona discharge is maintained between a series of points or a fine wire on one side of the belt and a well-rounded electrode or inductor plate on the other side. Ionization takes place only near the sharp ends of the charging needles. If the needles are at a positive potential with respect to the inductor plate, positive ions move toward the inductor plate, which in many cases is a grounded metal pulley carrying the belt. The belt intercepts many of the ions and carries them into the metal shell, which serves as a high-voltage electrode. Here the charge is removed by an array of needle points electrically connected to the high-voltage electrode. The machine can be made to provide negative current to the high-voltage electrode by operating the charging needles at a negative voltage with respect to the inductor plate. Belt-charging electrodes must be electrically shielded from the field of the high-voltage terminal, and charge must be carried well within the high-voltage terminal before removal is attempted. Charging current is then independent of the potential of the high-voltage terminal. Terminal voltage will rise until it is limited by corona discharge, by leakage current along insulators, by spark-over or by some load such as ion current through an accelerating tube.

A working model which Van de Graaff built at Princeton consisted of a metal sphere 2 ft. in diameter supported by two Pyrex rods and charged by a silk belt 2.2 in. wide. Early machines followed closely the pattern of Van de Graaff's first model. Charging currents of several milliamperes were achieved, and voltages were commonly limited by spark-over through air from the high-voltage terminal. A smooth terminal approximately spherical in shape, with a radius of 1 m., was found to hold 1,000,000 v. satisfactorily; and from tests with a number of machines the maximum voltage appears to be approximately a linear function of the radius of the terminal.

Work at Princeton and at the University of Wisconsin, Madison, showed that the machine could be made much more compact by enclosing it in a pressure tank and utilizing the high dielectric strength of high-pressure gases. A series of developments at Wisconsin resulted in 1940 in a compact machine operating up to 4,500,000 v. From later development work at the Massachusetts Institute of Technology, Cambridge, a machine was completed in 1950 operating up to nearly 8,000,000 v. Nearly all machines of this type use high-pressure gases for insulation.

These machines came into wide use in nuclear physics laboratories throughout the world. They are specially suited for experiments requiring moderate currents of ions with accurately defined energies. Van de Graaff machines operating up to 6,000,000 v. became commercially available in the 1950s.

Cockcroft-Walton Generator.—This is a particle accelerator

FIG. 5.—SCHEMATIC DRAWING OF A COCKROFT-WALTON GENERATOR. The original machine consisted of two stages; dotted lines show the circuit arrangement for a third stage. After 1950 selenium rectifiers were developed for use in place of the electronic diodes previously used for rectification.

in which a voltage multiplier is used to develop power at high voltage. The accelerator developed by Cockcroft and Walton for their transmutation experiments filled a need so successfully and proved so versatile that it was very widely copied.

In describing their early work, preceding completion of their successful machine, Cockcroft and Walton pointed out the advantages of a steady voltage for acceleration of charged particles. The stream of particles is then uninterrupted; and if fluctuation in voltage is held to a low value the variation of particle energy is small, and accurate measurement of transmutation phenomena is facilitated. Million-volt machines had been developed for the study of high-voltage insulators and for X-ray work, but they did not give the steady voltage desired.

For their high-voltage supply Cockcroft and Walton chose a circuit, commonly called a voltage multiplier, originated by H. Greinacher in 1920. This circuit consists of two stacks of series-connected condensers. One stack is fixed in voltage, except for ripple, with one terminal connected to ground and its other terminal connected to the load. One terminal of the second condenser stack is connected to a transformer; and if the peak voltage of this transformer is V , the voltages at all points along this condenser stack rise and fall within an amplitude of approximately $2V$. Series-connected rectifiers link the two stacks as shown in fig. 5. As the voltage on the oscillating stack rises and falls, charge is transferred stepwise from ground to the high-voltage terminal. Here the voltage is steady except for ripple caused by power drain and stray capacitance, and for no load it has a value of $2VN$ where N is the number of multiplier stages used.

Although extremely high voltages would appear to be attainable by use of many stages, certain practical difficulties set an upper limit to the voltage. One of the most severe limitations is imposed by electrical breakdown through air between neighbouring parts. A 1,000,000-v. machine must be housed in a large room. Exposed terminals must be well grounded, and components must be grouped to minimize electrical gradients. The practical upper voltage limit for these machines when operating in air at atmospheric pressure appears to be about 1,500,000 v.

The high-voltage supply serves to furnish power to an accelerating tube which is equipped with an ion source at its upper terminal. Many of the early machines were limited in voltage by electrical breakdown in the accelerating tube. Multisection tubes of large physical extent have been required to avoid this difficulty. Condensers and rectifiers were a major problem in early machines, and Cockcroft and Walton had to build these components for their

first machine. Later they became commercially available.

These machines are capable of relatively intense ion beams. The high-voltage supplies are usually capable of delivering many milliamperes of current, and ion sources yielding several milliamperes of ion current have been developed. Cockcroft-Walton machines are more numerous than any other type of particle accelerator. Many are designed for operation at only 100 or 200 kv. These are relatively compact and inexpensive and are used to provide neutron sources. Usually to provide neutrons, deuterons accelerated by the machine are directed onto a target containing deuterium or tritium. These reactions give prolific yields of high-energy neutrons at accelerating voltages even below 100 kv.

Low-voltage Cockcroft-Walton machines designed to serve as neutron sources are also commercially available. The N. V. Philips Gloeilampenfabrieken, Eindhoven, Neth., built a number of machines for 1,000,000 v. or more for general research work in nuclear physics. The company also produced machines of this type housed in pressure tanks. By taking advantage of the good insulating properties of high-pressure gases it developed a compact model operating up to 2,000,000 v. (R. G. HB.)

CYCLOTRONS AND SYNCHROCYCLOTRONS

The cyclotron is a major instrument for nuclear research. It is a device for accelerating protons and deuterons, as well as other heavier ions, to energies high enough to produce nuclear transformations in even the heaviest nuclei. The first machine to accelerate particles to high energies without the use of high voltages, it was for many years the only accelerator able to produce heavy particles with energies above 5 Mev. Among the various accelerators which were developed to produce high-energy particles, the cyclotron proved to be the most useful and the most popular.

The synchrocyclotron is a modification of the cyclotron that makes practical the acceleration of ions to energies about 20 times greater than otherwise: energies great enough to make possible the production of new particles of intermediate mass, called mesons. The creation of mesons by the synchrocyclotron is a striking example of the conversion of energy into matter.

Cyclotron.—The first cyclotron, constructed by E. O. Lawrence and M. S. Livingston in the early 1930s, had a magnet of only 2½-in. pole diameter and accelerated protons to 80,000 ev. This was followed at the University of California by the 9-, 11-, 27½-, 37- and 60-in. cyclotrons and finally by the 181-in. machine. The construction of cyclotrons was taken up all over the world, wherever nuclear research was being actively pursued.

The development of the cyclotron opened up vast new areas of research in nuclear science. It produced ions having considerably higher energies than those produced by any of its predecessors in beams of considerable intensity. Nuclear transformations even in the heaviest elements were produced with the cyclotron. A large variety of new radioactive substances was produced and isolated. It is fair to say that the whole important field of radioactive tracer

technique in medical, biological and chemical research received a tremendous impetus as a result of the development of the cyclotron. The first tracer amounts of plutonium produced with the Berkeley cyclotron played an important role in the development of the plutonium bomb. By using the accelerated deuterons to bombard internal beryllium targets, neutron sources 50,000 times as intense as those obtainable previously from radon-beryllium mixtures were made available. Moreover, studies of the scattering of protons by protons and of neutrons by protons, carried out in an energy range otherwise inaccessible! advanced the knowledge of the interaction of the fundamental particles.

In the cyclotron (see fig. 6) two semicircular (D-shaped) hollow electrodes, called dees, are arranged within a vacuum chamber

FIG. 6.—ARRANGEMENT FOR ACCELERATING IONS IN THE CYCLOTRON.

between the poles of a magnet. The ions starting near the centre circulate inside the electrodes, crossing the gap between them twice in each revolution. A high-frequency potential difference impressed across the dees will produce a repeated acceleration at each crossing, provided its frequency is very close to the circulation frequency of the ions.

It is necessary to keep the ions from striking the dees. By arranging for a small radial decrease in the magnetic field, a slight outward curvature to the magnetic field is obtained (see fig. 7). The magnetic force on the particle then always has a small component toward the median plane. This keeps the particle within an inch or two of the plane median to the two magnet poles. This is important because the total length of the spiral path which the ions traverse may be several hundred feet.

The necessity of this focusing, together with the effect of relativity in increasing the mass of the particle as its energy increases, makes inevitable a difference between the circulation of frequency of the particle and the oscillation frequency of the accelerating potential over a considerable portion of the path. Under these circumstances the particle will get out of step with the dee voltage. The effect accumulates with each revolution; and if very many revolutions are made the particle will ultimately arrive at a phase in which the voltage is of the opposite sign, which means that the particle will be decelerated. Thus, a large number of revolu-

FIG. 7.—MAGNETIC FOCUSING IN THE CYCLOTRON

Arrows indicate direction of force on a particle moving in a radially decreasing magnetic field. The force is inward and toward the median plane

tions has to be avoided and a very high voltage must be put on the dees. An extreme example is the 86-in. cyclotron at the Oak Ridge National laboratory, Oak Ridge, Tenn., where a dee voltage of 500 kv. is used to accelerate protons to 22 Mev. This requires a 400-kw. oscillator and represents a practical limit to what can be obtained from a conventional cyclotron.

At the University of Washington, Seattle, a 60-in. cyclotron modeled after the one at the University of California was completed in 1952. It has a 200-ton magnet operating at a field strength of 15,000 gauss with a power input of about 60 kw. The radio-frequency oscillator operates with a power input of 125 kw. and develops a peak dee-to-dee voltage of 250 kv. In discussing the performance of cyclotrons it is important to distinguish between the internal circulating beam and that fraction of it which is extracted by means of a deflector. In the University of Washington cyclotron the internal beam has about 800 μ amp of 21-Mev deuterons. Thus, more than 12% of the oscillator power is converted to useful kinetic energy. About 25% of this beam can be extracted.

Some 50 cyclotrons are in use in research laboratories throughout the world. One-half of these are in the United States, and roughly an equal number are distributed throughout the world. These are of various sizes and some have special features. Thus; some of the more recent designs are arranged for easy changing of the energy. An example is the 90-in. cyclotron installed at Livermore, Calif., which can accelerate protons from 2.6 Mev to 14.0 Mev; deuterons from 5.2 Mev to 12. j Mev; and tritons from 7.7 Mev to 8.3 Mev. Others are used largely for accelerating heavy ions. An example is the 1.2-m. pole diameter machine in Lenin-grad, U.S.S.R., which can accelerate nitrogen ions to 2 j Mev.

The Oak Ridge National laboratory cyclotron produces what may be the world's record output of high-energy particles, 60 kw. of 22-Mev protons on an internal target.

Azimuthal Focusing.—In 1938, quite early in the period of cyclotron development, L. H. Thomas of Ohio State university described a means of obtaining additional focusing of the ions in the cyclotron by providing azimuthal variations in the magnetic field.

This feature promised more stable and efficient operation of the machine in general, and a considerable improvement in the maximum energy attainable.

The idea was not taken seriously until 15 years later when an extensive study, both theoretical and experimental, was undertaken at the Radiation laboratory at Berkeley, Calif. Models were built, and these verified the soundness of the ideas. At Los Alamos, N.M., the performance of the 42-in. cyclotron was greatly improved by the incorporation of Thomas focusing. This was accomplished rather simply by the insertion of three iron sector plates on the magnet poles. This kind of focusing can be augmented by spiraling the sectors. Such spiraled "hill and valley" magnetic fields appear to have useful applications in a variety of accelerator types for producing particles in the relativistic range of energy while using a fixed magnetic field and constant radio frequency. These designs were originated and have been developed extensively by the Midwestern Universities Research association (M.U.R.A.), Madison, Wis., under the name FFAG (fixed-field alternating-gradient accelerators).

Synchrocyclotron.—A more obvious way to overcome the energy limitation of the cyclotron is to provide a means of varying the frequency applied to the dees in accordance with the needs of magnetic focusing and the relativistic increase in the mass of the particle. The scheme is made practical by the existence of phase-stable orbits. Such an orbit is one in which the circulation frequency of the ion is the same as the oscillation frequency of the dee voltage. The circulation frequency of the ion decreases with increasing radius because of the decreased value of the magnetic field and the relativistic increase in the mass of the particle. When the frequency of the oscillator approaches the circulation frequency of the ion in the centre of the machine, some of these ions are caught into phase-stable orbits. As the frequency of the oscillator is decreased, the ions tend to stay in these orbits by absorbing energy from the electric field of the dees. By keeping in synchronism with the radio frequency, the particles gain energy and move in orbits of increasing radius up to the maximum allowed by the magnet design.

An important advantage of the synchrocyclotron is that, provided the vacuum is good enough, there is no limit to the number of revolutions the particle may make to obtain the desired energy. The desired acceleration may take place in quite small steps, 10 kv. per turn being the usual amount. This allows a more modest radio-frequency supply. Moreover, the shape of the magnetic field is much less critical. Another feature of the synchrocyclotron is the use of a single dee. This gives half the acceleration per turn of the two-dee system but has many mechanical and electrical advantages for synchrocyclotron use.

FIG. 8.—INSTALLATION OF THE 170-IN. SYNCHROCYCLOTRON AT THE UNIVERSITY OF CHICAGO

Heavy concrete and steel walls shield the working areas from the penetrating radiations emitted by the machine

On the other hand, the output intensity is much lower since the frequency is modulated. The ions are captured into stable orbits only during a small fraction of the modulation cycle. In the 170-in. synchrocyclotron at The University of Chicago, the beam appears as a pulse about 100 μ sec. long at a repetition rate of 60 cycles per second. The mean circulation current is about 2 μ amp. However, the energy is 450 Mev so the total beam power is almost 1 kw.

FIG. 9.— THE 170-IN. SYNCHROCYCLOTRON AT THE UNIVERSITY OF CHICAGO

The MacKenzie system of frequency modulation is used in which a rotating condenser changes the resonance frequency from 29 to 17 mc. per second

Following E. M. McMillan's suggestion, the first test of a frequency-modulated cyclotron was made by converting the 27-in. machine at Berkeley. The test was so successful that immediately afterward the 184-in. cyclotron, which was originally designed for conventional operation with about 1,000,000 v. on the dees, was operated as a synchrocyclotron and gave beams of about 200-Mev deuterons and 400-Mev alpha particles. In 1948 its radio-frequency system was changed to the MacKenzie circuit for operation with protons, and it then gave a beam of protons of an energy of 350 Mev. More recently (1957), an extensive conversion of both the magnet and the radio frequency brought the operating energy up to 750 Mev. This placed the Berkeley machine higher in energy than the 680-Mev machine in Dubna, U.S.S.R. (near Moscow), in operation since 1953; and the 600-Mev synchrocyclotron completed in 1958 in the laboratory of CERN (European Council for Nuclear Research) in Geneva, Switz. By the late 1950s about 16 synchrocyclotrons were in operation throughout the world, but only 8 of these gave energies above 200 Mev and were thus able to produce π mesons. For energies higher than 800 Mev the synchrocyclotron becomes too costly. Instead, synchrotrons turn out to be more practical for energies in the billion-volt range.

These machines have opened up important new possibilities for research into the nature of fundamental particles. Notable discoveries made with these machines include the artificial production of π mesons, the stripping of the deuteron, the polarization of the proton and the formation of π -mesic and μ -mesic atoms.

(H. L. AN.)

SYNCHROTRONS

Synchrotrons for Electrons.— The electron synchrotron utilizes the principle of phase stability to maintain synchronism between the circulating particles and an applied high-frequency electric field. A magnetic field deflects particles in a circular orbit, and the intensity of the field is modulated cyclically from low to high field strength as the particles gain energy, to maintain orbits of nearly constant radius. Since the magnetic field is required to maintain the orbit, but is not used for acceleration, magnetic field lines are needed only in the annular region defined by the orbit. This field may be produced by a ring magnet. The relatively low weight and cost of such a ring magnet compared with

the solid-core magnets required for cyclotrons or betatrons gives the synchrotron a significant economic advantage for high particle energies.

Electrons are well adapted to acceleration in a ring-shaped magnetic field, since they acquire a velocity essentially equal to the velocity of light at relatively low energies ($v = 0.98c$ at 2 Mev); for higher energies they circulate about an orbit of fixed radius at constant frequency. An electric field to provide acceleration is developed (by a resonant electrical cavity) across a gap in the vacuum chamber enclosing the orbit. The potential across the gap alternates at a frequency tuned to be identical with the orbital frequency of the electrons. This applied frequency is determined by the orbit radius r and is

$$f = \frac{c}{2\pi r} = \frac{\text{velocity of light}}{\text{orbit circumference}}$$

During the half cycle when the electric field is positive, the electrons acquire energy; they are reduced in energy during the other half cycle. So they become bunched into a phase where the voltage maintains a rate of increase in energy which matches the rising magnetic field. Under these conditions, an electron which crosses the gap at the wrong time, and which has the wrong energy, traverses an orbit of slightly smaller (or larger) radius. The resulting change in orbital frequency causes the electron to migrate toward the correct phase. This migration represents an oscillation in phase about the mean or equilibrium phase, at which the energy acquired per traversal is exactly that required to match the rate of rise of magnetic field. This type of stable-phase oscillation is inherent in the synchrotron. Electrons will follow any reasonable rate of rise of magnetic field; *i.e.*, 60 cycles per second. If sufficient accelerating potential is available across the gap, the electrons will maintain synchronism and be accelerated to maximum energy.

Electrons must be brought up to constant velocity (taken as 1 to 2 Mev energy) by some auxiliary means. In early synchrotrons this was accomplished by magnetic induction, as in the betatron, by providing some linkage flux threading the orbit. Other installations use a low-voltage accelerator external to the magnet to pre-accelerate the electrons, after which they are inflected into the orbit by a suitably shaped electric field. The vacuum chamber has the general form of a toroid, or "doughnut," and must be main-

tained at high vacuum (0.000001 mm. Hg) to avoid loss of electrons by scattering from the gas during the early stages of acceleration. When the electrons approach maximum energy, the oscillator providing the high-frequency accelerating field is turned off; the electrons spiral in to strike a target on the inside of the chamber and generate a narrow beam of energetic X-rays which emerge tangentially from the chamber and which can be used for experimentation.

The first electron synchrotron, for 8 Mev, was built in England in 1946 to test the principle of phase-stable acceleration. The first high-energy synchrotron developed 330 Mev in 1947, at the University of California. By 1956 more than 20 synchrotrons between 50 and 500 Mev were in use as research instruments in many countries. Two synchrotrons for 1,200 Mev were completed in 1957, one at the California Institute of Technology, Pasadena, and one at Cornell university, Ithaca, N.Y. The Cornell machine was the first of a new type of synchrotron using alternating-gradient magnets (see below, Synchrotrons for Protons). Electron synchrotrons have found their greatest use as X-ray sources for producing photonuclear reactions, especially the photoproduction of mesons, which occurs above a threshold of about 250 Mev. Synchrotrons of 100 Mev or less have also found useful applications in hospitals for treatment of cancer and in nuclear research laboratories.

The electron synchrotron has a unique property which leads to a practical upper limit of energy. When deflected in a magnetic field the electrons radiate electromagnetic energy in a continuous spectrum extending into the soft X-ray region, with an intensity which increases with the third power of electron energy. This radiated energy must be supplied by the high-frequency accelerating system, in addition to that required for synchronous acceleration. At very high energies the radiation disturbs particle orbits and produces transverse oscillations which throw the electrons out of the chamber. The Cambridge electron accelerator, a joint project of the Massachusetts Institute of Technology and Harvard university, is designed to produce electrons at an energy of 6,000 Mev (6 Bev), which approaches the practical energy limit. It uses alternating-gradient magnets in an orbit 236 ft. in diameter, op-

a ring magnet and utilizes the principle of phase stability to maintain synchronism with the high-frequency accelerating electric field. A ring magnet is much lighter and less costly than the solid-core magnet of a synchrocyclotron, which also accelerates protons, but requires acceleration at essentially constant orbit radius. The magnetic field must be varied cyclically from low to high field strengths during the acceleration interval, matching proton energy. High-energy protons are produced in short bursts at the peak of each cycle, which results in a low average beam intensity. However, the advantage of higher energies for scientific research justifies reduced beam intensity, and proton synchrotrons have displaced synchrocyclotrons for energies above 1 Bev (= 10^9 electron volts).

Proton velocity increases continuously with increasing energy; so, unlike the situation with electrons, orbital frequency increases during acceleration, by more than 1:10. The applied electric field must be varied in frequency to match exactly the orbital frequency of the protons, which requires a precisely determined schedule of frequency modulation. To vary the frequency, the resonant cavities which provide accelerating electric fields are equipped either with rotating capacitors or with ferrite cores which are magnetically biased, or with both. In high-energy accelerators many such cavities are spaced around the orbit and operated in phase.

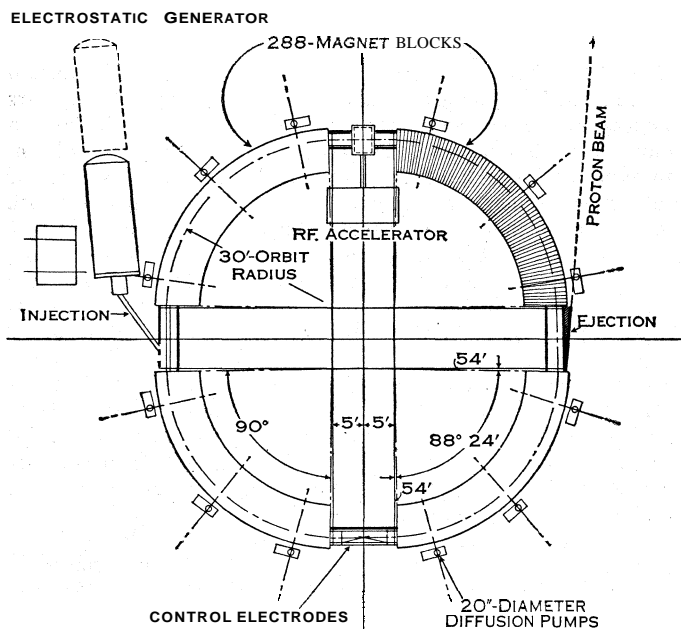

Protons are preaccelerated in an external accelerator to relatively low energy, and are inflected into the orbit when the orbit magnetic field reaches the proper value for deflection at the designed radius. At maximum energy the protons are directed against targets at the edge of the chamber by changing the applied frequency, or they can be deflected tangentially outward in an emergent beam for experimental studies.

The cosmotron at Brookhaven National laboratory, Upton, L.I., N.Y. (see fig. 10), completed in 1952, operates at 3 Bev and produces bursts of 5×10^{10} protons at 5-sec. intervals. The magnet is formed of four quadrants spaced by 10-ft. straight sections, forming a distorted circle of 75-ft. diameter. An electrostatic generator produces 4-Mev protons, which are inflected into the orbit at one straight section. A ferrite-loaded high-frequency resonant cavity in another straight section supplies about 3,000 v. per turn for acceleration and is modulated between 0.37 and 4.20 mc. per second. At high energy the protons are deflected outward in an emergent beam used for experiments. Significant research has been performed on the production of "strange" particles and the properties of high-energy mesons.

The bevatron at the Berkeley Radiation laboratory was completed in 1954. It produces 2×10^{10} protons per pulse of 6.2-Bev energy, at 10-sec. intervals. The magnet consists of four quadrants with 20-ft. separation, forming a circle of 160-ft. diameter. Protons are preaccelerated to 0.5 Mev in a Cockcroft-Walton generator and to 10 Mev by a linear accelerator, before being inflected into the orbit. Although structurally larger and heavier than the cosmotron, the bevatron is similar in basic principles of design and of operation. Research operations have been highly successful, the most dramatic results being the discovery of the negative proton (antiproton) and the antineutron.

The principle of alternating-gradient magnetic focusing, developed at Brookhaven starting in 1952, has been applied to several types of accelerators. It utilizes alternately positive and negative gradients in the magnetic field used to deflect particles around an orbit. A gradient field is one in which the field is stronger on one side of the orbit than on the other, so magnetic field lines are curved, and particles are deflected toward or away from the median plane and the central orbit. In effect, the successive sectors of alternating gradient are magnetic "lenses" which focus moving particles strongly about the chosen equilibrium orbit location. The use of such strong focusing fields reduces particle oscillation amplitudes, allowing much smaller magnets to be used and so reducing cost. Synchrotrons can be designed for larger orbit radii and higher energy.

An alternating-gradient proton synchrotron at the CERN laboratory in Geneva was brought into operation in 1959 at 28 Bev. and a similar machine at Brookhaven was completed in 1960. These

erating at 60 cycles per second, and has many high-frequency accelerating cavities to provide the energy lost by radiation. A similar electron accelerator was under construction (1960) in the DESY project at the University of Hamburg in west Germany.

Synchrotrons for Protons.—The proton synchrotron also uses

super-energy accelerators are located in underground circular tunnels for radiation shielding; that at Brookhaven is 750 ft. in diameter. Scientists anticipate an exciting wealth of new experimental information on the properties of high-energy particles when these machines come into full operation. (M. S. LN.)

LINEAR ACCELERATORS

Linear Accelerators for Electrons.—The term linear accelerator might be applied to any machine which accelerates particles in a straight line, but through common usage it has been restricted to the particular class of these machines which employs repeated use of a rapidly alternating potential in a resonant condition. It is a development and extension of the machine proposed by R. Wideroe, mentioned above under *Resonance Accelerators*. Because of the considerable difference in the design and operation of these machines for electrons and for heavy particles, they will be treated separately.

Linear accelerators were developed through the application of techniques developed by the radar programs of World War. II. With few exceptions, they use an electromagnetic (or radio) wave with a frequency of the order of 3,000 mc. per second traveling down an evacuated wave guide as the medium of acceleration. A wave guide is a cylindrical pipe with conducting walls in which a radio wave may be propagated under suitable circumstances. Electrons are injected into the wave guide so that they travel in the same direction as the wave; and the wave guide is so constructed that the principal wave and the particle have the same velocity at all points along the guide. The wave guide is also arranged so that the electric field component of the wave is directed along the axis. Electrons entering the guide at the proper time (or phase) experience a force resulting from the interaction of their charge and the electric field; and since wave and particle travel at the same speed, this force continues throughout the length of the wave guide, accelerating the electrons to ever-increasing energies. The effect is similar to that of a surfboard rider on an ocean wave.

There are several possible conditions of phase for acceleration. The particle can be ahead of the point of maximum electric field in the wave. In this case it is phase stable, for if the acceleration is not sufficiently large to keep the electron in step with the wave, the electron moves back to a position of greater field and greater acceleration. It can be shown, however, that the electron is then radially unstable; *i.e.*, if the electron is deflected from its path, the deflection becomes progressively worse. The particle can also be behind the position of maximum electric field. It is then phase unstable and radially stable. As a third condition, the particle may be at the position of maximum electric field (which incidentally has a sine wave variation). In this case, it is in unstable equilibrium in regard both to phase and radial deflections.

Since it is not possible to fabricate the wave guide so that the wave will have exactly the right velocity, it is generally advantageous to operate the machine so that the electrons have phase stability and to overcome the radial instability with an axial magnetic field along the guide. In one notable case, however, the position of unstable equilibrium is used (the accelerator developed at Stanford university, Stanford, Calif.). The rate of acceleration is very high; the wave velocity is made equal to the velocity of light; and, because of the relativistic velocity of the particles, the accelerator appears so short that neither phase nor radial instability has a chance to operate.

In an ordinary wave guide with smooth conducting walls, the phase velocity of the electromagnetic wave is always greater than the velocity of light. Since particle velocities cannot exceed the velocity of light, it is necessary to slow the wave down. This is accomplished by placing iris diaphragms in the guide. Thus a practical accelerator wave guide consists of a metal tube of high conductivity and circular cross section with metal diaphragms placed at intervals of one-fourth wave length throughout the length of the tube. Each of these diaphragms has a circular opening at its centre through which the electrons pass. The phase velocity of the wave is determined by the difference between the diameter of the hole in the diaphragm and the inside diameter of the

tube.

The final energy of electrons from a linear accelerator of optimum design is proportional to the square root of the product of wave-guide length and radio-frequency power input. Since the cost of long accelerator wave guides is very large, the power input must be as high as possible. Magnetrons operating at power levels of 500,000 to several million watts, and klystrons operating in the range of 10,000,000–30,000,000 w. have been used as power sources. These tubes are unable to handle such power continuously and therefore are turned on for periods of one or two millionths of a second, repeated 50 to 1,000 times per second.

Since magnetrons are free-running oscillators, it is very difficult to control the phase so as to operate several together. On the other hand, klystrons are power amplifiers, and it is easy to drive any number from a single source with complete control of the phases of the output. This fact makes possible the cascading of a number of separate sections of accelerator with each feeding into the next section with the proper phase. This scheme was adopted at Stanford university for acceleration to the 1,000-Mev (1-Bev) range. (L. S. Ss.)

The first linear accelerator was built by D. W. Fry and his associates at Malvern, Eng., in 1946. Further work continued in England and to some extent in the United States on obtaining large output currents and high efficiencies. A single magnetron feeding several feet of wave guide with magnetic focusing was used in this first accelerator. Subsequent accelerators were built in England, France and the United States that employed several klystrons feeding separate sections to obtain higher energies. In some of these machines, peak currents as high as 0.75 amp. have been obtained, with as much as 50% of the radio-frequency power being transferred to the electron beam. Some of these high-current accelerators are intended to generate pulsed neutrons for time-of-flight measurements. Others are intended for use in food and drug sterilization and for activation of chemical reactions. A number of lower-current accelerators are also in use as X-ray sources in the range of 4–6 Mev for the treatment of cancer. There are several machines in the range of 50 Mev being used for biological research and experimentation in the direct use of electrons for cancer treatment.

By the late 1950s, there was only one linear accelerator in operation for producing extremely high-energy electrons. This machine, at Stanford, was started by W. W. Hansen and completed by E. L. Ginzton and his associates. It ran for a number of years at energies in the range of 700–800 Mev and was found to be a unique research tool for nuclear physics. Since the electron beam can easily be brought out from the accelerator, certain types of precision experiments can be performed which are not possible with the circular machines from which such removal is very difficult. The high currents that are available also permit energy sorting which is another asset in nuclear experimentation. By 1959, the Stanford machine had been extended from a length using 21 klystrons to one using 30 klystrons so that electrons of 1-Bev energy could be achieved. (M. Cw.)

Linear Accelerators for Protons.—Linear accelerators for protons are so different from those for electrons in principle of operation, design and appearance that the two must be treated separately. The essential similarity is the resonant use of a radio-frequency voltage; the resonant principle appears, however, much more explicitly in the proton accelerator.

The great difference between the two accelerators is due to the large difference in mass of the two particles to be accelerated, the proton being 2,000 times heavier than the electron. Whereas an electron has a velocity which is nearly constant and equal to that of light at energies higher than 1 Mev, a proton is much slower and essentially obeys the classical laws of mechanics up to 100 Mev; that is, its velocity increases as the square root of its energy. This low velocity of the proton makes it impractical to reduce the velocity of an electromagnetic wave in a wave guide to the extent needed to use the principle of the electron linear accelerator. It is necessary to develop a new technique for protons.

Consider a large cavity in the form of a long, cylindrical tank with electrically conducting walls. When this cavity is fed with

radio-frequency power of the proper frequency, a resonant condition is set up. The cavity is equivalent to a wave guide with closed reflecting ends, so that the wave is reflected from side to side, resulting in a standing wave at the resonant frequency much the same as a sound wave in an organ pipe. The cavity and the way in which power is fed are so designed that the electric field of the electromagnetic wave is in the direction of the long dimension of the cavity. Therefore, if protons are injected with the right phase in the direction of the long axis of the cavity, they will be accelerated at first; but when the phase of the oscillation changes, they will be decelerated. The result is no net gain in energy. To avoid this difficulty, a number of hollow drift tubes are placed nearly end to end along the axis of the cavity. These shield the protons while they are within the tubes from the effects of the decelerating field. The lengths of the drift tubes are so adjusted and the gaps between so placed that the protons cross the gaps at the time the field is near a maximum in the accelerating direction. This requires the spacing between drift-tube centres to increase as the proton is accelerated; the distance being v/f , where v is the velocity of the proton and f is the frequency of the electromagnetic wave.

In proton linear accelerators, the particles must have the proper velocity at each gap. The machine will not operate unless the radio-frequency power level is above a minimum value. This disadvantage is not shared by the electron accelerator; but, on the other hand, the energy spectrum of the proton accelerator is much better (*i.e.*, the spread of energies of the emergent particles is much less).

The drift tubes must have sufficient diameter to pass a reasonable beam of protons, but at the same time they must not be so large that there is appreciable penetration of the electromagnetic field into their interior. This leads to the use of relatively low frequencies—in the region of 200,000,000 cycles per second. The large size of the cavity leads to a long time for the build-up of resonant oscillations, requiring a long pulse of power. This is an advantage in nuclear disintegration work.

There are positions of phase stability and radial instability, or phase instability and radial stability, as in the linear accelerator for electrons. The radial instability can be eliminated by placing metallic grids across the drift tubes, changing the shape of the electric field in the gap region to one that has a focusing action.

Wideroe's two-stage linear accelerator was developed by E. O. Lawrence and D. H. Sloan, who built several multistage accelerators in 1930-32. The logical extension of their ideas to the acceleration of protons was accomplished by L. W. Alvarez and his associates at the University of California in 1947. As in the electron accelerator, this accomplishment was materially aided by the very extensive technical advancements in radar during World War II. The California accelerator operates at a wave length of 150 cm. The cavity has a diameter of 3.5 ft. and a length of 40 ft. Protons are injected from a Van de Graaff generator at 4 Mev and accelerated to 32 Mev. The 2.5 megawatts of radio-frequency power comes from six triode oscillators which are pulsed on for 500 μ sec., 15 times per second. The average beam current is $\frac{1}{3}$ μ amp. (L. W. A.; L. S. Ss.)

A second proton machine, operating at 60 Mev, was built at the University of Minnesota, Minneapolis, by J. H. Williams. In addition to these two machines intended for nuclear research, a number of proton accelerators were built as injectors for circular accelerators. Examples are at Berkeley and Brookhaven in the United States, at several Russian laboratories and at CERN in Geneva, Switz.

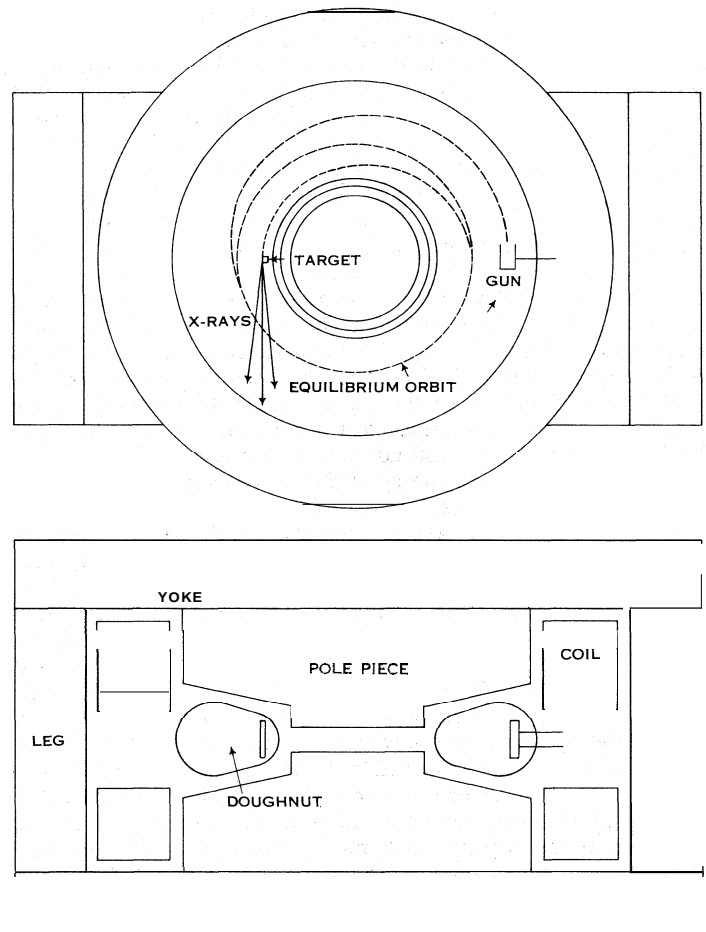

Another interesting application of linear accelerators is exemplified by two heavy ion accelerators at the University of California and at Yale university. These will accelerate a variety of ions, with energies of the order of 10 Mev per nucleon. These are also intended for bombardment experiments using such heavy nuclei as carbon, nitrogen, oxygen, etc. See also NUCLEAR ENGINEERING. (M. Cw.)

BETATRONS

The betatron is a circular accelerator for electrons, operating on

the same principle of electromagnetic induction as the transformer. It produces electrons or X-rays of millions of electron volts of energy without the use of excessively high voltages. The need for such a machine is threefold: (1) in nuclear physics a source of high-energy electrons or X-rays is used to study fundamental properties of matter and radiation; (2) in industry the X-rays are used in radiography, where they are able to penetrate 12 in. of steel and still produce a good radiograph; and (3) in medicine X-rays of high penetrating power, producing a low skin dose and a high depth dose of radiation, are valuable for the treatment of cancer.

Description.— In a transformer the electrons in the secondary winding are guided by the insulated copper wire wound around the core, while the changing magnetic flux in this laminated iron core induces a voltage in the secondary winding that makes the electrons move. Similarly in the betatron there is a means of guiding the electrons along their circular path; at the same time they are accelerated by the electric field induced by changing magnetic flux within the orbit. However, the guiding process in the betatron is quite different: in the first place, the circular orbit is inside a high-vacuum tube in the form of a hollow glass or ceramic "doughnut"; in the second, the electrons are kept in the circular orbit or focused toward it by a specially shaped magnetic guide field. The magnitude of this field must be in a definite proportion to the magnetic flux through the orbit so that the circular path does not become either a decreasing or an increasing spiral. By traveling around the tube thousands of times the electrons build up a

BY COURTESY OF GENERAL ELECTRIC CO.

FIG. 11.— HORIZONTAL CROSS SECTION (TOP) AND VERTICAL CROSS SECTION (BOTTOM) THROUGH BETATRON

high energy measured in millions of electron volts, without the insulation problems associated with the actual production of a high potential.

The upper part of fig. 11 is a horizontal cross section through

the centre of the betatron. The dotted line gives a rough indication of the path of an electron in the vacuum tube: starting from the electron gun, the electron goes thousands of times around at the equilibrium orbit and finally stops at the target where X-rays are produced, these being principally in the direction of the motion. The lower part of fig. 11 is a vertical section showing the magnetic circuit with the coils forming the primary winding and the doughnut representing the secondary. As can be seen, the magnetic guide field at the orbit and the magnetic flux passing through the orbit belong to a magnetic circuit. This consists of two specially profiled round pole pieces, two horizontal yokes and two vertical legs. All these parts are made of laminated silicon steel to keep eddy-current losses low. The frequency of operation ranges from the power-line frequency of 50 or 60 cycles per second to as high as 2000 cycles (in which case a motor generator is required). The magnetic circuit is energized by means of two primary windings which are connected to the power source in shunt with a capacitor bank. The capacitor bank is used to increase the power factor. The vacuum tube (or doughnut) is located between the profiled part of the pole pieces; its inside wall has a thin, high-resistance coating to keep static charges from disturbing the electron beam.

Electrons are introduced into the vacuum tube by an electron gun placed in the plane of the stable orbit and usually outside it. It is placed as far from the equilibrium orbit as possible in order to leave a maximum of unobstructed space, yet within the region where the magnetic field has the proper focusing effect. The electron gun is a small metal box with a slot through which the electrons emerge. They originate inside the box at a hot filament or other thermionic emitter. The emitter is provided with shielding and focusing electrodes so that when the filament is given a negative potential with respect to the box the emitted electrons are accelerated toward the slot and shot into the tube in the form of a narrow, directed beam. To avoid disturbances from electric fields outside the gun, the metal box or gun anode is grounded and connected to the conducting coating inside the doughnut. Electric fields of unwanted electrons from the space charge are minimized by applying the accelerating voltage to the gun filament for only a few millionths of a second. This pulse of the order of 50,000 v. is timed to occur after the magnetic field has passed through zero and at the instant the field has the proper magnitude and direction to guide the electrons into circular paths inside the doughnut. Many of the injected electrons strike the walls of the doughnut or the gun structure during the first few revolutions. The remaining electrons oscillate about the equilibrium orbit with an amplitude which decreases as the magnetic field gets stronger. The energy of the electrons rises, the rise continuing as long as the field increases.

When the electrons have reached the proper energy, they are made to strike a target to produce X-rays. This is done by suddenly upsetting the relationship between guide field and flux, which so far has kept the orbit circular. The simplest method is to allow the iron in the centre of the betatron to saturate, whereupon the guide field increases at a faster rate than the flux, and the electrons spiral inward toward the target. Another method is to pass a high-current pulse through a turn of wire wrapped around the central iron core within the orbit, so that the ratio of flux to guide field is diminished, and the electrons spiral in to the target. This type of orbit contraction is usually timed to occur at the peak of the sinusoidal variation of the magnetic field, since the electron energy is at a maximum at this time. After the electrons have hit the target and produced a short burst of X-rays, no electron acceleration takes place for the remaining three-quarters of the cycle. The useful current striking the target is of the order of a few microamperes.

Some betatrons are equipped to produce an external beam of electrons instead of X-rays. In this case the electron gun may be placed inside the equilibrium orbit. Near the outside of the doughnut is located an electrostatic or electromagnetic deflection system which, upon orbit expansion, directs the electrons toward and through a thin metal-foil exit window. The external electron beam has some use in physics research and cancer therapy.

Particle Dynamics.—The equations of motion of the electron in the radial direction and the tangential direction may be integrated, subject to the constraint of constant radius. Elimination of charge and momentum yields the required relationship between magnetic flux through the orbit and the guide field at the orbit. This condition is

$$\phi - \phi_0 = 2\pi r^2 B$$

Expressed in words, the equation states that the change of the magnetic flux ($\phi - \phi_0$) from the time that the guide is zero is equal to twice the product of the area (πr^2) of the circular orbit and the flux density (B) in the guide field. In most betatrons, $\phi_0 = 0$, and the equation then shows that the flux density averaged over the orbit is twice the guide-field flux density. Therefore the guide field is relatively weak even when the iron in the centre of the machine tends to saturate. A great weight and size reduction is obtained in the so-called biased betatron by making ϕ_0 negative; this is done by means of a bias winding and appropriate currents. One of the remarkable things about the equilibrium orbit is that it does not change form as the velocity of the particle changes from the nonrelativistic to the extreme relativistic region. It is this fact which makes the betatron so simple a machine for electron acceleration, since injection occurs at low velocities, and acceleration is carried to velocities very close to that of light. It is only when the betatron principle is applied beyond 100 Mev that the above relation is insufficient to maintain a circular orbit. With this high energy an electron in circular motion radiates so much electromagnetic energy, including visible light, that the loss of energy (unless compensated for by additional magnetic flux) causes an appreciable contraction of the orbit.

For energies larger than a few million electron volts the kinetic energy of the electrons in a betatron can be given by a simple expression:

$$E = 3 \times 10^{-4} B r - 0.51$$

where E is the kinetic energy in millions of electron volts (Mev); B is the flux density at the orbit in gauss; and r is the orbit radius in centimetres. Practical values of B range from 2,000 to 8,000 gauss, depending on the size and on the use of bias.

History and Present Status.—The successful operation of a betatron was first demonstrated by D. W. Kerst at the University of Illinois, Urbana, in 1940. The concept of the equilibrium orbit was known many years before that time, but the careful theoretical study by Kerst and R. Serber of the conditions for injection and Kerst's use of the pulsed electron gun placed near the equilibrium orbit made the betatron practical.

Betatrons are now in commercial production in the U.S. and Europe in the energy range from 10 to 30 Mev. Most betatrons are in industrial radiographic use; a few are being used in cancer therapy; and some, including the largest, rated 300 Mev, in high-energy physics research. Above 50 Mev the betatron was superseded by the development of the synchrotron in 1946.

ACCENT, in speech, is understood colloquially in at least three senses: (1) the presence in an individual's speech of articulations not typical of the community (e.g., a foreign accent); (2) a sustained quality of vocalization, outside the linguistic system, used to discriminate shades of meaning or personal characteristic (e.g., to speak in tender accents); (3) a prominence given to a short span of speech and manifested as stress or pitch or some extralinguistic component.

In linguistics, accentual (also called prosodic or suprasegmental) features are sound units which may be manifested as pitch or tone (i.e., acoustic fundamental frequency), stress (intensity), length or quantity (duration), and occasionally as glottalization, devoicing or nasalization.

In English, the most widely used notations for stress are: ' for primary stress; ^ for secondary stress; ` for tertiary stress; and ~ for weak stress. Different stresses applied to the same words convey different meanings. For example, the same four words, "a-black-bird's-nest," according to their stress sequence may convey the following: ^ˈ_ˈ^ˈ a nest (not a house) of a blackbird; ^ˈ_ˈ^ˈ a nest of a blackbird (not a jay); ^ˈ_ˈ^ˈ a nest of a black bird; or ^ˈ_ˈ^ˈ a bird's nest that is black (not green). The difference between the tertiary and weak stresses is further exemplified by comparison of the final syllables in "Andès" and "cándiès" or "pick-up" and "hiccough." Pitch notation consists of numbers from 4 (for the highest) to 1 (for the lowest). Differences in pitch sequence in the word "yes" may convey the following: 4-1, impatient agreement, as after persistent urging; 2-3, abruptness, as in answer to an interruption; 3-2, apprehensive admission or concession; 4-4, high-pitched frightened acquiescence; 2-4-1, leering, lascivious approval or conniving agreement. Cut-offs are indicated as follows: ↓ sharp; ↑ up-glide; and → trail-off. The word "well," depending upon the cut-off, may indicate the following: 2-2 ↓, "let's get

on with it"; 2-2 ↑, "and then—?" or "please explain yourself"; and 2-2 →, preoccupied indecision. (These examples are characteristic of a great many residents of the U.S., particularly in the north and east, but are not, of course, valid for all English-speaking persons.)

Accents form perhaps the most common basis in languages for the organization of syllables, most commonly by stress and pitch. While English seems to have four degrees of stress, one of which occurs with every vowel, Chinese has four tones, one of which occurs with most syllables. Occasionally (e.g., in Swedish) the pitch organizes a sequence of more than one syllable. The best-known language lacking an accentual organization of syllables is French.

Accent sequences frequently serve to integrate words; a word that lacks an independent accent pattern is either proclitic (if it depends upon the following word) or enclitic (if it depends upon the preceding word). Similar features, especially pitch (usually called intonation) and the distinctive manner of cutting off the voice (usually called terminal contour), are used to organize longer sequences—phrases and sentences. Spanish has an array somewhat similar to the four distinctive pitch levels and three types of cut-off of English. Japanese seems to have intonation patterns, but no terminal contours; Ojibwa has contours, but no intonations of the sort English has. No known language may be said to lack intonations and contours entirely. French employs stress, in addition to pitch, in contour patterns (as in *attention!*).

Languages show great variety in their exploitation and distribution of accents. Thus, while English has only one major stress in a polysyllabic word, many languages permit more than one. In English, stresses occur only with vowels; in Czech, they occur also with the semiconsonants *r* and *l*; in South African Bushman, tones occur with vowels and often with nasals; in the Wahgi language of New Guinea, the stress-pitch accent occurs with all vowels and most consonants. Within the syllable there is also endless variety; though one may hear the accent as acoustically overlying the whole syllable, in some languages it has a structural position within the syllable. Stress in English and Spanish and tone in Japanese, Navaho and Cuicateco (Oaxaca, Mex.) cannot be assigned a sequential position. But the tones of Chinese and Lushai (India) seem to belong to the end of the syllable; those of Trique (Oaxaca) to the middle; those of South African Hottentot to the beginning; while the mobile stress of Lithuanian and Karok (California) and the pitch of Lettish may occur at distinctively different points along the syllable. The greatest number of level tones (five) yet described is found in Trique. On the other hand, Mazateco (Oaxaca) has four, but permits combinations of up to three within a single syllable: as a result, the sequence of tones carries so much of the distinctive features of words that Mazatecs can whistle complicated messages over distance. In many languages the simple accents are not level, but have a broken or gliding contour; in Burmese tones, pitch is associated with glottalization.

Accents are usually more difficult to reconstruct than other phonemes of dead or prehistoric languages. They are rarely recorded in writing systems, and they usually change in the course of time, making recovery difficult. Weakly stressed syllables are frequently lost in time, as from Latin to French (*frigidum* to *frôid*). Other sounds may also change quite differently depending on their accentual environment.

The ancient Greek grammarians devised marks to indicate the accents of their language, the primary feature being pitch. The Greek term for accent was *prosodia* (literally translated by the Romans as *accentus*), which later came to be used to refer to metrical quantity (whence the English "prosody"). The ancient Hindus marked the accents in their Vedic hymns, and this system became known to Western scholars when they first learned Sanskrit. The modern scientific tradition represents a confluence of these two ancient traditions.

The diacritical marks, misleadingly called acute (´), grave (`) and circumflex (ˆ, ˘ and ˝) accents, used to distinguish different vowels in written European languages are not subsumed under any of the above senses.

ACCEPTANCE, in law, an act of consent or approval, having special significance in different situations. Thus, the term may be applied to the act of a person in signing his name (or his name with the word "accepted") across the face of a bill of exchange or draft addressed to him. He thereby obligates himself, as acceptor, to pay the bill according to its tenor or, if the acceptance is qualified, according to the terms of the acceptance. A bill accepted by a bank, typically in a letter-of-credit transaction, is called a "hanker's acceptance" and has the highest credit standing. (See *COMMERCIAL PAPER*.) Again, acceptance may refer to the act of a person in agreeing to the terms of an offer, thereby completing a contract with the offeror, as to perform services or to sell goods. The offeree, in so doing, makes himself liable to an action for damages in case of default, or, where the contract is for unique goods, to an action for specific performance. (See *CONTRACT*.) Acceptance may refer also to the act of a buyer in receiving goods delivered to him by the seller. Acceptance of the goods, although there is no written contract, will satisfy the Statute of Frauds. Acceptance of nonconforming goods, after inspection or a reasonable opportunity to inspect, will bar a subsequent return or rejection of the goods; but, to encourage acceptance in such cases and thus promote the flow of goods in commerce, an action against the seller for damages will survive. See *SALE OF GOODS*. (R. T. S.)

ACCESSORY, a person who incurs criminal liability for participating in the commission of an offense by another. An accessory before the fact is a person who urges or advises the principal offender to commit the crime; he is classed as principal in the second degree if he is present when the offense is committed and aids or abets its commission. At common law the distinction between principals and accessories applied only to felonies. In cases of misdemeanour or treason all participants were punishable as principals. The accessory after the fact falls in an entirely separate category and refers to a person who harbours or conceals a felon with intent to prevent apprehension of the felon. See *ABETTOR*; *CRIMINAL LAW*. (F. A. A.)

ACCIDENT: see *GRAMMAR*.

ACCIDENT (Latin *accidens*, "happening" or "occurring"), a term used in philosophy with various meanings according to the term with which it is specifically or by implication contrasted. The principal philosophical meanings, summarized in this article, are historically connected with one another; and one of them (see *Accident, Necessity and Design*, below) is in turn connected with the ordinary use of the term to designate an unforeseen and often disastrous event.

Accident and Substance.—Perhaps the oldest use of the term "accident" was by way of contrast with the term "substance" or "thing." "Substance" means the basic reality which has various qualities, stands in various relations, etc. These qualities, relations, etc., on the other hand, need a basis or support to qualify—they are "accidents," accessions to something that is there to bear them (substance). Among the schoolmen, accordingly, almost any quality was commonly called an accident; and this usage was fairly common even in the 17th century—"accident" and "substance" corresponding roughly to "quality" and "thing" respectively, as these terms are commonly used.

Accident and the Self-Existing.—In the strict sense of the term, as distinguished from its more usual meaning even among philosophers, the term "substance" means that which exists in itself and through itself; and when so interpreted its familiar contrast with "accident" naturally prompts the application of the term "accident" to anything that is dependent on some other thing. In this case, even what are commonly called "things" or "substances" will be classed among "accidents." Thus for Spinozism there is only one Substance, namely God, who alone is self-existing, while all finite things and even the so-called "infinite modes" (such as motion) are really "accidents," or dependent existents. Cartesianism, too, made this admission, or one very like it to all intents and purposes, but allowed the name "substance," in a qualified sense (that is, in the popular sense) to finite bodies and to

souls

Real Accidents.—The antithesis between "accident" and self-existing "substance" clearly cuts across the distinction between "accident" in the sense of "quality," and "substance" in the sense of "thing." In considering the latter distinction, however, some of the schoolmen maintained that there are certain sense-qualities of things which are not dependent on the substances with which they are sometimes combined, but can exist by themselves, apart from such substances. These alleged independent or self-existing qualities they called "real accidents."

Accident and Essence.—The distinction between "substance" and "accident" naturally led people to regard an "accident" as something less important than substance, as something not essential to substance; and so the term "accident" was contrasted with whatever is not really essential to anything. Thus in logic, for instance, the so-called fallacy of accident is the erroneous assumption that a claim to know anything or anybody implies a knowledge even of all that is nonessential in relation to it or him. Similarly, in the doctrine of the predicables (*q.v.*), as commonly expounded in books on logic, the predicable "accident" is contrasted with the other four predicables in the sense that any predicate asserted of a subject but not essential to it is called an "accident" of it, whereas any predicate essential to the subject of which it is affirmed belongs to one or other of the remaining predicables.

Accident, Necessity and Design.—The kinship between what is "essential" and what is "necessary" has prompted the common use of "accident" for what is otherwise called a chance occurrence. Likewise, the term "accident" has come to be applied in law to any occurrence or result that could not have been foreseen by the agent (because not necessarily involved in his action), or to a result not designed (and, therefore, presumably not foreseen) or, lastly, to anything unexpected.

"Essential" and "Accidental" Accidents.—One curious consequence of the multiplicity of meanings of "accident" is that by using the noun in the sense of "quality" and the adjective in the sense of "not essential," the schoolmen came to distinguish between "essential" accidents and "accidental" accidents.

ACCIDENTALS, in music, are signs signifying that the notes to which they are attached have to be raised, lowered or restored to their original pitch, as the case may be. Thus a sharp (♯) raises a note a semitone; a flat (♭) lowers it a semitone; while a natural (♮) restores it to its former status. Each sign may also be doubled, though in the case of the double sharp, signifying the raising of the note by two semitones, the sign × is used instead of ♯♯; ♭♭ indicates a double flat, signifying the lowering of the note by two semitones. A single natural is sufficient to cancel a preceding double sharp or double flat. Accidentals placed before a note normally affect that note only during the bar in which they occur. In some modern compositions, however, where the harmony is complex, accidentals refer only to the immediate notes with which they are associated. In such cases the composer gives a direction to this effect. Sharps and flats placed at the beginning of a staff denote the tonality of the music and are not classed as accidental-.

ACCIUS (*ATTIUS*), **LUCIUS** (170–c. 85 B.C.), greatest and most popular of the Roman tragic poets, came of freedman stock in Umbria. His plays, of which more than 30 titles and about 700 lines have survived, were mostly free translations from the Greek, ranging over the whole field of Greek tragedy from Aeschylus (*Myrmidones*, *Prometheus*) to Hellenistic drama (*Hellenes*, *Stasiastae*); some plays were taken from Sophocles (*Antigone?*, *Athamas*, *Tereus*), a great many from Euripides (*Alcestis*, *Bacchae*, *Phoenissae*, *Telephus*); others again apparently combined two originals (*Armorum iudicium*, from Aeschylus' *Hoplion krisis* and Sophocles' *Ajax*). But he also composed two plays, *Decius* and *Brutus*, on Roman subjects. Accius' passion, loftiness of diction and splendid use of rhetoric were admired by Roman critics and

are discernible in the fragments. His plays were performed until the end of the republic. He also wrote love poetry and verse treatises in various metres on the history of Greek and Latin poetry and on agriculture.

ACCLIMATIZATION, in biology, originally was taken to mean only the ability of human beings or animals or plants to accustom themselves within the span of a lifetime to new and strange climatic conditions. (Adjustments due to genetic changes are called adaptations, as also are the rapid adjustments constantly being made by the sense organs; see below.)

A man moves to a hot climate and is uncomfortable there; but after a time he is better able to withstand the heat. Aside from temperature, however, there are other aspects of climate. A man or an animal may become adjusted to living at altitudes higher than those to which he was originally accustomed. At ordinary mountain altitudes this does not involve much of an adjustment to change in atmospheric pressure, for mountain climbers suffer more from lack of oxygen than from change in pressure (see *HYPOXIA*). However, at really high altitudes, such as airplane pilots may be exposed to, the low atmospheric pressure becomes a factor of primary importance. In changing to a new environment a man may meet new conditions of temperature or pressure, and in addition he may have to contend with different chemical surroundings. On high mountains he encounters relatively low concentrations of oxygen; in crowded cities he may become exposed to relatively high concentrations of carbon dioxide or even carbon monoxide; and in various areas he may be exposed to conditions in which the water content of the atmosphere is extremely high or extremely low. Thus, in the case of man and higher animals, the concept of acclimatization includes the phenomena of increased toleration of high or low temperature, of altered pressure and of changes in the chemical environment.

Lower animals and plants are exposed to an environment very different from the environment of a terrestrial mammal. Fishes may live at or near the surface of the ocean or at great depths; in fresh water or in salt water. The ability of an aquatic animal to change from one type of environment to another is the same sort of a phenomenon as the ability of a terrestrial animal to change from one climate to another. Numerous investigators have tried to transfer fish: clams, crabs, etc., from salt water to fresh, or from fresh water to salt, and they have examined the conditions which favour the success of such transfers. In order to include, therefore, all types of organisms and all types of environments a broader definition of acclimatization is required: the process in which an organism or a part of an organism becomes accustomed or hardened to an environment which is normally unsuitable for it or deadly for it. By and large, acclimatization is a relatively slow process. The term, therefore, should not be taken to include relatively rapid adjustments such as our sense organs are constantly making—the type of adjustment commonly referred to by the physiologist as adaptation. Thus after a time we fail to hear the ticking of a clock; to detect an obnoxious odour; to squint in bright light; etc.

On the other hand, when an adjustment to an unfavourable environment requires several generations, this is scarcely acclimatization in the strict sense (although often in the past it has been so considered). If a species of animal or plant is moved to an unfavourable environment, the individuals of the species may, after a number of generations, be better able to withstand the unfavourable conditions than were the animals and plants that first moved into the new environment. This may be due not so much to any change or acclimatization during the lifetime of the original animals or plants, or their descendants, but rather to changes or mutations from generation to generation. Such mutations are now known to be of relatively frequent occurrence (see *HEREDITY*; *GENE*). The mutations that are more apt to prosper in a given environment tend to survive (as a result of natural selection); the unfavourable

mutations tend to die off. Thus, wheat plants that are moved to an excessively cold climate may, during successive generations, produce mutations that are better able to withstand the cold; these mutants, then, would tend to survive and would pass on to their progeny the same hardiness. This type of natural selection is well known, and it can be hastened by artificial selection on the part of the agriculturist. The end result is to produce new strains or races which are better able to withstand a particular environment than did the original species. (See *ADAPTATION*, *BIOLOGICAL*.)

The change in a species is a very different process from the acclimatization change which occurs during the life of an individual. If one considers the behaviour of a species for a number of generations, it is hard to distinguish between the changes produced as a result of mutation followed by natural selection and the changes produced as a result of true acclimatization.

The fundamental fact about acclimatization is that all animals and plants have some capacity to adjust themselves to changes in their environment. This is one of the most remarkable characteristics of living organisms, a characteristic for which it is extremely difficult to find explanations. Before entering into a more detailed treatment of the various facts and theories concerning the different types of acclimatization, a brief discussion of the ability of various animals and plants to change their habitat from one region of the earth's surface to another is presented. This subject has been studied primarily from the viewpoint of human welfare and human economy.

Acclimatization of Various Species, Including Man.—

Early writers on biology and natural history, as well as early travelers and explorers, were interested in the possibility of importing animals and plants from one country to another. Tobacco, originally found in America, was introduced into Turkey and other countries. Cotton likewise was transplanted. Rubber and quinine, originally produced in South America, became staple crops of the East Indies. Flowers and shade trees found their way from one country to another. So, too, horses were imported into the Americas, and various other domestic animals were introduced into different parts of the world. Sometimes noxious insects or other types of pests find their way into countries originally free of them. The entrance of such undesirable organisms is often a matter of great economic importance.

An animal or a plant from a strange country may be successfully introduced into the homeland, or it may not be able to live there. Usually the important variable is temperature. Some animals seem to be able to exist anywhere. As Charles Darwin pointed out in his *Origin of Species*, rats and mice can live in very cold climates as well as in the tropics. Some other animals are very sensitive to changes of temperature. Possibly, in part at least, the ability of rats and mice to live in different climates is due to their nocturnal habits. Both rats and mice are sensitive to high temperatures and are much more readily killed by heat than are cats and cows, for example. It is doubtful whether rats or mice could withstand any lengthy exposure to the rays of the tropical sun.

Years ago, as new countries were discovered and developed, societies were founded to promote the exchange of species of animals and plants from one part of the world to another. The most famous of these societies was the Société Nationale d'Acclimatation in Paris.

The introduction of a species is not always accompanied with difficulty. Some species thrive away from their natural habitat, often better than in their homeland. In such instances there is no need for the species to become accustomed to the new habitat, and in reality acclimatization does not occur. The organism becomes naturalized, but not acclimatized (see *NATURALIZATION OF PLANTS AND ANIMALS*).

The question of human acclimatization has interested historians, geographers, sociologists and medical men. The early Greek writers wondered why white men did not successfully colonize tropical countries. The difficulties of white settlers in the tropics are manifold, and the problems are extremely complex. It is hard to distinguish between the direct adverse effects of climate and the deterioration and death caused by the many types of tropical

disease. In addition, the white man in the tropics often has had to face the competition of coloured races perhaps more capable of withstanding the heat. Then too the conditions of life often are strange and difficult and this may be a factor in the causation of what has been called "tropical neurasthenia," a neuropsychological affliction.

In the 20th century, when sanitary and health conditions have been improved, as in Panamá and in northeastern Australia (eastern Queensland), acclimatization of white settlers is favoured. Some medical authorities have urged that if tropical disease could be prevented, white men in the tropics would prosper. Others have insisted that, quite apart from disease, the climate itself is harmful. Women are said to be paler in the tropics. In very hot regions, according to some observers, the effects of old age appear earlier. Some physicians claim that old-age vision (presbyopia), which in temperate climates usually is not noticeable until a man reaches the age of about 45, may become evident in Europeans in the tropics about 10 years earlier. Hot climates have been blamed also for premature loss of memory.

Surprisingly enough, little attempt has been made to study conditions that favour successful existence in hot countries. Of course, air conditioning can change the climate within the home, which, along with the introduction of modern methods of transportation, eventually may effect a partial solution of the practical problem of life in the tropics; however, knowledge of the physiological aspects, is meagre. Authorities agree that excessive use of alcohol is fatal to anyone who attempts to live under tropic conditions. Some Australian experts believe that manual labour is helpful to the health of dwellers in the tropics.

Because salt is lost through the sweat, men in the tropics, as well as workers in industries in which exposure to high temperatures is common, are urged to eat salt occasionally. Presumably there are benefits from this practice, but they are not great.

Diet may be an important factor in determining human resistance to heat. It is generally agreed that in warm climates there is an unconscious tendency for people to choose diets lower in protein and fat and higher in carbohydrates. Such a practice is perhaps beneficial and there may be a theoretical reason why it should be (see below).

As is well known, men can to some extent become acclimatized to life at high mountain altitudes. This acclimatization is primarily an adjustment to the low oxygen concentration of the air over the mountains. When a man first ascends a high mountain, his heart beats faster and he becomes breathless; he may also be nauseated and vomit, his head may ache and his nose may bleed. After a short time these symptoms of mountain sickness tend to disappear. The physiological adjustment is somewhat complex, but for one thing there is an increase in the ventilation of the lungs so that more air passes through them in any given interval of time. Also the hemoglobin of the blood acquires a greater affinity for oxygen than it normally possesses. In addition the actual concentration of hemoglobin in the blood increases.

Heat.—In general, animals show a very definite ability to become acclimatized to temperatures somewhat above those they can normally withstand. For example, the common American black bass (*Micropterus salmoides*) if kept in warm water at a temperature of 86° F. for four days becomes more resistant to heat. Normally 50% of these fish die when exposed for an hour to a temperature of 93° F., whereas those conditioned in the warm water for four days reached their death point at a temperature of 100° F. Thus their tolerance to heat had been raised approximately 7°. On the other hand, when the fish were kept for 16 days at a temperature of 50° F., half of them died when exposed to a temperature of 86° F. for an hour. Other fishes show a similar behaviour. Toad tadpoles raised in the warmth were found to be able to stand temperatures about 6° higher than those raised in colder water.

Lower animals show a somewhat similar behaviour. For example, protozoa can be acclimatized so that they will withstand temperatures 4°–5° higher than those temperatures which normally kill them.

In the summer, as might be expected, animals are commonly better able to resist heat than in winter. In the case of the com-

mon sand or mole crab (*Emerita talpoida*) of the Massachusetts coast the lethal heat temperature is 18° higher in summer than it is in the winter.

The mechanism of heat acclimatization is uncertain. In man changes in the sweating mechanism or in the blood circulation may play a part. Only a few mammals sweat, however, and yet acclimatization to heat is very generally exhibited by all sorts of organisms, even by those which completely lack blood. As a matter of fact, essentially all living cells are heat sensitive, and the temperatures which kill them often are only a few degrees above those at which they are accustomed to living. In lower animals heat death is simply due to the death of the constituent cells. In higher animals some cells appear to be more sensitive than others, and the death or injury of these cells apparently produces toxic substances which injure and eventually kill the animal as a whole.

In general those organisms which are killed at the higher temperatures have more solid fats; that is fats with higher melting points. This is a broad truth which holds both for animals and plants: fishes, which die at relatively low temperatures, have fats fluid at ordinary temperatures; whereas the warm-blooded mammals and birds have solid fats. Similarly plants which grow in the tropics seem generally to have more solid fats than those which grow in temperate climates. Various experimenters have shown that when animals are reared at higher temperatures their fats tend to become more solid. Such a change in the melting point of the fats may be a factor in the acclimatization of animals and plants to heat.

Further, recent nutritional studies have shown that if animals eat sugar, the fat produced within the body from this sugar has a high melting point. The fact that other animals (namely, rats) with fats of higher melting point are better able to survive higher temperatures perhaps indicates why men in hot countries seem unconsciously to prefer a diet relatively rich in carbohydrates.

Cold.—There have been relatively few studies on the ability of animals to become acclimatized to cold. Fishes accustomed to warm water are unable to withstand sudden transfer to cold water. At Naples, the eggs of the sea urchin (*Paracentrotus lividus*) cannot develop at temperatures below 61° F. in summer, but in the wintertime they can develop at temperatures as low as 47° F.

The ability of plants to become acclimatized to the cold is a matter of great practical importance. Tropical plants are killed at temperatures above freezing. In cold countries plants frequently suffer injury from frost. As a result of breeding experiments and as a result also of chance mutations, cold-resistant varieties of wheat and other crop plants have been obtained. These varieties have made farming possible in regions where it might otherwise have been impractical. But even for any given variety of a plant, some increase in so-called cold hardiness is possible. For when plants are grown at lower temperatures they are better able to withstand frost.

When plants are exposed to the cold, there may be an increase in the amount of sugar or salt contained in the plant cells, and such increases would tend to prevent freezing. Possibly also, in hardy plants, water is prevented from freezing by being bound chemically in such a way that it does not act as ordinary water. Some workers believe that cold hardiness primarily is caused by an increase in the amount of this "bound water." This explanation, however, does not seem to fit all cases. A protein jelly, such as a gelatin gel, does not freeze so readily as a fluid protein solution. It is possible, therefore, that the state of fluidity of the vital protoplasm may be a factor in determining cold hardiness.

Marine and Fresh-Water Acclimatization.—Ordinarily animals which live in the ocean die rather rapidly if they are placed in fresh water; also fresh-water animals die in sea water. This is not always true, however, for the eel and the salmon can pass from sea water to fresh water and back again without injury.

Fresh-water animals placed in water containing a large amount of salt tend to lose water from their cells (and in the case of simpler animals, there is a considerable loss of water); on the other hand, marine animals placed in fresh water tend to absorb water into their cells. The process producing this inflow and

outflow of water is called osmosis, a general phenomenon operating throughout the animal and plant kingdoms.

The cells of all animals are in equilibrium with the solutions in which they are bathed. If these solutions become more dilute, the cells increase in volume; if on the other hand, the concentration of the solutions is increased, the cells lose water and shrink. Many higher animals are enclosed in stiff integuments which prevent the free passage of water to the constituent cells, and such animals are less sensitive to changes in the salt content of the outer medium; although, of course, within the bodies of the animals the cells are in equilibrium with the blood or other fluids of the animal.

Sea water contains many types of salts, but by far the most abundant of these is ordinary table salt (sodium chloride). The concentration of salt in sea water is approximately the same as that of a 3% solution of table salt. If fresh-water animals, normally incapable of living in sea water, are placed in a very dilute salt solution to which salt is gradually added over a period of weeks or even months, it is in some instances possible to acclimatize the animals so that they can live in solutions as salty as or even saltier than sea water. Also, with the gradual addition of fresh water to the sea water in which marine forms are living, marine animals can be made to live in solutions whose lack of salt ordinarily would kill them rapidly.

Different types of animals vary widely in their capacity to become acclimatized; all sorts of adjustments are involved. Presumably with an increase in salt content of the surrounding medium, both the cells and the body fluids of the animals become richer in salt. An important factor is the ability of an animal to excrete salt. Ordinary fishes are able to excrete salt through their gills; this aids them in their adjustment to the salt water of their surroundings. Marine birds are able to excrete salt through an enlarged nasal gland.

On the other hand, the excretion of water by animals enables them to get rid of excess water taken in through the skin. Thus a frog immersed in water is continually taking up water through the skin and excreting it by way of the kidneys. Obviously, excretory processes may play an important part in the ability of animals to accustom themselves to changes in the salt content of their watery environment.

Chemical Acclimatization.—All sorts of organisms show some power of accustoming themselves to a wide variety of poisons. Bacteria and protozoa may acquire an increased resistance to such substances as mercuric chloride, quinine, etc. Such acclimatization becomes a factor in the treatment of disease, for protozoan and bacterial parasites that are normally killed by a certain concentration of a drug may after a time become resistant.

Bacteria and protozoa reproduce very rapidly—on the order of once every 20 or 30 minutes—and accordingly, in studies of acclimatization in these lower organisms, the acclimatized organisms are descendants of the original organisms. Consequently, new types of organisms may arise in successive generations as a result of mutation. Some of these newly mutated types may be more resistant than the original forms and would tend to be selected out, that is, they would show a greater tendency for survival.

In higher animals true acclimatization to chemicals undoubtedly occurs. Mice and rabbits can become somewhat acclimatized to the presence of carbon monoxide in the atmosphere. Man can train himself to eat increasing amounts of certain poisons and thereby acquire a tolerance for these poisons. Various types of explanation are possible. One theory is that when a tolerance to arsenic is acquired, there is less absorption of the poison from the intestine. Earlier, tolerance to alcohol was thought to involve a decreased absorption, an increased or more rapid excretion, a decrease in the amount of alcohol which reaches the brain or an increase in the rate at which alcohol is chemically transformed within the body. Modern studies, however, tend to disprove all these possibilities; it seems that human tolerance for alcohol is primarily due to an acclimatization of the cells of the central nervous system.

Many living organisms produce poisonous substances. Thus

toadstools are notoriously poisonous and so too are many higher plants, as well as scorpions, spiders, snakes, etc. In general the organism producing the poison is immune to its effects. A man can be made tolerant, that is, made immune, to a certain type of snake poison, and similar immunity may be acquired for various bacterial poisons. The attempt to understand this type of immunity is of such importance to bacteriology and medicine that an entire science, immunology, has been built around it.

One of the most interesting types of chemical acclimatization is that shown by bacteria and yeasts toward food substances in their environment. Yeasts, which commonly live by fermenting sugars, normally utilize certain types and not others. If, however, a yeast colony is grown in a medium containing an unusual type of sugar, one which it does not have the power to attack, it may after a time acquire this power.

In animals generally, cells and tissues may acquire an increasing ability to cope with substances originally more or less alien to them.

ACCOMPANIMENT, a musical term signifying an auxiliary part or parts of a composition designed to support the principal part or to throw it into relief. In secular medieval music and early folk music, instrumental accompaniments for singers consisted of unison or octave reduplications, novel rhythmic features or a primitive type of harmony in the form of a drone or sustained notes on wind or string instruments. In the 16th century, solo songs were sung with simple harmonic or contrapuntal lute accompaniments, notably those of John Dowland and the French *airs de cour*. With the introduction of the thorough bass at the beginning of the 17th century the art was gradually developed of harmonic accompaniments, improvised at the harpsichord or organ and based on chords which the composer indicated by figures. By the 18th century these improvised accompaniments, designed to support either a soloist as in the sonatas and solo cantatas of J. S. Bach, or an instrumental ensemble as in the operas of Alessandro Scarlatti, demanded from the performer a high degree of ornamental and contrapuntal invention. The accompaniment thus assumed a role as important as that of the soloist. (See also THOROUGH BASS.)

The term *obbligato* accompaniment was applied to this form, as opposed to *ad libitum* accompaniment, a term used for the optional reduplication of a part or unessential ornamentation performed on another instrument. *Obbligato* accompaniments were sometimes written out, among them one originally improvised by Bach for a movement of his Sonata in B minor for flute and harpsichord. In the second half of the 18th century the *obbligato* accompaniment assumed a primary role, the part of the solo instrument being reduced to an *ad libitum* accompaniment. Sonatas for harpsichord or piano with violin or flute accompaniment were written by Joseph Mondonville, and Mozart followed the example of Johann Schobert in writing four sonatas for harpsichord accompanied by the violin.

The influence of the *obbligato* style in the 19th century is suggested in Beethoven's statement, "I came into the world with *obbligato* accompaniment." It persisted in both the solo and the concerted works of the romantic composers where accompaniments became even more elaborate and expressive. The greater expressive resources of the piano, as opposed to the harpsichord, allowed the accompaniments of Schubert to illustrate pictorial or psychological aspects of the texts of his *Lieder*. His example was followed in the *Lieder* of Schumann, Brahms and Hugo Wolf. Piano accompaniments in works for string or wind instruments acquired the status of a concerted part. Orchestral accompaniment, which in the 18th century had hardly exceeded chamber-music proportions, was greatly developed in the romantic concerto and in songs or song cycles with orchestra by numerous composers from Berlioz to Alban Berg and Benjamin Britten.

The art of the piano accompanist flourished chiefly in response to the demands in the 19th century of the German *Lied* and the

French *mélodie*. Qualities of poetic and musical insight, and also of ensemble playing, distinguish the piano accompanist's art which resembles the art of performance in chamber music. Accompanists such as Gerald Moore and Conraed van Bos developed the art by their sensitive attitude to the soloist and by their power to interpret the composer's intention. Both Moore and van Bos have written valuable books on the art of the accompanist. (E. LR.)

ACCOMPLICE, a person who is associated with another in criminal activity. The category includes, but is not limited to, the accessory (*q.v.*). Some U.S. states provide by statute that testimony of accomplices is competent only when corroborated by other evidence. Elsewhere the jury is ordinarily cautioned as to the possible unreliability of testimony by accomplices. See **CRIMINAL LAW**. (F. A. A.)

ACCORAMBONI, VITTORIA (1557–1585), the Italian lady whose story forms the basis of John Webster's tragedy *The White Devil*, was born in Gubbio, near Perugia, on Feb. 15, 1557. In 1573 she was married to Francesco Peretti, whose uncle Cardinal Montalto (Felice Peretti) was regarded as likely to become pope. In Rome she found many admirers, among them Paolo Giordano Orsini, duca di Bracciano. Her brother Marcello, wishing to see her married to Bracciano, had Peretti murdered (1581). Bracciano, who was already believed to have murdered his first wife, Isabella de' Medici, was suspected of complicity in this murder also! but proceeded to marry Vittoria. Early attempts by the Peretti family to have the marriage annulled had no result except that Vittoria was imprisoned for a short time. In 1585, however, Montalto was elected pope as Sixtus V, and the couple, fearing that he would avenge his nephew's death, fled to Salo in Venetian territory, where Bracciano died (Nov. 1585). Vittoria then retired to Padua. There she was followed by Lodovico Orsini—a remote cousin of Bracciano's—who hated her personally and resented her marriage as degrading to the Orsini family. On Dec. 22, 1585, he had her murdered. He and his accomplices were executed by order of the Venetian republic. Besides Webster's play, Vittoria was the subject of Ludwig Tieck's novel, *Vittoria Accorambona* (1840).

ACCORDION, a musical instrument of the free reed class. The name first appears in the 1829 patent of C. Demian, Vienna, though an earlier model was patented by Friedrich Buschmann in Berlin in 1822. A free reed is a metal tongue screwed or riveted over a slot accurately cut in a metal frame. The pitch of a reed depends upon the length and thickness of the tongue, which can be tuned by filing near the free end to raise the pitch or near the fixed end to lower it. Each tongue is "sprung up" above its frame and vibrates when air is made to flow around the reed from this upper side; an air flow in the opposite direction does not cause the tongue to vibrate.

An accordion consists of a bellows fastened between two oblong wooden structures that carry the reeds, to which wind is admitted selectively through pallet valves controlled from a keyboard or set of finger buttons, each key or button bringing into action a pair of reeds, one of which is mounted to sound on the "press" of the bellows, the other to sound on the "draw." In some forms of accordion, including the early designs, the two reeds of a pair sound two adjacent notes of the scale, so that a button will give, for instance: G on the press, and A on the draw ("single action"). By this arrangement ten buttons suffice for a diatonic compass of over two octaves, though at the cost of rendering each note available with a bellows movement in one direction only. For the left hand there are, typically, two keys or "basses" to provide bass notes and major chords respectively, sounding the tonic on the press and the dominant on the draw, in one tonality only. This single-action accordion has been developed, chiefly in Austria and Switzerland, by adding a second row of buttons giving a scale of F (the first-row scale being C), so arranged that almost every note of the diatonic series becomes available with a C-row button on the press and an F-row button on the draw, or vice versa. Semitones are provided by additional rows and the number of basses

is increased.

In the piano accordion, with piano-style keyboard for the right hand, introduced in the 1850s and later perfected in Italy by Dallapè, the two reeds of each pair are tuned to the same note, thus making every note (also every bass) available from one key with both directions of movement of the bellows ("double action").

BY COURTESY OF THE PHILIP LESLY CO

ITALIAN ACCORDION. 19TH CENTURY

Among other improvements, steel reeds, instead of brass, give a steadier pitch to the notes. Couplers or "registers," developed in the 1930s, bring into action extra sets of reeds, one set pitched an octave below the main set and another off-tuned from the main set to give a tremulant through "beating." Other registers may include a high-octave set and a second tremulant. Each set may be used alone or in combination with others, by means of switches placed above the keyboard and identified by symbols or descriptive terms. The left-hand provision is also greatly extended, with up to 120 basses actuated by six rows of buttons. Two rows give bass notes arranged in cyclic order of tonalities (D, G, C, F, etc.), one row being offset against the other at the interval of a major third, to facilitate melodic passages for the left hand. The other rows give three-note chords, respectively major and minor triads and dominant and diminished sevenths. There are up to five registers for the basses, causing each bass note to sound over as many as five octaves if desired and each chord to sound in three.

A variant of the accordion is the bandoneon, a double-action instrument with square shape and finger buttons, invented by Band of Crefeld, Ger., and the leading solo instrument in modern Argentine tango orchestras. For precursors of the free-reed instruments, see the article **HARMONIUM**, and for other types see **CONCERTINA**; **HARMONICA**. (A. C. BA.)

ACCORSO (ACCURSIUS), **MARIANGELO** (c. 1480–1546), Italian poet and critic, known for his satirical dialogues and his edition of the letters of the Roman statesman Cassiodorus, was born at Xquila, c. 1480. He became a favourite at the court of Charles V, by whom he was sent on numerous foreign missions. He is considered the first scholar to have investigated Roman epigraphs.

Though an accomplished linguist and, in his day, an acknowledged judge of Greek and Latin poetry, Accorso was himself not more than an academic poet.

He died at Aquila in 1546.

ACCOUNTING, a broad term that denotes certain theories, behavioural assumptions, measurement rules and procedures for collecting and reporting useful information concerning the activities and objectives of an organization. In less general terms, accounting consists of procedures for recording, classifying and interpreting selected experiences of an enterprise to promote effective administration.

It is now generally agreed that accounting and similar information-control systems must serve the needs of those who direct the organization. This approach requires that accountants know who is to use the information and must understand the objectives involved and the nature of the decisions to be made. It also requires that accountants select a consistent set of rules and conventions to accumulate and report information in a manner designed to encourage desirable performance. Accounting is used to denote the occupation of those who devote themselves to these activities. The term bookkeeping (*q.v.*) is used to indicate the gathering and classifying of data according to established rules regardless of whether the work is done by individuals, machines or electronic devices.

Accounting Functions.—The primary function of accounting is to help society administer its financial affairs. Specialized combinations from the field of accounting often are found in such related fields as engineering and operations research, but the fol-

lowing functions are performed primarily by accountants: (1) Determining acceptable cost and revenue standards by detecting variations between actual and desirable performance and by determining the causes of the variations. Flexible budgets and other forms of performance budgeting are expressions of this function. (2) Measuring the progress of an enterprise in terms of income or profit. Such measurements help channel future investment and act as yardsticks for evaluating the enterprise's management. (3) Helping to safeguard the properties of the organization by employing suitable devices for discovering shortages and misuse of funds. Much of the network of red tape associated with accounting systems is devoted to this end. (4) Providing information to help solve problems of short-run liquidity and financial stability. (5) Determining the rights and relative positions of owners, creditors, income beneficiaries, remaindermen and other equity holders, including the interests of governmental taxing and regulating agencies.

Reporting Viewpoint.—The impossibility of collecting all information about an enterprise that conceivably might be useful to someone means that accountants must limit their reporting to data that are important and are clearly needed. Many events in the history of an organization may be neglected, and data on other aspects may be required only intermittently for specialized non-recurring decisions. Accountants must possess the ability to furnish such information through supplementary reports that do not interfere with the routine periodic reports.

One of the first requirements of an information-reporting system is the definition of an entity—an area of interest. Selecting an entity requires the identification of the purposes of collecting and reporting information. A large organization may be divided into many responsibility centres for certain reports; for other needs, the relevant entity may include many corporations, a sector of national activity or the entire world economy. Double-entry bookkeeping is sometimes based on the assumption that the entity and the proprietor are identical. Assets, liabilities, revenues, expenses and the interpretative viewpoint are defined and related to the position of the proprietor. The growth of large-scale enterprise has increased the number of identifiable interests (equities) in an organization, and reporting to the public now tends to take the form of stewardship reports that are focused on the entire organization as the basic entity and are geared to the needs of equity holders and other outside interests.

Internal reports to the various levels of management may be made frequently and may cover a wide range of topics. Reporting to outside interests is likely to include some combination of a financial status report in which assets are listed and classified in a meaningful fashion and are related periodically to equities, a profit-and-loss statement or a fund-flow report that summarizes changes in liquid resources.

System Requirements.—The design of an accounting system begins with a clear statement of the objectives of the enterprise, a description of the types of decisions required for guiding operations toward these objectives and an appraisal of the ability of individuals to adapt to new modes of reporting. An understanding of these features permits the designer to decide what information is necessary and to determine the form and content of the reports expected of the system. The data classification is set up to facilitate the preparation of the reports, and in turn the data-gathering system is designed to accumulate the required information with the least expenditure of enterprise resources. Inasmuch as accuracy and restraint of dishonesty are objectives, accountants have devoted considerable attention to devices of internal control so that the accuracy of the work of one employee will be checked by the work of another and so that misappropriation of assets will require collusion among two or more employees.

An important task for an accounting system often is to trace the cost of an operation, job, process or some other unit of activity with emphasis on accounting as an aid to internal managers. Special investigations and prospective cost studies improve decision-making in the fields of abandonment, expansion, shutdown, resource shifting, modernization and product planning. The field of cost accounting (*q.v.*) is concerned with aspiration levels and

acceptable costs of attaining these levels. Variations between actual and programed costs are shown in the accounts or on supplementary records with the hope that administrative action will be improved. Costs and variations are isolated and correlated insofar as feasible with individual responsibility so that remedial action can be made effective.

Budgeting is now acknowledged to be a major part of accounting and to be a legitimate accounting activity. The chief accounting officer—the controller—has responsibility for co-ordinating estimates, accumulating and reporting actual performance, issuing reports of variations from budget and in some cases for enforcing the budget by encouraging laggards to better performance. Systems that combine budgetary and historical data for ready comparison are widely used.

Income Measurement Rules.—The usual concept of income is related to values that may be withdrawn without changing the prospects of an organization. Attempts have been made to make this concept operational by specifying rules for comparing discounted expectations at the beginning and end of each period, but accountants have been disturbed by the amplified effect of changes in optimism or pessimism in such a subjective measurement system.

Professional measurement conventions for income determination are more modest and consist of rules for recognizing and measuring new asset values (revenues), corresponding rules for recognizing and measuring declines in value (sacrifice) and further rules for matching (correlating) the results in periodic reports.

Asset value increases must meet certain standards of evidence. In rare cases (*e.g.*, installment method) only cash receipts are considered to be sufficient, but in most cases bona fide sale is acceptable evidence. In construction work the progress of physical construction may be used to support partial recognition. Many accountants build into their definition of income a further requirement that the net value increase be available in the form of additional working capital. Tax assessments on income and the historical association of income with dividends or other withdrawals have tended to focus attention on the liquidity aspects of enterprise operation. Even though value may be added when a favourable contract is procured, accountants will not report income at this stage. They may, however, insist on some form of disclosure.

The second aspect of the income measuring process concerns the measurement of effort exerted (capital consumed) in terms of costs expired. The profession has favoured the recording of explicit historical costs and a definition of income that calls for deducting from revenues sacrifice in terms of historical costs. Normally at the time of asset acquisition discounted service expectations are at least as great as the acquisition price of the productive agent. Actual services may yield discounted values far above or below cost. Depreciation and similar amortization problems are reduced to rules for spreading cost in proportion to services given. Inventory valuation becomes a process for assigning cost of goods available for resale to current and to future periods in proportion to similar estimates of benefit.

In times of changing price levels, revenues tend to adjust faster than costs with the result that costs of different vintages are matched with revenues. The unit for measuring cost has also changed and service estimates may thus be affected. Some accountants feel that current replacement costs best measure the sacrifice in getting revenue. Last in, first out (lifo) advocates are willing to match latest actual costs with revenue but as a group they prefer to measure capital consumption in terms of replacement cost at the time of sale. The implied definition of income is that the deductions from revenue should be sufficient to keep the physical assets intact. Other accountants feel that historical cost should be preserved by applying a general price index and converting the original costs and equities into current monetary units. The usual benefit (service) rule is applied to the restated and modified historical costs. Depreciation on replacement cost implies that income emerges only after provision for keeping physical assets intact and is therefore related to last in, first out.

Measuring income for short intervals is clearly subject to grave hazards. Cost expiration is difficult because many capital assets

yield benefits over many accounting periods, and the critical tests for revenue recognition often are met in an irregular fashion. Accounting and some taxing authorities have recognized the difficulties of short-period profit measurement and permitted limited application of annual operating losses to past and future gains—a type of averaging. Obviously measuring and reporting rules for a concern that is presumed to be continuing are widely different from those appropriate for a liquidating enterprise. The going-concern convention hardly qualifies as a fundamental principle of accounting, but one of the first tasks of an accountant is to determine whether the measuring conventions for a going concern are or are not appropriate in the particular case.

A common misconception is that the grand total of all assets at current values should equal the value of the entire concern. Many specific assets may yield economic rents, and accountants traditionally do not consider all items of value (worker morale, for example) to be assets. The difference between the total of all recognized specific assets at current value and the value of the entire concern as a going business is normally taken to be goodwill (*q.v.*). Many have felt that accountants should value the entire business periodically and adjust the income and goodwill account to reflect this valuation, but accountants have preferred to let prospective investors make their own enterprise valuations.

The Field of Public Accounting.—Public accountants carry on many activities, but their chief function is to render independent, unbiased, professional opinions regarding the accuracy of representations made by a firm's management. The primary responsibility of auditors is not to management officials but to outside groups who are interested in the affairs of the concern and need dependable information. The primary problem of auditing is to establish standards of evidence to support professional opinion. Sampling procedures are clearly necessary, and in recent years auditors have supplemented their intuitive feeling of adequacy with statistical help. Management self-interest may sometimes lead to pressures that influence reporting, and the rules of evidence for accounting and auditing work are developed with regard to the direction of such pressures.

Many accountants devote a greater proportion of their time to management services, and many firms employ specialists in operations research, information theory, engineering, labour relations and the behavioural sciences. Public accounting firms are developing in the direction of industrial accounting, and a hoped-for by-product may be an increased acceptance of more responsibility to the public by controllers and other private accountants. They engage in many activities of a nonauditing nature. They may; for example, design and install accounting and related information systems; develop cost and efficiency programs and standards; advise on income and other tax matters; serve trustees in liquidation or bankruptcy; prepare schedules for property and business appraisals for loan and insurance purposes; testify in disputes involving financial liability and relative status of equity holders; consult on matters of wage and management compensation and incentives; install budgetary controls over expenditures; advise on such management problems as capital budgeting, expansion, shutdown, abandonment and modernization.

A code of ethics and highly formalized rules of professional conduct have developed over the years. A distinctive characteristic is the concept of independence which arises primarily because of the auditing function and the necessity for expressing an opinion that managements' representations fairly present the financial position and the results of operations. Independence is, of course, a frame of mind, but it is presumed that independence does not exist if the auditor has a financial interest in the business or is a director, officer, underwriter or promoter of the business. Following are some of the important rules of professional conduct recommended by the American Institute of Certified Public Accountants: Opinions or representations in financial statements must contain no false or misleading statements and must be prepared in accordance with accepted accounting and auditing principles. Professional fees for service must not be contingent upon the accountant's findings. There shall be no division of fees with nonprofessional persons. An accountant shall not violate any

confidence between himself and his client. Only partners or employees may use the accountant's name in professional practice. Accountants shall express professional opinions only with respect to work performed by themselves, their employees or other professionally qualified accountants with whom they have co-operated. Practice of accounting in the corporate form of organization is prohibited. An accountant may not advertise his professional attainments or services, or solicit clients or encroach upon the practice of another accountant, but he may give service and advice to any client upon request.

Status and Organization of Public Accounting.—Public accounting in Great Britain is regulated by professional institutes, societies and associations. The Institute of Chartered Accountants of Scotland is the outgrowth of local units, the first of which was established by royal charter at Edinburgh in 1854. The Institute of Chartered Accountants in England and Wales was chartered in 1880, as a merger of several associations, the first of which was established in 1870. The Irish institute was chartered in 1888.

The Society of Incorporated Accountants in England was registered in 1885, under the Companies act of that year. The Association of Certified and Corporate Accountants was established in 1904 and later absorbed the membership of several organizations. By 1960 total membership of these British accounting organizations was more than 50,000.

Each group imposed an experience requirement, and membership in an institute required a period of articulated clerkship under the direction of a chartered accountant. Admission requires written tests in accounting theory and practice, as well as in the related fields of law, economics and business administration. The practice of public accounting is not legally restricted in the British Isles, but certain responsibilities may be discharged only by members of an institute authorized by royal charter or of the societies and associations established in accordance with statutory regulations. The *Accountant*, weekly publication of the Institute of Chartered Accountants in England and Wales, was established in 1874.

The title of certified public accountant (C.P.A.) and requirements for the certificate were first created in the United States by the state legislature of New York in 1896. Pennsylvania followed in 1899, and by 1923 each state and the District of Columbia had enacted legislation by which a commission or an educational institution authorized use of the title C.P.A. on the basis of written examinations and acceptable education and work experience. College instruction may be substituted in some states for all or part of the practical experience requirements. In New York state a bachelor's degree became a requirement for eligibility to take the examination in 1938, and other states are rapidly increasing their requirements to that level.

Written examinations prepared by the American Institute of Certified Public Accountants are uniform in all states and consist of questions from the fields of accounting theory and practice, auditing and commercial law. All states have a C.P.A. society or its equivalent to co-ordinate activities and work with the national organization. Most states grant certificates on a reciprocal basis to residents who have met similar educational and experience requirements. Some states also license public accountants who are not certified and permit them to carry on limited accounting and even auditing work.

The number of certified public accountants in the United States in 1960 was approximately 60,000 as compared with 250 in 1900; 5,000 in 1920; 13,500 in 1930; 20,000 in 1940; and 38,000 in 1950.

The American Institute of Certified Public Accountants, whose name was changed from American Institute of Accountants in 1957, developed from the American Association of Public Accountants, organized in 1887, and several national groups, including the important American Society of Accountants, have been merged with the institute. The institute conducts a program of education, professional improvement and research on such subjects as accounting procedure, auditing methods, federal taxation, education, ethics and history. The institute publishes monographs, bulletins and books related to accounting, and in 1912 the *Journal*

of Accountancy, a monthly publication established in 1905, became the official periodical.

An institute of chartered accountants in Montreal received a royal charter in 1879, and later became a province-wide organization. Each Canadian province has an institute of chartered accountants with membership requirements patterned after those in Great Britain. Each provincial institute conducts an educational program as preparation for uniform examinations and membership. Their activities are co-ordinated through the Canadian Institute of Chartered Accountants, which publishes an official journal, *The Canadian Chartered Accountant*.

Societies of accountants in continental Europe have been established with much the same functions as those in Great Britain; *i.e.*, to examine and approve qualified persons for the duties of public accounting. There are records of an accounting association (*Collegio dei Rixxonati*) in Venice in 1581, and another was known to exist in Milan in 1739. Whether these groups were composed of independent accountants or accounting employees is not authoritatively established. The organization dates for associations of accountants in other countries are: France, 1881; Australia, 1885; Netherlands, 1895; Germany, 1896; Sweden, 1899; Belgium, 1903; Austria, 1904; Denmark, 1909; Finland, 1911; Switzerland, 1916; Japan, 1917. Auditing the accounts of private and communal enterprises in the Union of Soviet Socialist Republics became a governmental function in 1917, and accounting has received serious intellectual attention there and in other socialist states. Organizations of independent public accountants exist in some form in almost all countries that are beyond the embryonic stage of industrial development.

Government Control Through Accounting.—The possibilities for using accounting as an instrument of control increased with the rise of corporations and the separation of ownership and control. The English Companies act of 1844 permitted stock companies with limited liability of stockholders and provided that railroads should engage auditors to examine and certify to the accuracy and completeness of their financial reports. The Act of 1862 recommended that all corporations be audited by independent accountants. This feature became a legal requirement in England in 1900 with the auditors to be elected by the stockholders.

U.S. legislation affecting accounting practices began with the need for regulation of public utilities to determine fair and equitable rates. The fair-return-on-a-fair investment and similar guides lean heavily on accounting conventions for measurement of both return and investment. The Interstate Commerce commission, organized in 1887, supplemented its rules in 1906 by a uniform accounting system of reports. The Federal Power commission and many state commissions have stressed uniform accounting methods.

The income tax laws of 1909 and 1913, the formation of the federal reserve system in 1913, and the rapid growth of stock market transactions increased the need for uniform accounting reports and independent verification. Such requirements were established by the New York Stock exchange in 1932, and in 1934, by the newly formed Securities and Exchange commission. In the latter year, the national bankruptcy act prescribed uniform procedures for corporate reorganizations.

The Robinson-Patman act of 1936 defined price discrimination for purposes of the Sherman and Clayton acts in terms of price differentials not justified by differentials in cost. Numerous states developed legislation that prohibited sales at prices below cost to the seller. During and after World War II many contracts for government work and renegotiation procedures were framed in terms of allowable costs and made wide use of other accounting conventions. Needless to say, accounting devices for control are a necessity in socialist states and in the publicly controlled sectors of any economy.

Accounting Origins.—Records and reports have characterized the exchange of goods or services from earliest times. The levy and collection of taxes in the Babylonian empire required proof of individual obligations and payments. Clay tablets as well as stone and wood devices were used to record payments for services in temples. Tally systems that used notched and marked

branches as evidence of indebtedness and repayment were used in the British Isles. The development of papyrus (paper) and the calamus (pen) in Egypt, about 400 B.C., facilitated the recording of information. Government records of the Roman republic in 200 B.C. classified cash receipts in such items as rent and interest, and expenses included wages, entertainment and sacrifices. Officials known as quaestors were designated to examine the accounts of provincial governors. The emperor Augustus is said to have established the first government budget in the year A.D. 5.

During medieval times, advances in accounting were made by government and church officials. Charlemagne in 800 ordered in the *Capitulare de Villis* that an annual inventory of property be taken with separate books for income and expense. Audits were made in England during the reign of Henry I (1100–35). The English pipe roll, 1131, was a record of taxes, debts and other liabilities due the crown.

Accounting for private business in terms of ventures was an outgrowth of Italian commerce during the 13th century. Loans to trading firms and the investment of money by partners led to the development of double-entry records and reports (see **BOOKKEEPING**) which reflected the interests of both creditors and investors and helped the merchants control their relations with customers and employees. The auditing function was originally performed during the industrial revolution by certain accountants who placed their knowledge and competence at the disposal of other organizations, through part-time or intermittent employment. They were known as public accountants and also were employed to install bookkeeping systems for new enterprises. Many public accountants also engaged in the practice of law or the teaching of commercial subjects, foreign languages or arithmetic. These combinations were especially common in Holland, France and Great Britain during the 15th and 16th centuries. A Scotsman, Alexander Herriot, served annual engagements for a Haddington cloth manufacturer from 1681 to 1703 and was well established by 1697 as a teacher of bookkeeping in Edinburgh.

The first person definitely presumed to have practiced public accounting on a full-time basis in western Europe was George A. Watson, who was born in 1645 in Edinburgh. An Edinburgh directory listed seven accountants in 1773, and there were six names in a Glasgow record of 1783. The 1809–11 edition of *Holden's Triennial Directory* indicated that 24 public accountants were practising in London in 1800. The government of Milan, in 1742, announced a scale of charges to be made by accountants for services to clients, which suggests the existence of a profession of public accounting at that time.

Charles Emmanuel III, of Italy, in 1790, recognized chartered accountants as the only persons qualified to discharge the duties of public accountants. Napoleon decreed in 1805 that an accountant wishing to practice independently in Italy must pass a required examination after serving with an approved accountant. Uruguay, in 1825, became the first country in the western hemisphere to regulate the practice of public accounting.

The importance of independent examination of business records was increased by international trade and by wars such as the American and French Revolutions, which caused many bankruptcies for British businessmen and increased the need to determine the losses and equities of the owners and creditors of the various firms. Early public accounting methods in the United States were greatly influenced by practices in England and Scotland, and British accountants were frequently engaged for services in the U.S. during the latter half of the 19th century by British investors in American land and industry.

Education and Training.—The complexity of modern business, government and other organizations has increased the demands made on accountants and thus has emphasized the need for extensive education and training. While it is still true that many accountants begin as bookkeepers or as apprentices, have little formal education and develop on the job, a college education is generally recognized as a highly desirable if not necessary requirement. Early education for accounting careers was confined largely to the functional branches of business, narrowly conceived, with a heavy load of how-to-do-it courses in accounting practice

as it then existed. Many of the quantitative requirements of the profession are now furnished by courses in statistics, mathematics, econometrics, engineering and related subjects, so that accounting courses are tending to become integrating courses with stress on professional and managerial adaptation to a changing environment.

Formal instruction in accounting has been limited to public and private secondary schools until the late 19th century. In 1883, the Wharton school of finance and commerce of the University of Pennsylvania included an accounting course as part of the regular curriculum, and by 1900 accounting courses were offered at The University of Chicago and New York University.

Growth of the field and increased demands on practising accountants have led to the recommendation for a 5-year program of professional education for accounting. The American Institute has been active in education, and the American Accounting Association was organized in 1916 primarily for collegiate instructors and students of accounting. Many of the articles in *The Accounting Review* (1926) relate educational material to the teaching of accounting theory and practice.

Accounting courses for collegiate academic credit are less generally offered in universities in Europe than in the United States. Much basic instruction for public accounting in Great Britain is carried on by correspondence schools or through noncredit courses in the colleges and universities, but departments of accounting have been created in a number of universities. Emphasis is placed upon the economic and administrative aspects of the subject rather than training for careers in public accounting.

German universities regard accounting as an integral part of business administration (Betriebswirtschaft). Instruction places primary emphasis upon accounting as a tool of control, with special attention to such aspects as cost analysis and budgetary control. The public accountant (Wirtschaftsprüfer) offers opinions on the efficiency of management as well as on the accuracy and completeness of financial statements.

Educational training for public accounting in Canada is accomplished mainly through correspondence and special courses conducted by the provincial institutes of chartered accountants, but some instruction is offered at universities and colleges. See also **AUDIT; BOOKKEEPING; COST ACCOUNTING; INCOME; ECONOMIC DEFINITION; OFFICE MACHINES AND APPLIANCES; VALUE.**

ACCRA, capital, seaport and largest city of Ghana, formerly the Gold Coast. Pop. (1960) 388,231. The climate is warm and dry (temperatures, 73° to 86° F; relative humidity, 81%; average rainfall, 29 in. falling during two rainy seasons on 71 days in the year). The town lies in an earthquake zone and has suffered from shocks, one of the most serious of which occurred in 1939. The name Accra seems to be a Europeanization of *nkran* (literally, "black ant"), applied by the Akan peoples of the Gold Coast to the Ga groups who, in the 16th century, arrived from Nigeria to settle on the Accra plain and to mingle with its inhabitants. The town lies partly on a cliff, 25 to 40 ft. high, and spreads northward over the undulating plains. The cliff projects at three points to form coves that afford partial shelter for the landing of boats through the surf. During the latter part of the 16th century the Portuguese possessed a fortified trading post on one of these points. In the 17th century the English built Ft. James on the westernmost promontory, the Dutch built Ft. Crèvecoeur on the point ½ mi. to the east, and the Danes built Christiansborg castle on the promontory at Osu, 1½ mi. along the coast. The attractions of trade with these European nations caused the Ga to move their towns from inland to sites under the walls of the forts.

Accra developed from the settlements by the Dutch and English forts. The people of Osu were a politically distinct community,

BY COURTESY OF THE EMBASSY OF GHANA

CENTRAL LIBRARY IN ACCRA, GHANA

though today the built-up area of Accra includes Osu and extends even farther east. Christiansborg and Ft. Crèvecoeur (renamed Ft. Ussher) were transferred to the British in 1850 and 1872 respectively, and in 1876 Accra replaced Cape Coast as the administrative capital of the British colony. The principal public buildings of the capital, including government departments and the supreme court, were built between Christiansborg castle (formerly the governor's residence, now the official residence of the prime minister) and the old mercantile town. Higher ground to the north was laid out as a residential area for senior government officers. Still farther inland are large military cantonments and the airport, extensively developed during World War II and since used by international services of British, U.S., French, Portuguese and other airlines as well as by local services. A new international terminal building and another for internal services, as well as other improvements, were completed in 1957.

After 1961, Accra was largely superseded by an artificial harbour at Tema, 17 mi. E., to which it is linked by rail and road. Accra remains a busy port with about 1,000 tons a day being handled by surfboats. A 450-yd. breakwater running eastward from the Ft. James promontory affords increased shelter to the landing beach. The main export from Tema is cocoa, brought from points on the railway via Accra which extends 189 mi. inland to Kumasi, and on the numerous roads serving the hinterland.

From Accra tarred arterial roads lead westward along the coast to Cape Coast and Takoradi, eastward to Togoland and north to Kumasi and beyond.

Accra has electricity and piped water supplies, and an extensive municipal bus service. Besides the three forts, notable buildings include the State house, Parliament house, Korle Bu hospital, the Anglican and Roman Catholic cathedrals and many other churches, the Independence arch, the law courts, the law school, the National museum, the Central Ghana library, Broadcasting house, the Ambassador hotel, the offices of the Bank of Ghana, the Cocoa Marketing board and other public corporations, and the stores and offices of the major European trading concerns. On the northern outskirts are Achimota school, the leading secondary school in the country, opened in 1927; and, at Legon, the extensive new buildings of the University College of Ghana, founded in 1948 at Achimota. (J. D. F.)

ACCRINGTON, a municipal and parliamentary borough in Lancashire, Eng., 5 mi. E. of Blackburn. Pop. (1961) 40,987. Area 6.9 sq mi. It lies in the valley of the Hyndburn, a feeder of the Calder, on the western flank of the Pennines. The name of Accrington is said to derive from O.E. *Aecertūn*, "village where acorns grow." The De Lacys were lords of the manor of Accrington (Akarinton from 1194) in Norman times, and about 1200 it was given by Robert de Lacy to the Cistercian monks of Kirkstall.

Returned for a time to the De Lacys in 1287, it had so developed by 1507 that a "New Accrington" was created. Old and New Accrington, straggling villages with about 5,000 inhabitants in 1836, were united in 1853 by which time textile print works and cotton mills were employing many people. The population, 17,688 in 1861, increased with the development of the Lancashire coal fields; the town was incorporated in 1878. Cotton and artificial-silk weaving, printing and dyeing and textile machinery manufacture, together with brick- and tilemaking and engineering, form, with the collieries, the industry of the area. The church of St. James, rebuilt in 1763, dates from 1546; the original chapel was probably an oratory which was an offshoot of Kirkstall abbey. Ecclesiastically Accrington was dependent on Altham till after the mid-19th century. The Haworth art gallery contains mostly British paintings. Five miles north-northeast, at Whalley, are the remains of a 13th-century abbey, belonging partly to the Church of England and partly to the Roman Catholics.

ACCULTURATION, the processes of change in artifacts, customs and beliefs resulting from the contact of peoples of different cultural backgrounds. The term is also used to refer to the effects of those processes, as in "an acculturated Navaho Indian," meaning a Navaho who has adopted Anglo-American behaviour while retaining some traditional Navaho ways. The word "acculturation" was first given currency in the late 19th century by U.S. anthropologists interested in the changing cultures of North American Indians. German anthropologists later also employed the term. Not until the 1930s, however, did it assume the status of a technical term in anthropology.

Anthropologists speak of the whole way of life of a people—the body of techniques, behaviours and ideas transmitted from one generation to another—as a culture. Cultures constantly change. A culture may change, on the one hand, as a result of innovations from within, that is, through discoveries and inventions. On the other hand, a culture may change as a result of influences from without, that is, through contact of its bearers with persons of a different culture. Acculturation includes those processes of change which result from contact conditions.

While it is recognized that acculturation has been instrumental in the building of every civilization, the processes have been studied thus far chiefly as they have operated in the spread of western civilization. It has been possible, especially during the 20th century, to make direct observations on the response of native peoples to different varieties of contact with European and European-derived peoples.

Incorporation.—Two major types of acculturation may be distinguished. One takes place when people of different cultures maintain an interchange without the exercise of military or political domination by one group over another. Such conditions were the rule during the long period of human development prior to the appearance of conquest states, but they have also existed more recently. An example of this type of free "borrowing" of cultural elements was that which took place during the 18th century between Spanish colonists and Navaho Indians in the area now called New Mexico. Unconquered by the Spaniards, the Navahos remained a free tribe at the Spanish colonial frontier. Frequent contacts occurred, ranging from trade in seasonally established markets to raids in which Navahos appropriated sheep and horses from Spanish settlements and Spaniards carried off Navaho captives as slaves. Under these conditions Navahos selected livestock, clothing, metalworking techniques and other elements of Spanish culture, integrating these into their own culture in their own way. The result was a culture new in content but with an organization that remained basically the same from the 18th into the 20th centuries. This kind of free borrowing with modification of customs to fit the borrowers' culture has been called incorporation.

Directed Change.—The second general type of acculturation takes place when one people establishes dominance over another through military conquest, political domination or other means of control. This has been called directed culture change in reference to the fact that whenever one people establishes control over another it seeks to change in some degree the way of life of the domi-

nated group. It has been an important form of change ever since conquest states came into existence and it continues to be of great importance in the modern world. Extensive programs of directed change characterized the Roman conquest of the Mediterranean region and western Europe, the Spanish conquest of South and Central America, the British and American conquest of the Indians of Canada and the United States, the European domination of Africa, the Russian conquest of central Asia and Siberia and many other political expansions in the ancient and modern worlds.

Although they also involve selection and modification, the processes of directed culture change are more varied and their results more complex than those that take place under conditions of free contact. This is true because the changes are the result of interference in one cultural system by the agents of another. The determinants of change derive not from a single culture but from two or more in complex interaction. Three important processes which come into operation under various conditions of directed change may be discussed under the heads of assimilation, fusion and reaction.

Assimilation.—A term frequently used by anthropologists and sociologists to refer to the process by which one culture is replaced by another is "assimilation." It may also be used to refer to the replacement of single traits or trait-complexes. It is commonly believed by members of dominant societies that the cultural assimilation of subordinated ones is inevitable, as illustrated in American views concerning the future of North American Indians. Actually complete assimilation rarely takes place, unless the subordinated people are relocated and their family units broken up. The great diversity of local and regional cultures in Europe, despite centuries of conquest and recurrent attempts to force assimilation, testify to the rarity of the process continuing to completion. Some of the most notable instances of assimilation have taken place in the United States. A well-known one is that of the Negro slaves brought from Africa. The tribal cultures of the Negroes were almost completely replaced—languages, social organization, religions, as well as economic life. This came about under conditions of complete uprooting and breakup of family organization. However, even under such conditions some features of the older cultures survived. Another notable instance of assimilation is that of the millions of European immigrants to the United States, who through relocation, the influences of the public-school system and other forces in American life became almost completely assimilated within two or three generations.

Blending.—A commoner result of directed change is a blending of the cultures brought into contact, a process called fusion, accommodation or syncretism. Most of the North American Indian cultures in the area of the United States have undergone fusion, although this has been accompanied by varying degrees of replacement. The reservation system in the United States has operated strongly to set up conditions favouring fusion rather than assimilation. The results of fusion, embodying intricate combinations of Spanish, Anglo-American and various Indian elements, are to be seen in the cultures of the Pueblo Indians of New Mexico. The cultures of the Iroquois in the state of New York, the so-called "full-blood" Cherokees in Oklahoma, the Crow and other Plains Indians, as well as many others exhibit combination of elements from different cultures. In a more pervasive fashion among a far larger native population the results of similar fusional processes are to be seen in many parts of rural Mexico, Guatemala and South America. New syntheses of cultural elements, combining European and African or European and Asiatic cultures, seem to be a characteristic product of European expansion in the 20th century, as exemplified in India, Indonesia and west Africa. In such areas the processes of acculturation have resulted not in complete assimilation but rather in the formation of new cultures, which, with political autonomy, have begun their own independent courses of development, very much as new cultural syntheses arose after the termination of the Roman conquest.

Reaction.—A third common form of response to directed contact has been called reaction. It involves reaction against aspects of the culture of a dominant group by members of the subordinated society. Such reactions frequently take the form of nativistic

movements. One of the most famous was the Ghost Dance among Paiute, Plains and other Indians of North America. This was a new religious cult led by a Paiute Indian named Wovoka in the 1880s. Wovoka, inspired by supernatural visions, preached a future in which white men would be eliminated and the old way of life restored. To bring this about it was necessary to dance the Ghost Dance, in the course of which dancers communicated with the dead ancestors. The cult spread rapidly among Indians in western United States and culminated in the tragic massacre at Wounded Knee creek, South Dakota. Similar forms of reaction against European domination have occurred repeatedly, such as the Vailala Madness among New Guinea natives and the Mau Mau rebellion among the Kikuyu of Kenya, Africa.

ACEPHALI, the latinized form of a Greek word meaning "those without a head," has been used chiefly of the following:

1. According to Herodotus (iv, 191), a race of headless men in Libya whose eyes were in the breast, a characteristic which the elder Pliny's *Naturalis historia* (iv, 46) ascribed to the Blemmyae.

2. The strict Monophysites who rebelled against Peter Mongus, the patriarch of Alexandria, by refusing to accept the mediating formula (Henoticon) promulgated in 482 by the emperor Zeno to secure the union of Monophysites and Orthodox. Their most famous adherent was Severus, patriarch of Antioch (512–518; d. 538), whose followers continued for several centuries to be called acephali.

3. Those clergy, also called *clerici vagantes*, who in the middle ages were not attached to a benefice, usually because they were still university students. For their activities see GOLIARD.

ACERACEAE, the maple family of plants, comprising about 200 species of trees and shrubs in two genera, *Dipteromia* (two species) of central and southern China, and *Acer*, the maples, widely distributed in the northern hemisphere, crossing the equator only in Malaysia. In *Dipteromia* the seed is surrounded by a wing; in *Acer* it is winged only on the back. About 15 species of *Acer* are native to the United States. Leaves of Aceraceae are opposite, simple or compound, and usually toothed or lobed. The small, clustered flowers are mostly unisexual (that is, they are either pistillate or staminate) and are sometimes without petals. The fruit, a samara, splits into two (rarely three) winged, one-seeded parts. Many maples are cultivated for ornament and shade, including sugar maple (*A. saccharum*), Japanese maple (*A. palmatum*), Norway maple (*A. platanoides*), etc. (see MAPLE). All maples have a watery, sweet sap that in some species, especially sugar maple, is used to make sirup and sugar. Certain species of *Acer* are also important timber trees. In geologic times the genus *Acer* extended into what is now the arctic region, and *Dipteromia* grew in North America. (J. W. Tr.)

ACERRA, in Roman antiquity, a small box or pot for holding incense, as distinct from the turibulum (thurible) or censer in which incense was burned. The name was also given by the Romans to a small altar of incense placed near the dead before the funeral. In ecclesiastical Latin the term acerra is still applied to the incense boats used in the Roman ritual.

ACESTES (Gr. AEGESTES) was a mythological king of Segesta (Gr. Egesta) in Sicily. His mother, Egesta, had been sent from Troy by her parents to avoid feeding her to a voracious sea serpent that was ravaging the city because of Poseidon's anger against Laomedon (*q.v.*). Going to Sicily she met the river-god Crimisis, who appeared as a bear or a dog and by whom she became the mother of Acestes.

Acestes appears notably in the *Aeneid*, offering hospitality to Aeneas when he lands in Sicily (book 5). His function is to em-

phasize the mythological connection of that island with Troy: in Greek legend Aeneas traveled no farther than Sicily. Acestes brings the funeral games of Anchises to a climax by shooting into the air an arrow that becomes a comet, a sign of Anchises' eternal life (and a deliberate suggestion of the comet that appeared at Caesar's funeral games in 44 B.C. and that was hailed as proof of his divinity). (T. V. B.)

ACETALDEHYDE, an aldehyde important as an intermediate product in the synthesis of acetic acid, *n*-butyl alcohol, ethyl acetate and other chemical compounds. It occurs in crude ethyl alcohol (*q.v.*) obtained by the fermentation of sugars and in crude methyl alcohol obtained by the destructive distillation of wood. Manufacture is by the oxidation of ethyl alcohol and the hydration of acetylene (*q.v.*). Acetaldehyde is transformed by reduction into ethyl alcohol and by oxidation into acetic acid (*q.v.*). The molecular formula is C₂H₄O and its structure is CH₃CHO. See also ALDEHYDES AND KETONES: *Aldehydes*.

ACETAMIDE: see AMIDES.

ACETANILIDE (ANTIFEBRIN) is a drug made by interaction of glacial acetic acid with aniline (*q.v.*) and used in medicine to reduce fever. It does nothing to remove the cause of the fever and may result in aniline poisoning, a depressant action on the heart muscle resulting in collapse, nausea, vomiting and blueness of lips and nails. The last is caused by chemical changes in the blood, whereby red corpuscles lose their power to carry oxygen.

Acetanilide is a white, crystalline substance melting at 115° C., boiling at 305° C. and soluble in water, alcohol or ether. Its chemical formula is C₆H₅.NH.CO.CH₃.

ACETATES: see ACETIC ACID.

ACETIC ACID is the most important member of the carboxylic acid group (see CARBOXYLIC ACIDS). It is produced on a vast scale technically, and the two principal methods which are now used for its preparation involve either biological oxidation (vinegar manufacture) or its synthesis from acetylene. Acetic acid is an important intermediate in many biosynthetic reactions, and it occurs naturally as a constituent of biological fluids and plant juices.

Pure acetic acid (CH₃.CO₂H) is often called glacial acetic acid. It is a colourless liquid (boiling point, 118° C.; melting point, 16.7° C.) which is completely miscible with water. The liquid has a corrosive action.

Manufacture.—Many processes have been devised for the synthesis of acetic acid on a technical scale. The steps which form the basis of most of these methods are (1) the preparation of acetylene from calcium carbide, CaC₂ + 2H₂O → Ca(OH)₂ + C₂H₂; (2) the catalyzed hydration of acetylene to acetaldehyde, C₂H₂ + H₂O → CH₃.CHO, which takes place in dilute sulfuric acid with mercuric sulfate as the catalyst; (3) the vapour-phase oxidation of acetaldehyde to acetic acid (see below). This process constitutes a very simple method for the synthesis of acetic acid, and the starting material, calcium carbide, is easily prepared by an electric arc process from limestone and coal.

The manufacture of vinegar consists of a fermentation process whereby carbohydrates such as starch, sugar or malt are fermented to yield ethyl alcohol, and this ethyl alcohol is then oxidized to acetic acid (see below). There are numerous species of aerobic bacteria (*e.g.*, *Acetobacter aceti* and *A. pasteurianum*) which may be used to effect the oxidation. Various names are used to describe vinegar, including malt vinegar and cider vinegar, and these indicate the origins of the carbohydrates used in the fermentation process. Vinegars usually contain about 5%–10% of acetic acid.

The oxidation of ethyl alcohol to acetic acid proceeds through acetaldehyde as an intermediate.

This reaction may be achieved either by using oxidizing agents, such as potassium dichromate and dilute sulfuric acid; or by vapour-phase oxidation in which a mixture of air and ethanol is passed over a heated vanadate catalyst. The biochemical oxidation of ethyl alcohol involves enzymes of the dehydrogenase type. (The souring of wines is due to the oxidation of the contained ethyl alcohol to acetic acid.)

Industrial Uses.—Acetic acid is used in the preparation of (1) metal acetates which are used in some printing processes; (2) the plastic polyvinyl acetate; (3) the further plastic cellulose acetate, which also finds extensive use in photographic films and in textile fibres (rayon); and (4) volatile esters such as ethyl acetate and amyl acetate, which are used extensively as solvents for resins, paints and lacquers. Amyl acetate is used as a flavouring agent in confectionery.

See also Index references under "Acetic Acid" in the Index volume. (W. D. Os.)

ACETOACETIC ESTER, or ethyl acetoacetate, an organic compound used industrially in the manufacture of synthetic drugs and dyes, is an outstanding example of a chemical substance having a dual character arising from the possession of two different molecular structures. Such substances are called tautomeric compounds. The substance is an ester, and has the molecular formula $C_6H_{10}O_3$. The two tautomeric forms are represented by

ordinary specimens of the ester as handled in commerce may be regarded as consisting of 93% of the first in equilibrium with 7% of the second. When treated by reagents which combine with ketones, such as sodium bisulfite hydroxylamine, phenylhydrazine and hydrocyanic acid, the ketonic character of the ester is manifested, and when acted upon by reagents such as phosphorus pentachloride, diazomethane, ammonia and amines, which detect alcoholic (enolic) groups, then its enolic nature is revealed.

In 1911 L. Knorr separated the two forms of the ester in a state of purity. The ketonic modification was frozen out of the equilibrium mixture at $-78^\circ C.$ and the enolic modification was isolated in the liquid condition by decomposing the sodium derivative with hydrogen chloride at the same low temperature. In these experiments it was found to be essential to use silica vessels. The ester was first discovered by A. Geuther in 1863. The original method of production is still employed on a manufacturing scale. Sodium, either molten or in wire form, is added to dry ethyl acetate containing a little ethyl alcohol. When all the metal has dissolved, the mixture is acidified with dilute acetic or sulfuric acid and the crude acetoacetic ester, which is partially miscible with water, separates as an oil on addition of common salt and is purified by distillation under diminished pressure. The ester is a colourless, fragrant liquid and boiling, with slight decomposition, at $181^\circ C.$ under a pressure of 760 mm.

In the chemical laboratory acetoacetic ester is a valuable synthetic reagent, for its sodium derivative when acted on by an alkyl iodide yields an alkylacetoacetic ester, and the sodium derivative of the latter ester by similar means furnishes a dialkylacetoacetic ester. These alkyl- and dialkyl-acetoacetic esters may be employed in producing either higher ketones or higher fatty acids.

The ester has also been employed in the synthesis of pyridines, quinolines, furans, pyrazoles, pyrroles and compounds of the purine group.

ACETONE is an organic solvent of industrial and chemical importance, and is the simplest representative of the aliphatic ketones (see ALDEHYDES AND KETONES). It has very useful solvent properties, dissolving many fats and resins as well as cellulose nitrate and acetate. Because of the latter properties, it finds extensive use in the manufacture of explosives and artificial fibres. The numerous important chemical reactions of acetone make possible many organic syntheses in the laboratory and in industry.

Physiologically, acetone is present in the urine and in the blood; larger quantities are detected in diabetic patients. The ketones in general give rise to narcosis and lowering of blood pressure. Acetone itself produces intoxication and sleep but is less powerful than ether or chloroform, although less toxic than ethyl alcohol. When treated with chlorine, bromine or iodine in the presence of alkali, acetone is converted respectively into chloroform, bromoform or iodoform. It is the starting point in the production of the narcotic drug sulfonal.

Because of its valuable properties as a solvent and as an organic reagent, acetone is prepared commercially on a large scale, the processes available being as follows:

1. The dry distillation of calcium acetate leading to the formation of acetone and calcium carbonate.

2. The catalytic decomposition of glacial acetic acid into acetone, carbon dioxide and water when it is passed over heated metallic oxides such as alumina and thoria.

3. The fermentation of corn (maize), rice, horse chestnut meal or other starchy materials with a bacterium discovered by A. Fernbach, the starch present being converted into a mixture of normal butyl alcohol (6 parts), acetone (3 parts) and ethyl alcohol (1 part).

4. The dehydrogenation or oxidation by air of isopropyl alcohol in the presence of heated metallic or metal oxide catalysts.

Acetone has the molecular formula CH_3COCH_3 and is thus dimethyl ketone. It is a colourless, fragrant, inflammable, mobile liquid, boiling at $56.3^\circ C.$ and miscible in all proportions with water, alcohol and ether.

See J. F. Thorpe and M. A. Whiteley, *Thorpe's Dictionary of Applied Chemistry* (1937).

ACETOPHENONE or phenyl methyl ketone, is an organic compound with anesthetic and soporific properties; under the name hypnone it has been used as a drug to induce sleep. It is the simplest representative of the mixed aliphatic-aromatic ketones. Acetophenone melts at $20^\circ C.$ and boils at $202^\circ C.$, is volatile in steam and has the composition, $C_6H_5COCH_3$. It occurs to a small extent in coal tar and, having feebly basic properties, is extracted from the heavy oil fractions (boiling point $160^\circ-190^\circ$) with sulfuric acid.

ACETYLENE is a colourless, gaseous hydrocarbon, widely used as a fuel in oxyacetylene welding and cutting of metals, and as a chemical intermediate in the synthesis of many organic chemicals and plastics. It was discovered and identified in 1836 by Edmond Davey. The properties of acetylene were first determined in 1862 by M. Bertholet who also showed that acetylene is formed in many high-temperature pyrogenic reactions; for example, acetylene is usually present in small amounts in coal gas. However, it was not until the discovery by Willson and Moorehead in 1892 of the electric furnace method of producing calcium carbide from the combination of coal with lime that acetylene became of any commercial significance. Acetylene, generated when calcium carbide is brought in contact with water, was used for illumination because the acetylene flame, when supplied with the correct amount of air, gives a pure white light which is the nearest known artificial approach to sunlight. The widespread use of acetylene for illumination during the early part of the century has been supplanted by the incandescent electric light, except for locations where electric power is not available; e.g., in navigation buoys and miners' lamps.

The next stage in the growing importance of acetylene as an industrial commodity was the development of autogenous welding using an oxygen-acetylene flame in the so-called oxyacetylene torch. This oxyacetylene flame produces the highest flame temperature (about $6,000^\circ F.$) of any known mixture of combustible gases and, although originally limited to welding and joining of certain ferrous metals, can now be used to weld or cut practically all industrial metals.

Acetylene is an unsaturated organic compound, highly reactive toward many chemical reactants, so it soon became the basis for a rapidly growing chemical industry. Acetaldehyde, acetic acid, acetone and a wide range of chlorinated solvents were so derived. During the early 1930s, E. I. du Pont de Nemours and Co. developed in the United States the first synthetic rubber, Neoprene (Duprene) from acetylene. Subsequently the use of acetylene in chemicals continued to widen until more than 75% of the acetylene used was employed in synthetic chemicals, many of which appeared as such familiar household articles as water-base paints, vinyl fabric and floor coverings, dry cleaning solvents and aerosol insecticide sprays.

Manufacture of Acetylene.—Until about 1940, acetylene was usually derived from calcium carbide, the product of the reaction

of coal and lime in an electric furnace at about 2,000° C.

Reaction of water with calcium carbide in specially designed generators produces gaseous acetylene and solid hydrated lime.

During World War II Germany installed in the synthetic rubber plant at Huls the first successful commercial installation for the cracking of hydrocarbons to acetylene by means of a high temperature electric arc. During the same period, Germany also operated a plant at Oppau for the production of acetylene by partial combustion of methane with air or oxygen. The combustion of part of the methane provided the heat required to raise the temperature of the injected hydrocarbon up to the cracking temperature. This latter process, sometimes referred to as the Sachsse process, later was further developed, particularly in the southwest United States where ample supplies of natural gas are available cheaply. Unlike the calcium carbide or arc processes, the Sachsse process does not require electrical power as a primary source of energy. Still a fourth method, a purely thermal hydrocarbon cracking process known as the Wulff process, is carried out in a regenerative type furnace consisting of carborundum refractory tiles in the heated section. The heat required to raise the temperature of the tiles to the cracking temperature of 1,250–1,450° C. is supplied by burning the waste gases, consisting of carbon monoxide and hydrogen, from the purification section.

One fundamental requirement in all high temperature cracking operations for producing acetylene is that the hydrocarbon feed be heated to the highest possible temperature in the shortest possible time and that the temperature of the cracked gases be lowered rapidly to minimize decomposition of the acetylene produced.

Acetylene generated from carbide is generally rather pure, containing less than 0.4% impurities, and is suitable for most uses except chemical synthesis, for which traces of phosphine, arsine and hydrogen sulfide must be removed to prevent poisoning sensitive catalysts. On the other hand, acetylene generated from cracking of hydrocarbons is in very dilute form, comprising only about 8% to 16% of the total gas. Purification may be carried out by several methods but, in principle, all depend on the selective absorption of acetylene in a solvent, generally under pressure, in which, the acetylene is many times more soluble than the attendant impurities. This solvent stream, containing principally acetylene, when warmed up at lower pressures, releases the acetylene in fairly pure state. A major by-product in all cracking operations is a considerable amount of finely divided carbon, separation and disposal of which is often troublesome.

A substantial factor in the cost of pure acetylene from cracking operations is the expense of purification. In some cases this can be offset partially by processing the waste "tail gas," consisting essentially of carbon monoxide and hydrogen in roughly the correct percentages for synthesis of methyl alcohol (methanol), a useful industrial chemical. In other instances the carbon monoxide may be removed, leaving essentially pure hydrogen, also useful for chemical synthesis, for example, by reaction with nitrogen from the atmosphere to form ammonia, the basis of several forms of nitrogenous fertilizers.

Despite the wide differences in manufacturing technology, no one of these methods is universally used. Where electrical power is cheap and hydrocarbons scarce, the carbide method probably is prevalent, but where hydrocarbons are plentiful, as in the southwest United States, some form of hydrocarbon cracking is the method of choice.

Shipping of Acetylene.—Because of its inflammability and explosive nature under pressure, acetylene must be shipped in special containers, so constructed as to minimize danger. One basic feature of safe construction lies in packing the cylinders with a highly porous monolithic filler so that no pockets of significant size remain where free acetylene in gaseous form can collect. A

second factor is the use of a solvent, acetone, which dissolves many times its own volume of acetylene. By this technique, acetylene can be shipped safely at pressures of 250 lb. per square inch (p.s.i.). Even so, in the United States the construction and shipping of acetylene cylinders must follow the specifications and regulations of the Interstate Commerce commission.

From the above, it is obvious that the weight of acetylene available in each cylinder is very small, usually less than 10% of the total shipping weight. If one takes into account the return of the empty shipping container, the net efficiency of shipping is less than 5%. On the other hand, calcium carbide gives off 31% of its weight of acetylene and is thus the cheapest form in which to transport acetylene by common carrier.

Fuel Uses.—Acetylene requires 2.5 times its volume of oxygen or 11.95 times its volume of air to effect its complete combustion. It is used for lights in portable lamps, buoys, road signals, isolated premises, etc., but the consumption of acetylene for lighting is small compared with its use in the industrial welding and cutting of metals, for which purposes it is consumed in a blowpipe to which a supply of undiluted oxygen is fed from a steel cylinder containing that gas under pressure. In welding, a reducing flame is maintained by using less than the proportion of oxygen required for complete combustion, whereas in cutting metals an excess of oxygen is admitted to oxidize the metal. Since acetylene is an endothermic compound its heat of combustion is greater than that of the constituent carbon and hydrogen. For this reason acetylene affords a higher flame temperature than other fuel gases, about 6,000° F. in a correctly designed and operated torch.

Chemical Uses.—Ready availability, high reactivity and reasonable cost make acetylene a suitable starting material for the industrial synthesis of many organic chemicals. Together with ethylene, it forms the basis of much of the synthetic aliphatic chemical industry. In those countries having abundant electrical power but limited oil reserves, acetylene is usually favoured as a raw material. However, in the United States acetylene and ethylene are often competitive; acetylene is generally more expensive than ethylene but processing costs may be lower because, in many cases, acetylene may offer a more direct route to the desired chemical. The use of acetylene as a raw material for chemical synthesis has increased so rapidly that total usage in the United States may be expected to increase tenfold—up to about 3,000,000,000 lb. per year by 1975.

Many potentialities of acetylene as a raw material for synthetic products have been realized, primarily by J. W. Reppe in Germany; knowledge of Reppe's work became generally available only after World War II. Reppe recognized that inability to handle acetylene safely under pressure was a very serious limitation to the discovery of new reactions of acetylene. He initiated an exhaustive study of the explosive characteristics of acetylene, as a result of which new techniques were devised which permitted acetylene to be used in chemical reactions under pressures of up to 250–300 lb. p.s.i. In brief, these techniques involved: (1) dilution of the acetylene with an inert gas such as nitrogen; (2) use of small-bore transmission lines; and (3) subdivision of all large areas of the container by packing with ceramic or metal rings or gauzes so that no acetylene molecule was more than one-half inch from a wall surface.

With these new techniques allowing the use of acetylene under pressure, Reppe was able to develop four new areas of acetylene chemistry: (1) vinylation, in which an alcohol, mercaptan, acid, amine or amide is added across the triple bond to produce vinyl ethers, vinyl thioethers, vinyl esters, vinyl amines and vinyl amides; (2) ethynylation, in which the acidic hydrogens are added to aldehydes, ketones and amines to produce new acetylenic chemicals, still containing a triple bond; (3) carbonylation, in which carbon monoxide may be added in the presence of water or alcohol to give acrylate derivatives; and (4) cyclopolymerization, in which acetylene reacts with itself to produce cyclic hydrocarbons such as benzene, styrene and cyclooctatetraene.

This new chemistry of acetylene under pressure, sometimes referred to as Reppe chemistry, has made available many new acetylene chemicals, but few had obtained large-scale usage in the early

development of the new field.

The first major use of acetylene as a chemical raw material involved the addition of water to acetylene in the presence of sulfuric acid and mercuric sulfate to produce acetaldehyde. Oxidation of acetaldehyde gives acetic acid, a necessary component in the acetylation of cellulose to cellulose acetate, and in the synthesis of solvents for automobile lacquers.

Chlorination of acetylene to produce a series of chlorocarbons is a major consumer of acetylene. The chlorocarbons, which include trichloroethylene and tetrachloroethylene, are solvents for fats, oils and waxes and are widely used in metal degreasing, in dry cleaning, in scouring wools and in extracting oils. They are non-inflammable and, under most conditions, stable to oxidation and hydrolysis.

During the early 1930s, the du Pont company developed the first synthetic rubber, based on the original discovery of J. A. Nieuwland of the University of Notre Dame (Ind.) that acetylene could be converted to vinyl acetylene. Addition of hydrogen chloride to vinyl acetylene gives chloroprene which rapidly polymerizes to a rubberlike material, polychloroprene, known as Neoprene or Duprene. During World War II it was widely used as a substitute for natural rubber. Actually, Neoprene is superior to natural rubber in resistance to heat and oxidation and to fuels such as gasoline and oils.

Much of the rapid increase in the use of acetylene as a chemical intermediate paralleled the amazing development and growth of plastics. Addition of acetic acid to acetylene produces vinyl acetate. Polymerized vinyl acetate is a component of water-base paints and textile finishes. Hydrolysis of polyvinyl acetate gives polyvinyl alcohol, a unique polymer which, after chemical modification, is widely used in safety glass lamination and in synthetic sponges. Addition of hydrogen chloride to acetylene yields vinyl chloride, the polymer of which is familiar commercially in the form of vinyl upholstery, vinyl floor tile and inflatable toys. Combination of acetylene with hydrogen cyanide gives acrylonitrile, the major component of the acrylic fibres such as Orlon. Acrylate monomers are produced from the reaction of acetylene with carbon monoxide and an alcohol. Acrylate polymers such as Lucite and Plexiglas are familiar as transparent, optically clear plastic sheets and as the basic material in artificial dentures.

Acetylene is also a key raw material in the synthesis of vitamin A, an important food supplement. One of the chemicals based on acetylene reactions under pressure is polyvinyl pyrrolidone, a water-soluble polymer having many properties resembling natural proteins. Polyvinyl pyrrolidone was used in Germany as a blood plasma extender, but this use in the United States did not materialize.

Properties of Acetylene.—Acetylene or ethyne, $\text{HC}\equiv\text{CH}$, is the simplest and best-known member of the acetylenic hydrocarbon series. As the formula shows, acetylene contains two carbon atoms, each joined to one hydrogen atom, and linked by a so-called triple bond. It is this triple bond which distinguishes acetylene from ethylene ($\text{CH}_2=\text{CH}_2$) and which is responsible for many of its unusual properties and reactions.

Acetylene is an inflammable, gaseous compound having a molecular weight of 26.02 and containing 7.75% hydrogen and 92.25% carbon. When pure, it is a colourless gas with a pleasant ethereal odour. However, as prepared from calcium carbide, it usually contains traces of phosphine which cause an unpleasant, garliclike odour. The accompanying table lists many of the common physical properties of acetylene.

Physical Properties of Acetylene

Molecular weight	26.02
Melting point	-81.8°C. (-115.2°F.)
Boiling point	-88.5°C.; -83.6°C. sublimates
Critical temperature	36°C. (96.8°F.)
Critical pressure (atmospheres)	62
Density (g./l., 0°C., 760 mm.)	1.173
Density (lb./ft. ³ , 32°F., 1 atm.)	0.07323
Specific gravity (air=1)	0.9073
Inflammable limits in air (vol. %)	2.5 to 50
Auto-ignition temperature	635°F.
Heat of combustion/gram m.w.	1,238 B.T.U.

The heat of formation of acetylene is -54.34 kg.cal. per gram

mole (3,800 B.T.U. per pound); thus, it is a highly endothermic compound, and is the only hydrocarbon known whose thermodynamic stability increases with increasing temperature, although it is doubtful whether it ever becomes stable with respect to its elements.

Acetylene can be decomposed into its elements with the liberation of heat. This decomposition may or may not give rise to explosions, depending on conditions. If acetylene gas is ignited at atmospheric pressure, decomposition occurs, but usually is not propagated beyond the ignition source. On the other hand, pure acetylene under pressure in excess of about 15 lb. per square inch pressure, or in liquid or solid form, explodes with extreme violence from shock or ignition.

The hydrogen atoms in acetylene are somewhat acidic in character and can react with metallic salts to form metallic derivatives of acetylene, the so-called acetylides. For example, characteristic insoluble precipitates are formed when acetylene is passed into ammoniacal solutions containing cuprous or silver ions. Cuprous acetylide (Cu_2C_2) is reddish brown, while silver acetylide (Ag_2C_2) is white, darkening on exposure to light. Both are extremely sensitive to heat, friction or shock when dry and are powerful explosives. These acetylides, because of their characteristic colour and insolubility, may be used to detect small amounts of acetylene in other gases.

Industrial acetylene readily attacks copper; hence, in handling acetylene, it is imperative to avoid all contact with copper piping, valves and fittings in order to eliminate formation of the explosive cuprous acetylide.

The metallic acetylides, particularly the alkali metal acetylides (sodium or potassium), find application in chemical syntheses where, by addition to other unsaturated compounds, many new organic compounds containing the ethynyl group $\text{HC}\equiv\text{C}-$ are produced.

In addition to its reactive hydrogen atoms, acetylene also contains a carbon-to-carbon triple bond. This is a highly unsaturated bond having a great tendency to add many reactants to produce entirely new chemicals. For example, addition of water produces acetaldehyde, addition of acetic acid gives vinyl acetate and addition of hydrogen chloride yields vinyl chloride.

See also Index references under "Acetylene" in the Index volume.

(J.N. W. C.)

ACHAEA (ΑΧΑΪΑ), the name of a region of Greece, on the north coast of the Peloponnesus, bounded in ancient times to the south by Elis and the Erymanthus mountains and to the east by Sicyon and approximately corresponding to the modern Greek nomos or department of Achaea (area 1,210 sq.mi., pop. [1961] 236,770, administrative capital Patras [*q.v.*]). The 12 cities of ancient Achaea formed a religious confederacy, meeting in Poseidon's sanctuary at Helice; from this developed the Achaean league (*q.v.*) of Hellenistic times. After the war between Rome and the Achaeans in 146 B.C. Achaea was administered by Rome as part of the province of Macedonia and not organized separately as a senatorial province until 27 B.C., when the name was extended to comprise all of Greece south of Thessaly, with Corinth as capital. On the Latin conquest of the Byzantine empire in A.D. 1204, a Frankish principality of Achaea was established in the Morea or Peloponnesus. After various dismemberments, this was conquered by the Turks in 1460 (see GREECE: *Post Classical and Medieval History*).

The name Achaea was applied in ancient Greece to a region west of the Gulf of Pagasae (mod. Gulf of Volos) in southern Thessaly, this being usually referred to as Achaea Phthiotis. See also ACHAEANS.

ACHAEAN LEAGUE, a confederation of the towns of Achaea (*q.v.*) in ancient Greece. Isolated on their narrow strips of plain, these towns were exposed to piratical raids from across the Corinthian gulf. As a protection against such dangers the earliest league of 12 Achaean cities arose. In the 4th century B.C. it was fighting with Sparta against Thebes both before and

after the battle of Leuctra (371), and it shared in the resistance to Philip II of Macedonia (338) and Antipater (330) (see GREECE: *Ancient History*). In the period following the death of Alexander the Great this league fell apart. By 280, however, four towns had combined again, and soon the ten surviving cities of Achaea renewed their federation around the shrine of Zeus Homarios near Aegiurn. Much was due to Aratus (*q.v.*) of Sicyon, who in 251 brought his newly liberated city, and later other non-Achaeian cities, into the confederation on equal terms. He thus initiated an expansive policy, and by 228 the confederation included Arcadia, Argolis, Corinth and Aegina.

Aratus probably also organized the federal constitution. The league embraced city-states which maintained their internal independence. Only in foreign politics and war was their competence restricted. The central government claimed to be democratic, but its democracy was modified by a high minimum age (30 years) for membership of the assembly and by the absence of payment for attendance, with the result that the expense of officeholding in practice left power in the hands of the well to do. The chief magistracy was the *strategia*, which combined unrestricted command in the field with considerable civil authority and had practically the sole power of introducing measures before the assembly. There were two annual generals (*stratego*) down to 255, but subsequently only one; re-election was allowed only after a year's interval. Beside the general stood a board of ten *demiourgoi*, who shared in the administration and under his chairmanship presided over the assembly. There was a representative council (*boule*). Though the relations of this body with the assembly are a matter of controversy, the probability is that down to *c.* 200 B.C. there were regular meetings (*synodoi*) of both council and assembly throughout the year to transact normal business, but that after 200 the assembly was not ordinarily convened; thus from then onward Achaea was governed by a representative council, perhaps elected on a proportional system. At all times irregular meetings (*synkletoi*) of council and assembly could be summoned to debate such questions as war or alliance; and after 200 the primary assembly was convened only for this purpose or on the instructions of the Roman senate.

The confederacy prescribed uniform standards and coinage. There were federal law courts, and the assembly could transform itself into a court of justice. The federal authority summoned contingents, imposed taxes and fined or coerced refractory members.

The first federal wars were against Macedonia, against Antigonos Gonatas and Aetolia and, in alliance with Aetolia, against Demetrius II. But the admission of Megalopolis and other Arcadian cities to the league led to friction with Sparta. Shorn of much of its territory and in danger of complete disintegration before the assaults of the Spartan king Cleomenes III (*q.v.*), the confederacy was persuaded by Aratus to call in the Macedonians, victorious at Sellasia, Antigonos Doseon restored the lost districts, but retained Acrocorinth for himself (224–221). The Achaeans then joined his new Greek league and fought beside his successor, Philip V. first against Aetolia (220–217), then against Rome allied to Aetolia (211–205). Under Philopoemen (*q.v.*) a reorganized federal army defeated Nabis, the tyrant of Sparta (207). In the Second Macedonian War Achaea joined Rome (198), and this new policy led to the incorporation of nearly the whole Peloponnese; it also brought increased friction with Sparta and clashes with Roman officials, and after the Roman victory at Pydna (168) control by subservient representatives of the pro-Roman party. In 150, in defiance of Rome, the confederacy attacked Sparta. The federal army was routed near Corinth by Lucius Mummius (146), and the Romans dissolved the confederacy. However a smaller league was soon afterward set up, and this continued into the Roman imperial age; it was at one time a member of a larger Panachaeian confederacy within the Roman province of Achaea.

The chief defect of the Achaeian league lay in its lack of provision for securing efficient armies and regular payment of imposts and for dealing with disaffected members. Its achievement was to have combined city autonomy with an organized central administration, to have made noteworthy progress in the institution

of representative government and to have served the interests of Greek liberty for more than a century.

ACHAEANS, an ancient Greek people, whose eras of greatest importance belong to preclassical and postclassical times. In Homer, Akhaioi is the name chiefly used, along with Danaoi and Argeioi, of the Greeks besieging Troy, whereas the name Hellenes occurs only once ("Myrmidones and Hellenes and Achaeans"; *Iliad* ii, 684) and is used, as Thucydides noted, only of followers of the northern chief Achilles. Homer's Achaeans dominate the mainland and western isles of Greece (with "rich Mycenae" as capital of their strongest kingdom); Crete (where they are distinguished from "True-Cretans" and other peoples), Rhodes and adjacent isles, but not the Cyclades (where indeed Mycenaean imports recorded by archaeology are relatively scanty). Farther afield they are said to have contacts with Cyprus (where, according to Strabo, writing in the 1st century B.C., the place name "Achaeian Shore" commemorated the first landing of Achaeian settlers) and with Phoenicia and Egypt, a piratical raid on which is described by Odysseus in one of his "yarns." Their area as described by Homer is thus precisely that covered by the activities of the "Mycenaeans" in the 14th–13th centuries B.C., as revealed by archaeology. Moreover, the references in 13th-century Hittite documents to a powerful western kingdom of Ahhiawa, whose king is on occasion addressed as "brother" by Hittite monarchs, have been plausibly interpreted as referring to the Mycenaean world under Achaeian domination. Modern scholars have also, more dubiously, identified as Achaeans the people denoted as "K-w-sh" in Egyptian hieroglyphics and recorded as invading Egypt from the west in alliance with Libyans in 1221 B.C.—the name being vocalized as "Akhaiwasha" (for Greek "Akhaiwoi").

It might be concluded from the above evidence that the Achaeans are coeval with the Mycenaean and therefore the first Greeks in the Aegean, were it not that the linguistic affinities of the Achaeans present a more difficult problem. The language of the Mycenaean "Linear B" writing is generally believed to be an early form of Greek, having affinities with the Arcadian and Cypriot of classical times; and the written language of Mycenae was quite certainly also that of Crete, well before 1200 B.C. No break in the cultural development such as might be expected to accompany the coming of Greek, an Indo-European language, to the Aegean can be detected by archaeology later than the beginning of the Middle Bronze Age (*c.* 1900–1600 B.C.; see GREECE: *Ancient History*); however, the Achaeans of the northern Peloponnese in historic times, who were reckoned by Herodotus to be descendants of the earlier Achaeans, spoke a dialect of Greek akin to Doric (if we may judge by the inscriptions of their colonists in Italy), which suggests that they did not enter Greece until the Dorian invasions at the end of the Bronze Age (12th century B.C.). Since the genealogies of Homer's Achaeian chiefs are very short (two or three generations) and since Homer's only reference to writing is in a story referring to a time two generations before the Trojan War, it seems at least possible that these chiefs, whose infiltration into Mycenaean kingships by way of military service and dynastic marriages is a frequent motif of Greek saga, were not the first Greeks in the south, but that they held power in the Mycenaean world only for a few generations in its last, warlike and semibarbarous phase and were relatively close kindred of the Dorians (*q.v.*) who were to replace them.

In the classical period, Achaea (*q.v.*) was the name of two districts in Greece, neither of them important. Twelve small Achaeian cities held the coastal strip of the northern Peloponnese and were never brought by Sparta into the Peloponnesian league, Sparta being only at pains to keep the area out of hostile hands. The most important achievement of these little cities was their contribution to Greek colonization, with the foundation (by the "over-

spill" of population from their rocky and narrow land) of cities in southern Italy, *c.* 700 B.C.: Sybaris (*q.v.*), which colonized Poseidonia (Paestum, *q.v.*); Crotona (*q.v.*); Metapontum; and Caulonia. In their more spacious land, these Achaea colonists flourished so greatly that the region came to be known as Great Greece (Magna Graecia, *Megale Hellas*). Here, as in the line of Homer quoted above, Achaeans seem to have been early users of the Hellenic name. For Achaea's importance from the 4th century onward, see ACHAEAN LEAGUE.

The other Achaea of historic times, Achaea Phthiotis, was a district of southeastern Thessaly. Preserving, in the hill country of Othrys, a distinct dialect akin to Thessalian (Aeolic mingled with northwestern elements) and their own tribal organization, but politically dominated by the Thessalian league, these Achaeans played no independent part in Greek history.

ACHAEMENIDAE, Latin form of the Greek name of an ancient dynasty of Persian kings (see PERSIA: *History*). Achae-menés (Persian, Hakhmanish), their eponymous ancestor, is presumed to have lived early in the 7th century B.C., but nothing is known of his history. From his son Teispes two lines of kings descended. The kings of the older line were Cyrus I, Cambyses I, Cyrus II the Great and Cambyses II. After the death of Cambyses II the junior line came to the throne with Darius I, who in the Bisitun inscription traces his descent from Teispes through Ariaramnes, Arsames and Hystaspes, his father. Cyrus II, Darius I and all the later kings of Persia called themselves Hakhmanishiya (Achaemenidae). The dynasty became extinct with the death of Darius III, following his defeat (330 B.C.) by Alexander the Great.

The name Achae-menés was borne by a son of Darius I. After the first rebellion of Egypt, in 484 B.C., he was appointed satrap of Egypt by his brother Xerxes and commanded the Persian fleet at Salamis (480). In 460 B.C. he was defeated and slain by Inaros, the leader of the second rebellion of Egypt.

See also Index references under "Achaemenidae" in the Index volume. (J. M. M.-R.)

ACHATES, the companion of Aeneas in Virgil's Aeneid. The expression "fidus Achates" became proverbial for a loyal and devoted companion.

ACHELOUS (mod. ASPROPOTAMOS or AKHELOOS "white river"), the largest river in Greece, is 137 mi. long. It rises in the Pindus mountains, and, dividing Aetolia from Acarnania, falls into the Ionian sea. Its water is charged with fine mud, which is deposited along its banks in fertile, marshy plains. At its mouth a number of small islands (Echinades) were enveloped in this deposit. In winter the river, which has a rapid pace, overflows the whole of its lower plain, and Hercules is said to have attempted to drain the region by confining the stream within its banks. At its mouth it has a depth of less than two feet and so is not navigable from the sea.

The river was formerly called Thoas, from its impetuosity, and its upper portion Inachus, the name Achelous being restricted to the shorter eastern branch. The name is given to several other rivers in Greece and appears in cult and in Greek mythology as that of the typical river-god. (Wm. C. B.)

ACHENBACH, ANDREAS (1815–1910), German landscape painter, a pioneer of the German realistic school, was born at Cassel on Sept. 29, 1815. He studied at the Düsseldorf academy under Johann Wilhelm Schirmer, but emancipated himself from the contemporary school of landscapists which delighted in the representation of romantic scenery. He was the first artist of the Düsseldorf school who painted nature for its own sake. As a young man he sought inspiration in the Netherlands and Norway. His pictures of the stormy North sea, of Dutch canal scenes and of Rhineland villages contrasted favourably with the sentimental landscapes of his contemporaries. He died on March 31, 1910.

His brother, OSWALD ACHENBACH (1827–1905), is distinguished for his colourful renderings of the Bay of Naples, of Rome and

of Venice. He broke away from the traditional classicist interpretation of these scenes and reveled in strong and glowing colour effects.

ACHENE, a small, dry, one-seeded, indehiscent (closed at maturity) fruit with a thin pericarp, as the individual fruits of buttercups and sunflowers. See FRUIT.

ACHERNAR, a Eridani, the brightest star in the constellation Eridanus (*q.v.*), is located only 32.5" from the south celestial pole. The apparent magnitude of Achernar is 0.6 visual and it is one of the ten brightest stars in the sky.

The star is a blue subgiant about 120 light-years from the earth. Its true luminosity is more than 600 times that of our sun.

(D. L. H.)

ACHERON (Gr. etymology doubtful, traditionally river of woe), name of several rivers of Greece. In Greek mythology the name is specially given to a river of Hades, hence, particularly in Latin (Acceruns in Plautus), used to designate the lower world generally.

ACHESON, EDWARD GOODRICH (1856–1931), U.S. inventor who discovered silicon carbide (*q.v.*) and perfected a method for making graphite (*q.v.*), was born at Washington, Pa., on March 9, 1856. After completing elementary school he became interested in electricity, joining the staff of Thomas A. Edison in 1880. Acheson helped develop the incandescent lamp at Edison's laboratories at Menlo Park, N.J., and then in 1881 installed the first electric lights for Edison in Italy, Belgium and France. Upon returning to the U.S., Acheson began his own experiments on methods for producing artificial diamonds in an electric furnace. During these experiments he accidentally discovered silicon carbide (SiC), an abrasive of great cutting power, which he named carborundum. Later while studying the effects of high temperature on carborundum he found that silicon vaporizes from the compound at about 7,500" F., leaving behind graphitic carbon of superior quality. Acheson received patents for the graphite process and also for carborundum, and numerous others for methods for producing metallic silicon and graphite lubricants. He died in New York city July 6, 1931.

ACHILL, the largest island off Ireland, is separated from the Curraun peninsula of County Mayo on the west coast by the narrow Achill sound. It covers an area of 56.2 sq.mi. and is roughly triangular in shape. Pop. (1956) 4,493. Achill (meaning "eagle") is mountainous, the highest points being Slieve Croaghnaun, which rises abruptly to 2,179 ft. from the magnificent cliffs of Achill head at the western tip of the island, and Slieve More (2,194 ft.), a regular cone of quartzite, on the northern side. The pre-Cambrian quartzites, which make up most of the island, weather into infertile soils, and peat fills many depressions on wild moorlands. Cultivable areas are few and small and farming has to be supplemented by fishing to provide even a scanty livelihood. Population is highest on the more sheltered eastern coast where a bridge joins the mainland. Railway connection to this point was replaced by motor bus in 1940. Domestic knitting and a small knitting factory provide employment for women. The main source of income is derived from migratory labour. Many men are away from the island for three months or more each year, working as agricultural labourers in England or the Scottish lowlands. (T. HER.)

ACHILLES, in Greek mythology, son of Peleus (*q.v.*) and Thetis; bravest, handsomest and swiftest of the army of Agamemnon. According to Homer, he was brought up by his mother at Phthia with his cousin and intimate friend Patroclus; his teachers were Phoenix and Cheiron. The non-Homeric tales of his childhood contain obvious folk-tale themes. Thetis had seven children, all of whom she put into the fire or a cauldron (see HERCULES) to make them immortal. All died save Achilles; because Peleus interfered at this point, Thetis left him (fairy bride theme). Another version is that Thetis dipped the child in the waters of the river Styx, by which (like Sigurd Fafnirs-bane) he became invulnerable, except for the part of his heel by which she held him: the proverbial "heel of Achilles."

The later mythographers relate that Peleus, having received an oracle that his son would die fighting at Troy, sent him to the court of Lycomedes on Scyros, where he was dressed as a girl and

kept among the king's daughters. (From a liaison with one of these. Deidamia, Neoptolemus was born.) On the warning of Calchas, that Troy could not be taken without Achilles. Odysseus with Phoenix and Nestor searched for him. Coming to Lycomedes' court they presented to the king's daughters arms and stuff for weaving; the girls chose the latter, but Achilles revealed himself by seizing the arms.

During the first nine years of the war as described in the *Iliad*, Achilles ravaged the country around Troy and took 12 cities. In the tenth year the quarrel with Agamemnon occurred. In order to appease the wrath of Apollo, who had visited the camp with a pestilence. Agamemnon had restored Chryseis, his prize of war, to her father, a priest of the god. As compensation Xgamemnon deprived Achilles, who had openly demanded this restoration, of his favourite slave. Briseis.

Achilles refused further service and rejected offers of gifts as compensation for the insult. During Achilles' absence the Greeks were hard pressed, and at last he allowed Patroclus to impersonate him. lending him his chariot and armour. Hector slew Patroclus, and Achilles, having reconciled with Agamemnon, obtained new armour from Hephaestus and slew Hector. After dragging the body about at the wheels of his chariot, he gave it to Priam at his earnest entreaty.

The *Iliad* concludes with the funeral rites of Hector. It makes no mention of the death of Achilles, but hints at its taking place "before the Scaean gates." The *Odyssey* mentions his funeral. The *Aethiopis* took up the story of the *Iliad*. It told how Achilles, having slain Memnon (*q.v.*) and the Amazon Penthesilea, was himself slain by Paris, whose arrow was guided by Apollo.

Achilles was worshipped in many places: at Leuke, where he was honoured with offerings and games; in Sparta. Elis and especially Sigeum on the Hellespont, where his famous tumulus was erected. Behind these legends there probably lies a real man, certainly not a sun-, river- or other god. No certain statue of him but numerous other representations in art survive.

Wissowa, *Real-Encyclopadie der classischen Altertumswissenschaft*; Daremberg and Saglio, *Dictionnaire des antiquités*; W. Roscher, *Ausführliches Lexikon der griechischen und römischen Mythologie*; L. R. Farnell, *Greek Hero Cults and Ideas of Immortality* (1921). (T. V. B.)

ACHILLES, TENDON OF, the large tendon at the back of the ankle. It is the tendon of the calf muscles that extend and invert the foot, and is inserted into the heel bone (calcaneus). According to Greek legend, when Achilles was born his mother plunged him into the Styx river. This made his whole body invulnerable except for the part of the heel by which she held him, and in this area he later received a mortal wound.

ACHILLES TATIUS (fl. 2nd century A.D., as recent papyrus discoveries demonstrate, and not 4th–6th, as previously believed). of Alexandria, wrote the Greek prose romance of Leucippe and Cleitophon. Nothing certain is known of his life. The romance, a typical adventure story of love triumphant over innumerable obstacles—shipwrecks, tortures, abductions and attacks by pirates—is related in the first person (an unusual feature in this genre) by Cleitophon himself, whom Achilles claims to have met in Sidon. The style is typical of Atticism, with its extreme purity of diction, short unconnected sentences, parallel clauses: detailed descriptions and frequent declamations and disquisitions, often in antithetical form (*e.g.*, on love for women and pederasty). Achilles shows uncommon ingenuity in inventing *coups de théâtre* (Leucippe apparently dies three times, but always reappears), but his characterization is poor, and plot is relegated to the background by numerous and irrelevant interruptions. His work was admired by the Byzantines, and translations of it influenced the development of the novel.

ACHILLINI, ALESSANDRO (1463–1512), Italian philosopher and physician, was born on Oct. 29, 1463, at Bologna. Educated in the University of Bologna, he taught philosophy and

medicine there from 1484 to 1512, except for a period between 1506 and 1508 during which he lectured at Padua and also disputed with Pietro Pomponazzi. An outstanding Aristotelian, he cites the commentaries of Averroës with respect. The human intellect he held to be a separate substance, one throughout the human species, yet at the same time the substantial form of the individual to whom it is united. He died on Aug. 2, 1512. Achillini's chief works, printed at Bologna, are: *Quodlibeta de intelligentiis* (1494); *De orbibus* (1498); *De universalibus* (1501); *De elementis* (1505); *De distinctionibus* (1510); and *Annotationes anatomiae*, ed. by his brother G. F. Xchillini (1520).

(H. S. M.)

ACHIMENES, a genus of plants (family Gesneriaceae, to which belong also Gloxinia, Streptocarpus and the African violet): natives of tropical America, well known in cultivation as stove or warm greenhouse plants. There are over 30 species and many horticultural varieties, among the finest of which are Little Beauty, Dainty Queen, Margarita, Carmine Queen and Crimson Glory. They are herbaceous perennials, generally with hairy serrated leaves and handsome flowers. The corolla is tubular with a spreading limb and varies widely in colour, being white, yellow, orange, crimson, scarlet, blue or purple. The plants need a rich soil of compost, peat and manure, with enough sand to lighten the mixture. (N. Tr.)

ACHIN: see ATJEH.

ACHINESE (ATJEHNESE), a Sumatran tribe originally of Proto-Malayan stock, but much mixed because of contacts with foreign traders, slave raids and willingness to incorporate any person or group. The population is estimated at about 2,000,000.

The Achinese of northwestern Sumatra probably were the first people of that island to feel Indian influence. Prior to 500 A.D. they had accepted the rule of Indian princes and had embraced Indian religion. This led to ideas of state and of a graded society—nobles, middle class and serfs or slaves—which have persisted to the present. Later they were converted to Islamism and about 1520 founded an independent sultanate. For a time they maintained trade with the Portuguese, but the demands of the latter led to war and their expulsion from Sumatra in 1641. For the next 100 years the Achinese were dominant in northern Sumatra, but the expanding power of the Dutch ultimately reduced their influence. The attempt of Holland to gain full control led in 1873 to the Achinese War which lasted about 40 years.

Today western influence is evident in public buildings and in the homes of the well to do. Otherwise the native type of dwelling is the rule. This consists of a three-room structure of wood or bamboo raised high above the ground on piles. The front gallery serves as a gathering place for the family and guests. Behind this is the sleeping room, and in the rear, a kitchen. Furnishings are scanty but elaborate hangings are common.

Marriage is matrilineal. The bride's family adds a room or provides a new house and perhaps some land. These remain the property of the girl. Despite Islamic influence the position of the woman is high. Her dress consists of a skirt over trousers, a jacket and scarf and many ornaments. She does not wear a veil. The man wears a jacket or shoulder cloth and trousers of great width, over which a loincloth is draped.

Each town is supposed to have a mosque and a man's house. The latter is the night dwelling for boys and male guests. It also serves as a house of prayer and as a Muslim school.

See C. Snouck Hurgronje, *The Achinese* (1906); R. Kennedy, *Islands and Peoples of the Indies* (1943). (F.-C. CE.)

ACHROMATIC LENS, a combination of two or more lenses corrected for chromatic aberration. See OPTICS; *Chromatic Aberrations*; PHOTOGRAPHY: *Photographic Lenses*; TELE-

SCOPE: *Achromatic* Telescopes; MICROSCOPE: *Compound* Microscope; DOLLOND, JOHN.

ACIDS AND BASES. Acid is the name loosely applied to any substance that, in water solution, tastes sour, changes the colour of indicators (*e.g.*, reddens blue litmus), reacts with some metals (*e.g.*, iron) to liberate hydrogen and "neutralizes" bases. Base is the name loosely applied to any substance that, in water solution, is slippery to the touch, tastes bitter, reverses the colour changes produced by acids, on indicators (*e.g.*, turns red litmus blue) and neutralizes acids. Neutralization is the process whereby an acid and a base enter into a chemical reaction which destroys the characteristic properties of both and produces a compound known as a salt.

There are several different scientific definitions of acids and bases in current use; these will be explained below.

Among the industrially important acids are sulfuric, nitric, hydrochloric, phosphoric and acetic; among the industrially important bases are sodium and potassium hydroxides, sodium and potassium carbonates, calcium oxide (lime) and ammonia. Sulfuric acid is one of the most important of chemical products in the United States; the tonnage produced annually greatly exceeds that of any metal except iron. Sulfuric acid is used in the refining of petroleum, in storage batteries, in "pickling" steel, in the manufacture of fertilizer, etc. Nitric acid and acetic acid are widely used in the chemical industry. Among the uses for the former are the manufacture of explosives and of dyestuff intermediates; among the uses for the latter are the manufacture of plastics and of solvents. Among bases sodium and potassium hydroxide (see ALKALI) are used in soap manufacture; sodium carbonate is one of the important ingredients for the manufacture of glass and is used in the household as washing soda. Ammonia is widely used, in the form of ammonium sulfate, as a fertilizer; it is also the raw material for the production of much nitric acid. The details of manufacture are described under individual articles on acids; and, for bases under ALKALI MANUFACTURE. Here only the theory of acids and bases is considered. For the principles used in naming acids and bases see CHEMISTRY: Inorganic Chemical Reactions.

History. — In ancient Mesopotamia and Egypt, vinegar was produced by the action of air on wine (fermentation). Vinegar is a dilute and impure solution of acetic acid in water; impure acetic acid (vinegar) was utilized industrially by the ancients. Theophrastus of Eresus, in the 4th century B.C., gave directions quite similar to comparatively modern ones for the preparation of white lead pigment from vinegar and metallic lead. Sodium carbonate (obtained by the evaporation of alkaline water from arid regions) and potassium carbonate (from wood ashes) were known in ancient times; lime was obtained, as it is today, by roasting calcium carbonate. The manufacture of sodium and potassium hydroxides by the action of lime on sodium and potassium carbonates was also practised. The exact dates at which these substances were first prepared is unknown, but the manufacture of glass (which required sodium carbonate) was practised in Egypt at least as early as 1400 B.C.

During the middle ages, the alchemists slowly increased the knowledge of acids and bases. The preparation of nitric acid (*aqua fortis*) by the destructive distillation of a mixture of alum, iron sulfate and potassium nitrate was described in a work by Geber translated about A.D. 1310, and the preparation of sulfuric acid by the destructive distillation of iron sulfate was known before 1600. Still later, an explanation was sought for the behaviour of acids and bases. One of the early theories was that of Bertrand (1683), who suggested that "... an acid is a liquid body composed of small, firm and pointed particles, slightly resembling fine and delicate needles." He supposed that alkalis consist of "particles which have between their junctions pores of different structures" and that neutralization results when the needles of the acid enter the pores of the alkali. According to the phlogiston theory current early in the 18th century, such acids as sulfuric, phosphoric, etc., which are produced by combustion, were regarded as elementary substances. This misapprehension was abandoned along with the phlogiston theory and temporarily replaced

by Antoine Laurent Lavoisier's doctrine (1777) that oxygen is the acid-producing element. About 1808–10, the researches of Sir Humphry Davy and of J. L. Gay-Lussac and L. J. Thénard on hydrochloric acid established beyond doubt that hydrogen and not oxygen is the element essential (although not sufficient) for acidic properties. The hydrogen theory of acids was extended by S. A. Arrhenius, who showed (1887) that, in aqueous solution, acids are partly ionized—separated into electrically charged particles called ions. He further suggested that an acid should be defined as a substance that ionizes in water to yield hydrogen ions; a base should be defined as a substance that ionizes in water to yield hydroxide ions. The definitions of acids and bases given above will hereafter be called the "classical" ones. For example, nitric acid was assumed to ionize according to equation (1a); sodium hydroxide according to equation (1b):

The characteristic properties of acids and bases were ascribed respectively to the hydrogen ion, H^+ , and the hydroxide ion, OH^- . A substance containing hydrogen that does not ionize in aqueous solution to produce hydrogen ions (*e.g.*, methane, CH_4) is then not an acid. In qualitative terms, a strong acid, when dissolved in water, largely or completely ionizes and thus produces a high concentration of hydrogen ions, whereas a weak acid when dissolved in water is only slightly ionized, and thus produces only a low concentration of hydrogen ions. Modern concepts of both acids and bases have been developed from Arrhenius' theory.

The "Hydrogen-Ion" Theory of Acids.—An enormous amount of evidence supporting Arrhenius' theory of acids and bases has been accumulated since the 1880s. (See SOLUTIONS: Solutions of Electrolytes.) It is a pertinent fact, for example, that a solution of hydrochloric acid in water conducts electricity and that, when the current passes, hydrogen gas is liberated at the negative electrode or cathode. In dilute solutions of the acid, oxygen is liberated at the positive electrode or anode. These facts (and many others) can be explained by assuming that hydrochloric acid in aqueous solution is an assembly of chloride ions, Cl^- , and of hydrogen ions. The hydrogen ion, H^+ , exists in water only as the hydrate, H_3O^+ (H^+ plus H_2O), called the hydronium ion; the evidence for this statement will be presented later.

Many of the reactions of aqueous solutions of acids and bases can be explained on the basis of the ionic theory. For example, the existence of charged particles in the solution accounts for the fact that the solution conducts electricity. The existence of H_3O^+ ions (hydrated hydrogen ions) is consistent with the fact that hydrogen gas is liberated at the cathode, for these positively charged hydronium ions are repelled by the positive electrode and attracted to the negative one, where they are discharged; hydrogen and water are thus liberated.] Similarly, a solution of sodium hydroxide in water is assumed to consist of an assembly of sodium ions, Na^+ , and hydroxide ions, OH^- . During electrolysis, the negatively charged hydroxide ions migrate toward the anode and are there discharged to form oxygen and water. The interpretation here advanced is made much more plausible by quantitative experiments on the changes in composition which, during electrolysis, take place in those portions of the solution near the electrodes (transference experiments; see ELECTROCHEMISTRY).

The ionic theory helps to account for differences in the strengths of acids and bases. Any acid, HA, when introduced into water, rapidly comes to chemical equilibrium with its ions (see *Quantitative Studies of Acids and Bases*, below):

Bases ionize similarly to give (OH^-) hydroxide ions. Such an ionization reaction may be essentially complete, as it is in an

²Although all acids when electrolyzed liberate hydrogen at the cathode, it is not true that all compounds that liberate hydrogen at the cathode are acids. During the electrolysis of the aqueous solutions of some salts, the weak acid water, rather than the salt itself, is decomposed. Such salts, however, have no acidic properties; for example, they do not redden blue litmus.

aqueous solution of the strong base sodium hydroxide, which is largely ionized even in the solid state; or it may be far from complete, as it is in an 0.1 molar aqueous solution of acetic acid, where less than 1.5% of the acid is dissociated into ions, and the rest remains as un-ionized molecules.

Neutralization.—The ionic theory is also useful in explaining the process of neutralization, in which an acid and a base react to form water and a salt. When an acid and a base neutralize one another, the hydronium ion (hydrated hydrogen ion) and hydroxide ion combine to form water; if equivalent quantities of the two materials are present, the reaction proceeds essentially to completion because water is only slightly dissociated into ions. The chemical equation for the reaction between potassium hydroxide and hydrochloric acid is written

which may be simplified to

where the potassium and chloride ions, which do not really enter into the chemical reaction, are omitted. However, these ions are present after the neutralization; with the water produced by the neutralization and the excess water present as a solvent, the ions form a solution of potassium chloride (a salt).

Many acids ionize in water to give more than one hydronium ion; these are called polybasic acids because each molecule of acid can neutralize more than one molecule of base. For example, sulfuric acid is dibasic; it ionizes in two steps:

and forms two series of salts, corresponding to NaHSO_4 and Na_2SO_4 ; phosphoric acid (H_3PO_4) is tribasic and forms three series of salts. Bases (*e.g.*, $\text{Ba}[\text{OH}]_2$) that can ionize to give more than one hydroxide ion per molecule are called polyacid bases. The characteristic reactions of acids other than neutralization and salt formation (*e.g.*, the colour changes of indicators, the formation of hydrogen with metals and of carbon dioxide with carbonates) can also be explained in terms of the ionic theory. Furthermore, this theory has led to an understanding of the mechanism by which acids catalyze some reactions. For example, the role of strong acids in the bromination of acetone is explained in terms of ionization equilibria. The explanations for the characteristic reactions of bases parallel those for the reactions of acids.

Groupings of Acids and Bases.—Some acids are inorganic compounds and some are organic compounds. Among the former are sulfuric, nitric, hydrochloric, perchloric, hydrofluoric, hydrobromic, phosphoric, sulfurous, hypochlorous and arsenic acids. The organic acids are further subdivided according to the structural feature in the molecule which is responsible for the acid properties. For example, there are carboxylic acids (acetic, butyric, benzoic, phthalic, stearic, oleic, etc.), sulfonic acids (benzene sulfonic acid, naphthalene disulfonic acid, etc.), phenols (phenol or carboic acid, cresol, etc.), enols (ascorbic acid or vitamin C, etc.) and other types too numerous to mention.

Bases include the hydroxides of sodium, potassium, calcium, barium, copper, iron and other metals, as well as the hydroxides related to ammonia and to numerous organic compounds, most of which are amines (compounds closely related to ammonia) such as methylamine and aniline. There are a few compounds, such as aluminum and zinc hydroxides and water, which have both slightly acidic and slightly basic properties; these substances are called amphoteric.

The Hydronium Ion.—The hydrogen ion in aqueous solution was for a long time written simply as H^+ . This notation implied that the proton (the nucleus of a hydrogen atom) could exist free in solution. The proton has no electrons around its nucleus and is therefore a small particle. Hence, the electrostatic field in its neighbourhood should be great. On these theoretical grounds, the existence of protons in aqueous solution appears doubtful. All the ions known to exist under such conditions have two or more electrons around their nuclei. A number of experiments have lent

support to the notion that the hydrogen ion exists in aqueous solution only as the hydronium ion, H_3O^+ . Among these can be cited the fact that liquid hydrogen chloride is a nonconductor of electricity. This compound, however, when dissolved in water, conducts current well.

These phenomena are just what would be expected if pure hydrogen chloride did not ionize (*i.e.*, if H^+ alone could not exist under the conditions cited). When gaseous hydrogen chloride dissolves in water, the following strongly exothermic reaction presumably takes place:

X-ray analysis shows definitely that the hydronium ion does exist at least under certain circumstances. For example, the lattice of crystalline perchloric acid monohydrate consists of hydronium and perchlorate (ClO_4^-) ions. It is true that ions other than the hydrogen ion interact with water; moreover, hydronium ions in aqueous solution tend to combine with additional water to form heavily hydrated ions. But whereas, in crystalline and molten salts, ions other than the hydrogen ion can exist, there is no evidence for the existence of uncombined protons in either solid or liquid phases. (Free protons can exist under special circumstances in the gas phase; *e.g.*, in a cyclotron.) In view of these facts, the hydronium ion, H_3O^+ , will here be written for the hydrogen ion in aqueous solution.

Bronsted-Lowry Definition.—A broader definition of acids and bases was introduced by J. N. Bronsted and T. M. Lowry simultaneously and independently in 1923. According to this definition, any compound that can transfer a proton to any other compound is an acid; the compound that accepts the proton is a base. Two considerable advantages of the Bronsted-Lowry definition are that it can be applied to nonaqueous solutions and that it codifies and simplifies acid-base reactions. It is not inconsistent with the classical definition of acids in terms of hydrogen ions, but is rather an extension of the older concept. According to the Bronsted-Lowry scheme, all acid-base equilibria are then represented by the equation:

Here A^- and B are described as the conjugate bases of the acids HA and BH^+ , respectively; similarly, HA and BH^+ are the conjugate acids of the bases A^- and B .

In such generalized equations the presence or absence of an electric charge on any particle does not necessarily indicate the net charge on the particle in question. It merely shows that an acid has one more positive or one less negative charge than its conjugate base, and conversely that a base has one less positive charge or one more negative charge than its conjugate acid. Examples of acid base equilibria are shown in equations (7a) and (7b):

In these equations, ammonium ion is the acid conjugate to the base ammonia, acetic acid is the acid conjugate to the base acetate ion, hydronium ion is the acid conjugate to the base water, and water is the acid conjugate to the base hydroxide ion. (Water is thus seen to be amphoteric.)

According to the Bronsted-Lowry scheme, the existence of acids implies the existence of bases (and vice versa), just as the existence of oxidizing agents implies the existence of reducing agents (and vice versa).

It has long been known that an aqueous solution of pure sodium acetate gives a basic reaction toward litmus. This fact may be explained by equation (7b), which shows that the reaction between water and acetate ion produces some hydroxide ions, which are responsible for the colour changes of the indicator. In classical language, reaction (7b) is described as the hydrolysis of the acetate ion; in Bronsted-Lowry's terminology, it is called the ionization of the base, acetate ion.

The hydrolysis (equation [7a]) of ammonium chloride (classi-

cal) is similarly replaced by the ionization of the acid, ammonium ion (Bronsted-Lowry). A solution of aniline hydrochloride has about the same acidity as one of acetic acid; it is, therefore, both convenient and informative to state that the anilinium ion, $C_6H_5NH_3^+$, is an acid of about the same strength as acetic acid.

The Bronsted-Lowry definition considerably enlarges the number of compounds considered (on the basis of the classical definition) as acids and bases. The class of bases is expanded to include not only the hydroxide ion and amines but also the acetate ion, phosphate ion, carbonate ion, sulfide ion, etc., since each of these negative ions can acquire a proton from an appropriate acid. Similarly, the class of acids is expanded to include the ammonium ion, anilinium ion, the oxonium ion of alcohol, etc., since each of these positive ions can transfer a proton to an appropriate base.

Furthermore, the hydrogen (or hydronium) and hydroxide ions are no longer considered the exclusive bearers of acidic and basic properties; an example in which un-ionized molecules function as acids is provided by the phenomenon of general acid catalysis.

One of the characteristic properties of acids and of bases is that they catalyze or increase the rate of certain chemical reactions. There are a number of reactions, such as the hydrolysis (inversion) of cane sugar, that are catalyzed exclusively by hydronium ions; similarly, there are reactions catalyzed exclusively by hydroxide ions. But there are reactions (*e.g.*, the decomposition of tetryl) that are catalyzed by all bases, reactions (*e.g.*, the hydrolysis of ethyl orthoacetate) that are catalyzed by all acids and reactions (*e.g.*, the bromination of acetone) that are catalyzed by all acids and all bases, the terms acid and base being used here in the Bronsted-Lowry sense.

The rate constant for a reaction of the third type can be represented as a sum

$$k = k_o + \sum_A k_A c_A + \sum_B k_B c_B \quad (8)$$

where k_A is the rate constant associated with each acid present at a concentration c_A , k_B is the rate constant associated with each base present at a concentration c_B , k_o is the rate constant for catalysis by water and the symbol \sum indicates a summation over all acids (or bases) present in the solution. In those general acid or general base reactions, the mechanism of which is understood, the rate-controlling step is actually the acid-base reaction; *e.g.*, the reaction whereby a base removes a proton from a weak acid. Here the usefulness of the Bronsted-Lowry definition is obvious.

Lewis Definition. — G. N. Lewis has suggested (1923) a definition for the word acid which extends this class of compounds even beyond the limits set by Bronsted and Lowry. According to the electronic concept of valence (*q.v.*), a proton from an acid, during neutralization, becomes attached to an unshared pair of electrons in the molecule of a base. Lewis used the word acid to include all substances which, during a chemical reaction, become attached to an unshared pair of electrons in some other molecule. This definition includes, besides the conventional acids, such substances as aluminum chloride, boron trifluoride and zinc chloride.

For example, boron trifluoride (see equation [9a]) reacts with ammonia such as does hydrogen chloride (equation [9b]). The electronic structures of the reactants and reaction products are shown in equations (9a) and (9b):

Furthermore, in certain nonaqueous solvents, boron trifluoride and aluminum chloride react with indicators to produce the same

colour changes produced by conventional acids; these same reagents catalyze many reactions (*e.g.*, the Friedel-Crafts reaction) which are known to be acid catalyzed. It should be noted that the Lewis definition of acid departs from both the classical and Bronsted-Lowry use of the word in that hydrogen is no longer considered essential to acidity.

The analogy which Lewis has pointed out between conventional acids such as sulfuric and materials such as boron fluoride is an important one. Whether these materials should be called acids is a matter of nomenclature depending on personal preference and usage. Most chemists, however, refer specifically to the substances in question as "Lewis acids" or as "electrophilic reagents" or as "cationoid reagents."

Quantitative Studies of Acids and Bases.—It has previously been pointed out that those acids which in aqueous solution are largely dissociated into ions are called strong acids; those which under similar conditions are only slightly dissociated are called weak acids. There have been many quantitative investigations of the strengths of acids in various solvents; here only aqueous solutions will be discussed.

In water, any acid HA is ionized according to equation (2),

The equilibrium constant for the reaction is represented by equation (10):

$$\frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]} = K_A \quad (10)$$

where the expressions in brackets represent the activities of the acid and its ions. (The activity of each ion or molecule is approximated in dilute solution by its concentration; see THERMODYNAMICS: Thermodynamics and Physical Chemistry.) The activity of water is omitted from equation (10) because it is for all practical purposes constant and can therefore be included in the equilibrium constant K_A . A strong acid then is one with a large value for its ionization constant K_A ; indeed, the value of this constant is a quantitative measure of the strength of the acid in question. In accordance with the equation (10), the more dilute the solution, the more extensively is the acid ionized. If it is possible by some analytical technique to determine the concentration of hydronium ions in solution, where the gross concentration of ionized and un-ionized acid is known, K_A may be computed.

No purely chemical method of analysis for H_3O^+ can succeed because, when hydronium ions are removed by any reaction whatsoever, the equilibrium (2) is rapidly re-established and more acid is ionized. Chemical methods, therefore, determine only the gross amount of acid present, not the amount ionized at any given moment; these methods are then useful for quantitative analysis of solutions of acids and bases.

There are, however, many physical methods for determining the momentary concentration (or activity) of the hydronium ions. (See HYDROGEN IONS. Indicators of pH ; Glass Electrode.) They include colorimetric, conductometric, electrometric, catalytic and other methods. Here only the colorimetric method will be outlined, as an example of the type of procedure that can be employed.

If the ion A^- or the acid HA is coloured, or if both are coloured and the colours differ, then the ionization constant can be determined colorimetrically. The colour intensity per mole of the ion A^- is determined from a solution of its sodium or potassium salt; the colour intensity per mole of the acid HA is determined from an aqueous solution of a mixture of the acid in question and some strong acid (such as hydrochloric) which represses the ionization of the weaker acid. The concentrations of the ion A^- and of the acid HA are then determined colorimetrically, or spectrophotometrically, for any solution in which both are present. From considerations of electrical neutrality, the concentration of hydronium ion can then be computed. The method described can be extended to include ultraviolet and Raman as well as visible spectra.

The ion product of water, K_w , has been accurately determined (see equation [3a]) and from this constant and the ionization constant of any acid, the ionization constant of the conjugate

base may be computed as follows:

$$\begin{aligned} [\text{H}_3\text{O}^+][\text{OH}^-] &= K_w = 1 \times 10^{-14} \text{ at } 25^\circ \text{ C.} \\ \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]} &= K_A \\ \frac{[\text{HA}][\text{OH}^-]}{[\text{A}^-]} &= K_w/K_A = K_B \end{aligned} \quad (11)$$

Here as before the symbols HA and A⁻ do not necessarily represent uncharged and charged particles, respectively; they are intended only to show that any acid has one more positive charge (or one less negative charge) than its conjugate base. For example, it is convenient sometimes to speak of the acid strength of the ammonium ion and sometimes of the base strength of ammonia; the two ionization constants are related by equations (11).

It is to be noted that, with an amphoteric substance, HA, the equations (11) relate the acid ionization constant of HA with the basic ionization constant of the conjugate base A⁻ and also relate the basic ionization constant of HA with the acid ionization constant of the conjugate acid H₂A⁺. There is on the other hand no general quantitative relationship between the acid and basic ionization constants of the amphoteric substance HA itself.

In aqueous solution, sulfuric acid, nitric acid and hydrochloric acid are all strong acids; that is to say, they are all largely ionized. The ionization constant of hydrochloric acid and the first ionization constant of sulfuric acid are in fact so large that they have not yet been properly measured in water; the ionization constant of nitric acid, although large, is measurable. Most organic acids, on the other hand, are weak acids, and some of them are very weak.

Table I contains the ionization constants of some representative acids.

TABLE I.—The Ionization Constants of Selected Acids in Water (25° C.)

Acid	K _A
Perchloric acid (HClO ₄)	Too great to measure
Benzene sulfonic acid (C ₆ H ₅ SO ₃ H)	Too great to measure
Sulfuric acid (H ₂ SO ₄)	Too great to measure
Hydrochloric acid (HCl)	Too great to measure
Nitric acid (HNO ₃)	c. 24
Bisulfate ion (HSO ₄ ⁻)	1.01 x 10 ⁻²
Sulfurous acid (H ₂ SO ₃)	1.7 x 10 ⁻²
Phosphoric acid (H ₃ PO ₄)	7.5 x 10 ⁻³
Chloroacetic acid (CH ₂ ClCO ₂ H)	1.4 x 10 ⁻³
Formic acid (HCO ₂ H)	1.8 x 10 ⁻⁴
Acetic acid (CH ₃ CO ₂ H)	1.8 x 10 ⁻⁵
Carbonic acid (H ₂ CO ₃)	4.5 x 10 ⁻⁷
Dihydrogenphosphate ion (H ₂ PO ₄ ⁻)	6.3 x 10 ⁻⁸
Phenol (C ₆ H ₅ OH)	1.3 x 10 ⁻¹⁰
Bicarbonate ion (HCO ₃ ⁻)	4.7 x 10 ⁻¹¹
Water (H ₂ O)	1.8 x 10 ⁻¹⁶
Acetophenone (C ₆ H ₅ COCH ₃)	Too small to measure
Triphenylmethane (C ₆ H ₅) ₃ CH	Too small to measure

It should be pointed out that most of the ionization constants that cannot be measured for aqueous solution can be measured or at least estimated for solutions in other solvents. The strengths of some representative bases are shown in Table II.

It should be noted that with the aid of equations (11) all the data in Tables I and II could have been presented respectively in terms of the ionization constants of the conjugate bases and acids.

The differences in acid and base strength among compounds of the types listed have to a considerable extent been accounted for. The fact that ammonia is a much stronger base than water is related to the atomic structures of nitrogen and oxygen. Oxygen, with a higher nuclear charge, does not attract the positively charged protons as strongly as does nitrogen. The fact that aniline is a weak base compared with ammonia has been ascribed to quantum-mechanical resonance (see RESONANCE, THEORY OF), and the fact that chloroacetic acid is stronger than acetic acid has been ascribed to the electrostatic effect of the carbon-chlorine dipole.

For some purposes, it is convenient to speak not of the activity of the hydronium ion but of the logarithm of that quantity. For a discussion of this matter see HYDROGEN IONS.

TABLE II.—The Ionization Constants of Selected Bases in Water (25° C.)

Base	K _B
Sodium hydroxide (NaOH)	Too great to measure
Guanidine (NH ₂ C[NH]NH ₂)	Too great to measure
Diethylamine ((C ₂ H ₅) ₂ NH)	9.6 x
Ammonia (NH ₃)	1.8 x 10 ⁻⁵
Diethanolamine ((C ₂ H ₄ OH) ₂ NH)	7.6 x 10 ⁻⁷
Diethylaniline (C ₆ H ₅ N[C ₂ H ₅] ₂)	3.7 x 10 ⁻⁸
Aniline (C ₆ H ₅ NH ₂)	4.6 x 10 ⁻¹⁰
Water	1.8 x 10 ⁻¹⁶
Urea ((NH ₂) ₂ CO)	1.5 x 10 ⁻¹⁴
Acetanilide (C ₆ H ₅ NHOCCH ₃)	Too small to measure

Nonaqueous Solvents.—Water solutions have been more thoroughly investigated than any other solutions, but the phenomena of acidity and basicity are by no means limited to solutions in water; in fact, nonaqueous solutions exhibit a broader range of acidity and basicity than do aqueous solutions. In water solution, no acid much stronger than H₃O⁺ can exist, for otherwise it would transfer a proton to the solvent; similarly, in water solution no base much stronger than hydroxide ion can exist since otherwise this base would react with water and accept a proton from it.

For nonaqueous solvents, the classical definitions of acids and bases must be abandoned; the simplest adequate definition is that of Bronsted and Lowry.

Two solvents of particular interest, which illustrate the principles involved, are liquid ammonia (boiling point, -33.4° C.) and pure acetic acid (b.p. 118° C.). An acid dissolving in liquid ammonia reacts with the solvent according to equation (12):

This equation is analogous to equation (2) for water. In liquid ammonia, the ammonium ion is the solvated proton; it functions as an acid.

Similarly, the amide ion, NH₂⁻, functions as a base. Solutions of the ammonium ion in liquid ammonia liberate hydrogen from active metals (*e.g.*, sodium), change the colour of indicators, conduct electricity and neutralize solutions of amide ions. Both the acid in the ammonia system, NH₄⁺, and the base, NH₂⁻, exert strong catalytic effects on reactions carried out in ammonia.

Acids and bases function in analogous fashion in glacial acetic acid. Here the strongest possible base is the acetate ion; any stronger base reacts with the solvent

Strong acids such as sulfuric ionize according to the equation

Solutions of both acids and bases in acetic acid neutralize one another, conduct electricity and strongly catalyze chemical reactions.

A valuable acidity scale has been constructed for sulfuric acid as a solvent; many of the important chemical properties of this acid have thereby been correlated and explained.

ACIREALE, a town on the east coast of Sicily in Catania province, is built on terraces above the Ionian sea at the foot of Mt. Etna. 10 mi. N. of Catania city by road. Pop. (1951) 23,633. The cathedral (1597–1618) has a modern facade. Other features include the baroque church of S. Sebastiano; the church of SS. Pietro e Paolo; the town hall containing a library, museum and

picture gallery; an observatory; a fruit experimental station; and the sulfur springs called Terme di Santa Venera. Acireale is on the railway from Messina to Catania. Mineral water, leatherwork, wine, rice and herbs are produced and exported. Known as Xquilia by the Romans. Acireale was called Reale by Filippo IV in 1642. The first part of the name is derived from the river Aci, which according to mythology welled forth at the death of Acis, the shepherd beloved by Galatea and slain by the giant Polyphemus. After the earthquake of 1693 much of the present town was built. During World War II Acireale fell to the British 8th army in Aug. 1943. (SA. G.; F. V.)

ACIS, in Greek mythology, the son of Pan and the nymph Symaethis. He was a beautiful shepherd of Sicily, the lover of the Nereid Galatea. His rival, the Cyclops Polyphemus, surprised them together and crushed him to pieces with a rock. His blood, gushing forth from beneath, was metamorphosed by Galatea into the river bearing his name (modern Fiume di Jaci).

ACKERMANN, KONRAD ERNST (1712 [1710?]-1771), German actor-manager, was born at Schwerin on Feb. 1, 1712 (1710?). In 1740 he joined the company of Johann Friedrich Schonemann in Liineburg. Schonemann specialized in German adaptations of French plays (Corneille, Racine, Molière, Voltaire), and Ackermann's initial training as an actor consequently was along formal French lines. In 1749 he married the actress Sophie Charlotte Schroder, and with her and a good company toured in Russia, the Baltic states and East Prussia until the Seven Years' War forced him to move to the south and into Switzerland.

Gradually Ackermann developed a taste for domestic drama and a technique for parts in which he could mingle the comic and the sentimental. In 1765 he built a modest playhouse in Hamburg, but by opening night he was heavily in debt; dissension fell over his company, and the next year he had to lease his theatre, not regaining control over it until two years later. Shortly before his death, on Nov. 13, 1771, he turned the management over to his stepson, Friedrich Ludwig Schroder, who was to begin the "naturalization" of Shakespeare in Hamburg.

See J. G. Robertson, *Lessing's Dramatic Theory* (1939); H. Kindermann, *Theatergeschichte der Goethezeit* (1948). (A. M. N.)

ACKERMANN, LOUISE VICTORINE (née CHOQUET) (1813-1890): French poet, whose best work is imbued with a deep pessimism. was born in Paris on Nov. 30, 1813. Educated by her father in the philosophy of the Encyclopédists, she went to Berlin in 1838 to study German, and there married in 1843 Paul Ackermann, an Alsatian philologist. Two years later her husband died, and she went to live at Nice, France. In 1855 she published *Contes en vers* and in 1862 *Contes et poksies*, but her real reputation rests on the *Poksies, premières poksies, poksies philosophiques* (1874), a volume of sombre and powerful verse, expressing her revolt against human suffering. She died at Nice on Aug. 2, 1890.

ACKERMANN, RUDOLPH (1764-1834), Anglo-German inventor who promoted the fashion for coloured prints. He was born on April 20, 1764, at Stolberg in Saxony. In his youth he visited various German towns and Paris; later he settled in London where he made designs for coach-builders. In 1795 he married an Englishwoman and established a print shop and drawing school in the Strand, London. In 1801 he patented a method for rendering paper and cloth waterproof. He was also responsible for the invention of movable carriage axles.

In the artistic sphere Ackermann perfected the aquatint and was among the first in England to establish lithography as a fine art for which, in 1817, he set up a press. His new lithographic process was used in his monthly publication, *The Repository of Arts*, to which Thomas Rowlandson and other artists were contributors. In 1822 he introduced the illustrated annual from Germany, and in 1825 edited the English annual *Forget-me-not*. He published illustrated volumes of topography and travel including histories of the colleges at Oxford and Cambridge. He did much to help foreign exiles in London.

Ackermann died at Finchley, Middlesex, on March 30, 1834.

See W. J. Burke, *Rudolph Ackermann, Promoter of the Arts and Sciences* (1935).

ACKNOWLEDGMENT, a term used in law in various con-

nections. is a written admission that something has been given or done. In the United States it usually refers to a certificate of a public officer, the notary public, that a grantor of a deed has come to him and declared that he executed the instrument. See COMMERCIAL PAPER; REAL PROPERTY AND CONVEYANCING, LAWS OF; NOTARY. (A. DM.)

ACMITE, or AEGIRITE: see PYROXENE.

ACNE is a skin disease that has no specific cause. It is an inflammation located in and around the hair follicles and sebaceous glands of the skin. It is not peculiar to any age or to either sex, although certain age groups are more susceptible than others; it occurs most commonly at the time of puberty and in early adult life. The disease is related in a measure to diet and to hormonal activity. It may be an accumulation of sebaceous material within the follicles but there also may be superimposed infection with more or less marked inflammation and resultant scar formation.

The principles of treatment are based upon proper diet, personal hygiene and medication as prescribed by a physician. Some drugs, the bromides, and iodides, cause acneiform lesions.

The term acne rosacea is used to describe a chronic skin inflammation that is not related to the ordinary form of acne. In this disease there is marked redness of the nose and cheeks and sometimes inflammation with suppuration and disfigurement. The treatment is not always satisfactory and should be supervised by someone skilled in the treatment of skin disorders.

See also SKIN DISEASES.

(F. L. A.)

ACOELOMATA, a term used in zoology to denote those animals in which no second body cavity (coelom) is present. The group includes only the flatworms (Platyhelminthes) and ribbon-worms (Nemertinea). See PLATYHELMINTHES; NEMERTINA.

ACOEMETI, Latinized form of a Greek word meaning "sleepless ones," which was applied to the monks of the Byzantine monastery at Irenaiion (Tchiboukli), on the Asiatic shore of the Bosphorus, because the divine office never ceased, day or night, to be sung there. The monastery was first founded in Constantinople by St. Alexander, who after long study of the Bible put into practice his conviction that God should be perpetually praised by arranging for relays of monks to relieve one another without pause in the choir offices.

After his death in about 430 his successor John transferred the foundation to Irenaiion, where it became known as the monastery of the Xcoemeti. In their enthusiastic attacks on the Monophysites the Acoemeti fell into Nestorian error, and little is heard of them after the 6th century.

See S. Vailhé in A. Baudrillart (ed.), *Dictionnaire d'histoire et de géographie ecclésiastiques*, vol. 1, col. 274-282 (1912).

ACOLYTE, the highest of the four minor orders in the Latin Church. As its name suggests (Gr. *akolouthos*, "server," "companion," "follower"), the office, like that of the subdiaconate with which it is most often associated in ecclesiastical documents, was created in order to assist the deacons, who in a rapidly expanding church were no longer able to cope with all the duties traditionally assigned them (see DEACON).

The first probable reference to the officedates from the time of Pope Victor I (189-199). Pope Cornelius in 251, in enumerating the clergy of Rome, speaks of 42 acolytes active in the city's seven regions (Eusebius, *History of the Church*). After the 4th century, Roman documents mention them frequently. Cyprian (d. 258) witnesses to their existence in north Africa, where their role however seems to have been limited to "carrying candles when the Gospel is read and the Sacrifice offered" and to the personal service of the bishop. Elsewhere in the west, until the fusion of the Gallican and Roman rites after the 9th century, the office was virtually unknown. From the 10th century the order was gradually introduced everywhere as one of the four minor orders leading to the priesthood (the other three being porters, lectors and exorcists). It was so defined by the council of Trent (1545-63) in reply to the Protestant rejection of the sacrament of holy orders. At the present time, as a result of the liturgical movement in certain sectors especially of the Anglican and Lutheran churches, interest is occasionally expressed in the restoration of the pre-

Reformation offices of minor orders. In the east, though mention is made of acolytes in the Apostolic constitutions (Syrian, 4th century), the order did not find permanent acceptance, and it is not used by any of the churches except that in Armenia.

The duties of acolytes varied, historically, according to the extent to which they were permitted to assist the deacons and bishop. At first their tasks were chiefly charitable. In time they acquired a more prominent part in the divine worship: to the acolytes was entrusted the *fermentum* (part of the Host consecrated by the bishop) to be carried to the titular churches of the city as a sign of unity; acolytes accompanying the pope carried the chrism to be used for confirmation, and sometimes, when the number of catechumens was large, they were even permitted to administer the sacrament of baptism together with priests and deacons.

Originally the acolyte was simply named to the office; the present rite of ordination (in the Roman Pontifical) derives largely from an early 6th-century Gallican rite. It consists in the ordaining prelate's exhortation and prayers, and the candidate's touching a candlestick with unlit candle and an empty wine cruet, symbols of his office: for according to this rite the acolyte's duties are to light and carry candles for worship and to prepare the water and wine for the sacrifice. These tasks are now generally performed by laymen. The order of acolyte in modern times is no longer functional, except as a preparatory rite to major orders. The council of Trent had expressed hope for its reactivation on the pastoral level, and the modern liturgical movement has stirred up some concrete suggestions about its functional adaptation to present pastoral needs.

ACOMA, the westernmost Keresan-speaking Indian pueblo, located in Valencia county, N.M., U.S., 54 mi. W.S.W. of Albuquerque on an isolated 357-ft. high sandstone mesa rising from the piñon and juniper-dotted Cebolleta mesa country in which lie the village sheep-grazing lands and irrigated fields along the San José river. The total acreage of land is about 256,000 of which 94,159 was the Spanish grant of 1689. The Acoma reservation was created in 1928 and has been supplemented by purchased and rented land. The majority of the population of 1,500 lives in the daughter villages of Acomita (Tichuna) and McCartyst (Santa Maria), returning to the old town for ceremonies, the most

SAN ESTEBAN REY MISSION. ACOMA, NEW MEXICO. BUILT IN 1629 BY FRIAR JUAN RAMÍREZ

important of which are the winter solstice, summer rain dance, and harvest dance and St. Stephen's day fiesta on Sept. 2. Outsiders are unwelcome at all but the September fiesta.

Acoma was established no later than A.D. 1250, according to archaeological evidence and has been occupied continuously. The

name is from the native term *Akóme*, "people of the white rock," who call their stone masonry, terraced-house town, A'ko.

Marcos de Niza, Spanish Franciscan explorer, mentioned the town in 1539; in 1540 it was visited by Coronado's army, then in 1583 by Antonio de Espejo, and again in 1598 by Juan de Oñate. A Spanish force was ambushed at the pueblo in 1598, leading to Spanish reprisals in 1599 that killed half the population and partly burned the town.

The first church was established in 1629 and replaced in 1699 by the present adobe structure. Acoma participated successfully in the Pueblo revolt of 1680 against the Spanish, but in 1699 again submitted to Spanish rule. From a population of 1,500 at the time of the revolt the town dwindled to around 500 in the first quarter of the 20th century.

Acoma is an independent social, political and ceremonial unit, traditionally headed by a cacique, always a member of the Antelope clan. The war chief is the next most important official. The population is divided into 14 matrilineal, exogamous, totemically named clans, but the economic unit is the household. Religious organization centres in the medicine societies and kachina (masked god) cult into which both boys and girls are initiated. There are seven ceremonial rooms (kivas) in the pueblo. The secular government, post-Spanish in origin, comprises a governor and appointed and elected subofficials. Federal administration is by the united Pueblos agency of the bureau of Indian affairs in Albuquerque.

White, "The Acoma Indians," *47th Annual Report of the Bureau of American Ethnology*, 1929-30, pp. 17-192 (1932); E. C. Parsons, *Pueblo Indian Religion*, 2 vol. (1939); Fred Eggan, *Social Organization of the Western Pueblos* (1950). (N. F. S. W.)

ACOMINATUS: see CHONIATES, MICHAEL; CHONIATES, NICETAS.

ACONCAGUA, a province in the northern part of central Chile, bounded on the north by Coquimbo, east by Argentina, south by Santiago and Valparaíso, and west by the Pacific. It has an area of 3,940 sq.mi. and a population (1952) of 128,378. It is divided into the departments of Petorca, San Felipe and Los Andes. The surface of the land is mostly mountainous, interrupted by broad valleys, including the northern reaches of the famous Central valley of Chile, which lies between the coastal ranges and the piedmont alluvial slopes of the Andes. The major valleys, however, are transverse and include those of the Aconcagua and Ligua rivers, together with those of their tributaries. Climatologically the province lies in a transitional zone between the arid northern part of Chile and the subhumid central part. The annual rainfall, which amounts to but a few inches, coincides with the winter season; summers are rainless, but the drought is mitigated somewhat along the coast by the presence of persistent fogs. Inland the skies are clear in summer and the temperatures are high. The natural vegetation (cacti, scrub and grasses) resembles closely the *chaparral* of the southwestern Pacific area of the United States, or the *maqui* of Mediterranean Europe. The valleys are highly fertile! and where irrigation is employed crops of alfalfa, wine grapes, fruits and vegetables are produced in abundance. San Felipe, capital of the province, is on the Río Aconcagua in a rich agricultural area, connected by rail (Transandine railway) with Valparaíso (80 mi.), and by rail and car with Mendoza, Argentina.

ACONCAGUA, a mountain in the southern Andes, commonly regarded as the highest summit in the western world (22,834 ft. above sea level). It is on the boundary of Chile and Argentina in 32° 39' S. and 70° 1' W. The peak of Aconcagua is in Mendoza province in northwest Argentina, but its western flanks build up from the coastal lowlands of Chile. While Aconcagua is of volcanic origin it is not itself a volcano. The first attempted ascent, made by Paul Giissfeldt in 1883, failed. Aconcagua's summit was first reached by Stuart Vines and Mattias Zurbriggen of the Edward Fitzgerald expedition in 1897.

(J. L. Tr.)

ACONITE (*Aconitum*), a genus of flowering herbs belonging to the Ranunculaceae (*q.v.*; buttercup, crowfoot) family, includes

many species which grow in cool, damp, mountainous areas of the northern hemisphere. The common names monkshood and friar's-cap are descriptive of the helmet- or hood-shaped blue or yellow flowers of the plant. The synonym wolfsbane indicates its poisonous nature. The aconites are ornamental, hardy perennials which are propagated by divisions of the roots or by seed. Prolonged storage and drying of the seeds results in a decreased ability to germinate.

J. HORACE MCFARLAND CO.

COMMON MONKSHOOD (ACONITUM NAPELLUS)

Medicinally, aconite refers to the dried root of *Aconitum napellus*, which is extracted to provide useful tinctures and fluid extracts. Aconitine, an alkaloid present in the roots, is responsible for the pharmacological actions of the plant. The roots of *Aconitum ferox* are the source of the famous Indian (Nepalese) poison known as bikh, bish or nabee. *Aconitum ferox* owes its toxicity to the presence of pseudoaconitine, one of the deadliest poisons known. Other allied species include *Aconitum lycoctonum*, *A. heterophyllum*, *A. paniculatum* and *A. spicatum*, all of which contain alkaloids with varying degrees of pharmacological potency.

Medicinal Uses and Pharmacological Actions.—Since ancient times it has been known that aconite exerts a profound effect upon the physiological func-

tions of the body. The ancient Chinese, Gauls and hill tribes of India used various species of aconite for preparing arrow poisons. The rational use of aconite in medicine began with the observations of Anton Storerck in 1763. Storerck described the tingling sensation, salivation and sweating caused by ingestion of the plant, and proposed its use for relieving rheumatic and neuralgic pain, for reducing swellings and healing ulcers. Alexander Fleming (1824–75) accurately described the actions of aconite in a report of a comprehensive experimental and clinical study of *Aconitum napellus* in 1845.

When applied locally, preparations of aconite produce a tingling sensation with warmth followed by numbness and anesthesia. These actions are not accompanied by redness, pain, swelling or other signs of inflammation, and the apparent irritation is therefore sensory. Aconite in the form of oil base liniments or ointments is absorbed through the skin. Preparations of aconite were formerly applied locally for the relief of toothache, neuralgia, migraine, rheumatic and similar pains.

Systemically, aconite in therapeutic doses causes a slowing of the heart rate with a slight fall in blood pressure and weakening of the pulse. If taken orally a numbness and tingling of the fingertips and arms occurs. Respiration is moderately slowed and laboured. Because of its action on the heart and circulation, aconite has been used systemically in the treatment of heart disease, hypertension and severe fevers. Aconite is seldom used in modern medicine, however, because of the toxic nature of the drug and its general inefficiency at therapeutic dosage levels. The local application, of preparations of aconite to open wounds and abraded areas of the skin may also lead to systemic poisoning. The potency of aconite and its preparations is determined and standardized by biological assay. The assay consists of comparing the toxicity to guinea pigs of a tincture of aconite with the toxicity of a known quantity of the purified active ingredient aconitine.

Toxicology.—Poisoning by aconite may occur in connection

with its medicinal use or by the accidental ingestion of the plants, which are grown in gardens as ornamentals. Aconite is rarely used deliberately as a poison because the tingling sensation in the mouth, stomach and skin warns the victim and is diagnostic for the drug. Full therapeutic dosage as formerly used may cause toxic symptoms consisting of giddiness, confusion, lethargy and a feeling of cold. Moderately toxic doses cause nausea, vomiting, diarrhea, difficult respiration, muscular weakness, cold skin, impairment of the special senses and speech, convulsions and death from respiratory or heart failure. Very large doses may produce rapidly fatal ventricular fibrillation. No specific antidote for aconite poisoning is available. The drug should be removed from the stomach and the patient kept warm. Atropine may be useful, and artificial respiration can be lifesaving. Intravenous epinephrine may be of value in extreme emergencies.

Chemistry.—The pharmacologically active ingredients of the aconites are alkaloids (*q.v.*). Aconitine ($C_{34}H_{47}O_{11}N$), obtained from *Aconitum napellus* and also found in the Soviet aconite *A. karakolicum*, is the acetyl-benzoyl-ester of aconine, a base derived from quinoline. It decomposes readily upon heating in solution to form benzoyl aconine (picroaconitine, isaconitine) and aconine which are only $\frac{1}{50}$ and $\frac{1}{2,000}$ as active as aconitine respectively. Small quantities of aconitine may be identified by mixing with a few drops of sulfuric acid containing ammonium vanadate; an orange colour is produced.

Other species of aconite contain alkaloids with similar chemistry and pharmacological actions. Pseudoaconitine is obtained from Indian species of aconite: *A. deinorrhizum*, *A. balfourii*, *A. laciniatum* and *A. ferox*. Jesaconitine and japaconitine are found in the roots of the Japanese aconites. Bikhaconitine is present in *Aconitum spicatum*, and *A. chasmanthum* contains indaconitine. The base aconine is believed to be common to all aconitines.

(K. P. DU.)

ACONITINE, a poisonous alkaloid, the active principle of aconite, found particularly in plants of the monkshood or larkspur family. See ACONITE; ALKALOIDS.

ACONTIUS, in Greek legend, a beautiful youth of the island of Ceos. During the festival of Artemis, at Delos, Acontius saw and loved Cydippe, a girl of rich and noble family. He wrote on an apple the words "I swear to wed Acontius" and threw it at her feet. She picked it up and mechanically read the words aloud, thus binding herself by an oath. Therefore, although she was betrothed more than once, she always fell ill before the wedding took place. The Delphic oracle at last explained the matter, and she married Acontius.

ACONZIO (ACONCIO), **JACOPO** (JACOBUS ACONTIUS) (1492–1566?), pioneer of religious toleration, was one of the Italians who, like Peter Martyr (Pietro Martire Vermigli, *q.v.*) and Bernardino Ochino (*q.v.*), repudiated Roman Catholic doctrine and ultimately found refuge in England. His revolt against Roman Catholic doctrine, like theirs, took a more extreme form than Lutheranism. After a temporary residence in Switzerland and at Strasbourg he arrived in England soon after the accession of Elizabeth I. Aconzio had studied law and theology, but his profession was that of engineer, in which capacity he found employment with the English government. For some time he was occupied with draining Plumstead marshes, and in 1564 he was sent to report on the fortifications of Berwick. His importance, however, depends upon his contributions to the history of religious toleration.

Before reaching England he had published a treatise on the methods of investigation, *De Methodo, hoc est, de recta investigandarum tradendarumque scientiarum ratione* (1558), and his critical spirit placed him outside all the recognized religious societies of his time. On his arrival in London he joined the Dutch Reformed Church, but he was "infected with Anabaptistical and Arian opinions" and was excluded from the sacrament by Grindal, bishop of London. The real nature of his heterodoxy is revealed in his *Stratagemata Satanae* (1565). The "stratagems of Satan" are the dogmatic creeds which rent the Christian church. Aconzio sought to reduce dogma to a minimum in the hope of finding a common denominator for the various creeds.

ACORN SHELL, or acorn barnacle, popular name given to

sessile forms of barnacles common on rocks, piers, etc., on sea coasts. In the United States they are often called rock barnacles. See BARNACLE.

ACORUS CALAMUS, sweet sedge or sweet flag, a marsh plant of the family Araceae (*q.v.*), found throughout the north temperate zone. The name is derived from the Greek *acoros*, the classical name for the plant. It was the *Calamus aromaticus* of the medieval druggists and perhaps of the ancients, though the latter has been referred by some to citronella grass, *Cymbopogon nardus*.

The plant is a herbaceous perennial with a long, branched rootstock creeping through the mud, about three-fourths inch thick, with short joints and large brownish leaf-scars.

The leaves are tufted, flat, swordlike, sweet scented, three or four feet long and about an inch wide, closely arranged in two rows as in the true flag (*Iris*); the tall flowering stems (scapes), which very much resemble the leaves, bear an apparently lateral, blunt, tapering, spikelike cluster (spadix) of densely packed, very small flowers.

A long leaf (spathe) borne immediately below the cluster forms an apparent continuation of the scape, though really a lateral outgrowth from it, the spadix being terminal. The rootstock yields the drug calamus, and a variegated form is cultivated for ornament.

ACOSMISM. This term was coined by Fichte and Hegel on the model of the term atheism (*q.v.*). According to the ordinary view, reality consists of God and a world (cosmos) of finite objects usually conceived as having been created by Him and made to conform to certain laws. Now atheism is the theory which denies the existence of God; and so identifies reality with a godless world of objects and events which exist of themselves and have an inherent order of their own. Acosmism is the contrary view that denies the independent reality of a world of finite objects and events, and regards God as the sole ultimate reality. In accordance with the common practice of denouncing anybody as an atheist whose conception of God was different from theirs, Spinoza was generally described as an atheist by his contemporaries and others. Hegel protested against the injustice of this. Spinoza, he said, was so far from denying the existence of God that he acknowledged no other ultimate reality—so far from being an atheist he was an acosmist. Fichte similarly applied the term to himself in reply to similar accusations. The term acosmism has since been applied also to philosophies like those of the Vedanta, of Buddhism, and of Schopenhauer. Apart from its polemical uses the term acosmism, with its suggestion of an illusory world, is not a happy equivalent of the term pantheism. Strictly speaking, a pantheism like that of Spinoza no more denies the reality of the world than it denies the reality of God. It simply identifies the universe with God, and for that very reason regards the universe all the more as a world of order, a real cosmos. Moreover, there is an important sense in which pantheism is essentially cosmic, namely, in the sense that it regards man from the standpoint of the universe, instead of regarding the universe from the point of view of man. Acosmism is therefore not only an inadequate but also a misleading description of pantheism (*q.v.*).

ACOSTA, JOAQUÍN (1800–1852), Colombian scientist, historian and statesman, an officer in the patriot army under Simón Bolívar, who set himself the task of reviving Colombia's colourful past for his young fellow countrymen, was born in Guaduas, on Dec. 29, 1800. He first intended to reprint some of the chronicles originating during the period of discovery and colonization, but abandoned his plan on realizing that the accounts were incomplete, factually inaccurate and archaic in language. To fill what he considered a civic need, he composed his *Compendio histórico del descubrimiento y colonización de la Nueva Granada en el siglo décimosexto* ("A Historical Compendium of the Discovery and Colonization of New Granada in the 16th Century"), which was published in Paris in 1848. This work covers in 20 chapters the eventful years from Columbus' earliest landings and explorations on the mainland, in 1498, to the death in 1579 of the conqueror of New Granada, Gonzalo Jiménez de Quesada. The carefully documented account is based partly on Acosta's

findings in Colombian archives, partly on his research in the Archives of the Indies in Spain and partly on his travels throughout Colombia during military operations. Thus following the trail of the early conquerors, he was able to corroborate, or correct, the chronicles that served as his sources. Patriotism, humility and a succinct, unadorned, soldierly style mark the *Compendia*, as well as his many shorter historical and scientific works.

Acosta died in Guaduas on Feb. 21, 1852.

See Soledad Acosta de Samper, *Biografía del General Joaquín Acosta* (1883). (K. L. L.)

ACOSTA, JOSE DE (1540–1600), Spanish Jesuit missionary, who was the author of several works on the natural history of Spanish America, was born at Medina del Campo in Sept. or Oct. 1540. He joined the Jesuits in 1551, became a novice the following year and in 1571 was sent as a missionary to Peru. He acted as provincial of his order from 1576 to 1581, was appointed theological adviser to the council of Lima in 1582, and in 1583 published a catechism in Quichua and Aymará—the first book printed in Peru. After traveling to Mexico he returned, in 1587, to Spain where he remained thereafter, except for a visit to Rome in 1588. In 1597 he became rector of the Jesuit college at Salamanca, where he died on Feb. 15, 1600. His treatise *De natura novi orbis libri duo* (1588–89) may be regarded as the preliminary draft of his celebrated *Historia natural y moral de las Indias* (1590), which was speedily translated into Italian (1596), French (1597), Dutch (1598), German (1601), Latin (1602) and English (1604). Apart from his sophistical defense of Spanish colonial policy, Acosta deserves praise as an acute and diligent observer. Among his other publications is *De procuranda salute Indorum libri sex* (1588).

See Edward Grimston's translation of the *Historia* reprinted (1880) for the Hakluyt society, with introduction and notes by Sir Clements R. Markham; León Lopetegui, *El Padre José de Acosta y las misiones* (1942).

ACOSTA, URIEL (c. 1585–1640), portuguese-Jewish philosopher and a significant forerunner of Spinoza and the Enlightenment, rejected revealed religions as false, and advocated a religion based on natural law and reason which would cherish life, property and human dignity. Born in Oporto to a noble Catholic family of Jewish descent, Acosta studied canon law and became the treasurer of a cathedral chapter. Disturbed by the conviction that there was no salvation through the church, he turned to the Judaism of the Old Testament. After converting his mother and brothers to his beliefs, he and the family fled to Amsterdam and embraced Judaism. Acosta soon discovered, however, that the prevailing form of Judaism was not biblical but an elaborate structure based on rabbinic legislation. Stunned, he formulated 11 theses (1616) attacking rabbinic Judaism as nonbiblical, for which he was excommunicated. Acosta then prepared a larger work condemning rabbinic Judaism and denying the immortality of the soul (1623–24). For this denial, the Amsterdam magistracy arrested, fined and deprived him of his books. A sensitive soul, Acosta was unable to bear the isolation of excommunication, and he recanted. Excommunicated again, he made a public recantation. This humiliation shattered his self-esteem, and, after penning a short autobiography, *Exemplar Humanæ Vitæ*, he shot himself, April 1640. Acosta's *Exemplar* attacks revealed religion as disruptive of natural law and a source of hatred and superstition. In contrast, the religion of nature and reason bids us love our fellowman.

ACOUSTICS OF BUILDINGS. Acoustics of buildings, or architectural acoustics, is a field of engineering concerned with providing a satisfactory acoustic environment and good hearing conditions in every building. Acoustics is as important in the development of any building project as any other technical aspect

of modern construction. Available information about architectural acoustics usually permits the design and construction of acoustically satisfactory buildings without need for later corrective measures. If the acoustics of a finished building is found unsatisfactory, it is often too late to do anything without great difficulty. Good acoustics must be planned in advance.

Everyone knows that an auditorium or a church needs special attention to acoustics, but few realize that the apartment house and the office building pose equally important and difficult problems, many of which can be handled with little or no additional expense. In a sense every element of design and construction of a building has some influence on its acoustical characteristics. The selection and utilization of the site, the horizontal and vertical interrelation of the spaces within the building, the general choice of materials and construction, and the shapes of rooms all determine the result. These matters of functional analysis, together with specific methods, will be discussed in the following sections.

ACOUSTIC ENVIRONMENT

Range of Sounds.—The table shows that the range of sounds that must be tolerated by the ear is enormous, extending from a threshold value of 1 arbitrary unit for a faint sound that can just be detected to 1,000,000,000,000 units for a very loud sound.

Intensity of Sound

Units	Decibels	Type of noise
1,000,000,000,000 . .	120	
100,000,000,000 . . .	110	Airplane engine nearby
10,000,000,000	100	Airplane cabin (normal flight)
1,000,000,000	90	Heavy traffic, pneumatic drill
100,000,000	80	
10,000,000	70	Noisy office, telephone conversation, ordinary traffic
1,000,000	60	Average office
100,000	50	Ordinary conversation
10,000	40	Quiet home, quiet conversation
1,000	30	
100	20	
10	10	Rustle of leaves, whisper
1	0	

Smaller numbers to express this vast range have been developed by using the decibel unit, the number of decibels between two intensity levels being obtained by taking ten times the logarithm of the ratio of the intensities. Although the tolerable range is very great, the absolute energy of sound is very small, an average voice having only about one-millionth of the energy needed to operate an ordinary electric lamp. (For the general principles of acoustics and hearing see SOUND and HEARING.)

Noise.—A satisfactory acoustic environment is one in which the character and magnitude of all noises are compatible with the satisfactory use of the space for its intended purpose. Distracting noises can make it quite difficult to study in a library reading room, while the same noises might be acceptable in a large business office. But even in the business office there are limits of noise intrusion beyond which the workers find it difficult to maintain efficiency and composure. There is a wide range of acceptable background noise levels in rooms, depending on the occupancy, the time of day, the noise conditioning that the occupants have undergone, and other factors. A dripping faucet in the middle of the night can keep a person awake, while a gentle rain which actually makes more noise can put him to sleep. Noise, or unwanted sound in a building, comes from many sources: automobiles and airplanes, industry, adjoining apartments or offices, ventilating and air-conditioning equipment, typewriters, telephones, household appliances, children playing, and many others. A certain amount of noise from activity inside and outside gives the building life, but too much noise from any source can reach levels that actually impair health. (See also NOISE AND ITS CONTROL.)

"Acoustic Perfume."—We can understand the usefulness of a moderate amount of background noise in a case like a library located on a city street. Little attention is paid to continuous and expected traffic sounds unless something like a fire engine goes by. This background noise does, however, mask many sounds within the reading room, such as the conversations at the lending desk, the occasional telephone calls, the typewriting, the coming and going of other people. Privacy and lack of distraction

from the other activities in the room are made possible. This type of background noise is referred to as "acoustic perfume." The technique of hiding disturbing sounds with pleasant ones is sometimes the only solution to a problem of annoyance.

When a superhighway was constructed near a large country estate the owner was greatly annoyed. In his garden he felt the constant intrusion of automobile traffic. The solution he adopted was to install fountains. The splashing water hid the noise of the traffic, and gave the owner a sense of remoteness from the highway. There is a limit, however, to the use of noise as a "perfume."

GOOD HEARING CONDITIONS

In order to have good hearing conditions in any space, whether it be a courtroom, a church, a lecture room, an outdoor theatre or even a living room, it is essential that four basic requirements be met: (1) adequate loudness of the sounds to be heard; (2) good distribution of the sounds to be heard; (3) proper blending of the sounds with adequate separation for good articulation of music or speech; and (4) quiet.

Loudness and Distribution.—When sound is radiated from a source in free field, the spherical sound wave moves at about 1,100 ft. per second. The energy is spread over a sphere of increasing area, and the intensity decreases inversely to the square of the distance. When an audience is placed in front of a source (e.g., a person speaking), the conditions found in free field do not exist. If the person talking is at almost the same level as the audience, there is an additional loss of intensity as the sound grazes over the people seated in the audience. This is especially

FIG. 1.—DISTRIBUTION OF SOUND WHEN AUDIENCE IS SEATED ON LEVEL GROUND OUTDOORS

important when the audience is on level ground (see fig. 1). The ancient Greeks and Romans understood this very well; they built their theatres on steep hillsides in quiet locations (fig. 2) and found that, with the audience placed at a very steep angle, conditions were almost as good as in free field. An alternative is to raise the source of sound high above the audience, but this is not usually convenient. A more satisfactory arrangement is to let the ceiling of the room act as a sound mirror, bringing reflected sound down on top of the audience to reinforce the direct sound. In most auditoriums more sound energy is actually received from the ceiling than directly from the source of sound. The ceiling is the most important surface in the room in assuring adequate loudness and good distribution. A ceiling in any room where hearing conditions for an audience are to be good must always be hard and sound reflecting, never sound absorbing. There is much misunderstanding of this point.

It is obvious that a listener must be seated so that he can "see" the ceiling if he is to receive useful reflections from it. If he is seated under a deep balcony, he often will not receive these reflections and will get only the direct sound which has grazed over the sound-absorbing audience ahead of him. The undersurface of a balcony should always slope, giving the people seated on the main floor a view of a large area of the main sound-reflecting ceiling. Many auditoriums and churches have been built with sound-absorbing ceilings, and therefore require sound-amplifying systems for the spoken voice since ceiling reflections are lost. Without these reflections the members of a congregation do not hear each other very well, and each person feels as if he were singing or praying alone—there is little sense of congregational worship. This same principle of re-

FIG. 2.—DISTRIBUTION OF SOUND IN AN OUTDOOR THEATRE OF THE CLASSICAL GREEK DESIGN

flection applies to a chorus or orchestra. In order for the members to hear each other, and play together, it is essential to have a sound-reflecting ceiling not more than 25 or 30 ft. overhead. An orchestra finds it difficult to give a good performance in an auditorium filled with sound-absorbing scenery and draperies. Some surfaces in an auditorium can give reflections so long after the original sound that there are annoying echoes. Rear walls, excessively high ceilings and other distant surfaces can cause trouble of this sort. It is common practice to place sound-absorbing materials on these surfaces.

Sound Amplification.—If the background sound level is very high or if the volume of the room is too great, adequate loudness can sometimes only be achieved by using a sound-amplifying system. In general, the most realistic amplification is obtained when

FIG. 3. — DISTRIBUTION OF SOUND IN WELL-CONSTRUCTED AUDITORIUM

the loud-speaker is placed directly over the source being amplified. The direction from which a sound has come is very readily located, so the amplified sound should come from the same direction as the original source. It is confusing to see a person speaking from the middle of a platform and hear loud-speakers at each side of the platform. Even worse is to hear a loud-speaker from behind when the original source is in front.

If it is not necessary to associate the amplified sound with the original source, as in an airport terminal: a distributed system of loud-speakers can be used. These must all be operated at a low level so that a listener hears only a loud-speaker that is near him. A distributed system of loud-speakers may be considered as analogous to a lighting scheme, in which each light covers a localized area.

Loud-speaker systems are often used when they are unnecessary. In a hall smaller than 50,000 cu.ft., a loud-speaker system is almost never necessary, and until the volume is greater than 200,000 cu.ft. it is seldom needed. In larger auditoriums many voices will need amplification, especially if the room is bigger than 500,000 cu.ft. In very large sports buildings, where the wall and ceiling surfaces are usually treated with sound-absorbing materials for the control of echoes and audience noise, a good public-address system is essential. Its design must be carefully integrated with the disposition of the audience and the shape and acoustical treatment of the building.

Blending and Separation.—The sound that is radiated by a source will fall not only on the audience directly and by reflection from the ceiling but will be reflected many times from all surfaces until all of the energy has been absorbed. This actually results in a persistence of the sound after it has left the source and is called reverberation. Reverberation time in a room is defined as the time required for the intensity of a sound to decrease to one-millionth of its original value. A longer reverberation time is desirable in a church, where music is important, than in a conference room. A concert hall should have a reverberation time somewhat greater than 1.8 sec., while for a multipurpose auditorium it should probably not be more than 1.5 sec. If it is too high, there may be too much blurring of successive sounds or syllables. If it is too low, there will be too much articulation or separation, and there will be no sense of fullness, especially for musical performances. While optimum reverberation is an essential attribute of a good auditorium, it is important to realize that it is only one of the four essential requirements

Reverberation time is determined by the volume of the room

and by the sound-absorbing properties of the finishes, furnishings, and people in it. Sound absorption is specified in terms of sound-absorbing units. In most auditoriums the audience is the principal absorber of sound. Fabric upholstered seats which have about the same sound-absorbing characteristics empty or filled, will minimize the variation in the reverberation characteristics of an auditorium with large or small audiences. If hard seats are used, the auditorium will sound more reverberant when it is empty.

Sound-absorbing treatment for the control of echoes usually produces the desired reverberation characteristic. The treatment of the entire ceiling of a room with acoustical materials not only deprives the listeners of needed reflections for adequate loudness but also results in extremely low reverberation time.

Quiet.—Unless there is quiet, really good hearing conditions cannot exist. Good hearing cannot be expected in an outdoor theatre in a city park with cars going by on all sides. An air-conditioning system for a church should not be so loud that it must be shut off during the service. Too much noise is very often the cause of poor hearing conditions.

Noise Control.—Noise control in buildings is achieved by means of: (1) proper planning to separate noise from quiet spaces; (2) proper design in detailing of structures to block effectively the transmission of sound; and (3) proper utilization of finishes and furnishings to absorb sound (drain off sound energy).

These three techniques are based on distinctly different physical principles. The first and simplest way to control noise is to separate the source as far as possible from the listener. In a school, the band room should be placed far away from the library and other classrooms. If it must be placed next to the library, the surrounding construction will be expensive, and the result will probably not be as satisfactory as if it had been placed far away. A television studio should not be located under a printing plant, nor should air-conditioning compressors be placed on the floor above an executive office. This relation between noisy and quiet spaces occurs often, and the solutions are almost always expensive and seldom completely satisfactory.

There are problems of noise isolation that cannot be solved by separation, such as neighbouring apartments, hotel rooms, offices, the psychiatrist's office next to his waiting room, and the Sunday school in the church basement during the regular morning church service.

Sound is a wave motion in which individual molecules of the air move back and forth at a rate determined by the frequency of the source of sound. This motion results in alternate compressions and rarefactions which act on the eardrums or other receiver. When these oscillating molecules of air encounter a barrier, such as a wall, they try to set it in motion. An effective sound-isolating wall or floor is one that is heavy, solid, impervious, with no leaks or cracks in or around it. The heavier the wall, the less it will move under the action of the sound waves. If it is lightweight, or porous, or has holes or cracks in it, the sound will be transmitted.

The amount that a construction reduces the transmission of sound, usually given in decibels, is called the transmission loss. In fig. 4 the average transmission losses for some common constructions are shown. Relatively high noise isolation can be achieved by using two separated heavy elements rather than a single extremely heavy unit. The transmission loss of a four-inch brick or concrete wall can be attained with a double plaster wall, using separated studs so that the two faces are not in contact with each other or resilient clips connecting the two plaster skins to a single set of studs. The equivalent of 12 in. of brick can be achieved with two $\frac{1}{2}$ -in. sheets of glass, separated by 6 in. If the two elements of the wall are each reasonably heavy and airtight, and are not in direct contact with each other, they afford a much more efficient sound-isolating construction than a single massive unit. However, the control of the transmission of sound is governed almost entirely by the weight of the components.

Airtight construction can be very important in achieving good isolation between spaces. A solid flush wood door with a threshold crack has negligible transmission loss (perhaps ten decibels). With tight gaskets all around, it can have a transmission loss of 25 or

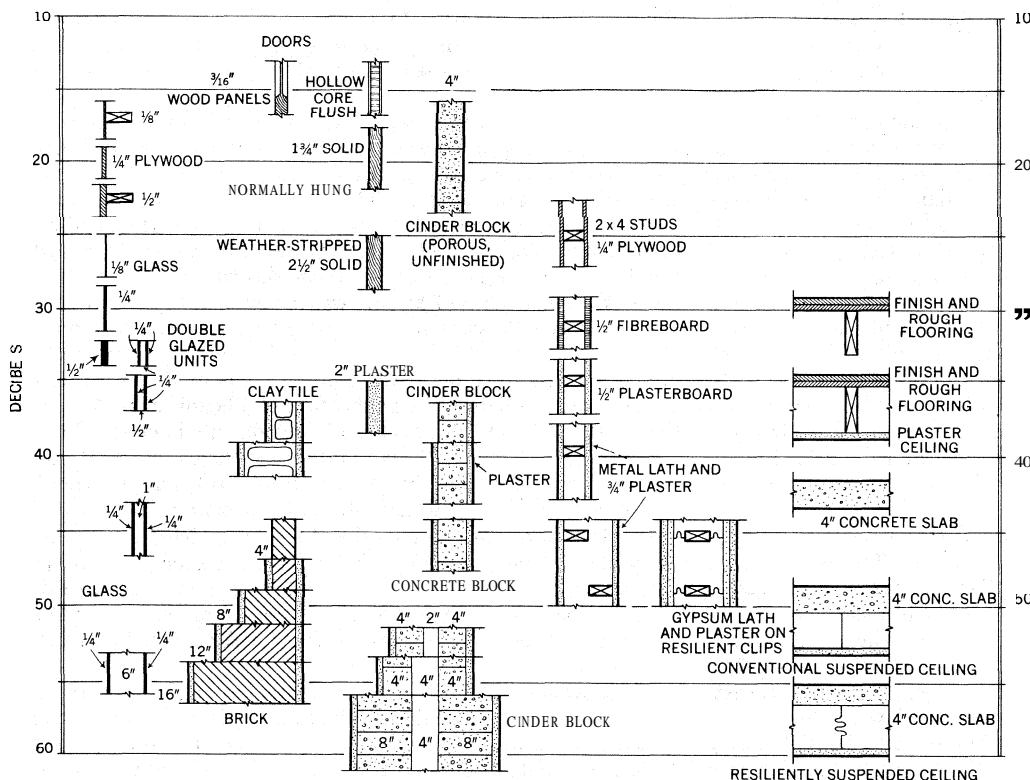

FIG. 4.— AVERAGE TRANSMISSION LOSS FOR TYPICAL KINDS OF CONSTRUCTION

30 decibels, which is enough to give adequate privacy in many cases. The back-to-back convenience outlet, the space around steam pipes and many other small leaks and cracks of this sort can ruin otherwise good construction. The design of a sound-isolating enclosure involves more than the choice of an adequate wall structure. Careful attention must be given to the proper detailing of all joints, inserted elements, and connections with the basic structure of the building.

Another difficult problem in noise isolation is that of impact sounds from spaces overhead. Pianos, footfall noises and the noises of machinery are transmitted directly through the floor construction. Carpets and resilient pads can help in reducing this problem. A piece of machinery should be mounted on resilient supports (specially designed rubber and steel spring mounts) so that there is no direct driving of the floor as a sounding board. Cork is seldom adequate for this although it is often used.

If extremely high sound isolation is required, as in a broadcast studio or a room for specialized audiometry research, it may be necessary to provide a completely floated interior construction, with the room itself forming an inner shell within the building structure. This involves many problems of resilient connection, of ventilation through lined sound-reducing ducts, etc., and is only necessary in extreme situations.

Sound Absorption.—In addition to planning for segregation of sound and designing and detailing structures to block effectively the transmission of sounds, one more control mechanism is available: sound absorption within a space. Every material in a room absorbs some sound, but those used for noise or reverberation control are usually soft, porous materials, like hair felt, carpeting, heavy fabrics and acoustical tiles. These materials almost always have fibrous structures which permit air to flow in and out. The air molecules in the sound wave encounter the fibres in the sound-absorbing material and experience a frictional drag. The spaces between the fibres must be very small if a significant amount of energy is going to be given up by the sound wave. This energy goes into heat, although the amount of heat produced is actually very small. A sound wave striking a one-inch blanket of hair felt can lose as much as 70% or 80% of its incident energy in heat and only 20% or 30% will be reflected back to the room.

The difference between sound absorption and sound isolation

must be understood. Sound absorption demands porosity which permits the molecules of air to move in and out freely. A sound-absorbing material, used alone as a barrier, permits a great deal of sound energy to go through it, and thus is a very poor sound isolator. A curtain hung over a wall, for example, will do almost nothing to increase its sound-isolation value. Sound isolation requires heavy, impervious elements. There is wide misunderstanding of this problem, and much time and money is wasted in attempting to improve sound isolation by the use of sound-absorbing materials. A common example is the home owner who nails standard acoustical tiles to the underside of the floor joist to improve the sound isolation between a noisy playroom and a living room. While the acoustical tile will absorb some sound energy in the noisy space below, it will add almost nothing to the sound-isolation properties of the floor construction. A plaster ceiling on the underside of the joists is needed, with the acoustical

tile applied to it for reverberation control in the playroom.

Sound-absorbing treatment in a room, by controlling reverberation and spread of sound, gives a sense of comfort. Sounds stay where they belong and do not seem to jangle from everywhere. Everyone knows the difference between the sound of an empty house and of a furnished one. Sensible use of sound-absorbing materials can improve the acoustic environment in almost any space.

ACRANIA, an obsolescent term for Cephalochorda, a sub-phylum of small marine animals, members of the phylum Chordata (see CHORDATE). The group is typified by the well-known lower chordate *Amphioxus* (q.v.).

ACRE, a territory of Brazil named for the Acre river which rises in Bolivia and flows in a northeasterly direction through the territory to join the Purus river. The territory of Acre has a common border with Peru on the west and with Bolivia on the south. It lies entirely within the Amazon drainage system. The territory is in a region of heavy rainfall and dozens of rivers traverse its low, level lands. River boats provide the principal means of bulk transportation. Acre has an area of 58,915 sq.mi. and in 1956 had an estimated population of 143,000. Its capital, Rio Branco, in the eastern portion of the territory, had a population of 9,371 in 1950. From the mid-1890s until about 1910, Acre was economically important as a rubber-producing area. Agricultural crops produced for local consumption include rice, sugar, manioc, coffee and corn. Cattle and hogs are raised on a small scale. The rivers contain many edible fish.

Until the 1890s when rubber gatherers from Brazil flocked into the region, Acre was considered to belong to Bolivia, although distances and jungles made tenuous that nation's hold on the area. In 1898, when it undertook to enforce its revenue laws by establishing a customhouse at Puerto Alonso (Pôrto Acre) on the Acre river, Bolivian authority was openly challenged by the rubber gatherers, armed by Brazilian entrepreneurs. Unrest and official indecision led to the proclamation of an independent state of Acre

in July 1899 under the leadership of a Spanish adventurer, Luis Gálvez Rodríguez. Bolivian authority was not re-established until April 1901. About that time Bolivia granted to an English group a concession which gave it nearly complete control over the area. The Brazilian foreign office, fearing such a circumstance, retaliated by closing the Amazon to commerce in transit to and from Bolivia. Early in 1903 war appeared imminent but Bolivia, suffering from internal disorders, accepted a Brazilian offer to undertake the pacification of the area. The English group was bought out, and on Nov. 17, 1903, at Petrópolis, Brazil, a treaty was signed fixing the terms of the settlement. Brazil received Acre and certain other concessions of little consequence. In exchange Bolivia was given 890 sq.mi. of land in an angle south of the confluence of the Abuna and Madeira rivers and an indemnity of £2,000,000. Brazil also agreed to build a railroad from the port of Santo Antônio on the Madeira to Guajará-Mirim on the Mamoré in order to give Bolivia access to the Amazon river. This railroad, a narrow-gauge line, 227 mi. long, was opened in July 1912, but by that time the rubber boom had collapsed and there was little need for it. (J. J. J.)

ACRE (אֶקּוֹ), a small seaport town of Israel, a city of ancient Phoenicia and later of Palestine, and a former Turkish fortress, lies at the northern point of the Bay of Acre, or Haifa, on a tongue of land ending in a reef which forms a natural harbour. Pop. (1956 est.) 20,200. Acre is at the centre of the coastal plain stretching from the Ladder of Tyre (Ras en-Naqura) to Mt. Carmel and eastward to the foothills of Galilee. To the southeast, via the plain north of Nazareth, it was linked with the ancient caravan route from Mesopotamia and Damascus to Egypt. Early names for it were Egyptian 'Ak (a); Assyrian 'Akku; Hebrew 'Akko; Greek Ake, or in Josephus Arke; Latin Ac(c)e; Xrubic 'Akka; under the crusaders, Ac(c)on, Ac(c)hon, Ackon, or after the Arabic, Acre, Acri, whence St. Jean d'Acre, from the once prominent ruin of the hospital and church of the knights of St. John. The name Ptolémaïs, which was in use from the 3rd century B.C. until the 7th century A.D., is still the title of the Orthodox episcopal see.

The present town lies mainly within its Turkish ramparts of c. 1800. Its buildings date mostly from the 18th and 19th centuries but incorporate some remains of crusader times. There are four large caravanseries, one of which, Khan al Faranj, was originally that of the French merchants. The great mosque of Jazzar Pasha with its college, the citadel (Burj al Khazna), the Pasha's Baths (Hammam al Basha) and the covered "white" market (Suk al Abyad) are all of c. 1800. The Greek Orthodox cathedral (St. George) dates from early 17th century, the Franciscan convent from 1729 and their church (St. John) from 1737, the Maronite church from 1750; there is a rebuilt Greek Catholic cathedral (St. Andrew) on the site of the Templars' church. A modern residential and industrial quarter has been developed north and northeast of the old town. About 15 mi. N. is the Pilgrims' house of the Bahais, with the tomb of Baha'ullah (d. 1892), the chief prophet of the sect. Nearby is a government experimental farm.

In the old city Jews, Muslims, Christians, Druses and Bahais live and work side by side. Crafts are still carried on, such as the making of straw brooms and brushes, silver and bronzeware, earthenware and sponges, and

there is coastal fishing. In the industrial area are steel-rolling mills and light industries. The town is served by a coastal road and railway and by road eastward to Safad and the Syrian border.

History.—By a name close to the biblical form, Accho first appears on the Egyptian monuments as part of the new empire, 15th to 13th centuries B.C., the seat of a client prince who is known from the Tell el Amarna letters. The Hebrews failed to conquer this part of the coast and lived "among the Canaanites, the inhabitants of the land" (Judges, i, 32), so Accho became the southernmost of the Phoenician cities. The Assyrian records claim that it submitted to Sennacherib (700) and was depopulated by Ashurbanipal. Yet under the Persians it was used as a base against Egypt by Cambyses (526) and by Artaxerxes II (374). It admitted Greek merchants and apparently was minting coins of Greek as well as Phoenician type before the annexation of Phoenicia by Alexander the Great (332). With Phoenicia it was disputed between his successors, the Ptolemies of Egypt and the Seleucids of Syria. It got its name Ptolemais from the former (from 261), was recovered by the latter (from 200), but kept its civic autonomy. A walled city, it defied the Jews under Simon the Maccabee (164–163) and under Alexander Jannaeus (103), only to fall to Ptolemy Lathyrus of Cyprus and (in 71) to the Armenian king Tigranes. Freed by Pompey (63), for long it dated its coins from the year (47) in which Julius Caesar made it his advanced base against Pharnaces in Asia Minor.

In the Roman province of Syria it was an outpost toward independent Judea and Arabia, from the entry of Herod the Great (39) to the capture of Jerusalem in A.D. 70 (see the Antiquities and Jewish War of Josephus). From the emperor Claudius it received the Roman status of *colonia* (52–54). St. Paul landed there "and saluted the brethren" in c. 57 (Acts xxi, 7); and bishops of Ptolemais are known to have attended local and general councils of the church from c. 190. There is archaeological evidence that the inhabited area then reached its greatest extent.

Resuming its older name under the Arabs (from 638), it was developed as a naval base by several caliphs. It submitted to the invasions of the Fatimid caliphs of Egypt (from 969), the Seljuk Turks (from 1079) and the first crusade (1099). Then the best harbour on the Palestine coast, its seizure by King Baldwin I (1104) helped to establish the Latin kingdom of Jerusalem.

BY COURTESY OF ISRAEL OFFICE OF INFORMATION

THE GREAT MOSQUE AT ACRE. BUILT IN THE 18TH CENTURY BY JAZZAR PASHA

For nearly two centuries Acre was a gateway for pilgrims and for trade between Asia and Europe. When Saladin took it (1187), King Guy and the third crusade made its recovery their first objective. The long siege of 1189–91 is an epic of medieval warfare, narrated in the Anglo-Norman poem *Carmen Ambrosii* ("Song of Ambrose") (see CRUSADES). Pending the recovery of Jerusalem, Acre became the capital and remained as such for another century. The walled town then stretched about twice as far from west to east as the present ramparts. It was refortified with a double wall (1202–12) which was extended (1250–54) to the north of the present line. It contained a patchwork of quarters or wards representing the religious and military orders of the Holy Land and European cities and nations. Not only for their merchants was it a base but also for St. Francis (1219) and his friars, e.g., William of Rubruquis whose journal of his visit to the Great Khan was written there (1255), and for the journeys of the Venetian Polo brothers to China (1269, 1271). Twice threatened by the most powerful Mameluke ruler of Egypt, Baibars (1265, 1269), it was overwhelmed by one of his successors (1291). With its fall the remaining crusader strongholds on the coast were abandoned.

Out of its vast ruins the older part of the modern town has been built. There was little more than the Khan al Faranj (early 16th century) and some of the churches, when a semi-independent Arab chieftain Dahr al-'Omar began to rebuild about the middle of the 18th century. Ahmad al-Jazzar, the Turkish governor who replaced him, made the new town his capital and gave it much of its character, partly before and partly after the damage done by Napoleon's siege (1799). It was then fortified only with a new wall of medieval pattern, still to be seen in part behind the present ramparts, and the French attacks were foiled less by that wall than by the steadiness of the Turks and the ready aid of the small supporting British squadron. Afterward the present ramparts were constructed and the sea wall strengthened. Within these a Turkish garrison resisted an Egyptian army and fleet for six months (1831–32) before surrendering to Ibrahim Pasha. His subsequent victories over the Turks led to the bombardment of Acre by a combined British, Austrian and Turkish fleet (Nov. 3, 1840), and the fortress was restored to Turkey.

After the Allied conquest of Palestine and Syria in the war of 1914–18 the League of Nations included the town and district in the British mandate for Palestine (1920–48). In plans to partition Palestine into Arab and Jewish states, the town was allotted to the Jewish state by Britain but to a detached Arab district of western Galilee by the United Nations commission, whose report was accepted by the general assembly (Nov. 29, 1947). It was occupied by Israeli forces on the expiry of the British mandate (May 1948).

ACRIDINE, an organic compound, is the parent substance of several dyes and pharmaceuticals. The antimalarial quinacrine (Atabrine), for example, is an acridine derivative.

Acridine is a solid found in coal-tar anthracene. It is characterized by its irritating action on the skin and by the blue fluorescence shown by solutions of its salts.

Acridine and its homologues are stable compounds of feebly basic character, belonging to the general class of heterocyclic ring compounds (see CHEMISTRY: *Organic Chemistry*). They combine readily with the alkyl iodides to form alkylacridinium iodides, which are readily transformed by the action of alkaline potassium ferricyanide to N-alkylacridones.

Acridine has the molecular formula $C_{13}H_9N$.

ACRIFLAVINE, an acridine derivative obtained from coal tar, is a reddish-brown powder with antiseptic properties. Introduced as an antiseptic in 1912 by Paul Ehrlich as tryptaflavine, it was used extensively in World War I but later was largely replaced by such chemotherapeutic agents as the sulfonamides and antibiotics. In solution it is used as the hydrochloride or as the less irritating base, neutral acriflavine, for irrigating wounds and for the treatment of gonorrhoea. As a urinary antiseptic, it may be taken by mouth. (F. L. A.)

ACRILAN: see SYNTHETIC FIBRES.

ACROMEGALY, a chronic disease characterized by overgrowth of the tissues, is caused by excessive production of growth hormone by the pituitary body (*qv.*). (See DWARFISM AND GIGANTISM.) The disease is a form of gigantism occurring in persons who develop hyperpituitarism only after full growth has been achieved. It is usually first brought to notice by the necessity of increasing the size of the hat, gloves and shoes. The teeth of the lower jaw separate due to growth of the mandible, which results in a characteristic prognathism. The nose, lips, tongue, hands and feet broaden and enlarge, as do also the visceral organs. Treatment consists of X-ray irradiation of the pituitary. If loss of vision is threatened or if there is no response to irradiation, surgical removal of the gland may be necessary. (A. GR.)

ACROPOLIS, in Greek literally "city at the top," is the general name in ancient Greek history for citadels built on elevated and easily defensible sites and usually forming the nuclei of large cities. By extension it can be applied to any such citadels, even outside Greek history. In several ancient Greek cities the acropolis survives, the most famous being that of Athens. See ATHENS; ARGOS; CORINTH; THEBES (Greece).

ACROPOLITES, GEORGE (1217–1282), Byzantine scholar and statesman, whose history provides a reliable and objective account of the Byzantine empire of Nicaea, was born in Constantinople and brought up at the imperial court which was then at Nicaea. He served John III Ducas Vatatzes, and his successors, Theodore II Lascaris and Michael VIII Palaeologus, and in 1246 held the office of logothete of the treasury and subsequently grand logothete. Under Theodore II he was active on campaigns against the Bulgarians and the Epirotes. He returned to Constantinople when it was recaptured from the crusaders in 1261, and his scholarly activities were interspersed with diplomatic missions. He represented Michael VIII in the negotiations for the reunion of the western and Byzantine churches which culminated in the second council of Lyons in 1274, where he acknowledged the papal primacy. In 1282 he was ambassador to John II Comnenus, ruler of Trebizond.

His *Chronike Syngraphe* continues the history of Nicetas Choniates and covers the years 1203–61. He also wrote theological and rhetorical works and poems; of these his funeral oration on John III is of special historical value.

BIBLIOGRAPHY.—Works ed. by A. Heisenberg in the Teubner series (1903). The *Chronike Syngraphe* is also ed. by I. Bekker in the Bonn corpus (1836) and in J.-P. Migne, *Patrologia Graeca*, vol. 140, col. 957–1220 (1887). For further bibliography see G. Moravcsik, *Byzantinoturcica*, vol. i, pp. 266–268, 2nd ed. (1958), and G. ACROSTIC, a short verse composition, so constructed that the initial letters of the lines, taken consecutively, form words (Gr. *akros*, "at the end," and *stichos*, "line" or "verse"). The fancy for writing acrostics is of great antiquity, having been common among the Greeks of the Alexandrine period, as well as with the Latin writers since Ennius and Plautus, many of the arguments of whose plays were written with acrostics on their respective titles. One of the most remarkable acrostics was contained in the Greek verses cited by Lactantius and Eusebius in the 4th century, the initial letters of which form the words *Iesous Christos Theou Uios Soter*, "Jesus Christ, the son of God, the Saviour." The first letters of each word make up the word *Ichthys* (fish), to which a mystical meaning has been attached, the fish being a symbol for Christ in early Christian literature and art, thus constituting another kind of acrostic.

The monks of the middle ages were fond of acrostics, as well as the poets of the Middle High German period, notably Gottfried von Strassburg and Rudolph von Ems. The great poets of the Italian renaissance, among them Boccaccio, indulged in them, and in 1599 the English poet Sir John Davies wrote 26 elegant *Hymns to Astraea*, each an acrostic on "Elisabetha Regina."

Acrostic verses, however, have been held in slight estimation from a literary standpoint. Samuel Butler says, in his "Character of a Small Poet." "He uses to lay the outside of his verses even, like a bricklayer, by a line of rhyme and acrostic, and fill the middle with rubbish." Addison (*Spectator*, No. 60) found it impossible to decide whether the inventor of the anagram or of the acrostic was the greater blockhead; and in describing the latter, says, "I have seen some of them where the verses have not only been edged by a name at each extremity, but have the same name running down like a seam through the middle of the poem." And Dryden, in *Mac Flecknoe*, scornfully assigned Shadwell the rule of "Some peaceful province in acrostic land."

The name acrostic is also applied to alphabetical or abecedarian verses. Of these we have instances in the Hebrew psalms (e.g., Ps. xxv and xxxiv), where successive verses begin with the letters of the alphabet in their order. The structure of Ps. cxix is still more elaborate in the Hebrew, and in the King James version this is indicated in the translation by the successive letters of the alphabet standing before each of the 22 parts of the psalm.

At one period much religious verse was written in a form imitative of this alphabetical method, possibly as an aid to the memory. The term acrostic is also applied to the formation of words, from the initial letters of other words. *Ichthys*, referred to above, is an illustration of this. So also is the word "Cabal," which, though it was in use before, with a similar meaning, has, from the time of Charles II, been associated with a particular ministry, from the accident of its being composed of Clifford, Ashley, Buckingham, Arlington, and Lauderdale. In the 20th century a great many organizations were being named with this acrostic principle in mind, e.g., CARE, the initials of Cooperative for American Remittances to Everywhere.

Double acrostics are such as are so constructed that not only initial letters of the lines, but also the middle or last letters, form words. For example: (1) By Apollo was my first made; (2) A shoemaker's tool; (3) An Italian patriot; (4) A tropical fruit. The initials and finals, read downward, give the name of a writer and his nom de plume. Answer: Lamb. Elia.

1. L yr E
2. A w L
3. M azzin I
4. B anan A

A curious and clever 20th-century development of the acrostic was the quadruple acrostic. The following, taken from R. A. Knox's *Book of Acrostics*, is a good example.

Uprights: Since there's no A, B, let us C and D.

Lights: 1. Reverse the name a schoolboy might apply, for briefness, to his weekly subsidy.

2. A lady thus (but with an S)
In Southern lands you might address.

3. Initials seen on many a truck.

4. To cattle breeders brings bad luck.

SOLUTION

Uprights: "Since there's no help, come, let us kiss and part."

Lights: 1. Hsa Cte Kco P (Reverse of pocket cash)

2. (s) En Or It A

3. L. M. S. R. (London, Midland & Scottish Railway)

4. P E S T

In the United States the Double-Crostic devised by Elizabeth Kingsley for the *Saturday Review*, beginning in 1934, had an acrostic in the answers to the clues giving the author and title of a literary work; the letters, keyed by number to blanks like those of a crossword puzzle, spelled out a quotation.

BIBLIOGRAPHY.—P. M. Pearson, *Acrostic Dictionary* (1901); R. A. Knox, *Book of Acrostics* (1924); L. C. Scott, *Acrostic Poems* (1924); Elizabeth Kingsley, *Double-Crostic*, 26 series (1934-52). (G. W. A.)

ACT, a statute or law adopted (enacted) by a national or state legislature or other governing body. Acts are distinguished from

resolutions, which are usually used to express legislative opinion or to regulate affairs of the governing body itself, and from ordinances or bylaws of municipal corporations and rules and regulations of administrative agencies. See LEGISLATION; STATUTE LAW.

(J. D. Ls.)

ACTA, the minutes of public business and gazette of political and social events in ancient Rome, began official publication in the first consulship of Julius Caesar (59 B.C.), in two forms: *acta senatus* and *acta diurna*.

The *acta senatus* or *commentarii senatus*, minutes of the proceedings of the senate, were published only occasionally and unofficially before 59 B.C. when Caesar ordered them to be issued regularly and with official authority. Augustus continued to keep them, but forbade their publication. From the reign of Tiberius a young senator was chosen by the emperor to draw up these *acta*, which were kept in the imperial archives and public libraries. Special permission from the *praefectus urbi* (city prefect) was necessary in order to examine them.

The *acta diurna*, which were called also *acta populi*, *acta publica* and simply *acta* or *diurna*, grew out of Caesar's arrangements for the recording and publishing of official business and matters of political interest. They were set up daily in a public place on a whitened board (*album*). After a reasonable time they were taken down and preserved with other public documents, so that they might be available for reference. Under the empire the *acta diurna* constituted a sort of daily gazette, providing an official account of noteworthy events at Rome. Its contents were partly official (court news, decrees, etc.), partly private (notices of births, marriages, deaths). Thus to some extent it filled the place of the modern newspaper. The publication of these *acta* continued until the transference of the capital to Constantinople in A.D. 330.

(A. H. McD.)

ACTAEON, in Greek mythology, son of Aristaeus and Autonoe, Boeotian hero and hunter. According to Ovid's *Metamorphoses*, having accidentally seen Artemis on Mt. Cithaeron while she was bathing, he was changed by her into a stag, and pursued and killed by his 50 hounds. The story was well known in antiquity; Pausanias says that he saw on the road from Megara to Plataea the very stone on which Actaeon sat as he gazed at Artemis. Several of the tragic poets presented it on the stage (e.g., Aeschylus' lost *Toxotides*, "The Archeresses"), and many sculptured representations of Actaeon's death are known. Actaeon was worshiped in Plataea and Orchomenus.

(T. V. B.)

ACTA SANCTORUM, a collection of the lives of the saints, compiled by the Bollandists. The work, first conceived at the beginning of the 17th century, was carried on thereafter, except during the period of the suppression of the Society of Jesus in Belgium. See BOLLANDISTS.

ACTING, DIRECTION AND PRODUCTION. The summits of world theatre are the Everests of dramatic literature and, as G. H. Lewes said, "the greatest artist is he who is greatest in the highest reaches of his art." But the sublimest theatrical mountaineering always begins before an audience, on one small, particular stage. Such masters of the drama as Shakespeare and Molière wrote for specific actors working within a specific kind of aesthetic and economic organization. Their work may be read with admiration in the study, but it is only in performance that it comes to life completely. Below those heights it is even more apparent that the play text is only one factor in the arts of the theatre and that its form, content and communication are intimately affected by the state of the stage. As critics in the 20th century came increasingly to emphasize, the history of acting, direction and production is integrally linked to the history of the drama. Upon the status and style of the actors, the ownership of the stage, the finance of "show business" and the control of its constituent arts depend, to a large extent, the dramatist's communication with his public and the condition of the theatre in general.

ACTING

Classical.—The essential words with which the nature of theatre is defined are of Greek origin: theatre, drama, chorus, tragedy,

comedy, scene. The Greek theatre was a development from the primitive. But the theatre became a conscious creative art.

The actor occupied an honourable and special place. Contests were held not only for the best play but for the best actor. Acting began to be appreciated as a separate art and the discussions of acting sound oddly contemporary. Actors accused each other of over-acting and Aristotle censured the performers of his own day for representing degraded women. The speeches of the Greek plays created special problems, calling for strength, flexibility and emphasis in expression, but the drive toward naturalness and truthfulness gained as the art developed. The tragedian Theodoros was commended for his natural delivery, and his voice was described as sounding like a real person's whereas the others sounded artificial and "actory." The striving for reality or conviction in acting is illustrated by the story of the actor Polus, who is said to have taught Demosthenes elocution. In the scene where Sophocles' Electra brings on stage the remains of Orestes, Polus carried on the ashes of his own recently deceased son, and thereby expressed his own sorrow and pain.

Roman acting, like the Roman theatre, is shrouded in uncertainties. But the struggle between Christianity and paganism found the actor a victim, and at this time the conventional image of the actor was created, that of a vagabond, lascivious and vulgar, a mountebank, a comedian, whose sole purpose was to entertain. The rise of medieval Christian drama changed nothing in this respect.

The Beginnings of Modern Acting.—Modern acting began with the *commedia dell' arte*. The sudden efflorescence of these acting companies, the earliest mention of which is in 1545, is still unexplained. Until then, acting was an amateur occupation. The actor remained confined to simply illustrating the text by means of a narrow scheme of gesture and rhetorical speech. But in the *commedia dell' arte* the actor used only an outline, a plot; he improvised the play, giving free rein to the actor's art, developing his own characters or masks repeated in each play. Since this demanded high skill, the actors joined into companies. The actor became professional. By doing so he stimulated the development of modern drama. The essential requisite for the drama is its performance. The dramatist's creation finds its fulfillment not in the writer's study but on the stage. This fulfillment can best be achieved through the contribution of the professional actor. The amateur only repeats the words of the writer; the actor fuses with them and creates the real image of word and deed. "The professional actor is the prerequisite of great drama." (Max J. Wolff in Robert F. Arnold [ed.], *Das deutsche Drama*, C. H. Beck'sche Verlagsbuchhandlung, Munich, 1925.)

With Shakespeare the modern theatre created its major classic, and modern acting was fully born. It is unthinkable that Shakespeare would have created his major roles for actors who were unable to perform them. Shakespeare's "capital discovery is that physical action in itself and by itself is the least effective thing upon that stage . . . the why and the wherefore, what went before and what is to come after . . . they are the fruitful stuff of drama. From which it soon follows that not rhetoric merely or mainly, nor what may be openly said, but the thing only thought or felt will need to be expressed." (H. Granville-Barker and G. B. Harrison, *Companion to Shakespeare Studies*, Cambridge University Press, 1934.) It is not enough for the actor to pose and move and speak his lines magnificently. He must be able to create a character immersed in a situation, behaving in it and thinking and feeling beyond it. Shakespeare was aware that while the intention in acting is to "suit the action to the word, the word to the action," the real problem and mystery in acting is that the actor must be able "but in a fiction, in a dream of passion, [to] force his soul so to his own conceit." The exploration of this became the problem of the post-Shakespearean actor.

18th Century.—While the 17th century was taken up with the struggle for the acceptance of these principles, the 18th century dedicated itself to a deeper exploration of character and the actor's ability to fuse with his role. David Garrick (1717–79) "raised the character of his profession to the rank of a liberal art," according to Edmund Burke, who considered him "the first of ac-

tors, because he was the most acute observer of nature." His influence reached into the other arts and "his easy and familiar yet forcible style in speaking and acting, and the expression of the features from the genuine workings of nature" became the exemplar of 18th-century acting.

James Quin (1693–1766), who was more declaimer than actor, remarked that "if the young fellow is right, I and the rest of the players have been all wrong." Garrick's triumph was aided by the achievements of actors such as Lekain (Henri Louis Cain; 1729–78), described as "small, ugly and possessing a harsh voice," and François Joseph Talma (1763–1826) in France, and of Konrad Ekhof (1720–78), August Wilhelm Iffland (1759–1814), Johann Fleck (1757–1801) and Friedrich Schroder (1744–1816) in Germany. Discussion about acting and its problems flourished within the profession. Contrary to the philosophic ideas of Denis Diderot (1713–84) that "the possibilities of a good actor lie in the complete absence of sensibility," Luigi Riccoboni (c. 1675–1753), Remond de Ste. Albine, Talma and others concluded that acting demands a combination of "sensibility" (or "enthusiasm," "fire") and "intelligence."

19th Century.—The art of acting is kept alive by the performances of great actors: Sarah Siddons (1755–1831), the greatest tragic actress of the English stage, of whom Hazlitt wrote "Passion emanated from her as from a shrine. She was tragedy personified"; Edmund Kean (1787–1833), whose performances, "too often in the highest key of passion," were described by Coleridge as "reading Shakespeare by flashes of lightning"; Marie Dorval (1798–1849); Frédéric Lemaître (1800–76), whom Victor Hugo called "the greatest actor of his day, and perhaps the greatest of all time," who would have failed his examination at the Conservatoire except for Talma's voice saying "He has that which cannot be taught: the holy fire [spirit]"; Rachel (1820–58), who died early leaving a tradition of tragic acting which has hardly been surpassed; Gabrielle Réjane (1857–1920), who stated "I understand only what I feel, and I feel only what I also understand"; Ludwig Devrient (1784–1832), who after one of his death scenes, when he regained his senses, said, "I thought I had really died."

But by the last quarter of the 19th century the emphasis had shifted from the individual to the ensemble. The Meiningen players, though containing few outstanding actors, set a standard for ensemble acting and attention to the details of staging which proved what the actor of lesser talent could accomplish with proper direction. At the same time a number of Italian actors again electrified Europe with their terrific temperament and almost brutal theatrical realism. Ernesto Rossi (1827–96), Adelaide Ristori (1822–1906), Tommaso Salvini (1829–1915), Ermete Novelli (1851–1919), Ermete Zacconi (1867–1948) and Giovanni Grasso (1875–1930) were able to play both classics and contemporary plays. The appearance of Eleonora Duse (1859–1924) was a fitting climax. With a sensitivity so extreme that she could blush on the stage, yet simple and unmelodramatic, with gestures of great beauty and expressiveness, she set a standard for future generations.

Stanislavski.—Stimulated by this activity and supported by the traditions of the best of Russian acting, Konstantin Stanislavski (1863–1938) set himself to fuse all the random thought and experiences into a form that could help the beginner and be of service to the experienced actor. His aim was to find a "grammar of acting," to achieve that level of inspiration, or of living on stage, which great actors had found accidentally and sporadically. Without minimizing the value of voice, speech and body training, which are the actor's tools, Stanislavski tried to find means to stimulate and develop the actor's essential requirements: concentration, belief and imagination. He did not seek to fabricate inspiration, but to create the proper foundation for its appearance.

The actor, according to Stanislavski, should come on the stage not to play-act but to perform the activities required of the character, to act. His appearance on the stage is not the beginning but a continuation of the given circumstances that have previously taken place. The actor trains his concentration so that he is able to create the impression of being private in public. He trains his senses so that he is able to see, hear, touch, taste, smell and relate to the many objects which compose his imaginary situa-

tion. He learns to use not only intellectual knowledge but emotional experience by means of affective memory. Wordsworth defined poetry as originating in "emotion recollected in tranquillity." Shaw emphasized that "vital art work comes from a cross between art and life." Thomas Wolfe in one of his short stories and Proust in a passage in *Swann's Way* brilliantly described the workings of affective memory. It is not limited to the ability to recreate one's previously experienced real emotions, but also to learn to repeat previously experienced stage emotions. The actor's training of himself goes hand in hand with the actor's work on a role. The actor learns to delve beneath the lines to find the meaning or subtext of a play. He learns to find the "kernel" or core of a part, to find the actions of the character that define the important sections, to set smaller tasks or problems for his concentration throughout each section. In later years Stanislavski tried to correct the overly intellectual approach of this part of the work by simplifying the action work in terms of physical or psychophysical actions. Some have interpreted this as a reversal of his previous methods. Actually, it was intended not to rule out or contrast with but to serve as a life belt by means of which the previous preparation and work on a role could be securely held.

After **Stanislavski**.—Stanislavski's work with the actor was not limited to the realistic form. His own realistic productions tended to create that impression. But the pupils of Stanislavski, especially E. V. Vakhtangov (1883–1922), succeeded in combining the truthfulness and conviction of the actor that Stanislavski sought with the theatrical methods of V. E. Meyerhold (1874–1942), whose brilliant work represented a more formalized or stylized approach, without, however, following Meyerhold's "biomechanics" system of acting. In France Jacques Copeau (1879–1949) combined methods of inner truth with a search for theatrical form and this also characterized the work of H. Granville-Barker (1877–1946). While he never developed any complete system of aesthetics, the work of Max Reinhardt (1873–1943) combined an amazing variety of production methods with a use of ensemble, and he developed a group of actors of unusual talent and variety. Albert Bassermann (1867–1952), Emil Jannings (1886–1950), Werner Krauss (1884–), Alexander Moissi (1879–1935), Paul Wegener (1874–1948) and Rudolph Schildkraut (1862–1930) combined an extraordinary ability in the realistic drama with the temperament demanded by the classics.

In England, as elsewhere, acting was ruled by adherence to traditional patterns, strengthened by the principle that an actor played the same line of parts and usually the same way. But the profession boasted of this as the result of art and study. Sir Henry Irving (1838–1905) and others broke the spell. Irving's Iachimo was a new and independent creation—no bagful of tricks but a true impersonation, unbroken in its life current. Mrs. Patrick Campbell (1865–1940) as Ophelia, instead of being a strenuously earnest young lady giving a recitation, was mad—inspiredly mad. Sir Johnston Forbes-Robertson (1853–1937) created a Hamlet of "light, freedom, naturalness, credibility." Sir Gerald Du Maurier (1873–1934) established the acting thought of as typically English. He walked, talked and behaved as he believed the character would behave in natural circumstances ("Can't you just say, 'I love you,' and yawn, and light a cigarette and walk away?"). (Daphne Du Maurier, *Gerald: A Portrait*, Victor Gollancz, London, 1934.) What he achieved others only imitated. William Poel (1852–1934), most of whose work was done with largely amateur casts, revolutionized Shakespearean productions by preaching a return to the principle of Elizabethan staging. This placed the actor in a dilemma. He could not continue the development toward a realistic character approach and remain true to Elizabethan convention. Performers such as Sir Laurence Olivier (1907–), Sir John Gielgud (1904–) and Sir Ralph Richardson (1902–) reached great heights without, however, creating a style or basic approach. Michel Saint-Denis (1897–), a pupil of Copeau, tried to remedy this but left England without accomplishing his purpose.

It was at this point that United States acting began to influence the world arena. The U.S. theatre was conditioned in its beginnings by the tradition of English acting. Among the first actors

to develop typical American characters were "Yankee" Hill and "Jim Crow" Rice of U.S. minstrel shows and vaudeville, though Edwin Forrest (1806–72) and especially Edwin Booth (1833–93) became known in Europe. Toward the end of the 19th century, actors such as William Gillette (1853–1937) and Minnie Maddern Fiske (1865–1932) began to develop a more distinctively American type of acting, colloquial but forceful. After World War I American actors created outstanding performances that could be called great: Jeanne Eagels in *Rain*, Pauline Lord in *Anna Christie* and *They Knew What They Wanted*, Alfred Lunt in *The Guardsman*, Jacob Ben-Ami in *Samson and Delilah*, Laurette Taylor in *The Glass Menagerie*, the performances of John Barrymore and others. But these remained without influence in the rest of the world. The visits of Eleonora Duse and the company from the Moscow Art theatre created an additional stimulus which bore fruit in the ensemble acting created by the Group Theatre. For the first time the ideas of Stanislavski were tested and achieved unusual results outside of Russia.

The growth of motion pictures, especially the rise of the "talkies" beginning in 1927, greatly affected American acting. Two generations of theatre talent were diverted from the stage.

The requirements of acting in motion pictures, television, the theatre and opera are basically the same, although some of the techniques are different. It is possible to put strips of film together and create a performance that was never actually given. The performance is created by the director rather than by the actor. There were many performers in the silent pictures who were thus completely products of the camera and contributed little from an acting point of view, depending on their physical charms and personality (Rudolph Valentino, Theda Bara and others). However, individuals such as Charlie Chaplin and Lillian Gish were authentic actors. Chaplin being one of the greatest of all time in any medium. Werner Krauss in *The Cabinet of Dr. Caligari* created a masterpiece of the fantastic; the actors in Erich von Stroheim's *Greed* (Zasu Pitts, Jean Hersholt) attained a terrifying verisimilitude hardly matched on the screen since then, or, for that matter, on the stage. In the pictures directed by the Russians S. M. Eisenstein and V. I. Pudovkin, despite their use of the new principles of montage developed from D. W. Griffith, the acting reached a conviction and believability that revolutionized the medium, though it was difficult to tell whether it was achieved by the actor or the director. With the rise of sound movies, the role of the individual actor increased. Greta Garbo, Emil Jannings, Harry Baur, Bette Davis, Paul Muni, Luise Rainer, Spencer Tracy, Sylvia Sydney, Humphrey Bogart, Katharine Hepburn, Sir Laurence Olivier, Marlon Brando and others created authentic acting performances which could have held their own on the stage. In the U.S. motion-picture stars have come from the theatre to a greater extent than that permitted by the classical training of the English or French actor. Actors from the Actors' Studio, especially under the direction of Elia Kazan (1909–), made a powerful impression, and showed a remarkable ability to bridge the gap between stage, screen and television to an extent that aroused excitement and interest in the rest of the world. So strong was the fusion of performer and role that many of the traits of the character were confused with those of the actor and led to serious misunderstanding. But at mid-20th century, for the first time, an American style of acting was being born.

The Nature of Acting.—Acting is the most appreciated and least understood of the arts. Taste is too often confused with judgment. But acting has a history of struggle, progress and development. Acting is not mimicry, exhibitionism or imitation. It is the ability to react to imaginary stimuli; and its essential elements remain the twin requisites enunciated by Talma, "unusual sensitivity and extraordinary intelligence," this latter not in the form of book learning but in the ability to comprehend the workings of the human soul. The essential problems in acting—does the actor "feel" or does he merely imitate? should he speak naturally or rhetorically? what is natural? etc.—are as old as acting itself. They derive not from the realistic movement but from the nature of the acting process. The commercial conditions of the theatre, screen and television make necessary a greater degree

of training for the actor than ever before if the enormous talent that exists is not to be swamped by time and technical requirements. The training of the actor today is not a luxury but a necessity.

(L. Sg.)

Schools of Acting.—During the greater part of the theatre's history actors have learned by doing. Their schools have been professional companies; their classroom, the stage; their curriculum, the drama in performance; their teachers, the audience and their fellow players. Academies of dramatic art, isolated from theatres or companies, are a relative innovation and are unknown in several European countries. Perhaps the most celebrated of all schools of acting, the Conservatoire in Paris—whose pupils have included Rachel, Sarah Bernhardt and Constant-Benoît Coquelin—has been intimately linked for nearly 200 years with one playhouse, the Comédie Française; and in the U.S.S.R. most of the major theatres include schools of acting as part of their basic organization. To such schooling there is no counterpart in the Anglo-American theatre.

In the pre-1640 English theatre training was organized inside the companies. Individual actors bought boy apprentices, coached them for a certain number of years (while renting their services to the company) and later sold them as trained actors. After the Restoration, "nurseries" were briefly in existence under the sponsorship of the rival "patent theatres," but this short-lived experiment was not repeated. At Drury Lane theatre, London, Garrick ran for some months in the mid-1750s a class of children who included Jane Pope, later celebrated on the stage. Some actors—notably, Charles Macklin—gave individual tuition to stagestruck aspirants: Sir Henry Irving, as a young clerk in London, went without food to pay for private lessons from a small-part player. And one couple, Samuel and Julia Glover, managed to establish a school in 1848 which kept alive for several years. Yet it was not until the beginning of the 20th century that a would-be actor could hope to learn his craft in an academy: if not "nursed on rose-pink and cradled in properties" (like Kean, Ellen Terry, Eleonora Duse or Lemaitre), he joined a company and picked it up as he went along. In the stock-company system, before the advent of the metropolitan long run and the provincial touring company, there was ample opportunity for histrionic education. During three years of his provincial apprenticeship Irving played over 400 roles: in contrast, Gielgud played 80 roles in his first nine years on the stage and Sir Alec Guinness 54 roles in 21 years.

With the dissolution of the stock companies and the new respectability and popularity of acting among the Victorian middle class, the need for theatrical training on a less empirical basis became apparent in the 1880s, although the project of a dramatic academy—so often discussed in the past 200 years—was still hotly opposed by many actors. It was an actor-producer, Sir Herbert Beerbohm Tree, who took the lead by establishing a school of acting in 1904 in the dome of his London theatre, His Majesty's. In 1905 he moved it to a house in Gower street under the name of the Academy of Dramatic Art and set up a presiding council of other leading actors. A royal charter was granted in 1920 and from 1924 onward the Royal Academy of Dramatic Art—generally known by its initials as R.A.D.A.—received a small annual grant from the state. Other schools of acting such as the London Academy of Music and Dramatic Art and the Central School of Speech Training and Dramatic Art were instituted and were run on roughly similar lines, preparing pupils, in two-year courses, for the kind of work they might hope to find on the commercial stage in the open market.

The first school in the United States for the professional study of acting was the Lyceum Theatre school founded in 1884 by Franklin H Sargent, Steele MacKaye and others. In 1888 it was renamed the American Academy of Dramatic Arts.

More radically comprehensive in their approach to acting, as an integral function of theatrical art rather than as an occupation for young ladies and gentlemen or as a form of casual labour marketable in the entertainment industry of the day, were several influential schools established in England and the U.S. in the 1930s and 1940s. Michel Saint-Denis, nephew of Jacques Copeau and former director of the Compagnie des Quinze, founded the London

Theatre Studio in 1936 but had to close it down on the outbreak of war in 1939. After the war he created the Old Vic school, linked with the Old Vic theatre, which offered instruction not only in acting but also in direction, design and other stagecrafts; and although the school was shut down in 1951 on grounds of economy, many of its pupils made their mark in the following decade. Saint-Denis' master, Copeau, was deeply influenced by Stanislavski and it was to Stanislavski that the leading U.S. schools of acting were principally indebted. Among them was the school established in New York in 1938 by Michael Chekhov, who had first opened it in England in 1936. Chekhov, nephew of the dramatist, had worked at the Moscow Art theatre with Stanislavski for many years. More than ten years earlier, when the Moscow Art theatre had visited the U.S., two members of the company—Richard Boleslavsky and Maria Uspenskaya—remained there and founded schools of acting. Among their pupils were three Americans who, in turn, became leader-teachers: Stella Adler, Harold Clurman and Lee Strasberg. Strasberg's Actors' Studio, which was attended in the 1950s by many professional actors in search of re-education, prompted the institution on both sides of the Atlantic of other post-graduate schools under the Stanislavski banner.

DIRECTION

Among the principal changes in the balance of theatrical power during the 20th century was the actor's loss of control over the economic and aesthetic organization of the drama. New processes of specialization in function gave rise to the professional producer (the economic organizer of the play) and the professional director (the aesthetic organizer). Outside Anglo-American show business the director frequently exercised both economic and aesthetic control; in Britain he was generally known as the producer and elsewhere in Europe as the *régisseur* or *metteur en scène*; but to avoid confusion one may agree to call this specialist the director (a distinction officially made in Britain in the 1950s by the Society of West End Theatre Managers). He is responsible for the casting of a play (wholly or in part) and the conduct of rehearsals. He supervises the tempo, tone and traffic of the stage. As the interpreter of the text to the players and the audience, he is charged with the integration of performance, script, lighting and décor into a harmony of style and unity of theatrical effect. He is chairman, coach, umpire, conductor, choreographer and ideal spectator.

The Actors as Directors.—For more than 2,000 years the professional theatre existed without such an independent organizer of the show. During the middle ages something of the modern director's power was enjoyed by the pageant master or *maître du jeu* appointed by civic authorities to direct miracle and morality plays (with amateur actors), and throughout the history of the modern stage a small, subordinate role in the preparation and regulation of entertainment was played by the stage manager, the director's immediate ancestor. Playwrights were sometimes in control: from Sophocles to G. Bernard Shaw authors have directed their own plays. Yet aesthetic organization—as far as it went—was mainly the responsibility of the actor, who worked inside conventions of staging and performance. Instead of looking for realism and unity of effect in a coherent stage picture where every detail is planned and controlled, the audience up to the mid-19th century was content with scenic and histrionic clichés as the framework to displays of acting for "points." Painted scenery and standard properties out of stock were changed in full view of the public; plays of the past were costumed in a mixture of traditional, modern and haphazardly fancy dress from the theatre wardrobe; movement, grouping and even gestures were regulated by custom rather than

dramatic truth; rehearsals were called mainly to demonstrate their exits, entrances and positions to subordinate actors; the stars—like operatic singers—played most of their big scenes by the footlights while the rest of the cast waited disinterestedly for their cues.

In the new art and industry of the theatre which began to emerge in the 1880s the need for an independent organizer of the play became apparent on several counts: the sheer physical expansion in the volume and range of theatrical production; the growing complexity of stage machinery, lighting and organization; the requirements of a new drama for a new mode of acting and for fidelity not only to the text but (as in the plays of Ibsen and Chekhov) to the stage directions; the public's mounting expectation of realism (both external and psychological) and unity (both visual and emotional); the influx of middle-class actors, outside the old craft system, who had to be coached and welded together from play to play; the eclecticism of taste, especially in revivals of past drama in appropriate styles; the breakup of the old conventions of performance and production; and (in the Anglo-American theatre, especially) the transference of productive power from the actor to the entrepreneur, who employed the director as his artistic agent.

First Directors in the 19th Century.—The era of the modern director was inaugurated in 1874, when a minor German aristocrat, George, duke of Saxe-Meiningen, startled Berlin playgoers with a revolutionary company from his court theatre. The duke was his own producer with his own stage, and a working guarantee of financial security (from his private fortune) freed him from the restrictions of immediate box-office budgeting. He designed all the sets and costumes; he supervised every detail in lighting and make-up, introducing a more realistic use of light and shade; he broke up the surface of the stage floor, establishing new levels of acting area; and he insisted on "the continuous and direct relation between the design of a setting and the actor's movements within it" (Lee Simonson, *The Stage is Set*). In training actors he attacked the baroque tradition of strut-and-bluster playing and with iron discipline he fused his players into an ensemble of which Europe had never seen the like. Especially impressive were the Meiningen crowd scenes, for every individual in the crowd was a trained actor (not, as was usual, an amateur "supernumerary"). Months of rehearsal went into every production and between 1874 and 1890 the Meiningen company visited 36 cities.

Other, more fundamental pressures were at work in the theatre—notably, the pressure toward naturalism, in the attempt to make the stage a more candid and "scientific" reflection of the contemporary world outside it. It was under the banner of Emile Zola that in 1887 the *Théâtre Libre* was founded in Paris by André Antoine. Photographic verisimilitude, in recreating the physical environment of the drama, was Antoine's aim as a director. He established "fourth wall" scenic realism (already heralded by Madame Vestris), developed a new ensemble pattern of naturalist playing among his troupe of amateurs and not only introduced outstanding foreign dramatists to the Paris stage—Ibsen and Tolstoi among them—but also brought new French writers (such as Eugène Brieux) into the theatre. Later in his career, during his ten-year directorship of the officially subsidized *Odéon*, he extended his methods from the contemporary drama to the classics. In Germany, within two years, the *Théâtre Libre* was followed by the *Freie Bühne*, which opened in Berlin with *Ghosts*. This company was founded and directed by Otto Brahm, a literary critic who did for the German stage what Antoine did for the French. Unlike Antoine he began with a company of professional actors, and his productions were sporadic and limited to matinee performances. The *Freie Bühne* collapsed after two seasons, but Brahm later worked at the *Deutsches theatre* in Berlin. In Russia in 1898 Konstantin Stanislavski—a wealthy dilettante who had worked for years with amateurs—founded the *Moscow Art theatre*, in collaboration with the playwright Vladimir Nemirovich-Danchenko. As in France and Germany, this enterprise was a platform for naturalist drama and new writers, notably Chekhov and Gorki, were introduced to the stage. Stanislavski's first productions, like those of Antoine and Brahm, were obsessively concerned with the

exact reproduction of reality (he insisted upon buying properties and clothes in the actual places where plays were set), although in the course of his long and influential career he moved away from external to inner realism, from scenery to psychology and from drilling his actors to collaborating with them, which illustrates the general trend of naturalistic direction.

After the foundation of the *Théâtre Libre*, stage realism and naturalism (the terms were never satisfactorily distinguished) survived as dominant influences in theatrical direction, especially in the Anglo-American theatre. Yet the early champions of the director's art advocated its use in the service of very different theatrical ideals: to express men's inner, emotional truths and to reflect not particular fact but universal reality. Richard Wagner developed the conception of the *Gesamtkunstwerk*, in which all components of the theatre arts were to be synthesized under the single authority of the director. In studying the problems of staging Wagnerian opera Adolph Appia demonstrated in two seminal books of the 1890s that the director had a new weapon at his command in electric light, used with deliberate unreality to suggest (not to reproduce) in the illumination of three-dimensional settings without painted scenery or realistic properties. And Gordon Craig eloquently argued the need for the stage manager's dominion over the art of the theatre. Three years after the *Théâtre Libre* was established, the *Théâtre d'Art* was opened in opposition by a poet-director, Paul Fort. Believing in a theatre of fantasy not of fact, in evocation and not imitation, Fort introduced a simplified décor of draped curtains and formalized backcloths, instead of the "naturalistic lies" of the scene painter. Heralding later directors' attempts to subjugate the intransigent actor, Fort also ventured upon some stylization of performance by immobilizing his players in statuesque poses. The *Théâtre d'Art* lasted for only two years, yet Fort stands for all those directors who followed him in opposition to the naturalistic theatre, under the banners of symbolism, theatricalism, expressionism and other causes.

The 20th Century.—Selective realism and theatrical eclecticism characterized the leading directors of the 20th century. In Germany Max Reinhardt experimented in many kinds of theatres on many kinds of stages. Borrowing from Japanese, Greek and Elizabethan styles, from the circus and the passion play, Reinhardt directed plays old and new in places as different as Salzburg cathedral and the square outside it, a Venetian piazza and a Viennese ballroom, the Boboli gardens, Florence, and the vast arena of London's Olympia. He was as much at home as a director in the intimate *Rammerspielhaus* with Molière as in the *Grosses Schauspielhaus* in Berlin, a converted circus ring where he hoped to revive the mass theatre of antiquity. Reinhardt tried to change the theatre's relationship with its audience and with its past, especially in his insistence on the play script as being one element only in production. Whereas the realistic theatre of Antoine, Brahm and their successors depended upon the complete separation of the actor from the audience behind the proscenium arch and orchestra pit, Reinhardt brought the actor out of the picture frame into the middle of his public. He transformed German acting style in the classics, had a special gift for the orchestration of crowds which helped to make his international reputation as a master showman and founded the first school for directors.

Among other notable German directors were Leopold Jessner, whose productions at the Berlin State theatre between 1919 and 1925 were celebrated for his use of broad symbolic and expressionist effects on massive stairways connecting different levels of acting area, and Erwin Piscator, the pioneer of "epic theatre" who, after a stormy career in Berlin through the 1920s, settled in the U.S. in 1930. Piscator was a ruthless opponent of theatrical illusion, atmospheric production and identification of the actors with their roles. He made no attempt to mesmerize the audience into oblivion: stridently and aggressively they were reminded that they were watching actors at work who were trying to prove a case, not to create a world of make-believe. Slogans blazed in electric lights above the proscenium; searchlights roved across the stage and the auditorium; loud-speakers blared and mobile scenic units were trundled on and off; while Piscator's actors were

employed to present types, rather than to imitate people. Piscator made extensive use of stage machinery, which had been widely developed in the German theatre, and he believed in combining live and filmed action by the frequent interpolation of cinematic sequences. His theories of "epic theatre" were developed and enlarged by one of his early collaborators and authors, Bertolt Brecht, who later in the 1950s created and directed his own company, the Berliner Ensemble, with state aid from the German Democratic Republic.

In the G.S.S.R. Vsevolod Meyerhold experimented for 30 years in antirealistic theatre until his arrest in 1939. Like Reinhardt, Meyerhold pushed the actors into the audience and attempted a new social integration in his Theatre of the Revolution but, whereas Stanislavski ignored the audience, he attacked it. In place of Reinhardt's eclectic theatricalism, Meyerhold—"the Picasso of theatre," as he has been called—worked restlessly and adventurously toward a narrower aesthetic of abstraction. Often he filled the stage with constructivist settings—scaffoldings, ladders and ramps—and coached his actors as gymnasts and acrobats in a system of "biomechanics." Exhorting them to practise "the vigorous elimination of all humane feeling" and to suppress their "little, rickety egos," Meyerhold did his best to stylize them into puppets and machines. At Moscow's Kamerny theatre, from 1914 to 1934, Alexander Tairov worked along similar lines, putting his actors in exaggerated make-ups and masks and drilling them in formalized speech and gesture. For a few years in the 1920s E. V. Vakhtangov, a pupil of Stanislavski, tried to reconcile the methods of his master and Meyerhold against the background of a new socialist society at the Moscow Art Theatre Third Studio; and in the 1930s Nikolai Okhlopkov made significant experiments in central staging at the Realistic theatre in Moscow. After the disappearance of Meyerhold, experimental direction in the U.S.S.R. came to a virtual standstill: but the director—under political guidance—remained in supreme authority.

In France the outstanding director of the 20th century was Jacques Copeau, a literary critic who in 1913 founded the Théâtre du Vieux-Colombier in Paris. Copeau's explicit aim was to serve the author and to show the actor how to do it. Every play, Copeau insisted, has a rhythm of its own which determines its use of stage space and every literary style engenders its own appropriate style of performance: this rhythm and this style must be discovered by the director as the interpreter of the text and the actors' leader. He encouraged his actors to make their voices and bodies more flexible and to share his own dedicated sense of duty toward theatrical reform. Believing that the physical structure of the playhouse could enhance the intellectual structure of the drama, he presented his productions at the Vieux-Colombier on a small platform stage in front of a permanent architectural background, without footlights or proscenium. Copeau's first company included Charles Dullin and Louis Jouvet, who later emerged as two of Europe's leading directors. Other eminent French directors between World Wars I and II were Georges Pitoëff, Gaston Baty and Michel Saint-Denis, the nephew and disciple of Copeau, while in the 1940s Jean-Louis Barrault and Jean Vilar appeared as actor-director-producers at the summit of European theatre.

Thus throughout Europe after 1887 directors led the theatre in the service of a new drama, coaching new breeds of actors: introducing new methods of staging, reaching out for a new kind of audience. From the start, many of them controlled playhouses and companies of their own which played a significant and continuing part in the theatrical life of their nation. Many were supported by state or civic subsidy. In Britain and the U.S., however, the situation was very different. The outstanding director in the U.S., then and for years to come, was David Belasco, who was also his own producer at his own theatres, but this showman did nothing to promote new drama or acting. Although acclaimed for the meticulous efficiency of his stage management and lighting, Belasco's realism was an end in itself. The exact reproduction of life, in Zola's terms) shrunk to the careful copying of clothes and furniture. In the 1920s notable individual directors emerged inside the commercial theatre, such as Arthur Hopkins and Guthrie McClintic, with occasional productions of individual plays; Ken-

neth Macgowan worked with the play-producing societies of the Provincetown players and the Greenwich Village theatre; but it was not until 1931—when the Group Theatre was launched—that a U.S. director could enjoy any continuity of creative purpose among the anarchy and waste of the long-run system. In that year Harold Clurman, Lee Strasberg and Cheryl Crawford developed a more or less permanent ensemble of actors dedicated to and coached in the principles of naturalistic acting formulated by Stanislavski, employed in the production of new, naturalistic dramatists, of whom Clifford Odets was the most important. The Group Theatre exerted a far-reaching influence in the U.S. during the next 20 years and among its eminent graduates was Elia Kazan, who became one of the leading directors on the Broadway commercial stage.

In Britain, unlike the U.S., two significant attempts were made to establish a national equivalent of the Théâtre Libre before World War I. The first of these ventures, the Independent theatre, was founded in 1891 by an Anglo-Dutch dramatic critic, J. T. Grein, as a society of enthusiasts who financed special performances of plays, with scratch casts, on any stage that could be rented for a matinee or Sunday night. The direction was done by anyone available. Through this group and the Stage society many outstanding plays were shown to members and both helped to extend the horizons of the British drama. Yet, lacking an organizing director and a permanent home, their impact on acting and production was negligible compared with their European contemporaries. Their work, however, helped to prepare the way for a far more influential enterprise—the three-year management of the Court theatre from 1904 to 1907, backed by a commercial producer, John Vedrenne, and directed by Harley Granville-Barker. Avoiding conventional "slice of life" realism, Granville-Barker—perhaps the outstanding British director of the century—insisted on truth as opposed to effect. In an era of star-acting and spectacular scenery, he carefully schooled his company in "natural" ensemble playing, where even the smallest part was rehearsed and studied in detail and every actor was encouraged to develop for himself the truth of his role. Like Copeau, Granville-Barker put the author first and, as part of his ambition to reform the stage, he sought to raise the art of acting to new heights, not in histrionic display but in serving the drama. Later at the Savoy theatre from 1912 to 1914 he set new standards of production and performance in Shakespearean staging. But thereafter Granville-Barker—self-exiled from the commercial stage—made no further sustained contribution as a director to the British theatre.

Few other English directors enjoyed a similar opportunity in the next 50 years and for two generations the London stage seemed curiously insulated from cross-channel developments in dramaturgy, lighting, design and acting. Among the rare artists who achieved some continuity of theatrical control was Sir Nigel Playfair, who from 1918 to 1932 was director-producer of the Lyric theatre, Hammersmith. In 1926 a wealthy dilettante, Terence Gray, established Britain's only venture in antirealist staging at the Cambridge Festival theatre: under his control, until 1933, a wide range of plays was produced without props, scenery or proscenium arch on a multi-level stage jutting out into the auditorium, but these isolated experiments had little effect on the British theatre at large. It was in Shakespearean staging that the individual director had most power and prestige. At the turn of the century William Poel—Granville-Barker's master—had organized his Elizabethan Stage society which, from 1894 to 1905, demonstrated the importance of the theatrical conditions under which Shakespeare wrote. Attacking the "vice of scenery," the cluttering traditions of stage "business," the star-actors' mutilation of the text and the limitations of the picture-frame stage, Poel emphasized swift and musical speech, continuity of action in nonlocalized scenes, fidelity to the script and greater intimacy between the players and the public. Outside the commercial stage, at the Old Vic theatre, London, and the Shakespeare Memorial theatre, Stratford-upon-Avon, other directors made their name in Shakespearean revival. Among the most eminent were Tyrone Guthrie, Peter Brook, Peter Hall, Michael Benthall and Glen Byam Shaw, while Theodore Komisarjevsky and Michel Saint-Denis had a

strong influence in the 1930s.

By 1960 stage direction in general was characterized by empiricism and eclecticism. In Britain and the U.S. most directors were still—compared with their European contemporaries—displaced persons without a theatre or company of their own. Hired by commercial producers as artistic free lances to organize scratch casts in a few weeks of rehearsal, they were committed to the diluted realism of the picture-frame stage, the dominant aestheticism of the entertainment industry on both sides of the Atlantic. Yet in the 1950s the London theatre was infiltrated by two highly successful and influential ventures under the control of individual directors (subsidized by state and civic enterprise) with permanent bases in the capital: Joan Littlewood's Theatre Workshop, which presented a bold range of classics and new drama under Brechtian influence with Britain's only permanent acting ensemble, and George Devine's English Stage company, which introduced many new writers, actors, designers and directors at the Royal Court theatre.

PRODUCTION

In the course of its history the theatre has been variously sustained by the love of God, art, gold and glory—as a royal diversion, a religious ritual, a social service or a commercial speculation—but throughout its changing styles and forces of production it always depends upon one prime mover, the man who puts on the plays. In the London theatre he is the manager; in Germany, the *intendant*; in the English provincial repertories and other European playhouses, the director or administrator; in the G.S. theatre, the producer. To simplify the confusing nomenclature of the stage he will be called the producer in this article: the central organizer of the play's economics and administration as distinct from the aesthetic organizer, who will be called the director. It is the producer (in this sense of the term) who selects the plays; who engages the cast, designer, director, composer, orchestra and technical staff; who controls or (in the commercial theatre) rents the playhouse; who finds and spends the money required to finance the show. As the main middleman between the artists of the theatre and the audience, it is on his initiative, taste and industry—in using artistic supply to create and/or satisfy public demand—that the welfare of the theatre largely depends.

Subsidiary Role of Early Producers.—Sometimes theatrical production was organized by an outside financier, shoaman or theatre owner. In Shakespeare's day Philip Henslowe, a wealthy property dealer, owned three London playhouses and controlled several companies in turn. David Garrick's first producer at Drury Lane theatre in 1742 was a rich dilettante, Charles Fleetwood. Outside the Anglo-American theatre, production was often subsidized by the state and supervised by an official administrator (as in the *Comédie Française*). Yet, generally speaking, it was for nearly 2,000 years the main responsibility of the theatre's authors and actors. The artists of the theatre were usually their own producers.

At times the playwrights were in control of production. At the tragic festivals of Athens, Aeschylus was actor, director and producer. Shakespeare not only played in some of his own works but he was also co-producer, as a leading member of his fellowship with a share in both the company and the playhouse: it was his producer's profits, and not the relatively meagre rewards of his writing, that set him up as a country gentleman in Stratford. Molière, too, combined the roles of actor, author and producer. Ludwig Tieck in Dresden, Ferdinand Raimund in Vienna, August Iffland in Mannheim, Goethe in Weimar, Ludwig Holberg in Copenhagen, Henrik Ibsen in Bergen, Alexandre Dumas *père* in Paris, Henry Fielding and Samuel Foote in London—all for a time com-

manded theatres of their own.

But it was the actors who usually ruled the roost, especially in the Anglo-American theatre. Production was sometimes shared by the leading members of a troupe, as in the Elizabethan fellowships or Italian *commedia* companies, but more often it was organized by the star player who was, until the beginning of the 20th century, his own director, producer and even landlord. It is not only as actors but as producers that such names as Garrick, Samuel Phelps, William Macready, Charles Fechter, Richard Mansfield, William Evans Burton and the Wallacks are remembered; and all of them worked without official subsidy in the open market, usually with a permanent company of their own and sometimes with a playhouse on a long lease, often helped by a business manager. The heyday of the actor-managers (as they were known in England) came toward the end of the 19th century, with the recruitment of a vast new middle-class audience as the customers of a rapidly expanding entertainment industry. In England knight-hoods signaled the unprecedented success and respectability of Sir Squire Bancroft, Sir Herbert Beerbohm Tree. Sir Charles Wyndham. Sir George Alexander. Sir John Martin-Harvey, Sir Johnston Forbes-Robertson and Sir Henry Irving. Commissioning plays, remodeling theatres, organizing tours, setting styles and standards, these actors ensured a continuity of production unknown to the modern commercial stage. But with their reign ended the traditional supremacy of the actor in theatrical production. Accelerated by World War I. the social forces that had helped them to make their fortunes also destroyed their kind of theatre. The actor's authority over both playhouse and production was dissolved and new powers took control.

Development of the Professional Producer.—The enormous increase in the potential profitability of theatrical enterprise, with the development of the long run and its provincial touring companies, attracted outside speculators and financiers who supplied the capital needed to build new playhouses and exploit new fields of production. Theatre owners in the 20th century sometimes engaged in production themselves, or let their stages to the highest bidder for the run of one show, and this bidder was, after World War I, no longer an actor but an entrepreneur, the old-style business manager transformed from the actor's servant into his master. Productive power was dominated increasingly by a few syndicates—notably, at first, in the U.S., where the Theatrical syndicate (formed in 1896) controlled for approximately 16 years most of the New York theatre and many playhouses outside it. Later the Shubert brothers—Lee, Sam S. and J. J.—dominated the U.S. stage for over 40 years: in 1950 the U.S. government filed a civil antitrust suit (later dropped) charging them with monopolistic practices. The Shubert Theatre corporation was then said to control 37 playhouses (including 17 in New York) and a large part of the nation's theatre bookings. In Britain it was not until 1942 (when Sir Oswald Stoll's death threw the control of his Theatres corporation on the market) that a concentration of power comparable to the Shuberts' empire was initiated. Under the leadership of Prince Littler, a small group of men extended control over nearly half of London's theatres and the chief "number one" stages in the provinces. By 1960 this group had a large stake in theatrical insurance, advertising, catering, entertainment agencies, the recording industry and independent television; it was linked with the country's most powerful producer of "straight" drama; and its members included Britain's biggest producers of light entertainment outside the legitimate theatre.

The golden age of theatrical expansion lasted, at most, about 30 years between the 1890s and the 1920s. When business declined, in an era of steadily rising costs and fierce competition first from the cinema and then from television, theatre owners on both sides of the Atlantic found compensation in the inflation of urban land values. Playhouses were destroyed in increasing numbers as expendable units in property deals: in Britain the number of professional stages, which had risen from about 100 in 1800 to about 700 in 1900, dropped by 1960 to less than 200. This liquidation of the theatre's physical assets, the concentration of economic power and the steep rise in costs had obvious repercussions on the forces of production in both Britain and the U.S., where there

was no tradition—as in France and Germany—of state or civic subsidy and protection.

In London and New York commercial producers had to compete from play to play for the hire of a restricted number of theatres in private ownership. They were often obliged to present plays in buildings of the wrong size, or to jettison productions because no stage was available. Continuity in casting or policy was virtually impossible in the uncertain conditions of the entertainment industry. A show was rehearsed for a few weeks by a company of actors starting from scratch and was allowed to run just as long as it paid the lessee of the theatre and the producer, which might be for three years or three days. The producer had to mobilize his audience at once: a very high level of takings was necessary from the first week of the show's run if he was to keep a stage for it. For as soon as box-office receipts fell below a certain figure, the theatre lessee usually had the right to give the producer notice to quit. It was the man with the theatre who had the power in the long-run system. His rent was among the biggest items in the inflationary production budget, together with star salaries and (in the U.S.) the excessive backstage payroll caused by trade union "featherbedding" and restrictive practices. While prices of admission, on average, doubled between 1940 and 1960 in London, costs more than trebled. Yet a straight play costing £5,000 to stage in London would cost three times as much on Broadway, and a U.S. musical would probably have to run the best part of a year before it paid back its production costs (which might be in the region of \$200,000) and the producer began to make a profit. In New York prices might soar to as much as \$40 a ticket, but only a few shows every season inspired such speculation and only a small fraction of such inflated prices was taken by the producer. Generally speaking, his actual costs increased at a far higher rate than his potential revenue; he had to count in New York (and increasingly in London) upon an immediate smash-hit success, knowing the alternative to be an instant flop; and the virtual liquidation of the commercial stage outside these theatrical capitals radically reduced the possible compensations of a post-metropolitan tour.

In both Britain and the U.S. the primary factor in the future of the commercial theatre was that, in an era of continuing real-estate development, a playhouse was an uneconomic user of urban land. Moreover, the making of profits became—in New York especially—an increasing gamble every year. Between the 1920s and 1950s about 75% of New York's stages were lost to the living theatre and, although in the 1950s new outlets developed for productive forces in the "off-Broadway" theatre, the costs rose so rapidly that the producer of a success was lucky to break even. Whereas in the 1920s the U.S. producer was generally self-financing, in the 1950s he had to enlist the support of professional backers or "angels" to raise the necessary capital. This trend, still less significant in London during the 1950s, represented a further specialization in the forces of theatrical production and a decline in the authority of the individual producer.

Yet producers in the 1950s experienced little difficulty in recruiting the necessary cash for individual shows with a possible commercial future. For although the odds against survival were increasingly heavy, the rewards of success were increasingly high, not only from the local box office but from foreign rights, film rights, television rights and so on. Moreover, the system brought not only financial but artistic results. In spite of the wastage of talent involved in the hit-or-flop system, its successes were often widely staged throughout the western world. The Anglo-American commercial stage compared favourably in dramaturgical fertility and histrionic variety with the noncommercial theatre in Germany and the C.S.S.R.

For this, one reason was the developing importance of the non-commercial theatre as a training ground and shopwindow for actors, authors, directors and audiences. A vital role in British production was occupied by the leading repertory theatres in such cities as Birmingham and Bristol, which took the place of the stock companies in the 19th century. The pioneering producer of the repertory movement was Miss A. E. F. Horniman, who established the Repertory Theatre of Ireland at Dublin's Abbey

theatre in 1904 and founded the first "rep" in Britain in 1908 at the Gaiety theatre in Manchester.

The principal British repertories are supported by state aid, distributed through the Arts Council of Great Britain, an independent body outside direct ministerial control and established in 1946, which played an important indirect role in production after World War II. After the Local Government act of 1948 civic authorities were also empowered to subsidize theatres from the rates and, by 1960, about a dozen municipalities gave direct aid to their local repertory companies. Production in the leading "reps" was organized on a short-run basis of two or at most three weeks, financed by a nonprofit-distributing trust which generally appointed a director-producer to control the theatre, assisted by a business manager. Although most of these repertories were afflicted by lack of capital, inadequate housing and the widening gap between costs and prices, there were signs by 1960 that their future role would be more secure. State aid was, in the late 1950s, increasingly supplemented by subsidies from television and other industries; and more civic authorities seemed ready to follow the lead of Coventry and build new playhouses for their local companies.

Of especial importance in noncommercial production of the classics was the Old Vic theatre in London, since 1914 the home of Shakespeare and the workshop of most of the stage's leading talents. Production was controlled, under a board of governors, by a director and an administrator in partnership and subsidized by the state and (in the 1950s) by various donations from industry. At Stratford-upon-Avon the Shakespeare Memorial theatre, after many years of relative obscurity, achieved in the 1950s an unprecedented commercial and artistic success—without any external subsidy—under the control of a director-producer, assisted by a business manager. In London the West End stage was transformed in the 1950s by the impact of two noncommercial organizations, both with a permanent stage of their own outside central London and both controlled by a producer-director: Joan Littlewood's Theatre Workshop and George Devine's English Stage company, based at the Theatre Royal, Stratford, and the Royal Court theatre, Chelsea, respectively.

In the U.S. theatre, unlike the British, noncommercial production in the first half of the 20th century was largely controlled by amateurs, often with stages of their own which put to shame the theatrical housing of London and New York. Ever since George Pierce Baker established his "47 Workshop" at Harvard in 1912 the arts of the stage occupied a place of increasing importance in the curricula of U.S. universities. By 1960 there were over 400 university stages, which represented almost the only U.S. theatre subsidized by public funds. Community theatres, usually financed by seasonal subscription, began to sprout in the 1920s as the old-style professional stage declined. By 1960 there were about 2,300 of them, including a few (as at Kalamazoo and Indianapolis) supported by civic funds, and an increasing number were partly or completely professional. The outstanding community theatres were—like Gilmore Brown's Pasadena playhouse and Frederic McConnell's Cleveland playhouse—created and run by director-producers. In the U.S. the state's only venture into theatrical production was the epoch-making Federal Theatre project, administered under the relief program of the Works Progress administration from 1935 to 1939. Under the leadership of Hallie Flanagan, Federal theatre sponsored nationwide production on an astonishing scale and with an immensely creative effect upon artists and audiences. In New York several attempts were made to establish a producing organization with a consistent policy and a continuous existence outside the cash nexus of Broadway show business. Eva Le Gallienne ran her Civic Repertory theatre from 1926 to 1933 and the Group Theatre (see *Direction*) survived from 1931 to 1941. Yet few of these enterprises did more than to introduce individual talents into the commercial stage and most were quickly swallowed up by the entertainment industry. See also MOTION PICTURES; STAGE DESIGN; THEATRE; MAKE-UP (STAGE, MOTION PICTURE AND TELEVISION). (R. F.)

ACTINIUM. The metallic element actinium (after the Greek *aktis* or *aktinos*, "ray," in recognition of its radioactivity), with

symbol Ac and atomic number 89, was discovered by A. Debierne in 1899 and independently by F. O. Giesel in 1902. The radioactive isotope discovered is known to have the mass number 227 and half-life 22 years and is a member of the natural, $4n+3$ radioactive family. A number of other isotopes, natural and artificial, are known and are too short-lived to isolate in macroscopic quantity. Before 1950 the chemical properties were investigated by the tracer method.

The isotope Ac^{227} can be isolated in pure form from uranium ores, containing its precursor U^{235} , only with difficulty. A better source is the transmutation of radium through intense pile neutron bombardment according to the reactions $\text{Ra}^{226} (n, \gamma) \text{Ra}^{227} \xrightarrow{\beta^-} \text{Ac}^{227}$. This latter source was used by F. Hagemann in 1950 for his first isolation of actinium in the form of pure compounds and was used for subsequent investigation of the chemical properties of pure actinium compounds.

Actinium is colourless and exclusively tripositive in solution, closely resembles the tripositive rare-earth (lanthanide) elements in its chemical properties, and may be regarded as the prototype for the 13 following rare-earthlike (actinide) elements of atomic numbers 90–102 inclusive. It forms insoluble compounds of the same type as the rare-earth elements such as fluoride, oxalate, hydroxide and a number of crystallized double salts. However, actinium is more basic than even lanthanum, contributing to differences from rare-earth elements in the extent to which certain complex ions are formed. It may be separated from the rare-earth elements and the heavier tripositive actinide elements by use of ion exchange resins or distribution between aqueous and organic solvents. Known solid compounds are all tripositive, colourless (except the sulfide), isostructural with the analogous lanthanide and actinide compounds, and include the halides, oxyhalides, sesquioxide, sulfide, hydroxide, phosphate, oxalate and some double salts. See also RADIOACTIVITY, NATURAL. (G. T. SG.)

ACTMOLITE: see AMPHIBOLE.

ACTINOMETER, an instrument or process for measuring the chemical effect of radiation, taking its name from the so-called "actinic" or chemically active rays. Intensity of fluorescence of various salts, rate of darkening of bromide paper, rate of decomposition of potassium permanganate or of hydrogen iodide, rate of formation of ozone and other chemical effects have been used to standardize the intensity of radiation in different frequency bands. Comparative measurements are relatively simple; absolute measurements of efficiency of quantum yield are difficult. Most actinometers are of an integrating type.

For more rapid measurements of radiation intensity, without respect to specific actinic or chemical action produced thereby, numerous electrical instruments are also available in recent forms of light meters, exposure meters and photoelectric cells (see PHOTO-ELECTRICITY).

The thermojunction, thermopile and bolometer were earlier instruments in this category. (R. M. SN.)

ACTINOMYCOSIS (STREPTOTRICHOSIS or LUMPY JAW), a chronic infectious disease, occurring in cattle and in man and caused by the fungus *Actinomyces*. See FUNGUS INFECTIONS.

ACTION, in law, a proceeding in a court for enforcing legal rights. It may be civil or criminal, personal, real or mixed, local or transitory. Its objective is a judgment settling the rights asserted. See JUDGMENTS AND DECREES; PRACTICE AND PROCEDURE. (C. E. CL.)

ACTIUM (modern AKRA NIKOLAOS), the ancient name of a promontory in the north of Acarnania in Greece, on the southern side of the strait leading from the Ionian sea into the Ambracian gulf. Actium belonged originally to the Corinthian colonists of Anactorium, who probably founded the worship of Apollo Actius and the festival of games called Actia, which was later amplified by Augustus. In the 3rd century B.C. it fell to the Acarnanians, who subsequently held their synods there.

Actium is famous chiefly as the site of Octavian's decisive victory over Mark Antony (Sept. 2, 31 B.C.), which made him in fact the undisputed master of the Roman world (see AUGUSTUS; also ANTONIUS). Both men had large naval and land forces: Antony commanded about 500 ships and 70,000 infantry; Octavian had

400 ships and 80,000 infantry. Octavian's forces arrived from the north and, by occupying Patrae and Corinth, cut Antony's communications with the Peloponnese. Deserted by some of his allies, Antony twice failed in attacks on Octavian's camp, and lack of provisions soon forced him to take action. He rejected a plan to retire to Macedonia and fight by land and followed Cleopatra's advice to use his fleet. His ultimate purpose is obscure. He probably hoped for a decisive battle, with the expectation that, if he failed, he might break off and escape to Egypt; alternatively, he may have been attempting merely to escape from the blockade. He drew up his fleet offshore, facing west, with Cleopatra's squadron behind. The course of the action is not certain; perhaps while he, on the right, was trying to turn the northern left wing of Octavian's fleet, which was commanded by M. Vipsanius Agrippa, part of the centre and left of his line retreated to harbour. He signaled to Cleopatra, who had the treasure chest aboard, to escape, broke off the engagement and with a few ships managed to follow her. Octavian received the surrender of the fleet and, a week later, of the land forces. He founded the city of Nicopolis Actia (*q.v.*) on the other side of the strait, in commemoration of his victory.

ACTON, JOHN EMERICH EDWARD DALBERG ACTON, 1ST BARON (1834–1902), English historian and philosopher of freedom, was one of the first to lay bare the tyrannical tendencies of the modern state. The grandson of the Neapolitan admiral, Sir J. F. E. Acton, 6th baronet (*q.v.*), he was born at Naples on Jan. 10, 1834. His father came from the English Roman Catholic squirearchy and his mother from an old south German aristocratic family.

In 1840 his widowed mother married Lord Leveson, the future Lord Granville and Liberal foreign secretary, an alliance which brought Acton early into the intimate circle of the great Whigs. Educated at Oscott college, Warwickshire, he went to Munich to study under Dollinger (*q.v.*), who grounded him in the new German methods of historical research.

Civilized and cosmopolitan, rich, learned and widely traveled, he spent much time in Europe and the United States, and then in 1859 was returned to the house of commons for Carlou. In the same year he became editor, following John Henry Newman, of the Roman Catholic monthly, the Rambler, but this experience was unfortunate. He himself believed that a rigorously scientific history would ultimately strengthen the church and that Christian doctrine would be harmonized with the findings of history. But when Pius IX indicated that it was wrong, though not heretical, to reject the opinion of the Roman congregations, Acton did not dispute the pope's authority, but held that it condemned the intellectual independence of his journal (by then called the Home and Foreign Review) and so laid down the editorship. In the crisis in the Roman Catholic Church in 1870 over the dogma of papal infallibility, Acton was in complete sympathy with Dollinger. "We have to meet," he wrote to Gladstone, "an organized conspiracy to establish a power which would be the most formidable enemy of liberty as well as of science throughout the world." He had a hatred of the papal temporal power and an outraged sense of the many instances of its misuse in history. But he was deeply rooted in Catholicism and, unlike Döllinger, did not secede. He regarded "communion with Rome as dearer than life." His parliamentary career had ended in 1865—he was an almost silent member—but his friendship with Gladstone, a fruit of the Whig connection, was of great consequence for the minds of both men. Matthew Arnold used to say that "Gladstone influences all around him but Acton; it is Acton who influences Gladstone." He claimed, in fact, to be the author of the home rule policy for Ireland. He was raised to the peerage by Gladstone in 1869, and in 1892 Gladstone repaid his services as adviser by making him a lord-in-waiting. Queen Victoria uttered the wish that Prince Albert could have known him. In 1865 he married Marie von Arco-Vallery, daughter of a Bavarian count, by whom he had one son and three daughters.

After 1870, Acton wrote little, his only notable publications

being a masterly essay in the *Quarterly Review* (Jan. 1878) on "Democracy in Europe"; two lectures delivered at Bridgnorth in 1877 on "The History of Freedom in Antiquity" and "The History of Freedom in Christianity" (both published in 1907)—these last the only tangible portions put together by him of his long-projected "History of Liberty"—and an essay on modern German historians in the first number of the *English Historical Review*, which he helped to found (1886). In 1895, on the death of Sir John Seeley, Lord Rosebery appointed him to the regius professorship of modern history at Cambridge. His inaugural lecture on "The Study of History" (published in 1895) made a great impression in the university, and his influence on historical study was felt in many important directions. He delivered two valuable courses of lectures, on the French Revolution and on modern history, but it was in private that the effects of his teaching were most marked. He died at Tegernsee, Bavaria, on June 19, 1902.

Although Acton sometimes fell into credulous error, no earlier English historian had inculcated such rigorous standards of accuracy. The ethical principles that he expected to see maintained in politics he applied to history; in his famous memorandum for contributors to the *Cambridge Modern History*, of which he was the planning editor, he declared: "Contributors will understand that our Waterloo must satisfy French and English, German and Dutch alike; that nobody can tell without examining the list of authors where the Bishop of Oxford laid down his pen and whether Fairbairn or Gasquet, Liebermann or Harrison took it up."

His fame rests less on his few historical writings than upon his prescient concern with problems of political morality. Deeply influenced by Plato, a disciple of Edmund Burke and sympathetic to De Tocqueville, he saw the threats to liberty contained in democracy and socialism, and the evils of power when concentrated in the modern state. A stern critic of racialism and nationalism, his Liberalism was rooted in Christianity. "I fully admit that political Rights proceed directly from religious duties, and hold this to be the true basis of Liberalism." For him, conscience was the fount of freedom and its claims superior to those of the state. "The nation is responsible to Heaven for the acts of the State." If democracy could not restrain itself, liberty would be lost. The test of a country's freedom was the amount of security enjoyed by minorities.

For Xcton, in his judgment of politics as of history, morality was a matter of life and death. He was the great modern philosopher of resistance to the evil state.

Acton's *Lectures in Modern History* (1906), *History of Freedom and Other Essays* (1907) and *Historical Essays and Studies* (1907) were edited by J. N. Figgis and R. V. Laurence and his *Essays on Church and State* were edited with an introduction by Douglas Woodruff (1952). *Letters of Lord Acton to Mary . . . Gladstone* were edited with an introductory memoir and valuable references to authorities by H. Paul (1904); a selection from Acton's correspondence was edited with an introduction by J. N. Figgis and R. V. Laurence (1917-).

ACTON, SIR JOHN FRANCIS EDWARD (1736–1811). English baronet who was prime minister of Naples under Ferdinand IV (*q.v.*), was the son of Edward Acton, a physician at Besançon, France, and was born there in 1736. He succeeded to a distant cousin's baronetcy and estates in 1791. Acton served in the navy of Tuscany and in 1775 commanded a frigate in the joint expedition of Spain and Tuscany against Algiers. In 1779 Queen Maria Carolina of Naples persuaded her brother the grand-duke Leopold of Tuscany to allow Acton to reorganize the Neapolitan navy. He became commander in chief of both services, minister of finance and finally prime minister. His policy aimed at substituting Austrian and British influence for Spanish in Naples, and consequently involved open opposition to the French in Italy during the French Revolutionary and Napoleonic Wars. In Dec. 1798 he shared the flight of the king and queen. For the reign of

terror which followed the downfall of the Parthenopean republic. five months later, Xcton has been held responsible. In 1804 he was for a short time deprived of the reins of government at the demand of France; but he was soon restored to his former position which he held until, in Feb. 1806, on the entry of the French into Naples, he had to flee with the royal family into Sicily. He died at Palermo on Aug. 12, 1811.

Acton's elder son, Richard, was the father of Lord Acton, the historian. His second son, Charles Januarius Edward (1803–47), became a member of the Curia Romana, helped to secure the increase, in 1840, of the English Roman Catholic vicariates-general to eight (which paved the way for the restoration of the English Roman Catholic hierarchy in 1850) and was created cardinal in 1842.

See Harold Acton, *The Bourbons of Naples* (1956).

ACTON, a municipal (1921) and parliamentary borough of Middlesex, Eng., is a western suburb of London adjoining Hammersmith, about 9 mi. W. of St. Paul's cathedral. Pop. (1961) 65,274. The best derivation offered for its name is from *ac-tun*, "settlement near oaks," in reference to the extensive forest which formerly covered Middlesex. The land belonged from early times to the see of London, a grant being recorded in 1220. At the time of the Commonwealth, Acton was a centre of Puritanism and in the 18th century it became a fashionable inland watering place with an assembly room and houses for people of rank. From 1870 onward Acton's position with regard to communications with London made it into an industrial centre with general engineering, plating, map and music printing works, etc. It received its charter of incorporation in 1921. Famous residents include Richard Baxter (nonconformist minister), Sir Matthew Hale (lord chief justice), Henry Fielding (the novelist), Lord Lytton, who lived at the Priory, and John Lindley (the botanist).

ACTS OF THE APOSTLES, the fifth book of the New Testament. This book was written in Greek by Luke as the sequel to his gospel, though it may have been penned after a first draft and before the final one of the gospel. Acts is historically of unique interest and value, being the one church history that is primitive both in spirit and in substance; apart from it a real picture of the apostolic age would be impossible. With it, the Pauline epistles are of priceless historical value; without it, they would remain bafflingly fragmentary, often even misleading, owing to their "occasional" nature and emphasis.

Contents.—After the first five introductory verses, addressed to Theophilus (an unknown person to whom the gospel of Luke also is addressed), Acts may be divided into six sections:

1. i, 6–v, 42. The origins of the church at Jerusalem (the Ascension; the choice of Matthias to take Judas' place as an apostle; the coming of the Holy Ghost at Pentecost; Peter's first speech, which won 3,000 converts; the healing of a lame man at the gate of the Temple by Peter and John, which led to their imprisonment by the Jewish authorities because they were preaching the resurrection of the dead; their release the next day after a severe caution to which they replied that they must obey God rather than man; the attempt among the Christians to have all things in common; further imprisonment of the apostles and their release on the Jewish rabbi Gamaliel's advice).

2. vi, 1–ix, 31. The death of Stephen and the spread of the church in Palestine, leading to Paul's conversion (the appointment of seven men to relieve the administrative burden of the apostles; the arrest of one of them, Stephen, by the Jews on charges of blasphemy; his defense and execution; the Jewish persecution of the church in Jerusalem which caused dispersal of Christians through Judaea and Samaria; the conversion of an Ethiopian eunuch by Philip, another of the seven; the conversion to Christ of Saul [Paul] the Pharisee on his way to Damascus to persecute the Christians).

3. ix, 32–xii, 24. The missionary work of Peter (Peter's curing of diseases at Lydda and Joppa; his dream at Joppa that he must not call things common which God had purified, followed by his visit to a gentile named Cornelius to whom the Holy Spirit was given in his presence; his baptizing of Cornelius and his household; his justification of disregarding the Jewish Law which convinced

the Jewish Christians in Jerusalem; the visit of Barnabas and Saul to Antioch and to Judaea with aid for famine relief; the martyrdom of James the son of Zebedee; the imprisonment and miraculous escape of Peter).

4. xii, 25–xvi, 5. The beginning of Paul's missionary travels and the apostolic council (Barnabas and Saul's journey from Antioch to Cyprus, Antioch in Pisidia, Iconium, Lystra and Derbe and their return; the apostolic council at Jerusalem which decided on what terms gentiles should be admitted to the church; the sending of Paul and Barnabas to Antioch with this message; Paul's second missionary journey with Silas to Syria and Cilicia).

5. xvi, 6–xix, 20. Paul's travels from Philippi to Ephesus (Paul and Silas' journey through Phrygia and Galatia to Philippi, Thessalonica, Beroea, Athens and Corinth; their return via Ephesus to Antioch; the third missionary journey through Galatia and Phrygia to Ephesus).

6. xix, 21–xxviii, 31. Paul's return to Jerusalem, his arrest and voyage to Rome (his address to the Ephesians after an uproar in favour of the goddess Diana; his visit to Macedonia; his return via Ephesus to Jerusalem, where he was arrested by the Jews for defiling the Temple; his appearance before the Sanhedrin; his removal to Caesarea and defense before Felix; his subsequent defense before Festus and appeal to Caesar; his voyage to Rome, including shipwreck on Malta; his meeting with the Jews in Rome, where he remained two years).

Authorship.—The name of the author of Acts appears in neither the title nor the book itself, but both external and internal evidence point to Luke, who is almost universally accepted as the writer. It is here assumed that Luke wrote the gospel that goes under his name (see LUKE, GOSPEL ACCORDING TO SAINT).

The earliest external evidence for Lucan authorship is found toward the end of the 2nd century. The so-called anti-Marcionite prologue to Luke's gospel (usually dated c. 180, though it may be later) states that Luke wrote Acts after his gospel. The Muratorian canon (c. 180–200; the oldest extant list of New Testament writings) also affirms Lucan authorship, and Irenaeus (c. 180) implies it. Clement of Alexandria (c. 200) and later church fathers accept it as Luke's work.

Internal evidence is found in the opening verse of Acts ("In the first book, O Theophilus, I have dealt with all that Jesus began to do and teach . . ."), which is addressed, like the dedication of Luke's gospel (Luke i, 1–41, to Theophilus, a Christian convert. It is natural to suppose that these two books, one of them apparently referring back to the other ("the first book") and both addressed to the same person, are the work of one author. Luke's gospel and Acts have strong affinities in both style and approach, which minute linguistic analysis has not been able to minimize.

Further, Luke is mentioned by Paul as a close friend and fellow worker (Col. iv, 14; Philem. 24). Now there are passages in Acts which appear to be written by a companion of Paul; in xvi, 10, without any previous warning, the narrative passes from the third person to the first: "And when he had seen the vision, immediately we sought to go on into Macedonia." Thenceforth "we" re-emerges at certain points in the story until Rome is reached. These parts at least are generally held to have been written by an eyewitness. If so, this eyewitness was almost certainly the author of the whole work, for the style of the "we" passages cannot be distinguished from that of the rest of the book. Thus Luke as a known companion of Paul is a possible author.

That Luke was a medical man is shown by Paul's reference to him as "the beloved physician" (Col. iv, 14), and some scholars have seen the medical cast of the language in certain passages of Acts as confirmation of Lucan authorship, though others have pointed out that no more medical knowledge is betrayed in Acts than would be possessed by any educated writer. The early tradition that Luke was born in Antioch suits the way in which the origin of the Antiochene church and its place in the extension of the gospel are described.

Although no one of the points here enumerated is alone conclusive, taken together they make a strong case for Lucan authorship, especially when it is remembered that this tradition is uncontradicted by any early Christian source. If Luke were not the

author there would have been no reason why his comparatively obscure name should ever have been associated with Acts at all.

Plan and Aim.—Acts is the work of an author of high literary skill, who exercised careful selection in the use of his materials, in keeping with a definite purpose and plan. It is therefore important to discover what these were. Luke himself gives hints about his aim at the beginning of the book (i, 1–11):

1. He implies that this second book is the logical sequence to his first. As his gospel set forth in orderly sequence the providential stages whereby Jesus was led, "in the power of the Spirit," to begin the establishment of the Kingdom of God, so Acts sets forth its extension by means of His chosen representatives or apostles.

2. This involves emphasis on the identity of the power, divine and not merely human, visible in the great series of facts from first to last; God's Spirit appears as active throughout.

3. But further, the divine energy in the disciples is conditioned by the continued influence and volition of their Lord at His Father's right hand in heaven: "Holy Spirit," the holy power of His personality (cf. xvi, 7 "the Spirit of Jesus"), is the living link between his actions and theirs (i, 2, 4 ff., 8; ii, 1–5; cf. Luke xxiv, 49).

4. And the scope of this action is nothing less than all mankind (i, 8; ii, 5 ff.), especially within the Roman empire.

5. Finally, as the parallel in Luke xxiv, 46–48 shows, the divinely appointed method of victory is through suffering (Acts xiv, 22), as it was for Jesus himself. This explains the space devoted to the tribulations of his witnesses, and their constancy amid them. It forms part of the virtual apologia for the absence of that earthly prosperity in which the ancient mind was apt to look for divine approval. Moreover, the church's enemies were chiefly Jews, whose opposition Luke regards as due to blindness to the wider reading of their own religion—to which the Holy Spirit had from of old been pointing (cf. Stephen's speech)—and to jealousy of those who, by preaching the wider messianic good news, were winning the gentiles, and particularly proselytes, in such numbers.

These, then, seem to be Luke's main motifs. the universality of the gospel, the jealousy of national Judaism, and the divine initiative, shown particularly in the gradual stages by which men of Jewish birth were led, in spite of their own prejudices, to recognize the divine will in the setting aside of national restrictions as alien to the universal destiny of Christ's church. The practical moral of the book is the divine character of the Christian religion, as evinced by the manner of its extension in the empire no less than by its original expression in its founder's life and death. Thus both of Luke's books tend to produce assured conviction of Christianity as of divine origin.

This view gives Acts a practical religious aim, for all early Christian writings were propaganda. In spite of the difficulties, Luke implies, this religion is worthy of belief, even though it means opposition and suffering. To meet this source of doubt Luke holds up the picture of early days, when Paul, the great apostle of the gentiles, enjoyed protection at the hands of Roman justice. It is implied that present distress is but a passing phase, resting on misunderstanding; for Christianity, as the true fulfillment of Israel's religion, had once been (and might again be) treated as a recognized (licita) religion, the more so in that it had deep kinship with non-Jewish philosophic monotheism. Meantime the example of apostolic constancy should inspire like fidelity. Acts is in fact an apologia for the church as distinct from Judaism, the breach with which is accordingly traced with fullness and care.

From this standpoint Acts does not, as some have thought, seem to end abruptly. Whether as exhibiting the divine leading and aid, or as recording the normal attitude of the Roman state, Luke at his conclusion reaches the climax of the gospel's progress: the arrival of Paul in Rome. In keeping with this, the solemn close of the book is xxviii, 26–28, the last two verses (30, 31) describing Paul's two-year stay in Rome being an appended observation. Yet even here, by the final word of all ("unhindered") Luke ends most fittingly on one of his keynotes.

The Question of Sources.—It is known that Luke used Mark's gospel and probably other sources when composing his own gospel. The question therefore naturally arises as to whether he also depended on earlier documents when writing Acts. He would perhaps

have had more need to do so in the first 15 chapters, which describe events in which he had not taken part, but he might also have used sources for some of the rest of the book.

Attempts have been made to postulate sources deriving from the place that forms the setting of certain sections of the narrative. For instance, in the first part of the book some scholars have distinguished a Jerusalem source, a Jerusalem-Caesarean source and a Jerusalem-Antiochian source. Others have made supposed differences in theology, outlook and style the basis for the postulation of sources. The "we" passages can be pressed into service in this connection. If their author is not the same as the author of Acts, then they would be an earlier source used by the latter but so insufficiently edited as to stand out as unassimilated fragments of a diary. There is no trace in Acts of dependence on the Pauline epistles, the only relevant documents still extant which Luke might have read.

But the search for passages in Acts that are based on earlier documents is bound to be guesswork, for no such sources have actually survived, so suppositions about them cannot be checked. In any case it is perhaps more probable that Luke elicited the material for his book by questioning the persons directly concerned with the events.

Historical Accuracy of Acts.—Acts shows accurate knowledge of both geographical and political conditions in the Roman empire of Luke's day, insofar as it can be checked by secular sources and by archaeology. The different titles of the Roman imperial officials mentioned are correctly given; for instance: *anthypatos* ("proconsul") in Cyprus (xiii. 7), Asiarchs at Ephesus in the province of Asia (xix, 31). The historicity of the famine in xi, 28 is supported by contemporary information. The trustworthiness of Acts on such matters is an indication that it is also to be generally relied upon in giving an accurate account of events in the early church.

Problems of Correlation With Paul's Epistles.—It is not possible to check the accuracy of the narrative in the first 12 chapters of Acts—which deal with the church in Jerusalem and Judaea and with Peter as the central figure—with any other contemporary document, as there is none that touches on the same events. But the last part of the book pursues the history of the apostle Paul, and here it can be compared with the latter's epistles. The result of such correlation reveals a general harmony, without any trace of direct use by Luke of the epistles, and there are many minute coincidences. But there are also two remarkable discrepancies: the account given in Paul's epistle to the Galatians of his visits to Jerusalem as compared with the narrative of Acts, and the nature of his mission as it appears in his letters generally and in Acts.

Briefly, the first problem here is the difficulty of correlating the three visits of Paul to Jerusalem described in Acts with the two only that are mentioned by Paul himself in Galatians (*q.v.*). If the council visit in Acts xv is to be identified with the second visit in Galatians (Gal. ii, 1–10), for the subject of circumcising gentile converts to the faith came up on both occasions, it is surprising that Paul in Gal. ii, 1–5 never even mentions the actual council decision, which would have been relevant to the point he was trying to make in Galatians, namely that in Christ the gentile Christian is freed from the Law, including the necessity of circumcision. If, on the contrary, it is the visit of Acts xi, 27–30 (when Paul and Barnabas brought famine relief to the Jerusalem Christians) that is to be identified with the second visit in Galatians, then naturally the council decision is not mentioned in Galatians, as the council had not yet taken place. Too much however can be made of the difficulties of reconciling Acts and Galatians on this point. Both Luke and Paul had their own special aims in writing, and either may have omitted material that to the modern reader might seem essential but that to him was irrelevant. It must for instance be remembered that Paul's purpose in Galatians was to give an account not of his movements but of his authority as a preacher of the gospel.

The other discrepancy concerns the nature of Paul's mission. In his epistles Paul insists that he was the apostle to the gentiles, as Peter was to the circumcised, and that circumcision and the

observance of the Jewish Law were of no importance to Christians as such. But in Acts it is Peter who first opens up the way to the gentiles (x, xi), and who uses the strongest language in regard to the intolerable burden of the Law as a means of salvation (xv, 10 ff.). Acts says nothing of the occasion in Gal. ii, 11 ff. when Paul rebuked Peter for inconsistency in his behaviour to gentile converts for fear of the Jewish Christians. In Acts, Paul is not shown as the unbending champion of the gentiles; he seems anxious to reconcile the Jewish Christians by personally obeying the Law. he circumcises his disciple Timothy, who had a Jewish mother, he performs his vows in the temple, he is particularly careful in his speeches to show how deep is his respect for the Law. On the other hand, however, Acts implies something other than what it sets in relief, for why should the Jews hate Paul so much if he was not in some sense disloyal to their Law?

There is, nevertheless, no essential contradiction here, only such a difference of emphasis as belongs to the standpoints and aims of the two writers and to different historical conditions. Peter's function in relation to the gentiles belongs to early Palestinian conditions, before Paul's distinctive mission had taken place. Once Paul's apostolate had proved itself by tokens of divine approval. Peter and his colleagues frankly recognized the distinction of the two missions, and were anxious only that the two should not fall apart through religiously and morally incompatible usages (Gal. ii, 10; *cf.* Acts xv). Paul on his side clearly implies that Peter felt that "a man is not justified by works of the law" (Gal. ii, 15 ff.), and argues that the Law could not now be made obligatory in principle, though for Jews it might continue for the time (pending Christ's second coming) to be seemly and expedient. To this he conformed his own conduct as a Jew, so far as his gentile apostolate was not involved (I Cor. ix, 9 ff.). Peter must have largely agreed with him, since he acted in this spirit himself until coerced by Jerusalem sentiment to draw back for expediency's sake (Gal. ii, 11 ff.). It did not fall within the scope of Acts to narrate this incident, since it had no lasting effect on the church's extension.

Speeches.—Ancient Greek historians used the liberty of working up in their own language the speeches they inserted into their narrative; they molded a speaker's thoughts to their own methods of presentation. Some went so far for the sake of vividness as to give to their characters speeches never really uttered. The author of Acts, heir to the Jewish as well as to the Greek methods of writing history, cannot be assumed to have used speeches as freely as Herodotus had done; some of the speeches in Acts are bare summaries. Others claim to be reports of speeches actually delivered. Many are based on the *kerygma* or pattern of apostolic preaching (see **PREACHING**). Though all have passed through one mind, and some mutual assimilation in phraseology and idea may have resulted, yet these circumstances, while inconsistent with complete verbal accuracy, do not destroy authenticity: in most cases there is varied appropriateness (*e.g.*, xiv, 15–17), as well as allusiveness, pointing to good information. There is no evidence that any speech in Acts is a free composition by Luke without either written or oral basis; and in general he seems nearer than most ancient historians, even Thucydides, to the essentials of historical accuracy.

Date.—External evidence points to the existence of Acts at least as early as the opening years of the 2nd century. Both Ignatius and Polycarp appear to quote from it, and if the author of the Second Epistle to Timothy drew his knowledge of Paul's career from Acts (II Tim. iii, 11) then Acts must have been written well before the year 100. It is further just possible that the unusual form of a quotation from Ps. lxxxix (lxxxviii), 20 in the first epistle of Clement may have been borrowed from Acts xiii, 22, in which case Acts was written before c. 96. It has been suggested that Acts used the later works of the Jewish historian Josephus, which would place it after 94, but the only passage which might show contact between them (the reference to Theudas and Judas in Acts v, 36 ff., compared with the account of Theudas and the sons of Judas in Josephus' *Antiquitates*) is more probably due to dependence on a common source.

The *terminus ad quem* of Acts is probably c. 90. The terminus

a quo cannot be settled without consideration of the date of Luke's gospel, the relation of Acts to it, the ending of Acts and its lack of reference to Paul's death, to the fall of Jerusalem in 70 or to any Pauline epistle. A date prior to 70 can be maintained, for this would leave time for Luke to use Mark's gospel, written c. 64–67, as he clearly did (*e.g.*, Acts i, 7 picks up Mark xiii, 32; Acts vi, 11–12 alludes to Mark xiv, 58, 64; Acts xii, 4 picks up Mark xiv, 12; Acts ix, 40 echoes Mark v, 40). Acts may even have been written by Luke after an early draft of his gospel and before the final text of it (which omits Marcan parallels already used in Acts). However, many scholars, assuming that Luke wrote Acts after his gospel, prefer a date from 75–80. This later date is favoured by form critics and typologists, as it allows more time for the growth and formulation of oral traditions. Those who hold the unlikely theory that "Q" (the postulated common source other than Mark for the gospels of Matthew and Luke; see GOSPEL) did not exist, but that Luke's gospel used Matthew's, also welcome the extra time allowed by the date 75–80.

Text. — Acts offers complicated problems to the textual critic. There are two groups of manuscripts, the "Alexandrian" and the "Western" (see BIBLE: New Testament; Text). The misleading term "western" really stands for a glossing or paraphrastic text, comparable to a Targum (*q.v.*) on an Old Testament book; it became widespread in the east as well as the west from the 2nd century. The Western text of Acts seems to be a 2nd-century recension of a popular nature, to which other Western additions were made later; the Alexandrian revision was slighter and nearer the archetype. It is not possible that Luke himself was the author of both texts, the Western being, for Acts, the original. The Western text is of value not only because it preserves some variants lost in the Alexandrian stream of transmission but also because it sheds light on ecclesiastical thought as early as the 2nd century. Acts, from its very scope, was the book least likely to be viewed as sacrosanct in its text; indeed there are signs that its undogmatic nature caused it to be comparatively neglected at certain times and places.

ACTUARY, an expert who calculates insurance risks and premiums. He computes the probability of the occurrence of various contingencies of human life such as birth, marriage, sickness, unemployment, accident, retirement and death. The actuary also deals with the contingencies concerned with the hazards of property damage or loss and the legal liability for the safety and well-being of others. On the basis of these evaluations, risks affecting lives or property can be insured. This embraces the areas of life insurance, accident and health insurance, annuities, pensions and social insurance as well as fire, casualty and marine insurance.

The name is derived from the Latin *actuarius*, denoting the clerk who recorded the *acta* or proceedings of the senate, a court or a similar body. In its English form the word has undergone a gradual limitation of meaning. At first it seems to have been applied to any clerk or registrar in the sense that a clerk represented a person of book learning, and was especially applicable to a notary, secretary or accountant; then, before acquiring its present specialized meaning, it denoted the secretary and adviser of an insurance company.

Actuarial science developed from the concept that the experience of the past may be utilized to measure the chances of the future. It deals with monetary questions involving separately or in combination the mathematical doctrine of probabilities and the principles of compound interest.

Ever since an actuary was designated the founding chief executive officer of the first modern life insurance company in 1762 (the Equitable Society of England), most actuaries have been employed by insurance companies. The actuary is, in a way, the engineer of the insurance company; he makes statistical studies to establish basic mortality and morbidity tables, develops corresponding premium rates, establishes underwriting practices and procedures, determines the amounts of money (reserves) required to assure payment of benefits, analyzes company earnings and counsels with the accounting staff in establishing adequate records and preparing financial statements; he plays a major role in the development of new forms of coverage and the establishment of investment policy. He is also concerned with the application of electronic data processing machines to these operations. In many insurance companies he is a senior officer and in some the chief executive officer.

Some actuaries serve as consultants and some are employed by large industrial corporations to advise on insurance and pension matters. The government employs actuaries in its work of regulating the insurance business and in connection with social security programs, retirement plans, census taking and operations research for the military services.

There are two professional societies of actuaries in Great Britain and two in the United States to which membership admission is by formal examinations. These societies include members from Canada. The British societies are incorporated by royal charters—the Institute of Actuaries, London, founded in 1848, the oldest professional actuarial body in the world; and the Faculty of Actuaries, Edinburgh, founded in 1856. The United States societies are the Society of Actuaries, Chicago, formed in 1949 through merger of the Actuarial Society of America (founded in 1889) with the American Institute of Actuaries (founded in 1909); and the Casualty Actuarial society, New York, organized in 1914. The examinations for membership deal with fundamental mathematics; actuarial theory (including life and other contingencies, probability theory, statistics, demography and mathematics of finance); and elements of social security and insurance law, investments and accounting.

The Conference of Actuaries in Public Practice, Chicago, was organized in 1950. There are also many local actuarial clubs.

Besides Great Britain and the United States, many other nations have actuarial associations. The International Congress of Actuaries, with headquarters in Brussels, Belg., held its first meeting in 1895. Its affairs are directed by a permanent committee, membership of which is on an international basis. It customarily meets in a different country every third year if world conditions permit. The first International Conference of Social Security Actuaries and Statisticians was held in Brussels in 1956. (A. C. O.)

ACUÑA, CRISTÓBAL DE (1597–c. 1676), Spanish Jesuit missionary and explorer in the Amazon. was born at Burgos in 1597. He was sent on mission work to Chile and Peru and became rector of Cuenca college. In 1639 he accompanied Pedro Teixeira in his second exploration of the Amazon to take scientific observations and draw up a report for the Spanish government. The journey lasted ten months; on the explorer's arrival in Peru, Acuña prepared his narrative, while awaiting a ship for Europe. The king of Spain, Philip IV, received the author coldly and it is said even tried to suppress his book, fearing that the Portuguese, who had just revolted from Spain (1640), would profit by its information. Eventually Acuña returned to South America where he died, probably soon after 1675. His *Nuevo Descubrimiento del Grn Rio de las Amazonas* was published at Madrid in 1641; French and English translations (the latter from the French) appeared in 1632 and 1698.

ACUPUNCTURE, also known as needling, is a form of surgical procedure devised in China many centuries B.C. Its practice consists of the insertion of needles of various metals, shapes and sizes into one or several of 365 spots which are specified for this purpose on the human trunk, the extremities and the head. Acupuncture has been in continuous use in China and in Japan where it was introduced together with Chinese medicine. Since it is supposed to relieve internal congestion and to restore the

equilibrium of the bodily functions, acupuncture has been used for a vast variety of diseases and especially for the treatment of arthritis, headache, convulsions, lethargy, colic, etc. In the 1930s the practice of acupuncture became popular and years later was still in use in several European countries, especially France and Germany.

A practice similar to acupuncture and of equal antiquity is that of moxibustion or moxa treatment, which also originated in China and thence spread to Japan. It is practised by placing little combustible cones of the dried leaves of *Artemisia moxa*, or wormwood, on certain designated spots, which generally coincide with those used for acupuncture. The cones are then ignited and burned down to the skin where a small blister arises. While moxa treatment has not been adopted by western medicine, it is practised in the United States by Japanese physicians, and occasionally Japanese patients with recent scars of moxa burns are seen in U.S. hospitals. There is no known physiological basis to either acupuncture or moxibustion.

See Ilza Veith, *The Yellow Emperor's Classic of Internal Medicine* (1949). (I. V.)

ADAB (mod. BISMAYA), an ancient city of the Sumerians situated in southern Iraq, about 25 mi. S. of Nippur. Small excavations made there by E. J. Banks in 1903–04 revealed buildings dating back from the reign of Ur-Nammu (at the end of the 22nd century B.C.) to prehistoric periods, as well as an inscribed statuette of a king Lugal-dalu, dressed in the characteristic Sumerian fleece garment. Adab was important only up to c. 2000 B.C. The Sumerian king list ascribed to it one of the early dynasties, comprising only one king, Lugal-anne-mundu, said to have reigned for 90 years; according to his position in the list, this would have been about 2400 B.C. An inscription of later date claims for him sovereignty over many lands east and west of Babylonia and the suppression of revolts. Otherwise, fragments discovered at the site show that Adab was held by successive rulers over the whole country such as Me-silim, Naram-Sin, Shulgi and Hammurabi. Its principal deity was the goddess Ninkhursag, whose temple was called *e-sar* or *e-makh* ("the exalted house"). During the 3rd dynasty of Ur in the 22nd and 21st centuries B.C. Adab was under governors appointed by the kings of Ur.

See E. J. Banks, *Bismaya or the Lost City of Adab* (1912); S. A. Pallis, *The Antiquity of Iraq*, p. 367 (1956). (C. J. G.)

ADAD, the great weather god of the Babylonian and Assyrian pantheon, was known to the Sumerians as Ishkur and to the Canaanites and Arameans as Xddu or Hadad (both variants of Adad) and as Ramman (Old Testament Rimmon, "the thunderer"). The name Adad would appear to have been brought into Mesopotamia during the later years of the 3rd millennium B.C. by western (Amorite) Semites. Related to this is the fact that one of the god's Babylonian names is Amurru.

Adad has a twofold aspect, being both the giver and the destroyer of life. His rains cause the land to bear grain, mine and food for his friends; hence his title "lord of abundance." His storms and hurricanes, evidences of his anger against his foes, bring darkness, want and death upon the earth. His destructive energy is represented on some seal cylinders which show him erect on a bull and holding a thunderbolt. The bull and the lion are sacred to him.

Adad's father was the heaven god Anu, but he is also designated as the son of Bel, "lord of all lands." His consort was Shalash, whose name may be Hurrian, and who is represented sometimes naked, at other times clothed. The symbol of Adad was the cypress, six was his sacred number and Shabat his month. In Babylonia and Assyria he was god of oracles and divination, being accompanied in the former country by the sun-god Shamash and in the latter by the heaven god Anu.

At Aleppo in Syria, too, Adad was an oracle-deity, and he sometimes figures alongside Sin (the moon-god) and Shamash in the secondary cosmic triad. Adad also figures in local myths. In the epic of the divine punishment of men, plants and grain fail because he withholds rain. In the deluge story he thunders in a black cloud which rises up from the horizon. In the ensuing darkness men are unrecognizable even by the gods, who, in terror,

ascend to the heaven of Anu. In the myth of the Zu-bird, who had stolen the tablets of destiny, Adad is asked to slay the thief, but his father forbids it.

Unlike the greater gods, Adad quite possibly had no cult centre peculiar to himself. Early in the 2nd millennium B.C. his cult is evidenced chiefly by theophoric names which are almost all Semitic in form. In succeeding millennia he was worshiped in Babylon, where his temple bore the name "house of abundance," and in many of the important cities and towns of Mesopotamia. A great temple to him and to Anu has been found at Assur, the capital of Assyria. See also BABYLONIA AND ASSYRIA: *Religion: Sumerian Pantheon*.

ADAIR, JOHN (c. 1654–56 to 1720–22), Scottish surveyor and map maker, who completed maps of the counties along the Forth and charts of the Forth, Clyde and west of Scotland, of a high standard for their period (c. 1680–86). Manuscripts of these are in the Scottish National and other libraries. Other maps and charts prepared by Adair—those of the west coast at considerable risk and peril—were not printed. In 1688 he was elected a fellow of the Royal Society. At about this time Capt. John Slezer claimed, and was granted, a share in the tax allotted by the government to Adair for surveying Scotland and navigating its coasts. In 1693 Slezer produced his *Theatrum Scotiae* (reprinted 1814), and in 1703 Adair published the first part of his *Description of the Sea Coasts and Islands of Scotland*, for the use of seamen. The second part never appeared. Judging from his delicate delineations, Adair's search for perfection may have delayed completion of his work. In 1723 a payment was made to Adair's widow for unpublished manuscripts which were deposited in the Bodleian library and British museum. (AR. G.)

ADALBERN (ASCELIN) (d. c. 1030), Frankish bishop of Laon remembered for his role in the accession of the Capetian dynasty to the crown of France and as a poet. Bishop of Laon from 977, he was imprisoned for a time when Charles, duke of Lower Lorraine, the Carolingian claimant to the crown, took the city in 988. Subsequently, however, he won the duke's confidence and so was able, in 991, to betray Laon, together with Charles and Arnulf his relative, archbishop of Reims, into the hand of Hugh (q.v.) Capet. In 1017 Adalberon wrote a satirical poem, dedicated to Robert II of France, in which he criticized the elevation of men of humble origin to bishoprics and claimed that bishops had the right to guide the local princes. The text is printed by J. P. Migne in *Patrologia Latina*, cxli (1853).

Olleris, *Vie de Gerbert, premier pape français sous le nom de Sylvestre II* (1867); the Benedictine *Histoire littéraire de la France*, vii, new ed. (1867); A. Luchaire, *Les Premiers Capétiens* (1901). (J. DE.)

ADALBERT (ADELBERT), **SAINT** (c. 700), English deacon, accompanied Willibrord in 690 in the evangelization of Friesland and is said to have been appointed archdeacon of Utrecht. He established a church at Egmont and apparently died there. His cult there is ancient; many miracles have been reported. In the 10th century he became the patron saint of a Benedictine abbey constructed by Theodoric, duke of Holland. At about the same time his life's story, attributed to Rupert of Meitlach, appeared which remains the chief source. St. Adalbert's feast is on June 25. See H. Thurston and D. Attwater (eds.), *Butler's Lives of the Saints*, vol. ii, pp. 641–642 (1956). (Fs. P. C.)

ADALBERT (VOYTECH), **SAINT** (956–997), the first bishop (982) of Prague of Czech origin, was descended from the Slavnikovs, Bohemian princes. He was trained in theology at Magdeburg, which conformed to the strict principles of the Cluny reform; there he received the name Adalbert at his confirmation. As bishop he promoted the political aims of Boleslav II, the ruler of

Bohemia, by extending the influence of the church beyond the borders of the Czech kingdom. Critical of the superficial attitude to Christianity prevalent in the country, he departed in 988 with the intention of leading the ascetic life of a monk. On papal orders he returned in 992 to find but little change. He came into sharp conflict with some of the nobility, being probably drawn into the growing feuds between the Czech kings and the Slavnikov princes, and in 994 left the country again to become a missionary to Prussia, where he was martyred. He was canonized in 999, and his feast day is April 23.

ADALBERT (ADELBERT) (c. 1000–1072), German archbishop, the most brilliant of the medieval prince bishops of Bremen, and a leading member of the royal administration, was the youngest son of Frederick, count of Goseck (on the Saale river). Destined by his father for an ecclesiastical career, Adalbert attended the cathedral school at Halberstadt, becoming subsequently subdeacon and, in 1032, canon. In May 1043 he was appointed archbishop of Hamburg-Bremen by the emperor Henry III. High in the emperor's favour, Adalbert had ambitious plans for his see, dreaming of a "patriarchate of the North" which, by forestalling the creation of Scandinavian archbishoprics, would confirm the ecclesiastical supremacy that German missionaries had won for Bremen over all northern countries from Lapland to Iceland and Greenland. Pope Leo IX, however, though he made Adalbert his vicar for the northern countries in 1053, never allowed him to exercise the greater authority that he desired. In imperial politics, on the other hand, during the minority of Henry IV, Adalbert gained considerable influence as guardian and tutor to the young king. His secular ambitions involved him in conflict with the Saxon nobles and especially with the house of Billung (*q.v.*). In 1056 the lands of his bishopric were ravaged by Bernard II Billung, and he was humiliated in his own residence and had to flee to Goslar. Henry IV, however, granted Adalbert extensive powers in Saxony in 1063, but was obliged to dismiss him as royal adviser at the diet of Tribur in 1066, in view of the protests of the nobility. Although he was frequently at court after 1069, Adalbert never regained his political ascendancy. He died of dysentery at Goslar on March 16, 1072, and was buried in the cathedral at Bremen, the building of which he had done much to advance.

Adalbert's death was a serious blow to Bremen's commerce which under him had developed so rapidly that the town could be described as rivaling Rome in celebrity and as "the market of the northern peoples." Adam (*q.v.*) of Bremen has left a vivid description of his haughty, ambitious, pompous and yet personally irreproachable contemporary.

BIBLIOGRAPHY.—G. G. Dehio, *Geschichte des Erzbistums Hamburg-Bremen bis zum Ausgang der Mission* (1877); B. Schmeidler, *Hamburg-Bremen und Nordost-Europa vom 9.-11. Jahrhundert* (1918); G. Misch, "Das Bild des Erzbischofs Adalbert in der Hamburgischen Kirchengeschichte des Domscholasters Adam von Bremen," *Nachr. Akad. Wiss. Göttingen*, no. 7 (1956). (F. J. D. P.)

ADAM, the name of a family of French sculptors. **LAMBERT SIGISMUND** (1700–1759) executed many pieces for the French royal residences and for Frederick the Great of Prussia. **NICOLAS SÉBASTIEN**, his brother (1705–1778), was responsible for the tomb of Catherine Opalinska at Nancy. Another brother, **FRANÇOIS GASPARD BALTHASAR**, executed many of the monuments at Sans Souci and Potsdam.

ADAM OF BREMEN (11th century A.D.), German historian whose work on the archbishops of Hamburg-Bremen not only provides valuable information on German politics under the Salian emperors but also is one of the great books of early medieval geography. Of Franconian origin, he was probably educated at the cathedral school in Bamberg, but was introduced in 1066 or 1067 into the cathedral chapter at Bremen by Archbishop Adalbert (*q.v.*). In 1069 he was head of the cathedral school at Bremen. After Adalbert's death (1072), Adam began his *Gesta Hammaburgensis Ecclesiae Pontificum*, which he continually revised. He died on Oct. 12, in a year not long after 1081.

In four books, written with great care on the basis of old chronicles and documents, the *Gesta* constitutes a major source both for the diocese of Hamburg-Bremen in general and for the

life of Adalbert in particular, book iii containing a candid and vivid description of his personality and activities, which in turn leads inevitably to an account of the political affairs of the time. Book iv of the *Gesta*, moreover, gives a "description of the islands of the north" based on some trustworthy reports though also containing much hearsay. Besides dealing with Russia, the countries of the Balts, Scandinavia, Iceland and Greenland, Adam makes the earliest known reference to Vinland, that part of America reached by Leif Ericsson. The original Latin text is printed in *Monumenta Germaniae Historica*, vol. vii (1846). Translations include a German one edited by B. Schmeidler and S. H. Steinberg, *Hamburgische Kirchengeschichte* (1926); and an English one by F. J. Tschan, *History of the Archbishops of Hamburg-Bremen* (1959).

See B. Schmeidler, *Hamburg-Bremen und Nordost-Europa vom 9.-11. Jahrhundert* (1918); M. Drejer, *Strøvtåg kring mæster Adams av Bremen Nordenframsjalling*, with Eng. summary (1952). (F. J. D. P.)

ADAM, ADOLPHE CHARLES (1803–1856), French composer, is remembered chiefly for his music for the ballet *Giselle*, which, although not distinguished in its own right, is notable for its power to enhance the dramatic situations which make the ballet one of the most popular with dancers and audiences. He was born in Paris, July 24, 1803, and became a pupil of Adrien Boieldieu. A prolific composer and a victim of his own facility, he wrote over 60 operas, of which the best are *Le Postillon de Longjumeau* (1836) and *Giralda* (1850). His ballets, subordinating music to choreographic demands, were written for production in London, Berlin and St. Petersburg as well as Paris, where the success of *Giselle* (1841) led to its inclusion in the repertory of most 20th-century ballet companies. He died in Paris, May 3, 1856.

ADAM, PAUL (1862–1920), French author whose early works exemplify the naturalist and symbolist schools and who later won considerable reputation for his historical and sociological novels. He was born in Paris, Dec. 7, 1862. Publication of his first naturalist novel, *Châir molle* (1885), led to his being prosecuted; his second, *Le Thé chez Miranda* (1886), written with Jean Moréas, is an early example of symbolism. In 1899, with *La Force*, he began a series of novels depicting French life during the period 1800–30; the last, *Au soleil de juillet*, appeared in 1903. He traveled widely and wrote two books on his American journeys, *Vues d'Amérique* (1906) and *Le Trust* (1910). His autobiography, in the form of a novel, *Jeunesse et amours de Maxwel Héricourt*, appeared in 1913. He died in Paris, Jan. 1, 1920.

Adam's style is sometimes turgid, and he is better at conveying the force of ideas than of personalities, but his power of descriptive and poetic writing, nurtured by naturalism and symbolism, gives his work lasting literary value.

See F. Jean-Desthieux, *Paul Adam* (1928); T. Fogelberg, *La Langue et le style de Paul Adam* (1939).

ADAM, ROBERT (1728–1792), foremost British neoclassic architect and creator of the style named after him, was the second son of William Adam (1689–1748) and the most celebrated of four brothers, John, Robert, James and William. He was born at Kirkcaldy in Fife, Scot., on July 3, 1728. His father was the leading Scottish architect of his day and designed many country houses in a crude but vigorous Palladian style. Robert Adam was educated at Edinburgh high school and university. His architectural training was begun under his father and completed at Rome between 1755 and 1757 when he made an intensive study of imperial Roman architecture under the guidance of C. L. Clérisseau, the French architect and antiquary. With Clérisseau he also visited Naples, Florence, Vicenza and Venice, from where he made a voyage to Split in Dalmatia. The results of this archaeological expedition were published as *The Ruins of the Palace of the Emperor Diocletian at Spalatro* (1764).

After his return to England in 1785 Robert Adam rapidly achieved fame as an architect, being appointed architect of the king's works in 1761, together with Sir William Chambers. His younger brother James (1730–94), who made the grand tour with Clérisseau between 1760 and 1763, joined him in London.

In 1773 appeared the first volume of *The Works . . . of Robert and James Adam* in which the authors claimed "to have brought about . . . a kind of revolution in the whole system" of English architecture. By that date the Adam style (*see* the relevant sections of INTERIOR DECORATION; FURNITURE), an elegant and sophisticated interpretation of neoclassicism, had completely superseded Palladianism in England and within a few years its influence had spread abroad as far as Russia in the east and America in the west. As designers of furniture the Adam brothers can claim to have been the precursors of the Louis XVI style in France. Their designs for ceilings and chimney pieces were widely copied by London and provincial builders and their influence was also felt in silver, metalwork and the applied arts generally.

Except at the Adelphi in London and, toward the end of his life, in Scotland, Robert Adam never obtained an opportunity to build on the scale his genius demanded. His English country houses were mostly adaptations of existing buildings and in some cases, for example at Syon house, his work was restricted to the interior. His best country houses—Harewood house, Kedleston, Newby hall, Kenwood, Luton Hoo, Nostell priory and Saltram—date from the 1760s and early 1770s. During the next decade he designed several important town houses, notably Home house, Portman square, London, which are masterpieces of ingenious planning and sophisticated decoration. He also prepared grandiose plans for Cambridge and Edinburgh universities, but neither was carried out. His only surviving monumental building is the Register house at Edinburgh. Although the Adam style is strictly

meaning "man," and usually designates man as a species. With the definite article or in the phrase "son of 'adam'" the word indicates an individual man. In Gen. i, 26–27 the word is used to designate the human species, created male and female, with no implication that a single couple or a group is meant. The word is used with the article through Gen. ii, 4—iii, 24 to designate the first man, the ancestor of the species. It does not appear as a proper personal name "Adam" before Gen. iv, 25 and v, 1. It is read as a proper name in the present Hebrew text of Gen. ii, 20 and iii, 17, but this is due to the vocalization of the Hebrew text, not to the consonantal text, which permits the word to be read as a proper name only in these verses. The use of the word as a personal name in later writings, including the New Testament, and in modern speech is not based upon the original text but upon a Jewish interpretation of the last few centuries B.C. The word has an assonance with the Hebrew word for soil ('adamah), and the two words may be etymologically connected, both coming from a root signifying "reddish," "ruddy."

The name Eve (Hebrew hawwah) is given to the first woman in Gen. iii, 20. The name is explained in this verse by a popular etymology as connected with the Hebrew word for "life." Modern scholars doubt the genuineness of this etymology, but of the several etymologies proposed none has been generally accepted.

The controversy between theologians and natural scientists concerning the story of Adam and Eve (Gen. ii, 4—iii, 24) was the result of a tacit understanding that the story was intended to convey historical and scientific information concerning human origins. Exegetes no longer understand the story in these terms. They take the chapters as an expression, in the form of a story, of certain Hebrew beliefs concerning the mutual relations of God, man and the universe. That the first man is called simply "the man" (or "Man") is not insignificant; he is intended to be typical. Hebrew folklore often represents the ancestor as a prototype, prefiguring not only in his character but also in his life the character and the experiences of his descendants. The early Hebrews had no historical or scientific information concerning human origins and constructed their story by the skilful combination of details drawn from popular traditions. The symbolism of most of these details can be understood by comparisons with the traditions of the ancient near east.

The story is attributed to the Jahwist source of the Pentateuch. It is often called "the second creation account" (after Gen. i, 1—ii, 4) but this designation is misleading. It contains nothing corresponding to the creation of the visible universe in Gen. i. It is an account of the origin of man, more precisely of man and of woman as sexually differentiated. In the religions of the ancient near east sexual differentiation was found in the gods and was thought to be as much a primary datum as the gods themselves. The Hebrews, rejecting any sexual character in the deity, insisted that sex is instituted in lower forms of being by a deity who is himself above sex.

Man is compounded of clay and of the animating breath of God (Gen. ii, 7). That man is clay is a literary commonplace not only in the Bible, but also in Mesopotamian and Egyptian literature. Man's origin from the soil is deduced from his return to the soil. Even the "molding" of the clay has an explicit parallel in Egyptian art, where the potter god Khnum is represented molding the human figure on the potter's wheel. The divine component in Mesopotamia was the blood of a slain god; Hebrew belief could not tolerate this grossness and replaced it with the more subtle element of breath. The man is placed in a garden in Eden (Gen. ii, 8–14); the geography of the passage is unreal and the garden has no location. The contrast between man's primitive bliss in the garden and the conditions of historical experience is explicit. No restraint is placed upon the man except the prohibition of eating the fruit of the tree of knowledge of good and evil (Gen. ii, 16–17). This tree has no parallel in ancient near eastern traditions; its symbolism is most probably to be understood in the context of the fall narrated in Gen. iii (cf. below). The tree of life, on the other hand, has numerous parallels in Mesopotamian literature and art. The tree stood next to the temple and was protected by guardian genii. In Mesopotamia life was communi-

VESTIBULE OF THE SYON HOUSE (C. 1761). ISLEWORTH, ENGLAND, BY ROBERT ADAM

neoclassical, Robert Adam occasionally worked in a romantic neo-Gothic manner, notably in the now-destroyed interiors at Alnwick castle. He died on March 3, 1792.

See also Index references under "Adam, Robert" in the Index volume.

BIBLIOGRAPHY.—John Swarbrick, *Robert Adam and His Brothers* (1916); A. T. Bolton, *The Architecture of Robert and James Adam* (1922); J. Lees-Milne, *The Age of Adam* (1948). (J.Fg.)

ADAM AND EVE. *Adam* is one of several Hebrew words

cated by touching a branch of the tree to the nostrils. The symbol in Genesis is obscurely drawn; the story is not interested in whether the fruit was to be eaten once or at regular intervals. The point of the symbolism is that primeval man had life without death within his grasp.

The story of the creation of the animals shows the difference between man and the animals and his superiority over them (Gen. ii, 19–20). The man gives them names; in the ancient world to confer a name was a sign of authority, and here also of superior intelligence. None of the animals is fit to live with man in society, and so the scene is set for the creation of woman. The creation of woman comes as the climax of the chapter, and this solemnity is not merely accidental. Her creation from the body of the man shows her community and equality with the man and her capacity to share his life. The protest against the depressed condition of woman in ancient society is as clear as it is surprising. The story places the institution of monogamous marriage, which is presented as the ideal relation of the sexes, at the beginning of the race; this ideal was not highly esteemed in the ancient east or even in Israel, but it was recalled by Jesus when he quoted the passage (Matt. xix, 3–8; Mark x, 2–9). The reflection upon the relation of the sexes in Gen. ii, 24 (union in one flesh) makes it highly improbable that the story intends to present the man and the woman as sexually immature, as many scholars have maintained. Rather their common life "without shame" seems to indicate an ideal of sexual morality in which the appetite is controlled. Gen. ii, 25, however, is somewhat obscure. It is possible that the original story contained at this point an account of the consummation of sexual union, which has been displaced by Gen. iii.

The situation of this couple suggests in its external features some details of Semitic mythology which it may echo. In the Mesopotamian deluge myth Ut-napishtim and his wife, the survivors of the deluge, live in isolated bliss in "a paradise of delight at the mouth of the two rivers" (the Tigris and Euphrates). The epic of Gilgamesh describes Enkidu, the companion of Gilgamesh, as created of clay, half man and half beast, living with the beasts in the open field. Gilgamesh instigated a harlot to seduce him; after his experience with the harlot Enkidu abandoned his wild manner of life and became a city dweller. The similarity must be pointed out, although the differences must not be ignored; Hebrew literature elsewhere has certainly borrowed colourful descriptive details from Semitic mythology.

The connection between Gen. ii and iii is obscure. Scholars have suggested various isolated stories from which the present narrative was composed; that these stories preceded the literary form is evident, but there is no agreement on their form. One may suggest three: the creation of man and the woman (perhaps originally two independent stories); the sin of the man; and the sin of the woman. The story of the sin of a man unaccompanied by a woman appears in Ezek. xxviii, 12–15. On the other hand, the man is strangely silent and inactive in Gen. iii, and it may be suspected that he has been inserted where he did not originally appear.

The symbolism of the serpent in ancient near eastern literature and art is multiple, but in general the serpent is a symbol of life (cf. the caduceus). In art the serpent is often represented with the nude goddess of fertility in such a way that it can be nothing but a sexual symbol. This suggests that the fall of man is represented as in some way a deviation from sexual morality. There is no probability in the opinion that the fall was the simple discovery and use of sex. This view is so foreign to the Hebrew attitude that it demands much more solid evidence than can be given. The presence of the serpent suggests the fertility cults of the ancient Semitic world, so often reprobated in the Old Testament.

The fertility cults, which attributed sex to the gods, expressed the belief that the renewal of life on earth is an earthly counterpart of the sexual union of the god and the goddess of fertility. This myth was re-enacted in the cult, and the worshippers shared in the divine life force by sexual intercourse with the sacred prostitutes, the representatives of the goddess. The story seems to present the radical deviation of man from God in terms of these cults, the worship of the mystery of sex made personal in divine

beings. The chapter so interpreted is a symbolic description of human corruption, not an essay in the history of human corruption; in the context of the Israelite monarchy, when these cults were so popular that they threatened the integrity of the Hebrew religion, such a description easily finds its place. Man's helper has become the goddess of fertility, inviting him to share in the life of the gods ("knowing good and evil," Gen. iii, 5 and 22) by participating in the mysteries of her cult.

This view also suits the curses uttered upon the man and the woman. The curse of the woman reduces her to the degraded position which she occupied in ancient society; once she becomes a goddess of pleasure, she loses the dignity and the security which are hers as the monogamous wife. The man is cursed in the cultivation of the soil; he has sought fertility from the cultic myth and ritual and not from Yahweh, and therefore the soil refuses its bounty. The serpent is not a symbol of the life force but a beast crawling on the ground. And man is cursed with death (*i.e.*, is denied immortality) because he has sought life where it cannot be found.

The story and the beliefs which it expresses are distinctively Israelite, unparalleled in the ancient world, resting upon Israel's unique conception of God and of his relations to the universe and man. Mesopotamia and Egypt could accept the historical condition of man because the will of their gods, more powerful than the human will, did not surpass the human will in morality. The Israelites believed in the divine moral imperative and did not conceive that God could create a disorderly world. Therefore the evident disorder in the existing world cannot be due to the inability of God to create a world worthy of himself; it must be attributed to the rebellion of man—in the story, to man's refusal to recognize the true character of the deity. This rebellion of man is primeval and universal. Because of it man suffers in his family life, in his struggle with nature, in strife with his fellow man (cf. Gen. iv) and finally in death. None of these is his intended portion from his creator; they are the fruits of his efforts to rise to the divine level through superstitious cults.

One's wonder that Adam and Eve do not appear elsewhere in the Hebrew Old Testament (except I Chron. i, 1) is less if one remembers that the Old Testament rarely cross-references itself. They appear as the ideal of marriage in Tob. viii, 6. Adam is the first man (Wisd. Sol. x, 1). The tendency to exaggerate Adam's endowments is suggested in allusions to his wisdom (Wisd. Sol. x, 1) and to his excellence over every living being in his creation (Sirach [Ecclus.] xlix, 16). Sirach xxxiii, 10 alludes to his creation from the ground. The heavy yoke which rests on the sons of Adam (Sirach xl, 1) is the only possible allusion in the Hebrew or Greek Old Testament to the fall.

In contrast, the story of Adam and Eve was popular with the writers of the pseudepigrapha, who retold it with many embellishments. The Life of Adam and Eve contains a much fuller account of the fall and what followed. The fall of man is rationalized in a modern manner by the author of II Baruch, who states that each man is his own Adam.

Adam is mentioned in the Lucan genealogy of Jesus (Luke iii, 38). Paul illustrates human frailty by the serpent's seduction of Eve (II Cor. xi, 3). In I Tim. ii, 13 the authority of man over woman is argued from the chronological priority of the creation of the man; this is a rabbinical type of argument. Elsewhere in the New Testament Adam appears only in the Pauline writings, where he is given some theological importance. The conviction that all men die in Adam was already fixed in Paul's mind when he wrote I Cor. xv, 22. Here Adam, who brought death to all men, is the type of Christ, who brings the life of the resurrection to all men. In answer to the question of what kind of body the risen shall have, Paul appeals to the typology of Adam and Christ. Here he plays on the omission of the Hebrew word for spirit in Gen. ii, 7; the omission is probably coincidental, since the word is used elsewhere in the Old Testament for the animating principle, but Paul finds in it an occasion to explain what he understands by resurrection (I Cor. xv, 44–53). Adam had a "body" of earth and a "soul"; he did not receive the "spirit," and so he was mortal. His descendants like him have only a "psychic" body, a body with a "soul," and they too must die. Paul is certain that flesh

and blood cannot possess the kingdom of God (I Cor. xv, 50); therefore the body must be changed. It will be changed by the reception of the life-giving spirit which is conferred by Jesus Christ. Adam is from the earth; Christ, the second Adam, who lives forever, is from heaven. The Christian becomes "heavenly" through his union with the heavenly man, Christ; his body is changed into a "spiritual" body, and he is free from death.

Paul again introduces Adam as "a type of the one who was to come"; *i.e.*, Christ (Rom. v. 14). As Adam initiated the life of man upon earth, so Christ initiates the new life of man. Because of the sin of Adam, death came upon all men; because of the righteousness of Christ, life is given to all men (Rom. v, 12-21). This had important consequences for Paul's theology. It was Adam's sin and not failure to observe the Law of Moses which made the gentiles sinners; therefore Jews also stood in need of the grace of Jesus Christ. Just as failure to observe the Law was not the formality under which man is sinful, so observance of the Law is not sufficient to reconcile man with God. It is likely also that this Pauline rereading of Genesis is responsible for his emphasis upon the universality and the gratuity of the redemption wrought by the Father in Jesus Christ. For if men, as attested by their universal mortality, are subject to the wrath of God for reasons which are antecedent to their personal conduct, so it is fitting that deliverance from wrath should come by the act of another antecedent to their personal conduct. This other is Christ, the new Adam, head of a new race. The Pauline theology of Adam as the type of Christ is the basis of the Christian belief in original sin, on which the reality of the redemption and the efficacy of baptism depend. ADAMAWA, a region of tropical Africa, lies roughly between 6° and 11° N. and between 11° and 15° E. Formerly an independent native kingdom, it is now partitioned between the Northern Region of Nigeria and Cameroun. In these territories administrative units with the name Adamawa survive.

Adamawa owes its origin and name to Adama, a Fulani emir, who established the emirate during the first half of the 19th century. In 1809 the Muslim Fulani of the western Sudan, under the leadership of Othman dan Fodio of Sokoto, began a holy war (*jihād*) against the non-Muslim Negroes. Adama and his followers conquered the area now known as Adamawa and established a ruling aristocracy over the Negro tribes. Adama, who died in 1848, made Yola his capital and founded such cities as Garoua and Ngaoundéré.

Adama was succeeded by four of his sons. Lowal (1848-72) was ruling when H. Barth visited Adamawa (1851); Saanda (1872-90) consolidated the empire; Zubeiru (1890-1901) attempted to defend it against Great Britain and Germany but in 1903 he was killed by rebels when fleeing from his pursuers. After Adamawa had been partitioned in 1901, Bobo Amadu, Adama's fourth son, became emir of Yola in the British section of the state. His titular suzerainty as *lamido* of Adamawa continued to be recognized by Fulani (*q.v.*) across the frontier.

Western Adamawa includes the broad plains of the middle Benue valley, between 500 and 1,200 ft., which extend eastward to the foot of the highland masses which compose the rest of the area. The larger highland area runs from west to east along the southern boundary, with summits above 6,000 ft. A second highland area follows the present Nigerian frontier, though trenched through by the Benue valley east of Yola, also with summits above 6,000 ft. in the Vogel massif and the Mambila plateau, with slightly lower summits in the Mandara mountains north of the Benue.

The chief crops grown are millets, maize, rice, peanuts and cotton. Agriculture is the occupation of the Negro groups whereas the Fulani are primarily cattle breeders. Cattle are found on the mountain grasslands farther south than in other parts of West Africa.

ADAM DE LA HALLE (ADAM LE BOSSU) (c. 1240-1288), Old French lyric poet, musician and dramatist—both his surnames were inherited—who is first mentioned in 1272; his *Jeu de la Feuille'e* and his *Congé* (farewell to Arras) may be dated about 1276. Adam became a minstrel in the service of Robert II, count of Artois, and followed him in 1283 on an expedition supporting the Angevin king of Naples and Sicily, Charles I of Anjou. He composed the *Jeu de Robin et Marion* (perhaps at Naples) and after Charles's death in 1285 began an epic poem in his honour. He died in Italy in 1285.

The *Jeu de Robin et Marion*, the most popular of Adam's works today, is a dramatized *pastourelle* in which a knight makes advances to a shepherdess; she prefers her Robin and all ends happily with pastoral songs and dances. This elegant court entertainment is less remarkable than the *Jeu de la Feuille'e*, a revue show or May day revel, in which Adam (posing as a young student entrapped in matrimony) satirizes himself, his wife, his father and the citizens of Arras. In spite of attempts to build Adam's stage personality into his biography, it is likely that the play is merely a fantasy picture of Adam's career and of life in Arras.

Adam also composed chansons, *jeux-partis*, motets and rondeaux. See TROUVÈRE.

ADAMITES, a sect of Christian heretics that flourished in north Africa in the 2nd and 3rd centuries. Basing itself probably on a union of certain gnostic and ascetic doctrines, it aimed to return to Adam's state of original innocence by practising nudism.

ADAMNAN (ADOMNAN or EUNAN), **SAINT** (c. 628-704), the biographer of St. Columba, was born in County Donegal, Ire. In 679 he was elected abbot of Iona, the ninth in succession from St. Columba, the founder. While on a visit to Northumbria he adopted the Roman rules on the date of Easter and on the tonsure, but failed to enforce the change at Iona. He then traveled much in Ireland to promote the same observances and, at the council of Birr (County Offaly), succeeded in ameliorating the condition of women, particularly by their exemption from military service, and in making regulations protecting children and clerics (Law of Adamnan).

Adamnan wrote two valuable works, the *Vita S. Columbae*, in three sections, describing the saint's prophecies, miracles and visions, and the *De locis sanctis*, an account of the travels of Arculf (*q.v.*) to the Holy Land. Adamnan is sometimes credited with *Adamnan's Vision*, an Irish composition of the 10th or 11th century, on the other world. His feast day is Sept. 23.

BIBLIOGRAPHY.—The *vita S. Columbae* was edited with introduction, Eng. trans. and notes by W. Reeves (1857 and 1874); ed., with Eng. trans., by A. O. and M. O. Anderson (1961). GN.)

ADAMS, ABIGAIL (née SMITH) (1744-1818), wife of John Adams, second U.S. president, and mother of John Quincy Adams, sixth U.S. president, was born in Weymouth, Mass., on Nov. 23, 1744. Scantly educated but intelligent and broad-minded, she became a terse and vigorous letter writer. In 1764 she was married

to John Adams, then practising law in Boston. She resolutely supported him in his insistence upon the Declaration of Independence and aided him and his cause with loyal zeal. In 1784 she joined her husband in France and in 1785 accompanied him to England, where, as the wife of the first minister of the United States to the court of George III, she met with social discourtesies which she long resented. From 1789 to 1801, when her husband was successively vice-president and president, she lived in a simple manner. The publication by C. F. Adams in 1875 of *The Familiar Letters of John Adams and His Wife* increased interest in her career. She died at Quincy, Mass., on Oct. 28, 1818. (J. R. AL.)

ADAMS, BROOKS (1848–1927), U.S. historian, son of Charles Francis Adams and grandson of John Quincy Adams, was born in Quincy, Mass., June 24, 1818. He graduated from Harvard college in 1870 and practised law in Boston until 1881. A large inheritance enabled him to travel extensively in Europe, the middle east and India. Very close to his elder brother Henry, also a historian, Brooks carried on with him an active correspondence in which they both developed the idea, revolutionary at the time, that by its nature and substance U.S. democracy was foreordained to degradation and decay. In 1895 he published his *Law of Civilization and Decay* in which he developed his theory of history, the conviction that the centre of trade had consistently followed a westward movement from the ancient crossroads in the east to Constantinople, Venice, Amsterdam and finally London, occurring in accord with a law relating to the density of populations and the development of new and centralizing techniques of trade and industry.

His *America's Economic Supremacy* (1900) accurately foresaw within 50 years a world in which there would be only two powers, Russia and the United States, with the latter possessing economic supremacy. In 1913 he published *The Theory of Social Revolutions*, a study of defects in the American form of government, developing the idea of the imminent danger in the existence of great wealth exerting private power but declining to accept responsibility. After Henry Adams' death, Brooks Adams prepared for publication his brother's book *The Degradation of the Democratic Dogma* (1920), to which he wrote the introduction, a kind of family chronicle that began with John Quincy Adams' troubles and ended with the renunciation by the two grandsons of the democratic dogma. The roots of his Puritan ancestry were deep. An agnostic, a profound skeptic, he returned in the last years of his life to the church at Quincy where, overcoming his lifelong shyness: he stood up and made a public profession of his faith. He died in Boston, Feb. 13, 1927.

Adams' other writings include *The Emancipation of Massachusetts: Ilze Dream and the Reality* (rev. ed., 1919); *The New Empire* (1902); *America's Economic Supremacy* (rev. ed., 1947).

See A. F. Beringause, *Brooks Adams* (1955). (M. W. CH.)

ADAMS, CHARLES FOLLEN (1842–1918), U.S. regional humorous poet, is best known for his Pennsylvania German dialect poems. He was born on April 21, 1842, in Dorchester, Mass., where he received a public school education.

Early in the American Civil War he entered the Union army and at Gettysburg, Pa., was wounded and taken prisoner. In 1872 he began writing humorous verses for periodicals and newspapers in a Pennsylvania German dialect similar to that used by Charles Godfrey Leland in his "Hans Breitmann" ballads.

Collections of his verse are *Leedle Yawcob Strauss, and Other Poems* (1877) and *Dialect Ballads* (1888). His complete poetical writings, *Yawcob Strauss, and Other Poems*, with illustrations by "Boz," were published in 1910. He died in Boston, Mass., March 8, 1918.

ADAMS, CHARLES FRANCIS (1807–1886), U.S. diplomat, son of Pres. John Quincy Adams and grandson of Pres. John Adams, was born in Boston, Mass., Aug. 18, 1807. His father, having been appointed minister to Russia, took him in 1809 to St. Petersburg, where he acquired a perfect familiarity with French, learning it as his native tongue. After eight years spent in Russia and England, he attended the Boston Latin school for four years, and in 1825 graduated from Harvard. He lived for two years in the executive mansion, Washington, during his father's presidential

term, studying law and moving in a society where he met statesmen such as Webster, Clay, Jackson and Randolph. At the age of 22 he married Abigail Brooks, daughter of Peter Chardon Brooks, wealthy Boston insurance broker.

Having returned to Boston, he devoted ten years to business and study and wrote for the *North American Review*. He also undertook the management of his father's financial affairs, and actively supported him in his contest in the house of representatives for the right of petition and the antislavery cause. In 1835 he wrote an effective and nicely read political pamphlet, entitled, after Edmund Burke's more famous work, *An Appeal from the New to the Old Whigs*. He was a member of the Massachusetts general court from 1840 to 1845, and from 1846 to 1848 he edited a party journal, the *Boston Whig*.

In 1848 he was prominent in politics as a "Conscience Whig," presiding over the Buffalo convention which formed the Free-Soil party and nominated Martin Van Buren for president and himself for vice-president. He was a Republican member of the 36th congress, which assembled Dec. 5, 1859, and during the second session (Dec. 3, 1860–March 4, 1861) he represented Massachusetts in the congressional committee of 33 at the time of the secession of seven of the southern states. Together with William H. Seward, he stood for the Republican policy of concession. For this he was criticized severely and charged with inconsistency in view of his record as a "Conscience Whig." He was of the same mind as President Lincoln, willing to concede nonessentials but holding rigidly to the principle that there must be no extension of slavery. He believed that as the Republicans were the victors they ought to show a spirit of conciliation and that the policy of righteousness was likewise one of expediency, since it would have for its result the holding of the border slave states with the north until March 4, when the Republicans could take possession of the government at Washington.

After inauguration of the new administration, Secretary Seward secured for Adams the appointment as minister to Great Britain. So much sympathy was shown in England for the south that his path was beset with difficulties. His mission was to prevent the interference of Great Britain in the struggle; as American minister, Adams was insistent and unyielding, and knew how to present his case forcibly and with dignity. He laboured with energy and discretion to prevent the sailing of the Confederate cruiser "Alabama," built in a British shipyard; and, when unsuccessful in this, he persistently urged upon the British government its responsibility for the destruction of American merchant vessels by the privateer (see "ALABAMA" ARBITRATION). His diary shows that underneath his calm exterior was keen anxiety. Adams remained in England until May 1868. His last important work was as a member, in 1871–72, of the tribunal at Geneva which settled the "Alabama" claims. He died at Boston, Nov. 21, 1886.

He edited the *Works of John Adams* (1850–56) and the *Memoirs of John Quincy Adams* (1874–77).

See the biography (1900) by his son, Charles Francis Adams, Jr.; and E. D. Adams, *Great Britain and the American Civil War* (1925). An authoritative biography is by Martin B. Duberman, *Charles Francis Adams, 1807–1866* (1961). (S. F. B.)

ADAMS, CHARLES FRANCIS (1835–1915), U.S. railroad specialist, civic leader and historian, was born in Boston, Mass., May 27, 1835. He was one of the four sons of Charles Francis Adams (*q.v.*; 1807–86) and was the grandson of Pres. John Quincy Adams and the great-grandson of Pres. John Adams. He received his education at the Boston Latin school and Harvard college. He fought through the American Civil War, rising from the rank of lieutenant to colonel of the 5th cavalry (Negro). After the war his journalistic articles on railroad scandals led to the creation of the Massachusetts board of railroad commissioners (1869) with himself as chairman (1872–79). He was president of the Union Pacific railroad from 1884 to 1890.

The most important part of Adams' career was that of historian. He published several major works in history, politics and biography and served as president of the Massachusetts Historical society from 1895 until his death on March 20, 1915.

See *Charley Francis Adams, 1835–1915: an Autobiography*, with a

"Memorial Address" by Henry Cabot Lodge (1916). (S. F. B.)

ADAMS, CHARLES FRANCIS (1866–1954), U.S. secretary of the navy, philanthropist and yachtsman, was born in Quincy, Mass., Aug. 2, 1866. He was a great-grandson of John Quincy Adams, sixth president of the United States, and great-great-grandson of John Adams, second president. He graduated from Harvard in 1888, took his law degree four years later and was admitted to the bar in 1893. He had a long career as a public-minded Boston lawyer, capitalist and sportsman. He was amateur skipper of the yacht "Resolute," which won the international yacht races, 1920. From 1929 to 1933 he served as President Hoover's secretary of the navy. He was one of the three trustees of the Adams Manuscript trust, a great collection of several generations of the Adams family papers turned over in 1956 to the Massachusetts Historical society for the use of all scholars. Adams died in Boston on June 10, 1954. (S. F. B.)

ADAMS, CHARLES KENDALL (1835–1902). U.S. teacher and historian, introduced the European seminar method in the U.S. He was born in Derby, Vt., on Jan. 24, 1835. Graduating from the University of Michigan (Ann Arbor) in 1861, he taught history there until 1885. Study in Germany and France in 1867–68 led to his introduction of the seminar method, which spread to other U.S. universities. Among his historical works were *Democracy and Monarchy in France* (1874), *A Manual of Historical Literature* (1882) and *Christopher Columbus* (1892). He edited *Representative British Orations* (1884). In 1885 he became president of Cornell university (Ithaca, N.Y.) and was president of the University of Wisconsin (Madison) from 1892 until his death. Under his administration both universities grew substantially in physical and academic assets.

Xdams died in Redlands, Calif., on July 26, 1902.

ADAMS, HANNAH (1755–1831). U.S. writer and compiler, said to have been the first woman in the U.S. to write professionally for a livelihood, was born in Medfield, Mass., on Oct. 2, 1755. The daughter of Thomas Adams, Jr., dubbed "Book Adams" because of his voracious reading, Hannah early learned Latin, Greek, geography and logic from her father's student boarders. From the age of 17, because of her father's financial reverses, she was obliged to support herself. Her first compilation, in which she endeavoured to avoid the errors and bias of similar works, was *Alphabetical Compendium of the Various Sects . . . From the Beginning of the Christian Era to the Present Day* (1784). It passed through four editions, the final title being *Dictionary of Religions*, and was republished in England. She also wrote *A Summary History of New England* (1799), of which an abridgment became a school text; *The Truth and Excellence of the Christian Religion* (1804); *History of the Jews* (2 vol., 1812); and *Letters on the Gospels* (1826). Her writing did not bring her much money but won her friends and reputation. She died in Brookline, Mass., on Dec. 15, 1831.

ADAMS, HENRY BROOKS (1838–1918), U.S. historian, son of Charles Francis Adams and grandson of John Quincy Adams, was born in Boston, Mass., on Feb. 16, 1838. He graduated at Harvard in 1858, traveled abroad, and was private secretary to his father when the latter was a congressman and later minister to Great Britain. For a brief time he did political writing in Washington, D.C. and then in 1870 became assistant professor of history at Harvard. He taught at Harvard from 1870 to 1877 and became the first U.S. college professor to use the seminar method of teaching history. For most of the period he also served as editor of the *North American Review*, to which he had earlier contributed articles. At about this time he dropped the use of his middle name.

Adams wrote two novels: *Democracy* (published anonymously, 1880), and *Esther—A Novel* (under the pseudonym of Frances Snow Compton, 1884). His nine-volume *History of the United States from 1801 to 1817*, (1889–91 with new editions in 1909 and 1930), is considered to be the best work on the administrations of President Jefferson and President Madison. It is particularly notable for its account of the diplomatic relations of the United States during the early 1800s, and for its essential impartiality. Two books that represent editings of portions of this history are *War of*

1812, edited by Maj. H. A. DeWeerd, 1944, and *The Formative Years*, edited by Herbert Agar, 1947. The *History*, like his other historical and biographical works, such as *Chapters of Erie and Other Essays* (1871, with Charles Francis Adams, Jr.), *Life of Albert Gallatin* (1879), *John Randolph* (1882) and *Historical Essays* (1891), won for Adams a reputation among scholars. A prolonged visit to the South seas led him to edit and publish *Memoirs of Marau Taaroa, Last Queen of Tahiti* (1893, revised and enlarged 1901). His *Mont-Saint-Michel and Chartres* (1913, privately printed 1904) and *The Education of Henry Adams* (1918, privately printed 1906) revealed him to a much wider audience. *Mont-Saint-Michel and Chartres* is one of the most valuable studies of medievalism produced in America, not only for the aid it affords in the appreciation of the literary and architectural monuments of the past, but also for the conception it gives of the social and religious forces that produced these monuments. The *Education*, which attempted to show how ill-adapted 19th-century man and education were for the needs of the 20th century, was one of the most widely discussed books of its decade in the United States and is one of the world's great autobiographies. Other notable works by Adams are: "King" in *Clarence King Memoirs* (1903); *A Letter to American Teachers of History* (privately printed 1910); *Life of George Cabot Lodge* (1911); and *Degradation of the Democratic Dogma* (posthumously, 1920, with introduction by Brooks Adams). In the years after his death in Washington on March 27, 1918, many of his letters began to appear in magazines, biographies and other books. They gave him the distinction of being one of America's great letter writers. The principal collections of these letters are: *Cycle of Adams Letters, 1861–1865*, in two volumes (1920); *Letters to a Niece and Prayer to the Virgin of Chartres, by Henry Adams, with a Niece's Memoirs*, by Mabel La Farge (1920); *Letters of Henry Adams, 1858–1891* and *Letters of Henry Adams, 1892–1918*, both edited by W. C. Ford (1930 and 1938 respectively); *Henry Adams and His Friends, A Collection of His Unpublished Letters, Compiled, with a Biographical Introduction*, by Harold Dean Cater (1947). Two volumes of an extended biography by Ernest Samuels are: *The Young Henry Adams* (1948) and *Henry Adams, The Middle Years* (1958). (H. D. C.)

ADAMS, HENRY CARTER (1851–1921), U.S. economist, was born at Davenport, Ia., Dec. 31, 1851. He was educated at Iowa college (Grinnell, Ia.), Johns Hopkins university, and French and German universities, afterward teaching at Cornell university. In 1887 he became professor of political economy and finance in the University of Michigan. Adams served as statistician to the Interstate Commerce commission and was in charge of the transportation department in the 1890 census. His principal works include *The State in Relation to Industrial Action* (1887); *Public Debts* (1887); *The Science of Finance* (1898); *Economics and Jurisprudence* (1897); *Description of Industry* (1918); and *American Railway Accounting* (1918). He died Aug. 11, 1921.

ADAMS, HERBERT BAXTER (1850–1901), U.S. historian and educator was born at Shutesbury, Mass., on April 16, 1850. After graduating from Amherst college, Amherst, Mass., at the head of his class in 1872, he studied in Germany at Gottingen and Berlin before receiving the degree of Ph.D. from the University of Heidelberg in 1876. That same year he was appointed a fellow in the new Johns Hopkins university, Baltimore, Md. There he remained, becoming professor of American and institutional history in 1891, until his death on July 30, 1901. It was a crucial period for historical scholarship in America and he played an important part in it. The common belief that he introduced German methods is exaggerated as he had almost no contact with German scholars after his return to America while his correspondence and contacts with British scholars were numerous. He was an organizer and promoter of scholarship rather than a producer. He was one of the founders of the American Historical association and served as its secretary until 1900. He initiated in 1882 the "Johns Hopkins University Studies in Historical and Political Science," the first such series in the United States. To his seminar came the best graduate students of the period. They included Woodrow Wilson, J. Franklin Jameson, Frederick Jackson

Turner, Charles H. Haskins, Charles M. Andrews and many others who achieved distinction and who testified to the personal and generous interest Adams took in his students. None of his own scholarly work was distinguished. Among his writings are: *Maryland's Influence in Founding a National Commonwealth* (1877); *Methods of Historical Study* (1884); *Maryland's Influence upon Land Cessions to the United States* (1885); and the *Life and Writings of Jared Sparks* (1893).

ADAMS, JOHN (1735-1826), the first vice-president and the second president of the United States of America was born Oct. 30 (new style; Oct. 19, old style), 1735, in what is now the town of Quincy, Mass. His father, a farmer, also named John, was of the fourth generation in descent from Henry Adams, who emigrated from Devonshire, Eng., to Massachusetts about 1636; his mother was Susanna Boylston Adams. Young Adams graduated from Harvard college in 1755, and for a time taught school at Worcester and studied law in the office of Rufus Putnam.

In 1758 he was admitted to the Boston bar. From an early age he developed the habit of writing descriptions of events and impressions of men. The earliest of these is his report of the argument of James Otis in the superior court of Massachusetts as to the constitutionality of writs of assistance. This was in 1761, and the argument inspired him with zeal for the cause of the American colonies. Years afterward, when an old man, Adams undertook to write out at length his recollections of this scene; it is instructive to compare the two accounts. John Adams had none of the qualities of popular leadership which were so marked a characteristic of his second cousin, Samuel Adams; it was rather as a constitutional lawyer that he influenced the course of events. He was impetuous, intense and often vehement, unflinchingly courageous, devoted with his whole soul to the cause he had espoused; but his vanity, his pride of opinion and his inborn contentiousness were serious handicaps to him in his political career. These qualities were particularly manifested at a later period—as, for example, during his term as president. He first made his influence widely felt and became conspicuous as a leader of the Massachusetts Whigs during the discussions with regard to the Stamp act of 1765. In that year he drafted the instructions which were sent by the town of Braintree to its representatives in the Massachusetts legislature, and which served as a model for other towns in drawing up instructions to their representatives; in Aug. 1765 he contributed anonymously four notable articles to the *Boston Gazette* (republished separately in London in 1768 as *A Dissertation on the Canon and Feudal Law*), in which he argued that the opposition of the colonies to the Stamp act was a part of the never-ending struggle between individualism and corporate authority; and in Dec. 1765 he delivered a speech before the governor and council in which he pronounced the Stamp act invalid on the ground that Massachusetts, being without representation in parliament, had not assented to it. In 1768 he removed to Boston. Two years later, with that degree of moral courage which was one of his distinguishing characteristics, as it has been of his descendants, he served as a lawyer for the defense in the trial of the British soldiers charged with murder as the result of the so-called "Boston massacre." Public sentiment was strongly against the accused. The trial resulted in an acquittal of the officer who commanded the detachment, and most of the soldiers; but two soldiers were found guilty of manslaughter. These claimed benefit of clergy and were branded in the hand and released. Adams' upright and patriotic conduct in taking the unpopular side in this case met with its just reward in the following year, in the shape of his election to the Massachusetts house of representatives by a vote of 418 to 118.

John Adams was a member of the continental congress from 1774 to 1778. In June 1775, with a view to promoting the union of the colonies, he supported the nomination of Washington as commander in chief of the army. His influence in congress was great, and almost from the beginning he was impatient for a

separation of the colonies from Great Britain. On June 7, 1776, he seconded the famous resolution introduced by Richard Henry Lee (*q.v.*) that "these colonies are, and of a right ought to be, free and independent states," and no man championed these resolutions (adopted on July 2) so eloquently and effectively before the congress. On June 8 he was appointed on a committee with Jefferson, Franklin, Livingston and Sherman to draft a declaration of independence; and although that document was by the request of the committee written by Thomas Jefferson, it was John Adams who occupied the foremost place in the debate on its adoption. Before this question had been disposed of, Adams was placed at the head of the board of war and ordinance, and he also served on many other important committees.

In 1778 John Adams sailed for France to supersede Silas Deane in the American commission there. But just as he embarked that commission concluded the desired treaty of alliance, and soon after his arrival he advised that the number of commissioners be reduced to one. His advice was followed and he returned home in time to be elected a member of the convention which framed the Massachusetts constitution of 1780, still the organic law of that commonwealth. With James Bowdoin and Samuel Adams, he formed a subcommittee which drew up the first draft of that instrument, and most of it probably came from John Adams' pen.

Before this work had been completed he was again sent to Europe, having been chosen, Sept. 27, 1779, as minister plenipotentiary for negotiating a treaty of peace and a treaty of commerce with Great Britain. Conditions were not then favourable for peace, however; the French government, moreover, did not approve of the choice, inasmuch as Adams was not sufficiently pliant and tractable and was from the first suspicious of Vergennes; and subsequently Benjamin Franklin, Thomas Jefferson, John Jay and Henry Laurens were appointed to co-operate with Adams. Jefferson, however, did not cross the Atlantic, and Laurens took little part in the negotiations. This left the management of the business to the other three. Jay and Adams distrusted the good faith of the French government. They persuaded Franklin to break the instructions to the commissioners from congress, which required them to "make the most candid confidential communications on all subjects to the ministers of our generous ally, the king of France; to undertake nothing in the negotiations for peace or truce without their knowledge or concurrence; and ultimately to govern yourself by their advice and opinion"; and, instead, they dealt directly with the British commissioners, without consulting the French ministers. Throughout the negotiations Adams was especially determined that the right of the United States to the fisheries along the British-American coast should be recognized. Political conditions in Great Britain, at the moment made the conclusion of peace almost a necessity with the British ministry, and eventually the American negotiators were able to secure a peculiarly favourable treaty. This preliminary treaty was signed Nov. 30, 1782. Before these negotiations began, Adams had spent some time in the Netherlands. In July 1780 he had been authorized to execute the duties previously assigned to Henry Laurens, and at The Hague was eminently successful, securing there recognition of the United States as an independent government (April 19, 1782), and negotiating both a loan and, in Oct. 1782, a treaty of amity and commerce, the first of such treaties between the United States and foreign powers after that of Feb. 1778 with France.

In 1785 John Adams was appointed the first of a long line of able and distinguished American ministers to the court of St. James's. When he was presented to his former sovereign, George III intimated that he was aware of Adams' lack of confidence in the French government. Replying, Adams admitted it, closing with the outspoken sentiment: "I must avow to your Majesty that I have no attachment but to my own country"—a phrase which must have jarred upon the monarch's sensibilities. While in London Adams published a work entitled *A Defence of the Constitutions of Government of the United States* (1787). In this work he ably combated the views of Turgot and other European writers who had criticized the framework of the state

governments. Unfortunately, in so doing, he used phrases savouring of aristocracy which offended many of his countrymen—as in the sentence in which he suggested that "the rich, the well-born and the able" should be set apart from other men in a senate. Partly for this reason, while Washington had the vote of every elector in the first presidential election of 1789, Adams received only 34 out of 69. As this was the second largest number he was declared vice-president, but he began his eight years in that office (1789–97) with a sense of grievance and of suspicion of many of the leading men. Differences of opinion with regard to the policies to be pursued by the new government gradually led to the formation of two well-defined political groups—the Federalists and the Democratic-Republicans—and Adams became recognized as one of the leaders of the Federalists. He was less conservative than many other Federalists.

In 1796, on the refusal of Washington to accept another election, Adams was chosen president, defeating Thomas Jefferson; though Alexander Hamilton and other Federalists had asked that an equal vote should be cast for Adams and Thomas Pinckney, the other Federalist in the contest, partly in order that Jefferson, who was elected vice-president, might be excluded altogether, and partly, it seems, in the hope that Pinckney should in fact receive more votes than Adams, and thus, in accordance with the system then obtaining, be elected president, though he was intended for the second place on the Federalist ticket. The electoral college cast 71 votes for Adams, 68 for Jefferson, 59 for Pinckney and 78 scattered among other candidates. Adams' four years as chief magistrate (1797–1801) were marked by a succession of intrigues which embittered all his later life; they were marked, also, by events such as the passage of the Alien and Sedition acts (see UNITED STATES [OF AMERICA]: *History*), which brought discredit on the Federalist party. Moreover, factional strife broke out within the party itself; Adams and Hamilton became alienated, and some members of Adams' own cabinet looked to Hamilton rather than to the president as their political chief. The United States was, at this time, drawn into the vortex of European complications, and Adams, instead of taking advantage of the militant spirit which was aroused, patriotically devoted himself to securing peace with France, much against the wishes of Hamilton and of Hamilton's adherents in the cabinet. In 1800, Adams was again the Federalist candidate for the presidency, but the distrust of him in his own party, the popular disapproval of the Alien and Sedition acts and the popularity of his opponent, Thomas Jefferson, combined to cause his defeat. He then retired into private life. On July 4, 1826, on the 50th anniversary of the adoption of the Declaration of Independence, he died at Quincy. Jefferson died on the same day. In 1764 Adams had married Abigail Smith (1744–1818), the daughter of a Congregational minister at Weymouth, Mass. She was a woman of much ability, and her letters, written in an excellent English style, are of great value to students of the period in which she lived. (See ADAMS, ABIGAIL.) President John Quincy Adams (*q.v.*) was their eldest son.

ADAMS, JOHN COUCH (1819–1892), British mathematical astronomer who discovered the planet Neptune, independently of V. Leverrier, was born at Laneast, Cornwall, on June 5, 1819. Educated at St. John's college, Cambridge, he was senior wrangler and first Smith's prizeman in 1843 and was elected fellow of his college in the same year. On July 3, 1841, he had entered in his journal, "Formed a design in the beginning of this week of investigating, as soon as possible after taking my degree, the irregularities in the motion of Uranus, which are yet unaccounted for; in order to find whether they may be attributed to the action of an undiscovered planet beyond it; and if possible thence to determine the elements of its orbit, etc., approximately. which

would probably lead to its discovery." By Sept. 1845 he obtained his first solution and handed to J. Challis, the director of the Cambridge observatory, the elements of what he described as "the new planet" and its position for Oct. 1, 1845. This position was actually within two degrees of the position of Neptune at that time but unfortunately the planet was not searched for at Cambridge until much later. Meanwhile, the French astronomer Leverrier, working successfully along similar lines, had sent a request for observations to the Berlin observatory where, as a result, Neptune was discovered on Sept. 23, 1846. A heated controversy arose, motivated largely by nationalistic feelings, but reason soon prevailed and the credit for this unsurpassed intellectual feat was equally divided between the two astronomers and the planet given the neutral name of Neptune.

In 1851 Adams became president of the Royal Astronomical society and in 1853 Pembroke college elected him to a fellowship which he held for the rest of his life. He became professor of mathematics at St. Andrews in 1858 and Lowndean professor of astronomy and geometry at Cambridge in 1859. Two years later he succeeded Challis as director of the Cambridge observatory where he resided until his death on Jan. 21, 1892.

Although Adams' researches on Neptune are his best-known work, subsequent memoirs on the moon's motion, terrestrial magnetism and the November meteors—or Leonids—were no less remarkable and won him the gold medal of the Royal Astronomical society in 1866. He presented his celebrated paper on the secular acceleration of the mean motion of the moon to the Royal society in 1853, revolutionizing that branch of physical astronomy. Some of his work in terrestrial magnetism, such as the determination of the constants in Karl Gauss's theory of magnetism, was published posthumously. The anticipated meteor shower of 1866 turned his attention to the Leonids, which, as he showed, traveled in an elongated ellipse with a period of 33 years and 3 months and were subject to planetary perturbations.

Adams wrote an account in 1888 of Newton's unpublished mathematical material in the Portsmouth collection *The Scientific Papers of John Couch Adams* were edited by W. G. Adams, 2 vol. (1896–1900).

See Sir H. S. Jones, *John Couch Adams and the Discovery of Neptune (1947)*. (O. J. E.)

ADAMS, JOHN QUINCY (1767–1848), eldest son of Pres. John Adams, and sixth president of the United States, was born on July 11, 1767, in that part of Braintree that is now Quincy, Mass. He had two notable careers: first as one of America's greatest diplomatists, and second as outstanding champion of the antislavery cause in the house of representatives during the last 16 years of his long life; between these two careers was the period of his presidency of the United States, from 1825 to 1829.

The infant entered the world at the same time his maternal great grandfather John Quincy (1689–1767), for many years a prominent member of the Massachusetts legislature, was leaving it; hence his name. He grew up as a child of the American Revolution. Tugging at his mother's apron strings he watched the battle of Bunker hill from Braintree on Penn's hill and heard the cannons roar across the Back bay. His patriot father, at that time a delegate to the continental congress, and his patriot mother, one of the intellectual mistresses of those stirring times, had a strong molding influence on his education after the war had deprived Braintree of its only schoolmaster. In 1778 and again in 1780, the boy accompanied his father to Europe. He studied at a private school in Paris in 1778–1779 and at the University of Leiden in 1780. Thus at an early age he acquired an excellent knowledge of the French language and a smattering of Dutch. In 1780, also, he began to keep regularly the diary that forms so conspicuous a record of the doings of himself and his contemporaries through the next 60 years of American history.

In 1781, at the age of 14, he accompanied Francis Dana (1743–1811), American envoy to Russia, as his private secretary and interpreter of French. Dana, after lingering over a year in St. Petersburg, was not received by the Russian government, and in 1782 Adams, returning by way of Scandinavia, Hanover and the Netherlands, joined his father in Paris. There he acted in an

informal way as additional secretary to the American commissioners in the negotiation of the treaty of peace that concluded the American Revolution. Instead of remaining in London with his father, who had been appointed U.S. minister to the court of St. James's, he chose to return to Massachusetts where he graduated at Harvard college in 1787. He then read law at Newburyport under the tutelage of Theophilus Parsons, and was admitted to the bar in Boston in 1790. While struggling for a practice he wrote a series of articles for the newspapers in which he controverted some of Thomas Paine's doctrines in the Rights of *Man*. In another later series he ably supported the neutrality policy of Washington's administration as it faced the war that broke out between France and England in 1793. These articles were brought to President Washington's attention and resulted in Adams' appointment as United States minister to the Netherlands in May 1794.

The Hague was then the best diplomatic listening post in Europe for the war of the first coalition against revolutionary France. Young Adams' official dispatches to the secretary of state and his informal letters to his father, the vice-president, (read also by President Washington) kept the government well informed of the diplomatic activities and wars of the distressed continent and the danger of becoming involved in the European vortex. Some of his phrases appeared in Washington's Farewell Address of 1796. During the absence of the regular minister at London, Thomas Pinckney, on his famous mission to Spain (Pinckney's treaty, 1795), Adams transacted public business with the British foreign office relating to exchange of ratifications of Jay's treaty of 1794 between the United States and Great Britain. In 1796 Washington appointed him minister to Portugal, but before his departure his father John Adams became president and changed the young diplomat's destination to Berlin. While there John Quincy Adams negotiated (1799) a treaty of amity and commerce with Prussia. President Washington had come to regard Adams as the ablest officer in the foreign service. President Adams, after the election of Thomas Jefferson to the presidency in 1800, recalled the younger Adams from his post at Berlin. He reached Boston in 1801 and the next year was elected to the Massachusetts senate; in 1803 the Massachusetts legislature elected him as a member of the senate of the United States.

Up to this time John Quincy Adams was regarded as belonging to the Federalist party, but he found its general policy displeasing to him. He was frowned upon as the son of his father by the followers of Alexander Hamilton and the Essex junto, and soon found himself practically powerless as an unpopular member of an unpopular minority. Actually he was not then, and indeed never was, a strict party man: all through his life, ever aspiring to higher public service, he considered himself a "man of my whole country." Adams arrived in Washington too late to vote for ratification of the treaty for the purchase of Louisiana, opposed by the other Federalist senators, but he voted for the appropriations to carry it into effect, and announced that he would have voted for the purchase treaty itself. Nevertheless, he joined his Federalist colleagues in voting against a bill to enable the president to take possession of the newly acquired territory under officials of his own appointment: such a bill, he vainly protested, violated the principles of the constitution, the right of self-government, and imposed taxation without representation. In Dec. 1807 he supported President Jefferson's suggestion of an embargo and vigorously urged instant action, saying: "The president has recommended the measure on his high responsibility. I would not consider, I would not deliberate; I would act!" Within five hours the senate had passed the Embargo bill and sent it to the house of representatives. Support of a measure so unpopular in New England and so hated by the Federalists cost Adams his seat in the senate; his successor was chosen on June 3, 1803, several months before the usual time of electing a senator for the next term and five days later Adams resigned. In the same year he attended the Republican congressional caucus which nominated Madison for the presidency, and thus allied himself with that party. From 1806 to 1809 Adams was Boylston professor of rhetoric and oratory at Harvard college.

In 1809 President Madison sent Adams to Russia to represent the United States at the court of the tsars. He arrived at St. Petersburg (Leningrad) at the psychological moment when the tsar had made up his mind to break with Napoleon. Minister Adams therefore met with a favourable reception and a disposition to further the interests of American commerce in every possible way. From this post of vantage he watched and reported Napoleon's invasion of Russia and the final disastrous retreat and dissolution of the *grande armée*. On the outbreak of the war between the United States and England in 1812 he was still at St. Petersburg. In September of that year the Russian government suggested that the tsar was willing to act as mediator between the two belligerents. Madison precipitately accepted this proposition and sent Albert Gallatin and James Bayard to act as commissioners with Adams; but England would have nothing to do with it. In Aug. 1814, however, these gentlemen, with Henry Clay and Jonathan Russell, began negotiations with English commissioners which resulted in the signing of the treaty of Ghent on Dec. 24 of that year. After this Adams visited Paris, where he witnessed the return of Napoleon from Elba, and then went to London, where, with Henry Clay and Albert Gallatin, he negotiated (1815) a "Convention to Regulate Commerce and Navigation." Soon afterward he became U.S. minister to Great Britain, as his father had been before him, and as his son, Charles Francis Adams, was after him. After accomplishing little in London, he returned to the United States in the summer of 1817 to become secretary of state in the cabinet of President Monroe. This appointment was due primarily to his diplomatic experience but also to the president's desire to have a sectionally well-balanced cabinet in what came to be known as the Era of Good Feeling.

As secretary of state, Adams played the leading part in the acquisition of Florida. Ever since the acquisition of Louisiana successive administrations had sought to include at least a part of Florida in that purchase. In 1819, after long negotiations, Adams succeeded in bringing the Spanish minister to the point of signing a treaty in which the Spaniards abandoned all claims to territory east of the Mississippi, and the United States relinquished all claim to what is now known as Texas. This Transcontinental treaty was the first treaty to draw a boundary of the United States from the Atlantic to the Pacific ocean. It was the greatest victory ever won by a single man in the diplomatic history of the United States. Adams himself was responsible for the idea of running the line from the Rocky mountains to the Pacific—a stroke of real diplomatic genius. In his own word it marked a triumphant "epoch" in our continental expansion. As secretary of state, Adams was also responsible for conclusion of the treaty of 1818 with Great Britain laying down the northern boundary of the United States from the Lake of the Woods to the Rocky mountains along the line of 49° N. lat. Years later, as a member of the house of representatives he supported 49° N. lat. as the boundary of Oregon from the Rocky mountains to the Pacific ocean: "I want that country for our Western pioneers." Polk's Oregon treaty of 1846 drew that boundary along the line of forty-nine. Before the Spanish government ratified the Transcontinental treaty in 1820, Mexico, including Texas, had thrown off allegiance to the mother country, and the United States had occupied Florida by force of arms. The Monroe Doctrine (*q.v.*) rightly bears the name of the president who in 1823 assumed the responsibility for its promulgation; but it was the work of John Quincy Adams more than any other single man.

As President Monroe's second term drew to a close: there was a great lack of good feeling among his official advisers, three of whom—John Quincy Adams, secretary of state, John C. Calhoun, secretary of war and William H. Crawford, secretary of the treasury—aspired to succeed him in his high office. Henry Clay, speaker of the house, and Gen. Andrew Jackson were also candidates. Calhoun was nominated for the vice-presidency. Of the other four, Jackson received 99 electoral votes for the presidency, Adams 84, Crawford 41 and Clay 31; as no one had a majority, the decision was made by the house of representatives, which was confined in its choice to the three candidates who had received the largest number of votes. Clay, who had for years

assumed a censorious attitude toward Jackson, cast his influence for Adams and thereby secured his election on the first ballot. A few days later Adams offered Clay the secretaryship of state, which was accepted. The wholly unjust and baseless charge of "bargain and corruption" followed, and the feud thus created between Adams and Jackson greatly influenced the history of the United States.

Up to this point Adams' career had been almost uniformly successful, but his presidency (1825-29), in which the country's affairs were so prosperous, was in most respects a political failure because of the virulent opposition of the Jacksonians; in 1828 Jackson was elected president over Adams. (*See UNITED STATES [OF AMERICA] : History.*) It was during his administration that irreconcilable differences developed between the followers of Adams and the followers of Jackson, the former becoming known as the National Republicans, who with the Antimasons were the precursors of the Whigs. In 1829 Adams retired to private life in the town of Quincy; but only for a brief period, for in 1830, largely by Antimasonic votes, he was elected a member of the national house of representatives. When it was suggested to him that his acceptance of this position would degrade an ex-president. Adams replied that no person could be degraded by serving the people as a representative in congress, or, he added, as a selectman of his town. He served in the house of representatives from 1831 until his death in 1848. But he had not abandoned his hopes for a re-election to the presidency, whether as nominee of the Antimasonic party, in which he was very active as long as that party had political possibilities, or of the National Republican party, or of a union of both, or even of the later Whig party—always in his own mind as a "man of the whole nation." Gradually he had to abandon these hopes.

His long second career in congress was at least as important as his first career as a diplomatist. Throughout he was conspicuous as an opponent of the expansion of slavery, and was at heart an abolitionist, though he never became one in the political sense of that word. In 1839 he presented to the house of representatives a resolution for a constitutional amendment providing that every child born in the United States after July 4, 1842, should be born free; that with the exception of Florida no new state should be admitted into the Union with slavery; that neither slavery nor the slave trade should exist in the District of Columbia after July 4, 1845. The famous "gag rule" imposed by southern members of congress against all discussion of slavery in the house of representatives, effectively blocked any discussion of Adams' proposed amendment. His prolonged fight for the repeal of the so-called gag laws and for the right of petition to congress for the mitigation or abolition of slavery was one of the most dramatic contests in the history of congress. These petitions, from individuals and groups of individuals from all over the northern states, were increasingly sent to Adams and he dutifully presented them. Adams contended that these gag rules were a direct violation of the first amendment to the federal constitution, and refused to be silenced on the question, fighting for repeal with indomitable courage, in spite of the bitter denunciation of his opponents. Each year the number of antislavery petitions received and presented by him grew in great numbers; perhaps the climax was in 1837, when Adams presented a petition from 22 slaves, and, when threatened by his opponents with censure, defended himself with remarkable keenness and ability. At each session, also, the majority against him decreased until in 1834 his motion to repeal the 21st (gag) rule of the house was carried by a vote of 108 to 80 and his long battle was over.

Another spectacular contribution of Adams to the antislavery cause was his championing of the cause of the Africans of the *Anzistad*, slaves who had mutinied, escaped from their Spanish owners off the coast of Cuba and brought the slaveship into United States waters in Long Island. He defended these Negroes as freemen before the supreme court in 1831 against efforts of the Van Buren administration to return them to their masters, and inevitable death, and won their freedom.

As a member of congress—in fact, through all his life—he was a constant supporter of improvement of the arts and sciences and

the diffusion of knowledge, and did much to conserve the Smithsonian bequest, of an eccentric Englishman to the United States, and to create and endow the Smithsonian institution (*q.v.*) with the money.

The most dramatic event in Adams' life was its end. On Feb. 21, 1848, in the act of protesting an honorary grant of swords by congress to the generals who had won what Adams considered a "most unrighteous war" with Mexico, he suffered a cerebral stroke, fell unconscious to the floor of the house and died two days later in the capitol building. His obsequies in Washington and in his native Massachusetts assumed the character of a countrywide pageant of mourning, as if it were an emotional release at the end of a war which had troubled the conscience of millions of his fellow Americans.

Few men in American public life have possessed more intrinsic worth, more independence, more public spirit and more ability than Adams, but throughout his political career he was handicapped by a certain personal reserve and austerity and coolness of manner which prevented him from appealing to the imaginations and affections of the people. He had few intimate friends, and not many men in American history have been regarded, during the period of their lifetime, with so much hostility and attacked with so much rancour by their political opponents.

Adams was married in London in 1797, on the eve of his departure for the post as minister to Prussia, to Louisa Catherine Johnson (1775-1852), daughter of the United States consul Joshua Johnson, a Marylander by birth, and his wife, Catherine Nuth, an Englishwoman.

Morse, *John Quincy Adams* (1883, new ed., 1899); Dexter Perkins, "John Quincy Adams" in *American Secretaries of State and Their Diplomacy*, vol. iv (1928); Bennett Champ Clark, *John Quincy Adams, The Old Man Eloquent* (1933). Two basic volumes by Samuel Flagg Bemis, *John Quincy Adams and the Foundations of American Foreign Policy* (1949) and *John Quincy Adams and the Union* (1956), utilized the fabulous archives of the Adams family, now in the possession of the Massachusetts Historical society and in the process of voluminous publication, and a wealth of other official and private collections.

(E. C.; S. F. B.)

ADAMS, MAUDE (1872-1953). U.S. actress, best known for her charming portrayals of J. M. Barrie's heroines, was born in Salt Lake City, Utah, Nov. 11, 1872, daughter of James and Annie (Adams) Kiskadden. Her mother, whose maiden name she adopted, was leading lady of the Salt Lake theatre. Miss Adams was carried on stage as an infant and as soon as she could walk and talk played child parts, enjoying her first triumph at the age of five as Little Schneider in *Fritz* at the San Francisco theatre. She played all the usual child roles, and after an interval for education in 1888 joined E. H. Sothern as ingénue. From her appearance in C. H. Hoyt's *A Midnight Bell* (1889) her popularity grew rapidly. The next year Charles Frohman cast her in William Gillette's *All the Comforts of Home*, and when John Drew left Daly for the Frohmans in 1892 she became leading lady for five years to the "first gentleman of the stage." From 1897 she was for many years a Frohman star, especially successful in *The Little Minister*, *Peter Pan*, *What Every Woman Knows*, *Quality Street* and *A Kiss for Cinderella*. But she also played Juliet, Viola, Rosalind, and Joan of Arc in Schiller's play. She left the stage in 1918, experimented for a time with stage lighting, returned in 1931 as Portia to Otis Skinner's *Shylock*, and made her last appearance as Maria in *Twelfth Night* in 1934. She became professor of dramatic art at Stephens college, Columbia, Mo., in 1937. Miss Adams died at Tannersville, N.Y., on July 17, 1953. (B. Ht.)

ADAMS, ROBERT (c. 1791-1875), Irish clinician noted for his contributions to the knowledge of various forms of heart disease and of rheumatic gout, was born in Ireland c. 1791 and educated at Trinity college, Dublin. After spending some time in medical study in Europe, he settled in practice in Dublin. He was surgeon successively to the Jervis Street and Richmond hospitals and was three times elected president of the Royal College of Surgeons in Ireland. In 1827 he described a condition of the heart characterized by a very slow pulse and by transient giddiness. Twenty years later attention was again drawn to this curious

combination of symptoms by his colleague William Stokes, and it became known as the Adams-Stokes syndrome (or disease). In 1861 he was appointed surgeon to the queen in Ireland and regius professor of surgery in the University of Dublin. He died in Dublin on Jan. 13, 1875. (W. J. Bp.)

ADAMS, ROGER (1889–). U.S. chemist, best known for his studies of organic compounds, was born in Boston, Mass., on Jan. 2, 1889. Educated at Harvard university, he received the degree of Ph.D. in 1912. Following study in Germany and a period of teaching at Harvard, he went in 1916 to the University of Illinois, where he became professor of organic chemistry in 1919 and head of the chemistry department in 1926. In 1954 he accepted a research professorship and in 1957 he retired.

Adams' most important researches determined the chemical constitution of such natural products as chaulmoogra oil, gossypol, marijuana and numerous alkaloids. His other fields of research were stereochemistry, synthesis of medicinal compounds, and platinum catalysts. In recognition of his career as research chemist, teacher, consultant to the chemical industry and scientific adviser to the government in World War II, Adams was awarded many honours, including the Priestley medal (1946). (D. C. Bm.)

ADAMS, SAMUEL (1722–1803), political leader of the period of the American Revolution and signer of the Declaration of Independence. He was born in Boston, Mass., on Sept. 27, 1722, a second cousin to John Adams, second president of the United States. He graduated from Harvard college in 1740, briefly studied law, and failed in several business ventures. He also performed badly as a tax collector in Boston, neglecting to collect the public levies and to keep proper accounts, so exposing himself to suit.

With the passage by parliament of the Sugar act in 1764 (*see* UNITED STATES [OF AMERICA]: *History*) Adams began a swift rise to power in Massachusetts. He denounced the measure, being one of the first of the colonials to cry out against taxation without representation. He played an important part in instigating the Stamp act riots in Boston, and he soon acquired influence second only to that of James Otis among those who struggled against British authority in the colony. Elected to the lower house of the Massachusetts general court from Boston, he served in that body until 1774, after 1766 as its clerk. In 1769 Adams assumed the leadership of the Massachusetts "radicals." According to his cousin John, Samuel had committed himself to American independence a year earlier. John Adams may have erred in ascribing this extreme stand to his cousin at so early a time, but certainly Samuel Adams was one of the first American leaders to deny any authority over the colonies to parliament; and he was also one of the first to establish independence as the proper goal, this surely before 1774.

John Adams described his cousin as a plain, modest and virtuous man. But Samuel Adams was in addition a propagandist who was not overscrupulous in his attacks upon British officials and policies, and a passionate politician as well. In innumerable newspaper letters and essays over various signatures he described British measures and the behaviour of royal governors, judges and customs men in the darkest colours. He was a master of organization, arranging for the election of men who agreed with him, procuring committees that would act as he wished and securing the passage of resolutions that he desired.

During the crisis over the Townshend duties (1767–70) Adams was unable to persuade the Massachusetts colonists to take extreme steps, partly because of the moderating influence of Otis. However, the British troops who were sent to Boston in 1768 offered a fine target for his propaganda; and he saw to it that they were portrayed in the colonial newspapers as brutal soldiery oppressing inoffensive citizens and assailing their wives and daughters. He was one of the leaders in the town meeting which demanded and secured the removal of the troops after the Boston massacre. When news came that the Townshend duties, except for that on tea, had been repealed, his following dwindled. Nevertheless, during the years 1770–73, when other colonial leaders were inactive, Adams persistently revived old issues and found new ones; he was responsible for the foundation (1772) of the

committee of correspondence of Boston and of similar bodies in other towns, these later becoming effective engines against British tyranny.

The passage by parliament of the Tea act of 1773 gave Adams ample opportunity to exercise his remarkable talents. Although he did not participate in the Boston Tea Party, he was undoubtedly one of its planners. He was again a leading figure in the opposition of Massachusetts to the execution of the Coercion acts; and as a member of the first continental congress, he insisted that the delegates take a vigorous stand against Britain. As a member of the provincial congress of Massachusetts in 1774–75 he participated in making preparations for warfare, should Britain resort to arms. When the British troops marched out of Boston to Concord, Adams, with Hancock, was staying in a farmhouse near the redcoat line of march; and it is often said that the arrest of the two men was one of the purposes of the expedition. However, the troops made no effort to find them; and British orders called only for destruction of military supplies gathered at Concord. When Gen Thomas Gage issued an offer of pardon to the rebels some weeks later, he excepted Adams and Hancock.

As a member of the continental congress, in which he served as a delegate until 1781, Adams was less conspicuous than he was in town meetings and the Massachusetts legislature. He and John Adams were among the first to call for a final separation from Britain. Both men signed the Declaration of Independence. They formed a political alliance with the Lees of Virginia and exerted considerable influence by means of it. With the departure of John Adams for Europe, Samuel became of less consequence in congress. In that body there were many men as able as he.

Adams was a member of the convention which framed the Massachusetts constitution of 1780, and also sat in the convention of his state which ratified the federal constitution. He was at first an anti-Federalist, but finally abandoned his opposition when the Federalists promised to support a number of future amendments, these including a bill of rights. He was defeated in the first congressional election by Fisher Ames. Returning to political power as a follower of Hancock he was lieutenant governor of Massachusetts from 1789 to 1794 and governor from 1794 to 1797. When parties developed on a national scale, he affiliated himself with the Democratic-Republicans. He was defeated as a presidential elector favouring Jefferson in the election of 1796, and soon thereafter retired to private life. He died on Oct. 2, 1803.

Cushing (ed.), *The Writings of Samuel Adams*, 4 vol. (1904–08); and *Warren-Adams Letters*, 2 vol., Mass. Hist. Soc. Collections (1917–25). (J. R. AL.)

ADAMS, SAMUEL HOPKINS (1871–1958), U.S. journalist and author of more than 50 books, was born in Dunkirk, N.Y., on Jan. 26, 1871. He graduated from Hamilton college (Clinton, N.Y.) in 1891 and was a reporter and later a special writer for the *New York Sun* until 1900; from 1901 to 1905 he was associated in various editorial and advertising capacities with McClure's syndicate and *McClure's Magazine*.

One of the muckrakers (*q.v.*) of the period, he contributed to *Collier's Weekly* in 1905 a series of articles exposing quack patent medicines, followed by *The Great American Fraud* (1906), which furthered the passage of the Pure Food and Drug act in 1906. In 1915–16 in the *New York Tribune*, he exposed dishonourable practices in advertising. The novel *Revelry* (1926), and in 1939 a biography of Warren G. Harding, *The Incredible Era*, set forth the scandals of the Harding administration. Adams also wrote biographies of Daniel Webster (*The Godlike Daniel*, 1930) and of Alexander Woollcott (1945). *Average Jones* (1911) was one of many detective stories. Several novels became movie scenarios, notably *It Happened One Night* (1934). *Grandfather Stories* (1955) was based on reminiscences of his grandfather in upper New York state. Some of his books were published under the name Warner Fabian. He died Nov. 15, 1958, in Beaufort, S.C.

ADAMS, SARAH (*née* FLOWER) (1805–1848), English poet, best known for the hymn, "Nearer, My God, to Thee" (1840), was born at Great Harlow, Essex, on Feb. 22, 1805, the daughter

of the republican author Benjamin Flower. In 1834 she married William Bridges Adams, a railway inventor and political pamphleteer. She contributed to the *Monthly Repository* and wrote many unpublished poems, chiefly for the Anti-Corn-Law league. A Unitarian, her writings were chiefly religious and her longest work, *Vivia Perpetua* (1841), a dramatic poem about the conversion to Christianity of a Roman girl, shows genuine feeling. Her hymns remain popular for their strong rhythms, simple imagery and their expression of devout self-dedication.

ADAMS, WALTER SYDNEY (1876–1956), U.S. astronomer, was for many years director of the Mount Wilson observatory near Pasadena, Calif. He was born in Syria on Dec. 20, 1876, of missionary parents who returned to the U.S. when he was 8 years old. He studied astronomy at Dartmouth college, The University of Chicago and the University of Munich, Ger.

From 1901 to 1904 he worked on stellar spectra at Yerkes observatory, Williams Bay, Wis. In 1904 he was invited to become a charter member of the staff of a new observatory being established by the Carnegie Institution of Washington on Mount Wilson in southern California. For many years he shared with George E. Hale responsibility for the administration of the growing observatory with its powerful solar apparatus and 60-in. and 100-in. stellar telescopes. He served as director from 1923 to 1946.

As an observer of the spectra of the sun and stars Adams was skillful and indefatigable. His most important investigations included: (1) a close study of the spectra of sun spots; (2) spectroscopic measurements of the rotation of the sun at various solar latitudes; (3) spectroscopic determinations of the velocities and distances of thousands of stars; (4) detailed observations of the spectra of peculiar stars; (5) studies of gases in interstellar space.

Adams was an important member of committees set up by the California Institute of Technology to plan and construct the zoo-in. telescope on Palomar mountain. For outstanding contributions to solar and stellar astronomy he received many high honours. He died in Pasadena on May 11, 1956. See also OBSERVATORY (ASTRONOMICAL). (P. W. M.)

ADAMS, WILLIAM (1564–1620), English navigator and merchant adventurer, the first Englishman in Japan, was born at Gillingham, Kent, in 1564. When 12 years old he was apprenticed in the mercantile marine, afterward entering the British navy and later serving the company of Barbary merchants as master and pilot. Attracted by the Dutch trade with India, in 1598 he shipped as pilot major with a fleet of five ships which were to sail westward from the Texel via the Straits of Magellan to the East Indies. After storms and hostile attacks by Indians off the coast of Chile, the fleet was scattered, but in April 1600 the "Charity," with a crew of sick and dying men and with Adams on board, anchored off the island of Kyushu, Japan.

Summoned to Osaka, he was examined by Iyēyasu the guardian of the young son of Taiko Sama, the ruler who had just died. His knowledge of ships and shipbuilding and his nautical smattering of mathematics raised him in the estimation of the shogun who presented him with an estate at Hēmi near Yokosuka, but refused him permission to return to England. In 1613, however, Adams decided to postpone his return home (permission for which had now been given him) in order to help with the establishment of an English trading factory for the East India company. He spent the rest of his life in Japan and married a Japanese woman. He was given the title Anjin Sama, and a street in Tokyo, Anjin-cho, was named in his memory. Adams died on May 16, 1620.

See N. Murakami (ed.), *Letters Written by the English Residents in Japan, 1611–23* (1900); C. J. Purnell (ed.), *The Log-Book of William Adams, 1614–19* (1916). (A. M. F.)

ADAMS, WILLIAM TAYLOR (1822–1897), U.S. juvenile writer, popularly known under the pseudonym of Oliver Optic, was born in Bellingham, Mass., on July 30, 1822. For 20 years he was a teacher in the public schools of Boston, and he served for a term in the state legislature. He wrote more than 100 books, chiefly juvenile stories of adventure and patriotism, which appeared in several series. In large part these were contributed to *Oliver Optic's Magazine*, of which he was founder and editor. Among the

best known are the "Boat Club Series" (1854), the "Army and Navy Series" (1865–94) and the "Great Western Series" (1875–82). He died in Boston on March 27, 1897.

ADAM'S APPLE, a prominence in the middle of the front of the neck, which moves up and down with swallowing. It is more noticeable in men than in women. It is formed by the thyroid cartilage of the larynx, commonly known as the voice box. It is sensitive to pressure and blows and is vulnerable to attack in systems of personal combat.

ADAM'S BRIDGE (RAMA'S BRIDGE), a chain of sandbanks between the island of Mannar, near the northwestern coast of Ceylon, and the island of Rameswaram, off the Indian coast, and lying between the Gulf of Mannar on the southwest and Palk strait on the northeast. More than 30 mi. long, it seriously hinders navigation. Some of the sandbanks are dry and no part of the shoal has a greater depth than 3 or 4 ft. at high water. Dredging operations were begun as early as 1838 but were never successful in maintaining a channel for any except vessels of light draft; they have been abandoned. Geological evidence suggests that Adam's Bridge is all that is left of a former land connection between India and Ceylon. The banks and shoals of the "Bridge" are traditionally supposed to be the remains of a huge causeway constructed by Rama, the hero of the *Ramayana*, to facilitate passage of his army from India to Ceylon for the rescue of his abducted wife Sita. (B. H. F.)

ADAM SCOTUS (ADAM ANGLICUS) (d. c. 1180), theological writer, was born in the south of Scotland in the first half of the 12th century. About 1150 he was a Premonstratensian canon at St. Andrews, and about 20 years later was perhaps abbot and bishop of Candida Casa (Whithorn) in Galloway.

He gained a European reputation for his writings, which are of mystico-ascetic type and include an account of the Premonstratensian order, a collection of festival sermons and a *Soliloquia de instructione discipuli*, formerly attributed to his contemporary Adam of St. Victor.

ADAMSON, PATRICK (1537–1592), archbishop of St. Andrews, Scot., from 1576 and opponent of the Presbyterian party in the Scottish Kirk. He was born at Perth, probably in March 1537, educated at St. Andrews, was a tutor in Paris, Padua and Geneva, where he studied Calvinist theology, and returned to Scotland c. 1572. As archbishop he won the king's support but opposed the Presbyterianism of the general assembly and was excommunicated by the synod (1586). He lost the king's favour and spent his last years in poverty, although recantations of his earlier views, apparently signed but not necessarily written by him and not printed until 1598, gained him remission of the sentence. He died on Feb. 19, 1592. His collected works were published in 1619. His ability as scholar and preacher and his determination as theologian and controversialist were admired even by his enemies.

ADAM'S PEAK, a mountain in Ceylon, about 45 mi. E. by S. of Colombo. It rises steeply to a height of 7,360 ft. and commands a magnificent view.

CAMERA PRESS, PIX FROM PUBLIX

ADAM'S PEAK, CEYLON

Its conical summit terminates in an oblong platform, 74 by 24 ft., on which there is a hollow, resembling the form of a human foot, 5 ft. 4 in. by 2 ft. 6 in. The footprint is held in veneration by Buddhists, by Muslims and by Hindus alike, and by them it is ascribed respectively to Gautama, to Adam and to Siva. It is in charge of Buddhist monks, and is a famous place of pilgrimage. Heavy chains on the southwestern face, said to have been left there by Alexander the Great, and mentioned by Marco Polo, mark the original route. The ascent is usually made from Maskeliya. At dawn the peak frequently casts a very well-defined shadow upon

the clouds.

ADANA (SEYHAN), the capital of Seyhan *il* (province) in southern Turkey, on the banks of the Seyhan river, of which it stands about 32 mi. from the sea; it is the fourth largest city in the country and one of the most prosperous. Pop. (1960) 230,024. The climate is cold in winter but hot and humid in summer with frequent thunderstorms. Most of the buildings are of mud brick but the streets are wide. There are several banks, a hospital, a museum, modern hotels, a meteorological centre, a government-sponsored agricultural research station and a malarial-investigation-commission centre. Industries include cotton, flour and saw mills; factories for soap, tobacco and explosives; olive oil refineries; and a government weaving plant. Adana lies on the Istanbul-Baghdad railway, with a branch line to the port of Mersin from which its produce is shipped. It is connected by tarmac roads via Tarsus to the west and eastward to Iskenderun (Alexandretta).

The modern town overlies the ancient one, which dates back at least to the period of the Hittite empire, when it was known as Ataniya, and probably earlier. It has been suggested that Velican Huyuk, lying nearer the sea, was the site of the early settlement. Excavations at Adana Tepe Bag, a mound in the centre of the town, have yielded material from the Islamic to the Hellenistic periods. One of the earlier standing monuments is the 220-yd.-long stone bridge across the Seyhan (ancient Sarus), dating from the time of Justinian and restored in the time of the Arab rulers al-Walid (743) and al-Mu'tasim (840) when they controlled this area. On the right bank of the river is the ruined fortress built by Harun al-Rashid in 782. The principal mosque, the Ulu Cami, dates from 1542. Situated close to the narrow pass known as the Cilician Gate, Adana was often taken by conquering armies, from those of Alexander to those of Ibrahim Pasha. After the Turkish defeat at Konya it was held by the Egyptians from 1832 to 1840. After World War I it was occupied for a short time by French forces in 1920–21, until the treaty of Lausanne returned the *il* to Turkey.

The *il* of Seyhan was known in classical times as Cilicia, and under the Hittites as Kizzuwatna. Adana is the centre of the cotton trade and the surrounding plain grows cereals, tobacco, sugar cane, sesame and citrus fruits. (M. V. S.-W)

ADAPA was a legendary sage, a citizen of Eridu, a city of Babylonia. Endowed with vast intelligence by Ea, the god of wisdom, he became the hero of the Eridu myth of the Fall of Man. Adapa, in spite of his possession of all wisdom, was denied immortality. One day, while he was fishing, the south wind blew so violently that he was thrown into the sea. In his rage he broke the wings of the south wind, which then ceased to blow. Anu, the god of heaven, summoned him before his gates to receive punishment, but jealous Ea cautioned him not to touch the bread and water that would be offered him. When Adapa came before Anu, Tammuz and Gishzida interceded for him and explained to Anu that as Adapa had been endowed with omniscience he needed only immortality to become a god. Anu then offered Adapa the bread and water of eternal life, which he refused to take. Thus mankind became mortal. The legend is preserved among the cuneiform tablets discovered during the 19th century in Ashurbanipal's library at Nineveh. (T. V. B.)

ADAPAZARI (ADAPAZAR), the chief town of the *il* of Sakarya, Turkey, lies about 75 mi. E. of the Bosphorus, on the old military road from Istanbul to the east. Pop. (1960) 80,160. It is an important commercial and industrial centre, and is connected by a branch line to the Anatolian railway. Its industries include sugar refining, silk, linen and the manufacture of pipes; its exports are tobacco, walnut wood, cocoons and vegetables for the Istanbul market. The country around is fertile and extensively cultivated, its chief crops being sugar beet, tobacco, potatoes and cereals. (N. Tu.; S. ER.; E. Tu)

ADAPTATION, BIOLOGICAL. The adaptations which, in the widest sense, fit an animal or plant to its environment are the result of natural selection acting upon heritable variation. Even the simpler organisms must be adapted in a great variety of ways: in their structure, physiology (the working and chemistry of their bodies) and genetics, in their locomotion or dispersal,

means of defense and attack, in their reproduction and development and in other respects. It should initially be noticed that there are two distinct means of achieving these results, though all intermediates between them may be encountered. Either the body may be adjusted accurately to particular types of environment or it may develop a tolerance to a wide range of them.

Accurate adaptations may involve migration to, or survival in favourable conditions such as temperature. Alternatively, organisms may manufacture their own environment as do the mammals that are precisely adjusted to their optimum temperature. This they create for themselves in whatever situation (consistent with survival) they may be. On the other hand, forms with a wide tolerance are fitted to the environmental range, great or small, to which they are normally exposed; they cannot evolve appropriate reactions to conditions they seldom or never experience.

It will be evident that, to be useful, adaptations must often occur simultaneously in a number of different parts of the body. A change from a more carnivorous to a more vegetarian diet necessitates alterations in the teeth, digestive juices and length of the digestive tract; it necessitates also modifications in habit and imposes a need for new types of defense. Such profound effects demonstrate that individuals best adapted to their environment tend to survive. (See SELECTION.)

Some of the most fundamental of biological adaptations are of a chemical and genetic kind. The conditions in which the cells of the body can live are really very restricted. They have, indeed, changed but little since life first arose. It did so in the sea, and it was not until long afterward that it became practicable to colonize fresh water and land. That achievement was possible only through the evolution of adaptive mechanisms capable of maintaining something like the original constitution of the body-fluids. Thus even in man and other mammals today, the blood is chemically quite closely related to sea water.

For general information on the genetic adaptations of organisms see GENETICS: *Evolutionary* Genetics. It is useful, however, to draw attention to one or two aspects of them here. The gene-complex of an organism is controlled by selection to give rise to the most favourable effects in the genes and, as far as possible, to minimize the unfavourable ones. Furthermore, it might even have been deduced on logical grounds, in advance of the discovery, that some mechanism exists for holding together, generally but not irrevocably, those genes that interact in a favourable way. Not only, then, is the chromosome mechanism a predictable necessity, but it follows that the genes which each chromosome carries are not, as might appear from the linkage maps, a purely random assortment. That is to say, the chromosomes must be highly adapted systems.

C. D. Darlington has pointed out that the stability of the chromosome numbers in plants is associated with the length of the reproductive cycle. The values frequently vary within species, and usually within genera, in annuals; they do so within tribes in perennials, but hardly within families in trees. For chromosome changes at their onset interfere with fertility, and an error in the sexual mechanism does not become effective until maturity. This will be in a few weeks in an annual, but only after many years and great biological expenditure in a tree. Here we have one aspect of the way in which adaptation controls the chromosome system.

The means by which organisms are adjusted to their ecology may be either environmental or genetic. Thus we find that many plants are, for obvious reasons, of more prostrate growth in exposed positions, high up on mountains or by the seashore, than in sheltered habitats. In some species the forms maintain their characteristics when grown together in the same environment. Of this the bittersweet, *Solanum dulcamara*, and its dwarf phase *maritimum*, from shingle beaches, provides an instance; in others, the sea plantain, *Plantago maritima*, for example, they do not. The adaptations for pollination (*q.v.*) and seed dispersal (see ANGIOSPERMS: Reproductive Characters; FRUIT; WEED) possessed by plants are diverse and related to their ecology (see PLANTS AND PLANT SCIENCE: Plant Ecology). Among animals, habits, in addition to structure, must be adapted correctly. Thus

the swallowtail butterfly, *Papilio machaon*, is wide-ranging and scatters far over the countryside in continental Europe. In England, it is adapted strictly to life in the fens of East Anglia and from these it seldom strays, though powerful on the wing; for in these circumstances the wandering habits of the continental race would prove fatal.

Of all the adaptations, those involving colour-pattern are probably the best known. One of the most general of these is the evolution of paler colouring on the underside of animals to counterbalance their own shadow, as an aid to concealment. However, the heavy caterpillars of some moths habitually hang upside down from the branch upon which they feed. Consequently, their counter-shading is reversed, the back being paler than their true underside, as in the privet hawkmoth, *Sphinx ligustri*; this is an example that demonstrates clearly the force of selection and that the darker colour in the dorsal position is not merely an anatomical necessity.

In general, animal colour-patterns can be classified according to their adaptive functions. The cryptic or concealing type may enable a predator to approach its prey unobserved, as in the tiger, or to escape predation. Beautiful instances of the latter type are, of course, extremely numerous and familiar. They may involve a general resemblance to the background, like the woodcock when sitting in undergrowth or a leaf butterfly. They may, on the other hand, give security by matching some particular inanimate object likely to be avoided, such as a bird-dropping. Alternatively, the pattern may be so arranged as to alter the apparent shape of some well-known type of prey for which a predator is searching. (See ANIMAL COLORATION; BIRD: Coloration.)

Cryptically coloured forms sometimes, in addition, possess "flash coloration." Here some conspicuous mark, easily visible, is apparent when the animal moves, but is hidden when it comes to rest protected by its background. For instance, the gray and mottled forewings of the red underwing moth, *Catocala nupta*, match tree trunks and dark stones to perfection. In these circumstances, the scarlet hindwings are, of course, hidden, and the sudden disappearance of this colour when the flying insect settles is extremely confusing to a potential enemy. On the other hand, species that possess means of defense, such as certain wasps, or are inedible, like many butterflies and moths, advertise the fact by conspicuous warning colours, and these, unlike flash colours, are usually exhibited even at rest. Such species frequently move or fly slowly; it is to their advantage to be recognized and therefore avoided by their predators. Warning devices other than colour-patterns are sometimes employed, such as the rattle of the rattlesnake. Some of the most remarkable adaptations are those that involve deception, in which edible species without means of defense copy those that are genuinely protected and display warning colours (see MIMICRY).

A striking demonstration of natural selection is provided by those instances in which organisms have had to fit themselves to new environments. Since the mid-19th century more than 80 species of moths have lost their original pale cryptic colouring and have become black in the industrial areas of Britain, the United States, and elsewhere (see MELANISM). These species rest fully exposed on tree trunks or walls, deriving protection by their resemblance to bark and lichen; but the black forms are better concealed in the blackened countryside of manufacturing districts. A selective interpretation of this phenomenon implies that such species are preyed upon by birds or other predators hunting by sight. The proof of this contention, long denied by ornithologists, was supplied in Britain by H. B. D. Kettlewell, who showed that insect-eating birds selectively eliminate the inappropriately coloured specimens in great numbers, in this case the black ones in the normal countryside and the pale ones in regions polluted by soot. Here we can see biological adaptations evolving at the present time.

ADDA (anc. ADDUA), a river of north Italy, rises in small lakes in the Rhaetian Alps at 7,660 ft. In its upper course, from Bormio to Tirano, it flows southward, turning west at Tirano and entering Lake Como near its northern end. The upper course of the Adda is sometimes known as the Valtellina (*q.v.*). Leaving Lake Como (*q.v.*) at Lecco, the Adda crosses the Lombardy plain, flowing past Lodi, and reaches the Po, after a course of 194 mi., just upstream from Cremona. The drainage basin of the Adda covers 3,081 sq.mi., its average flow in the lower course is about 8,800 cu.ft. per second, varying between 600 and 28,000. There are numerous hydroelectric plants on the upper Adda, and there is extensive irrigation on its lower course. (G. KH.)

ADDAMS, JANE (1860–1935), U.S. social reformer, founder of Hull House in Chicago, Ill., and co-winner of the Nobel peace prize in 1931, was born at Cedarville, Ill., Sept. 6, 1860. After graduating from Rockford college, Rockford, Ill. in 1881, she entered the Woman's Medical college of Philadelphia, Pa., but her health failed, and after two years of invalidism she traveled extensively in Europe. In London she visited the Toynbee Hall "settlement" in the Whitechapel industrial district. After her return she founded Hull House (1889), a pioneer U.S. social settlement (*q.v.*) in the old Hull mansion on Chicago's west side, where well-known social reformers lived as residents. In this large settlement she worked with labour and other reform groups for many pioneer welfare laws such as the first juvenile court law and the first "mother's pension" law, tenement house regulation, an eight-hour working day law for women, factory inspection and workmen's compensation. She was also an able supporter of woman suffrage. A well-known pacifist, she was chairman of the International Congress of Women at The Hague, Neth., in 1915, following which the Women's International League for Peace and Freedom, of which she became president, was established. She was the first woman president of the National Conference of Social Work (1910) and took an active part in the Progressive presidential campaign with Theodore Roosevelt in 1912. Author of many books and articles, Jane Addams used her influence for social justice for the immigrant, for the Negro, for labour and for the rights of women and children. She died in Chicago on May 21, 1935. (E. AT.; X.)

ADDAX (*Addax nasomaculatus*), a large antelope once distributed throughout the Sahara desert, but now much reduced in number and distribution. The summer coat shades from white underparts to sandy above; in winter, long brown hair develops on the neck, shoulders and forehead. Below the dark-brown forehead a white streak crosses the face. A heavy, short-legged, oryx-like antelope, the addax stands about 40 in. high. The closely ringed horns, up to 43 in. long, have a slight spiral twist. Desert adaptations include broad hoofs for travel in loose sand, moisture-conserving specializations and an ability to follow rains to vegetation-covered dunes. (H. K. B.)

ADDER, originally meaning "any snake," is now usually applied to the viper *Vipera berus*, a poisonous snake of Europe and northern Asia. In Norway it occurs slightly above the Arctic circle, farther north than any other known snake. Its colour is variable, with usually a zigzag black band running along the back; its length, 18 to 30 in. Six to 20 young are born during August or early September. Food consists of lizards and small mammals. The adder's bite is rarely fatal to man.

The puff adder (*Bitis arietans*), large and dangerous, and the night adders (Causus species), small and not so dangerous, are African vipers. The death adder (*Acanthophis antarcticus*), of another family, the Elapidae, is a dangerous Australian snake remarkably similar to a viper in appearance. (S. A. M.)

ADDIS ABABA ("New Flower"), the capital of Ethiopia, Africa, lies in the Shoa province about 8,000 ft. above sea level and in the centre of a well-watered plateau surrounded by hills and mountains. In place of the original forest is a profuse growth of eucalyptus trees. The climate is healthful with warm, sunny days and cool nights. The rainy season extends from July to late September and the average rainfall is about 50 in. Addis Ababa is the administrative and business centre of the Ethiopian empire and the seat of government. Pop. (1956 estimate) 400,000, including about 10,000 foreign nationals.

The present site of Addis Ababa, then known as Finfinnie, was chosen in 1896 by Emperor Menelik II, whose capital was on Mt. Entoto a few miles to the north. Construction began in 1897, when the foundation stone of the palace (the "Old Gibbi") was laid. The city grew in a desultory fashion until, in 1936, the Italians occupied it and made it the capital of Italian East Africa. They carried out many constructive improvements during their occupation. The city was captured by the Allies in 1941 and Ethiopian rule was restored. Its growth accelerated after World War II, with considerable building and road construction, but although developing rapidly on modern lines it retained much of its character as an African town. The main thoroughfare, Churchill road, is long and rather steep and the city is laid out on different levels, owing to the hilly terrain. A town-planning scheme of Sir Patrick Abercrombie's was being gradually made effective, with striking results.

The University College of Addis Ababa was founded in 1950 and there are also two teacher-training colleges; a college of engineering; technical, commercial and handicraft schools; secondary schools; and a large number of primary schools. Certain of the foreign communities maintain schools which are open to all races.

There are two imperial palaces of modern design with large gardens; a national library and museum; and public buildings in various styles, notably a striking new parliament house. Among the numerous churches, some of which are picturesque, are a Coptic and a Roman Catholic cathedral. Addis Ababa has several large hospitals, an impressive opera house and several cinemas. Electricity and water supplies are adequate and keep pace with the city's growth. There are a large diplomatic colony and some imposing embassies. The United Nations Economic Commission for Africa has its headquarters in Africa House.

Addis Ababa is the centre of the growing coffee trade of the empire. There is no heavy industry, but light industries such as textile mills, shoe factories, a brewery, distilleries and flour mills are established on the outskirts of the city. In its large and colourful markets is distributed much of the produce grown throughout the empire.

Interest is being shown in developing Addis Ababa as a tourist centre and there are several first-class hotels. An automatic telephone system and modern telegraphic facilities are available and there is a radio station. From the airport, 2½ mi. from the city, there are services to Frankfurt, Ger.; Athens, Greece; the port of Aden; and to Nairobi, Kenya; Cairo, Egy.; Khartoum, Sudan; and other African towns. There is also a network of internal services. Addis Ababa is the terminus of the Franco-Ethiopian railway, which runs to Djibouti. A highway system, which is constantly being extended, fans out from the city to the provinces.

The city, which is divided into ten municipal districts, is governed by a nominated *kantiba* (mayor) with the aid of a council which comprises both elected and nominated representatives.

(F. E. Sp.)

ADDISON, JOSEPH (1672–1719), English essayist and critic who, with Sir Richard Steele (*q.v.*), wrote most numbers of *The Tatler* (1709–11) and *The Spectator* (1711–12 and 1714), was born at Milston, Wiltshire, on May 1, 1672, the eldest son of Lancelot Addison. His father, who had at one time been chaplain to the British garrison at Tangier, was rector of Milston; he later became the dean of Lichfield. Joseph Addison was educated at Lichfield grammar school and at the Charterhouse, where he made friends with Richard Steele, who often spent his holidays at the

deanery. At the age of 15 Addison went up to Queen's college, Oxford, later being elected to a demyship and subsequently (in 1698) to a fellowship at Magdalen college which he retained until 1711. He first distinguished himself by his skill at Latin verse. His first biographer, Thomas Tickell, tells us that he "was admired as one of the best authors since the *Augustan* age, in the two Universities, and the greater part of Europe, before he was talked of as a Poet in Town." At this time he met John Dryden and the publisher Jacob Tonson, for whom he soon undertook some literary commissions. "To Mr. Dryden," his first English poem, was published in Dryden's third miscellany of poems, *Examina Poeticum* (1693), and an ode, two translations and a poem entitled "An Account of the Greatest English Poets" in the fourth, the *Annual Miscellany* (1694). He was soon introduced to William Congreve and other men of letters and through them he was presented to the lord chancellor, Sir John (later Baron) Somers, and to Charles Montagu (later earl of Halifax), then chancellor of the exchequer and leader of the Whigs, who persuaded him to write his *Poem to His Majesty* in 1695. He had to choose between taking holy orders, thus confirming his fellowship, and taking up a life of affairs in London. Montagu and Somers secured him a pension of £300 from the crown to enable him to travel and prepare for further literary undertakings. His Latin poem *Pax Gulielmi*, on the peace of Ryswick, and his essay on the *Georgics*, in Dryden's translation of Virgil, had appeared in 1697. Shortly afterward Addison left England for four years (1699–1703). During his travels, for much of the time as tutor to young Edward Wortley Montagu, he wrote his *Letter from Italy* (1704), one of the most agreeable of his poems. *Remarks on Several Parts of Italy* (1705) and *Dialogues upon the Usefulness of Ancient Medals*, posthumously published in Tickell's edition of the *Works* (1721) and separately in 1735.

The months immediately following his return to England in 1703 were among the least propitious of his career (though he became acquainted with many notable Whigs at this time, having been introduced into the Kit-Cat club), the Whigs being out of office and his principal patron in particular discredit at court; but his fortunes were quickly restored when the earl of Godolphin asked Halifax to find him a poet to celebrate Marlborough's glorious victory at Rhenheim. Halifax recommended Addison, who was immediately offered a commissionership of appeal in the excise (virtually a sinecure) and began work on his heroic poem *The Campaign* (1705). About this time he helped Steele to complete the comedy *The Tender Husband* (1705). Soon after (in 1706) he was promoted undersecretary of state to Sir Charles Hedges and some months after to his successor, the duke of Sunderland. It was at this time that his opera, *Rosamond* (1707) was produced. It failed. Later in his political career he was made chief secretary to the earl of R'harston, who became Lord Lieutenant of Ireland (1708–10); this gave Addison an opportunity of renewing his friendship with Jonathan Swift when he accompanied the lord lieutenant to Ireland, where he was also appointed keeper of the records, in 1709. Addison had been elected in 1708 as member of parliament in the Whig interest for Lostwithiel, Cornwall, and after 1710 represented Malmesbury, a seat he retained until his death, though he never spoke in the house of commons. In the Dublin parliament he was one of the members for Cavan (1709–10). One of his clerks in Ireland was his relative Eustace Budgell (*q.v.*), who later became his private secretary and contributed to *The Tatler* and *The Spectator*.

Addison's fame rests above all on these two periodicals, *The Tatler* and *The Spectator*. The honour of founding *The Tatler* (April 12, 1709) must go to Steele, but Addison quickly became involved and played a considerable part in determining the nature of the new periodical. In a sense *The Tatler* was an example of the increase in journalism which followed the refusal of the house of commons to renew the licensing act in 1695; but Addison, who was less passionate and less interested in politics than Steele, realized that it would be prudent to exclude politics altogether from their new publication. Within six months, accordingly, *The Tatler*, to which Addison contributed 46 numbers, collaborating with Steele in the writing of 36 other numbers, was almost wholly

devoid of political news or comment. "Is it not much better," as he once asked, "to be let into the knowledge of one's self, than to hear what passes in Muscovy or Poland?" The concern of the essayists was not politics but life. "The general purpose of this paper," Steele wrote in the dedication of the first collected volume (1712-15), "is to expose the false arts of life, to pull off the disguises of cunning, vanity, and affectation, and to recommend a general simplicity in our dress, our discourse, and our behaviour." The last number of *The Tatler* appeared on Jan. 2, 1711, and the first number of its successor, *The Spectator* (in which Addison was from the first the leading spirit, contributing in all 274 numbers), came out on March 1, 1711. The object of the new work, which lasted until Dec. 6, 1712, and was revived by Addison for 24 numbers from June 18 to Sept. 29, 1714, was similar to that of its predecessor. "It was said of Socrates," as Addison wrote, "that he brought philosophy down from heaven to inhabit among men; and I shall be ambitious to have it said of me that I have brought philosophy out of closets and libraries, schools and colleges, to dwell in clubs and assemblies, at tea-tables and in coffee-houses." The club that centres in the *Spectator* himself is a brilliant device. Sir Roger de Coverley, Captain Sentry, Sir Andrew Freeport and the others represent important sections of the society of the day. Addison's instinct was to bring people together for reasonable discussion. Hence his hatred of rancorous party politics. "There cannot a greater judgment befall a country," as he wrote in No. 125, "than such a dreadful spirit of division as rends a government into two distinct peoples and makes them greater strangers and more averse to one another than if they were actually two different nations." Although he was equally opposed to violent religious controversy, he did not exclude religion from his pages. At one time he had intended to take holy orders and his resemblance to a parson was noted not only by Bernard de Mandeville (q. v.)—with his sneer about "a parson in a tye-wig"—but also by Tonson, who told someone that he "ever thought him a priest in his heart." The Saturday essays have usually a serious tendency. But although Addison wished to "recommend Christianity" he had no intention of encouraging passionate religious feeling, "enthusiasm" of the sort that had caused so much trouble in the previous century. His attitude is summed up in the motto of the *Spectator*, No. 112: "Honour the gods according to the established modes."

Two features of *The Spectator* deserve particular mention: the critical essays which it contained and the attention which it paid to the tastes of women readers. From the first Addison made a point of devoting a considerable proportion of the essays to literary criticism. He was a good critic, but to understand his historical importance in this respect it is as well to remember Dr. Samuel Johnson's observation that most earlier criticism had been intended "rather for those that were learning to write, than for those that read only to talk." Accordingly, "an instructor like Addison was now wanting, whose remarks being superficial might be easily understood, and being just might prepare the mind for more attainments." Here, as in so many other respects, Addison felt the pulse of his time and dispensed precisely what was required. His criticism proved more influential than that of many profounder critics, helping (above all) to bring it about that writers and writing were considered proper subjects for conversation throughout the century. One reason for the essential simplicity of his critical essays was that they were intended for women as well as men. The accession of a woman to the throne had made the time propitious for the advocacy of a change of attitude to women. "There are none to whom this paper will be more useful than to the female world," Addison wrote in the tenth number. "I have often thought there has not been sufficient pains taken in finding out proper employments and diversions for the fair ones." Most people now agree with Snift, who found the tone in which Addison "fair-sexed it" intolerably condescending; but there is no doubt that the essayists of the period did a great deal to improve the status of women in English society.

In 1713 (to conclude the account of his life) Addison contributed 51 numbers, few of which were memorable, to Steele's periodical *The Guardian* (March 12—Oct. 1) and completed his tragedy,

Cato, which was produced and received with the greatest approbation. Dr. Johnson considered it "unquestionably the noblest production of Addison's genius," yet described it as "rather a poem in dialogue than a drama, rather a succession of just sentiments in elegant language than a representation of natural affections." It may still be read with admiration but it will never again excite an audience. Its success may be regarded as the climax of Addison's good fortune. In 1714 he was secretary to the lords justices who formed the council of regency, from 1714 to 1715 chief secretary to the earl of Sunderland, who was then Lord Lieutenant of Ireland, and in 1715 became one of the commissioners for trade and the colonies. *The Freeholder, or Political Essays*, of which there were 55 numbers (Dec. 23, 1715—June 29, 1716) was entirely Addison's work. Though ell-written, it is unremarkable. It seems unlikely that his marriage to the dowager countess of Warwick (in 1716) was a particularly happy one: his health was beginning to decline and he had a quarrel with the most gifted satirist of the age which made him the subject of what is perhaps the most celebrated satiric "character" in the language. In the summer of 1715, angered by Addison's support of a rival translation of the *Iliad*, Pope sketched the lines on "Atticus," the narcissistic and envious man of letters, "Willing to wound, and yet afraid to strike." A year later he sent Addison a copy of the lines. The details of the quarrel are obscure and it can merely be said that Addison seems to have behaved correctly to Pope for the remainder of his life and that Pope did not publish the "character" until 1735, when it appeared in *An Epistle to Dr. Arbuthnot*. Addison's prose comedy *The Drummer*, which was produced anonymously in 1716, was unsuccessful. In 1717 Addison became secretary of state, an arduous position from which he resigned in the following year. He was involved in a quarrel with Steele in the spring of 1719, defending, in two numbers of *The Old Whig*, the Peerage bill which Sunderland had introduced and Steele had attacked in the *Plebeian*. References became personal and the argument ended bitterly. Two months later, Addison died, on June 17, 1719, at Holland house, London, at the age of 47. He remains an outstanding example of a writer of the highest talents (rather than genius) who achieved celebrity in his own age and significantly influenced the course of English literary history by his application to the problems of his art and a careful study of the taste and the needs of his time.

See also Index references under "Addison, Joseph" in the Index volume.

BIBLIOGRAPHY.—There are collected editions of the *Works* by Thomas Tickell, 4 vol. (1721) and Richard Hurd, 6 vol. (1811, reprinted 1898). *The Miscellaneous Works*, ed. by A. C. Guthkelch, 2 vol. (1914), gives the best text of poems, plays and prose works (English and Latin) other than the periodical essays. The *Letters* were ed. by Walter Graham (1941). Of many reprints of *The Tatler*, the best is that of G. A. Aitken, 4 vol. (1898-99): of the numerous editions of *The Spectator*, that by G. Gregory Smith, 4 vol., "Everyman's Library," nos. 161-167 (1907, 1950) may be recommended. The definitive edition is that by D. F. Bond (1962). A good brief biography is that by W. J. Courthope in the "English Men of Letters Series" (1884): there is a much fuller one by Peter Smithers (1954).

For criticism and comment, see Johnson's *Lives of the Poets*, ed. by Birkbeck Hill, vol. ii, pp. 79-158 (1905); T. B. Macaulay, *Critical and Historical Essays*, vol. ii, pp. 453-522, in "Everyman's Library," no. 266 (1907); A. Beljame, *Le Public et les hommes de lettres . . . 1660-1744* (1881); Eng. trans. *Men of Letters and the English Public in the Eighteenth Century, 1660-1744*, (1948); B. Dobrée, *Essays in Biography, 1680-1726*, pp. 201-345 (1925), *English Literature in the Early Eighteenth Century, 1700-1740* (1959), pp. 102-120 and 612-614, including a bibliography; C. S. Lewis, "Addison," *Essays on the Eighteenth Century presented to David Nichol Smith*, pp. 1-15 (1945).

(J. H. J. A.)

ADDISON, THOMAS (1793-1860), English physician famous for his descriptions of Addison's disease of the suprarenal capsules and of pernicious anemia, was born at Long Benton, Northumberland, in April 1793. In 1837 he became full physician and joint lecturer on medicine to Guy's hospital: London, with Richard Bright. He died at Brighton, Sussex, on June 29, 1860.

Addison gave a preliminary account in 1849 of the two diseases named after him and described them fully in *On the Constitutional and Local Effects of Disease of the Supra-Renal Capsules* (1855). He was the first to correlate a set of disease symptoms with patho-

logical changes in one of the endocrine glands, and it has been well said that "the whole of endocrinology dates from March 15, 1849." He was author with John Morgan of *An Essay on the Operation of Poisonous Agents Upon the Living Body* (1829), the first English book on the subject. Of Bright and Addison's *Elements of the Practice of Medicine*, only the first volume appeared (1839). Addison's original and important writings on pneumonia, tuberculosis and skin diseases mostly appeared in the *Guy's Hospital Reports* and were republished with a prefatory memoir as *A Collection of the Published Writings of . . . T. Addison* (1868). (W. J. B.P.)

ADDISON'S DISEASE (ADRENAL CORTICAL HYPOFUNCTION), a morbid state first described by Thomas Addison in 1855 as being characterized by "anemia, general languor and debility, remarkable feebleness of the heart's action, irritability of the stomach, and a peculiar change of the color of the skin." The cause of the symptoms (to which may be added also signs of emotional instability) is deficiency of adrenal cortical function, this deficiency resulting from fibrocaceous tuberculosis of the adrenal gland or from atrophy of the adrenal cortex of unknown cause (surgical removal of the gland of course also produces the same symptoms). The symptoms are related to the functions of the adrenal cortex, chief among which are regulation of the body's mineral metabolism (sodium, potassium and chloride), regulation of water balance and regulation of organic metabolism (carbohydrate, protein and fat).

Diagnosis of Addison's disease in its severe form is not difficult, but demonstration of limitation of adrenal cortical function requires objective laboratory tests.

Before the development of crystalline cortical steroids for use in replacement therapy, life in the presence of Addison's disease was difficult and precarious. Any condition that resulted in loss of sodium and chloride, as excessive perspiration or a diet with high content of potassium and low sodium, could cause prostration or death. Physical exertion, strain from a surgical operation or administration of an anesthetic alone often was sufficient to precipitate a critical condition.

Moderately effective treatment of Addison's disease began to be possible in 1930, when an extract of the adrenal cortex was made available for patients in a critical condition; this material, however, remained scarce, not always reliable and very expensive. In 1932 Robert Loeb discovered that if the loss of sodium chloride was stopped by daily administration of large amounts of this salt, clinical improvement was often marked and sustained, and in 1937 the unfavorable effect of excess potassium was shown. The availability of desoxycorticosterone after 1937 made it possible to control mineral metabolism, but since desoxycorticosterone tended to increase the concentration of sodium and decrease that of potassium in the blood when large amounts were used, it was necessary to limit the intake of sodium and increase potassium in the diet. Many patients were greatly benefited by this treatment, but few were restored to a state of well-being and some patients died even though the electrolytes in the blood were within normal limits. It became evident that something more than control of mineral metabolism was essential.

Cortisone (*q.v.*) was prepared on a commercial scale in 1948, and in 1949 it was shown that a daily dosage of cortisone and desoxycorticosterone restored strength and a sense of well-being to patients who had Addison's disease. Treatment with cortisone alone is not satisfactory because sodium and chloride are rapidly lost from the body; but when mineral metabolism is controlled with desoxycorticosterone at the same time cortisone is administered, patients are able to resist fatigue and to enjoy an almost normal state of health.

ADDRESS, FORMS OF. Forms of address are the modes in which one person may speak or write to another. They vary from country to country, and in the great majority of cases are the result of custom and courtesy. Occasionally a form of address

is prescribed by official ruling.

This article is divided into the following sections

- I. United States
 1. Spoken Forms of Address
 - Presentations and Introductions
 - Self-Introduction
 - Presentation of a Speaker
 2. Written Forms of Address
 - Business Forms of Address
 - Social Forms of Address
- II. Great Britain
 1. The Royal Family
 2. The Nobility
 3. Other Ranks
- III. Europe
 1. France
 2. Spain
 3. Italy
 4. Germany
- IV. Asia
 1. The Arab World
 2. India and Pakistan

I. UNITED STATES

1. Spoken Forms of Address.—In the United States the forms of address emphasize the position occupied by the person addressed. They are concerned with the correct use of the name or the label designating the position. Thus the president of the United States is addressed as "Mr. President" in speaking to him and as "Sir" when in conversation with him. In speaking of or quoting him he is referred to as "The President." In presenting him for an address he is announced as "The President of the United States of America." When the wife of the president is included in the address the speaker says "The President and Mrs. Surname." The vice-president is addressed and referred to in the same manner as the president.

An ambassador is addressed as "Mr. Ambassador" or "Your Excellency," his wife as "Mrs. Surname." The governors of the states are addressed as "Governor." The mayor of a city is addressed as "Your Honor."

In unofficial or private life the trend is away from the use of titles in verbal forms of address. It is not correct, according to distinguished social usage, to make the professional title of major importance in speaking to a person. This is especially true in academic and business circles. Such titles as "Dean," "Doctor" and "Professor" are gradually being dropped from social usage.

When in a strictly business or professional relationship! the title should be used. A student would address a dean as "Dean Surname"; he would probably address a professor with a doctor's degree as "Dr. Surname." It is generally considered antiquated to say "Professor Surname"; the term "Mr." is preferable if he is without a doctor's degree or administrative position. However, some persons, according to local customs, cling to the recognition by title.

In the medical profession "Doctor Surname" is always used. The title "Reverend" is seldom used verbally in addressing a clergyman; if he holds a doctor of divinity degree frequently he is addressed as "Dr. Surname." If he holds a position of rank in denominational organizations, such as bishop, he is addressed with a title according to the dictates of the church.

In business it is generally considered poor taste to refer to anyone as "the boss," or by his given name, although there is an increasing habit of using given names in informal fellowship. Defiance to a superior should be shown in manner of approach; he is politely addressed as "Sir" or "Mr. Surname." In all of these and similar situations care must be taken not to offend the sense of dignity a person may feel about his position or rank. The speaker must be guided by his own wishes and local custom in choosing the form to use. When in doubt as to the proper title, or as to the use of a title as the proper courtesy, it is always acceptable to address the person as "Mr.," "Mrs." or "Miss."

Presentations and Introductions.—One of the most important forms of address is that used in introductions. An introduction is the form for making easier the beginning of an acquaintance between strangers. It must provide a means of identification

for the persons being introduced. The form used may also indicate the degree of sponsorship the person making the introduction is assuming for the new relationship.

The simple form of "Miss Smith, Miss Jones" or "Mr. Blank. Mr. Doe," spoken with a genial smile or simple gesture, a glance (never point) or voice inflection! is the easiest form and most generally accepted for all chance meetings, whether in public places, among work associates or on informal occasions.

When respect or additional identification is to be shown, as when the sex, age or position is different, the introduction would be more formal, as "Mrs. Blank, may I present (or may I introduce) (or I would like you to meet my friend Miss Smith) (or Mary Smith) my escort Mr. Doe"; the names would then be repeated: "Miss Smith, Mrs. Blank." The name of the person to whom the greater respect is to be shown is spoken first—in this case Mrs. Blank.

In business introductions, the official title of the person of superior rank is used, as "President Brown, may I present (or introduce) Mr. Newcomer? Mr. Newcomer, Mr. Brown." Then give some identification as the reason for Mr. Newcomer's presence, as "Mr. Newcomer is a new employee in my department; we would like to discuss with you . . ."

Self-Introduction.—Frequently a person must introduce himself. In a business interview he should announce himself by giving his name or presenting a business card, give some identification such as place of residence or business connection, and then state the purpose of his visit, as "I am John Stranger, a senior at New York university. I would like to talk with you about . . ." In answering a telephone a person should always identify the telephone by number and himself by position, as "extension 262, secretary to the president speaking."

Presentation of a Speaker.—In presenting a speaker to an audience the person making the introduction should select carefully only such biographical facts about the speaker as have a direct relation to his qualifications to address the audience on the particular subject, or to the occasion for which they are assembled. These remarks should include the name of the person and his present position, and conclude with: "It is my pleasure to present you Mr. Surname (title if preferred)." The person making the introduction should then turn toward the speaker and say "Mr. Surname."

When the speaker is a person of great distinction, such as the president of the United States, no introductory remarks are made about him; the presiding officer simply announces "The President of the United States."

2. Written Forms of Address.—In all written forms of address the proper use of labels, identity and recognition of position are of paramount importance.

Business Forms of Address.—Great care should be taken in giving correct identification by title, name and position in the address at the head of a business letter. The salutation should be carefully worded so as to indicate a recognition of the respect due the person because of his position.

The title "The Honorable" should be used in writing to: governors, cabinet officers, United States ambassadors and ministers; judges, senators, members of the house of representatives, the secretary to the president, assistant secretaries of executive departments and the heads of independent boards and commissions.

The title "Esquire" should be used after the names of: chief clerks and chiefs of bureaus of the executive departments, mayors of towns and cities (when the name is used before the title, as "James Burrows: Esquire, Mayor of . . ."); although considered antiquated by some. "Esquire" may be added after the name of any individual gentleman.

Beginnings of formal letters should be as follows: to the president, "The or Mr. President"; to an ambassador, "Sir"; to a minister, "Sir." To the cabinet officers and the justices of the U.S. supreme court, "Sir" is used for formal salutations. To a senator, informally, the salutation would be "My dear Senator Smith"; to a member of the house of representatives, "My dear Mr. Jones." For the U.S. supreme court the informal form is "My dear Mr. Chief Justice" and "My dear Mr. Justice." For the

supreme court of a state it is also "My dear Mr. Justice"; for the court of appeals of the state, it is "Chief Judge" and "Judge."

Social Forms of Address.—The president of the United States, according to social form, should never receive an engraved invitation to dinner from an individual. When his presence is desired the person inviting him should either call at the White House and ask him to select a date or write to him to that effect.

The most formal invitation should read:

Mr. and Mrs. John Doe
request the honor of
the company of

The American Ambassador to Great Britain and Mrs. Surname
(occasion, time and place)

The envelope addressed to officials should read:

The Title of the Position
and Mrs. Surname

The same form is used for invitations and envelope addresses for all dignitaries. The word "honor" instead of "pleasure" is suggested because of the position of the recipient of the invitation. Between host and guest who are officially equal in rank the word "pleasure" is preferable, but either is correct in all forms of invitations where the name of the guest is to be included.

Acknowledgment of the invitation, either accepting or declining, should be written in the same form as the invitation:

The Governor of the State of Virginia
and Mrs. Surname
regret that they cannot
accept the invitation of
Mr. and Mrs. John Doe
(occasion, time and place)

The place card would read "The President"; his wife's card would read "Mrs. Surname." Similar form for place cards should be used for ambassadors and governors and other ranking dignitaries who are addressed by title of office and not by name. In the case of the American ambassador to Great Britain and his wife, his place card would read "The American Ambassador to Great Britain," his wife's "Mrs. Surname."

The titles "Reverend" and "Honorable" should not precede a surname. The Christian name or title as "Dr." or "Mr." should be used:

The Reverend John Pastor, or the Reverend Dr. Pastor.

Academic degrees and title of position should follow the name: Mr. John Collegian, M.A., or Dr. John Collegian, Director of Admissions.
(E. W. CH.; E. PT.; M. L. MT.)

II. GREAT BRITAIN

Forms of address have evolved over many centuries. They are almost all customary and are therefore variable by changes in the same usage which brought them into being.

1. The Royal Family.—A person speaking to the queen should begin ("Your Majesty" and continue "Ma'am." Letters, headed "To the Queen's Most Excellent Majesty," should begin "Madam" and end "I remain, with the profoundest veneration, Your Majesty's most faithful subject."

The spoken form of address for the queen mother is the same as for the queen. Letters, headed "To her Gracious Majesty Queen Elizabeth the Queen Mother," should begin "Madam" and end "I remain Your Majesty's most faithful servant."

A person speaking to a prince of the royal family should begin "Your Royal Highness" and continue "Sir." Letters, headed "To H.R.H. the Duke of—" (or, if not a duke, "To H.R.H. Prince—"), should begin "Sir" and end "I remain, with the greatest respect, your Royal Highness's most obedient servant." Princesses of the royal family should be addressed *mutatis mutandis* as for princes, "Ma'am" taking the place of "Sir."

Those wishing to address royalty in writing should approach them through the lady or gentleman in waiting.

2. The Nobility.—The peerage in Great Britain has five degrees of rank, namely duke, marquess, earl, viscount and baron. Each of these, their wives and children require a different form of address.

Dukes and duchesses are always dukes and duchesses when addressed either in speech or in writing; the prefixes are "His Grace"

for dukes, "Her Grace" for duchesses; *e.g.*, His Grace The Duke of Norfolk. The spoken form of address is "Your Grace." Letters should begin "My Lord Duke" and end "I have the honour to be, my Lord Duke, Your Grace's obedient servant."

The full formal title is not used in addressing any member of the four succeeding grades of peers either in conversation or in the intimacy of a private letter. On envelopes, on invitations, in and on legal documents or tradesmen's communications and bills, they are addressed as marquesses and marchionesses, earls and countesses, viscounts and viscountesses. In conversation, and in letters beginning "Dear . . .," they must be addressed as "Lord So-and-So" or "Lady So-and-so." In formal correspondence "The Most Honourable" for marquesses and marchionesses and "The Right Honourable" for earls, countesses, viscounts, viscountesses, barons and baronesses may be used.

For a baron, the use of the title is more restricted; it is used only in or on legal documents. On envelopes in nonlegal correspondence, on all invitations or in letters written in the third person, he is styled "Lord." However, a baroness in her own right is always called "Baroness" (*e.g.*, Baroness Ravensdale, Baroness Wentworth) except in speech and in letters beginning "Dear."

In invitations, the full title, except in the case of barons, is always used. In letters written in the third person, the full title is used in the first place, but afterward reference is made by means of the colloquial designation; *e.g.*, "The editor presents his compliments to the Marquess of Piccadilly and will be much pleased if Lord Piccadilly . . ." etc.

In the case of the three higher grades of peers, the eldest son bears a courtesy title; *i.e.*, he is known by one of his father's subsidiary peerages (this, however, does not provide him with a seat in the house of lords).

The eldest son of the eldest son of a duke or of a marquess is also customarily known by one of his grandfather's subsidiary peerages. Never is the bearer of a courtesy title addressed as "The Right Honourable." The younger sons of dukes and marquesses have the prefix "Lord" placed before their Christian names and surnames; the younger sons of earls and all the sons of viscounts and barons have that of "Honourable," generally shortened to "Honble." or "Hon."

The daughters of dukes, marquesses and earls bear the title of "Lady" prefixed to the Christian name and surname. Thus Lady Mary will remain Lady Mary all her life, unless she marries a peer or a younger son whose father has a higher rank than her own father. If she marries a commoner, a knight, a baronet or an Honble., she remains Lady Mary and should always be addressed as such. It is wrong to use only her surname, as "Lady Debrett."

The prefix "Honble." is applied to the unmarried daughters of viscounts and of barons. When a daughter marries, the Christian name is dropped and she becomes The Honble. Mrs. Blank, unless she marries a peer or a man with a courtesy title in the peerage higher than her own. If, for example, she marries a younger son of a duke or a marquess, she becomes Lady (husband's full name), as Lady Edward Jones; she can never become Lady Mary Jones unless her father becomes a marquess or a duke. One great difference between these courtesy titles of Lord and Honourable is that the latter title is not used in conversation, and is never printed on visiting cards.

3. Other Ranks.—The wives of baronets and knights are known as "Lady X," but there is nothing in the wife's title to show to which order her husband belongs. The baronet's name is differentiated in writing because the abbreviation "Bt." or "Bart." (preferably the former) follows it on envelopes; the nine different orders of knighthood have their initial letters placed after the name (K.G., knight of the order of the Garter, etc.), but their "ladies" have no right to use these letters. To specify which lady of the same surname is meant, it has become the practice to use the husband's Christian name between parentheses, as Lady (James) Debrett, although this is contrary to tradition and heraldry.

Knights bachelor are knights who do not belong to any of the

nine specified orders. They are correctly given the abbreviation, "Kt.," or "Kt. Bach." after their names. They may lay claim, if they possess the necessary qualifications, to such letters as M.D., R.N. or M.P.; the M.P. is always added to the name of any member of the house of commons, no matter what his titles may be.

The title of "Right Honourable" (Rt. Hon.; Rt. Honble.) is the prerogative of H.M.'s privy councilors and, as such, is borne by those of them who are not peers. It is used, in the same way as "Honble.," directly in front of the Christian name (*e.g.*, Rt. Hon. R. A. Butler).

Professional designations, such as "Dr." or "Rev.," or naval or military rank precede the prefix of "Honourable," whereas titles of baronetcy and knighthood follow the prefix; *e.g.*, The Rev. The Honble. Jonathan Kenworthy; Colonel The Honble. Edward Wyndham; The Honble. Sir Trevor Bigham, K.B.E., C.B.

Sailors, soldiers and airmen are always addressed by their professional titles—admiral, general, air marshal, captain, colonel, commander, squadron leader and so on, except sublieutenants in the navy, lieutenants and second lieutenants in the army and flying officers in the air force, who in private life remain Thomas Smith, Esq. Captains in the royal navy add R.N. after their names to show that they belong to the senior service.

Judges and doctors may choose titles as a matter of personal preference from equally correct forms of title. This can generally be discovered by noticing how they style themselves on their visiting cards; *e.g.*, "Sir Henry Barnard" or "Mr. Justice Barnard"; or "Dr. Drennan."

Clergymen are spoken to and of as "Mr.," and on invitations and envelopes they are addressed as "The Revd. (or Rev.) George Burke." In conversation a canon is addressed as "Canon X," but on envelopes it must be as "The Revd. Canon X." Archdeacons when written to are "The Venerable," and deans are "The Very Reverend." but they are addressed orally as "Mr. Archdeacon" and "Mr. Dean." Bishops and archbishops on envelopes are respectively "The Rt. Revd." and "His Grace." The archbishop of Armagh, retired archbishops, the bishop of Meath and the primate of Scotland are "Most Revd." In the Roman Catholic Church archbishops are "Most Revd." and "His Grace," while a cardinal is "His Eminence." In formal speech and in formal writing the form of address for bishops is "My Lord." (Archbishops and bishops are never referred to by their surnames until they have retired; *e.g.*, Archbishop Lang or Bishop Gore, but during tenure of office, His Grace the Archbishop of Canterbury,, etc.)

Although men in holy orders may be created knights of various orders (*e.g.*, the Royal Victorian Order and the Order of St. Michael and St. George) they do not receive the accolade and consequently must never be addressed as "Sir"; neither are their wives "Ladies." Peers and baronets in holy orders are, of course, given their titles, as the Revd, the Viscount Hurlingham.

Ambassadors, ministers (in diplomacy): governors general and governors have the words "His Excellency"—often abbreviated to H.E.—prefixed to their official titles. It has also become a matter of courtesy to give the wives of ambassadors, of ministers accredited to foreign courts, and of governors general the same titles and precedence accorded to their husbands. Neither the precedence nor the title applies outside the limits of the country in which the official holds office.

Special sections for women and the title "Dame" exist in the Order of the British Empire and the Royal Victorian Order. "Dame" is followed immediately by the Christian name (*e.g.*, Dame Edith Evans); and the title is not used by peeresses or by ladies whose rank is higher than that of "Dame."

Men who have no titles are termed "Esquire" (commonly shortened to "Esqre." or "Esq.") on their envelopes, and this mode of address is almost universal. This usage has completely swamped the small class of persons who are entitled to be called "Esquire," *e.g.*, landed gentlemen and bearers of coats of arms. Any qualifying letters, such as M.P., C.B., follow after the Esqre. A medical specialist may be addressed "C. Medico, Esqre." or as "Mr. Medico," but a general practitioner should be addressed as

"Dr. J. Smith."

In the City of London and in large provincial towns, aldermen and mayors bear their titles in daily life, in speech and writing; in such cases, they should always be addressed on their envelopes according to their style: "Mr. Sheriff Jones"; "Alderman Brown"; "the Worshipful the Mayor of—". In speaking it is usual to say "Mr. Mayor," except in the case of lords mayor, where "my Lord" takes the place of "Mr."

In no case should "Esqre." end an address beginning "Alderman" or "Councillor." There is no definite rule for the use of civic titles, but when a letter is written to the holder of a municipal office at his official address, the envelope must be addressed to him showing his official capacity. In the case of a letter sent to him as a private citizen, at his home address, the civic title may be dropped.

Ministers and certain other holders of official positions in some of the dominions and crown colonies enjoy the prefix "Honble." during their term of office, and often on their retirement it is bestowed on them for life. Care should be taken, therefore, not to omit the prefix where it has been earned.

The word dowager is a source of perplexity to many people. The real meaning of the word (a woman who receives a dowry) has been lost. In medieval times, such recipients were almost always the widows of men belonging to the baronage or landed gentry, who lived in the "dower house" and remained under the protection of the head of the family. In those days, the widow was designated as dowager to differentiate her from the wife of the head. In modern times, its use is entirely a question of personal choice but the widow should show through her name that she no longer holds the position of wife of the leading member of her husband's family.

If the term dowager is disliked, the widow can use her Christian name instead. In that case the Christian name must precede the title; e.g., May Lady Hemphill. The term dowager can either precede the title or be interpolated between the title and the surname; e.g., the Countess Dowager of Plymouth, or the Dowager Viscountess Hailsham.

BIBLIOGRAPHY.—For social forms of address see Ellen Countess of Desart and Constance Hoster, *Style and Title: a Complete Guide to the Forms of Social Address* (1924). For official forms of address see *Debrett's Peerage, Baronetage, Knighthood and Companionage*; and *Burke's Peerage, Baronetage and Knighthood* (many editions).

III. EUROPE

The varied and elaborate forms of address in Europe are the result of monarchical systems of government, with their hereditary and privileged social groups. They are numerous and their usage is sometimes complicated. Examples of them and the general principles from which they derive are given below for four major European countries.

1. France.—The republican constitution of 1792 abolished nobility as a social institution, but the first empire, the two monarchies (the absolute monarchy of 1815 and the liberal one of 1830), as well as the second empire continued to create titles of nobility. Beginning with the third republic new titles ceased to be bestowed, and officially titles are ignored. If, for instance, a Comte de X is appointed ambassador he is officially addressed as Monsieur de X. It is in fact an offense to give oneself a title.

In private intercourse traditional forms of address continue to be observed. Members of former reigning families are addressed as *Altesse Royale*; other princes as *Altesse Sérénissime*. A letter to one of them should begin with *Monseigneur* and end with *Je prie votre Altesse (R. or S.) d'agréer les assurances de ma très respectueuse considération* ("I beg your highness to receive the assurance of my very respectful consideration").

A letter to a *duc* (and similarly to a *marquis*, a *comte*, a *vicomte* or a *baron*) is addressed to *Monsieur le Duc* and ends with a formula, *Veillez agréer, Monsieur le Duc, les assurances de ma très haute considération* ("please accept . . . the assurance of my very high consideration").

In conversation a prince is addressed as *Monseigneur* and other nobles as *Monsieur*; in the latter case, the title should be used

once but not repeated.

The president of the republic is addressed as *Monsieur le Président de la République*, and a letter to him should end thus: *Veillez agréer, Monsieur le Président de la République, l'hommage de mon profond respect* ("the homage of my deep respect"). When speaking to him the shorter form of *Monsieur le Président* is sufficient.

A cardinal is addressed as *Eminence Révérendissime* and a letter to him begins with *Éminentissime Seigneur*. An archbishop or a bishop is addressed as *Excellence* and, at the beginning of a letter or in speech, as *Monseigneur*.

A minister or an ambassador is addressed as *Excellence*. When writing or speaking to an army officer his rank is mentioned. In speech he is addressed as *Mon Colonel* or *Mon Général* (but *Monsieur le Maréchal*).

A barrister is addressed as *Mon cher Maître*. There are, of course, many variations in forms of address depending on the degree of personal relations between two people. A friend writing to a friend starts his letter with *Mon cher Ami* or *Cher Paul* and ends with *affectueusement votre* or *bien à toi*. A letter addressed to an untitled lady starts with *Madame* or *Chère Madame* and ends generally with a formula *Je vous prie, Madame, d'agréer les assurances de mon profond respect*.

2. Spain.—Officially a monarchy with a regent. Spain preserves its traditional and rather elaborate forms of address. The pretender is addressed as *Su Majestad* and his son as *Su Alteza Real*. A *grande de España* is addressed as *Excelentísimo Serlor*. Nobles who are not grantees are addressed as *Ilustrísimo Señor el Conde* (or *Vizconde* or *Barón*).

In writing both forms are abbreviated (*Excmo.* or *Ilmo.*). Every man who had been awarded the grand cross of a Spanish order is also addressed as *Excmo.*, and every knight commander as *Ilmo.* Cardinals are addressed *Vuestra Eminencia* (*V.E.* in the text of a letter), ministers, ambassadors and bishops *Vuestra Excelencia* (*V.E.*).

An untitled gentleman (*caballero*) writing to another one addresses his letter to *Señor Don*—and starts with *Muy Señor Mio*. In the text he addresses him as *V.S. (Vuestra Señoría)* and ends his letter thus: *De Vd. atto. y s.s., q.e.s.m. (De usted atento y seguro servidor, que estrecha su mano, "your attentive and constant servant, who shakes your hand")*. Writing to a lady the last four initials would be *q.b.s.p. (que besa sus pies, "who kisses your feet")*.

3. Italy.—There is less formality in Italy than in Spain in modes of address, but because of different historical traditions the Italian modes vary between the south and the north. The old titles were not abolished by the republican constitution of 1948. The pretender is styled by his supporters as *Sua Maestà* and members of the former reigning family are addressed with the qualification of *Altezza Reale*.

A letter to a nobleman should be simply addressed to *Il Principe* (or *Marchese, Conte* or *Barone*), followed by his full name. A letter to him should begin with *Gentilissimo Marchese* (never *Signor Marchese*, a form used by servants). The president of the republic, a minister, an ambassador or a bishop is addressed as *Eccellenza* (a cardinal as *Eminenza*). Writing to a prominent professor a usual form is *Chiarissimo Professore*; to a famous writer in Naples the form *Illustre* would be used, while in Piedmont *Egregio* would be courteous enough. A letter never begins with the surname of the addressee, but always with his position or degree if he has any, the last-named being always abbreviated on the envelope (*Chiar^{mo} Sr. Prof., Gent^{mo} Sig. Dott.*, etc.). At the end of a letter the commonest forms are. *Con i più vivi saluti ed ossequi* ("with the most sincere wishes and respect"; formal, to a superior) or *Con i migliori saluti ed ossequi* ("with the best . . ."; formal, to an equal); or simply *Distinti saluti* ("respectfully yours," a business letter). To a lady, the form *Gentile Signora* is always correct, the ending being as to a gentleman but a degree more formal.

4. Germany.—The German republican constitution of 1920 did not abolish titles of nobility but stipulated that they were to be an integral part of the surname. The constitution of the German

Federal Republic of 1949 confirmed that. In private intercourse the head of the Hohenzollern house would expect to be addressed as *Kaiserliche Hoheit* ("Imperial Highness"), while the head of a former reigning house in Bavaria, Saxony or Württemberg claims the qualification of *Königliche Hoheit* ("Royal Highness"). The latter form is used when addressing a former reigning grand duke. The heads of houses which were formerly principalities of the Holy Roman empire but which were later mediatized (see *MEDIATIZATION*) are entitled to the style *Durchlaucht* ("Serene Highness") and the heads of mediatized countships to that of *Erlaucht* ("Illustrious Highness"). A count (*Graf*) or a baron (*Freiherr*) is addressed simply by his name (i.e., Karl Gf. von— or Georg Frh. von—).

A letter to a *Fürst* (prince) begins *Euer Durchlaucht* ("Your Serene Highness") and ends *Mit vorzüglicher Hochachtung, bin ich Euer Durchlaucht sehr ergebener* ("Yours respectfully, I am very devoted to your serene highness").

A letter to a member of the lesser nobility begins *Hochverehrter* (or *Sehr verehrter*, or *Sehr geehrter*) (all meaning "Honourable") *Graf Arnim* (von is dropped in this case), and ends as in the previous case, but without such qualification as *Euer Durchlaucht*. In a letter to a member of a liberal profession the beginning would be the same but the title would be replaced by the position or degree (examples: *Hochverehrter Herr Professor* or *Sehr geehrter Herr Doktor*).

The letter would end differently, according to the position of the addressee in relation to that of the writer, but *Mit vorzüglicher Hochachtung* ("Yours respectfully") is always correct. A slightly less formal ending would be *Ihr ganz* (or *sehr*, or *stets*) *ergebener* ("Yours completely, or very, or always devoted").

A letter to a lady generally begins *Sehr verehrte Frau* (adding the title, position or degree) or *Gnädige Frau* ("Dear Madam"; followed by surname). In both cases it would end *Mit vorzüglicher Hochachtung, Ihr sehr ergebener*.

IV. ASIA

1. The Arab World.— In the Arab countries which until World War I had been part of the Ottoman empire, the old Turkish titles of pasha, bey and effendi were abolished at different dates after World War II. (In Turkey they were suppressed in 1934.) An Arab king (malik) is addressed as *Salzib el-Jalalat* ("Majesty"), a royal prince as *Salzib el-Semon el-Malaki* ("Royal Highness"), a prince (emir) not of royal blood as *Salzib el-Semon* ("Highness"). A prime minister (*rais el-wuzara*) is addressed as *Siadat el-Rais* ("His Excellency the Premier").

2. India and Pakistan.— The Indian and Pakistani princes continue to enjoy their titles in courtesy. They are usually known as His Highness (H.H.). The great division is between Hindus and Moslems. The Hindus had the following: maharaja bahadur (bahadur means "warrior"), maharaja, raja bahadur, raja; raj bahadur, rai sahib and rai. The Moslems had the following: nizam, nawab bahadur, nawab, khan bahadur, khan sahib and khan. Maharani is the female equivalent of maharaja and begum the female equivalent of nawab. The usage in address in writing and speech follows that used in addressing European royalty.

ADE, GEORGE (1866–1944), U.S. author, playwright and humorist, whose *Fables in Slang* summarized the kind of wisdom accumulated by the country boy in the city, was born in Kentland, Ind., Feb. 9, 1866, and graduated from Purdue university, Lafayette, Ind. For ten years (1890–1900), he was on the staff of the *Chicago Record*, and his editorial page column, "Stories of the Streets and of the Town," illustrated by his friend John T. McCutcheon won wide acclaim. Characters introduced in his column became the subjects of his earlier hooks. *Artie* (1896), *Pink Marsh* (1897), and *Doc Horne* (1899). His greatest recognition came with the publication of *Fables in Slang* (1899), which became a national best seller, and was followed by a weekly fable syndicated to newspapers, and by 11 other books of fables. The fables actually contained only a little slang being, rather, examples of the vernacular. The fables had such flippant morals attached as, "Early to bed and early to rise, and you'll meet very few prominent people," and gave readers a chance to laugh at themselves.

In 1902 Ade's light opera, *The Sultan of Sulu*, was produced, and had a long run in New York. Then he did successful comedies, among them *The County Chairman* (produced 1903) and *The College Widow* (1904). Even before three of Ade's plays ran simultaneously in New York, he was recognized as one of the most successful playwrights of his time. His books and plays brought him wealth, and he established an estate of 2,000 ac. near Brook, Ind., which was his home for the rest of his life. He wrote many motion-picture scripts, and late in life during the prohibition era wrote what many called one of his most amusing books, *The Old Time Saloon* (1931). He died at Brook, May 16, 1944.

BIBLIOGRAPHY.—Fred C. Kelly, *George Ade: Warmhearted Satirist* (1947); Dorothy Russo, *Bibliography of George Ade* (1947); *The Permanent Ade*, ed. by Fred C. Kelly (1947) is an anthology of Ade's writings. (F. C. K.)

ADELA (1062?–1137), daughter of William I (*q.v.*) of England and mother of King Stephen (*q.v.*), whose claim to the English throne was inherited through her, was born about 1062. In 1080 she married Stephen count of Meaux and Brie, son and heir of Theobald count of Blois and Chartres, who died in 1090. Adela shared actively in the government of her husband Count Stephen, ruling on his behalf during his absence on crusade from 1095 to 1099, and again in 1101 when he went back to the Holy Land. After his death at the siege of Rames (mod. Ramle), her regency continued, since her sons were minors, until 1109 when she had her second son Theobald made count of Blois, setting aside his elder brother as unfit to rule. After handing over the government to Theobald, Adela retired to the Cluniac priory of Marcigny-sur-Loire, in Burgundy, but this scarcely lessened her participation in public life, especially ecclesiastical politics. Before her retirement she had formed close friendships with St. Yves de Chartres and St. Anselm of Canterbury and given hospitality to Pope Paschal II. In disputes between lay rulers and reforming church leaders, Adela sometimes acted as mediator, but it is clear that the ruling passion of this forceful woman was the preservation and the strengthening of the great fief of Blois and Chartres: to this end she called in French aid in 1108, while in 1117 she brought about an alliance between Blois and Henry I of England against France. She died in 1137. (G. W. S. B.)

ADELAER (ADELER [Norwegian, "eagle"]; properly **CORT SIVERTSEN**) (1622–1675), Norwegian sailor, distinguished in Venetian and in Danish naval history, was born on Dec. 16, 1622, at Brevik. He entered the Dutch navy in 1639 and served under Martin van Tromp but moved into Venetian service in 1642 where he was known as Curzio Suffrido Adelborst (the last name being Dutch for "naval cadet"). He soon distinguished himself and in 1650 was sent to patrol the Dardanelles. On May 16, 1654, his Venetian squadron took part in the battle of the Dardanelles, when his ship alone sank 15 Turkish galleys, and on the following day he compelled the surrender of the Turks at Tenedos. In 1659 he was made a knight of St. Mark and given a pension for life (heritable to the first three generations of his descendants) and in 1660 he became lieutenant-admiral of the Venetian fleet. Two years later, however, he returned to Denmark as admiral of the Danish fleet, receiving at the same time various honours and revenues from Frederick III. His most important work was the refitting and reorganization of the fleet. In 1665 he received an invitation to command the Dutch fleet against England, but this he refused. He was ennobled by Frederick III in 1666 and was sent to India to negotiate with the court of Coromandel three years later (1669–70). Under Christian V he was appointed to command the Danish fleet against Sweden but died before the expedition, at Copenhagen on Nov. 5, 1675.

See P. Holck, *Cort Adeler* (1934).

ADELAIDE (ADELHEID) (931–999), queen of Italy and empress, was the daughter of Rudolf II, king of Burgundy, and Bertha, daughter of Burchard, duke of Swabia (d. 926).

Rudolf II had for a short time been king of Italy, and when he died, in 937, Hugh of Arles, who replaced him there, came north and married Bertha while betrothing Adelaide to his young son and heir Lothair. They married in 947, but Lothair died three years later, whereupon Berengar, margrave of Ivrea, took the Italian

crown. Adelaide fell into Berengar's hands at Como in April 951 and was maltreated, stripped of her treasure and imprisoned at Garda. Then the German king Otto I came to the aid of Berengar's opponents. With a large German host, Otto marched into Lombardy in Sept. 951, seized Pavia, declared himself king and married Adelaide—who shortly before his arrival had escaped from custody.

Adelaide's entry into the Ottonian family circle led to a crisis, the rising of Otto's son by his first marriage, Liudolf, and his son-in-law Conrad the Red. It was suppressed with great difficulty, but from then onward Adelaide could enjoy her husband's almost unbroken success and in 962 she was crowned empress with him in Rome by Pope John XII. Of their children only Mathilda (d. 999), who became abbess of Quedlinburg, and Otto, who succeeded his father, lived. After Otto I's death (973) Adelaide's position at court deteriorated and her influence was challenged during the reigns of both her son Otto II (973–983) and her grandson Otto III (983–1002). During the latter's minority she shared responsibility and power with Theophano, her Byzantine daughter-in-law, and together they defended Otto III's rights and the integrity of his inheritance against the claims of his kinsmen Henry duke of Bavaria and the Carolingian king of France, Lothair. In 985, however, Adelaide had to give way to Theophano in Germany and went to Lombardy, where her authority always counted for something. After Theophano's death in 991 the old empress ruled—none too successfully—in Otto III's name until 994, when the young king assumed his majority. A small group of prelates headed by archbishop Williges of Mainz were her most influential advisers. After 995 she devoted herself mainly to enlarging and embellishing the monastery that she had founded at Selz in Alsace, where she chose to be buried. The monks fostered her memory, miracles were reported at her tomb and a cult developed. She was canonized by Pope Urban II, probably in 1097.

Adelaide brought to the Ottonian dynasty a rich inheritance, connections in Burgundy and Italy and cultural traditions which are new to it and helped to change its character. It became less Saxon and through her also its religious interests were drawn toward the leaders of Cluniac monasticism, St. Maiolus and St. Odilo.

BIBLIOGRAPHY.—Odilo of Cluny's biography of Adelaide, *Epitaphium Adalheidae imperatricis*, is ed., with the book of her miracles added to it at Selz in the middle of the 11th century, by G. H. Pertz in *Monumenta Germaniae historica: Scriptorum tomus iv* (1841). See further M. Kirchner, *Die deutschen Kaiserinnen . . .* (1910), with bibliography; R. Holtzmann, *Geschichte der sächsischen Kaiserzeit, 900–1024* (1943); G. Fasoli, *I Re d'Italia, 888–962* (1949). (K. J. L.)

ADELAIDE, the capital city and chief port of South Australia, named after Queen Adelaide, consort of King William IV, is in the county to which it gives its name. It is situated near the middle of the curving, eastern side of Gulf St. Vincent. Pop. of the city proper (1954) 30,102; including suburbs 483,508, (1960 est.) 584,900 (on this basis Adelaide is the fourth largest city in Australia). Total area 161 sq.mi. A fairly regular annual rainfall of about 21 in. falls largely between April and November. Temperatures are high in summer (January mean 73.4° F. with fairly frequent hot spells; highest recorded temperature in the shade 117.7° F.); but it is cool and bracing in winter (June mean 53.6° F. with occasional frosts). Land and sea breezes along the coast complete a typical Mediterranean climate.

As a result of the genius of Charles Sturt (*q.v.*) and, later, of William Light, the first surveyor general of the colony, a site was selected in 1836 upon fertile plains which swept up gently from the coast to a curving line of hills about 9 mi. inland. Light chose, not without opposition, a spot on rising ground, close to the Torrens river, the chief early source of water supply. Within eight miles lay the only considerable sheltered waterway along the coast, known as the Port Adelaide river, in reality a tidal inlet. This water—shallow and muddy but improved by dredging—became the site of Adelaide's port until the construction of the outer harbour provided a more accessible anchorage for larger vessels near the mouth of the inlet and facing the open gulf. Easy movement was possible also through mountain gaps to the Murray lowlands to the east and southeast and Adelaide thus soon became an im-

AUTHENTICATED NEWS

STATUE OF WILLIAM LIGHT OVERLOOKING ADELAIDE FROM MONTEFIORE HILL

portant centre for lines of movement by land and sea. The fertility of the plains (deep alluvium washed down from the torrent-scarred hills), the presence of minerals in the hills (though in relatively small quantities) and the climate formed the bases of the city's prosperity.

After a somewhat checkered early history, Adelaide, by virtue of its commanding situation in relation to all parts of the state, steadily grew until by 1959 it had more than 61% of the total population of the state. Its commercially central position, good communications and ready supplies of raw materials, including brown and imported coal, aided the growth of a number of flourishing industries—the manufacture of motor bodies, farm implements and machinery, woollens, cottons, furniture, etc. To Adelaide gravitate the products of the agricultural and pastoral areas; it receives the bulk of the products—wool, wheat, fruit, meat, wines and timber—of the lower Murray valley, which has no river-mouth port. The trade of Port Adelaide represented about 76% of the bverseas trade of all South Australian ports during 1958–59. The city's main airport, West Beach, 4½ mi. S.W., provides services to the other chief Australian cities.

Surrounding the city of Adelaide and completely separating it from the suburbs which spread beyond are the park lands of 1,710 ac. which have been reserved for recreation. In the course of planning, Light made the best use of the geographical advantages of the site selected. The city is laid out in two-distinct sections, one to the south being square in form and the other, to the north, divided into rectangular blocks. The southern section, which has developed into the principal business area, is completely separated from the northern residential section by the Torrens river and extensive reserves and gardens. The park lands and reserves form the great playground and "lungs" of the city, which claims to have no slums. The climate and the presence of the Torrens, now artificially dammed to form a lake, lend Adelaide the peculiar charm and beauty of diversified vegetation—northwestern European, southern European and subtropical.

Adelaide's main thoroughfare, King William street, runs north and south. It is crossed, south of the Torrens, by North terrace, a tree-lined boulevard with gardens and many fine buildings, including Parliament house, Government house, the public library, art gallery and university. There are also an Anglican and a Roman Catholic cathedral. North of the Torrens, in a beautiful setting, is the Adelaide Oval, where many cricket test matches have been played. The Adelaide Festival of Arts, held in 1960, was the first international festival of its kind in the commonwealth of Australia. Adelaide was the birthplace of municipal government in Australasia and gained a lord mayoralty in 1919. In 1956 construction work began on a new town, Elizabeth (*q.v.*), as a satellite of Adelaide, 16 mi. to the north of the city. (W. C. D. V.)

ADELARD OF BATH (fl. early 12th century), English scholastic philosopher who was one of the first interpreters to western Europe of Arabic scientific knowledge. Adelard studied and taught

in France and traveled in Italy, in Cilicia, in Syria, in Palestine and perhaps also in Spain (c. 1110–25) before returning to Bath and becoming a teacher of the future king Henry II. In his platonizing dialogue *De eodem et diverso*, philosophy and the liberal arts, embodying permanent values (idem, "the constant"), are made to hold their ground against love of the diverse (*philocosmia*), but his atomism and his attempt to reconcile the reality of universals with that of the individual distinguish him from other Platonists. His *Quaestiones naturales* (76 discussions covering human nature, meteorology, astronomy, botany and zoology) are based on Arabic science, and his translation of an Arabic version of Euclid's *Elements* was to be for centuries the west's chief textbook for geometry. His other writings include works on the abacus, on the astrolabe and on hawking and a translation of Maslama's edition of al-Khwarizmi's astronomical tables.

There are editions of *De eodem et diverso* by H. Willner (1903); of the *Quaestiones* by M. Muller (1934; see also Eng. trans. by H. Gollancz with Berechiah ben Natronai's Hebrew adaptation, *Dodi venechdi*, 1920); of the *Regulae abaci* by B. Boncompagni, *Bullettino di bibliografia e di storia delle scienze*, vol. xiv (1881); of the work on hawking, *De cura accipitrum*, by A. E. H. Swaen (1937).

(L. M.-Po)

ADELUNG, JOHANN CHRISTOPH (1732–1806), German grammarian and philologist whose grammars, dictionary and various works on style helped to rectify the orthography, refine the idiom and fix the standard of the German language. Born at Spantekow, in Pomerania, on Aug. 8, 1732, he was educated at the University of Halle. In 1787 he was made principal librarian to the elector of Saxony at Dresden, where he lived until his death on Sept. 10, 1806.

His German dictionary—*Grammatisch-kritisches Wörterbuch der hochdeutschen Mundart* (1774–86)—bears witness to his intimate knowledge of the history of the different dialects on which modern German is based. No man before Jacob Grimm (*q.v.*) did so much for the language of Germany. At the time of his death Adelung was engaged on a work on general philology, entitled *Mithridates, oder allgemeine Sprachkunde*. The first volume on Asian languages was published immediately after his death; the other two were issued under the superintendence of Johann Severin Vater (1771–1826).

ADEN, a British colony and port in southern Arabia. The port lies about 100 mi. E. of the Straits of Bab al Mandeb, the entrance to the Red sea. The colony includes the island of Perim (*q.v.*), at the southern end of the Red sea, and the five Kuria Muria islands (*q.v.*) off the Dhufar coast of Oman, which are controlled on behalf of the governor by the British resident in the Persian gulf. The island of Kamaran (pop. [1959 est.] 2,500; area 22 sq.mi.) about 100 mi. N. of Perim, is administered by the governor of Aden but does not form part of the colony. The climate is tropical, hot and humid from April to October and cooler during the northeast monsoon. Rainfall is low and in some years there is none. Aden itself consists of two peninsulas of volcanic rock rising to more than 1,000 ft. The eastern peninsula, on which is situated the town and port of Aden, is joined to the western peninsula, known as Little Aden, by a flat, sandy foreshore. The population of the colony, which is about 90% Muslim, in 1955 was 138,441 of which 55,791 were Arabs, 48,088 Yemenis, 15,817 Indians, 10,611 Somalis, 4,484 Europeans, 831 Jews and 2,819 others. The area of Aden is 75 sq.mi., that of Perim 16 sq.mi., and of the Kuria Muria islands 28 sq.mi.

The old town of Aden (formerly Aden Camp), known as Crater, is built in the crater of an extinct volcano in the northeast of the peninsula, surrounded on three sides by precipitous crags. The old harbour lay off the town, but the new port is on the north-western side of the peninsula. In a rocky gorge above the town are the ancient Taweela rainwater storage tanks, which can hold about 10,000,000 gal. of water. To the northwest is the suburb of Ma'ala where dhows have been built for centuries; the Somali inhabitants, who are concentrated there, largely run the harbour launches; wharves, warehouses, etc., have been built at Ma'ala on land reclaimed from the sea. To the west is Steamer point, urban section of Tawahi, with the consulates and the principal banks and shipping offices. To the north is Khormaksar, another suburb,

where Aden civil airport is located (1952), about seven miles from the port. Further north is the town of Sheikh Othman, known for its cotton-dyeing industry, producing handprinted bedspreads and headcloths, and for its gardens and camel caravans. Artesian wells there and at Bir Nasr supply drinking water to Aden. Aden possesses a technical institute, a teachers' training centre, secondary and intermediate schools for boys and primary schools for boys and girls. Some students are given higher education overseas. There is a general government hospital and other medical services. There are no railways; land travel is by road. Internal airlines are operated as well as international services.

Aden is a free port and an important oil bunkering point. More than 30 berths (including oil berths) accommodate vessels of various sizes, and there are also four floating docks. The colony is the centre of a large transshipment and distributive centre for the surrounding areas of Somaliland, Ethiopia, Eritrea, Yemen, Saudi Arabia and the African coast; the chief goods passing through are skins, hides, coffee, cotton, piece goods, cotton yarns, dates, grain, pulse and flour, sugar, tea, spices, oils, tobacco, gum, shells and salt. There is considerable trade between the colony and the protectorate. Main occupations are those related to the bunkering of ships and handling of cargoes; others include the crushing of oil-seeds; the re-export of hides, skins, coffee, gum, incense and oyster shells; the making of soap, aluminum utensils, printed cotton cloth and mineral waters; and inshore fishing.

At Little Aden a large oil refinery, with a refining capacity for 5,000,000 tons of crude oil a year, started operating in 1954, as did an oil harbour specially constructed to accommodate four 32,000-ton tankers at a time. A new 20-mi. road was made across the desert between Little Aden and Aden and a new town was built to accommodate workers at the refinery.

History and Administration.—Aden early became an important entrepôt of trade between Europe and the east. Spices, incense, etc., were brought to Aden and other south Arabian ports through the hinterland kingdoms of Saba (Sheba), Ma'in, Qataban and Himyar until their high tolls made sea traffic cheaper and led to a decline. Produce from India, China, Indonesia and Africa was transhipped for carriage by camel caravans up to Egypt, Syria and beyond until about the time of the Roman occupation of Egypt, when adventurous traders developed more direct and less taxed routes via the Nile valley, Red sea and Indian ocean, water transport replacing caravans where possible. Ancient ruined cities, with elaborate dams and irrigation works, and fortifications along these routes both in Aden protectorate and in the Yemen indicate the importance and wealth of the traffic during the 1st millennium B.C. *Periplus* of the Erythrean Sea, a Greek geographical work written about A.D. 50, describes the sea traffic which had by then replaced it, giving detailed descriptions of the ports and the goods passing through them; Aden is called Eudaemon Arabia.

In 1513 Aden was unsuccessfully attacked by the Portuguese under Alphonso d'Albuquerque but fell into the hands of the Turks in 1538. A century later the Turks were forced to relinquish it when the peninsula was captured by the Yemen Arabs from the north. In 1728 the sultan of Lahej revolted against the Imam of Yemen and seized Aden, which he included in his own sultanate. It was captured by the British East India company in 1839, after an Indian ship was plundered off the coast, and annexed to British India. This was followed by the establishment of a coaling station and a renewal of trade, which developed enormously after the opening of the Suez canal in 1869. Aden again became the important port of call on the shipping route to the east and, from having been reduced to a fishing village before 1839, it rose once more as a thriving town and was made a free port. The Island of Perim was occupied by the British in 1857, Kamaran was taken from Turkey in 1915, Little Aden was obtained by purchase in 1868, and the coastal strip between the two peninsulas was acquired in two purchases, in 1882 and 1888.

In April 1937 Aden ceased to be administered from India and became a crown colony, and the rupee was superseded by the East African shilling in 1951. The colony is administered by a governor assisted by an executive council and a legislative council (inaugurated in 1947 and expanded in 1955 when the electoral principle

was first introduced). At the end of 1957 a new constitution, which became effective in 1959, was published and provided for a legislative council of an elected majority and a ministerial system. Aden town is controlled by a municipality and the port is administered by the Aden Port trust.

(W. C. Bu.)

ADENA MOUND, a large, conical-shaped earthen burial mound just northwest of the city of Chillicothe, O., the type site of the North American Adena culture and period. It was probably built in late Adena times, about A.D. 400, and was excavated in 1901 by William C. Mills. The mound, as well as the cultural remains and the culture to which they belong, takes its name from the estate on which it stood.

The mound at the time of exploration was 26 ft. in height, with a basal circumference of 445 ft. It had been constructed in two different stages. The first stage represents the original or primary structure, which was 20 ft. high and 90 ft. in diameter and composed of a dark sandy loam soil. The second stage shows construction over and slightly to the north of the primary mound with a light-coloured soil secured from the surrounding surface.

The disposition of the dead in the first stage was different from that of the second. The remains, wrapped in coarsely woven textile or bark, were placed in rectangular log tombs, roofed with logs and poles. Burials made in the secondary stage were simple extended inhumations placed on bark and covered with bark.

One of the finest and most unusual objects discovered during the exploration of the mound is the Adena pipe, a stone pipe carved in the form of a human figure, found near the left hand of one of 23 burials. Standing eight inches in height, it is basically tubular in type with the figure of a dwarf carved in relief about the tube. The smoking chamber, drilled in the tube, extends nearly the entire length of the body, tapering from an opening between the feet to a small drilled perforation in the block-end mouthpiece at the top of the head. See also NORTH AMERICA: *Prehistory and Archaeology*.

(R. S. BA.)

ADENAUER, KONRAD (1876–), the first chancellor of the Federal Republic of Germany, the "grand old man" of Germany whose name is inseparably connected with the revival and rearmament of his country but who nevertheless, as a Rhineland and as a Catholic, stands outside the nationalist and militarist tradition of German statesmen, was born in Cologne on Jan. 5, 1876. Having studied law at Freiburg im Breisgau, at Munich and at Bonn (not because of any special aptitude for it but because a good degree in jurisprudence and a doctorate of law were the accepted qualifications for the civil service in state, province or city), he had at first no more ambition than to be a leading citizen of his own town. Elected to the city council in 1906, he rose to be chief burgomaster (*Oberbürgermeister*) of Cologne from 1917 to 1933. In this post he was virtually master of all the city's affairs, and his regime, no less than that of other chief burgomasters, tended to be dictatorial in its methods and grandiose in its effects. He made Cologne an extensive, beautiful and flourishing city, refounded the university on a lordly scale and created new harbour facilities, a green belt, sports grounds and exhibition sites.

On the collapse of the German monarchy in 1918, Adenauer was in favour of an independent Rhenish republic within a German federal state, but all such schemes were discredited when the French tried to detach the Rhineland from Germany altogether. Having been elected in 1917 to the Prussian *Landtag*, of which he was speaker from 1928 to 1933, Adenauer came to play a vital role in Prussian affairs, though it received little public recognition. Never conspicuous in the affairs of the Weimar republic as a whole, he nevertheless lost all his offices under the Hitler regime, during which he was twice arrested (1934 and 1944), though he was spared the worst consequences of such imprisonment. After the collapse of Nazi Germany in 1945, he was restored as chief burgomaster of Cologne by the British occupation authority only to be dismissed soon afterward as too obstinate.

Adenauer's chance came in 1947, when he became the leader of the newly founded Christian Democratic Union (C.D.U.), which was a compromise between the old Catholic Centre party and the

middle-class Protestant traditions. Germany's Catholic party thus became a Christian one. Adenauer exercised a powerful influence in the so-called parliamentary council set up in 1948 to make a state out of western Germany and to design its constitution. He was wholeheartedly behind the foundation of the federal republic and, when the course of international politics made the division of Germany an unalterable fact, he put the development of the federal republic's links with the west before the reunification of Germany. By his tactics he was in fact able to succeed in a policy based on understanding with the west. He would indeed have been willing to conform to the French and U.S. project under which the federal government would have been given only the most slender competence, and it was only through the resistance of his Social Democratic opponent Kurt Schumacher that this project was discarded in favour of the constitution which was to give Adenauer his great and often-criticized powers.

In the elections of 1949 to the first federal parliament, Adenauer's party with 139 seats out of 402, had only a slight lead over the Social Democrats with 131. Adenauer however outmaneuvered the opposition and, thanks to his party's coalition with the Liberals (*Freie Demokratische Partei*), was elected chancellor by a majority of one in the *Bundestag*. Resignedly, he gave his assent to the occupation statute which considerably restricted the federal administration's authority, as he believed that the world conflict between east and west must, sooner or later, force a recognition of the federal republic as a full partner in the western defensive alliance. The new administration's first declaration of policy made clear that Adenauer was determined to base the future of the republic on close ties with the United States and that, in the European sphere, he would endeavour to win the friendship of France. The entry of the federal republic into the Council of Europe and the foundation of the European Economic Community (E.E.C.) deepened Germany's involvement with western Europe. Adenauer was the guiding spirit of the E.E.C., that is, of the "little Europe" which, on the map, has much the same boundaries as the empire of Charlemagne.

A turning point in German history was reached in 1950 when Adenauer as chancellor gave his support to western plans for the rearmament of federal Germany. He intended this rearmament to be a step toward the creation of an international western European army, a military force for the European community, but this plan foundered on the opposition of the French national assembly. The rearmament of Germany, however, was achieved in 1954 within the framework of the North Atlantic Treaty organization. Meanwhile, in 1953, in the elections to the second *Bundestag*, the C.D.U. had won 243 seats out of 487. Elections to the third *Bundestag*, in 1957, gave an absolute majority to Adenauer's party (270 seats out of 497) — a result that no other German party had ever achieved in a free election. The C.D.U. lost this majority, however, in the elections of 1961, when it obtained 242 seats out of 499. Nevertheless Adenauer, with some support from the Free Democrats, was re-elected chancellor on Nov. 7. by 258 votes against 206.

As a statesman, Adenauer was characterized by determination to govern and by readiness to assume, whenever necessary, the sole responsibility for decisions. Foreign policy was his overriding interest, in which his aim was the consolidation of the west against the Soviet threat. In domestic affairs, his main concern was to ensure victory at the polls in order to remain in control of foreign policy. Not overscrupulous in his methods, he was a gifted political tactician with a talent for ingratiating himself with parties and people. He swayed the masses by the direct, simple quality of his speech and thought.

(M. FR.)

ADENET LE ROI (c. 1240–c. 1300; called by himself ROI ADAM, LI ROIS ADENÉS and officially styled ADAN LE MENESTREL, ADAM REX MENESTRALLUS), French poet and musician. The interest of Adenet for the literary historian lies not in his poetry, which is pallid and unoriginal, but in the detailed documentary evidence for his career as a household minstrel. He received his training in the court of Henry III, duke of Brabant; after his patron's death in 1261, his fortunes wavered, owing to dynastic rivalries and the growth of Flemish literature at the court of

Louvain, until in 1268 or 1269 he entered the service of Guy of Danipierre, heir to the county of Flanders, as principal minstrel (whence his title of *roi*, *i.e.*, king of minstrels). Adenet accompanied Guy in 1270-71 on the Tunisian crusade led by St. Louis IX and Charles of Anjou; Guy returned by way of Sicily and Italy and Adenet's poems contain many precise references to parts of this itinerary. Of Adenet's written work there are preserved three *chansons de geste*: *Buevon de Connarchis*, *Les Enfances Ogier* and *Berte aus grans pie's*; and a romance in octosyllabic couplets, *Cléomadès*; this last work was written at the suggestion of Marie de Brabant, daughter of his old patron and queen to Philip the Bold. Adenet was still alive in 1297 when Edward I visited Ghent.

BIBLIOGRAPHY.—A. Henry (ed.), *Les Oeuvres d'Adenet le Roi* (1951-) contains much useful background information, as well as a critical edition of the works: vol. i, *Biographie d'Adenet, La tradition manuscrite* (1951), vol. ii, *Buevon de Connarchis* (1953), vol. iii, *Les Enfances Ogier* (1956). *Berte* can be read in the editions of A. Scheler (1874) and U. T. Holmes, Jr. (1946) and *Cléomadès* in the edition of A. van Hasselt (1865-66). See also R. Bossuat, *Manuel bibliographique de la littérature française du moyen âge*, no. 254-264, 268-269, 598-614, 849-851, 1095-98 (1951) and *Supplement*, no. 6059-63, 6067, 6213-19 (1955) and the reviews of A. Henry's vol. i and ii listed in his vol. iii, pp. 369-370. (C. A. R.N.)

ADENINE: see NUCLEIC ACIDS; PURINES.

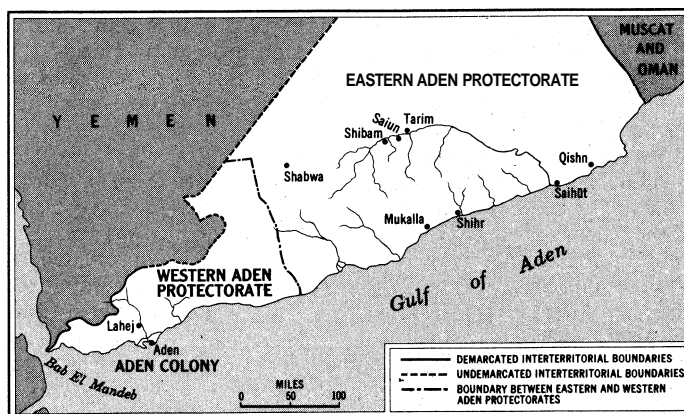

ADENOIDS or ADENOID is an enlarged pharyngeal tonsil, which is a pad of lymphoid tissue attached to the upper and posterior walls of the upper or nasopharynx (the part of the throat that lies above the soft palate). The nasal passages open into the front of the nasopharynx, and on the sides are the openings of the Eustachian tubes leading to the middle ear, the air space behind the eardrum. The pharyngeal tonsil is a part of a ring of lymphoid tissue known as Waldeyer's ring that encircles the throat or pharynx.

The adenoid is made up of rounded, pale-staining germinal centres surrounded by mature lymphocytes. The surface is formed into ridges or clefts but no branching crypts. The surface layer consists of ciliated epithelium similar to that in the nose and lower respiratory passages and is covered by a thin film of mucus. The cilia, which are microscopic hairlike projections from the surface cells, move constantly in a wavelike manner and propel the blanket of mucus from the nasal passages down to the pharynx proper. From that point the mucus is caught up by the swallowing action of the pharyngeal muscles and sent down to the stomach. The adenoid also contains glands that secrete mucus to replenish the surface film. The fibrous tissue that surrounds and forms the framework of the adenoid does not form a distinct capsule.

The function of the adenoid as well as that of the other lymphoid tissue of Waldeyer's ring is protective. The moving film of mucus tends to carry infecting agents and dust particles from the nose to the pharynx, where the epithelium is more resistant. Immune substances or antibodies are thought to be formed within the lymphoid tissue, which, combined with phagocytic action, tends to arrest and absorb infecting agents. The lymphoid tissue usually enlarges in early childhood, the degree being influenced by infection and probably also by hormonal influence.

Infections in childhood cause acute swelling and inflammation of the adenoids and appear to be the main cause of a permanent enlargement. Large adenoids tend to obstruct breathing through the nose and interfere with drainage, thus predisposing to infection of the sinuses during an acute infection. Chronic obstruction and mouth breathing produce vacant facial expression. Enlargement and infection of adenoids predisposes to Eustachian tube blockage and middle ear disease. The detection of chronic tubal obstruction in the child is usually an indication for removal of adenoids as the first step toward preventing hearing impairment. Adenoids normally decrease in size after childhood. See also TONSILLITIS. (J. R. L.)

ADEN PROTECTORATE comprises a group of Arab states or tribal districts under the protection of the United Kingdom. The protectorate extends along the southern coast of Arabia east of the Red sea, bounded on the north by the desert plateau and Yemen and on the south by the Gulf of Aden. It is divided into two areas: the Western protectorate, which consists of a coastal plain behind which rises a mountainous plateau dissected by rivers

ADEN COLONY AND PROTECTORATE ON THE SOUTHERN COAST OF ARABIA

and fertile valleys, and the Eastern protectorate, which is largely desert and barren mountains but contains also some fertile valleys. The Hadhramaut (*q.v.*) is included in the Eastern protectorate. The population, which is mostly Muslim, was (1955 est.) the Western protectorate 400,000, the Eastern protectorate 350,000. Area about 112,000 sq.mi. including the Island of Socotra (Sokotra; *q.v.*).

The climate is tropical with hot damp summers on the coastal plain, which also experiences sandstorms, high winds and extremes of heat and cold with scanty rainfall on the plateau; the air is less damp than that of Aden and the temperature range is greater. There are no made-up roads, but the rough tracks can be used by motor traffic though most of the transport is by camel or donkey. There is an airport at Riyan, in the Eastern protectorate, about 300 mi. N.E. of Aden, as well as several landing grounds, and there are ports at Mukalla, Qishn and Shihir, also in the Eastern protectorate, for small craft and coastal steamers. The principal towns are Lahej in the Western and Mukalla and Sa'uni in the Eastern protectorate. Most of the inhabitants are employed in agriculture, cotton being the chief crop. Cotton is ginned and there is fish curing. The Abyan scheme, in the Western protectorate, is an irrigation project utilizing flood waters from the mountains; much of the acreage is planted in cotton. There are three farmers' associations in the Western and a date farmers' association in the Eastern protectorate. Oil prospecting was done by private enterprise after 1938. By the early 1960s the prospectors were sufficiently satisfied regarding the existence of oil to enter into negotiations with states of the Eastern protectorate for boring rights. The main imports include foodstuffs, kerosene, cotton piece goods, cotton-ginning and agricultural machinery and motor vehicles. The chief exports include cotton, coffee, skins and hides. Most of the trade passes through the port of Aden. East African shillings and riyals (Maria Theresa dollars) are used as currency. Health services are provided in several hospitals and many health units. Each protectorate has a health training centre and mobile sanitation unit. There are many primary schools, mostly for boys, and several intermediate schools.

History and Administration.—After Aden was occupied by the British in 1839, the tribal chiefs from neighbouring territories entered into protective treaty relations with the British government, all the states being covered by treaty in 1914. From 1915 until the World War I Armistice in 1918, three districts of the Western protectorate were occupied by Turkey, which had conquered Yemen in 1872. In 1934 an Anglo-Yemeni treaty was signed to protect the frontier (then undemarcated) between Aden and Yemen, and this was followed in 1951 by an agreement to set up a frontier commission. Yemen (*q.v.*), however, has continued to claim the whole of the protectorate. Between 1937 and 1955 chiefs of both protectorates (including the sultan of Socotra) signed new treaties bringing them into closer relationship with the British government.

In the Eastern protectorate the Qu'aiti sultan, who had gradually come to rival the Kathiri sultan in power and wealth, first entered into treaty relations with the British government in 1882.

These ties were strengthened in 1888 by the signing of a protectorate treaty which the Kathiri sultan acknowledged in 1918 as binding on his people also. By the present treaties the chiefs agreed to accept the advice of a British resident officer in all matters except those concerning Islam and Islamic customs.

The governor of Aden colony is also governor of the Aden protectorate, but the protectorate is administered by the local rulers with the help of the British advisory staff rather than by the British government directly. The various sultanates, shiekhdoms and amirates of the Western protectorate nominate their chiefs, who have to be recognized by the governor. The two principal states in the Eastern protectorate, the Qu'aiti and the Kathiri, are administered by their sultans, who are constitutional rulers with state councils. These and the other states are advised by a British agent stationed at Mukalla. The Federation of Arab Amirates of the South, which was formed in Feb. 1959, signed a treaty of friendship and protection with the United Kingdom. The federation included six sultanates—Beihan, Dhala, Audhali, Fadhli, Lower Yafa and Upper Aulaqui. In Oct. 1959 Lahej formally joined the federation and in Feb. 1960 the integration of Lower Aulaqui, Dathina confederacy and Aqrabi was achieved. Thus in 1960 the federation consisted of ten sultanates, amirates and shiekhdoms of the Western protectorate. The treaty also provided for financial and technical assistance from the British government. Construction of the new federal capital, Ittihad City, was begun after 1959 on land leased from the Aqrabi amirate adjoining Aden colony.

ADEODATUS, SAINT (d. 676), pope from April 672 to June 676. sometimes styled Adeodatus II or Deusdedit II, was a Roman. He played no known role in the political events of the day or in the liquidation of Monothelitism. Easy of access, he devoted his attention chiefly to restoring dilapidated churches. Himself a Benedictine monk, he took the abbey of SS. Peter and Paul, Canterbury, under his protection and seems to have recognized the exemption of the abbey of St. Martin of Tours from episcopal authority. He was the first pope to date his correspondence by the year of his pontificate. Some hagiographers give him June 26 as a feast day, although there is some doubt that this was ever done officially. (A. G. BI.)

ADHÉMAR DE CHABANNES (c. 988–1034), Frankish chronicler chiefly important for the history of Aquitaine, was born of a noble family at Chabannes in Limousin, France. At the monastery of St. Cybard in Angoulême, where he rose to high office, he made a large collection of manuscripts, most of which passed after his death to the abbey of St. Martial of Limoges. He died as a pilgrim in Jerusalem. Adhkmār's *Chronicon Aquitanicum et Francicum* (critical ed. by J. Chavanon. 1897) traces the history of Aquitaine and of the Franks from the times of the legendary king Pharamond. Books i and ii are of little value but book iii is of great interest, particularly for the history of western France between 814 and 1028. His minor works, printed by J. P. Migne in *Patrologia Latina*, vol. cxli (1553), are an *Epistola de apostolatu S. Martialis* (representing St. Martial of Limoges as one of the apostles of Gaul), hymns in praise of St. Cybard and a work on the Limousin abbots.

ADHÉMAR (AIMAR) DE MONTEIL (d. 1098), French bishop who, as papal legate, was one of the leaders of the first crusade. He became bishop of Le Puy when Pope Gregory VII deposed the former bishop in 1077 and is known to have made a pilgrimage in

1086–87, perhaps to Jerusalem. In Nov. 1095, when Pope Urban II began preaching the crusade at Clermont, Adhémar was the first of his hearers to take the cross and was appointed by Urban to lead the crusade as legate. He traveled to Constantinople with Raymond IV of Toulouse and the Provençal contingent. During the crossing of Asia Minor (May–Oct. 1097) and during the siege of Antioch (Oct. 1097–June 1098), when there was no supreme commander of the crusaders, Adhkmār took a leading part in military counsels and operations. He also organized mass religious devotions at times of crisis, but hesitated to accept Peter Bartholomew's claim to have discovered the holy lance when the crusaders in turn were besieged in Antioch by Kerbogha. As well as beginning to establish friendly relations with the eastern Christians, Adhémar used his prestige to restrain the guards that arose from the conflicting ambitions of the lay crusaders. This was his greatest service to the expedition, as he commanded universal respect and affection. After his death of the plague in Antioch (Aug. 1, 1098), disputes within the army became so acute that the crusade almost foundered.

See S. Runciman, *History of the Crusades*, vol. i (1951).

(R. C. SMA)

ADHESIVES, natural and synthetic substances used for joining or bonding other materials together by surface attachment. Examples are glue, paste, mucilage and rubber cement.

Adhesives have been used since prehistoric times, the first ones used probably being natural gums and waxes such as rosin, rubber, shellac and beeswax. All of these are exuded by certain trees and insects and still find limited use. One of the earliest uses of adhesives was the employment of animal and casein glues by the early Egyptians in making wood furniture and attaching ornamental veneers to wood surfaces. Both these glues are still commercially important in the woodworking industry.

Until the late 1930s the only adhesives in common use were animal, casein and vegetable glues and natural resins. The principal commercial use was in the woodworking and paper industries. After synthetic plastic resins became available in almost limitless variety about 1935, new uses for adhesives were found in almost all industries, including the manufacture of automobiles, aircraft, electrical and electronic equipment and many other products. Many of the new adhesives give excellent bond strength in joining metals, glass, plastics and other nonporous materials as well as the more conventional porous ones such as paper and wood.

Uses.—Examples of uses of adhesives by industry in the early 1960s included the following:

In the automotive industry, adhesives are used for attaching sound-absorbing materials to metal surfaces, linings and floor covering to bodies, and rubber stripping to doors and trunk covers. Safety glass is made of two layers of glass with an adhesive film between. In some cases the entire automobile body is made of glass fibres bound together with an adhesive.

In the manufacture of aircraft, boats and house trailers, honeycomb cores of paper, fibre, wood veneer or metal are bonded by adhesives to surface layers of similar materials to form structural panels possessing very high strength-to-weight ratios. Many boats are made of glass fibres bound together by a synthetic resin adhesive. In some aircraft, the outer covering, or "skin," is bonded to the structural members by an adhesive instead of by rivets, resulting in a reduction of cost and air resistance. In electronics, copper foil is bonded to insulating panels to form the "printed circuits" that replace hand wiring in most radio and television sets, computers, and military and industrial electronic equipment. In electronic equipment for missiles and other applications requiring resistance to high shock and vibration, the resistors, capacitors, transistors, diodes and other components may be firmly cemented to the printed circuit board.

Theory of Adhesion.—The chemical or physical processes of adhesion are not completely understood, and so the technology tends to be experimental rather than theoretical.

The strength of a joint bonded by an adhesive depends on (1) adhesion of the adhesive to the surfaces joined and (2) cohesion within the adhesive itself. The adhesive must cover the surfaces thoroughly and form a continuous glue line. It is very desirable

to have the glue line as thin as possible since the strength of a properly bonded joint, either in tension or in shear, is much greater than that of the adhesive in bulk. Surfaces to be joined must be clean and properly prepared. In the case of metals it is usually best to roughen the surface slightly, although this requirement differs according to the adhesive used.

To obtain good strength in adhesive bonds, it is important that the joints be properly designed. Adhesives are stronger in shear or tension than they are against a peeling stress. Some adhesives remain slightly flexible, which is desirable when materials with differing expansion and contraction characteristics are to be joined, but flexible adhesives are likely to be weak and to creep under continuous load. The area of the surfaces to be joined should be as large as possible in order to provide maximum strength. In the case of lap joints in thin sheets of metal or plastics, the joints should be supported or reinforced to make sure they are subjected only to a straight shearing stress rather than to bending and peeling. Joints that are designed and made properly with the most suitable adhesive can be strong and reliable.

NATURAL ADHESIVES

The principal types of natural adhesives, their general characteristics and chief uses are as follows:

Animal Glues.—These are made from hides and bones of various animals and are an impure form of gelatin. They are usually sold in the form of granules or flakes, which are heated in water before being used. They are applied hot and harden both by cooling and the absorption or evaporation of water. Animal glues, including fish glue, are also made in a liquid form that is used cold. The principal uses of animal glue are in woodworking and the manufacture of coated abrasives such as sandpaper. Even in these applications the newer synthetic resin adhesives are often preferred because of their shorter curing time and better resistance to moisture. All of the animal and vegetable glues may be attacked by fungus under tropical conditions of high temperature and humidity.

Casein Glue.—This type of glue, made from milk, is better suited than animal glue for some uses in woodworking and in the paper industry. Its adhesion to porous materials is good and its moisture resistance is somewhat superior to animal glue. It is usually sold as a powder that is mixed with water just before being used.

Vegetable Glues.—These are made from starches or dextrans and find their principal uses in the paper products industry and in woodworking in that order. They are low in cost but possess limited strength and moisture resistance. Gum arabic is a water soluble vegetable adhesive often used on gummed paper and stamps.

Natural Gums and Resins.—These usually possess low melting points and may be used hot or mixed with solvents. Natural rubber compounds are used in the building industry for bonding linoleum or tiles to floors and acoustical material to ceilings. The rubber cements used for bonding paper, rubber or leather are often made of natural rubber in a solvent, although synthetic rubber is also used for this purpose. Natural asphalt, which probably is of plant origin at least in part, serves as an adhesive in paving by bonding together the crushed rock or sand used as a filler.

"Marine glues" are often natural resins dissolved in a solvent that evaporates during hardening. Sealing wax is an example of a hot melt adhesive made of natural resins. Natural gums and resins usually have excellent moisture resistance and fair adhesion but soften and lose strength rapidly at even moderately elevated temperatures.

Sodium Silicate.—Water glass, or sodium silicate, is the only inorganic adhesive in general use. It is also the only adhesive that will stand temperatures in excess of about 500° F., although it has a tendency to deteriorate and crumble on aging, especially on nonporous materials. It is low in cost and used widely in the manufacture of corrugated boxes, for attaching labels to glass containers and as a binder for asbestos fibres in wallboard. Mixed with inorganic fillers it forms high-temperature cements used for electric lamp bases, heating elements and other high-temperature applications.

SYNTHETIC RESIN ADHESIVES

Synthetic resin adhesives may be divided into (1) the thermosetting types that undergo a chemical change on hardening and (2) the thermoplastics that can be softened repeatedly by the application of heat. The thermosetting types retain their strength much better at elevated temperatures.

Synthetic resins can be modified in many ways and are often combined to obtain the best characteristics for a particular application. For these reasons the following listings are quite general in nature.

THERMOSETTING SYNTHETIC ADHESIVES

Epoxyes.—These are the most versatile of all the adhesives, providing excellent adhesion to both porous and nonporous materials, including metals. They harden by chemical action and so can be made without solvents. When used without solvents they shrink only slightly on hardening; this quality adapts them for use on poorly fitted joints or where a considerable build-up is required.

Epoxyes are usually furnished in two parts, the resin and a catalyst, which are mixed together just prior to use. After mixing, the hardening proceeds quite rapidly. Formulations designed to harden at room temperature must be used within a short time after mixing, often within a half hour or less. This is known as the "pot life." Formulations that require heat to complete their cure may be kept at room temperature for several days or even months before hardening but will harden very rapidly if heated. The resin can be modified to cure quite hard or with slight flexibility. For joining metal to metal, epoxy gives very strong bonds with an average shear strength of 3,000 pounds per square inch (p.s.i.) and up to 7,000 p.s.i. under closely controlled conditions.

The epoxyes are rather high in price but are widely used in the aircraft industry and in electronics, where their excellent electrical properties are valuable. Their moisture resistance is excellent and their bond strength is good up to about 350° F.

Phenolics.—Phenolics, also widely used in industry, are available as liquids that cure by evaporation of the solvents. For greatest bonding strength, the solvents are allowed to evaporate before the parts are joined under heat and pressure. Phenolic adhesive also is made available in thin sheets that are applied to the surfaces to be bonded; bonding with sheets also is done under heat and pressure. Sheets of adhesive are often used in the manufacture of plywood and of the lightweight honeycomb panels mentioned earlier. The commonly used phenol-formaldehyde adhesive provides good adhesion to wood and other porous materials but is not suitable for use with metals or glass. Other phenolic compounds and blends such as phenolic-epoxy, phenolic-polyamide, phenolic-vinyl acetals and phenolic-elastomers are excellent for this purpose.

Ureas.—Another important group of synthetic adhesives are the ureas. Like the phenolics, they work best on porous materials and are often used in the manufacture of plywood and in other woodworking applications. Urea-formaldehyde is the most commonly used adhesive of this group, but blends of urea and other resins, especially melamine, are better for certain applications. A related group of resins, the polyurethanes, are among the best of all adhesives for metal and glass as well as the porous materials.

Polyester Resins.—These adhesives are used in large volume as a binder for glass fibres to form structural panels, boats, luggage, electrical insulation, specialized automobile bodies, caskets and machine tool housings. Like the epoxyes, they are usually made to harden by chemical action rather than by the evaporation of solvents; for this reason they cure with almost no shrinkage. Parts of complex shape can be built up over simple forms or in more elaborate molds by applying successive layers of glass fibre cloth or matting and polyester adhesive or binder. The curing of the resin is accelerated by heat.

Silicones.—Silicones withstand the highest temperatures of all the synthetic adhesives and retain good strength to about 500° F. While the bond strength of the harder resins is not as good as some of the other types of adhesive, some silicone rubber compounds are excellent in this respect. The silicones also have very high moisture resistance. They are used as binders for glass fibres to

form electrical insulating sheets with characteristics that make them especially valuable in the electronics industry.

Resorcinol Resins.—These are excellent adhesives for wood and other porous materials although not generally satisfactory for metal and glass. Their water resistance is very good and they are often used in manufacturing plywood for exterior use.

Alkyd Resins.—Adhesives of this type are formulated with solvents to make adhesive varnish that is widely used in electrical and electronic manufacturing. The adhesion to metals is fair but not as good as that of the epoxies sometimes used for the same purposes.

Synthetic Rubbers.—In addition to the natural rubber mentioned above, synthetic rubbers are important bases for adhesives. They are flexible and well-adapted to such applications as the attachment of felt or similar materials to automobile body panels, fabric coating to metal and the joining of leather and rubber. The moisture resistance is excellent and the bond strength is adequate for many purposes, although flexibility and the tendency to creep under stress make most rubber adhesives unsuitable for highly stressed joints.

THERMOPLASTIC SYNTHETIC ADHESIVES

The following synthetic resin adhesives are of the thermoplastic type and do not retain their bond strength under elevated temperatures, although some of them display characteristics that make them useful below 180° F.

Vinyl Resins.—The most commonly used of the thermoplastic adhesives are the vinyl resins. Many modifications are available with the bonds formed either by fusing with heat or by solvent release. Some of the vinyl acetate, vinyl chloride and vinyl butyral formulations provide good adhesion to metal and glass. Vinyl resins are used in large volume in the manufacture of safety glass for the automobile industry. Polyvinyl emulsions have largely replaced the older types of animal and fish liquid glues for woodworking applications, since they harden more quickly and are more resistant to moisture.

Cellulose Derivatives.—Derivatives of cellulose, especially cellulose acetate and cellulose nitrate, are dissolved in solvents to form quick-drying, general purpose adhesives for household use. They are excellent for wood and paper and are moisture resistant, but their adhesion to metal and glass is rather poor.

Acrylics.—These are the most transparent of all the synthetic resins. Their transparency makes them useful for some applications even though their adhesion in general is not as good as that of some other resins. A notable exception is a cyano-acrylate formulation that hardens by chemical action, often in a few seconds or minutes, when it is pressed into a thin film between close-fitting surfaces. This form of acrylic displays excellent adhesion to metal and glass.

ADIABATIC CHANGE, a change in the physical state of a body, whether this change be one of volume, strain, electric charge, etc., which occurs without loss or gain of heat in the body.

See **THERMODYNAMICS: Thermodynamics and Heat Engines**; see also Index references under "Adiabatic Change" in the Index volume.

ADIABATIC PROCESSES IN ATMOSPHERE. Because of the large volumes of air involved and the relatively small temperature differences between adjacent air parcels, it is common to assume that no heat is added to or withdrawn from the air (adiabatic process) during atmospheric processes.

This assumption appears to be justified for air which is not in contact with the ground and for processes which are completed in from a few hours to a day. When air ascends or descends it expands and contracts as a result of the change in pressure. If no condensation or evaporation of water occurs the air will cool about 1° C. per 100 metres rise (5.4° F. per 1,000 feet), which is called the dry adiabatic lapse rate.

When moist air is lifted it will cool at the dry adiabatic rate

(the presence of moisture has a negligible effect until saturation is reached) until it becomes saturated. Further lifting will result in the condensation of water vapour or cloud formation. The latent heat of condensation is added to the air and as a result it cools less rapidly, at the so-called moist or saturated adiabatic lapse rate.

See **LAPSE RATE OF TEMPERATURE; METEOROLOGY; THERMODYNAMICS; UPPER AIR SOUNDINGS.** (H. G. HN.)

ADIAPHORISM is the theory that certain doctrines or practices in morals or religion are "indifferent matters" (Gr. *adiaphora*). There were two adiaphorist controversies in Germany after the Reformation.

The first controversy arose over the religious compromise which certain post-Lutheran theologians, chiefly Philipp Melancthon, were willing to make with Catholicism. It was an issue of the provisional scheme of compromise drawn up by Charles V in May 1548 and known as the Augsburg Interim, whose essentially Catholic theology made little concession to Protestant views. The elector Maurice of Saxony succeeded in making the Wittenberg theologians, for political reasons, accept the Leipzig Interim (Dec. 1548), which sanctioned the jurisdiction of Roman Catholic bishops and observance of certain rites (*e.g.*, extreme unction and confirmation), while all were to accept justification by faith, the added word "alone" being treated as one of the *adiaphora*. Matthias Flacius passionately opposed this policy on the grounds that under compulsion there could be no *adiaphora*, that the intention was to bring back popery and that no concessions would in fact be allowed. In practice the controversy was ended in Sept. 1555 by the religious peace of Augsburg, when Lutheranism was acknowledged as legitimate, but much bitter and dangerous internal strife was kept up by Protestants on the theoretical question of *adiaphora*. The tenth article of the Formula of Concord (1577) was an attempt to settle the matter on the lines laid down by Flacius.

Another adiaphorist controversy arose in the field of morals in 1681, when the building of a theatre in Hamburg was opposed by the Pietists (*see* **PIETISM**). They denounced worldly amusements as anti-Christian, whereas Lutherans normally defended the Christian freedom to use them.

ADIGE (anc. **ATHESIS**; Ger. **ETSCH**), an important river of north Italy, 255 mi. long, with a drainage basin of 4,710 sq.mi. It rises as a small stream from two lakes below the Resia pass: at a height of 4,947 ft. During the first part of its course it flows as a rapid mountain stream through the Val Venosta, from Glorenza east to Merano and Bolzano. Having received the waters of the Isarco river at Bolzano, the Adige turns south and after a long and narrow middle course enters the Po lowland at Verona. Turning southeast at Verona, after several long meanders it enters the Adriatic sea at Porto Fossone, a short distance north of the Po delta. In the lower course, near the sea, the average volume of the Adige is about 9,000 cu.ft. per second, varying, however, from a maximum of 70,500 to a minimum of 2,000. In the early centuries of the Christian era, the river's course was probably several miles farther north, until, about A.D. 589, the river broke through its banks and built its present course. The dikes built during the past several centuries had to be raised several times, and the last 50 mi. or so of the river's course are entirely man-made. Besides hydroelectric plants utilizing the waters of the Adige and of its tributaries in its upper Alpine section, the river provides irrigation for the Veneto in its lower course. Sudden floods, as in 1951, can do great damage and require constant control of the river bank. (G. KH.)

ADILABAD, a town in Andhra Pradesh, India, the headquarters of Adilabad district and an agricultural trade centre, is 114 mi. S.S.W. of Nagpur. Pop. (1951) 17,196. It is on the Nagpur-Hyderabad section of the Benares-Cape Comorin national highway, and at the end of a branch from Mudkhed on the Central railway.

ADILABAD DISTRICT lies on a 2,000-ft. plateau between the Godavari (*q.v.*) and Penganga rivers. Pop. (1951) 831,600. Area 6,501 sq.mi. The eastern part of the district is served by the Wardha-Secunderabad broad-gauge section of the Central railway. Asifabad is a commercial centre on this line. Annual rainfall is about 40 in. and the district is well forested; teak and ebony are extracted. There is plentiful game in the milder parts of the district. The main crops are jowar, rice, wheat, oilseeds, fibres and cotton. Coal is mined in the Pranhita valley and other minerals extracted are talc, limestone, iron ore (hematite) and sulfur. Local manufactures include paper, silk, chemicals and wooden toys. The fort near Mahur, 37 mi. N.W. of Adilabad, is a relic of the Muslim Bahmani and Imad Shahi dynasties (14th–16th centuries). (S. AH)

ADIPOSE TISSUE is a body tissue composed of specialized connective tissue cells that contain large globules of fat. The chief chemical constituents of this fat are the neutral glycerol esters of stearic, oleic and palmitic acids. The fat stored in these cells comes in part directly from the fats eaten, and in part is manufactured within the body from fats and carbohydrates in the food and sometimes from protein. The main reservoir of fat in the body is the adipose tissue beneath the skin, called the *panniculus adiposus*. There are also deposits of fat between the muscles, among the intestines and in their mesentery, around the heart and elsewhere.

Besides acting as a fuel reserve against times of starvation or great exertion, adipose tissue helps conserve the heat of the body and forms soft and elastic pads between the various organs.

ADIRONDACKS, a mountainous region in northeastern New York state, U.S., discovered by Samuel de Champlain in 1609. Adirondack means "tree eater," a name bestowed on a local tribe of Indians who sometimes were reduced by food shortages to making soup from the bark of trees. Covering 5,000 sq. mi., the region is bounded on the east by Lake Champlain, on the north by the St. Lawrence river and on the south by the Mohawk river valley. Although often included in the Appalachian system, the mountains are related geologically to the Laurentian highlands of

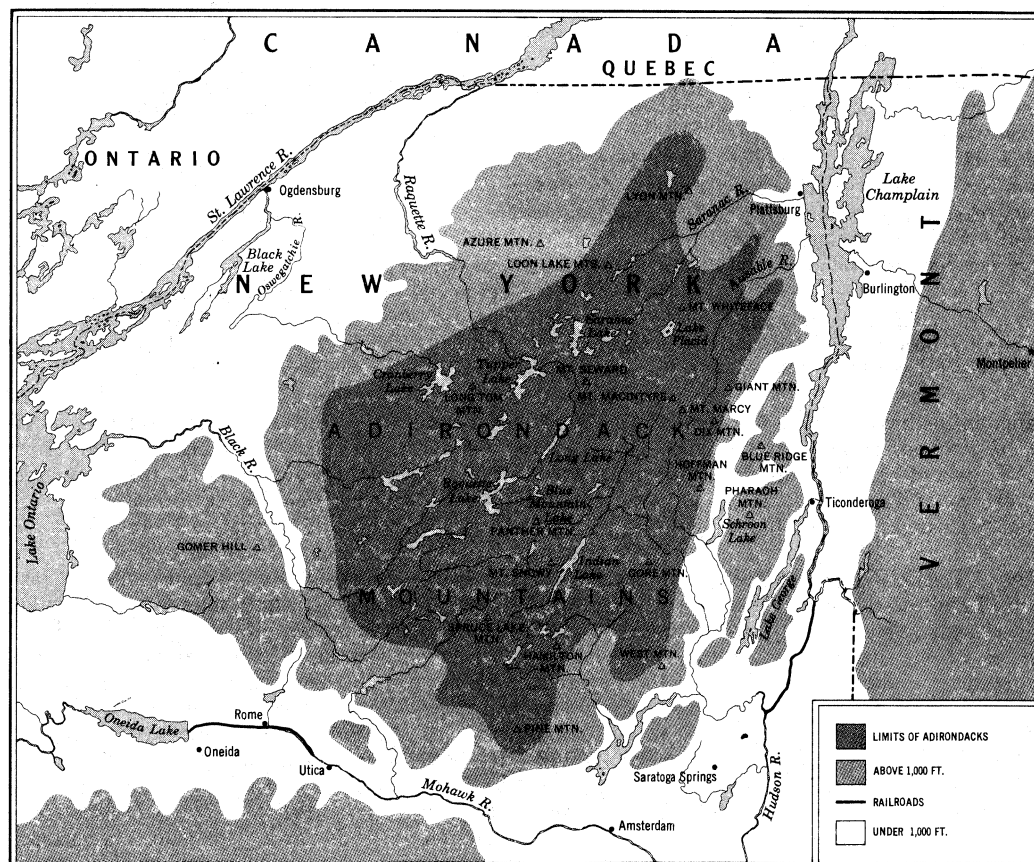

Canada. The Adirondacks were formed partly by fracturing of the earth's crust, a process known as faulting, but mainly by long years of erosion. While they are primarily rounded in outline, several of the higher peaks reveal bare rock walls in vertical escarpments. Unlike the Appalachians, the Adirondacks do not form a connected range, but consist of many summits in isolation or in groups. There are about 100 peaks, ranging from 1,200 ft. to more than 5,000 ft. in height; the highest, Mt. Marcy, attains an elevation of 5,344 ft., and Whiteface mountain reaches a height of 4,867 ft. Motorists may approach the summit of Whiteface on the Whiteface Memorial highway.

As the Adirondacks were completely covered by an ice sheet during the last glacial period, glacial till (clay, sand, gravel and boulders intermingled) covers all but the highest surface areas of the region. The retreating glaciers contributed much to the beauty of the landscape by creating many spectacular gorges and waterfalls, and hundreds of lakes, ponds and swamps. More than 200 lakes, each more than a square mile in area, lie in a general northeast and south west direction. The lake shore lines are usually rocky and irregular. The mountain region is circular in outline, with radial drainage from the centre forming many miles of streams that flow into the Hudson, Mohawk and St. Lawrence rivers and into Lake Champlain and the lakes of Ontario. The important rivers, famous for game fish, include the Black, Oswegatchie, Grasse, Raquette, Saranac and Ausable.

A large part of the Adirondack region is still in a primitive natural state, protected by state law. The state of New York set aside a conservation and recreation area in 1892 and has continued to acquire land and control forest utilization in the Adirondacks since that time. The Adirondack forest preserve and state park consists of over 5,000,000 ac., and is one of America's outstanding attractions for tourists. Numerous state parks and private resort communities provide excellent facilities for camping, bathing, hiking and canoeing. Additional attractions include famous historical landmarks located at Ft. Ticonderoga, Saratoga, Lake George and Plattsburg. Good highways afford access to nearly all parts of the Adirondacks and to the many resort villages

located along the shores of such lakes as Placid, Saranac, Tupper, Schroon, Long, Raquette, Cranberry, and Blue Mountain. There are no large cities in the Adirondacks; population density is very low compared to other regions of the state. The summer climate is moderated by cool mountain breezes. Although the winters are cold, the sub-zero temperatures are moderated by a normally dry atmosphere. As the climate has been considered beneficial to those suffering from pulmonary ailments, many sanitariums have been established in the Adirondacks, especially in the vicinity of Saranac Lake and Lake Placid.

Lumbering, although once a major industry in the Adirondacks, has been considerably restricted by the creation of the state forest preserve. The mountains, largely covered with spruce, hemlock, and pine forests with some hardwood trees growing on the lower slopes, appeal to the outdoorsman. Mineral deposits that have been mined profitably include iron and graphite. State counties in the region include Clinton, Essex, Franklin, Hamilton and Lewis, and parts of Ful-

ton, Oneida, St. Lawrence, Warren and Herkimer. (D. E. A.)

ADIT, a horizontal opening, or entrance, made from the earth's surface to intersect a seam of coal or a mineral vein. The accompanying figure shows a seam of coal outcropping on the side of a hill with ventilating shaft, incline and adit. An adit is frequently called a tunnel, although the latter term is more properly reserved for a working open at both ends, such as through a mountain or a ridge, and inclines are sometimes erroneously called adits. Among U.S. miners adits also have been known in the past

AN ADIT CUT ACROSS THE STRATA, TO WIN AND DRAIN A COAL SEAM

as adit levels and drifts, and among British miners as day drifts, day holes, surfs, soughs, watergates and audits.

The use of adits was perhaps the earliest method of gaining access to mines. Adits were driven at such a level as to drain off the water from the workings. In modern times and where topography permits, adits are driven below earlier mine workings for the purpose of draining water from old abandoned mines and also to enable mining on deeper levels.

The choice as to whether an underground objective is to be reached by shaft, slope or incline or by adit is dependent upon topography and economic considerations. Adits can be driven only in hilly country where the portal will be at such an elevation as to provide an adequate slope for water to flow out and to favour removal of coal or ore. Where either shaft or adit can be used, the saving in the generally lower cost of driving an adit over the cost of sinking a shaft, plus the saving in the cost of pumping water and hoisting the coal or ore in the shaft, will dictate that the adit is more economical. Consequently, adits of greater length than shafts, sometimes reaching one or two miles, are economically feasible.

The cross section of adits is square, round, elliptical or, more commonly, horseshoe shaped. The size range is from that which will allow a man to stand erect to that which will allow passage of haulage equipment. The walls may be of the natural rough rock, or may be lined with concrete, masonry, wood or steel.

(W. A. V.)

ADJUSTMENT (IN PSYCHOLOGY) is the process of behaviour by which men, and other animals as well, maintain an equilibrium among their various needs, or between their needs and the obstacles of their environments. A sequence of adjustment begins when a need is felt and ends when it is satisfied. For example, a hungry man is stimulated by his physiological state to seek, obtain and prepare food. He eats and thereby reduces the stimulating condition that impelled him to activity. He is then adjusted to this particular need.

Social adjustments are similar. Most people in many cultures want to be recognized and approved by their fellows. When a man is criticized, that need is thwarted. In response he may try various ways to regain approval; or he may belittle the critic or argue that someone else is to blame. The latter behaviours do not really bring approval, but they are adjustments of a sort because they tend to reduce the man's feeling of distress.

In general, the adjustment process involves four parts: (1) a need or motive in the form of a strong persistent stimulus; (2) the thwarting or nonfulfillment of this need; (3) varied activity, or exploratory behaviour; leading to (4) some response that removes or at least reduces the initiating stimulus and completes the adjustment.

Motives.—Some of the motives that stimulate adjustive behaviour are primary physiological needs such as hunger and thirst.

Certain other strong motives, such as the sex drives, combine physiological elements and cultural or learned factors. Of greatest importance in complex human adjustments are the social motives involved in interactions with other persons, including needs for security, approval, recognition, affection, conformity, prestige, mastery, self-realization and the like.

Social motives are not inborn, but are learned by each person during the course of his early development and socialization. Innate emotional responses provide the base from which many important social motives develop. A child fears pain instinctively. If scolding accompanies painful punishment, he may learn to fear all social criticism. The scolding thereby becomes an acquired drive which will evoke fear and arouse a need for adjustment. Similarly, motives to compete, strive and succeed may be learned as elaborations of the primitive response of anger which is caused by restraint.

Social motivation also may originate from the learning of secondary rewards. Feeding and comforting are intrinsically satisfying to a little child. If these are accompanied by attention and kind words, then recognition and approval from other people will become gratifying in themselves. Their absence will become an annoyance and will arouse adjustive behaviour. Repeated experiences during a lifetime of development typically cause certain social motives to be learned so thoroughly that they become stronger than some primary physiological drives. A hungry man often will not steal food because his socialization provides a stronger motive than his hunger.

Since social motives are learned, they tend to differ from one culture to another. Each society provides different learning experiences for its children. Thus, typical persons in the middle-class European-American culture have strong urges to succeed and excel, which are markedly lacking in members of some so-called primitive cultures.

One type of emotional motivation, anxiety, has an especially important role in the process of adjustment. The feeling-tone of anxiety is much like that of fear, but there are differences. Fear is evoked by a present external stimulus, anxiety by an apprehension of threat and a feeling of helplessness. A boy fears a larger bully, but he may have anxiety about his own strength or his acceptance in his group. There is no specific effective adjustment to anxiety. Anger may lead to aggression and fear to flight, but the anxious person is stirred up futilely. Anxiety is therefore at the root of many of the less effective adjustments. (See also MOTIVATION.)

Frustration and Conflict.—Two kinds of thwarting may prevent the fulfillment of motives—frustration and conflict.

A frustration is an external circumstance or an act of another person which prevents the satisfaction of an aroused motive. An adolescent may want to drive the family automobile to a dance, but be frustrated because the automobile is out of order or because his father forbids him to use it. Frustrations usually lead to increased effort, to anger and aggressive impulses or to immature and ineffective behaviour, but they do not often result in serious psychological difficulties. Some frustrations are even socially constructive, for they may cause the person to discover new solutions to problems.

A conflict is the arousal of two or more strong motives that cannot be solved together. A youngster wants to go to a dance to feel that he belongs to a group and does what his friends do. For an adolescent in western culture, that is a strong motive. But the youth may be a clumsy dancer, and sensitive to the real or imagined ridicule of his fellows. Therefore, he also has a motive to avoid the dance to escape humiliation. He is in a dilemma; whether he goes or stays he will experience distress. Psychologically, a conflict exists when the reduction of one motivating stimulus involves an increase in another, so that a new adjustment is demanded.

Conflicts are not all equally severe. A conflict between two desired gratifications, as when a youth has to choose between two attractive and practicable careers, may lead to some vacillation but rarely to great distress. A conflict between two dangers or threats is usually more disturbing. A man may dislike his job intensely but fear the threat of unemployment if he quits. A conflict

between a need and a fear may also be intense. A child may be dependent on his mother but fear her because she is rejecting and punitive. The conflicts which involve intense threat or fear are not solved readily but make the person feel helpless and anxious. His subsequent adjustments may then be directed more to the relief of his anxiety than to the solution of his real problems.

Conflicts are often unconscious, in the sense that the person cannot clearly identify the source of his distress. Many strong impulses—such as fear and hostility—are so much disapproved by the culture that a child soon learns not to acknowledge them, even to himself. When such impulses are involved in a conflict, the person is anxious but does not know why. He is then less able to bring his rational thinking to bear on the problem.

Varieties of Adjustment.—Every person experiences some frustrations and conflicts, but is able to solve most of them normally with his own resources. A person engages in exploratory behaviour, trying one act and then another until he discovers one that overcomes the frustration, resolves the conflict or at least reduces its intensity.

Adjustments vary in quality. Suppose, for example, that a university student fails his examinations. This situation demands adjustment, for it not only thwarts his educational and vocational plans but also evokes conflicts about his personal adequacy. The student may adjust by finding and remedying the cause of his difficulties, by increasing effort or by making a rational change in his goals, all of which are direct and constructive solutions. Or he may adjust by blaming others for his failure, by emphasizing his attainments in other areas (as in athletics), by daydreaming of imaginary successes or by developing an apparent illness that excuses his failure. These acts do not solve his problem, but they are adjustments because they help him relieve his tension and reduce his anxiety. The indirect, substitutive methods of adjustment are often called adjustment mechanisms. (See DEFENSE MECHANISMS.)

The problem of defining what is a "good" adjustment is clarified by the concepts of integrative and nonintegrative behaviour. An integrative adjustment is one that not only satisfies the present motive but also facilitates the solution of subsequent problems. A nonintegrative adjustment, in contrast, reduces the anxiety of the moment but leads to more trouble in the future. A person who is one-sided in his satisfactions, who reduces one intense need at the expense of thwarting the rest, is nonintegratively adjusted. Such a person is usually so preoccupied with the overpowering need to reduce his immediate anxiety that he is blinded to other considerations more relevant to his ultimate welfare.

Counseling and Psychotherapy.—A person whose adjustments are not optimal often can be helped by the professional services of a counselor, a psychologist or a psychiatrist.

The term counseling is often used to designate the process of helping a person to make adjustments that deal with realities, such as educational or vocational plans, or the success of a marriage. A part of such counseling may be the giving of information that enables the person to increase the scope of his exploratory behaviour. The counselor, for example, may give him information about his own abilities and interests as determined by psychological tests, or about educational opportunities and the requirements of various occupations. The competent counselor does not attempt, however, to solve the person's problems for him. Adjustment is an individual matter which each person must discover for himself, and the counselor tries mainly to clarify the person's own thinking. The process has to be inductive and may require considerable time.

Psychotherapy is the process of helping a person, by psychological means, to resolve adjustive difficulties that are more personal and more pervasive in his whole life. The patient in psychotherapy may be an essentially normal person who is anxious and ineffective. Psychotherapy is also widely used to help neurotic persons and sometimes is an aid to the psychotic.

Psychotherapy establishes a special kind of interpersonal relationship. The therapist's task is to show a warm, calm, understanding and permissive interest. He is never shocked and never scolds. The patient's task is to keep talking about his anxieties.

In this trusting relationship a kind of learning takes place. The patient finds that he can remember, feel and express aspects of his life that he was unable to face earlier because of his emotional distress. He learns, at his own pace and through his own thinking, to respond with constructive exploration instead of with helpless anxiety. Improvement in his everyday adjustments is likely to follow.

Integrative adjustment does not imply conformity. The aim of the therapist, therefore, is not merely to make the patient "normal" in the sense of being like all other people. The adjustments which a person may develop when he is no longer impeded by his own intense anxieties may be highly individual and creative. See also PSYCHOTHERAPY; PSYCHOLOGY, APPLIED; PSYCHOLOGY, ABNORMAL.

(L. F. SR.)

ADJUTANT, a helper, or junior in command, who assists his superior. In military language the term applies to an officer who assists the commander of a military unit. In the British and U.S. services the adjutant is the principal administrative staff officer of the commander of a battalion, battle group, regiment, squadron or military post. An officer holding an appointment as adjutant in such units usually has the rank of captain. The adjutant publishes official orders of the unit, is responsible for superintending clerks and other administrative personnel, submits reports to higher head-

quarters, handles official correspondence and maintains records. "Adjutant's call" is a special bugle call sounded before certain ceremonies. An officer performing the adjutant function in a larger formation of the U.S. army, such as a division or corps, is entitled adjutant general (*q.v.*). In the French army, an officer performing the adjutant function is entitled *adjoind*, the word *adjutant* being the rank of senior noncommissioned officers, comparable to warrant officers in the U.S. services. See AIDE-DE-CAMP. (T. N. D.)

BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

INDIAN ADJUTANT BIRD (LEPTOPTILUS DUBIUS)

ADJUTANT BIRD, the name given to large storks (*q.v.*), of the genus *Leptoptilus*, distinguished by their dull plumage, black scabrous head and enormous breast pouch; the last is of doubtful function, connected with the respiratory system.

The largest (six or seven feet tall) adjutant bird is *L. dubius* of India. It feeds on carrion, frogs and fish; and is a most efficient scavenger, for which reason it is usually protected. Other species are *L. javanicus*, the lesser adjutant, of southeast Asia and *L. crumeniferus*, the African adjutant or marabout stork, of Africa. The original marabout feathers of commerce were the undertail coverts of the latter bird, but the name has come to be applied to a large number of kinds of downy feathers.

ADJUTANT GENERAL, an army or air force official, originally the chief assistant or staff officer to a general in command, but more recently a senior staff officer with solely administrative responsibilities. In Britain the second military member of the army council is styled adjutant general to the forces. His department is charged with all duties pertaining to personnel. The adjutant general of the U.S. army serves as a principal assistant to the chief of staff. He heads the adjutant general's corps, an administrative service that publishes all army orders, is responsible for army correspondence and takes charge of personnel actions, records, decorations and awards, publications, postal service, recre-

ational activities and career guidance. The adjutant general of the U.S. air force has comparable functions. The principal administrative staff officers of large subdivisions of the U.S. army, such as divisions, corps and armies, are entitled adjutants general, though they usually hold the rank of lieutenant colonel or colonel. Each U.S. state has its own adjutant general, with administrative duties regarding the state national guard or militia. (T. N. D.)

ADLER, ALFRED (1870-1937), Austrian psychiatrist and founder of individual psychology, was born Feb. 17, 1870, in a Vienna suburb. Invited by Sigmund Freud (*q.v.*) in 1902 to join his circle, Adler became a prominent associate. Gradually, however, theoretical differences between the two became irreconcilable; he separated from Freud in 1911 and founded his own school and journal. In 1919 Adler founded the first child guidance clinics in the Vienna school system. After 1925 he regularly visited the United States and settled there in 1935. He died in Aberdeen, Scot., on May 28, 1937, while on a lecture tour.

Adler's main concepts are: (1) The dominant motive is the striving toward a goal of superiority or perfection, in compensation for the inferiority feeling postulated for everyone. (2) The individual cannot be considered apart from society; all important problems, including certain drive satisfactions, are social. (3) The socialization of the individual is afforded through social interest, an innate ability that must, however, be developed; socialization is not achieved at the cost of repression. (4) The individual is unique. His personality structure, which includes his unique goal and ways of striving for it, is his style of life. (5) The goal and the life style are more or less unconscious. (6) The individual is a self-consistent unity; psychological categories such as specific drives or the consciousness-unconsciousness contrast are only aspects of a field of processes subordinated to the life style. (7) The individual's opinion of himself and the world influences all psychological processes. (8) All objective biological and social conditions are mere raw material used by the self according to his life style. (9) Birth order or the sibling situation influences the individual at an early, formative stage. (10) The life style is ultimately the product of the individual's creativity.

While the normal person with a well-developed social interest will, according to Adler, compensate by striving on the useful side of life, the neurotically disposed person is characterized by increased inferiority feelings, underdeveloped social interest and an exaggerated, unco-operative goal of superiority, manifesting themselves as anxiety and more or less open aggression. Organ inferiorities and neglect or overprotection as a child make unfavourable development more likely, yet may lead to successful overcompensations.

Therapy consists in providing the patient with insight into his mistaken life style through material furnished by him in the psychiatric interview. The life style can be diagnosed from all verbal and bodily expressions, the individual speaking with his entire body ("organ dialect") as well as his tongue. Particularly useful are dreams, and early recollections as thumbnail sketches of the patient's opinion of himself and the world. Social interest is strengthened and inferiority feelings are reduced by encouragement and by an atmosphere of relaxed equality between patient and therapist.

Adler accepted from Freud the theorem that no psychological expressions are accidental (*i.e.*, psychological determinism). But whereas for Freud the determiners were in the last analysis objective biological factors such as instincts, especially sex, and past events, for Adler they were subjective psychological factors such as opinions and values, unified under the life goal.

Representative books by Adler include *The Practice and Theory of Individual Psychology* (1920; English trans., 1927); *Problems of Neurosis* (1929); *Social Interest* (1933; English trans., 1938).

ADLER, CYRUS (1863-1940), U.S. scholar and educator, a leader of Conservative Judaism in the United States, was born

in Van Buren, Ark., on Sept. 13, 1863. He was graduated from the University of Pennsylvania, Philadelphia, in 1883 and received the Ph.D degree in 1887 from Johns Hopkins university, Baltimore, Md., where from 1884 to 1893 he was an instructor and associate professor of Semitic languages.

He was librarian, 1892-1905, and assistant secretary, 1905-08, of the Smithsonian institution, Washington, D.C. From 1889 to 1908 he was curator of historic archaeology and historic religions at the U.S. National museum, Washington. Adler became president of Dropsie College for Hebrew and Cognate Learning, Philadelphia, in 1908; he was acting president of the Jewish Theological Seminary of America, New York city, from 1916 and president from 1924. In 1892 he founded the Jewish Historical Society of America. He was an editor of the *Jewish Encyclopedia* and in 1899 was made editor of the *American Jewish Year Book*. He died on April 7, 1940.

Among his published works are *The Shofar, Its Use and Origin* (1893); *Told in the Coffee House*, with Allan Ramsay (1898); *International Catalogue of Scientific Literature* (1905); *Jews in the Diplomatic Correspondence of the United States* (1906); and *Jacob H. Schiff: His Life and Letters*, two volumes (1928).

ADLER, DANKMAR (1844-1900), U.S. architect and engineer, whose partnership with Louis Henri Sullivan (*q.v.*) was perhaps the most famous and influential in U.S. architecture, was born at Stadtlengsfeld, Ger., on July 3, 1844. He and his father emigrated to the United States in 1854 and settled in Detroit, Mich., where he began his study of architecture in 1857. Later father and son moved to Chicago, where Adler became a draftsman in the office of Augustus Bauer. The American Civil War interrupted his career until 1865. On his return to Chicago he held a succession of positions in the offices of Bauer, A. J. Kinney and Edward Burling. The first of his important buildings was the Central Music hall in Chicago, in which he made the initial use of his unique knowledge of acoustics.

In 1881 the partnership of Adler and Sullivan was founded. The commercial buildings which they designed—particularly the Auditorium (Chicago), Wainwright (St. Louis), Guaranty (Buffalo)—constituted a new architectural style with the essential features of modern building art. Adler acted as engineering designer and administrator, while Sullivan worked as planner and artist. This fruitful association was terminated in July 1895. Adler did no distinguished work in the few years remaining before his death on April 16, 1900.

He wrote extensively on the technical and legal aspects of architecture and building construction. His most important paper is "The Influence of Steel Construction and Plate Glass Upon the Development of Modern Style" (1896).

BIBLIOGRAPHY.—Carl W. Condit, *The Rise of the Skyscraper* (1952); Hugh Morrison, *Louis Sullivan: Prophet of Modern Architecture* (1935); Arthur Woltersdorf, "Dankmar Adler," *West. Archit.*, 33:7 (July 1924). (C. W. Co.)

ADLER, FELIX (1851-1933), U.S. educationalist and founder of the Ethical Movement, was born at Alzey, Ger., Aug. 13, 1851. His father, a Jewish rabbi, emigrated to the United States in 1857, and the son graduated at Columbia college in 1870. After studying at Berlin and Heidelberg, he became professor of Hebrew and oriental literature at Cornell university, Ithaca, N.Y. (1874-76). He was appointed professor of political and social ethics at Columbia university in 1902.

In 1876 Adler established in New York city the Society for Ethical Culture. The history of the Ethical Movement and Adler's relation to it are described in the article ETHICAL MOVEMENT.

Adler took a prominent part in philanthropic and social reform movements, such as the erection of model tenement houses and the abolition of child labour. He published *Creed and Deed* (1877), *The Moral Instruction of Children* (1892), *Marriage and Divorce* (1905), *The Religion of Duty* (1905), *The World Crisis and Its Meaning* (1915), *An Ethical Philosophy of Life* (1918) and *The Reconstruction of the Spiritual Ideal* (Hibbert lectures at Oxford, 1923).

Adler died April 24, 1933.

ADLER, HERMANN (1839-1911), British chief rabbi, who

was for many years a prominent figure in English-public life, was born at Hanover, Ger., on May 30, 1839, the son of N. M. Adler (*q.v.*). He was educated at University College school and University college, London, and then at Prague, where he received the rabbinical diploma. Returning to England, he became temporary principal of the Jewish Theological college in London for two years. With this college he was associated in one capacity or another all his life.

He began his ministry at the Bayswater synagogue in 1864 and continued to preach there until 1891, when he became chief rabbi on the death of his father. Adler served on many Mansion House committees and on various bodies concerned with the improvement of social conditions in London. He died on July 18, 1911. A collection of his sermons, entitled *Anglo-Jewish Memories and Other Sermons*, was published in 1909.

ADLER, NATHAN MARCUS (1803–1890), British chief rabbi, a moving spirit behind the establishment of the United Synagogue, was born at Hanover, Ger., Jan. 15, 1803. He took his Ph.D. degree at Erlangen in 1828 and was ordained the same year. He became chief rabbi of Oldenburg in 1829 and of Hanover in 1830, and on Oct. 13, 1844, was elected chief rabbi in London. There he originated and carried out his scheme for a Jewish college for teachers, which was founded in London, Nov. 11, 1855, with himself as first president. In 1860 he suggested the establishment of a United Synagogue which should bring all the British congregations under one central administration; this idea was realized in 1870, when the United Synagogue bill was passed in parliament. Adler died Jan. 21, 1890, at Brighton. He was succeeded as chief rabbi by his son, Hermann Adler (*q.v.*).

His writings include sermons and commentaries on Hebrew texts, the best known of which is *Nethinah la-ger*, a commentary on the Aramaic paraphrase of Onkelos on the Pentateuch (1874).

ADLER, VIKTOR (1852–1918), Austrian Social Democrat, mainly responsible for the continuing unity of the Austrian Social Democratic party, was born, the son of a wealthy merchant, at Prague in Bohemia on June 24, 1852. As a medical student at Vienna university he belonged to a German nationalist association, in which he met E. Pernerstorfer, later his associate, and also H. Friedjung and G. von Schonerer. In 1881 Adler, a qualified doctor, joined the Social Democrats and worked on problems of industrial insurance. During a tour of Germany, Switzerland and England in 1883 he met Friedrich Engels and August Bebel. In 1886 he founded the Vienna weekly *Gleichheit*. When this was proscribed in 1889, he founded the *Arbeiterzeitung*, which became the main organ of the Austrian Social Democratic party.

Adler's greatest achievement was when, during the party convention at Hainfeld (Dec. 1885–Jan. 1889), he reconciled diverging factions among the Austrian Social Democrats. In 1899, moreover, he published a program for the Socialist parties of the various nationalities of the Austrian lands designed to maintain the unity of the empire. Between 1887 and 1899 he was imprisoned for 18 months for his political activities. He was elected, however, to the *Landtag* of Lower Austria in 1905 and had much to do with the introduction of general suffrage into the Austrian lands in 1907. In 1911, the breakaway of the Czech Social Democrats frustrated his hopes of complete party unity. Before and during World War I Adler used the Second International in repeated efforts for peace; *e.g.*, at Basel in 1912 and at Stockholm in 1917. After World War I he joined the provisional administration of "German Austria," advocating union with Germany. He died in Vienna on Nov. 11, 1918.

His speeches and letters are collected as *Aufsätze, Reden und Briefe*, 11 vol. (1922–29); there are also selections by A. Tesarck, *Aus Piktors Adlers Reden und Briefen* (1957).

See K. Renner, *An der Wende zweier Zeiten* (1946); L. A. Windisch-Grätz, *Ein Kaiser kämpft für die Freiheit* (1957). (L. J.E.)

ADMETUS, in Greek legend, son of Pheres, king of Pherae, in Thessaly. Having sued for the hand of Alcestis, the most beautiful of the daughters of Pelias, king of Iolcus, he was first required to harness a lion and a boar to a chariot. Apollo, who served him—either as a punishment for having slain the Cyclopes or out of affection for his mortal master—yoked the pair himself

and gave them to Admetus, who thus obtained Alcestis.

Finding that Admetus was soon to die, Apollo persuaded the Fates to prolong his life, provided anyone could be found to die in his place. His parents refused, but Alcestis consented. She was rescued by Hercules, who wrestled with Death at the grave and made him give her back. The death and resurrection of Alcestis form the subject of many ancient reliefs and vase paintings, as well as the *Alkestis* of Euripides, which is extant.

See A. Lesky, *Alkestis: der Mythos und das Drama* (1925); W. Roscher, *Ausführliches Lexikon der griechischen und römischen Mythologie* (1884–1937). (T. V. B.)

ADMINISTRATION, in lam. is the management of an estate by a person, other than the legal owner, appointed or supervised by a court; especially the management of a decedent's estate by an administrator or executor, a ward's estate by a guardian, an insane person's estate by a conservator or committee, a bankrupt estate by a trustee in bankruptcy and, generally, of a trust fund by a trustee. Every such fiduciary is held to a high standard of care and is strictly accountable for his management. Ordinarily he is entitled to a fee. Fiduciary management is to a large extent carried on by professional trustees, especially trust companies. The total amount of personal funds administered by banks and trust companies in 1959 has been estimated to amount to approximately \$50,000,000,000 in the United States. For the principles applicable to specific kinds of administration, see **BANKRUPTCY**; **ESTATES, ADMINISTRATION OF**; **CHILDREN, LAWS CONCERNING**; **INSANITY**; **TRUST**. (Hl. RN.)

ADMINISTRATION, MILITARY: see **LOGISTICS**.

ADMINISTRATIVE AREAS. An administrative area is a portion of the earth's surface that has been officially delimited for the administration of one or more governmental functions. Administrative areas come into being in three ways. First, the total area of each government, whether national, state or local, is automatically an administrative area. Second, any such government may subdivide its area into smaller areas for administrative purposes. Thus, a city government may have police precincts, a state government have highway districts, a national government have administrative regions or districts. Third, an administrative area may be intergovernmentally created to combine all or parts of the areas of two or more governments for defined administrative purposes. Thus, the New York Port authority, established jointly by interstate compact between the states of New York and New Jersey, has jurisdiction in both states; similarly, three counties may agree to set up a joint health department with tri-county jurisdiction.

Number and Types of Areas.—An administrative area may be used for many functions or for only a single function. Of the 102,000 governmental units in the United States in 1957, about one-third were multifunctional and two-thirds unifunctional. The more than 37,000 multifunctional units included the national government, the 48 states and about 3,000 counties; 17,000 municipalities and 17,000 towns and townships. In England and Wales the major multifunctional governmental areas numbered 145, including 62 administrative counties and 83 county boroughs (larger urban areas whose governments have both county and urban powers); in addition, the two-tier administrative counties included more than 1,000 urban and rural county districts, and more than 300 noncounty boroughs; still lower were 14,000 parishes. France's 38,000 communes were multifunctional local governments.

The United States has, and England earlier had, a perplexing number of substantially autonomous single-function governmental units, each with its own area. In 1957 the United States' 65,000 unifunctional areas included over 50,000 school districts and over 14,000 other special districts for such functions as fire protection, soil conservation, drainage, cemeteries, housing, water supply and highways. The trends were downward for school districts, which were half as numerous as in 1942, but upward for other special districts, as they increased 75% between 1942 and 1957.

When a national or state government subdivides its territory it may establish a single master set of administrative areas and channel the field work for all its functions through a chief ad-

ministrator of each area. Napoleon I established this system for France. It persists into the second half of the 20th century, with 90 administrative *départements* (i.e., areas), each headed by a prefect. The major alternative is to allow each national agency to design its own scheme of administrative areas to fit its own function without any necessary regard to the areas used by other national agencies or to other governmental areas, such as states and counties; each agency, of course, directs its own field work. This pattern is followed by the national governments in the United States and England, neither of which has any official comparable to the French prefect.

Suggested Reforms.—Areal reform is widely advocated. It is not difficult to demonstrate that areas could be redesigned to satisfy criteria of symmetry, simplicity, uniformity and geographical correctness. But these are not the substantial questions. A more meaningful approach takes account of the degree to which existing administrative areas contribute to or obstruct effective governmental services to the people, democratic control of officials and maintenance of local government.

English, French and American all-purpose administrative areas were inherited from the 19th century—an age of less population, less urbanization, fewer governmental services, less need for staffs of professional, full-time officials and less technological mastery of transportation and communication. The artificiality of existing multifunctional administrative areas becomes more pronounced as the premises on which they were built increasingly lose validity.

A substantial official and professional literature in the United States urges increase in the average size of counties, expansion of city and town boundaries to include the suburbs and fringe areas, amalgamation or federation of immediately adjacent cities and towns to provide a single government for each large urban and metropolitan community and drastic reduction of special districts. Action along these lines has been slight.

The proposals rest on such premises as these: that the natural areas, self-defined by the problems with which a government is to deal, should be embraced by the official area of that government; that modern financing and staffing requirements for each of a number of functions dictate in each case a larger supporting and service area than was true earlier; that well-to-do sections of a community should not escape a share of responsibility for depressed sections or for leadership of the whole community, nor should residents of "dormitory suburbs" escape responsibility for supporting central city services they enjoy daily; that fragmentation of government among a variety of autonomous agencies, such as special districts and *ad hoc* joint authorities, precludes a unified approach to a community's interlocking problems and impairs popular control; that intergovernmental co-operation is an inadequate mode of action for an important continuing problem, as the least co-operative autonomous governmental unit in a community may exercise an absolute veto and so set the pace of joint action; and that local democracy is best served by areas that permit effective performance by government, control by a majority of the whole community and retention of responsibilities that might otherwise go by default to higher levels of government.

In Great Britain there have been proposals for devolution to English, Welsh and Scottish parliaments and for regional divisions of England itself. But the principal proposals have been for reform of local government areas. From 1945 to 1949 a Local Government Boundary commission studied the problem but hesitated to act, partly because of the county councils' unqualified resistance to important recommendations for urban areas. When the commission did announce its intention to act, parliament abolished it. In the 1950s the government negotiated with local officials to identify types of areal changes they would not oppose.

In France there is considerable regionalist literature, critical of the small size of the 90 administrative *départements*. This bore practical fruit under the Vichy government, which established 18 regions, and under the fourth republic, which grouped *départements* into 9 regions largely for internal security reasons. French national ministries tended increasingly to establish their own administrative area schemes, instead of channeling their functional

field work through the prefect and his *département*.

Metropolitan Areas.—Major urban communities—the 174 metropolitan areas in the United States and the "conurbations" in Great Britain—present the most pressing areal problem. Greater London contains more than 8,000,000 persons, but the London county council serves only between 3,000,000 and 4,000,000 of them. The 3,000 sq.mi. metropolitan area of New York and northeastern New Jersey in the 1950s included over 1,000 governmental units; New York city served only 8,000,000 of the 13,000,000 inhabitants in the area.

In the United States, efforts to provide suitable administrative areas for the metropolitan community and to rationalize the hodgepodge of governmental layering have been piecemeal and not widely successful. Among the methods advocated and attempted were annexation, unifunctional and multifunctional special districts, city-county consolidation, city-county separation, designation of the county as the metropolitan government, granting to the core city of extraterritorial jurisdiction over its fringe and voluntary co-operation among governmental units operating in the metropolitan community.

The most probable solution appeared to lie in metropolitan federation, whereby existing general-purpose local governments would continue to perform certain functions and a government with metropolis-wide jurisdiction would perform certain other functions. The first tests of this pattern in North America occurred in Toronto, Ont., and Dade county (Miami) Fla.

Area and Function as Conflicting Factors.—The common element in experiences with the administrative area problem is the conflicting and complementary claims of area and function. Function may dictate area. Thus, a school administrative area, it is said, should have at least 1,500 pupils (though 90% of school districts have less), and a local tax assessment district should have at least 10,000 inhabitants; health, welfare, police, fire and other functional requirements can be stated, each statement leading to a different area. So, too, each national agency can argue persuasively for a strictly functional administrative geography; customs collection and apprehension of counterfeiters have differing geographical requirements, though both are in the treasury department.

But over against the claim of function is the claim of each natural area, such as an urban community or an economic region, to be looked at as a whole for which the total range of administrative functions should make sense and so be co-ordinated. Reconciliation of these claims is thwarted both by the failure of existing local all-purpose administrative areas to expand to a size that would accommodate 20th-century functional requirements, and by the reluctance of functional specialists to accept direction by administrative generalists and political officials.

(J. W. FR.)

ADMINISTRATIVE LAW is the law concerning the powers and procedures of administrative agencies, including the law gov-

erning judicial review of administrative action. An administrative agency is a governmental authority, other than a court or legislative body, which affects the rights of private parties through either adjudication or rule making, *i.e.*, through deciding cases or through subordinate legislation. An administrative agency may be called a commission, board, authority, bureau, office, officer, administrator, department, corporation, administration, division or agency. Nothing of substance hinges on the choice of name, and usually the choices have been haphazard.

Administrative law, as the term is generally but not always used, is limited to law concerning powers, procedures and judicial review. In England and the U.S. the term is used to some extent to include the mass of substantive law produced by the agencies; it is probably better to designate this substantive law by such names as tax law, labour law, transportation law, communications law, and zoning law. Some political scientists regard administrative law as all the law that relates to public administration, but this usage is uncommon among lawyers.

Administrative law consists of constitutional law, statutory law, common law, and agency-made law. The great bulk of administrative law is judge-made law. Some of the judge-made law either is or purports to be constitutional or statutory interpretation; some of it is common law in the sense that it is produced by courts without reliance on either constitutional or statutory provisions; and some of it is judge-made law that may or may not be directly or remotely anchored to constitutional or statutory provisions.

The three large segments of administrative law relate to transfer of power from legislatures to agencies, exercise of power by the agencies, and review of administrative action by courts. The important segment has become the exercise of power by the agencies, *i.e.*, rule making and adjudication, and such incidental powers as investigating, supervising, prosecuting, advising and declaring.

The Place of Administrative Action in Governmental and Legal Systems.—Justice Robert Jackson of the U.S. supreme court once asserted in a formal opinion: "The rise of administrative bodies probably has been the most significant legal trend of the last century and perhaps more values today are affected by their decisions than by those of all the courts, review of administrative decisions apart." The statement relates to U.S. law, but can perhaps be applied almost equally well to the law of western European nations, the major difference being that industries which are regulated in the United States are often directly operated by the governments of western Europe.

Another associate justice of the supreme court has pointed out: "Review of administrative action, mainly reflecting enforcement of federal regulatory statutes, constitutes the largest category of the (Supreme) Court's work, comprising one-third of the total cases decided on the merits." Constitutional law, including "cases with constitutional undertones," was in second place, with less than one-fourth of the cases.

The average person is much more directly and much more frequently affected by the administrative process than by the judicial process. The pervasiveness of the administrative process may be illustrated by samples of what it typically protects against in the U.S.: excessive prices of electricity, gas, telephone and other utility services; unreasonableness in rates, schedules and services of airlines, railroads, streetcars, and busses; disregard for the public interest in radio and television broadcasting; unwholesome meat and poultry; adulteration in food; fraud or inadequate disclosure in sale of securities; physically unsafe locomotives, ships, airplanes, bridges, and elevators; unfair labour practices by either employers or unions; false advertising and other unfair or deceptive practices; inadequate safety appliances; uncompensated injuries related to employment; cessation of income during temporary unemployment; subminimum wages; poverty in old age; industrial plants in residential areas; loss of bank deposits; and perhaps undue inflation or deflation. Probably the list could be expanded to a thousand or more items the public is accustomed to taking for granted.

Political Groups Affected.—The administrative process is a

governmental tool, and as a tool it can be neither conservative nor liberal. It is used to promote probusiness policies, antibusiness policies, and policies having little or nothing to do with business. It has often been used as an instrument of lam reform, but it is also used as a means of protecting vested interests. Yet the administrative process is always a tool for positive government, never a tool for *laissez faire*.

The all-too-prevalent assumption that positive government is contrary to the interests either of business or of big business is false about as often as it is true. Many measures are designed to protect the public against abuses by business, but many major regulatory programs are sponsored by business. In the U.S., radio broadcasters brought about the regulation of radio broadcasting because they wanted a system of assignment of frequencies. Airlines in need of subsidies helped promote the establishment of an administrative authority to dispense subsidies and to supervise the development of an orderly system of routes. Railways and large motor freight carriers joined in sponsoring regulation of the motor carriers. When corporations gained the political power to enact antiunion legislation in 1947, they did not destroy the National Labor Relations board but added to its powers; they authorized the board to administer a system of preventing labour unions from engaging in unfair labour practices. The major petroleum companies initiated the most drastic system of regulation administered by any state agency—oil proration in Texas. Nearly all occupational licensing agencies set up by state legislation, averaging perhaps thirty or forty in each state, have come into being at the instance of regulated groups.

Sometimes agencies established to protect the public are in some measure taken over by the regulated industry. Although much is spoken and written in criticism of the zeal of some agencies, deficiency of administrative zeal may be as grievous a fault as excessive zeal. One of the greatest dangers of the administrative process is that an agency, through lethargy or through immoderate yielding to the influence of the regulated groups, may thwart the democratic mill by acting only when prodded by private interest. "Administrative arteriosclerosis" is a common disease among the older agencies. Excessive zeal, much feared, may be less dangerous than administrative apathy, much ignored.

Historical Development.—Administrative law existed long before the term for it came into use. In 1893 Frank J. Goodnow wrote: "The general failure in England and the United States to recognize an administrative law is really due, not to the non-existence in these countries of this branch of the law but rather to the well-known failure of English law writers to classify the lam. For . . . there (has) always existed in England, as well as in this country, an administrative law."

In the U.S. about one-third of federal peacetime agencies were created before 1900, and another third before 1930. The first federal agency was established in 1789 to "estimate the duties payable" on imports.

In 1916 Elihu Root said: "There is one special field of law development which has manifestly become inevitable. We are entering upon the creation of a body of administrative law . . . There will be no withdrawal from these experiments. We shall go on; we shall expand them, whether we approve theoretically or not, because such agencies furnish protection to rights and obstacles to wrong doing which under our new social and industrial conditions cannot be practically accomplished by the old and simple procedure of legislatures and courts as in the last generation." But leaders of the bar for the most part rejected this wise counsel. Emotional resentment against the rise of administrative power gradually welled up.

In 1929 Lord Hewart's book, *The New Despotism*, gave emphatic and emotional expression to the concern shared by most lawyers both in England and the U.S. But the British committee on ministers' powers investigated and reported "no ground for public fear, if the right precautions are taken." In the U.S. in the 1930s, with the coming of the New Deal, the agencies were not cut back but mere multiplied. A host of new agencies were thorns in the sides of businessmen. If before the New Deal the

antagonism toward administrative agencies was fast reaching the breaking point, the reasons for alarm were now explosive.

In 1937 came the report of the president's committee on administrative management, approved by Pres. Franklin Roosevelt: "Commissions . . . constitute a headless 'fourth branch' of the Government, a haphazard deposit of irresponsible agencies and uncoordinated powers." But congress rejected the recommendations of that committee, and in 1939 the attorney general's committee on administrative procedure was created. The elaborate report of this committee, together with the descriptive monographs on which it was based, has been a primary source of information about the federal administrative process. Out of the report grew the Administrative Procedure act, 1946, which regularized, improved and strengthened administrative procedure, and which preserved the basic limits upon judicial review of administrative action. The American Bar association seemed satisfied even though it had lost its battle for such propositions as "the decisions of controversies must be brought back into the judicial system." But in the late 1950s the American Bar association, following the lead of the second Hoover commission, was again sponsoring legislation designed to cut back administrative power. Attorney General Herbert Brownell, however, said of the Hoover commission's proposals: "These changes would substantially 'judicialize' the administrative process, with disastrous results to efficient and effective government. . . . Far from achieving the Commission's objectives of attaining economy, efficiency, and improved service in the transaction of public business, these proposals would do exactly the contrary."

In 1957 came the report of the British committee on administrative tribunals and enquiries, known as the Franks committee: "In recent years most other western Governments have been called upon to govern more extensively and more intensively. . . . Reflection on the general social and economic changes of recent decades convinces us that tribunals as a system for adjudication have come to stay. . . . Our general conclusion regarding tribunals is that, despite the haphazard way in which they have developed, this method of decision works reasonably well. . . . We regard both tribunals and administrative procedures as essential to our society."

Reasons for Growth of the Administrative Process.—The fundamental reason for resort to administrative agencies is the undertaking by government of tasks which from a strictly practical standpoint can best be performed through them. When U.S. collectors of customs were authorized in 1789 to decide the amounts of duties payable on imported goods, no one was thinking in terms of judiciary v. bureaucracy, capitalism v. socialism, or *laissez faire* v. governmental interference. The same is true of the creation of most other agencies. Practical men were seeking practical answers to immediate problems.

In the 1870s, railroad abuses were insufficiently checked by shippers' common-law actions for refund of unreasonable charges. Farmers in the midwest saw that what was needed was a governmental authority having power not merely to adjudicate but to initiate proceedings, to investigate, to prosecute, to issue regulations, to supervise. State legislatures responded, and then in 1887 the federal congress took action. The Interstate Commerce commission thus came into being and later congresses enlarged its powers as needs were felt. The impetus came not from philosophers or theorists but from down-to-earth men who sought workable machinery for stamping out particular evils.

Gradually the legislative bodies throughout the world developed the system of legislating only the main outlines of comprehensive programs requiring constant attention, and leaving to administrators the tasks of working out subsidiary policies.

The reasons for using agencies rather than courts for adjudication of controversies are numerous and variable. A major reason is that adjudication of issues often grows directly out of administrative handling; for instance, if 99 veterans are admitted to a hospital and only in the 100th case does a controversy arise, the hospital officials or members of their organization may most conveniently conduct whatever proceeding is needed. Much adjudication is outside the competence of courts, which are not qualified

to fix rates or to determine what practices related to rates are to be preferred. Similarly, judges cannot supply the skills of an agency like the Interstate Commerce commission, which requires the assistance of experts on rates, locomotive inspectors, railroad reorganization specialists, explosives experts, valuation engineers, tariff interpreters, accountants, specialists in long- and short-haul problems, and experts on rail traffic congestion. Neither can judges handle 2,000,000 social security claims per year. Even for adjudication of workmen's compensation cases, widespread experience has shown that the courts are not the appropriate tribunals.

Another major reason for the legislative preference for the administrative process has been the belief that the judicial process is unduly awkward, slow and expensive. The public has demanded a speedy, cheap and simple procedure. The fact is that the administrative process is by no means always fast and inexpensive, but the prevailing belief has been that it is.

Some programs have been committed to the administrative process because of a widespread belief, whether or not justifiable, that the biases of judges disqualify them. Sponsors of reform legislation have often thought, rightly or wrongly, that judges, by reason of experience as advocates in favouring the interests of property, tend unduly to construe away sound and necessary reform legislation. In 1914 a senate committee in recommending creation of the Federal Trade commission said: "The people of this country will not permit the courts to declare a policy for them with respect to this subject."

The political outlook both in England and the U.S. is for a long-term continued growth of the administrative process. The Franks committee in England has found administrative tribunals "essential." The attorney general for a conservative administration in the U.S. said in 1955: "Administrative agencies must be enabled and permitted to function efficiently and effectively if the public interest, which is their primary concern, is to be preserved."

Supremacy of Law or Rule of Law.—Although the terms "rule of law" and "supremacy of law" are probably interchangeable their meaning is far from clear. The terms are often emotional: appraisals of the importance of the rule of law usually vary in direct proportion to the vagueness of the meaning the writer or speaker assigns to it.

Seven separate meanings are common:

1. Most people agree with the rule of law in the sense of law and order as distinguished from resort to force. But resistance to the rule of law in this sense crops out from time to time; Sen. James O. Eastland said in 1955: "You are not required to obey any court which passes out such a ruling. In fact, you are obligated to defy it."

2. Exponents of the rule of law often mean merely that they prefer fixed rules to discretion; i.e., what the Massachusetts constitution calls "a government of laws and not of men." The problem of the proper proportion of rule and discretion is of course a central problem in our governmental system. Solutions we work out in practice vary from one context to the other; we inevitably allow wide play for discretion in many areas. The administrative process, as distinguished from the executive process, confines discretion through procedural safeguards and through judicial check; in this respect, as the attorney general's committee on administrative procedure asserted, "the administrative process, far from being an encroachment upon the rule of law, is an extension of it."

3. The rule of law sometimes means elimination of all discretion from governmental processes, and in this sense the rule of law seems impossible of accomplishment. For example, how can a congress be bound by fixed rules on such a question as whether or not to enact social security legislation? Even the U.S. supreme court is not bound by fixed rules in deciding whether or not to overrule a batch of precedents, as it has often done.

4. Sometimes the rule of law means democracy and fairness. Thus, the British committee on administrative tribunals and enquiries, reporting in 1957, referred to "the notion of what is according to the rule of law, its antithesis being what is arbitrary."

But the antithesis of principles or laws is not necessarily arbitrary; it may be reasonable exercise of discretionary power. When the U.S. supreme court overrules a precedent, it may be creating a new principle, but it is not necessarily acting arbitrarily. Nor is an agency necessarily acting arbitrarily when it makes a change in announced policy.

5. The rule of law sometimes means due process, natural law or higher law. The concept of "a law which governs the governors" is a useful one. But the concepts of due process and of natural justice may often be more satisfactory.

6. The rule of law sometimes means a preference for decisions by judges rather than by administrators. John Dickinson, in his book *Administrative Justice and the Supremacy of Law in the United States*, says that "every citizen is entitled . . . to have his rights adjudicated in a regular common-law court." The existence of unreviewable administrative action contradicts Dickinson. His position borders on absurdity when he says that "the law ought to be applied by an agency whose main business is to know the law, rather than to enforce some part of it." This would mean that a judge, not an inspector of hulls and boilers, should decide whether a ship is seaworthy.

7. The rule of law sometimes means that administrative action should be reviewable. But the law, as stated by the U.S. supreme court, is that "courts are not charged with general guardianship against all potential mischief in the complicated tasks of government." Holdings preventing the courts from reviewing even questions of law are not at all uncommon. U.S. courts do not review (a) the budget bureau's recommendation that an appropriation be reduced; (b) the government's purchase of X's land but not Y's; (c) the president's recognition or refusal to recognize a foreign government; or (d) a refusal of executive clemency to a convicted criminal.

Separation of Powers.—Blackstone, drawing from doctrine stemming from Plato, Aristotle, Polybius, Cicero, Machiavelli, Harrington, Locke, and Montesquieu, wrote: "In all tyrannical governments, the supreme magistracy, or the right both of making and enforcing the laws is vested in one and the same man, or one and the same body of men; and wherever these two powers are united together, there can be no public liberty." But Joseph Story, in his *Commentaries on the Constitution*, wrote in 1833: "The slightest examination of the British constitution will at once convince us, that the legislative, executive, and judiciary departments are by no means totally distinct, and separate from each other." The British government of the 20th century continues to mix the three kinds of powers, and yet no government has been more completely free from tyranny.

The U.S. constitution contains no specific provision that the three kinds of powers shall be kept distinct, and the typical administrative agency exercises all three. The supreme court said in 1881 that "it is essential to the successful working of this system that the persons intrusted with power in any one of these branches shall not be permitted to encroach upon the powers confided to the others." But the court has never held that the blending of the various kinds of power in an agency is unconstitutional.

The realities of the law about separation of powers, along with innuendoes about its unrealities, have been stated by Justice Jackson in formal opinion: "They (administrative bodies) have become a veritable fourth branch of the Government, which has deranged our three-branch legal theories much as the concept of a fourth dimension unsettles our three-dimensional thinking. Courts have differed in assigning a place to these seemingly necessary bodies in our constitutional system. Administrative agencies have been called quasi-legislative, quasi-executive or quasi-judicial, as the occasion required, in order to validate their functions within the separation-of-powers scheme of the Constitution. The mere retreat to the qualifying 'quasi' is implicit with confession that all recognized classifications have broken down, and 'quasi' is a smooth cover which we draw over our confusion as we might use a counterpane to conceal a disordered bed."

In framing a constitution for a new government, the idea of separating the three kinds of powers from each other has much

to commend it; modern totalitarian regimes show the advantages of avoiding concentration of power in the hands of any officer or group of officers. But in making relatively small arrangements within a framework already established, the idea that the three kinds of power should not at any level be blended in any one set of hands becomes so impracticable that legislative bodies all over the world reject it. And in the U.S. the supreme court has approved the rejection.

The U.S. constitution itself provides that the president shall participate in the legislative process by approving or vetoing bills and in the judicial process by exercising the power of pardon, that the house of representatives shall act executively in impeaching officers, that the senate shall act judicially in trying impeachments, and that the senate shall participate in an executive function in advising on and consenting to appointments to public office.

The blending of power in a modern U.S. agency can hardly lead to tyranny, for administrative power is typically hemmed in on all sides. Administrators are appointed and reappointed by the president with the advice and consent of the senate. They get their power from congress, which can always withdraw or modify the granted power, and frequently does so. Congressional committees, including appropriations committees, investigate and recommend, threaten and cajole. Within the limits that congress has thought appropriate, administrative action is subject to the check of judicial review. Both congress and the courts have imposed the further checks of procedural safeguards.

The principle whose soundness has been confirmed by both early and recent experience is not the principle of separation of powers but the principle of check. We have gone far beyond Montesquieu. We have learned that danger of tyranny or injustice lurks in unchecked power, not in blended power.

Delegation of Power.—Not only does the British parliament delegate power to whatever extent it chooses but it commonly authorizes ministers to redelegate power to other authorities; the courts do not interfere.

Although the U.S. constitution says nothing about delegation of congressional power except that "all legislative Powers herein granted shall be vested in a Congress" and that congress may "make all Laws which shall be necessary and proper for carrying into Execution the foregoing Powers," the supreme court created a nondelegation doctrine which was especially troublesome during the 1930s and 1940s. In 1932 the supreme court asserted: "That the legislative power of Congress cannot be delegated is, of course, clear." In two cases in 1935 congressional delegations to governmental authorities were held invalid, the only such holdings in U.S. history. But throughout American history congress has delegated legislative power to administrative agencies. Except for unrealistic verbiage that tends to persist, the effective law is in accord with a 1940 statement of the supreme court: "Delegation by Congress has long been recognized as necessary in order that the exertion of legislative power does not become a futility." Much of the judicial talk about requiring a statement of legislative standards in order that a delegation may be valid is contrary to the action the supreme court takes when delegations without standards are upheld.

The problem of delegation is not merely one of determining what organ of government is best qualified to determine particular policies, for whether powers are delegated or not they are often exercised through co-operative arrangements in which many organs of government participate; sometimes the most effective method for expressing legislative will may be delegation, with virtually no standards, but with strong legislative influence upon policy creation after the delegation has been made.

The nondelegation doctrine has been to a considerable extent a judge-made corollary of *laissez faire*, inconsistent with positive government. The ultimate determination of desirable boundaries for delegation must therefore depend in part upon a determination of the proper role of government in society—a determination that the supreme court probably should allow congress to make.

The Power of Investigation.—111 England a ministry or tribunal may compel production of evidence pursuant to an authorizing statute and no constitutional principles stand in the way.

Witnesses have a privilege against self-incrimination, but since 1898 they can be compelled to give incriminating testimony or to produce incriminating documents if they are given a corresponding immunity from prosecution.

In the U.S., constitutional principles before the 1940s often stood in the way of effective administrative investigation. When in 1924 the Federal Trade commission sought records of a tobacco company, Justice Oliver Wendell Holmes said for a unanimous supreme court: "It is contrary to the first principles of justice to allow a search through all the respondents' records, relevant or irrelevant, in the hope that something will turn up." But during the 1940s the effective constitution with respect to the administrative power of investigation was largely turned right around backward by judicial decisions. In 1946 the supreme court made clear that a subpoena for records will be enforced if "the investigation be for a lawfully authorized purpose, within the power of Congress to command," including "general or statistical investigations authorized by Congress." In 1948 the court held that the privilege against self-incrimination does not apply to records required by law to be kept. In 1950 it declared: "Even if one were to regard the (Federal Trade commission's) request for information in this case as caused by nothing more than official curiosity, nevertheless law-enforcing agencies have a legitimate right to satisfy themselves that corporate behavior is consistent with the law and the public interest." Petty officials may now, when authorized by statute, enter a business establishment, demand that records and documents be made available for their inspection and enforce the demand by securing a court order requiring disclosure, even in absence of probable cause to believe that the law has been violated.

On the vital question of whether administrative agencies may have access to business records, three principal ways have been developed for getting around the 5th amendment's provision that "No person . . . shall be compelled . . . to be a witness against himself": (1) statutes provide for compulsory testimony or production of records and confer immunity from prosecution; (2) the courts have created law that records required to be kept are outside the scope of the privilege against self-incrimination; and (3) courts have created law that records of corporations and of some other organizations are not subject to the privilege.

Each step has followed inexorably: Industrialization brings regulation. Regulation necessitates administrative processes. Agencies cannot operate without access to facts. Ideas about privacy, standing in the way of agencies which seek information indispensable to intelligent regulation, have to give way. In the same way that the gasoline engine made inevitable the development of the airplane, mass production methods and all they symbolize produce complex business arrangements which bring forth equally intricate governmental mechanisms requiring effective exercise of the administrative power of investigation. And the courts as a result have felt called upon to write out of the constitution the protections that earlier courts felt called upon to write into it.

Rule Making.—A "rule" or a "regulation" is the product of administrative legislation. Interpretative rules have all degrees of authoritative effect, varying from about zero to full force of law, but legislative rules, if valid, have force of law; the authoritative effect in each instance goes back to statutory intent. Retroactive rule making is often permitted.

Rule-making procedures cover the spectrum from no party participation to full-fledged trials, but the mainstay is submission of tentative drafts to affected parties for written comments. The simple system of deferred effectiveness of published rules in order to allow criticisms has been quite successful. Other methods include consultations and conferences, advisory committees and speech-making hearings. The central problem about rule-making procedure usually is not whether a hearing ought to be held but whether parties should be allowed to participate by some other means.

The English parliament has a committee which systematically reviews rules issued by ministries, but the review concerns only such questions as improper use of power, not the wisdom of the

policy expressed in the rules. The U.S. government has never had a systematic arrangement for legislative review of administrative rules, but congress unsystematically supervises administration as the occasion arises.

Requirement of Opportunity To Be Heard.—A "hearing" is any oral proceeding before a tribunal. Hearings are of two principal kinds—trials and arguments. A trial is a process by which parties present evidence, subject to cross-examination and rebuttal, and the tribunal makes a determination on the record. The key to a trial is the opportunity of each party to know and to meet the evidence and the argument on the other side; this is what is meant by the determination "on the record." The opportunity to meet the opposing evidence and argument includes opportunity to present evidence, to present written or oral argument or both, and to cross-examine opposing witnesses. A typical hearing before an appellate court is an argument, not a trial. A trial is designed for resolving issues of fact, and an argument, not a trial, is normally the appropriate oral process for resolving nonfactual issues of law and policy and discretion. These simple propositions are sometimes misunderstood; agencies sometimes develop nonfactual issues of policy by having "witnesses" express argumentative opinions, and by having opposing counsel present argument in the form of cross-examination.

Facts pertaining to the parties and their businesses and activities, *i.e.*, adjudicative facts, are intrinsically the kind of facts that ordinarily ought not to be determined without giving the parties a chance to know and to meet any evidence that may be unfavourable to them, *i.e.*, without providing the parties an opportunity for trial. But facts which are used only for their bearing upon issues of law and policy, *i.e.*, legislative facts, may often be properly developed without trial, either through presentation to the tribunal in briefs or arguments or through the tribunal's own research.

The key principle is that a party who has a sufficient interest or right at stake in a determination of governmental action should be entitled to an opportunity to know and to meet, with the weapons of rebuttal evidence, cross-examination and argument, any unfavourable evidence of adjudicative facts, except in the rare circumstance when some other interest, such as national security, justifies overriding the interest in fair hearing. Some major exceptions to the principle involve emergency or temporary action, inspection or testing (of an airplane, meat, an obscene book) as a substitute for hearing, and cases involving *de novo* judicial review.

Whether (or when) a party is entitled to a hearing if only a privilege, gratuity or act of grace is at stake has been a troublesome problem. A donee ought not to be allowed to compel the government to make a gift. Nor should a applicant for an act of grace be permitted to coerce officers to make a favourable determination in the exercise of discretionary power. But the government cannot give to Baptists and withhold from Methodists; it cannot give to whites and withhold from Negroes. Can it, then, grant or deny privileges through flagrantly unfair procedure? The answer is sometimes yes and sometimes no.

Because of the concept of privilege, the U.S. supreme court in alien cases, even when human values of the highest order have been at stake, has interpreted vague statutory provisions against the alien and has observed: "Whatever the procedure authorized by Congress is, it is due process as far as an alien denied entry is concerned." Problems of privilege arise concerning government employment, passports, exemption from the draft because of conscientious objection, revocation of probation or parole, and revocation of certain occupational licences.

Institutional Decisions.—An institutional decision of an administrative agency is a decision made by an organization and not by an individual or solely by agency heads. The decision of a trial judge of an ordinary court is personal; the judge hears evidence and argument and decides the case. In the administrative process, evidence may be taken before an examiner (a subordinate officer who presides at a hearing), the examiner or other subordinates may sift the evidence, various kinds of specialists of the agency's staff may contribute to the writing of reports, and the agency heads may in fact lean so heavily on the work of

the staff that they know little or nothing about the problems involved in many of the cases decided in the agency's name. In the institutional decision lie elements of special strength and weakness of the administrative process. The strength springs from the superiority of group work—from internal checks and balances, from co-operation among specialists in various disciplines, from assignment of relatively menial tasks to low-paid personnel so as to utilize most economically the energies of high-paid personnel, and from capacity of the system to handle huge volumes of business and at the same time maintain a reasonable degree of uniformity in policy determinations. The weaknesses of the institutional decision lie in its anonymity, in its reliance on extrarecord advice, in frustration of the parties' desire to reach the men who influence the decision behind the scenes, and in the separation of the deciding function from the writing of the opinion or report.

Problems about the institutional decision are little developed in case law or legal literature outside the U.S. The law in the U.S. is that deciding officers need not personally hear the witnesses testify, that they need not read transcripts of testimony fully, that they may base their decisions upon reports of subordinates analyzing the evidence and making recommendations, and that they must develop their own understanding of the issues and of the relevant evidence.

The volume of business of some regulatory agencies in the U.S. is such that agency heads are forced to rely heavily upon subordinates. Any proposal that the extent of such reliance should be reduced is unrealistic unless it is coupled with some practical suggestion for disposing of the case loads.

Deciding officers are allowed to consult agency specialists freely, so long as extrarecord facts are not improperly used.

Bias.—Courts uniformly hold that bias in the sense of preconceived views about issues of law or policy is not a disqualification, thereby rejecting the surprising position taken by the British committee on ministers' powers that "bias from strong and sincere conviction as to public policy may operate as a more serious disqualification than pecuniary interest." Legislative bodies have often created agencies in order to escape supposed biases of the judiciary or in order to obtain administration of a program in accordance with a desired point of view or bias. Prejudgment of facts bearing upon law or policy is no more a disqualification than prejudgment of philosophy about law or policy; all educated people inevitably have such prejudgments.

Even prejudgment of facts about particular parties is not necessarily a ground for disqualification; this is seen most clearly in cases in which a trial judge who has announced findings of fact is held not disqualified to hear the case a second time after an appellate court has reversed and remanded, and these holdings are generally applied equally to the administrative adjudicator.

Personal prejudice—an attitude of favoritism or animosity toward a particular party—is a disqualification when it is substantial. Of course, a judge or officer who stands to gain or lose by a decision may be disqualified by interest; a disqualifying interest may be pecuniary or professional, it may be based upon a relation to a party, or it may involve a predetermination to achieve a particular objective.

Rules about disqualification of officers are often defeated by "the rule of necessity," under which a disqualified officer may serve when no provision has been made for a substitute tribunal. Resort to the rule of necessity may well induce a court to intensify judicial review.

Combining Prosecuting With Judging.—Judging should not be contaminated by allowing officers who judge to perform inconsistent functions such as prosecuting. Yet the modern administrative agency, as is often pointed out, is sometimes the investigator, accuser, prosecutor, judge, jury and executioner. How can this be justified?

The answer is that incompatible functions ought not to be combined in individuals, but no principle is opposed to a combination of functions in large and complex organizations. After all, in a typical criminal case the governmental unit both prose-

cutes and judges—through the prosecuting attorney and the judge—and no harm results. When an agency keeps separate the staffs engaged in prosecuting and those engaged in judging, the cry of improper combination of functions may have emotional appeal but it is unsound.

Yet, on a subtler basis, the ways in which incompatible functions may be fused are numerous and intricate. Insulation of individuals from personal contact with those who perform incompatible functions may not be enough separation; access to files containing the products of investigation or advocacy might disqualify. Agency heads often read investigators' reports in approving prosecutions and later serve as judges in the same cases. Sometimes the same individual serves as prosecutor in one case and as deciding officer in the next. Advocates and deciding officers may both serve on the staff of the same immediate superior—or of the same remote superior. A supervisor of a staff of advocates may give advice to the agency on questions of law or policy. Research staffs may prepare studies to assist prosecutors and then advise agency heads on the same subject. Staff members may testify as experts at hearings and later give informal advice on the same questions to the deciding officers. These samples of the problem's many facets show that a broadside condemnation or approval of combination of functions is likely to be the product of ignorance. The problem calls for many highly particularized solutions.

By and large, the courts have failed to provide leadership in working out solutions. The controlling cases in the U.S. have held, with few exceptions, that the combination of judging and prosecuting does not deny due process. The U.S. congress has taken several inconsistent positions for different agencies, the most important position being that functions may be combined in agencies but must be separated among individuals within agencies.

Evidence.—The Anglo-American system of law is unique in the world in the extent to which relevant evidence is excluded from consideration. The most important rule in numbers of exclusions is the rule requiring, with exceptions, that hearsay be excluded. Hearsay is any written or oral statement made outside the tribunal and offered for the truth of what is asserted. The hearsay rule is based upon the needs, real or supposed, of protecting untrained jurors from relevant but possibly misleading evidence.

Because the hearsay rule and some other exclusionary rules are based upon the jury system, they are and should be usually inapplicable to administrative proceedings. But they persist to a considerable extent in judge-trying cases, both in England and the U.S., and they still have a good deal of effect in administrative proceedings. Yet the hearsay rule is unknown to the law of the rest of the world except the nations whose legal systems are based upon the English system.

Throughout the Anglo-American system of law, the direction of movement with respect to problems of evidence in all types of tribunals is toward (1) replacing rules with discretion, (2) admitting all evidence that seems to the presiding officer relevant and useful and (3) relying upon "the kind of evidence on which responsible persons are accustomed to rely in serious affairs." The movement has generally gone farther in administrative proceedings than in court proceedings. No good reason can be given for a holding that a rule designed to govern admissibility of evidence before a jury should govern evaluation of evidence before an agency. The alternative to such a holding is not to compel an agency to rely upon hearsay; it is to allow the agency to use its judgment as to whether or not particular hearsay is sufficiently reliable in the circumstances.

Official Notice.—Anyone who uses judgment either about fact-finding or about lawmaking must draw upon previous experience; the determination cannot be limited to the facts in the particular record. When a court properly takes facts from outside the record, it "takes judicial notice" of the facts; similarly, an agency "takes official notice" of extrarecord facts. No other major problem of administrative law surpasses in practical importance the problem of use of extrarecord information in an adjudication.

The cardinal principle of fair hearing that comes into play is not that all facts used should be in the record unless they are indisputable, nor that, as the U.S. supreme court several times has asserted, "nothing can be treated as evidence which is not introduced as such," but it is that parties should have opportunity to meet in the appropriate fashion all facts that influence the disposition of the case. What the appropriate fashion is depends upon three main variables—how far the facts are from the center of the controversy between the parties, the extent to which the facts are adjudicative facts about the parties or legislative facts of a general character, and the degree of certainty or doubt about the facts. Nothing short of bringing the facts into the record, so that an unabridged opportunity is allowed for cross-examination and for presentation of rebuttal evidence, will suffice for disputed adjudicative facts at the center of the controversy. Debatable and critical legislative facts probably need not always be brought into the record, but such facts should be subject to challenge through briefs and arguments, and the tribunal should have a discretionary power to determine whether cross-examination is appropriate in the circumstances. The most obvious facts often may be used without even stating that they are being noticed; 99% of the facts a tribunal uses come from outside the record without mention—that trains run on rails, that coal is not a food, that France is not a part of China, that a man is never 60 ft. tall.

When an officer who is studying a record finds that additional information is both needed and readily available, either from agency files or from agency specialists, a rule forbidding him to go beyond the record will almost surely defeat either the objective of assuring informed decisions or the equally meritorious objective of assuring parties a fair hearing; for if he obeys the rule available information will be kept out of the case, and if he violates the rule he will almost surely act surreptitiously and thereby deprive parties of a chance to meet the extrarecord information. To encourage the officer to use the information and to summarize it in his report will produce a superior substantive result and will also provide a better protection for the parties' procedural rights, for the parties then have opportunity to present argument about the new information or to move to reopen the hearing for cross-examination and rebuttal evidence.

Tort Liability of Governmental Units.—The governments of continental Europe have long made themselves liable for torts their agents commit against private parties. But in both England and the U.S., the prevailing doctrine has been that "the king can do no wrong." For instance, a pedestrian injured by the negligence of a driver may collect damages if the vehicle is owned by a private corporation but not if it is owned by the government. The doctrine of sovereign immunity came into U.S. law through judicial decisions but without a deliberate choice; the supreme court acknowledged in 1882 that "while the exemption of the United States and of the several states from being subjected as defendants to ordinary actions in the courts has since that time been repeatedly asserted here, the principle has never been discussed or the reasons for it given, but it has always been treated as an established doctrine."

Tort liability of the U.S. and British governments was at last established, with some exceptions, by the Federal Tort Claims act of 1946 and the Crown Proceedings act of 1947. But most U.S. state and local governments retain a large degree of sovereign immunity; a good deal remains to be done to make governmental units liable in tort whenever a private party would be liable in the same circumstances.

The problem that is in need of further study is the planning of a system of liability and immunity with respect to functions that have no private counterpart.

Officers' Tort Liability.—The central principle that takes care of the great bulk of practical problems concerning tort liability of public officers and public employees is that officers are generally immune from liability for their unintentional fault in the exercise of discretionary functions. By and large, the law both in England and the U.S. is the antithesis of A. V. Dicey's proposition that "every official, from the Prime Minister down to a constable or a collector of taxes, is under the same responsi-

bility for every act done without legal justification as any other citizen." It is doubtful that English courts at any time would have held the prime minister liable personally on account of an exercise of discretionary power.

Some cases hold that an officer exercising discretionary power may be liable for malicious action; the U.S. supreme court has held, five to four, that such an officer is not liable even for malicious action. Some cases hold that such an officer may be liable for tortious action in excess of his jurisdiction.

An employee performing ministerial acts has long been liable for his own torts even when he works for a governmental authority. But the supreme court has held that the government, after it had been held liable under the Tort Claims act for an employee's negligence in driving a government automobile, cannot recover indemnity from the employee.

Judicial Review.—When private rights are at stake, administrative action is usually subject to a limited judicial review, although some administrative action is unreviewable and some is subject to *de novo* review. A limited judicial review does not weaken the administrative process but strengthens it. Cutting off what the courts have to offer to a governmental program may violate the cardinal principle that functions should be allocated between courts and agencies on the basis of comparative qualifications of each tribunal. And a check upon administrative authority is usually desirable for the same reasons that an appellate court's check upon a trial court is desirable.

Subject to exceptions and qualifications, a party who seeks judicial review of administrative action (1) must exhaust his administrative remedies; (2) must satisfy the requirements of ripeness for review (so that the issues will be real and present, not hypothetical or remote); (3) must have standing to obtain review (i.e., be properly qualified as a moving party); (4) must choose an appropriate form of proceeding; and (5) must satisfy the requirements of reviewability. The law of each of these four categories is highly technical and complex.

Although the scope of review of administrative action ranges from complete unreviewability to complete substitution of judicial judgment on all questions, the dominant tendency is toward a middle position under which the court decides issues of law but upholds discretionary determinations and findings of fact if they are reasonable.

Broadly, questions of law include not only common law, statutory interpretation and constitutional law but also questions of administrative jurisdiction, of fair administrative procedure and of protection against arbitrary or capricious action or abuse of discretion.

In general, the scope of review of administrative findings of fact is about the same as the scope of review of jury verdicts, but it is slightly narrower than the scope of review of findings made by a judge without a jury.

Unlike England, the U.S. has constitutional limits, both minimum and maximum, on judicial review. Two doctrines that have been important but are in process of dying are that a public utility which claims confiscation from a rate order is entitled to an independent judicial determination of both law and fact, and that a party to a workmen's compensation case is entitled to a judicial determination of facts on which constitutionality or the agency's jurisdiction depends. The maximum constitutional limit prevents a court from doing all over again what an agency has done in the exercise of nonjudicial functions.

Because review of law is broader than review of facts, the law-fact distinction becomes vital. But what is law and what is fact does not always reflect a literal meaning of those terms. Courts often decide on functional grounds whether or not substitution of judicial judgment is desirable; if it is, the question is called a question of law, and if it is not, the question is called a question of fact. The tendency to allocate powers between agencies and courts on the basis of policy considerations and then to attach labels accordingly resembles what common-law courts did centuries ago when they used policy reasons in dividing functions between judges and juries and then called jury questions "fact" and judge questions "law." Thus, what is fact and what

is law is not a question of fact but a highly artificial question of law.

The principal consideration that determines the extent to which a court substitutes judgment for an agency's judgment is the comparative qualification of the court and of the agency on the particular question. When a problem of radio engineering has been decided by radio engineers who are members of the Federal Communications commission's staff, legally trained judges can hardly be expected to try to substitute their judgment, even though the specialists' determination may well be checked by the judges. However, substitution of judicial judgment is desirable in many categories of cases, including those involving problems which (1) transcend the single field of the particular agency, (2) call for interpretation of the common law, (3) are primarily problems of ethics or fairness of a common-law type, (4) are affected substantially by constitutional considerations, whether or not a constitutional issue is directly presented, (5) require analysis of legislative history, especially when political conflict is the essence and not legislative inquiry into technical understanding within the agency's field of specialization, (6) bring into question judge-made law previously developed in the course of statutory interpretation and (7) impel the reviewing court to make a discretionary choice for any reason, explained or unexplained, to create or mold law as a guide for the agency and for affected parties.

ADMIRAL, the title and rank of a senior naval officer, often referred to as a flag officer, who commands a fleet or group of ships of a navy, or who holds an important naval post on shore. The term is also applied to the commander of a fleet of merchant vessels or fishing ships.

The title has an ancient lineage. It apparently originated with Moslem Arabs who combined *amir* (commander), the article *al*, and *bahr* (sea), to make *amir-al-bahr*, before the 12th century. Shortened to *amiral* it was adopted for naval use by the Sicilians. The French copied the word from the Genoese during the crusade of 1249. The Latin word *admirabilis* helped to produce the title admiral for the commander of the Cinque Ports (*q.v.*) in England before the end of the 13th century.

In Europe it became the title of a great officer of the crown: in France as *grand amiral*, in Spain as *almirante mayor*, and in England as lord high admiral. The noblemen who held these posts were not seamen and did not command at sea except on rare occasions; they were heads of departments that administered naval

affairs. They were responsible for providing ships for war and their duties usually brought them large fees. They also had jurisdiction in legal cases of the types afterward handled by admiralty courts. (See ADMIRALTY; ADMIRALTY, HIGH COURT OF.)

By 1620 the word admiral was used in England to denote a commander at sea. In that year the fleet was formed into three squadrons with the admiral commanding the centre squadron, his ships flying red ensigns. The vice-admiral in the van squadron flew white ensigns and the rear admiral flew blue ensigns in his squadron. By 1660 the fleet had grown so large that three divisions were created in each squadron and at the same time the white squadron was placed in the van and the blue squadron in the rear. There were then nine flag officers of the Royal Navy: an admiral of the fleet; admirals of the white and blue; vice-admirals of the red, white and blue; and rear admirals of the red, white and blue.

In 1718 the title admiral of the fleet ceased to be an office and became a rank. In later times it corresponded to the rank of field marshal in the army or marshal of the Royal Air Force. The rank of admiral corresponded to general or air chief marshal; vice-admiral corresponded to lieutenant general or air marshal; and rear admiral corresponded to major general or air vice-marshal. After 1864, ships of the Royal Navy flew the white ensign and the designation of admirals of the red, white and blue ended.

The U.S. navy had no admirals before the Civil War, the highest rank in those years being commodore. On July 16, 1862, congress authorized appointment of four rear admirals on the active list and eight on the retired list. David G. Farragut became the first officer of the U.S. navy to be promoted to the rank of vice-admiral, on Dec. 21, 1864. He attained the rank of admiral on July 25, 1866. David D. Porter succeeded him in these ranks, and Stephen C. Rowan succeeded as vice-admiral.

On March 3, 1899, following his notable service during the Spanish-American War, George Dewey was promoted to a new rank, admiral of the navy. Laws enacted in 1915 provided that the chief of naval operations and three commanders in chief of fleets were to hold the rank of admiral while serving in these positions. The laws also provided for three vice-admirals in the three fleets.

In Dec. 1944 congress created a new rank, fleet admiral, and bestowed it upon three officers, William D. Leahy, Ernest J. King and Chester W. Nimitz. William F. Halsey was promoted to this rank a year later. Without additional legislation no other officer could be promoted to this rank. A fleet admiral ranks with a general of the army or general of the air force, both new World War II titles. Admiral ranks with general, vice-admiral with lieutenant general and rear admiral with major general. A fleet admiral's flag is blue with five white stars and his uniform insignia consists of five stars, as does that of a general of the army or the air force. (See INSIGNIA, MILITARY.) An admiral's flag has four stars, a vice-admiral's three and a rear admiral's two. A rear admiral of the medical corps commanding a naval hospital flies a white flag with two blue stars; a rear admiral of the supply corps flies the same flag over a naval supply depot.

The Royal Navy appointed a second admiral of the fleet in 1862, a third in 1863. The number rose to four in 1898 and after World War II it increased until there were 16 in 1958. Admirals in the Royal Navy are not flag officers unless appointed as such; but they are officers of flag rank. The union flag is flown at the mainmast head by an admiral of the fleet. The flag of an admiral is the St. George's cross, that of a vice-admiral the cross with one red ball and that of a rear admiral the cross with two red balls.

(J. B. HN.)

ADMIRALTY. In Great Britain the board of admiralty, usually referred to simply as "the admiralty," is the government department that manages naval affairs. It corresponds in a general way to the navy department in the United States and to the ministry of marine in France. It is served by the admiralty divisions of the naval staff and by admiralty departments that deal with such matters as the provision of warships, aircraft, munitions, manning of ships, and the general organization and administration of the fleets and shore establishments.

The admiralty is unlike the ordinary British government de-

partments, which are under a secretary of state or minister with powers defined by act of parliament. In ancient times the navy was governed by a "great officer of state" called the lord high admiral of England. Early in the 18th century the office was placed in the hands of commissioners known as the board of admiralty, and with rare exceptions has so remained ever since. Thus the board of admiralty derives its powers from the royal prerogative; no act of parliament defines or circumscribes them, except inasmuch as the discipline of the navy is regulated by a Naval Discipline act. In pure law, the commissioners share a joint and equal responsibility, but an order in council of 1869 conferred upon the first lord of the admiralty overriding powers and responsibilities.

In the late 1950s the "commissioners for executing the office of lord high admiral of the United Kingdom" were ten in number. Three of them were members of parliament; six were naval officers; and one was the permanent secretary. Each of the lords commissioners has special duties and responsibilities. The first lord of the admiralty must by law be a member of parliament, sitting in either the upper or lower house, and a privy councillor. He is the minister responsible to parliament for the navy. The first sea lord is chief of the naval staff and is the principal adviser to the government on professional naval matters. The second sea lord is chief of naval personnel and the third sea lord is the controller, responsible for engineering, equipment, ordnance and research. The fourth sea lord deals with supplies and transport and the fifth sea lord has responsibility for naval aviation.

The other commissioners are the vice chief of the naval staff, the parliamentary and financial secretary (a member of parliament), the civil lord (also a member of parliament), and the permanent secretary. The latter is the senior civil servant in the admiralty with responsibility for the general conduct of admiralty business. The titles indicate the nature of the duties and responsibilities of the members. The first lord, the civil lord and the parliamentary and financial secretary resign automatically whenever the prime minister resigns, and the resignations of the sea lords may also occur at the same time. The composition of the board of admiralty can be changed by order in council, and has in practice varied widely in modern times depending on the needs of the moment. In general, the board has been enlarged in time of war by the addition of a deputy first sea lord, by separating the offices of parliamentary and financial secretary, and by other devices to secure the presence on the board of men with specialized knowledge.

Another way in which the admiralty differs from the other British service ministries is that it functions as an operational authority, sometimes actually issuing direct orders to ships at sea. This has been so for three centuries, and before the close of the 18th century a chain of mechanical telegraphs linked the admiralty in Whitehall to the principal naval ports. Another relic of earlier times is the wind direction indicator in the board room, operated from a weather cock on the roof of the old building. The advent of wireless telegraphy greatly increased the practice of direct control from the admiralty. During World War I, an order in council gave power to the first sea lord, acting in conjunction with one other sea lord, to issue operational orders to fleets and ships. During World War II, an operational plot of all shipping in the Atlantic and home waters was kept at the admiralty, and frequent interventions were made from Whitehall in the hour-to-hour conduct of operations at sea. Although this practice has been criticized by postwar historians, the fact remains that the admiralty's advice and warning to ships operating in enemy waters concerning the movements of hostile ships and aircraft was usually prompt and accurate to an extraordinary degree.

The admiralty is responsible for the government's economic policy in the shipbuilding and ship repair industries, and in certain minor allied industries. It undertakes research to meet naval requirements and administers both the Royal observatory and the National Institute of Oceanography.

The military and civilian staff of the admiralty was much increased in numbers during World War II and in successive years,

and was not afterward cut back to its prewar level. The admiralty building in Whitehall, London, adjoining the Horse Guards, dates from 1722-26, while the quadrangle in the rear along the north side of the Horse Guards parade was added after 1887. The admiralty arch at the end of the mall was completed in 1910. Bombproof additions to the quadrangle were made in the years 1930-42 to house the operational plotting activities.

BIBLIOGRAPHY.—The work and organization of the admiralty are described in a series of articles by Sir Oswyn Murray in *Mariner's Mirror*, the journal of the Society for Nautical Research (1937-39). See also S. W. Roskill, *The War at Sea 1939-45*, vol. i (1954); T. K. Derry, *The Campaign in Norway* (1952); *Britain, an Official Handbook* (1958). (J. B. Hx.)

ADMIRALTY, HIGH COURT OF. The high court of admiralty of England was the court of the deputy or lieutenant of the admiral. It is supposed in the *Black Book of the Admiralty* to have been founded in the reign of Edward I; but it appears that it was established as a civil court by Edward III in the year 1360, the power of the admiral to determine matters of discipline in the fleet, and possibly questions of piracy and prize, being somewhat earlier. At first there were separate admirals or rear admirals of the north, south and west, each with deputies and courts. These were merged in or absorbed by one high court early in the 15th century. Sir Thomas Beaufort, appointed admiral of the fleet 1407, and admiral of England, Ireland and Aquitaine 1412, certainly had a court, with a marshal and other officers, and forms of legal process—mandates, warrants, citations, compulsories, proxies, etc.

Jurisdiction.—The original object of the institution of the courts or court seems to have been to prevent or punish piracy and other crimes upon the narrow seas and to deal with questions of prize; but civil jurisdiction soon followed. The jurisdiction in criminal matters was transferred by the Offences at Sea act, 1536, to the admiral or his deputy and three or four other substantial persons appointed by the lord chancellor, who were to proceed according to the course of the common law. By the Central Criminal Court act, 1834, cognizance of crimes committed within the jurisdiction of the admiralty was given to the central criminal court. By an act of 1844 it was also given to the justices of assize; and crimes done within the jurisdiction of the admiralty are now tried as crimes committed within the body of a county.

The early jurisdiction of the court appears to have been exercised very much under the same procedure as that used by the courts of common law. Juries are mentioned, sometimes of the county and sometimes of the county and merchants. But the connection with foreign parts led to the gradual introduction of a procedure resembling that coming into use on the Continent and based on the Roman civil law.

Restraining Acts.—The material enactments of the restraining statutes were as follows: An act of 1389 (13 Ric. II c. 5) provided that "the admirals and their deputies shall not meddle from henceforth of anything done within the realm, but only of a thing done upon the sea, as it hath been used in the time of the noble prince king Edward, grandfather of our lord the king that now is." The act of 1391 (15 Ric. II c. 3) provided that "of all manner of contracts, pleas and quarrels, and other things rising within the bodies of the counties as well by land as by water, and also of wreck of the sea, the admiral's court shall have no manner of cognizance, power, nor jurisdiction; but all such manner of contracts, pleas and quarrels, and other things rising within the bodies of counties, as well by land as by water, as afore, and also wreck of the sea, shall be tried, determined, discussed and remedied by the laws of the land, and not before nor by the admiral, nor his lieutenant in any wise." The statutes of Richard, except the enabling part of the second, were repealed by the Civil Procedure Acts Repeal act, 1879. The formation of a high court of justice rendered them obsolete.

In the reign of James I the chronic controversies between the courts of common law and the admiralty court as to the limits of their respective jurisdictions reached an acute stage. It is recorded that, notwithstanding an agreement asserted to have been made in 1575 between the justices of the king's bench and the judge of the admiralty, the judges of the common law courts

successfully maintained their right to prohibit suits in admiralty upon contracts made on shore, or within havens, or creeks, or tidal rivers: if the waters were within the body of any county, whosoever such contracts were broken, as well as for torts committed within the body of a county, whether on land or water, and for contracts made in parts beyond the seas.

Judge's Patent.— All the while, however, the patents of the admiralty judge purported to confer on him a far ampler jurisdiction than the jealousy of the other courts would concede to him. The patent of the last judge of the court, Sir Robert Joseph Phillimore, dated Aug. 23, 1867, gave to him power to take cognizance of "all causes, civil and maritime, also all contracts, complaints, offences or suspected offences, crimes, pleas, debts, eschanges, accounts, policies of assurance, loading of ships, and all other matters and contracts which relate to freight due for the use of ships, transportation, money or bottomry; also all suits civil and maritime between merchants or between proprietors of ships and other vessels for matters in, upon, or by the sea, or public streams, or fresh-water ports, rivers, nooks and places overflowed whatsoever within the ebbing and flowing of the sea, and high-water mark, or upon any of the shores or banks adjacent from any of the first bridges towards the sea through England and Ireland and the dominions thereof, or elsewhere beyond the seas." Power is also given to hear appeals from vice-admirals; also "to arrest . . . according to the civil laws and ancient customs of our high court . . . all ships, persons, things, goods, wares and merchandise"; also "to enquire by the oaths of honest and lawful men . . . of all . . . things which . . . ought to be enquired after, and to mulct, arrest, punish, chastise, and reform"; also "to preserve the public streams of our admiralty as well for the preservation of our royal navy, and of the fleets and vessels of our kingdom . . . as of whatsoever fishes increasing in the rivers"; also "to reform nets too straight and other unlawful engines and instruments whatsoever for the catching of fishes"; also to take cognizance "of the wreck of the sea . . . and of the death, drowning and view of dead bodies," and the conservation of the statutes concerning wreck of the sea and the office of coroner (1276), and concerning pillages (1353), and "the cognizance of mayhem" within the ebb and flow of the tide.

Later Developments.— The contention of the common law judges prevailed, and the admiralty court (except for a temporary revival under Cromwell) sank into comparative insignificance during the 17th century. The great maritime wars of the 18th century gave scope to the exercise of its prize jurisdiction; and its international importance as a prize court in the latter half of the 18th and the first part of the 19th centuries is a matter of common historical knowledge. There were upwards of 1,000 to 2,000 prize causes each year between 1803 and 1811.

In the reign of Queen Victoria, two enabling statutes, 1840 and 1861, were passed and greatly enlarged the jurisdiction of the court. The manner in which these statutes were administered by Dr. Stephen Lushington and Sir R. J. Phillimore, whose tenure of office covered the whole period of the queen's reign till the creation of the high court of justice, the valuable assistance rendered by the nautical assessors from the Trinity House, the great increase of shipping, especially of steam shipping, and the number and gravity of cases of collision, salvage and damage to cargo, restored the activity of the court and made it one of the most important tribunals of the country. In 1875, by the operation of the Judicature acts of 1873 and 1875, the high court of admiralty was with the other great courts of England formed into the high court of justice. The principal officers of the court in subordination to the judge were the registrar (an office which always points to a connection with canon or civil law), and the marshal, who acted as the maritime sheriff, having for his baton of office a silver oar. The assistance of the Trinity masters was provided for in the charter of incorporation of the Trinity House. These officers and their assistance have been preserved in the high court of justice.

Practitioners in the Court.— Till the year 1859 the practitioners in the high court of admiralty were the same as those in the ecclesiastical courts and distinct from those who practised in

the ordinary courts. Advocates took the place of barristers, and proctors of solicitors. The place of the attorney general was taken by the king's or queen's advocate general, and that of the treasury solicitor by the king's or queen's procurator or proctor. There were also an admiralty advocate and an admiralty proctor.

In an act of 1859 the practice was thrown open to barristers and to attorneys and solicitors.

Upon the next vacancy after the courts were thrown open, the crown altered the precedence and placed the queen's advocate after the attorney general and solicitor general. There were two holders of the office under these conditions, Sir R. J. Phillimore and Sir Travers Twiss. The office was not filled up after the resignation of the latter, nor was the office of admiralty advocate filled up when next it became vacant.

Ireland.— The high court of admiralty of Ireland, being formed on the same pattern as the high court in England, sat in the Four Courts, Dublin, having a judge, a registrar, a marshal and a king's or queen's advocate. In peace time and war time alike it exercised only an instance jurisdiction, though in 1793 it claimed to exercise prize jurisdiction. No prize commission ever issued to it. By the Irish Judicature act of 1877 it was directed that it should be amalgamated with the Irish high court of justice upon the next vacancy in the office of judge, and this subsequently took place. There was no separate lord high admiral for Ireland.

Scotland.— At the union, while the national functions of the lord high admiral were merged in the English office it was provided by the Act of Union that the court of admiralty in Scotland should be continued "for determination of all maritime cases relating to private rights in Scotland competent to the jurisdiction of the Admiralty Court." This court continued until 1831, when its civil jurisdiction was given to the court of session and the sheriffs' courts (*see* MARITIME LAW). (P.; X.)

ADMIRALTY ISLANDS, a group of about 40 islands in the southwest Pacific about 380 mi. N.W. of Rabaul. New Britain. The group forms a northwest extension of the Bismarck archipelago and has an area of 800 sq.mi. With other small island groups to the west and southwest it constitutes the Manus administrative district of the trust territory of New Guinea (*q.v.*), administered by the commonwealth of Australia.

The only large island is Manus, or Great Admiralty Island, which is about 50 mi. long and 17 mi. wide. The highest point is Mt. Dremsel (2,356 ft.) in the southcentral part of the island; many ridges reach heights above 1,000 ft. Lowlands are restricted to the narrow east coast plain and the lower river valleys. Most of the island is densely forested, with mangroves along the coasts. The coasts are fringed with coral, which also composes most of the other islands.

Seadler harbour on the northeast coast is a good natural harbour, and near it is Lorengau, the administrative centre. The indigenous population of the islands, of Melanesian affinities, numbered 15,014 in 1954; three major groups of people can be distinguished. After World War II Manus became a centre of the so-called "cargo-cults" (*see* NEW GUINEA: Anthropology). The nonindigenous population numbered 840, of whom fewer than 50 were Europeans. The only important product is copra. The coconut plantations are all long-established, but were considerably reduced in area after World War II. Fishing and local trading are carried on by the natives in outrigger canoes.

The islands were first sighted by Willem Cornelis Schouten in 1616 and were named by Capt. Philip Carteret in 1767. They became part of the German protectorate in 1884, were occupied by the Australians in 1914 and were included in the territory mandated to Australia in 1921. Taken by the Japanese in 1942, they were liberated in March 1944. *See also* PACIFIC ISLANDS.

(D. W. F.)

ADMIRALTY JURISDICTION. The judicial power vested in the U.S. federal courts by the constitution extends "to all Cases of admiralty and maritime Jurisdiction," and by act of congress this jurisdiction is explicitly withheld from the courts of the states. The exclusiveness of the federal jurisdiction is, however, greatly modified by an exception, "saving to suitors in all cases all other remedies to which they are otherwise entitled."

In practical effect, while any admiralty or maritime case may be maintained in a federal court, any civil maritime case except a libel *in rem* may be maintained in a state court. See MARITIME LAW. (B. CE.)

ADOBE is a Spanish word for sun-dried clay bricks (*q.v.*); it also applies to a structure built from such bricks and to the clay soil from which the brick or structure is made. It comes from the Arabic word atob meaning "sun-dried brick." Adobe is basically a calcareous, sandy clay, having good plastic qualities and drying to a hard uniform mass. Its use (or that of clays with similar properties) dates back many thousands of years in several parts of the world, particularly those areas with an arid or semi-arid climate. Techniques varied, but all took advantage of the special properties of adobe.

This use of earth for building construction resulted partly from the scarcity of wood as a building medium, partly from the ease of such construction and its insulation value against both heat and cold. Adobe or sun-dried bricks are found in the old world in the dry areas east of the Mediterranean sea, in north Africa and in southern Spain. In the western hemisphere adobe appears in many of the pre-Columbian sites from the G.S. southwest to Peru, always, again, in those regions with a dry climate. The American aborigines built walls by hand manipulation of the plastic clay into courses, allowing each course to dry before adding the next. Forms such as are necessary for rammed earth or concrete construction were not used.

Sometimes the bricks were hand shaped and more or less loaf-like. Molds for shaping the bricks, probably introduced into Spain from Africa, came to the new world at the time of the Spanish conquest.

The usual modern method of making adobe is very simple. It consists of wetting a quantity of suitable soil and allowing it to stand for a day or more to soften and break up clods. A small quantity of straw or other fibrous material is added and the materials are mixed with a hoe or similar implement. The mass is then trampled with the bare feet.

When it is brought to the proper consistency, the adobe is shaped into bricks in simple molds. The molds, made of smooth lumber or sheet metal, are four-sided and open at the top and bottom. Although they vary widely in size, depending on the intended use of the finished brick, they are usually from 3 to 5 in. thick, 10 or 12 in. wide and 14 to 20 in. long. The plastic adobe must be moist enough to fill the mold completely but not too wet to prevent its easy removal. The bricks are allowed to dry partially while flat on the ground; then they are stacked on edge to permit more thorough and uniform drying. The bricks are not used until thoroughly dry. This usually takes at least two weeks under average dry climate conditions. The addition of straw or similar material helps to prevent shrinkage cracks during the curing process but does not add any structural advantage to the finished product.

Adobe walls should be built on a solid, waterproof foundation of stone or concrete because otherwise the capillary action of ground water will cause the lower courses to disintegrate. The bricks are laid in a mortar of the same material, then finished with a coat of adobe, or sometimes with lime or cement plaster. With care in construction and protection against moisture by proper attention to repair, an adobe wall is very enduring. Some such walls, centuries old, are still in use.

The chief advantages of adobe as a building material lie in its availability in dry regions; its relative cheapness, particularly when labour costs are low; and its remarkable insulation properties.

The physical properties of adobe when tested as a building material indicate an optimum value for one-story structures with a possible limitation to three or four stories.

ADOBE SOIL, a term used in the western United States, particularly in California, to designate the structural quality of various clay soils, referring usually to the characteristic breakage of such soil material into small angular blocks when it dries. These soils are very heavy in texture, being composed of extremely fine-grained material, a large part of which is colloidal. Sands and loose sandy loams, for example, never display an adobe soil structure. Under proper conditions of moisture, soils of adobe structure are readily worked, but when too dry their hardness and coherence make tillage extremely difficult. When placed under irrigation, soils of this type usually display great fertility. For adobe building materials, see ADOBE.

ADOLESCENCE is usually defined as the period of transition between childhood and adulthood. Although some writers equate adolescence with puberty and the cycle of physical changes culminating in reproductive maturity, a more common view is to define adolescence in psychological and social terms as beginning with pubescence and terminating vaguely with "adulthood." Perhaps a better usage of the term is as a convenient label referring to a period of years (approximately ages 12 to 20) in the life of an individual, since such usage makes no a priori commitments regarding the character of adolescent development or the specific nature of the causal variables (*e.g.*, pubescence).

Any period of life tends to be characterized by a group of developmental problems which are biological, psychological and social in origin and timing. Among those which typically but not necessarily occur during the second decade of life are adjustments in the areas of heterosexual relations, occupational orientation, the development of a mature set of values and the development of responsible self-direction and the breaking of close emotional ties to parents. In a sense, such developmental tasks define adolescence and represent areas in which satisfactory adjustments must be made if future psychological development is to be possible.

Interpretations of Adolescence.—Authorities are not in agreement as to the nature of adolescence. To the popular mind and to many specialists, adolescence is presumed to be a psychologically stressful and critical period, characterized by a variety of special types of behaviour.

According to one viewpoint, essentially biological and stemming mainly from psychoanalytic literature, adolescence is initiated at pubescence by the sudden upsurge of sex feelings following the sexually tranquil period of latency. Adolescence is the period when the individual is learning to control and properly direct his sex urges and is terminated when such control and direction are established. The whole process is presumed to be highly stressful emotionally and to give rise to a variety of behaviours, ranging from avoidance of the opposite sex to the writing of diaries, which are thought to be characteristic of adolescence and which serve to reduce the sex-generated anxiety. A biological view of adolescence implies a certain universality of occurrence.

Cultural views, while typically assuming adolescence to be stressful, nonetheless specify that "adolescence" will occur only under certain circumstances. It is asserted that quite generally children are not given gradually graded opportunities for maturing experiences compatible with their physical and intellectual development, and thus they experience a sudden widening of their world during their teens. This relatively sudden encountering of new ideas, new concepts, new values, new types of people, as well as the relatively sudden responsibility for self-determination and self-sufficiency, force a whole array of adjustments upon the comparatively inexperienced young person and generate much apprehensiveness and anxiety. Furthermore, the teen-ager has no defined role of his own in society but is caught in the ambiguous overlap between the reasonably clearly defined roles of childhood and adulthood. Sometimes treated as a child, sometimes expected to be adult, he is uncertain how to behave. It is also pointed out that society serves to frustrate important psychological needs of the young person (*e.g.*, sex and desire for independence), thus generating aggression or other reactions, many of a socially disapproved type. Whatever the specific formulation, cultural views recognize that adolescence, as typically defined, will exist in the

degree that conditions such as the foregoing prevail in a particular culture or a particular home.

The "Storm and Stress" Hypothesis and Adolescent Behaviour.—Theories of adolescence such as the preceding may be summarized as involving (1) causal conditions either biological or cultural (sudden emergence of the sex drive, sudden widening of life space, moving into an unstructured period of life where a well-defined role does not exist) which (2) generate anxiety or emotional stress to an unusual degree compared with other age periods, which, in turn, (3) provoke a variety of defensive behaviours or symptoms which constitute "typical" adolescent characteristics. Since in one way or another, explicitly or not, many professional and most popular views of adolescence assume some such sequence as the foregoing, the conception requires careful consideration and evaluation.

As will be noted later with respect to the first of these three phases, there is serious question as to whether the biological and cultural conditions assumed by various interpretations are in fact present. With respect to the second phase, actual data suggest that emotional stress is much less than ordinarily assumed; in fact, most studies involving sufficiently large samples of subjects and a wide enough age perspective show no increased incidence of anxiety symptoms associated either with pubescence or with the teens. Surveys of frequency of worries, observations of emotional episodes in classrooms, actual counts and questionnaire surveys of specific nervous symptoms, as well as data derived from specialized psychological tests (*e.g.*, the Rorschach ink-blot test), reveal no increased emotional disturbance. One extensive study (based on 3,300 subjects) led to the conclusion that while age gains were evident over the range 9 to 17 years, in measures reflecting competence (skill, problem solving, work habits) there were no increases correlating with age in measures relating to feelings and emotions.

The picture is not entirely one-sided, however. In one study 9th and 12th graders had more unpleasant and fewer pleasant experiences than did 6th graders. In another investigation, reaction time to stimulus words such as "worry," "afraid" and "unhappy" shoned a sharp increase at age 13 for girls and 14 for boys and stayed high until 17 but declined in adult years. Such inconsistent findings are difficult to interpret, but if adolescence is a period of emotional upheaval, indications should appear in most rather than in only a few studies.

With respect to the third phase of the sequence, that relating to the types of behaviours presumed to be characteristic of adolescence and generated by the presumed emotional turmoil, the evidence is no more consistent. Marked vacillation in interpersonal attachments is often assumed, yet research indicates that teen-agers are more stable in their friendships and in other respects than are younger children. It is assumed that the frustrations posed by society will lead to aggressive behaviour which may find expression in delinquency (a striking out against society) or more commonly in conflict or belligerence toward adult authority figures such as parents or teachers. In general, available evidence shows that aggressive tendencies decline with age, with no peak at adolescence. Delinquency data pose special problems of interpretation since the term has a legal rather than a psychological definition. Crime rates (as reflected in admission to penal institutions) do increase during the teens but reach a peak in the young adult years. No special relationships to pubescence or adolescence are evident in the over-all picture. Evidence bearing on parent-child relationships fails to provide convincing proof of increased belligerency (see below). Daydreaming, which may be construed as a means through which gratification of frustrated needs is achieved, does seem to increase during the teens and to decline in frequency in the adult years.

The psychopathology of adolescence is of interest to many, and data showing the incidence of suicide and mental illness are often cited as indicative of one outcome of adolescent turmoil. While suicide and mental illness increase markedly from the early to the late teens, there is no adolescent peak; the rate curve continues to climb in adulthood. (See PSYCHOLOGY, ABNORMAL)

Physical Growth.—On the average a child enters a period of

accelerated growth just prior to pubescence. The greatest increase in height is at about 11.5 years of age for girls and about 13.8 years for boys according to one study, and at 12.6 and 14.8 according to another. There is no strong evidence that the general prepubertal growth spurt or the differential timing of growth in various dimensions causes a decline in motor co-ordination. Since larger children tend to enter the period of rapid growth early, the range of differences among individuals at any given age increases until the average ages noted above for the two sexes and then decreases as the slower developers catch up. Thus children of junior high school age are more heterogeneous in size and general maturity than young people of any other age. Because of their earlier development, girls are notably taller and more mature than boys at about this age.

The mean age of first menstruation, usually taken as the age of pubescence in girls, is approximately 13. About one-sixth reach the menarche before 12 and about the same proportion after 14, and about 95% between 11 and 15 years of age. However, the first externally discernible signs of sexual development occur at about 10½ in girls (beginning of breast development) and at just under 12 in boys (increase in size of genitalia), but adult status as judged by external developments is not reached until the average ages of just under 14 in girls and just after 15 in boys. Reproductive capacity is not achieved in girls until some time after the menarche.

It is clear from this that the cycle of sexual maturation covers a substantial period of time and, since cultural adjustments are made to the first signs, it seems unlikely that the major psychological impact of sexual maturation can be specifically located in time. This, plus evidence suggesting the probability that sex interests increase steadily during childhood (*i.e.*, that a latency period does not exist), calls into question biological interpretations of adolescence that assume a sudden upsurge of sexuality.

Sexual maturation may not be a general cause of psychological stress, but its pervasive effect upon developing behaviour is evident in changing interests and social behaviour. Boys who mature early, for example, are on the average better poised and more adult in their social interactions than are those who mature late, a difference which persists, though to a lesser degree, beyond adolescence. Where ignorance regarding the nature of the physical changes he is experiencing characterizes the individual adolescent, where there exist marked deviations (as in time) from the generality or from the cultural ideal for the particular sex group, or where rearing has generated marked guilt feelings about sex, there may well be some anxiety or maladjustment. Thus early-maturing girls (who are likely to be oversized) and late-maturing boys (who are likely to be undersized) are most apt to exhibit anxiety about their growth. Many children pass through a temporary phase of moderate obesity during the prepubertal growth spurt; this circumstance often causes emotional disturbance which presumably could be alleviated if they were made aware that the condition is probably temporary.

Culture and Adolescence.—Studies of primitive societies reveal marked differences in the ages at which various ceremonies, or rites of passage, give recognition to the individual as an adult. Variations among technological societies are also great. At about mid-20th century, to take one illustration, the proportion of males in their late teens (15–19) who were economically active was 45% in the United States, 59% in Japan, 83% in the United Kingdom, 87% in Italy and 90% in Yugoslavia. The proportions of girls in these countries who were economically active were 26%, 54%, 78%, 47% and 87%, respectively. These employment figures suggest substantial differences from culture to culture in the degree to which teen-agers occupy significant responsible roles, but equally striking contrasts are to be found within any one country between social class groups, between urban and rural areas and between races.

Cultural heterogeneity poses special problems for the modern adolescent. Reared with one set of values, he is exposed to a broad and inconsistent array of other values in the larger society as he ranges farther from home. The degree of his bewilderment will reflect the suddenness of his introduction to this larger scene.

Rapid cultural change introduces further complications. Such change may not only pave the way for intergeneration misunderstanding and conflict, but may also pose problems for the parent who is uncertain as to the ends toward which training should be directed. In certain respects—as delay of admission to full-time employment—modern societies, as typified by the United States, seem to be prolonging adolescence, but in other respects—age of marriage—young people appear to be assuming adult roles at a younger age.

Although the broad cultural setting is important in determining the ease of transitions to adult roles, parents typically have sufficient control over the course of the child's development in the restricted "culture" of the home to effect important differences in the degree to which the child is gradually provided with opportunities for maturing experiences, self-direction and responsibility, and is afforded opportunity gradually to learn the values and ways of the larger society. Since adolescence does not, in fact, seem as stressful as ordinarily assumed, it may be inferred that parents and society are actually effecting a gradual introduction of the child to his larger world. With the passage of time, at least in the United States, this seems to be increasingly true. According to one investigation, 9th graders in 1959 were as mature as were 12th graders in 1938.

Areas of Adolescent Growth and Adjustment.—If adolescence is defined essentially as an age range during which certain patterns of development and adjustment typically occur, some description of these growth trends and adjustments is necessary to complete the definition. Although, as earlier noted, existing data do not unequivocally support the concept of generalized emotional disturbance in adolescence, there does seem to be increased tension (which later subsides) associated with particular adjustment areas, a finding consistent with a developmental task conception of adolescence.

Social Development.—One of the most striking developmental changes is the increasing cleavage between the sexes up to around 12 or 13 years of age with a subsequent reversal of the trend as interest in the opposite sex emerges. Although sexual maturation probably gives impetus to this reorientation, interactions between the sexes occur in a social context and subject to social controls to such a degree that wide variations in the timing and nature of the interaction exist from culture to culture and the influence of biology may be obscured. For example, despite the early maturity of girls, in the United States dating begins on the average at 14 years of age for both sexes.

Contrary to the popular view that adolescents are notably unstable in their friendship relations, evidence indicates that each year of age brings increasing stability in social relations, reflecting a gradual and steady trend toward maturity. However, shifts during childhood and adolescence in the social desirability of certain personal characteristics may cause gradual individual shifts in degree of social acceptance and create a degree of ambiguity, making perception of one's own status difficult. On the average, girls have stronger affiliation needs than do boys; this is reflected in closer friendships and greater cliquishness. During the course of development, the peer group becomes an increasing influence in the life of the young person, in some instances in opposition to parental influences but often reinforcing parental views and values.

Changing Values and Interests.—The basic values of a culture seem to be inculcated in the child well before adolescence. Nonetheless, significant changes occur as the child develops greater abstract ability, moves about more freely in his culture, reads more widely and comes more and more under influence of the peer group. Significant changes occur in religious values, social responsibility and attitudes toward truth. Generally there is a greater liberality of attitude toward borderline moral wrongs and a more tolerant attitude toward many matters, at least on a verbal-intellectualistic level. Compared with their parents and especially their grandparents, members of the younger generation seem more inclined to make moral and ethical judgments on the basis of intelligent judgment and aesthetic standards rather than on a strict right-wrong moral basis. These trends would seem to be in a desirable

direction and reflect greater maturity.

Interests, hobbies and the like represent means of achieving satisfaction of various motives and needs. The relationship between breadth of interests, a positive orientation toward experience, and quality of adjustment has been well demonstrated. In view of the trend toward increased leisure and fewer opportunities for finding need satisfaction in work, this assumes special importance. During childhood and adolescence there is a decrease in number of activities but a greater involvement in those remaining. Better adjusted children appear to achieve deeper interests earlier. In view of such relationships and trends, it is notable that gaps in one's repertoire of interests and related skills that are not corrected in adolescence are likely to continue throughout life and thus restrict the range of satisfactions open to a person, especially when the significant and time-demanding roles of family rearing or career are terminated.

Vocational Orientations.—Occupational and career orientations develop slowly and reflect the personality and need structure of the individual. Consciously or unconsciously, the adolescent will tend to select that occupation which he perceives as potentially satisfying to his needs while at the same time being compatible with his personality characteristics. Compromises must be made, of course, if reality, in the form of limited ability, limited finances or strong opposing motives, stands in the way. Sound choices are more apt to emerge to the degree that there is opportunity during the course of development for adequate reality and role testing; *i.e.*, genuine opportunities to test one's own interests and abilities and to find if the work is really satisfying. Problems related to vocational choice in adolescence are relatively urgent because of the impending termination of school and are often critical because of the irreversibility of certain decisions. However, final decisions often are not made in adolescence; the typical person works on several jobs before settling down to one.

The importance of work and career and their meaning for the individual vary greatly with social class level. Middle-class individuals appear more concerned with career, are more future oriented and are more likely to be stimulated to career planning by parents and teachers. Lower-class individuals seem to be relatively apathetic regarding career, to view work mainly as a means of livelihood and to live in an environment relatively lacking in stimulation with respect to career planning.

Changing Relations With Parents.—It is not unlikely that the persistence in popular and professional opinion of the conception of adolescence as a period of stress and emotional upheaval is a product of the anxiety generated in the parents of adolescents. Such anxiety is likely to be perceived by the parent not as characterizing himself but as existing within the adolescent. Adolescence may be threatening to parents for a number of reasons. There are threats to parental authority and to parental codes of conduct. Parents become anxious because of the physical risk involved when inexperienced young people drive cars and are likely to experience a sense of personal failure if the teen-ager fails to conform to the hopes and ideals the parent held for him. Instead of accepting the youngster for what he is (there are many differing patterns of good adjustment and maturity), the parent may well experience ambivalent feelings and as a result increase the degree of pressure toward his goals and become even more restrictive.

Under these circumstances it would be expected that adolescence would be characterized by increasing conflict with parents, and this is probably true in individual homes or in cultures where parental domination is marked. The bulk of evidence on the teenager in the United States suggests that girls but not boys tend to experience increased conflict with parents, possibly because of the greater supervision and control exercised over daughters and hence the greater frustration experienced by them. Boys, in contrast, are likely to be given greater freedom and training for independence—marked differences, of course, exist among cultures and subcultures. It seems reasonable to expect that the path of development may be smoothed for both adolescents and their parents if unnecessary frustrations are reduced; if the child and adolescent are given increasing opportunities for freedom and self-direction

and if restrictions, when necessary, are imposed only with due consideration of the adolescent's commitments and desires and after objective discussion of the situation; *i.e.*, reasonably rather than autocratically and arbitrarily.

It should be emphasized that the evidence dealing with age trends in parent-child relations is not consistent nor conclusive. One extensive study concluded that there is no strong evidence that adolescence is commonly a time of rebellion against parents.

Long-Term Outcome.—If adolescence is a critical period during which important personality reorganizations occur, significant shifts in developmental patterns of the types just described should result in the case of individual adolescents. However, the available information points toward continuity rather than marked reorganization in the sense that patterns of personality and adjustment once established tend to persist over long periods of time and to be modified only gradually. In laboratories where long-term studies have been conducted and individual growth curves plotted into the adult years, evidence points to long-term stability of traits. Changes do occur, and individual cases are occasionally noted in which the shifts are marked, but such shifts presumably could result from marked environmental changes (as moving to a new town, resulting in escape from reputation and social expectations that may have existed in the previous environment) or from changing physical status (as in the instance of an undersized late-maturing boy who finally catches up with his agemates and is no longer at a physical disadvantage). These exceptions must be noted as a qualification of the generality relating to continuity of psychological development.

The whole question of adolescence obviously needs further study. While the character of adolescence will vary in important respects from society to society and from one point in time to another, there is evidence indicating clearly that many existing views of adolescence do not gain unequivocal support. It may well be that in many settings adolescence is a calmer period than ordinarily assumed, and where this is not true, that appropriate changes in the environment may have the effect of reducing its stress and even of basically altering its nature. See CHILD PSYCHOLOGY AND DEVELOPMENT; CIVILIZATION AND CULTURE: *Role of Childhood*; FAMILY.

ADOLF OF NASSAU (c. 1250-1298), German king from 1292 to 1298. was the son of Walram II, count of Nassau, whom he succeeded as count in 1277. His inherited territories around Wiesbaden and Idstein were small in extent but he gained a military reputation as a mercenary captain over the next 14 years. On May 5, 1292, Adolf was elected German king at Frankfurt in succession to Rudolf I (the first Habsburg king), who had vainly attempted to engineer the election of his son Albert, duke of Austria. Adolf was crowned at Aachen on June 24, 1292, but his position was weakened by his inability to meet the exorbitant demands of his electors and by the hostility of Albert of Austria, whose territorial and financial resources were far superior.

Adolf sought to broaden the territorial basis of his power by seizing Meissen as a vacant fief and by purchasing the right of succession in Thuringia from the landgrave Albert II. His alliance with Edward I of England against France, signed on Aug. 24, 1294, brought him an initial subsidy of £20,000, which he expended in crushing the resistance of the landgrave's disinherited sons, Frederick and Dietzmann (Dietrich).

The growing power of Adolf alarmed his electors who, after reaching an understanding with Albert of Austria, decided in Feb. 1298 to depose the king. The sentence of deposition was pronounced by six of the seven electors at Mainz on June 23, 1298. Albert, whose forces were present in strength, was elected king, as Albert I (*q.v.*), on the same day. Adolf attempted to reverse this

decision on the field of battle but was defeated and slain by the superior forces of his rival at Göllheim, near Worms, on July 2, 1298.

See V. Samanek, *Studien zur Geschichte König Adolfs* (1930). (C. C. BA.)

ADOLPHUS FREDERICK (1710-1771), king of Sweden from 1751 to 1771, was born at Gottorp on May 14, 1710. His father was Christian Augustus (1673-1726), duke of Schleswig-Holstein-Gottorp, bishop of Lübeck and administrator of the duchies of Holstein-Gottorp from 1702 to 1718 during the minority of his nephew Charles Frederick; his mother was Albertina Frederica of Baden-Durlach. Adolphus Frederick was bishop of Lübeck from 1727 to 1750 and administrator of Holstein-Kiel from 1739 to 1745 during the minority of Duke Charles Peter Ulrich (afterward Peter III of Russia). In 1743 he was elected heir to the throne of Sweden by the "Hat" faction in order that they might obtain better conditions of peace from the Russian empress Elizabeth, whose fondness for the house of Holstein was notorious. He succeeded to the throne in 1751 on the death of Frederick I.

During his whole reign Adolphus Frederick was little more than a state decoration, the real power being lodged in the hands of an omnipotent *riksdag* (parliament), distracted by fierce party strife. Twice he tried to free himself from its intolerable tutelage. The first occasion was in 1756 when, stimulated by his imperious consort Louisa Ulrica, sister of the Prussian king Frederick the Great, he tried to regain a portion of the attenuated royal prerogative and nearly lost his throne in consequence. On the second occasion (1768-69), under the guidance of his eldest son the crown prince Gustavus, he succeeded in overthrowing the tyrannous "Cap" party in the *riksdag* but was unable to make any use of his victory.

He died in Stockholm on Feb. 12, 1771.

See C. G. Malmstrom, *Sveriges politiska historia*, vol. iii-vi (1897-1907); Ingvar Andersson, *A History of Sweden*, trans. by Carolyn Hannay (1956). (E. O. H. J.)

ADONAI, the name traditionally used in the synagogue liturgy as a surrogate for the ineffable name of the God of Israel (probably Yahweh). In form it is a plural of dignity of the noun *adon* ("lord") with a first person singular suffix: literally "my Lord." Long before the Christian era it had become customary to substitute this expression for the sacred tetragrammaton (YHWH) wherever the latter appeared in the consonantal Hebrew text. After the invention of vowel points, the tetragrammaton was provided with the vowels of Adonai, thus unintentionally giving rise to the bastard and impossible form "Jehovah" (YeHoWaH).

(R. C. DE.)

ADONI, a town in Kurnool district, Andhra Pradesh, India, 142 mi. S.W. of Hyderabad. Pop. (1951) 53,583; (1959 est.) 80,000. It is an important cotton cloth and carpet manufacturing centre on the Madras-Bombay railway route, 307 mi. from the former.

Adoni was a stronghold of the Hindu kings of Vijayanagar (*q.v.*). After their downfall it changed hands between local and imperial Muslim regimes until 1792 when, following the East India company's first war with Tipu Sahib (*q.v.*), it was allotted to the Nizam of Hyderabad. The Nizam ceded it to the British in 1800, however, in payment for military aid. Among Adoni's monuments are Jain figures carved in the rocks of the ruined fort and the beautiful Jami Masjid (great mosque) built in 1680 by Sidi Masud Khan.

(G. KN.)

ADONIJAH (in the Douai version of the Bible, ADONIAS), a name borne by several persons in the Old Testament, of whom the most noteworthy was the fourth son of David (*q.v.*). Adonijah was the natural heir to the throne. On the death of Absalom, and shortly before the death of David, he made preparations to seize his birthright, receiving the support of Joab and Abiathar the priest. However, Bathsheba, David's favourite wife, organized a counterintrigue in favour of her son Solomon (*q.v.*). Shortly after his accession Solomon had Adonijah put to death on the ground that by seeking to marry David's concubine Abishag he was aiming at the crown (I Kings i ff.).

ADONIS, in classical mythology, a youth of remarkable beauty, the favourite of Xphrodite. According to Apollodorus he was the

son of the Syrian king Theias by his daughter Smyrna (Myrrha), who had been inspired by Aphrodite with unnatural love for her father and, by deceiving him as to her identity, conceived Adonis by him. When Theias discovered the truth he would have slain his daughter, but the gods in pity changed her into a tree of the same name. After ten months the tree burst asunder and from it came forth Adonis. Aphrodite charmed by his beauty, put the infant in a box and handed him over to the care of Persephone, who afterward refused to give him up. Zeus, on appeal being made to him, decided that Adonis should spend a third of the year with Persephone and a third with Aphrodite, the remaining

served that whenever sacrifices of swine occur in the ritual of Aphrodite there is reference to Adonis. In any case, the conception of Adonis as a swine-god does not contradict the idea of him as a vegetation or grain spirit, which in many parts of Europe appears in the form of a boar or sow.

Lambrechts, "La Résurrection d'Adonis," *Annuaire de l'Institut de Philologie*, vol. xiii, pp. 207-40 (1953). (T. V. B.: X.)

ADONIS, a genus of showy garden plants of the crowfoot family (Ranunculaceae) including the pheasant's-eye and several other cultivated species. They comprise about 20 Eurasian species, all with solitary flowers and dry fruits crowded into a head. They are erect herbs with much-divided leaves and yellow or red flowers.

Adonis vernalis is the perennial pheasant's-eye, with yellow flowers, but *A. aestivalis* and *A. annua* are annuals with red flowers, and are sparingly naturalized in eastern North America. The perennial species are easily cultivated in ordinary garden soil. Annuals should be sown one-fourth inch deep in sandy loam. The name is also given to the Adonis Blue butterfly (*Lysandra bellargus*), occurring in the chalk downs of southern England. (N. TR.)

ADOPTION has been described as a way of conferring "the privileges of parents upon the childless and the advantages of having parents upon the parentless" (*Clarke Hall and Morrison's Law Relating to Children and Young Persons*, 5th ed., p. 502, Butterworth & Co. [Publishers] Ltd., London! 1956). More precisely, the act of adoption establishes a person as parent to one who is not in fact or in law his child. Adoption is so widely recognized that it can be characterized as an almost world-wide institution with historical roots traceable into antiquity. Greek and Roman practices form the earliest examples of persistent use of adoptions, notwithstanding the recording of adoptions in previous civilizations.

In ancient Greece and Rome, however, and in certain later cultures as well, the purposes served by adoption differed substantially from those emphasized in modern times. Continuity of the male line in a particular family was the main goal of these ancient adoptions. The importance of the male heir stemmed from political, religious or economic considerations, depending on the nation. The person adopted invariably was male and often adult, whereas contemporary adoptions commonly involve infants of either sex. In addition, the welfare of the adopter in this world and the next was the primary concern; little attention was paid to the welfare of the one adopted. As a result of the impact of Roman civil law upon the legal systems of Europe, the ancient traditions have left their mark on the adoption laws of a number of European and Latin-American nations and, in the United States, on the laws of Louisiana and Texas, which were colonized by French and Spanish settlers.

Nevertheless, it seems fair to state that in English-speaking and European countries, on the whole, contemporary laws and practices aim to promote child welfare and are regarded as but one facet of the state's program to protect its young. While the desire to continue a family line or to secure rights to inheritance are still among the motives for adoption, interest now centres more on the creation of a parent-child relationship between a married couple and a young child. This attitude developed primarily in the period following World War I, when vast numbers of children were left homeless by virtue of orphanage and an increase in illegitimate births. Adoption had popular appeal as a way to provide homes for these children. Its popularity was reinforced not only by the havoc of later wars but by the influence of psychiatry and allied fields, which have stressed the importance of stable family life from an early age in furthering the desired development of children.

Among English-speaking countries the United States is noteworthy for its relatively high rate of adoption and substantial experience in the administration of child welfare laws. Adoptions

"VENUS AND ADONIS" BY TITIAN (TIZIANO VECELLIO, C. 1477-1576)

third being at his own disposal. In another version, given by Ovid, Adonis was killed by a boar, and this version was followed by Shakespeare. Apollodorus clumsily combines the two. Numerous other variants exist.

The name is generally supposed to be of Phoenician origin (from *adon*, "lord"); Adonis himself being identified with Tammuz (*q.v.*). (See also ATTIS.) Annual festivals called Adonia were held in his honour at Byblus, and also, from the 5th century B.C. onward, at different places in Greece. The central idea was the death and resurrection of Adonis and the mourning for Adonis, generally represented by an effigy which was afterward flung into the water. The very elaborate Alexandrian festival is described by Theocritus.

Most authorities agree that Adonis is a vegetation spirit, whose death and later return to life represent the decay of nature in winter and its revival in spring. He is born from the myrrh tree, the oil of which is used at his festival, and is connected with Aphrodite in her character of vegetation goddess. A special feature of the Athenian festival was the "Adonis gardens," small pots of seeds forced to grow artificially which rapidly faded (the custom is still practised by Christians in Cyprus). The dispute between Aphrodite and Persephone for the possession of Adonis finds a parallel in the story of Tammuz and Ishtar (see APHRODITE). In other words, Aphrodite is the oriental mother-goddess: Adonis her lover; the details have been influenced by the legend of Demeter (*q.v.*). The ceremony of the Adonia was intended as a charm to promote the growth of vegetation, the throwing of the gardens and images into the water being supposed to procure rain.

J. G. Frazer suggested that Adonis is not a god of vegetation generally, but specially a grain spirit, and that the lamentation is not for the decay of vegetation in winter but for the cruel treatment of the grain by the reaper and miller (*cf.* Robert Burns's *John Barleycorn*).

An important element in the story is the connection of Adonis with the boar; possibly Adonis himself was looked upon as incarnate in the swine. For a god sacrificed to himself as his own enemy, *cf.* the sacrifice of the goat and bull to Dionysus. It has been ob-

in the United States have grown in number and national interest. As elsewhere, the effects of war, as seen in increased illegitimacy, orphanage, divorce and separation, have accounted for much of the numerical growth. The adoption movement, however, began as early as the mid-19th century, when the first adoption statute, providing for judicial approval of such alliances, was passed in Massachusetts in 1851. The need for a judicial proceeding is universally recognized in the United States, save for a few exceptions related to a father's adoption of his illegitimate child. Adoption of adults is permitted in most jurisdictions; the legal provisions are generally formulated, however, in terms of child adoption, and the adopter must usually be an adult. It is not customary to require an age difference between adopter and the person sought to be adopted. The laws typically provide for the consent of the child's natural parents or guardian to the adoption, the consent of any older child (commonly one over 12 or 14 years), an investigation of the suitability of the prospective home according to criteria stated in the governing statute and a probationary period of residence in the adoptive home. During the probationary period, entry of a final decree of adoption is withheld pending evidence of the satisfactory adjustment of parent and child to one another. Provisions exist to secure the secrecy of the legal proceeding and to effect the necessary alterations on the child's birth certificate. In short, the laws endeavour to erase the natural parent-child relationship and create a wholesome replacement which intimately resembles it.

In the matter of inheritance, however, laws in the United States differ considerably. As a general rule, the child may inherit from the adopting parents and they from him. Inheritance by the child from his natural parents, once commonplace, is increasingly prohibited, with the exception of cases of adoption by stepparents. In addition, there has been a tendency to broaden the child's right to inherit from relatives of the adopting parents, although great variation appears among state laws on this subject.

In England adoption was first permitted only as recently as 1926. It was unknown to the common law, and the delay in passage of legislation can be attributed in part to the availability of devices which served to protect the continuity of family titles and estates, and in part to other legal means for protecting and caring for the dependent or homeless child. Under English adoption law the applicant must be 25 years old, he must generally be 21 years older than the person adopted, and the relationship is created through a judicial proceeding. In every case a guardian *ad litem* (for the purpose of the suit) is appointed for the child. The guardian's duties are not limited to the fulfillment of formal statutory requirements, as is often the case in the commonwealth countries and the United States; he also is required to investigate all aspects of the proposed adoption with a view to safeguarding the child's interests. The Adoption act, 1958, is a consolidating measure embodying the changes made in the Adoption act, 1950, and the Children act, 1958. The latter was of particular importance in giving effect to the recommendations of the Curtis committee in regard to the responsibilities of local authorities in relation to adoption.

The effects of an adoption order are to establish the usual parental rights and duties relating to support, education and custody. Inheritance follows the lines established for natural children, their parents and relatives, and inheritance by the child from his natural parents is prohibited. The adoption once made—if properly made—is final; the law does not permit annulment. English policy in this respect differs from that followed in several of the commonwealth and European nations, as well as a few U.S. jurisdictions. English law, in brief, though it was late in dealing with adoption, is advanced in its insistence on the similarity between natural and adoptive families.

Several of the commonwealth nations passed adoption laws well in advance of the English statute of 1926. In New Zealand, for example, the first law was enacted in 1895, and in Canada adoptions have been permitted in Nova Scotia since 1896. The statutes vary widely throughout the commonwealth. Some have been modeled on the English acts, while some reflect the influence of other nations.

Adoption of minors in the sense of creating permanent, comprehensive bonds between adopter and adoptee is a relatively recent phenomenon in France, dating from 1923. The law specifies the minimum age of the adopter and requires a 15-year difference in the ages of the parties. Two types of adoption are recognized. Simple adoption is available to single persons and is designed to restrict the effects of adoption to the relationship of adopter and adoptee. Adoptive legitimation, on the other hand, can be undertaken only by married people who propose to adopt a child under five years; this process has the consequence of creating ties between the child and the greater family of the adopter. The process is always a matter of public record.

In Germany and the Scandinavian countries adoption is part of comprehensive child welfare legislation. German provisions require that all adoptions involve the services of trained welfare workers. The validity of adoptions depends on confirmation by competent tribunals. Similarly, in Norway and Sweden adoption work is supported by sound social services for children and unmarried mothers. The extent to which adoption is regarded as an integral part of the Swedish child welfare program can be seen in the fact that adoptions do not become irrevocable, as they do in so many other places, but can be set aside when such action is in the best interest of the child. See also CHILDREN, LAWS CONCERNING.

BIBLIOGRAPHY.—Margaret Kornitzer, *Child Adoption in the Modern World* (1952); Chester G. Vernier, *American Family Laws*, vol. iv (1936); Michael Schapiro, *A Study of Adoption Practice*, 2 vol. (1956). (M. K. R.)

ADOPTIONISM, the title given to two Christian heresies, one originating in the 3rd and the other in the 8th century.

Adoptionism in the first sense is the belief that Christ was not the pre-existent Son of God but a mere man (Gr. *psilos anthropos*, hence psilanthropism), "adopted" by God at his baptism when he received the divine power (Gr. *dynamis*, hence dynamic monarchianism; *q.v.*) to enable him to fulfill his mission of redemption. Propounded first by Theodotus of Byzantium *c.* 190, it was continued by Paul of Samosata (*q.v.*), who was condemned by a council at Antioch in 269. Nestorius was charged, probably incorrectly, with holding such a view, and hotly repudiated it. It was revived at the Reformation by certain Anabaptists and is the belief, at the present day, of many Unitarians.

Adoptionism is also the name given to a controversy that broke out in Spain at the end of the 8th century. Under Islamic rule the Spanish church had tended to become isolated, and in an effort both to bind it closer to the apostolic see and to reform it a delegate was sent, named Egila, who took as his companion Migetius. Elipandus, archbishop of Toledo, resented this intrusion and found opposition easier because Migetius' teaching was suspect, the latter asserting that Jesus was one of the three persons of the Trinity and so confusing the two natures and the one person of the incarnate Son of God. Migetius was condemned by a council at Seville and Elipandus himself published a declaration of faith containing Christological statements that were soon to be challenged. Concerned to distinguish in Christ, who is both human and divine, the operations of each nature, Elipandus referred to Christ in his humanity as "adopted son" in contradistinction to Christ in his divinity who is the Son of God by nature.

He who is man among us was united in a single person with the Word. But it was not by him who was born of the Virgin that the world was created, but by him who is Son, not by adoption but by status, not by grace but by nature. It was by him who is both son of man and Son of God, adopted son according to his humanity, not-adopted Son according to his divinity, that the world has been redeemed. And if all the saints are imitators of the Son of God according to grace, they are also adopted sons like he.

The son of Mary, assumed by the Word, thus was not the Son of God by nature but only by adoption. Although this was not entirely unlike Nestorianism, no connection can be supposed; it was a somewhat archaic way of asserting that the divine Word had taken to himself a concrete human nature, whose properties were not impaired by the union.

Opposition to these views was first voiced by the priest Beatus and Etherius (later bishop of Osma), who, resident in Asturia, were

motivated in part by a desire to be free from the jurisdiction of Toledo. At their instigation Pope Adrian I intervened and condemned Elipandus' teaching. The latter would have been wise to have let matters rest but instead he sought the support of Felix, bishop of Urgel, who expressed agreement. Urgel however had been occupied by the Franks between 785 and 790, and Charlemagne, who was not prepared to allow this questioning of the pope's decision, summoned Felix to Regensburg in 792, induced him to recant and sent him to Rome to be enlightened and disciplined by Adrian. Whereupon the Spanish church sent an open letter to the bishops of Gaul and a second to Charlemagne supporting the essential orthodoxy of both Felix and Elipandus. A council was summoned to Frankfurt in 794 which renewed the condemnation but an incursion of Arabs into Gothia prevented Charles from taking action and Felix returned to Urgel. A literary duel then ensued between him and Alcuin of York. In 798 Pope Leo III held in Rome a council of some 60 bishops which condemned the "adoptionism" of Felix and anathematized him. A commission was dispatched, under archbishop Leidrad of Lyons, which brought Felix to Aix-la-Chapelle (Aachen) in 799; after six days' dispute with Alcuin, Felix recanted again, was placed under the surveillance of Leidrad and died in 818. Elipandus remained unrepentant and despite further treatises by Alcuin continued undisturbed in his see; the adoptionist view, however, was almost universally abandoned after his death, apart from a temporary recrudescence in the 12th century in the teaching of Abelard and his followers.

See J. N. D. Kelly, *Early Christian Doctrines* (1958); E. Amann, *L'Époque carolingienne* (1937), vol. vi of A. Fliche and V. Martin (eds.), *Histoire de l'église*. (J. G. D4.)

ADORATION, ultimately from the phrase *ad ora*, "to the mouth," designating the Roman's act of kissing the hand to the statue of the god he wished to honour, came to denote acts whereby man acknowledges God's supreme perfection and dominion. The chief of such actions in Christian worship is sacrifice, which can be made to God alone, accompanied normally by prayers of praise, etc. The Greek Christians used two words to distinguish carefully between the worship of God (*latreia*) and the veneration given to other sacred persons or objects (*proskynesis*). Both Greek words were translated into Latin by the one word *adoratio* and as a result the distinction of concepts was at times obscured. In English this confusion has been avoided by the use of "veneration" to designate the reverence paid to saints and images or relics of saints, Roman Catholics add a further distinction between such veneration as paid to the Blessed Virgin because of her singular pre-eminence (hyperdulia) and as paid to saints and sacred objects (dulia). By a natural transition "adoration" was also applied to the homage rendered to monarchs by the ceremony of striking the earth with the forehead. See also WORSHIP.

ADOUR, a river of southwest France, rises in the *département* of Hautes-Pyrénées, south of the Pic du Midi de Bigorre, and flows in a wide curve to the Bay of Biscay. It traverses the beautiful valley of Campan and, after passing Bagnères de Bigorre, enters the plain of Tarbes (*q.v.*). Beyond Tarbes numerous canals are drawn from the river for irrigation purposes; the most important is the Canal d'Alaric which follows the right bank for 36 mi. Within the *département* of Landes it flows west and later southwest becoming navigable at St. Sever, beyond which it is joined on the left by the Larcis, Gabas, Louts and Lup, and on the right by the Midouze. After Bayonne the river enters the sea through a dangerous estuary, after a total course of 208 mi. The mouth of the Adour has repeatedly shifted, its old bed being represented by *étangs* and lagoons extending northward as far as the village of Vieux Boucau (223 mi.), where it debouched in the 14th century. The present channel was constructed in 1579.

ADRANO (ADERNO), a town of Sicily in the province of Catania, is near the Simeto river on a lava plateau on the western slopes of Mt. Etna, 36 km. (22 mi.) N.W. of Catania by road. Pop. (1951) 26,952. The ancient walls with ruined towers remain and there are traces of baths and burial grounds. The Ponte dei Saraceni, with bold 13th-century architecture, the 18th-century Ponte dei Biscari, an aqueduct with 40 arches, the 13th-century Norman castle and the 15th-century monastery of Sta. Lucia are

worthy of note. Oranges are the most important product of the district, but other fruits and vegetables are cultivated and honey is made. The old town, Hadranum, was founded by Dionysius the Elder, tyrant of Syracuse, in 400 B.C. near a sanctuary dedicated to the god Adranus, from which it took its name. It was conquered by the Romans in 263 B.C. In the middle ages it belonged to Roger I, count of Sicily. Emperor Frederick II made it a countship and in 1549 it passed to the Moncada, princes of Paterno, who held it until 1812. In 1928 it reassumed the classical name of Adrano, which had been corrupted into Adernb. In World War II Adrano was captured in Aug. 1943.

(M. T. A. N.)

ADRENAL GLANDS. These are two virtually identical glands, one situated above each kidney. Each gland consists of two parts. The inner portion, the medulla, produces epinephrine, also designated adrenaline, and norepinephrine or noradrenaline. The outer portion, the cortex, elaborates a group of hormones that are steroids closely related to progesterone.

The physiologic activity of the cortical hormones can be summarized under three aspects. First, mineral metabolism: the maintenance within narrow limits of the concentration in the blood of sodium, potassium and chloride is essential for life. The adrenal cortex exerts an important influence on this phenomenon by the secretion of the hormone aldosterone. Second, organic metabolism: the utilization and distribution of carbohydrates, proteins and fats are modified by cortisone and hydrocortisone. Third, tissue reactions such as hypersensitivity, allergic states and collagen diseases: the beneficial results produced by cortisone and hydrocortisone are manifested in the relief of rheumatoid arthritis and about 50 other diseases. The adrenal cortex did not appear to be directly involved in the etiology of any of these diseases and the manner in which cortisone and hydrocortisone produce their effect was not known as of the early 1960s. The activity of the adrenal cortex is controlled by the pituitary gland through an agent designated as adrenocorticotrophic hormone or ACTH. (See PITUITARY BODY: *Hormones of the Pituitary Gland.*)

Until 1930 the mortality of patients who lacked adrenal secretion, a condition called Addison's disease (*q.v.*), was close to 100%. Administration of cortisone or hydrocortisone and small amounts of desoxycorticosterone or aldosterone permits these patients to lead a normal life and to undergo unusual stress, such as surgical operations.

Preparation of Extract.—To prepare an extract that contains these hormones, frozen adrenal glands from animals are passed through a meat grinder and extracted with cold alcohol. Water from the glands mixes with the alcohol and compounds soluble in water dissolve in the aqueous alcohol. The meaty portion of the gland, fat and other products remain insoluble. The aqueous alcohol is separated from the insoluble material, which is discarded. The alcohol and a large part of the water are removed by distillation under reduced pressure. The water solution that remains contains the hormones of the adrenal cortex. It also contains epinephrine that was originally present in the middle portion of the gland. For clarity this is designated solution A.

The concentrated solution A is thoroughly extracted with chloroform. Since hormones of the adrenal cortex are much more soluble in chloroform than in water this treatment provides a way to separate them from epinephrine and other compounds that remain in solution A. The chloroform is completely separated from solution A and is evaporated to dryness leaving a residue that contains the cortical hormones. In the commercial preparation of the extract the residue is dissolved in a volume of water such that one millilitre contains the extract of a constant amount of adrenal glands. Some pharmaceutical manufacturing companies have used 40 g. of adrenal glands for each millilitre of the water solution; other companies have used 75 g. of glands.

Solution A after extraction of the cortical hormones with chloroform still contains epinephrine. To obtain this valuable product solution A is concentrated to a small volume and ammonia is added. Epinephrine separates as a white crystalline precipitate that is filtered off and subsequently purified.

An extract of the adrenal gland was first prepared by methods similar to this by two groups of investigators working independ-

ently in 1929. Such extracts have served to provide substitution therapy for patients who were deficient in adrenal cortical function; to allow physiologists and clinicians to determine the physiologic activity of these essential compounds; and to permit chemists to isolate, identify and finally synthesize all of the cortical and medullary hormones.

Nature and Effects.—Epinephrine is a methylamine ethanol derivative of catechol. Norepinephrine has the same structure except the amino group is not substituted with a methyl group. Epinephrine when administered mimics the action produced by stimulation of the sympathetic nervous system and fortifies the body in an emergency—W. B. Cannon's theory. Among these effects are a rapid rise in blood pressure, an increase in the concentration of blood sugar and the flow of blood to the muscles and inhibition of digestion. However, the adrenal medulla is not essential for life. Activity of the medulla is controlled largely by stimulation of sympathetic nerves and by such agents as acetylcholine and insulin. Norepinephrine shares the stimulatory rather than the inhibitory properties of epinephrine.

Between 1930 and 1938 almost 30 different crystalline compounds were separated from the cortical adrenal extract and their chemical structures were determined. In 1937 the member with the simplest chemical structure, desoxycorticosterone, was made commercially available by alteration of the structure of another abundant steroid. Cortisone and hydrocortisone were made in small quantities in 1948 and in 1951 respectively. The last important member of the hormones, aldosterone, was separated in 1953, identified in 1954 and made synthetically in 1955. See ENDOCRINOLOGY: Adrenal Glands; ANIMAL EXTRACTS: Adrenal Extracts; ADRENAL GLANDS. DISEASES OF. See also Index references under "Adrenal Glands" in the Index volume.

ADRENAL GLANDS, DISEASES OF, may be divided into diseases of the cortex and diseases of the medulla (see ADRENAL GLANDS). The only known disease of the medulla is a tumour (pheochromocytoma) which results in secretion of excessive quantities of epinephrine and norepinephrine. Symptoms are periodic episodes of high blood pressure, palpitation of the heart, sweats, pounding headaches, anxiety, nausea and vomiting. The only treatment is surgical removal of the tumour.

Adrenal cortical disease may be manifested as hyperfunction (overactivity) or hypofunction (insufficiency). The latter, known as Addison's disease, is discussed in a separate article (see ADDISON'S DISEASE).

Adrenocortical hyperactivity may be congenital or acquired; the former always is due to bilateral adrenal hypertrophy (enlargement), the latter to either tumour or hypertrophy. Congenital adrenal hypertrophy in the female infant results in masculinization with pseudohermaphroditism; in the male, sexual precocity occurs. In both, the virilism may be associated with a salt-losing syndrome. Acquired adrenocortical hyperfunction may be due to an adrenal tumour, benign or malignant, or to adrenal hypertrophy. Not infrequently, nontumorous adrenal hyperfunction is associated with no demonstrable enlargement of the adrenals. In nontumorous adrenal hyperfunction, a basophilic adenoma or basophilic hyperplasia is often present in the pituitary body.

Acquired adrenocortical hyperfunction is manifested by Cushing's syndrome, the adrenogenital syndrome, or both. Cushing's syndrome is characterized by obesity, rounding of the face, amenorrhea, high blood pressure, diabetes, osteoporosis, thinning and easy bruisability of the skin with appearance of violaceous striae. weakness and, often, mental disturbances. The adrenogenital syndrome consists of virilizing manifestations in the female, sexual precocity in the preadolescent male, and varying degrees of demasculinization in the adult male.

Treatment for adrenal tumour is surgical removal. For congenital hypertrophy, treatment consists of administration, for an indefinite length of time, of an adrenal hormone such as cortisone

or one of its synthetic analogues. In the presence of the salt-losing syndrome, a salt-retaining hormone, desoxycorticosterone or 9-alpha-fluorocortisol, may be added to the regimen. The forms of therapy available for acquired nontumorous adrenal hyperfunction with Cushing's syndrome are: (1) pituitary irradiation; (2) pituitary irradiation and removal of one adrenal gland, (3) removal of most of the adrenals; (4) total removal of the adrenals; (5) removal of the pituitary. Where both adrenals are removed or almost entirely removed or the pituitary body destroyed, replacement therapy with adrenal hormones must be instituted. See also ENDOCRINOLOGY

Primary aldosteronism represents a selective form of adrenocortical hyperfunction, usually due to tumour, occasionally to nontumorous adrenal hyperfunction with respect to secretion of aldosterone. The syndrome is characterized by (1) hypertension, (2) reduction in the serum potassium level, (3) an increase in the blood CO₂ content, (4) evidence of renal damage, (5) an increase in the urinary excretion of potassium and (6) a considerable increase in the urinary excretion of aldosterone. The clinical manifestations often include tetany, muscle weakness and passage of large amounts of urine. Successful removal of the adrenal tumour generally results in a reversal of the laboratory and clinical manifestations.

See Louis J. Soffer, *Diseases of the Endocrine Glands* (1956); Louis J. Soffer, R. Dorfman and J. L. Gabilove, *The Human Adrenal Gland* (1961). (L. J. so.)

ADRENALINE AND NORADRENALINE (epinephrine and norepinephrine or levarterenol) are separate, active principles secreted by the medulla of the adrenal glands. They are also liberated at the ends of sympathetic nerve fibres where they serve as chemical mediators for conveying the nerve impulses to effector organs. Chemically, the two compounds differ only slightly, and they exert similar pharmacological actions that resemble the effects of stimulation of the sympathetic nervous system. They are therefore classified as sympathomimetic agents. The active secretion of the adrenal medulla contains approximately 80% adrenaline and 20% noradrenaline, but this situation is reversed in the sympathetic nerves, which contain predominantly noradrenaline.

The purified, active compounds are used clinically and are obtained from the adrenal glands of domesticated animals or prepared synthetically. The administration of adrenaline results in an increase in blood pressure by increasing the rate and force of contraction of the heart and by constricting the peripheral blood vessels. It also dilates the bronchioles and in this way is an aid to respiration. Adrenaline exerts a metabolic effect manifested by a rise in blood glucose. Noradrenaline elicits similar responses, but its metabolic effects and actions on the heart are much less than those of adrenaline. The rise in blood pressure after the administration of noradrenaline is due to its powerful vasoconstrictor action.

Adrenaline is used in combination with local anesthetics, since its vasoconstricting properties delay the absorption of the local anesthetics and in this way it prolongs their activity and reduces their toxicity. It is useful in acute allergic disorders such as drug reactions, hives and hay fever. Occasionally it is applied as a local vasoconstrictor in the control of superficial hemorrhage from the skin and mucous membranes and to relieve the nasal congestion of certain allergic conditions. Noradrenaline is administered by intravenous infusion to combat the acute fall in blood pressure associated with certain types of shock. Large doses of these compounds may result in such serious consequences as cerebral hemorrhage and cardiac abnormalities. See ADRENAL GLANDS; ANIMAL EXTRACTS; ENDOCRINOLOGY; HORMONES. See also Index references under "Adrenaline and Noradrenaline" in the Index volume. (K. P. Du.)

ADRIA, a town of Rovigo province, region of Veneto, Italy, is situated in the flat Po valley, only 13 ft. above sea level, between the lower reaches of the Po and the Adige rivers, 16 mi. E. of Rovigo by rail and 14 mi. W. of the Adriatic sea to which it gave its name. Pop. (1951) 12,780. It is an agricultural centre on the railway from Rovigo to Chioggia with another line to Mestre

and Venice. Known to the Greeks and Romans, it was an important Etruscan harbour (Hatria or Atria) and was famous in Aristotle's day for a special breed of fowls. Even then river silt rendered access difficult and the historian Philistus excavated a canal to the sea which had gradually receded from the town. The canal was still open in the imperial period and the town possessed its own guild of sailors, but its importance gradually decreased in the middle ages because of continued silting by the Po and Adige. The Bocchi Municipal museum contains a fine collection of Etruscan remains and Roman glass from the old town, 10–20 ft. below the modern level. In World War II Adria was freed on April 27, 1945. (Gr. S.)

ADRIAN (HADRIAN), **SAINT**, OF NICOMEDIA (3rd/4th century A.D.). Two saints of this name, both martyred at Nicomedia and buried at Argyropolis, one under Diocletian and one under Licinius, are commemorated on Aug. 26 in the Orthodox Church. Only the former, whose wife Natalia was a Christian, appears in the Roman martyrology, on March 4 and Sept. 8. Attempts to identify the two are probably mistaken, as their legends are quite distinct.

See A. Butler, *Lives of the Saints*, ed. by H. Thurston and D. Attmater, vol. 3, pp. 507–508 (1956).

ADRIAN (HADRIAN), the name of six popes.

ADRIAN I (d. 795), pope from 772 to 795, was a Roman aristocrat by birth and education. He was elected Feb. 1, 772. As pope he invoked Frankish aid against the Lombard king Desiderius and his Roman partisans. By Easter 774 Charlemagne was in Rome, having destroyed the Lombard kingdom. Thenceforth the Frankish alliance, and not that with Constantinople, determined Adrian's policies. Amicable rivalry marked the relations between Charlemagne and the pope. The former made use of the church to hold his empire together and enforced overlordship on the papal states while Adrian fought firmly but adroitly for ecclesiastical autonomy and painstakingly pieced together a papal domain that was lost only in the 19th century. Constantinople was conciliated by Adrian's co-operation in the anti-Iconoclast Council of Nicaea (787), which Charlemagne attacked. Adrian died on Dec. 25, 795. Charlemagne commemorated him in an epitaph, composed by Alcuin and preserved at St. Peter's.

ADRIAN II (792–872), pope from 867 to 872, was a Roman by birth and a relative of two previous popes, Stephen V (816–817) and Sergius II (844–847). He was elected on Dec. 14, 867. The papacy had reached a high point under his vigorous predecessor, Nicholas I, and Adrian struggled to maintain the advantageous position, not without some success. He readmitted Lothair II of Lorraine to communion but Lothair's early death created a difficult problem of succession in which Adrian ineffectually intervened. Adrian also had difficulties with Hincmar of Reims who developed a doctrine not unlike that of the later Gallicans.

Adrian approved the use of the Slavic language in liturgy by Cyril and Methodius and, by making Methodius archbishop of Sirmium, won the adhesion of the Moravians to the church. His legates took part in the eighth ecumenical council, the fourth of Constantinople (869–870), which deposed the patriarch Photius. For the sake of peace, Adrian accepted the 21st canon of this council which gave the patriarch of Constantinople rank second only to that of the pope. He refused, however, to sanction the transfer of the Bulgarians to the patriarchate of Constantinople, which was decided at the same time. He died on Dec. 14, 872.

ADRIAN III, **SAINT** (d. 885), pope from 884 to 885, was a Roman. He died, probably in Sept. 885, near Modena on his way to the diet of Worms, summoned by Charles the Fat to settle the succession to the empire. His feast day is July 8.

ADRIAN IV (Nicholas Breakspear) (d. 1159), pope from 1154 to 1159, the only Englishman to occupy the papal throne, was born at Abbot's Langley near St. Alban's in Hertfordshire. He was elected on Dec. 4, 1154. He became a canon regular of St. Rufus near Avignon and in 1150 cardinal bishop of Albano. Eugenius III sent him as legate to Scandinavia in 1152 to reorganize the hierarchy. His mission was a success and on his return he was chosen pope. Adrian crowned Frederick Barbarossa emperor in 1155 after Frederick had captured and handed over Arnold of Brescia

to him. The papal policy in regard to the Normans of southern Italy, however, aroused the emperor's anger and thereafter the relations between Adrian and Frederick form a preamble to the struggle between Alexander III and Barbarossa. Henry II of England in 1156 asked Adrian for permission to conquer Ireland. Even if the bull *Laudabiliter* were authentic: which is doubtful, it does not grant hereditary possession of Ireland to the English king. Adrian died on Sept. 1, 1159.

ADRIAN V (Ottobono Fieschi) (d. 1276), pope for about five weeks in 1276, was a native of Genoa and a nephew of Innocent IV who created him cardinal. He was legate to England (1265–68), charged with establishing peace between Henry III and the rebellious barons. Elected as successor of Innocent V on July 11, 1276, he died on Aug. 18, having, however, revoked the stern conclave regulations of Gregory X.

ADRIAN VI (Adrian Florisze Boeyens) (1459–1523), pope from 1522 to 1523, was born March 2, 1459, in Utrecht. He was elected on Jan. 9, 1522. The last non-Italian and the only Dutch pope, he studied at Louvain where he became priest, professor of theology, chancellor and rector of the university. Erasmus was one of his pupils. In 1507 Adrian was appointed tutor of Charles V, who afterward entrusted him with the highest offices. Bishop of Tortosa in 1516, he was created cardinal in 1517. He was crowned pope at Rome in Aug. 1522. Despite opposition and ridicule, Adrian took up the task of reform with great earnestness, beginning with the curia. An excellent but misunderstood pontiff, he reigned such a brief time that his accomplishments are disappointing. He did, however, point out the way to reform. He died on Sept. 14, 1523. (E. A. R.)

ADRIAN, EDGAR DOUGLAS ADRIAN, 1ST BARON, OF CAMBRIDGE (1889–), English physiologist and winner, with Sir Charles Sherrington (*q.v.*), of the 1932 Nobel prize in physiology and medicine for discoveries regarding the neuron, the ultimate anatomical unit of the nervous system. He was born in London on Nov. 30, 1889, and educated at Westminster school and Trinity college, Cambridge, qualifying in medicine in 1915. Apart from medical service during World War I his career was spent at Cambridge, as fellow of Trinity (from 1913), Foulerton professor of the Royal society (1929–37), professor of physiology (1937–51) and master of Trinity (from 1951). He was awarded the Order of Merit in 1942; elected president of the Royal society in 1950; and raised to the peerage in 1955.

Adrian became known for brilliant experimental researches in electrophysiology. His early work was concerned with nerve impulses from sense organs. The variations in electrical potential associated with such impulses amplified many thousands of times by means of thermionic valves, and it was found possible to record them. He later made recordings of nerve impulses from single sensory endings and from single motor nerve fibres. This made possible a better understanding of the physical basis of sensation and the mechanism of muscular control. After 1934 Adrian studied the electrical activity of the brain itself. His work on the variations and abnormalities of the changes known as the Berger rhythm opened up new fields of investigation in epilepsy and in the location of cerebral lesions. (W. J. Bp.)

ADRIANOPOLE: see EDIRNE.

ADRIATIC (anc. MARE ADRIATICUM), an arm of the Mediterranean sea between Italy and the Balkan peninsula, extends northwest to southeast from latitude 40° N. to latitude 45° 45' N., a distance of nearly 500 mi. Its average width is about 110 mi., but at the Strait of Otranto only 45 mi. It shallows rapidly in its northern half, its depth north of Dubrovnik (Ragusa) being nowhere more than 130 fathoms, beyond Ravenna less than 50 fathoms. A narrow minor depression with depths of more than 100 fathoms crosses the sea between the Abruzzi and Sibenik (Sebenico). From Mt. Gargano southward to opposite Bari there is a much more extensive and deeper basin (more than 500 fathoms) where soundings of more than 765 fathoms have been recorded. Structurally the Adriatic sea and its western extension in the basin of the Po river occupy a downfold between the Tertiary fold ranges of the Apennines on the west and those of the Alps to the north, and the Dinaric system to the east. In the Po basin the

depression has been infilled with detritus brought down from both the Alps and the Apennines, but more especially the former, partly by glacial action during the Ice Age but mainly by the violent flood streams characteristic of the tributaries of that river. The combined delta of the Po, Adige, Brenta and Piave rivers shows that this process is still continuing, for its front is advancing seaward, in places by as much as 30 ft. a year. It is only with great difficulty that the channels necessary to the continued existence of Venice as a port are kept open.

Adria (*q.v.*), which was a flourishing port in Roman times and up till the late 12th century, and which gave its name to the sea, is now 14 mi. inland. Beside being the shallowest of all the sections of the Mediterranean, the Adriatic is also distinguished in parts by the relative freshness of its waters. Its mean salinity is approximately $35^{0}/_{00}$ near the Strait of Otranto but falls to $18^{0}/_{00}$ near the head of the sea where it receives the surface flow of Alpine and Apennine streams and also submarine flows from the limestone plateaus of Istria and Dalmatia.

Though in general the Adriatic may be said to experience a Mediterranean climate, the more continental conditions prevalent over the north Italian lowland and the Danube basin are not without their effect on its northern sections. Their low winter temperatures, for example, cause the waters of the Gulf of Venice to show uniformly low temperatures at all depths during that season while off the Dalmatian coasts the surface waters are more than 3° F. colder than the underlying layers. When the cyclonic depressions that develop over the Po basin and Gulf of Genoa during the same season move southeastward, the whole coastal area is swept by the cold wind from the northeast (the bora) which brings some danger to small craft as well as general discomfort to the population. In southern areas, a warm damp sirocco (not to be confused with the dry dusty Saharan wind of the same name experienced on the north African coast) blows from the southeast. Surface currents move anticlockwise, entering the Adriatic on the east side of the Strait of Otranto, passing northward along the Dalmatian coast, southward along the Italian shores and leaving on the westward side of the strait. The southward movement, by carrying silt from the Po delta, has extended the lowland toward Ravenna and beyond.

There is a marked contrast between the Balkan and the Italian coasts. The former is rugged everywhere north of Albania, its main features evidently formed by submergence; the latter shows mainly emergent features, though the coastal belt shrinks to a narrow ledge in the Abruzzi. Marshes, lagoons and sandspits border the shores of the Gulf of Venice and extend for some distance south of the Po delta, low marshy ground reaching as far south as Rimini though narrowing to less than a mile beyond Ravenna. In northeastern Emilia-Romagna, side tracts were reclaimed by poldering. Foothills of the Apennines lie close behind the coast through the Marche and Abruzzi e Molise but from Mt. Gargano southward these are replaced by bare limestone plateaus and hills.

There is a marked absence of natural harbours all along the Italian coast. Ancona, on a bay sheltered by a limestone promontory, is the only port for many miles along the middle section. The marsh and lagoon type of coast stretches around the Gulf of Venice almost to Trieste where begins the low limestone plateau of the Istrian peninsula. Southward from the Gulf of Kvarner the coastlands rise very steeply inland, the 1,500-ft. contour being close to the sea everywhere. As far as Dubrovnik the land is fringed with islands (*e.g.*, Krk, Cres, Brac and Curzola) and its coastal margin interrupted by frequent inlets (T- and L-shaped gulfs), all obviously produced by the submergence of valleys between the fold ranges which are there parallel to the shore line. In Albania the coastal plain is wider and more continuous but imperfectly drained.

Penetrating northward so close to the heart of central Europe, the Adriatic has always been of importance as a trade highway. From very early times traffic has passed across it between Italy and the Balkan lands in spite of the obvious difficulties presented by the lack of shelter on the Italian side and the absence of good natural routes leading inland from either shore. Durres (Durazzo) was the western terminus of the great Roman and Byzantine high-

way from Constantinople and Salonika. Dubrovnik and Split were Roman ports on the Balkan side linking with Ancona, Ravenna and Adria on the Italian. Through routes across the Apennines were difficult but, in spite of this, the latter ports also handled trade between Rome and the eastern Mediterranean because of the difficult navigation involved in the voyage by way of the Straits of Messina.

The rise of Venice gave special importance to Adriatic routes because of its easy communication with southern Germany and northwestern Europe by the Brenner pass, as well as to Vienna and the Danube highway by the Semmering pass. Long before the opening of the Suez canal (1869) the main currents of Mediterranean trade had been diverted away from the Adriatic ports. Neither that event nor the frequent boundary changes around its northern land termini have completely robbed it of its former importance. The trade of Venice and Trieste indeed increased as a result of the opening of the Suez canal. Rijeka (Fiume and its suburb Susak), Dubrovnik and Split still carry on more than purely local trade; Trieste handles a large traffic and Venice manages to maintain its position as an outlet for the Lombardy plain. Of the other Italian ports Bari is the most important though Brindisi is still used as a port of call for some liners passing to the east. Ancona is now mainly concerned with fishing and the coastal trade. See also separate articles on the ports.

(T. HER.; C. G. SM.)

ADSORPTION. All solid substances are known to be capable of attracting to their surfaces molecules of gases or solutions with which they are in contact. This phenomenon is known as adsorption. The solids that are used to adsorb gases or dissolved substances are called adsorbents; the adsorbed molecules are usually referred to collectively as the adsorbate. A well-known example of an excellent adsorbent is the charcoal used in gas masks. With its area of about 125 ac. per pound, it is capable of adsorbing and holding large quantities of poisons or impurities that one wishes to remove from a stream of air.

Adsorption refers to the taking up of molecules by the external surface or internal surface (walls of capillaries or crevices) of solids or by the surface of liquids. Absorption, with which it is often confused, refers, on the other hand, to processes in which a substance penetrates into the actual interior of crystals, of blocks of amorphous solids or of liquids. Sometimes the word "sorption" is used to indicate the process of the taking up of a gas or liquid by a solid without any specification as to whether the process is one of adsorption or of absorption.

It is now generally recognized that adsorption can be either physical or chemical in nature. For convenience, these two types of adsorption will be discussed separately. Adsorption from solution is also treated separately.

Applications of Adsorption.—Traditional applications of physical adsorption include the use of charcoal for removing poison gases from the air; hydrocarbons from natural gas; and oxygen, nitrogen or other gaseous impurities from helium during the separation and purification of the latter. Later applications were concerned with the measurement of the surface area of finely divided or porous solids and with the measurement of the pore size and pore distribution of porous solids. Also, in the analytical process known as gas chromatography (see CHROMATOGRAPHY) physical adsorption is responsible for the separation of the various components of a gaseous mixture to produce separate and characteristic peaks on the chromatograms.

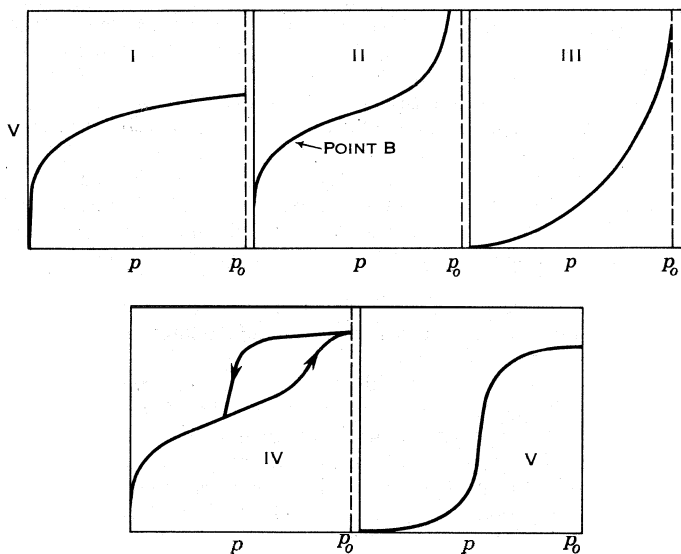

Chemical adsorption or chemisorption, as pointed out below, is of general interest mostly because of its being one of the steps in catalytic processes (*see* CATALYSIS). Typical examples of important catalytic processes include, among others, the synthesis of ammonia, the cracking of hydrocarbons to form gasoline, the synthesis of methanol, the cyclization of heptane to form toluene, the oxidation of sulfur dioxide to sulfur trioxide and the hydrogenation of oils to edible fats. Chemisorption is, however, not an unmixed blessing in catalytic reactions, since it can also slow them down by holding poisons on the catalyst surface.

Adsorption from solution has even more applications than adsorption from the gas phase. Its importance in dyeing, photog-

raphy, brewing, the purification of water, the clarification of oil and in making lubricants more effective is well known. Soils and soil colloids with their large surface areas (30 to 50 ac. per pound) are able by adsorption to remove from solution and retain fertilizer components essential to plant growth. Finally, the separation of components of a solution by liquid chromatography became important not only as an analytical tool for chemists but for separating out specific compounds from liquid solutions. For example, the aromatic, olefinic and paraffinic portions of liquid hydrocarbons can be separated by chromatography on a scale that promises to prove important in petroleum technology.

Physical Adsorption of Gases and Vapours on Solids.—Physical adsorption resembles the condensation of gases to liquids. It depends upon the physical or van der Waals forces of attraction between the solid adsorbent and the adsorbate molecules. As one might expect for a given solid, the adsorption of a gas will become larger as the temperature at which the gas and solid are in contact decreases toward the boiling point of the gas or as the pressure of the gas at a given temperature is increased toward the pressure that would be necessary to actually condense it to a liquid. There is no chemical specificity in physical adsorption, any gas tending to be adsorbed on any solid if the temperature is sufficiently low or the pressure of the gas sufficiently high.

The five fundamental types of isotherms (plots of volume of gas adsorbed against pressure), which separately or in combination can describe the behaviour of all known examples of physical adsorption, are shown in fig. 1.

FROM S. BRUNAUER, "THE ADSORPTION OF GASES AND VAPORS," PRINCETON UNIVERSITY PRESS (1934)

FIG. 1.—TYPES I, II, III, IV AND V ADSORPTION ISOTHERMS. IN EACH PLOT THE VOLUME OF GAS ADSORBED (AS MEASURED AT A STANDARD TEMPERATURE AND PRESSURE) IS PLOTTED AGAINST GAS PRESSURE, p , THE LIQUEFACTION PRESSURE IS p_0

Type I isotherms are representative of solids such as activated charcoals, or natural or synthetic chabazites (*q.v.*) having very small pores (one to ten times the size of ordinary gas molecules). Type II isotherms are obtained on finely divided nonporous solids or on solids having fairly large pores, using as adsorbates inert gases such as nitrogen at temperatures close to their boiling points. Water vapour adsorbed on graphite yields a type III curve. It is generally believed that the heat of adsorption of the adsorbate molecules for type III isotherms is equal to or a little smaller than the heat of liquefaction of the gas being studied. On solid adsorbent having all of their areas located on the walls of cracks or crevices smaller than about $\frac{1}{1,000,000}$ in. in size, isotherms of type IV will normally be obtained. Finally, if the heat of adsorption is small but the pore size is also small, type V curves will be obtained as adsorption isotherms. Water vapour on charcoal gives such a curve provided the amount of surface oxide on the charcoal is relatively small.

Even though the chemical relationship of the gas and solid that is being studied is usually not important in determining the extent or nature of physical adsorption, a certain differentiation among the adsorbents can be made on a basis of the polarity of the solid or the adsorbate. For example, water vapour on graphite gives isotherms of type III, whereas nitrogen, argon, krypton and similar gases give type II isotherms. Apparently the exceptional behaviour of water vapour is to be attributed to the polar character of the —OH group and the nonpolar character of the carbon surface. On the other hand, polar solids such as silica gel adsorb water vapour even more strongly than adsorbates such as nitrogen.

Physical adsorption is characterized by low heats of adsorption and by rapid adsorption and desorption. The only systems in which physical adsorption is slow are those in which the pores are so small that an appreciable time is required for the adsorbate molecules to diffuse down the pores or capillaries to the inner surface on which they are finally to be adsorbed.

Numerous equations have been developed for representing the volume, v , of gas adsorbed as a function of pressure, p . One of these, the Langmuir equation, is of the form

$$v = \frac{abp}{1+ap}$$

Another, called the Freundlich equation, is

$$v = kp^{1/n}$$

In these equations, a , b , k and n are constants. The Freundlich equation usually represents isotherms over certain restricted pressure ranges. At very low pressures or high temperatures the value of n approaches 1; at intermediate pressures, the constant $1/n$ assumes fractional values characteristic of the particular solid-gas system that is involved.

One of the more useful relationships for estimating the extent of adsorption at one temperature from that at another was due to M. Polanyi and his co-workers. In it the volume of gas adsorbed is plotted against the adsorption potential defined by the equation

$$\text{adsorption potential} = RT \ln p_0/p$$

where p_0 is the liquefaction pressure of the gas being studied, T is the temperature, R is the gas constant and p is the pressure at which the volume adsorbed (at a standard temperature and pressure) is being measured. Plots of such data show that except for a slight correction for the two-dimensional expansion of the adsorbed gas, the adsorption volumes taken at a series of temperatures and pressures will fall on a smooth curve.

In 1931 it was postulated that point B on type II isotherms for iron catalysts corresponded to a statistical monolayer of adsorbed gas and that the linear part of these isotherms and the portion convex to the pressure axis (to the right of point B in the type II curve of fig. 1) represents the building up of multimolecular adsorption layers. A theory designed to explain the shape of these isotherms in terms of multimolecular layers may in its simplest form be written

$$\frac{x}{v(1-x)} = \frac{1}{v_m C} + \frac{(C-1)x}{v_m C}$$

where v is the volume of gas adsorbed at the relative pressure, x , of the adsorbate gas and C is a constant. A plot of the left side of the equation against the relative pressure, x , yields a straight line from which v_m , the volume of gas in a monolayer, can be evaluated.

This equation has become known as the Brunauer-Emmett-Teller or BET equation. A simple multiplication of v_m by the cross-sectional area of each adsorbed molecule (as estimated from the density of the liquefied or solidified adsorbate) yields directly a value for the surface area of the solid in any convenient unit such as square metres per gram or acres per pound.

One theory of physical adsorption assumes that in porous solids a considerable portion of the adsorbate is held by what is known as capillary condensation. To express the vapour pressure, p , of a liquid in a capillary, Lord Kelvin derived the equation

$$\ln p_0/p = \frac{2\sigma V \cos \Theta}{rRT}$$

where σ is the surface tension of the liquefied adsorbate gas, Θ

is the contact angle between the liquid and the wall of the capillary, r is the radius of the capillary, V is the molal volume of the adsorbate and R , T and p_0 are as defined above. The existence of capillary condensation is usually assumed to account for the hysteresis that is frequently found in adsorption isotherms representing physical adsorption of gases or vapours on porous solids (see type IV curve in fig. 1). By making proper allowance for the amount of monomolecular or multimolecular adsorption that occurs at a given relative pressure for a particular gas-solid system, it is possible to use the desorption isotherm of the type shown in fig. 1 for the type IV isotherm to calculate with the help of the Kelvin equation the pore size and the pore size distribution of capillaries.

This application of physical adsorption is one that is very valuable in studying the size of pores in catalysts and in other porous solids.

Chemical Adsorption of Gases on Solids.—When certain specially prepared samples of porous iron are placed in contact with a mixture of the two simple gases hydrogen and nitrogen at a dull red heat and at high pressure, a chemical reaction takes place between the hydrogen and nitrogen to form ammonia. In this typical catalytic reaction it can be shown that both the hydrogen and nitrogen are capable of being adsorbed on the surface of the catalyst.

The temperatures involved (450° to 550° C.) are too high to permit physical adsorption to take place. It is concluded that the gases in this high-temperature range are held by chemical forces and hence by what has been called chemical adsorption or chemisorption.

Chemical adsorption occurs usually at higher temperatures than those at which physical adsorption occurs; furthermore, chemical adsorption is ordinarily a slower process than physical adsorption and like most chemical reactions frequently involves an energy of activation.

The heat of chemical adsorption is much higher than that of physical adsorption and corresponds to heats that are involved in chemical reaction

Thus, for example, the heat of physical adsorption of nitrogen on an active iron synthetic ammonia catalyst at -195° C. is in the range 1,360 to 3,000 cal. per mole of nitrogen compared with a liquefaction heat of 1,360 cal. per mole; in contrast with this the heat of adsorption of nitrogen at 450° C. on the same iron catalyst is about 35,000 cal. per mole of nitrogen. Chemical adsorption is perhaps most easily visualized as a surface compound between the atoms of the catalyst surface and the gaseous adsorbate formed under conditions which preclude the possibility of the adsorbate reacting with the main bulk of the catalyst to form a regular chemical compound.

As might be expected, chemisorption is chiefly of interest in connection with the occurrence of catalytic reactions. Apparently at least one of the reacting gases in a catalytic reaction has to be chemically adsorbed on the surface of the catalyst prior to reaction (see CATALYSIS).

One other application of chemisorption should be mentioned. It can be used to measure the surface concentration of components called promoters which are added to catalysts to the extent of a few per cent by weight to improve their activity. For example, the chemisorption of carbon monoxide by the iron atoms and of carbon dioxide by the alkali promoter has made it possible to ascertain that a few per cent of added promoter may cover as much as 50% to 75% of the surface of a doubly promoted iron synthetic ammonia catalyst.

Until relatively recently, little information was available as to the state of chemisorbed molecules on the surface of adsorbents. Only general inferences could be drawn based on the expected nature of interaction of the adsorbate and the adsorbent as judged by their respective chemical properties. In 1953 successful measurements were finally made of the infrared absorption bands of ammonia adsorbed on silica-alumina cracking catalysts and of carbon monoxide chemisorbed on such metals as iron, nickel, cobalt, platinum and palladium. The information obtained from such spectra relative to the nature and the strength of the bonds hold-

ing the adsorbed molecules onto the surface without doubt opened an entirely new approach to a better understanding of chemisorption.

Adsorption in Solution.—When a substance (solute) is dissolved in a liquid (solvent) to form a solution, the solute usually tends to concentrate either in the surface or in the bulk of the solvent. For example, soap tends to concentrate preferentially in the surface of an aqueous soap solution (positive adsorption). On the other hand, inorganic salts, such as ordinary table salt, tend to concentrate in the bulk of an aqueous solution rather than in its surface (negative adsorption).

These qualitative observations have been expressed in a formal manner by the Gibbs adsorption equation

$$\Gamma = -\frac{c\delta\sigma}{RT\delta c}$$

where Γ is the excess surface concentration of the solute in gram-moles per square centimetre; c is the mean concentration of the solute; $\delta\sigma/\delta c$ is the change of surface tension of the solution with the concentration of solute; and R and T are as defined above.

Adsorption From Solution by Solids.—The adsorption of a solute on the surface of a solid in contact with a solution is of fairly common occurrence. For example, activated carbon is used for removing coloured impurities from solution; clay can remove coloured components from oil; and bone char is used to remove impurities from sugar solutions in sugar refining.

The adsorption of solutes by added solids is generally explained according to the same Gibbs concept used for explaining the adsorption at a gas-liquid interface. However, it is much more difficult to measure surface tension at a liquid-solid interface. Accordingly, quantitative proof of the applicability of the Gibbs equation to adsorption from solution onto a liquid-solid interface is for the most part still lacking.

It is to be expected that the extent of adsorption from solution will depend on the nature of the solid adsorbent, the nature of the solute and the nature of the solvent. The detailed manner in which each of these influences the extent of adsorption is still not understood in spite of the large amount of research done on the subject in the first half of the 20th century. However, the influence of certain factors has been well documented and will now be briefly summarized.

The adsorption per gram will, for a given solid, increase with an increase in its accessible surface area. The accessible area, in turn, will for a given particle size depend upon the size and distribution of pores within the solid adsorbent. Since the adsorbate in a solution must reach the inner surface of a porous adsorbent by diffusion through capillaries filled with solvent, the amount of adsorption in any given time will depend on the nature

TABLE I. — Adsorption of Various Fatty Acids on Charcoals of Different Porosities

Weight ratio*	Propionic acid		Valeric acid		Enanthic acid	
	Per cent ads.†	Time for 75% equil.	Per cent ads.	Time for 75% equil.	Per cent ads.	Time for 75% equil.
1.00 . .	15	96 hr.	5	150 hr.	3	380 hr.
.86 . .	47	< 3 hr.	58	< 3 hr.	45	< 60 hr.
.83 . .	30	< 1 hr.	68	< 1 hr.	95	< 1 hr.
.55 . .	55	< 1 hr.	88	< 1 hr.	98	< 1 hr.

*100 (1-weight ratio) is the percentage weight loss in the charcoal during activation. †25 c.c. of .6N acid and 0.1 g. of charcoal were used in each case; "Per cent adsorption" is the per cent of the added acid that is adsorbed.

of the pores and capillaries as illustrated by the data in Table I (see M. Dubinin, *Z. physik. Chem.*, 1931).

In the original unactivated material the pores were so small as to tend to screen out the larger molecules. With increased activation the charcoals increased their total adsorptive capacity and the pores became sufficiently enlarged to permit all of the solutes to be adsorbed regardless of molecular size.

It goes almost without saying that the time required to reach a given percentage of the final equilibrium values decreases as the pores become enlarged by activation. The rate of adsorption can be judged on these four charcoals by the time required to reach

FROM F. E. BARTELL, G. H. SCHEFFLER, AND C. K. SLOAN: "J. AM. CHEM. SOC." 53, 2501 (1931)

FIG. 2.— THE ADSORPTION OF ETHYL ALCOHOL FROM A BENZENE SOLUTION ON SILICA GEL (CURVE 1) AND ON CHARCOAL (CURVE 2). THE POSITIVE ADSORPTION REGION CORRESPONDS TO A HIGHER RATIO OF ALCOHOL TO BENZENE ON THE SURFACE THAN IN THE BULK LIQUID; THE NEGATIVE REGION, TO A LOWER RATIO

75% of the final equilibrium adsorption (see Table I).

An excellent illustration of the influence of both solvent and solute is given by the data in Table II (see M. Dubinin and E. D. Zaverina, *J. Phys. Chem.* [U.S.S.R.], 1933).

TABLE II.— Adsorption* of Fatty Acids From Water and From CCl_4 on Birch Charcoal

Acid	From water		From CCl_4	
	k	$1/n$	k	$1/n$
Formic	0.316	0.340	2.239	0.115
Propionic646	.238	.851	.131
Heptylic	1.203	.180	.158	.433

*The adsorption is given in terms of the constants k and $1/n$ of the Freundlich equation.

As is evident, the adsorption from water increases with the molecular weight of the acid, whereas from CCl_4 the extent of adsorption decreases with an increase in molecular weight. In both solvents the adsorption increases as the solubility of the solute decreases.

Not only the nature of the solute and solvent but the actual composition of a solution has a strong influence on the extent and nature of the adsorption on an added solid. This is illustrated by the curves in fig. 2, taken from the work of F. E. Bartell, G. H. Scheffler and C. K. Sloan, *J. Am. Chem. Soc.* (1931).

The solid curve shows that on silica gel small amounts of ethanol are strongly adsorbed from a benzene solution. At high concentrations of ethanol, on the other hand, benzene is preferentially adsorbed. The dotted curve shows the corresponding adsorption isotherm for a sample of activated carbon. Clearly, the polar ethanol is relatively much more strongly adsorbed by silica gel than by activated carbon.

Attempts are sometimes made to list adsorbents in order of their efficiencies. However, the nature of the adsorbate, the presence or absence of a solvent, the concentration of adsorbate, the temperature and the surface area and pore size of a particular sample of adsorbent are all factors that can influence the efficiency of a given chemical species of adsorbent. Reference should therefore be made to some of the comprehensive treatises for detailed information that would enable one to select the proper adsorbent for a given adsorption problem.

One special type of adsorption from solution merits special mention. It can be illustrated by zeolitic materials commonly used in water softening. Certain ions such as Ca^{++} , Mg^{++} , etc., are taken up by the zeolites. In the process, an equivalent amount of Na^+ , H^+ or other ion is released to the solution. The resulting "adsorption" of the Ca^{++} is really an exchange reaction of the type

where NaX represents the original zeolite or synthetic ion ex-

changer. Exchange adsorption does not represent a true adsorption in the strictest sense of the word. Nevertheless, it is extremely important in modern living and is fairly closely related to adsorption.

ADULLAM, a Canaanite city with a king (Josh. xii, 15) in the Shephelah (Josh. xv, 35), fortified by Rehoboam (II Chron. xi, 7) and still a place of importance at the time of the Maccabees (II Macc. xii, 38). Its chief interest lies in its connection with David, who took refuge in its stronghold ("cave" is now generally admitted to be a scribal error; I Sam. xxii, 1); hence the allusion in the name Adullamites (*q.v.*) to seceders from a political party on some special issue. A site on the eastern edge of the Shephelah (Shefela) depression in southern Israel, in the neighbourhood of Socoh (Shuweikeh), seems to be indicated. Conjectural identifications have been (1) Khareitun in Jordan, southeast of Bethlehem, which has a large cave; (2) Deir ed-Dibban, about 6 mi. E. of Shuweikeh, where there are caves; and (3) 'Aid el-Ma' (an Arabic popular version of the name), south of Shuweikeh. The last identification is the one most favoured and the particular site is now held to be Tell esh-Sheikh Madhkur to the south of it.

See G. A. Smith, *Historical Geography of the Holy Land*, 25th ed. (1931).

ADULLAMITES is the name given to the English politicians who rebelled against their Liberal leaders and defeated the Reform bill of 1866, designed by Lord John Russell and W. E. Gladstone to enlarge the electorate by about 40%. These dissidents were aptly described by John Bright as a "political Cave of Adullam," attracting "every one that was in distress, and every one that was discontented." They eventually became about 40 strong; Russell's majority disappeared and his ministry resigned in June. Throughout a session remarkable for brilliance of debate and skill in parliamentary maneuver, the main attack upon the bill came from the Xdullamites, a heterogeneous association with varying motives; and especially from Robert Lowe (later Viscount Sherbrooke, *q.v.*), who, according to Gladstone, "really supplied the whole brains of the opposition" and "had such a command of the Rouse as has never in my recollection been surpassed."

Lowe's speeches form a classic statement of the view that democracy is inimical to good government. Such "distress" was genuine; but "discontent" was also important. Lowe and his lieutenants, E. Horsman and Bernal Osborne, were unrepentant Palmerstonians with frustrated ambitions, who resented the mounting influence of Gladstone and the radicalism of Bright in the Liberal party. Powerfully supported by John Thadeus Delane (*q.v.*) in the *Times*, they could rely upon "a last rally of aristocrats of the Whig decadence," in which heirs to peerages, notably Lord Elcho and Lord Grosvenor, played a prominent part; and they were followed by certain members for small constituencies who feared the loss of their seats.

The Adullamite revolt was symptomatic of the divisions within Liberalism after Lord Palmerston's death, and foreshadowed later secessions to Conservatism. However, its success was short-lived and the group soon dissolved. Popular demand for reform, previously limited, had been sharply stimulated by the bill's defeat; and in 1867 their recent ally, Benjamin Disraeli, passed a much more drastic measure, the second Reform act. (A. F. T.)

ADULT EDUCATION, in its broadest sense, signifies any form of learning undertaken by or provided for mature men and women. Because of the scope of this meaning, the term has had many special interpretations, each built on a conception of the learning process, a historical movement or an institutional pattern.

Adult education deals with that whole span of life which begins when childhood is left behind and continues until death. The mature person passes through several stages that are perhaps as clearly differentiated as are the various periods of childhood. He lives in a social climate that influences his values and shapes the meth-

ods by which he achieves his goals. He is also an individual with his own abilities and interests. It is not surprising, therefore, that education carried out in such diverse circumstances presents a vast and varied panorama and one that obstinately defies exact analysis.

The very breadth of the picture, however, provides at least one safeguard: the student of adult education is less likely than the student of earlier education to believe that learning is purely an institutionalized process. Thus the education of the child from 6 to 12 years of age is often thought to be synonymous with the work of the elementary school in the U.S. and the primary school in England despite the obvious fact that the child learns many things not taught him in school. In adult education it is self-evident that no single institution or program can be dominant; central attention must always be given to the learning processes of individuals and groups and not to particular organizational forms.

Many who discuss adult education start from the premise that "education" and "life" are synonymous terms. Since the early Greeks, philosophers have argued that the duty of the statesman is to build a society which will instruct its citizens in the virtues. John Stuart Mill believed that "in its largest acceptation" education (either good or bad) is the result of all experience, a point also central to John Dewey's philosophy. Those who hold this view emphasize the educative impact of motion pictures, television and other mass media; they urge programs of housing, slum clearance or prison reform because of their positive influence; they contend that each person is a product of his relationships with other individuals and groups; and they argue that democratic government, voluntary association and other arenas of practical decision are the proper centres of adult education.

Despite the truth of this viewpoint, most people use the term "adult education" to mean only those experiences that are undertaken with the intent to learn or to teach others some skill, knowledge, understanding, attitude or appreciation. This limitation of the term is supported theoretically on the ground that purposeful learning is more effective than indirect learning, and practically by the fact that purposeful learning tends to be systematic and therefore can be analyzed and appraised without broadening the frame of reference to include all human existence. Those who hold that adult education is activity consciously directed toward learning tend to be interested in the self-education of individuals or to concentrate upon the work of such institutions as the school, the university, the library and the museum, or such educational programs as those carried on by churches, corporations, unions, government departments and co-operatives.

Some form of organized adult education may be discerned in virtually every human society. Anthropologists have noted that some tribes have mysteries to which the individual is not inducted before the years of maturity; one might say, therefore, that organized adult education appears even in primitive communities. Certainly it is present in every civilized society and, in general, the more complex that society, the more ample are its provisions for the education of mature people. The programs of all countries have surface similarities since many of the needs of adults for learning are universal, but essentially each country's work is unique, reflecting the distinctive culture of the nation.

AIMS

The conception underlying much adult education throughout the world is that of helping men and women acquire the knowledge they missed in childhood. Those who pioneer in developing schools for children quickly become aware of how many adults also are ignorant. In country after country the realization of this fact has led to the provision of night schools, evening colleges and other programs because adults demanded learning for themselves, because educators felt a mission to take knowledge to everyone regardless of his age, and because schools for children would not long survive if they had to depend for support on an ignorant citizenry. The major world-wide task of adult education is suggested by the often-quoted observation of James Yen that "three-fourths of the world's population are under-housed, under-clothed, under-fed, and illiterate." These people are to be found in even the most advanced nations, but they are concentrated in under-developed coun-

tries. Throughout the world there are significant efforts to use education to help such people attain a better material life. The governments of such countries as India, Mexico and Ghana support projects designed to educate increasing numbers of their citizens. Most nations feel an obligation to help develop their colonies, their territories and the lands they protect. The financing of developmental activities (including adult education) has become an established foreign policy in many countries. Private efforts are supported by philanthropy or as a part of industrial development. International organizations—most notably, UNESCO—sponsor and stimulate many forms of fundamental education. These various approaches, however, have been inadequate to meet the massive need.

A closely allied conception of adult education is that it is the means by which society will be improved. The quality of a community or a nation rests fundamentally on the wisdom of its citizens. The central task of adult education, therefore, should be to help mature members of society make wise choices on social matters and carry out needed changes. Such education may focus on the individual with the expectation that he will use his knowledge to improve society or it may operate more directly to analyze social ills and remedy them. The Danish folk high school, a secondary school for adult education, for example, became effective as an instrument of national regeneration after defeat by Germany in 1864. The program of St. Francis Xavier university in improving the conditions of fishermen, farmers and miners in the maritime provinces of Canada through the Antigonish movement combining adult education, credit unions and co-operatives is another outstanding example. Efforts to improve society by adult education are going forward throughout the world in countries at all levels of civilization.

The third and most profound conception is that education should be a continuous process throughout maturity, so that the individual may develop, as far as his span of years permits, the vast potentialities of his nature and so that society may benefit as he does so. Those who operate in terms of the first conception sometimes assume that when the existing group of underprivileged adults is cared for and a sound system of schooling for children is established, the need for adult education will disappear. What actually happens is that the need and desire for adult education increase and the ends sought become more varied and intricate. The same development often occurs in efforts to use education to advance society. As specific social needs are met, the surviving institutions broaden their programs to provide for lifelong learning. The folk movements of Sweden, for example, which were originally dedicated to such social goals as temperance, the organization of co-operatives and the advancement of labour unions, came to provide for a wide range of interests and needs.

The various institutions and movements of adult education can find their unifying aim only in such general conceptions as the three expressed above. This point is often obscured because the term "adult education" acquires certain values as it is used within a particular setting. It is sometimes assumed, for example, that adult education is inherently democratic or that it necessarily is concerned with the self-development of the individual. In fact, the massive efforts of Russia, China and other communist countries to use education to build a totalitarian society may closely resemble comparable programs in the free world. See also HIGHER EDUCATION: *Points of View*.

MEANS

Each major institution of adult education has its own method of work and its unique terminology. A librarian, a museum curator, a head resident of a settlement house, a dean of university extension and a director of an evening school each will have strong traditions that guide his efforts. Even though all may serve the same city, they may find it hard to communicate with one another or to discern the common unity of their work. The increasing alliance of such people with one another in various associations and councils indicates, however, that they have not only common aims but also fundamental methodological principles.

Since most studies of the learning process have used children

as subjects, the psychology of adult education has not been very fully explored. Observation, however, makes clear some outstanding differences between learning in adulthood and in childhood. The adult, for example, has had more experience than the child, as well as kinds of experience that are denied to children, such as courtship, marriage and parenthood, which enrich and give perspective to his learning processes. Also, the child goes to school to fulfill an expected obligation, to prepare for later life and to receive the training which his society believes he needs, whereas adults undertake learning experiences chiefly in terms of immediate necessities or absorbing interests. The adult can learn most things more rapidly than can the child, although many adults encounter initial difficulties because of lack of practice and because their habit patterns are more fixed than are those of children, a fact which is often a deterrent, although not necessarily a block, to education. Another difference is that the teacher of adults has no generalized authority over his students such as that growing out of the adult-child relationship in earlier schooling. He has only the authority he can win by his demonstrated competence.

More exact investigation may lead to the conclusion that the successive stages of adulthood are as worthy of separate methodological consideration as are the various periods of childhood.

INSTITUTIONAL FORMS

As the foregoing suggests, organized adult education exists in all countries, although its institutional patterns vary markedly. In addition to the many illustrations already mentioned and the fuller treatment of activities in the United States and Great Britain, the following other significant programs might well be noted.

As a part of the process of helping its colonies toward full nationhood, Great Britain has established or assisted a number of institutions of higher learning in Africa, Asia and the Caribbean. These fledgling universities usually contain extramural departments, whose work is concerned chiefly with the further education of those who are capable of undertaking advanced studies.

The community development movement, by which local problems (chiefly in emerging nations) are attacked directly by the people themselves operating with skilled advice and assistance, has spread throughout the world. Such activities are supported by private ventures, by national governments, by colonial powers and by the United Nations and its affiliates. This movement has several emphases which are clearly educative in intent and execution. Among them are literacy campaigns and efforts to bring enlightenment to women, helping them to emerge from their subordinate positions and giving them a greater knowledge of sanitation, diet, child-rearing and other aspects of home and family living. The development and execution of local improvement projects (such as the building of roads, schoolhouses and latrines) is also treated in such a way as to create a greater awareness of the spirit and processes of democracy and is therefore fundamentally educational in purpose.

In many countries government departments often have an important role to play. The diffusion of agricultural knowledge, for example, which is essentially a university function in the United States, is a responsibility of the ministry of agriculture in almost all other countries. Many kinds of specialized assistance are also given by health, social welfare, correctional and other departments.

Public libraries are unevenly developed throughout the world. Where they do exist, they often provide important centres for individual study, supplementing the work of other institutions and helping to remedy deficiencies caused by the lack of formal and informal instructional programs.

Finally, it should be noted that throughout the world local initiative, individual leadership, and voluntary effort have produced many different kinds of institutions—missions, instructional centres, museums, mutual improvement circles, residential units and voluntary associations. Some are independent; others are affiliated with organizations which have more general purposes, such as churches, labour unions or political organizations. Each of these institutions approaches the task of education in its own distinctive fashion, and some of them mix education with fraternal, recreational or propagandistic purposes. While each of them is

small and may even appear insignificant (particularly in terms of the overwhelming needs of underdeveloped countries), their total impact throughout the world may eventually prove to be very great. Some of them are the sources for later movements of more significant size. Others will achieve their impact by influencing individuals who are destined for leadership.

UNITED STATES

Early Organizations.— In the United States, organized adult education has existed from colonial days. The need to create the basic conditions of a satisfactory life on a new and unsettled continent led the early migrants from Europe to organize various forms of activity, of which the most important was the private school, which usually met in the evening and taught vocational subjects and the rudiments of language and arithmetic.

When the new nation was created, its founders realized that while they had gained political independence there remained the necessity of creating culture in a relatively primitive land. The first half of the 19th century was a period of rich development of institutions, each one unique and often unrelated to the others but all providing new channels of learning. Most important were the lyceums, local associations of men and women who had had some formal education and were concerned both with their own further learning and with the creation of a public school system. Paralleling the growth of the lyceums and to some extent developing out of them were libraries, museums, mechanics' institutes, lecture series, endowed institutions, publicly supported evening schools, and a host of other institutions, many of which achieved permanent status. (See also LYCEUMS AND CHAUTAUQUAS.)

The 25-year period after the close of the American Civil War was another time of national appraisal and readjustment and therefore another era of growth for organized adult education. Old institutions gained strength. Sporadic university lecture series for the general public flowered into systematic programs of university extension. The Chautauqua institution had great influence and inspired other activities, such as reading circles, traveling chautauquas, summer schools and encampments, and correspondence instruction. Then and later the process of invention continued, often occurring by the creation of voluntary associations which in time were to achieve massive memberships. The National Congress of Parents and Teachers is the best known and largest organization of this type but it is paralleled by countless other groups which vary greatly in size and objectives.

20th Century Developments.— The drive toward the wider diffusion of scientific agriculture which had led earlier to the founding of land-grant colleges and experiment stations finally culminated in 1914 in the establishment by the federal government of the extension service in the department of agriculture. This service became the most highly organized and pervasive instrument of adult education in the United States (see AGRICULTURAL EDUCATION AND RESEARCH). When the country entered World War I in 1917, public attention turned to the need for vocational training and congress passed the Smith-Hughes act establishing widespread activities in this field for both young people and adults. The nation also became aware of the many illiterates and unassimilated foreigners in the population (see AMERICANIZATION). Programs designed for these two groups were greatly expanded, thereby treating a corps of teachers which later provided one nucleus for the development of a broad adult educational movement. The department of immigration education of the National Education association became the department of adult education in 1921.

In that same year the Carnegie corporation, under the leadership of Frederick Keppel, became interested in adult education and subsidized a number of exploratory inquiries. Observing European programs, Keppel believed that similar activities should be initiated in the United States, but eventually came to the conclusion that the chief need was not the creation of a new program but the extension and co-ordination of existing efforts. Accordingly the American Association for Adult Education (A.A.A.E.) was founded in 1926. This organization, largely financed by the Carnegie corporation until 1941, undertook a broad program studying adult education, bringing together those engaged in the field and,

in other ways, stressing the importance of lifelong learning. The A.X.A.E. was particularly successful in enlisting the support of leading figures in political, literary and academic life. Its executive director, Morse A. Cartwright, was for many years the dominant figure in U.S. adult education.

Two enormous programs, one in the 1930s and the other in the 1940s, brought adult education to the attention of the general public and provided initial experience for many of those who were later to be the leaders of the field. The work-relief programs of the depression years used professional and other skilled workers as teachers for adult classes, enrolling at one time more than 2,000,000 students. An even larger program began when the United States entered World War II. In addition to the task of training about 16,000,000 civilians to undertake highly specialized technological warfare, the armed services provided a broad program of off-duty education through classes, discussion groups and correspondence instruction.

By the close of the war, it was apparent that adult education had become a mass movement of great size. The same expansion was taking place at the adult level as had occurred during the 19th century in elementary education and in the first quarter of the 20th century in secondary education. However, while there was great extension of opportunities, programs of service were often poor in quality, brief in duration and guided by either improvisation or the borrowing of procedures originally used in the education of young people but extremely inappropriate for more mature students. A number of attempts to develop a more vital approach were initiated, the most sustained being the group dynamics movement, in which a key figure was Leland Bradford. This was the first major development of educational psychology which worked out its principles with mature students, although it was later seen to have great implications for the education of children as well. A number of university departments of education also began to develop research and training programs, the latter intended primarily for administrators in the field.

In 1951 both the department of adult education and the A.A.A.E. disbanded and the Adult Education Association of the U.S.A. was founded to provide a unified focus for all workers in the field. That same year the Ford foundation created an independent organization, the Fund for Adult Education, to study the whole field and provide financial resources to those efforts which offered the best hope for the development of broad liberal study by adults.

Categories of Institutions. — Education in the United States is generally characterized by its decentralization of control, but nowhere more conspicuously than in adult education. The institutions operating in the field are myriad but they may be grouped together into certain large categories distinguished in terms of basic purpose.

The first category includes those institutions which are primarily concerned with the education of adults. Grouped here are the extension services, the private schools (including those which teach by correspondence), the vocational rehabilitation agencies, and specially endowed institutions (such as Cooper Union).

The second category includes those institutions which educate both adults and young people. The chief examples are the public schools and the institutions of higher learning. Since the control of these institutions in the United States is highly autonomous, the extent and quality of adult education they offer vary markedly.

The third category includes those institutions in which adult education is a co-ordinate function paralleling such other purposes as recreation, community service or fraternity. In this category are libraries, museums, group work agencies, voluntary associations, settlement houses, community centres and co-operatives.

The fourth category includes those institutions in which education is a subordinate function used to accomplish a primary end. In this category are churches; labour unions; industrial and commercial companies; governmental departments interested in defense, health, welfare, safety, conservation, correction and other purposes; hospitals; commercial mass media of communication; and associations whose aim is to improve or reform society.

Many of those professionally engaged in adult education are primarily identified not with any one institution but with a field of

specialization which cuts across the work of many institutions. Health education, safety education, education for effective home living, vocational education and many other areas of work provide a focus for those with special training or interests.

A brief listing such as the foregoing can include only the major enterprises. It leaves out of account what may well be the largest and most important form of American adult education: the effort of the individual or of the small special group to achieve, with any resources at hand, a better understanding of the world and a greater capacity to deal with it.

GREAT BRITAIN

Early Organizations. — The rise of organizations to promote adult education in Great Britain is generally dated from the end of the 18th century. An adult school was founded in Nottingham in 1798, and lectures given to artisans by George Birkbeck in Glasgow in 1799 led to the establishment of the first mechanics' institute. In the first half of the 19th century adult schools and mechanics' institutes were established in many parts of England. The inspiration and purposes of the two kinds of institutions were different. The institutes arose out of the desire of artisans to understand the sciences and applications of science which were transforming industrial processes and social conditions. The adult schools were formed largely by religious people who wished to reduce adult illiteracy, often with the hope of encouraging the reading of the Bible. Both the schools and the institutes were supported entirely by voluntary effort and financial contributions. After the middle of the 19th century both tended to decline. Some of the institutes became technical colleges, others middle-class reading and lecture societies. The adult school movement revived in the latter part of the century and was still active in the second half of the 20th century.

Apart from organizations concerned with adult education in its less formal modes, the 19th century saw the appearance of educational work promoted by co-operative societies, the establishment of people's or workingmen's colleges and the rise of the university extension movement.

The workingmen's colleges were in part the result of dissatisfaction with mechanics' institutes, in part the product of Chartist and of Christian Socialist ideas. The first was started in Sheffield in 1842 but the best known was established in London in 1854 under the leadership of F. D. Maurice. Others were founded in a number of towns but disappeared or changed their character. All were nonresidential, unlike Ruskin college, Oxford, which was founded in 1899 to provide workingmen with education designed to equip them for their responsibilities as citizens and trade unionists. A "strike" in Ruskin college against the "orthodox" teaching of economics led in 1909 to the establishment of a labour college in London and later to the foundation of the National Council of Labour Colleges, which rejects the idea of "objective" adult education.

The university extension movement, in its narrower sense of a movement for part-time adult education, owed its inception to James Stuart, a Cambridge university lecturer who in a private capacity delivered courses of lectures to audiences in the north and midlands in the late 1860s. As a result of his work, Cambridge university in 1873 set up a Local Lectures syndicate to provide lecture courses in many parts of the country and the universities of London and Oxford took similar steps in 1876 and 1878 respectively, the London work being confined to the metropolitan area. The provision of lecture courses increased rapidly in the 1880s and 1890s, in spite of the fact that all the costs of lecturers' fees had to be borne by the students. This was a principal reason for the comparative failure of the movement to attract large numbers

of working-class students, but it met a strong middle-class and feminine demand for facilities for higher education, and in several towns extension societies were among the institutions out of which new university colleges, later to become universities, grew.

20th-Century Developments. — In the 20th century the term adult education has been used to denote the "liberal education of adults," in distinction from the term "further education," which has been used with reference to technological and other vocational education for adolescents and adults. Adult education thus interpreted has been the concern largely of voluntary organizations, especially the Workers' Educational Association (W.E.A.), and the extramural departments of universities, with financial assistance from the board and ministry of education and from local education authorities.

The W.E.A. was founded by Albert Mansbridge in 1903. Mansbridge's original intention was to create an organization which would bring together the university extension movement and working-class people and organizations. In 1907, however, a conference held at Oxford considered afresh the best way in which universities might contribute to working-class education and in 1908 the University of Oxford sponsored two university tutorial classes. The purpose of the classes was to provide opportunities for working-class students to pursue long and thorough courses of study under university teachers, and though lectures formed part of the class proceedings, much importance was attached to discussion of the lecture and to regular reading and writing at home by the students. In the interests of tutorial work the size of classes was limited. With R. H. Tawney as tutor, the first classes were very successful and the quality of the work done impressed observers in the universities and the board of education. More classes were promoted by Oxford and by other universities, and in 1909 Oxford instituted a joint committee of members of the university and working-class representatives nominated by the W.E.A. to be responsible for the organization of this kind of work.

Similar joint committees were shortly afterward set up by most of the other universities in England and Wales, and by 1914 the tutorial-class movement was well established, with every university and university college participating.

The establishment of university extramural departments followed the publication in 1919 of the final report of an adult education committee of the ministry of reconstruction. In addition to suggesting that universities should institute departments of adult education with full-time academic heads and full-time as well as part-time staffs, the committee strongly urged that grants should be made directly to voluntary organizations by the board of education to enable them to provide facilities of a less advanced kind. In 1924 the board issued grant regulations giving effect to this proposal and before the outbreak of World War II was making contributions to the teaching costs of courses attended by some 66,000 students, of whom over 12,000 were in university tutorial classes.

After the passing of the Education act of 1944 the provision of publicly assisted adult education in Great Britain increased considerably. The number of students attending classes provided by universities and the W.E.A. with financial assistance from the ministry of education was in the second half of the 20th century more than 150,000, of whom more than half were women, though the number in university tutorial classes was little more than before 1939. Four universities which had not previously done so set up extramural departments. Approximately 30 new residential colleges for adult education were established. Some were provided by universities, a small number by voluntary effort, but the majority by local education authorities. They all differed from Ruskin college and several others established earlier in the 20th century in that they provided only short courses, lasting anything from a weekend to a few weeks, or occasionally two or three months. Wartime arrangements for providing civilian aid to adult education in the armed forces were replaced in 1949 by a permanent scheme comprising a central committee for adult education in her majesty's forces and committees for services' education at most of the universities, all providing for representation of the universities, local education authorities, the W.E.A. and the

education branches of the services. A number of full-time tutors were engaged for this work by universities and the W.E.A. and a considerably increased number for work with civilian students. A Universities' Council for Adult Education and a National Institute of Adult Education were founded, while a Central Joint Advisory Committee for Tutorial Classes, which was established in 1909, continued to be active.

Organizations providing less formal kinds of adult education (notably women's institutes) expanded rapidly, and local education authorities concerned themselves more with "liberal" adult education than in the past.

The distinctive features of British adult education remained: the large part played by the universities; the recognition of the importance of voluntary organizations; the substantial state assistance given both to universities and to voluntary organizations; and the concern with liberal and social studies.

ADULTERATION, the act of debasing a commercial commodity or substituting an inferior article for a superior one in order to gain an illegitimate profit. The term is usually applied to the debasement of foods, drugs or cosmetics. See HEALTH AND SAFETY LAWS.

ADULTERY, sexual intercourse by a married person with someone other than the spouse. In some U.S. penal legislation the term includes also an unmarried person's sexual relations with one who is married. Adultery is almost universally regarded as the gravest infraction of marital vows and is, therefore, the commonest ground for divorce specified in the statutes. Except for an interlude in Cromwell's 17th-century theocracy, adultery has always been regarded in England as a matter exclusively within the cognizance of spiritual authorities. A number of other countries, e.g., Japan, Uruguay and the U.S.S.R., have no penal provisions on the subject. Some codes, e.g., those of France, Italy and Argentina, distinguish between adultery by a husband and adultery by a wife, punishing the latter more severely or in circumstances where the husband would not be guilty of an offense.

In the United States, as a result of Puritan influence and absence of any official church with acknowledged jurisdiction, criminal legislation against adultery (and even fornication between unmarried persons) is quite common. The maximum sentence authorized for adultery ranges up to 21 years, but 5 years is the typical maximum. It is remarkable that actual prosecutions have been extremely rare, even in a state such as New York where thousands of cases of adultery have been made a matter of judicial record every year in divorce proceedings. The practical nullification of the penal provisions against adultery probably reflects general recognition that adultery, although immoral, is not subject to effective restraint by the penal law and occurs so frequently as to make it unfair to select a few scapegoats for punishment. The American Law Institute voted in 1955 not to include adultery in its Model Penal code. See also DIVORCE; MARRIAGE.

ADUWA, a town in the province of Tigre, Ethiopia. It lies 6,500 ft. above sea level 17 mi. E. of Aksum, the ancient capital of Ethiopia, and 50 mi. W. of Adigrat, which is on the main Dessye-Xsmara highway. It is a market centre of an agricultural district. Pop. (1956 est.) 6,500. About 2½ mi. to the northwest, on a volcanic outcrop, are the ruins of Fremona, the headquarters in Ethiopia of the Portuguese Jesuits during the 16th and 17th centuries. The site of the crushing defeat of an Italian force under Gen. Oreste Baratieri by Emperor Menelik II on March 1, 1896, is about 10 mi. E. of Aduwa, in a fantastic region of volcanic

formations. His victory firmly established Menelik's authority in Ethiopia. The town was bombed and captured by the Italians in Oct. 1935 and incorporated into Eritrea. It was recaptured by British and Ethiopian troops in April 1941. See also ETHIOPIA OR ABYSSINIA: History; ITALY: History. (G. C. L.)

AD VALOREM, the term applied to tax rates, particularly of customs and excise levies, which are imposed on the basis of value of the taxed items. Literally the term means "according to value." Traditionally in Great Britain, the United States and, other countries most customs and excises had "specific" rates; that is, the tax base was defined in terms of physical units such as gallons, pounds or individual items. While many excises, such as those on gasoline, liquor and tobacco, and many customs duties (all in some countries, such as Switzerland) still have specific rates, there has been a definite trend toward increased use of ad valorem rates.

The ad valorem basis has the important advantage of adjusting the tax burden in terms of consumer expenditures on the taxed items and avoids the serious discrimination of specific rates against the low priced varieties of the commodities. Cigarette producers have long argued that the specific rate on cigarettes has drastically checked the growth of economy brands. If customs duties are designed primarily for protection, the ad valorem basis provides more adequate protection for the more expensive articles in the class, and avoids the extremely detailed classifications of goods and rate structures often established in specific rate tariffs in an effort to adjust the duty in a rough fashion according to value.

The primary difficulty with the ad valorem basis, one of particular concern with tariffs, is that of establishing a satisfactory value figure. The usual practice is to define the dutiable value as the foreign export value (converted, when necessary, at the current exchange rate), that is, the actual cost to the importer or the domestic sale value in the exporting country, whichever is greater. An invoice must be submitted at the port of entry giving details of cost and final decision is made by the customs appraisers. Firms engaged in foreign trade occasionally complain of unreasonable valuations. With excise taxes the task is simpler since the rates can usually be applied to the actual selling price of the vendor liable for payment of tax, a figure readily available. However, a few difficulties are encountered, particularly when an ad valorem excise is applied at the manufacturing level. If the tax is applied to the actual price in all cases, those manufacturers who perform wholesaling functions and sell to retailers or consumers will be discriminated against compared to firms selling competing goods in large volumes at low prices to wholesale distributors.

Sales taxes of broad scope of necessity must have ad valorem rates. Property taxes are sometimes referred to as ad valorem levies since the rates are applied to the value of the property, as distinguished from special assessments, which are frequently imposed on a specific unit (*e.g.*, front footage) basis. (J. F. D.)

ADVANCED GUARD, the protective detachment pushed forward in advance of an army or smaller force, moving towards the enemy. Although protective in purpose, its action is largely offensive in order to fulfill its duties. These are to gain information of the position and strength of the enemy's main forces, to deny similar information to the enemy's reconnoitring troops, to brush aside his advanced detachments and so prevent delay to the march of the main body. When the advanced guard eventually comes to grips with the real strength of the enemy, it should fix him securely in order to allow its own main force to deploy and maneuver. Gaining time is then as vital as saving time in the earlier phase and for this purpose the advanced guard may have to resort to attack, defense, or an alternation of both.

The role of an advanced guard may be likened to that of an outstretched arm of a man moving in the dark. Flank guards and rear guards are variations of an advanced guard, whose names explain their roles. Outposts are a protective detachment to a force halted.

ADVANCEMENT, in law, a sum of money or other benefit conferred by a parent or a person in loco parentis (acting in place of a parent) upon a child, later to be deducted upon the parent's death from the child's share in the estate. The rule that an ad-

vancement must be brought into hotchpot (*q.v.*) has its basis in the presumption that generally a parent does not wish to treat his children unequally. The presumption is rebuttable, however, and the determination of whether or not a benefit conferred upon a child by his parent was meant as a gift, an advancement, or perhaps only as a loan may be difficult in particular cases. In England a benefit conferred upon a child for the purpose of establishing him in life or upon the occasion of his marriage is rebuttably presumed to be an advancement. In the United States some state statutes provide that no benefit conferred upon a child is to be treated as an advancement unless it has been clearly stated to be so at the time it was conferred. The rules on advancement apply only where the parent dies intestate. Where the parent has made a will containing a provision for the benefit of a child and afterward actually confers to that child a benefit of property of a description similar to that given by the will, under the rule against double portions the benefit is presumed to have been given in full or partial satisfaction of the legacy. See also INHERITANCE.

See D. H. Parry, *Law of Succession* (1953); T. A. Atkinson, *Law of Wills* (1937). (M. R.N.)

ADVENT, a holy season of the Christian church, the period of preparation for the celebration of the Nativity or Christmas (Lat. Adventus, "coming"; *i.e.*, of Christ), and also as preparation for the second coming of Christ. In the Western Church Advent begins on the Sunday nearest to Nov. 30 (St. Andrew's day); in the Eastern churches it begins about the middle of November. It is uncertain at what date the season began to be observed. A council at Saragossa in 380 forbade the faithful to be absent from church from Dec. 17 to Epiphany, but the first unquestionable mention of Advent is at the Council of Tours (567). It had long been recognized in the west as the beginning of the ecclesiastical year. The season is a solemn one, though not now kept as Lent as it once was. The Roman Catholic Church forbids the solemnization of marriage during Advent. In many countries it was marked by a variety of popular observances, some of which still survive. See also CHRISTMAS; CHURCH YEAR.

ADVENTISM, a general term referring to a number of religious bodies an essential element of whose doctrine is the imminent second coming of Christ. In the early decades of the 19th century there developed spontaneously, in various countries, an interest in the prophetic portions of the Bible. The result was a conviction that the end of the world was near at hand, an event to be marked by the literal, personal coming of Christ in glory and the fiery destruction of sinners.

Millerism.—In the United States this became a rather well-defined interchurch movement led by William Miller (*q.v.*), a Baptist and a former officer during the War of 1812. Prominently associated with him was Joshua V. Himes, a Boston minister of the Christian Church, who had been a leader in the abolitionist movement. Miller began to preach in 1831 but aroused no great interest until 1839. From then onward he rapidly gained adherents, both ministerial and lay, from the various Protestant churches. The press labeled such adherents Millerites. In the spring of 1844 the Millerites seem first to have advocated the use of the name Adventists to describe themselves (from Lat. adventus, "coming").

At that time there was rather general agreement among theologians that the end of the world or, more accurately, the end of the present age of sin was near at hand. But what follows this soon expected end? The Millerites answered, fiery conflagration; other Protestant theologians declared, spiritual regeneration, this regeneration to be gradual till the whole world is converted. As the Millerite leaders sought repeatedly to emphasize, the heart of their preaching was not so much the time of Christ's coming as the nature of it. They affirmed that they were but restating the teaching of the apostles and 16th-century reformers. Their opponents declared that the coming of Christ would be spiritual, invisible, his spiritual coming into the hearts of men and converting them.

Miller set a tentative date for the coming of Christ as about a time that, by the Gregorian calendar, would be from March 21, 1813, to March 21, 1844. The spring of 1844 passed quietly but

the movement seems not to have been greatly shaken by what came to be called the First Disappointment. In the summer a second date was set by some (Oct. 22, 1844), though Miller, Himes and certain other prominent leaders hesitated almost to the last to advocate so specific a time. Oct. 23 brought the Great Disappointment. The Millerite movement was stunned, though not quite shattered. Its hard core of believers may be conservatively estimated as totaling at that time not fewer than 50,000, some say 100,000 persons.

Sharpening the distress of the Millerites were the fanciful, even lurid tales that had been circulated for years in the public press, picturing them as a wildly fanatical group. One of the chief of these stories was that they had prepared ascension robes in which to go to glory, but search of the original sources leads to the conclusion that the ascension robe story is wholly groundless. Those stories of fanaticism that can be proved true establish only that Millerism was troubled at times by the same kind of emotionally unstable enthusiasts that disturbed earlier religious awakenings, among them the Protestant Reformation and the Wesleyan movement.

Aftermath of Millerism.—On April 29, 1845, a representative company of Millerites met in Albany, N.Y., in what was announced as a Mutual Conference of Adventists. They had earlier been held together by the crusading momentum of the movement; now, in order to maintain cohesion, they needed a statement of doctrine and some kind of organization. But many of the Millerite leaders were suspicious of formal creeds and close-knit church organization, considering them to be repressive of the truth and fettering to the spirit. Though the meeting produced some results, it was soon evident that the Millerite movement as such had ended.

Certain modern church bodies, however! generally marked by a belief in the personal and imminent return of Christ, find their roots in Millerism. With variations, they hold that a man's failure to accept salvation through Christ will mean his final and complete extinction, not his conscious suffering in hell throughout eternity. With one exception (see below) they all observe Sunday as their weekly holy day. There is some question as to which of the presently existing Adventist-oriented churches are truly direct outgrowths of the Millerite movement rather than simply offshoots of one or another of such churches. There seems good evidence for accepting the following:

1. Advent Christian Church, organized in 1861, with a membership in the early 1960s of about 32,000.
2. Church of God (Abrahamic faith), incorporated as the National Bible institute, Oregon, Ill., in 1921; membership about 5,300. Though this church is generally found in the list of those considered Millerite in origin, some of its spokesmen believe that it should not be considered an outgrowth of Millerism.
3. Life and Advent union, organized 1863, membership 300.
4. Seventh-day Adventists, organized in 1863, membership in the early 1960s about 1,300,000, including about 350,000 in the United States and Canada.

Except in the last-mentioned church, the membership of these bodies is confined almost wholly to the United States and Canada.

Seventh-Day Adventists.—When no visible event occurred on Oct. 22, 1844, most Millerites took one of two positions: (1) that the date had been wrongly computed, thus putting the Advent into the future and stimulating believers to further time-setting, or (2) that the whole prophetic exegesis on which the date rested was invalid, thus prompting them to abandon the movement. Seventh-day Adventism began with the belief that the exegesis that produced the date was correct but that the event foretold was a heavenly one, the opening of an investigative judgment in heaven, which would terminate in the coming of Christ to execute judgment on all. This church early established as one of its prime tenets that man cannot know the time of Christ's coming, though, in harmony with Christ's own words, he can know when "he is near, even at the very gates" (Matt. xxiv, 33).

History.—In their earliest years these Sabbath-keeping Adventists—the name Seventh-day Adventist was not officially adopted until 1860—were found largely in the New England states. In

1849 they started a paper called Present Truth, reorganized in Nov. 1850 and renamed the Advent Review and Sabbath Herald, now one of the oldest continuously published religious journals in America. In 1855 a headquarters was established in Battle Creek, Mich., which marked the beginning of expansion westward. In May 1863 a formal denominational organization was created and in 1874 the first missionary, J. N. Andrews, was sent abroad. In 1903 the headquarters was moved to Washington, D.C.

Organization and Government.—Direction of the denomination's world activities is by the General Conference of Seventh-day Adventists, headquarters at Washington, D.C. Sessions of this General Conference, constituted of delegates chosen on a membership basis from the various subdivisions of the organization over the world, are held quadrennially. Interim business is conducted by the executive committee. Under the General Conference are division, union and local organizations, generally called conferences. Each subdivision has a president and an executive committee. The local congregations elect lay elders, deacons and other officers to carry on the local church work. Pastoral supervision of churches is provided from the local conference office, which pays these pastors from a central fund.

Doctrine.—Seventh-day Adventists believe, among other things, in one God revealed as Father, Son and Holy Spirit; in the Bible as the inspired Word of God; in creation by divine fiat; in the fall of man and his redemption only through the substitutionary death of Christ; in the Ten Commandments as man's eternal moral standard, understanding that the command to keep holy "the seventh day" requires observing the seventh day of the week as the Sabbath; in the gift of prophecy in the church; in the mortality of man and his unconsciousness in death; in the resurrection of the body at the last day, with immortality meted out to the righteous and annihilation by fire to the wicked; in the proper care of the body as the "temple of the Holy Ghost"; in the premillennial, personal, visible return of Christ at a time unknown but close at hand; in a new earth, created from the ruins of the old, as the final abode of the redeemed.

Activities.—The major activities of the church may be comprehended under four heads: (1) Evangelistic preaching is conducted in almost 800 languages and dialects. (2) Publishing houses are found in most of the principal countries; literature is sold from house to house by trained colporteurs. (3) A separate school system—primary, secondary and college—is maintained; there are also graduate schools and a medical college. (4) A chain of medical institutions, often called sanitariums, is operated; the first was the Battle Creek (Mich.) sanitarium, founded in 1866.

ADVERTISING, a form of paid public announcement intended to promote the sale of a commodity or service, to advance an idea or to bring about some other effect desired by the advertiser. It is essentially a form of communication through such diverse media as handbills, newspapers, magazines, billboards, letters, radio and television broadcasts and motion pictures. The term is broad enough to include a wide range of types, from a small two-line entry in a newspaper or magazine to a "spread" of several full pages, or from a small sign in a shop window to a huge billboard with changing designs in coloured lights. During the 20th century, particularly in the United States, advertising became a vital factor in merchandising. It was estimated that by 1960 more than \$11,000,000,000 was spent each year on advertising in the United States and over £400,000,000 (or \$1,128,000,000) in Great Britain. (See also PROPAGANDA; PUBLIC RELATIONS.)

To a manufacturer, advertising is usually considered part of the firm's marketing program along with personal selling, packaging, display, pricing and product design. To the retailer, it is also a part of his so-called "marketing mix," along with display, store promotions, etc. To the various media of communication it is both a major source of revenue and a means of providing information on products and services to their audiences. To the consumer it is a major source of information regarding products and services.

Purposes and Types.—Purposes of advertising may be divided, first of all, into two types, product and institutional. Product advertising emphasizes the type of product or the brand to be sold; institutional advertising concerns the firm that makes or sells the product. Automobile advertisements that emphasize the virtues of a particular car are examples of product advertising. Advertisements that strive to improve the public's impression of a firm by describing its research facilities are examples of institutional advertising. Retailers use product advertising to describe the products they have for sale, institutional advertising to build a favourable store image. Among both manufacturers and retailers, product advertising is the more common of the two types.

Advertisements may also be distinguished on the basis of whether they are designed for direct or indirect action. The direct-action advertisement aims at achieving some immediate action by the reader or viewer, such as buying a product or sending in a coupon. The indirect action advertisement is more concerned with building a favourable mental picture of the brand that will pay off later in sales. The manufacturer is more likely to use image-building advertisements, while the retailer is more concerned with gaining immediate action. The manufacturer thus builds acceptance for the brand and the retailer capitalizes on that acceptance at the local level and translates it into action.

A distinction may also be made between primary and selective purposes. When a dairy or group of dairies attempts to convince people they should drink milk rather than other beverages, it is engaging in primary advertising. When one dairy tries to build demand for its particular brand as compared with competitors, it is using selective advertising.

Historical Background.—The first advertising was by public criers in ancient times who circulated through the streets calling attention to the sale of such items as slaves, cattle and imports. An ancient written advertisement, perhaps 3,000 years old, was discovered by an archeologist delving in the ruins of Thebes. It offered a "whole gold coin" as reward for the return of a runaway man-slave named Shem. During the middle ages the spoken word was the principal means of communication and there was little of the activity that we now call advertising. The invention of movable type (c. 1450) by Johann Gutenberg made it possible to produce many copies of books and periodicals cheaply and quickly and ushered in the modern era of advertising.

Printing made possible the transition from simple announcement to the system of argument and suggestion which constitutes modern advertising, and the medium of this development was the newspaper. The weekly papers sometimes carried a few advertisements, including the first offerings of coffee (1652), chocolate (1657) and tea (1658). In June 1666 the *London Gazette*, no. 62, announced the first advertisement supplement as follows: "An Advertisement—Being daily prest to the publication of Books, Medicines, and other things not properly the business of a Paper of Intelligence. This is to notifie once for all, that we will not charge the *Gazette* with Advertisements, unless they be matter of state; but that a Paper of Advertisements will be forthwith printed apart, and recommended to the Publick by another hand."

The restriction of the word "advertisement," which for Shakespeare and the translators of the Authorized Version had meant information of any kind, to a business announcement was made in *The Tatler* of Sept. 14, 1710:

"It is my custom, in a dearth of News, to entertain myself with those Collections of Advertisements that appear at the end of all our Publick Prints. . . . Advertisements are of great use to the vulgar. First of all, as they are instruments of ambition. A man that is by no means big enough for the *Gazette* may easily creep

into the advertisements. . . . A second use which this sort of writings have been turned to of late Years, has been the management of Controversy. . . . The inventors of *Strops for Razors* have written against one another in this way for several years. The third and last of these writings is to inform the World where they may be furnished with almost everything that is necessary for Life. If a Man has Pains in His head, Cholick in his Bowels, or spots in his Cloathes, he may here meet with proper Cures and Remedies. If a Man would recover a Wife or a Horse that is stolen or strayed; if he wants new Sermons, Electuaries, Asses' milk, or anything else, either for his Body or his Mind, this is the place to look for them in."

In 1712 all advertising was dealt a blow when the British government imposed a tax of one halfpenny on every newspaper or magazine sold and an additional tax of one shilling on every advertisement. This move was aimed at silencing press criticism, not raising money. In spite of this tax, however, advertising prospered during the 18th century. In 1758 Samuel Johnson wrote in *The Idler*:

Advertisements are now so numerous that they are very negligently perused, and it is therefore become necessary to gain attention by magnificence of promise and by eloquence sometimes sublime and sometimes pathetic.

Benjamin Franklin is regarded by many as the father of advertising in the United States. He put advertising before editorial in the masthead of the first issue of the *Pennsylvania Gazette* in 1729. But the *Boston News-Letter* had contained advertisements for the sale or rent of houses, farms, shops, vessels and other items in its first issue published in April 1704. Much of the early newspaper advertising in the colonies was for patent medicines and gave advertising a bad name that persisted for many years.

The 19th century was a period of expansion in advertising as well as in business generally. The Industrial Revolution expanded the output of factories and advertising helped market this output. The growth of the penny press and of magazines, combined with an increase in the educational level, brought forth an increase in audiences. Improvements in transportation made it possible to distribute magazines on a national basis. In 1830 there were an estimated 800 magazines and newspapers in the U.S.; by 1861 the number had risen to more than 5,000. By 1870 the use of magazines for general advertising was established. This permitted vast increase in circulation and a reduction in price. By the turn of the century *Cosmopolitan* and *McClure's* carried about 100 pages of advertising in a single issue. Slogans and jingles became favourite advertising techniques. Total advertising expenditures rose from \$60,000,000 in 1867 to \$360,000,000 in 1890. Some of the trade-marks famous today were popularized during this period.

During the first two decades of the 20th century, advertising was re-examined. Certain excesses in its claims had developed and caused widespread resentment. Regulation came both from within the industry and from the government.

In 1914 the Audit Bureau of Circulations (A.B.C.) was organized. It quickly became the main source of reliable information about the circulation of periodicals in the United States and Canada. Such information was obviously of great value to advertisers as a means of determining the size of the audience reached by each publication.

After World War I came the era of salesmanship. Advertising was accepted as an essential tool in selling the booming output of the nation's factories. "It pays to advertise" became a standard slogan. Soap companies and automobile companies were among the most important advertisers. It was discovered that testimonials by movie stars were very effective in selling such items as soap and cigarettes. Good advertising copywriters were much sought after.

A major new advertising medium, radio, was added during the 1920s. At first most radio commercials were indirect and there was doubt as to whether advertising would be allowed on the air. However, commercial radio thrived and by 1928 it accounted for \$10,500,000 in advertising. Total advertising expenditures in the United States reached a peak of \$3,400,000,000 in 1929.

The depression of the 1930s brought on a searching re-examina-

tion of the entire economic system, including advertising. Advertising was blamed for some of the nation's economic problems and total expenditures for advertising dropped to \$1,300,000,000 in 1933, less than half the 1929 total. Much restrictive legislation was proposed and some of it passed. The sales resistance of consumers forced businessmen to turn to advertising research. Researchers like A. C. Nielsen, George Gallup and Daniel Starch were among the pioneers in trying to determine what kind of advertising was most effective.

During the years following World War II, U.S. advertising expenditures soared. From \$3,400,000,000 in 1946 they rose to \$5,700,000,000 in 1950 and exceeded \$11,000,000,000 by 1960. Meanwhile the industry experienced further criticism. Two books, *The Hucksters* (1946) and *The Hidden Persuaders* (1957), became best sellers. Each painted a picture of the advertising world which disturbed both the friends and the critics of advertising.

A new medium, television, was added to the U.S. advertising scene immediately after the war. It had a spectacular growth. By the 1960s there were more than 46,000,000 homes with television sets and approximately 600 broadcasting stations in the U.S. Within less than ten years television had grown to be the third largest advertising medium in the U.S. (after newspapers and direct mail) in terms of total dollars spent and the largest in the top national advertisers' budgets.

Two new research tools—motivation research, which emphasized man's subconscious motives (see *PSYCHOLOGY, APPLIED: Motivational Research*) and operations research, which emphasized mathematical approaches to advertising—were used by advertising and marketing specialists. Although advertising had long been considered a tool of marketing, new emphasis was placed on co-ordinating advertising with other tools of the marketing program.

In Great Britain the government became one of the nation's largest advertisers. Among its most striking successes was the campaign for diphtheria immunization. Between 1941 and 1954 it virtually banished diphtheria as an epidemic disease. Other campaigns were launched on behalf of the fighting services, civil defense, blood donation, safety, and national health and nursing services.

Total advertising expenditures in Great Britain rose from approximately £68,200,000 (\$273,000,000 before devaluation of the pound) in 1938 to over £400,000,000 (\$1,128,000,000 after devaluation of the pound) in 1960. The estimated British ratio of advertising to national income was 1.5% in 1953 and 2.1% in 1959. Comparable figures for the United States were 2.6% for 1953 and 2.9% for 1959. The U.S. figure slightly exceeded the prewar figure while the British figure was slightly below the prewar figure. On the other hand, if 1948 is used as a base year, the advertising ratio increased more in Britain than in the United States.

The proportion of the British advertising handled by agencies grew from 42% in 1938 to 49% in 1956. This rise was probably due in large part to the growth of national brand advertising, which is almost always handled through agencies.

By mid-20th century the press accounted for about half the total normally spent for advertising in Great Britain. Restrictions on newsprint introduced during World War II and continued for many postwar years brought about a change in the relative proportions of advertising within the press section. Before the war the national newspapers carried about 17% of all advertising and the provincial press 15%. In 1952 the proportions were almost reversed, with 16.1% carried by provincial newspapers and 12.2% by the nationals. Trade and technical journals, magazines and periodicals increased their share of advertising revenue as compared with prewar. A study of the press by the royal commission on the press (1947–1949) indicated that attempts by advertisers to sway newspaper policy or obtain omission or insertion of specific items of news were generally unsuccessful.

The printed media's share of total advertising expenditures dropped from 58% to 49% between 1954 and 1958. There was, however, an even more dramatic shift in the expenditures of the top 20 advertisers in newspapers, magazines and television. In 1957 the top 20 spent 57% in newspapers and magazines and 43%

in television. In 1958 they spent 46% in newspapers and magazines, 54% in television.

The Television act of 1954 made one television channel an advertising medium in Great Britain. Advertisers were not given control of the program and thus were not sponsors, but they were permitted to buy spot announcements. Control of the service was placed with the Independent Television authority (I.T.A.) which was made responsible for seeing that the Television act was carried out. According to Mark Abrams of the London Press Exchange, Ltd., there were over 10,000,000 British homes equipped to receive television at the end of 1960. This provided advertisers with a potential coverage of about 50% of all consumers in the country.

Film became an important advertising medium in Great Britain. Apart from special showings of films or documentaries, motion-picture advertising was usually in the form of short films lasting only for 15 seconds, one minute or two minutes. Most of the theatres accepted advertising films or slides. (See also *BROADCASTING*.)

Social and Economic Aspects.—In his exhaustive report on *The Economic Aspects of Advertising*, published in 1942, Neil H. Borden, professor of advertising at the Harvard Graduate School of Business Administration, concluded that advertising's chief economic contribution was its ability to promote a dynamic, expanding economy. He found that one of its principal means of accomplishing this was through its encouragement of the development of new products. He emphasized the role of advertising in capitalizing on differences in brands and thus making it possible for an entrepreneur to regain fairly quickly a substantial part of his growth costs. Advertising thus encourages pioneering in new products and services.

Many people believe that advertising makes the goods and services they buy more expensive. The evidence accumulated by Borden and other investigators indicates it is even more likely to make them cheaper. A change in price of a product may result from changes in (1) cost of producing or marketing it and (2) changes in the demand for it.

In the case of such products as automatic washers and power mowers, advertising made possible a substantial reduction in costs by helping stimulate demand. This increase in demand increased the output of each factory and brought about a lower cost per unit. Where there are large overhead costs involved in producing a product, it is often possible to decrease the costs per unit significantly as the volume is increased. Marketing costs may be reduced by substituting advertising for some other marketing elements (*e.g.*, personal selling), thus making the marketing operation more efficient. But we must conclude, as Borden did, that the evidence is sketchy and the role of advertising too complicated to make any generalizations regarding the ultimate effect of advertising on price.

Another economic problem is the relationship between advertising and the level of national income. Both Borden and E. A. Lever, an English economist, have examined in some detail the nature of this relationship. Both concluded that advertising alone was incapable of causing either depressions or booms. However, wisely used it can act as a stimulant when sales are difficult to get. During the depression of the 1930s, for instance, several companies made substantial profits by making important product improvements and using advertising to tell people about them. In general, advertising expenditures as a percentage of U.S. national income have been tapering off since the 1921 peak of 4.5% and by 1960 were about two thirds of the 1920s level.

Advertising is sometimes accused of causing monopoly and a decrease in the number of choices open to the consumer. The evidence indicates that the opposite is somewhat more likely to take place. In those fields where advertising plays an important part in the marketing mix, the number of brands has been increasing rather than decreasing. There are some who accuse advertising of influencing the news and editorial columns of the various media. This criticism is based on the fact that the average U.S. newspaper received about 70% of its income from advertising and most radio and television stations are financed entirely by

advertising. Although there have been various attempts to influence the press—some much publicized—there is little evidence that the attempts have succeeded. In its volume *A Free and Responsible Press*, the commission on the Freedom of the Press (copyright 1947 by The University of Chicago) concluded that "the evidence of dictation of policy by advertisers is not impressive. Such dictation seems to occur among the weaker units. As a newspaper becomes financially stable, it becomes more independent and tends to resist pressure from advertisers."

Advertising Agencies.—The advertising industry is divided into three principal types of organizations—advertisers, advertising agencies and the media of communication. The advertiser is the one whose brand or corporate name appears on the advertisement. The advertising agency handles the advertising for its client. The media carry the advertising to the various audiences. These three main types of organizations are aided by many specialists such as typographers, engravers, artists, film companies and research agencies.

An advertising agency, Reynell and Son, was founded in London as early as 1812 but advertising agencies have achieved their greatest development in the United States. In 1841 Volney Palmer, who had been an editorial writer and later a member of the advertising staff of the *Pottsville (Pa.) Miner's Journal*, opened in Philadelphia what is generally considered the first advertising agency in the U.S. Unlike modern agents, he was primarily an agent for the publishers. They paid him a commission of 25% for selling space, although he did not assume liability for the credit extended to advertisers. Shortly after he began operations he had several competitors, including his former clerk S. M. Pettengill.

George P. Rowell, who opened an agency in 1865, added two features—wholesaling and the "list system"—to agency operation. He contracted with a large number of weekly newspapers to sell him a column of space for a certain period of time. He then offered this space to advertisers in smaller units at retail rates which were below rates charged by competitors. He advertised his offering of "an-inch-of-space-a-month-in-one-hundred-papers-for-one-hundred-dollars." He was, like Palmer, primarily a seller of space but he offered exclusive lists of newspapers and magazines, and any advertiser who bought space in these had to buy through the exclusive agent.

In 1875 N. W. Ayer & Son of Philadelphia developed the "open contract" which gave advertisers access to the true rates charged by the publishers. Ayer thus put the emphasis on the agency's service to the advertiser rather than on selling space for the media.

The next major step was the development of a full line of services for the advertiser. In the late 19th and early 20th century emphasis was on writing the advertising copy. After copy came art services, advertising production and the selection of media. By 1920 most agencies could plan complete campaigns for their clients, including research and budgeting, and could also execute these campaigns by preparing the advertisements and arranging for their insertion in the various media, which now included outdoor advertising and direct-mail soliciting. The American Association of Advertising Agencies (A.A.A.A.) was founded in 1917 and the Association of British Advertising Agents (now the Institute of Practitioners in Advertising) that same year.

By 1960 there were slightly more than 3,000 bona fide advertising agencies in the United States, approximately 120 in Canada and 500 in Great Britain. According to *Advertising Age*, a leading trade publication, four U.S. agencies handled over \$200,000,000 worth of advertising in 1960 and nine handled over \$100,000,000. The only agency outside the United States to have billings of over \$100,000,000 was in Japan. The largest British agency had billings estimated at £17,000,000 (\$47,600,000).

Most of the general advertising (that done by firms not selling directly to consumers) and some of the retail (that done by firms selling directly to consumers) is handled by agencies. The former classification accounts for roughly 60% of the total advertising volume in the U.S. Most large agencies handle all types of accounts, but some of the smaller agencies specialize in a certain type, such as drugs, financial services or agricultural products.

Many of the larger advertisers have several agencies serving them, often one for each of their major brands, but as a rule agencies do not serve competing firms or products.

The typical advertising agency is staffed to perform the following services for its clients: (1) supervision and servicing of all advertising activities; (2) writing copy; (3) conducting market, media and copy research; (4) working out a complete marketing plan, budget and supporting activities; (5) selecting media; (6) arranging for mechanical reproduction of the advertisement and its insertion in the medium; (7) laying out the advertisement; (8) buying any artwork or film needed for the advertisement; (9) helping supervise the sales force; (10) arranging for appropriate merchandising and public relations activities to help make the advertising more productive. It has thus tended to become a marketing agency, supplying a full range of marketing services, rather than simply an advertising agency.

U.S. agencies tend to be organized on either a departmental or a group basis. Under the former, specialists (artists or writers) work in the same department and may service any of the accounts in the agency. Under the group system the various specialists are assigned to a group of accounts and work exclusively on these.

The bulk of the standard U.S. agency's income is derived from the 15% commission which the media grant to recognized agencies on the space or time bought in those media. Most U.S. agencies also charge a commission on artwork for clients or television programs which they buy for their clients. In addition, they may charge fees for special services such as research or public relations. British agencies that are recognized by the media receive between 10% and 15% commission. In France agency commissions range from 10% to 20%, with commissions generally higher in the provinces than in Paris. Only agencies recognized by the media are granted commissions. Among the usual requirements for recognition are the following: freedom from control by advertisers, financial resources sufficient to meet obligations incurred on behalf of clients, and personnel of sufficient experience and ability to serve general advertisers.

In 1955 the U.S. department of justice attacked this system of compensation. It filed suit against the American Association of Advertising Agencies and five media associations, charging them with conspiracy in restraint of trade. It questioned the uniform standards for recognizing agencies, the refusal to grant commissions to nonrecognized agencies and uniformity of the 15% commission. In 1956 the A.A.A.A. and the media associations entered into a consent decree with the department of justice and the case was dropped. They agreed to refrain from "fixing, establishing, or stabilizing agency commission."

ADVERTISING PRODUCTION

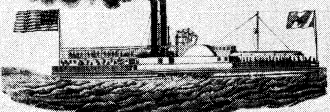

The starting point for the planning and production of an advertising campaign is usually the over-all marketing program. Although the advertisements may be brilliantly conceived they are not likely to be successful unless they are used in conjunction with personal selling, display, packaging, pricing, product design and other elements of the marketing program. Consequently agencies and advertisers frequently talk of their marketing plan rather than their advertising plan. The marketing plan consists of at least three major elements: marketing objectives, the "marketing mix" that is most likely to attain this objective, and the integration of the various elements used.

Once the marketing plan is decided on, the advertiser and the agency are ready to fit advertising into that plan. If they know, for example, that the manufacturer's objective is to increase the acceptance of his brand name within a certain segment of the market, they can decide what part advertising can play in carrying out that objective. In general, the steps an advertiser or agency will follow in producing an advertising campaign are the following: (1) finding all pertinent facts; (2) establishing objectives; (3) setting the budget; (4) creating the advertisements; (5) inserting them in the media.

Facts.—The most fruitful facts for planners of an advertising campaign are likely to fall into these categories: characteristics of the consumers, location of the markets to be covered, product or

service to be advertised, media to be used and past experience with different types of advertisements.

Among the facts which help the advertiser understand the consumer are the answers to questions such as these: What attitudes do people have toward this type of product? What psychological needs or desires does this product satisfy? What are the buying habits of people who buy this type of product? Research indicates that people often rationalize certain of their purchases. They will tell other people (and often themselves) that they bought a certain brand of automobile because it provides good gas mileage or has a high trade-in value. The real motivation is often more subtle and not so socially acceptable—for instance, the desire to keep up with one's neighbors. Among the most commonly used psychological wants featured in advertisements are: sex, food and drink, comfort, freedom from fear and danger, desire to be superior, social approval, long life and love of family.

Facts about the location of the market help the advertising people to select the correct media to reach the potential consumers and to design advertisements which will have maximum appeal. Some products are dramatic and easy to advertise. For instance, it is fairly simple to find some dramatic, want-satisfying feature of a new house or a new automobile. On the other hand, more prosaic products like tea or cleaning powder may require considerable analysis. There has been a decided effort since World War II to emphasize the building of a "product image." In a speech before the American Association of Advertising Agencies, David Ogilvy, a prominent agency president said, "Every advertisement must be considered as a contribution to the complex symbol which is the brand image . . . The manufacturers who dedicate their advertising to building the most favorable image, the most sharply defined personality for their brands are the ones who will get the largest share of these markets at the highest profits—in the long run."

Some of the media facts which are important in producing an advertising campaign are those dealing with where the medium is circulated, how thoroughly people read or listen to it, and whether they pay for it or receive it free of charge.

Facts on the message itself might cover the relative effectiveness of illustrations *v.* words for conveying various types of messages, long copy *v.* short copy, full-page advertisements *v.* fractional-page advertisements.

Objectives.—The ultimate objective of most advertising is to sell goods or services. Even public service campaigns are usually expected to produce some sort of long-range profit. However, individual campaigns may have various objectives. In the United States, where tea had been widely considered an effeminate drink, a successful campaign was designed for the Tea Council to convince people that tea was a drink for the hale and hearty. Illustrations of vigorous men such as truck drivers and bold, masculine typography were used to suggest that the very virile enjoy tea just as much as do elderly women.

Setting the Budget.—Sometimes the advertising budget is determined in advance of the plan; sometimes the plan is the basis for it. In general, the budget is likely to be constructed by using either the task approach or the percentage-of-sales approach. The task method defines the job to be accomplished and a sufficient advertising fund to accomplish this job is appropriated. It is, therefore, necessary that the objective be defined as carefully as possible. For instance, a company may be considering the marketing of a new food product. It will decide how many advertisements are needed and what media should be used to accomplish the acceptance of this product. If the firm decides it cannot afford the amount involved, it has simply to trim its sights to coincide with what it can afford. This method is becoming increasingly popular—particularly for new products and for products sold to industrial users.

There are many variations of the percentage-of-sales method. In its simplest form it involves multiplying a fixed percentage (*e.g.* 3%) by the sales of the previous year. This is a simple method and will work out fairly well if the fluctuations from one year to the next are not too great. Small retail stores which have a stable business sometimes use this method. A variation that

is somewhat more desirable is to predict next year's sales and then assign a certain percentage of that amount to advertising. For instance, a manufacturer may predict that his sales next year will be \$1,000,000. If he customarily spends 5% for advertising his advertising appropriation will be \$50,000. He can then divide this into the various media or functions as he sees fit. This method has the virtue of emphasizing the future instead of the past, but it is somewhat illogical to forecast what the results of advertising will be and then base one of the causes of those results on that figure.

Another variation of this method which is common in some industries is the unit-of-sale method. Instead of basing the appropriation on dollar sales it is based on the number of units sold or expected to be sold. For example, if a company produced 100,000 automobiles in a year it might appropriate \$20 per unit or \$2,000,000. If it increased production to 200,000 units, it would keep the same amount per car on the basis that this is the amount of money needed to sell a unit of this car. Similarly, makers of package goods may budget a fixed amount of money per case.

The Message.—The first purpose of the advertising message is to get the reader's or listener's attention and hold it. The message should then arouse his desire for the product or service, and finally get him to buy it, desire it, prefer it or perhaps just recognize it.

There are two important steps in the creation of every advertisement, deciding what is to be said and deciding how to say it. The first of these should grow out of the objective of the campaign. In other words, many successive advertisements in a campaign might say much the same thing—an idea decided on by a group of planners or perhaps the copywriter or artist. One successful series for a soft drink emphasized year after year the same general idea—that is, "a light refreshing drink"—in a variety of ways.

In deciding how the message should be constructed, the creative person has certain elements with which he can work: in a print advertisement the headlines, illustrations, captions, trademarks, body text, white space, colour and type faces; in radio the spoken word; and in television all the above plus motion. In the case of print advertising the arrangement itself may help to communicate the idea. For example, a crowded layout suggests to most people that the product or store whose name appears is a bargain-type product. Conversely, a lot of white space suggests style and sophistication.

Some advertisements are mainly visual and thus start with the visual elements. A typical case is the fashion advertisement one finds in most newspapers and many women's magazines. In these advertisements the illustration itself suggests to the reader what the product looks like, what sort of people may be seen wearing it, in what kind of surroundings it may be worn, and it may attempt to suggest certain aesthetic associations. The visual elements of an advertisement usually have three functions: (1) attract the attention of the desired audience; (2) tell the reader something about the product; and (3) arouse sufficient interest so that the reader will want to read the body text, if there is any.

Colour is another commonly used visual element. It is used mainly for portraying goods in their natural colour, dramatizing the rewards from a product, providing a refined or symbolic atmosphere for a product or aiding the identification of a trademark or package by showing it in natural colour.

Agency art personnel will usually make "layouts" or "visuals" to show how the finished advertisement will look. Sometimes they make a drawing or painting that is reproduced, although most finished art work is done by free lance artists or those in studios. Much of the television art work is done by specialists.

The headlines of a print or television advertisement may account for as much as 25% of the effectiveness, according to one authority, John Caples. The headline, like the illustration, is designed to attract attention and to arouse interest in the body of the text. If the product is a very dramatic one, a headline talking directly about the product is customarily used. On the other hand, in such products or services as life insurance, a curiosity approach is often used in an attempt to intrigue the reader.

In most advertisements the heart of the advertising message is

in the text. Some full-page newspaper advertisements have as much as several thousand words of copy. Some have practically none. The exact proportions of visual and verbal elements will be decided on by the advertising man. He will use either words or pictures according to how well he thinks each will tell the desired story.

ADVERTISING ORGANIZATIONS

United States. — Much of the improvement in advertising standards in the 20th century resulted from the efforts of various professional groups representing segments of the industry. In 1911 the Associated Advertising Clubs of America at their annual convention adopted the motto "Truth in advertising" and established a National Vigilance committee in the United States, later renamed the National Better Business bureau, to police advertising. The national committee worked with the local advertising clubs to organize local Better Business bureaus (*q.v.*) to eliminate objectionable or untruthful advertising. These bureaus are supported financially by local businessmen in an effort to curb unethical advertising and selling practices. Complaints concerning such practices are made to the local bureau, which then investigates the charge. If it finds the charge is true, it tries to persuade the offender to stop his methods of operation; if that approach fails, it may take legal action. Among the most common complaints are false and misleading comparisons of price and quality, exaggerated claims as to quality, and "bait" advertising (quoting a ridiculously low price for a product which is not really for sale in order to attract customers to a store).

The National Better Business bureau publishes a loose-leaf reference manual entitled *Do's and Don'ts in Advertising*, to keep advertising people up-to-date on current legislation, administrative orders, industry standards and court decisions. It covers a wide variety of product categories and is designed to assist advertisers and agencies in deciding what they may say and what should be avoided.

The Advertising Federation of America is the successor to the Associated Advertising Clubs of America. It was the parent of some of today's independent advertising associations, such as the Newspaper Advertising Executives association and the Direct Mail Advertising association. Like its predecessor organization it emphasizes the importance of truth in advertising. It often acts as the spokesman for the industry as a whole. For instance, during 1958 and 1959 much of its effort was directed toward opposing proposals made in various cities and states to levy a tax on advertising. It is also active in advertising club work and advertising education.

The Advertising Association of the West, a Pacific coast counterpart of the Advertising Federation of America, operates in 11 western states, British Columbia and Hawaii.

The Audit Bureau of Circulations is another organization supported by the entire advertising industry. It audits and verifies circulations of paid-circulation newspapers, magazines, business publications and farm publications in the United States and Canada. Another auditing organization, Business Publications Audit of Circulations, audits both paid and free-distribution publications.

The Advertising Research foundation is devoted to investigating problems of research interest to the entire advertising industry. For several years it sponsored readership studies of various media. The Advertising council is devoted to the planning, preparation and production of public service advertising campaigns. The defense bond campaign, safety, fire prevention and many others were Advertising council campaigns.

The Association of National Advertisers is an organization of about 500 companies which manufacture and advertise consumer goods. It was organized in 1913 for the purpose of exchanging information and conducting various activities of mutual benefit.

The National Industrial Advertisers association is an organization of firms engaged in marketing industrial, rather than consumer, goods.

The sales promotion division, National Retail Merchants association; studies methods of improving retail advertising. It is perhaps best known for its annual sales promotion budgeting planning calendar.

The American Association of Advertising Agencies is the leading organization of advertising agencies; 335 of the largest national agencies belong to it. It works with advertisers and media associations.

The American Newspaper Publishers association is the leading organization of daily newspaper publishers in the United States. It serves the advertising field primarily through its bureau of advertising, which acts as both a promotional and a research organization. Other newspaper organizations concerned with advertising are Newspaper Advertising Executives association, National Newspaper Promotion association, American Association of Newspaper Representatives and Association of Newspaper Classified Advertising Managers.

In the magazine field, the Periodical Publishers association, the Magazine Publishers' association, the Magazine Advertising bureau of the Magazine Publishers association, Associated Business Publications, National Business Publications, and Agricultural Publishers association represent the various segments of the industry.

The National Association of Broadcasters is the principal organization in the field of television and radio. Promotion and research for the radio industry are conducted by the Radio Advertising bureau and for television by the Television Bureau of Advertising.

Other important media groups are: Outdoor Advertising Association of America, Outdoor Advertising, Inc., the Direct Mail Advertising association, and National Association of Transportation Advertising.

All of these organizations exercise some control over the advertising excesses of their members, either directly or indirectly. The A.A.A.A. through its Committee on the Improvement of Advertising Content and the Advertising Federation of America have been among the most active in this respect.

The Federal Trade Commission (*q.v.*), established in 1914 by the Federal Trade Commission act and strengthened by the Wheeler-Lea amendment in 1938, is the main U.S. government agency for policing advertising. Its power to regulate advertising is derived from its authority to regulate "unfair methods of competition." It issues cease and desist orders for any advertising which it believes is deceptive and which is in interstate commerce. It cooperates with the Federal Communications Commission in policing false and misleading advertising on television and radio. The FTC also administers certain wool and fur labeling acts and the Food and Drug Administration checks the labeling of foods, drugs and cosmetics. Misleading labels or those lacking essential information are prohibited by law.

The Federal Communications Commission controls advertising through its power to grant (or refuse to grant) licences and renewals for television and radio stations. The post office department is most active in checking for obscenity, lottery and fraud in advertising which goes through the mails.

Other federal regulatory agencies of importance in advertising are: the seed act division of the department of agriculture (seed advertising), the alcohol tax unit (alcoholic beverages), the Securities and Exchange Commission (stocks and bonds advertising), the U.S. patent office (trade-marks), and the Library of Congress (copyrighted material).

Great Britain. — The Advertising association is the central organization of the advertising industry in Great Britain. It combines the various groups — advertisers, agencies, media and ancillary services — and is thus similar to the Advertising Federation of America. Among its objectives are the promotion of public confidence in advertising and advertised goods through the correction or suppression of abuses which undermine that confidence; encouragement of the study of the theory and practice of advertising and the improvement of its technique by the institution of courses of study, holding of examinations and awarding of diplomas; the adoption of standard practices in relations between publishers, agencies and advertisers.

The British equivalent of the American Association of Advertising Agencies is the Institute of Practitioners in Advertising. Its main purpose is, according to its own statement: "establishing,

once and for all, the position of the service advertising agency through the introduction and observance of professional standards of practice; thereby, helping to make possible as it has, both the quality and scope of the advertising and marketing services rendered to advertisers."

The Incorporated Advertising Managers includes many of the leading advertising people who work for manufacturers.

Self-regulation comes from the British Code of Standards in Relation to the Advertising of Medicine and Treatments. This code states that no advertisement should contain a claim to cure any ailment or symptoms of ill-health and that no advertisement should contain a word or expression used in such form or context as to mean, in a positive sense, the extirpation of any ailment, illness or disease.

Government regulation is carried out mainly through the various sections of the Food and Drug acts, together with the Merchandise Mark acts. Other government regulations deal with trade-marks, defamation, copyright and hire purchase. The last, which came into force in 1957, stipulates that in almost all advertisements for hire purchase (*i.e.*, credit sales) exact details of terms must be given.

Other Countries.—The parent advertising organization in France is Federation Française de la Publicité. There are approximately 1,300 "qualified intermediaries" (agents) in France. The Technical Advertising school gives a course in advertising, following which a student may take an examination which when passed entitles him to an advertising degree recognized by the state. Since 1956 three new organizations have been created in France: Center of Study of Advertising Media, Institute of Research and Advertising Studies (similar to the Advertising Research foundation in the U.S.) and the Great National Causes, an organization for promoting public interest campaigns. In most other western European countries there is an organization of the leading advertising agencies and in many a parent organization for all advertising. In west Germany most agencies that follow the American system of giving clients complete service are members of Gesellschaft U'erbeagenturen.

ADVOCATE, in law, a person who is professionally qualified to plead the cause of another in a court of law. As a technical term "advocate" is used mainly in legal systems derived from the civil law.

Thus in Scotland the word refers especially to a member of the bar of Scotland (see **ADVOCATES, FACULTY OF**), but is also used to denote a member of a society of solicitors in the city of Aberdeen. The chief law officer of the crown in Scotland is the lord advocate, the head of the public prosecution system.

In France *avocats* are an organized body of pleaders, but in Germany, until the distinction between counselor and pleader was abolished in 1879, the Advokat was the adviser rather than the pleader.

The term has traditionally been used of pleaders in courts of canon law, and thus in England, those lawyers who practised before the courts of civil and canon law were styled advocates (see **LEGAL PROFESSION**).

In the United States the term advocate has no special significance, being used interchangeably with such terms as attorney,

counsel or lawyer.

(M. C. ME.)

ADVOCATES, FACULTY OF, the collective term employed to designate the members of the bar of Scotland. The faculty has grown out of the Scots act of 1532, which established the college of justice, or court of session, in Scotland. The advocates had, and still have, the sole right of audience in the court of session and high court of judicary. By immemorial custom, they have formed themselves into a self-governing faculty under annually elected officers consisting of the dean of faculty and his council, the vice-dean, the treasurer and the clerk. When properly instructed by an agency of the law an advocate is, under pain of deprivation of office, bound and entitled to plead in any court in Scotland, civil or criminal, superior or inferior. He is also entitled to plead before the house of lords, the judicial committee of the privy council and parliamentary committees. The magnificent library collected by the faculty has now been formed into the National Library of Scotland.

ADY, ENDRE (1877–1919), probably the greatest Hungarian lyric poet, was born at Erdmindszent on Nov. 22, 1877, of an impoverished but noble family. On leaving school, he studied law for a time. In 1899 he published a somewhat insignificant volume of verse, *Versek*, and from 1900 until his death he worked as a journalist. In 1903 he published another volume of poetry, *Még egyszert*, in which signs of his exceptional talent could already be seen. With his next book, *Uj versek* ("New Poems"; 1906), he burst like a bombshell into Hungarian literary life. Poetry in Hungary had been dormant at the end of the 19th and at the beginning of the 20th century, and people had become accustomed to diluted and insipid imitations of Sándor Petöfi and János Arany. None of the few original poets was powerful enough to make an impression on the public which was thus faced without transition with the "new verses of a new era," as Ady himself described his work. These poems were, indeed, revolutionary in form, language and content. Though Ady's strict use of rhyme could not shock even the most conservative reader, his frequent repetition of whole lines (sometimes two out of four in each stanza) was found greatly irritating, while his unconventional, though splendid, language, with its unusual choice of adjectives, shocked a public not accustomed to the unexpected. The outrage was completed by the general tone of his poems. At that time, Ady was an "angry young man" in whom a visit to Paris had unleashed a storm of violent and insulting attacks against his country. Though the artistic value of these "new poems" is beyond question, it is understandable that their provocative tone did not remain unanswered. Ady became the target of violent attacks which persisted well beyond his death, and which soon degenerated into a political struggle. Ady, backed by the left-wing radicals who hailed him as a prophet, was abused by right-wing nationalists. He emerged from these battles purified, and, abandoning gratuitous insult, he attained a higher level of social and political censure in his later work. His understanding of his country and of the social and political evils by which it was beset inspired him to find new accents of pain, anger and castigation, which reached apocalyptic vigour at the sufferings inflicted by World War I. By that time, Ady's failing health, undermined by a profligate life, was unable to stand up to the pressure of constant hard work. (He had published ten volumes of poetry in 12 years, as well as short stories and countless articles.) He reached the haven of a happy marriage too late (1914), and died, a victim of alcoholism, on Jan. 27, 1919, in Budapest.

Ady's love of the Hungarian people and the political preoccupations which developed from it was only one of his themes. His love poems, most of which had been inspired by a remarkable woman whom he called Leda, are striking in their originality and their mystical approach to physical love. His religious poems, which seemed blasphemous to many, reveal his search for God "who is at the bottom of all things, to whom all the bells toll and on whose left I, alas, sit."

Ady's poems are concerned with eternal problems. And if in many respects his own life was a failure, he at least attained one of his aims: "To write splendid things."

ADYGEI AUTONOMOUS OBLAST, established in 1922, is located in Krasnodar *krai* of the Russian Soviet Federated Socialist Republic, U.S.S.R. Its area of 1,737 sq.mi. extends from the left bank of the Kuban river opposite Krasnodar in a strip along the Kuban and its tributary the Laba and thence southward to the lower foothills of the Caucasus around Maikop. Apart from the flood plain meadow soils along the rivers, the lower parts of the *oblast* are covered by black earth with steppe vegetation, giving way to deciduous forests on brown soil higher up.

The total population in 1959 was 286,000, of whom 95,000 were urban and about a quarter were Adygei, a branch of the Cherkess or Circassian people. It is one of the more densely settled parts of the territory. The administrative centre is Maikop with 82,000 people. Nearly three-quarters of the *oblast* is agricultural land, with arable dominating on the black earth and a preponderance of hayland and pasture higher up. The marshy lands, subject to serious flooding, which lie along the Kuban are suitable for reclamation and approximately 20,000 ac. were reclaimed in 1955 by the Chibisky drainage scheme with 36 mi. of canals and two reservoirs. These fertile lands provide market gardens to supply Krasnodar. Agriculture is, in general, intensive, with maize the chief crop, together with wheat, sunflowers, hemp, tobacco, melons, potatoes and other vegetables. Flowers, especially Crimean roses and lavender, are grown for scent, and there is bee-keeping. In the higher areas, dairy cattle and sheep are important. Food processing forms two-thirds of industrial production. The Adygei canning factory is located in Yablonovski. Timber processing is also important and oil is drilled in the neighbourhood of Maikop. The chief industrial centre is Maikop with a wide range of food-processing and canning industries, sawmills, factories for tannin extraction, furniture making, wood chemicals and machine building. In 1950 a hydroelectric power station was built there on the Belaya river. The town lies on a branch of the Armavir-Tuapse railway which crosses the southern part of the *oblast*.

(R. A. F.)

ADZHAR AUTONOMOUS SOVIET SOCIALIST REPUBLIC (ADZHARIA) lies in the southwestern corner of the Georgian S.S.R., U.S.S.R., on the Turkish frontier. Its area of 1,158 sq.mi. is largely mountainous. Only along the coast is a lowland strip, which widens somewhat south of Batumi and again in the north around Kobuleti, where it is swampy. The mountains consist of two main east-west ranges, the Adzharo-Imeretinski range, rising to 9,350 ft. (Mt. Mepistskaro), and the Shabshetski range, the crest of which, rising to 9,219 ft. in Mt. Kheva, forms the Turkish frontier. Between the ranges lies the deep valley of the Adzharis-Tskali, which is closed at the eastern end by a third range, the Arsianski mountains, where the Goderdzi pass leads into Georgia. The coastal lowland has a humid, subtropical climate with the smallest temperature range in the U.S.S.R., 27° F. Rainfall is high; the Batumi average is 93.3 in. Inland the climate becomes increasingly severe with height, and snow lies for six months on the summits. Rainfall there is still high, up to 60 in. or more. Vegetation ranges from the subtropical up through deciduous forest with rhododendrons and azaleas, to coniferous forest and alpine meadows.

From the 17th century to the end of the 19th century Adzharia was part of Turkey and suffered greatly in the troubled history of this area. It became Russian in 1878 and was made an A.S.S.R. in 1921. Its 1959 population of 242,000 includes, as well as Adzhars and Georgians, Russians, Armenians and others, most of whom live in Batumi (*q.v.*), the capital, which has 82,000 inhabitants.

The economy of Adzharia is based on the subtropical crops of the lowland, especially tea (11 tea-packing plants), citrus fruits (tangerines, oranges, lemons and grapefruits), other fruits, particularly avocados, tung trees (for oil) and, in higher areas, tobacco. The main field crops are maize in the lowland and potatoes in the mountains. There are sizable plantations of eucalyptus and bamboo. Stock-rearing is important in the mountains, while the lowland dairy cattle are noted for high yields. Most industries are concerned with processing agricultural products and are concen-

trated in Batumi. This town, at the terminus of two pipelines from Baku, is a large oil-refining centre and port. Adzharia is linked with the rest of Georgia by a road over the Goderdzi pass and by the Transcaucasian railway which runs north along the coast from Batumi, then eastward to Tbilisi and on to Baku. (R. A. F.)

AE.: see RUSSELL, GEORGE WILLIAM.

AEACUS, in Greek legend, was the son of Zeus and of Aegina, daughter of the river-god Asopus. His mother was carried off by Zeus to the island of Oenone, afterward called by her name. The island having been depopulated by a pestilence, Zeus changed the ants upon it into human beings, who were called Myrmidons (*myrmekes*, "ants").

Aeacus was celebrated for justice and in Attic tradition became a judge of the dead, together with Minos and Rhadamanthus. His successful prayer to Zeus for rain at a time of drought was commemorated by a temple at Aegina, where a festival, the Aiakeia, was held in his honour.

AEDESIUS (d. c. A.D. 355), Neoplatonist philosopher, from Cappadocia, was a pupil of Iamblichus in Syria and afterward taught at Pergamum, where his principal disciples were Maximus, Chrysanthius and Eusebius Myndius. No writings of his remain; there is a biography of him by Eunapius.

See T. Whittaker, *The Neoplatonists*, 2nd ed. (1918); F. Copleston, *History of Philosophy*, vol. i (1946).

AEDILE, a title, probably derived from Lat. *aedes*, "temple," of magistrates in ancient Rome, who at first had charge of the temple and cult of Ceres. Originally they were two officials of the plebs, created at the same time as the tribunes (494 B.C.), whose sanctity they shared. These magistrates were elected in the assembly of the plebs. In 366 two curule aediles (see *CURULE*) were created. These were at first patricians, but those of the next year were plebeians and so on year by year alternately until in the 2nd century B.C. the system of alternation between classes ceased. They were elected in the assembly of the tribes, with the consul presiding. The privileges of the curule aediles included a fringed toga, a curule chair and the right to ancestral masks, privileges perhaps extended to the plebeian aediles after 100 B.C. Aediles ranked between tribunes and praetors, a greater proportion of the curule ones attaining the consulship, but the office was not necessary for advancement in a senatorial career. Their functions were threefold: first, the care of the city (repair of temples, public buildings, streets, sewers, aqueducts, traffic, supervision of public decency and precaution against fires); second, the charge of the provision markets, weights and measures and the distribution of grain, a function for which Julius Caesar added two plebeian aediles called *Ceriales*; third, organization of certain public games, the Megalesian and the Roman games being under the curule aediles and the Plebeian games as well as those of Ceres and Flora being under the plebeian. They had judicial powers and could impose fines.

Augustus transferred the care of the games and the judicial functions to the praetors and the care of the city to appointed boards and to the prefects of the watch and of the city. Under the imperial regime the office became a step in the senatorial career for plebeians until it disappeared after the reign of Alexander Severus in the 3rd century A.D.

In Roman municipalities aediles were regular magistrates and are recorded as officials in associations and clubs.

(T. R. S. B.)

AEDON, daughter of Pandareus and wife of Zethus of Thebes, was the mother of a single son, Itylus. Envious of her sister-in-law Niobe for her many children, she undertook to kill the eldest while he slept, but in the dark she mistakenly killed her own son. She was transformed by the gods into a nightingale, whose song is a lament for Itylus.

(T. V. B.)

AEDUI, an ancient Celtic tribe of central Gaul (occupying most of what was later Burgundy), which was chiefly responsible for the diplomatic situation exploited by Julius Caesar when he began his conquests in 58 B.C. The Aedui had been supported by

Rome since 121, when they were recognized as "brothers and blood relations." but were heavily defeated c. 61 by their neighbours the Sequani, aided by the German Ariovistus. They then lost their revenue from the tolls on the Arar (Saône). Appealing to Rome, they were rescued by Caesar, who made them his principal allies; yet they joined the coalition against him in 52, though they quickly returned to their allegiance after the Gaulish leader Vercingetorix surrendered at Alesia. Under Augustus they became a *civitas foederata* (allied state) governed by magistrates with Roman titles; and their hill fort Bibracte, on Mt. Beuvray, was demolished, a new capital being built at Augustodunum (Autun). Another tribal centre of importance was Cabillonum (Châlon-sur-Saône). In A.D. 21 under Julius Sacrovir they joined the Treveri in a revolt against Roman exactions and were quickly crushed by the Rhine army. But it is unlikely that they still seriously wanted independence, for although they supported the revolt of Julius Vindex in 68 they resolutely opposed next year the attempt under Julius Classicus to establish an *Imperium Galliarum* ("Empire of the Gauls"). Moreover in A.D. 48 they had become the first tribe of Gallia Comata to send senators to Rome.

See T. R. Holmes, *Caesar's Conquest of Gaul*, 2nd ed. (1911).
(G. E. F. C.)

AEGADIAN ISLANDS (anc. Aegates Insulae; Ital. ISOLE EGADI), a group of mountainous small islands, lie off the western tip of Sicily in Trapani province and had a total population of 6,714 in 1951. Favignana, the largest (7 sq.mi., highest point 991 ft), lies 11 mi. from Trapani, the nearest point on Sicily. Levanzo, 2½ mi. N. of Favignana (4 sq.mi., highest point 912 ft), is known for the "Genovese" cave with prehistoric paintings. Marettimo, farthest west of the group, has an area of 5 sq.mi., highest point 2,251 ft; formerly a political prison, it is known as the largest tuna fishing centre of Sicily. In 241 B.C. the Carthaginian fleet was defeated there by Gaius Lutatius Catulus, signaling the end of the First Punic War. (G. KH.)

AEGEAN CIVILIZATION is a general term for the prehistoric Bronze Age cultures of the area around the Aegean sea covering the period from c. 2500 B.C. or earlier until c. 1100 B.C., when iron begins to come into general use throughout the area. From the earliest times these cultures fall into four main geographical groups: (1) Crete, (2) the Cycladic islands, (3) the mainland of Greece, including Thessaly, and (4) the Troad (the land of Troy) in northwestern Asia Minor, together with the coasts of western Asia Minor, the great coastal islands (Lemnos, Lesbos, Chios, Samos) and Macedonia. The cultures of this fourth group have many affinities with the early cultures of central and southern Asia Minor and are really more allied to them than to the other cultures of the Aegean area.

The Bronze Age cultures of these four groups are known as (1) Minoan, (2) Cycladic, (3) Helladic and (4) Troadic. The Minoan, Cycladic and Helladic cultures are divided for convenience into three phases. Early, Middle and Late Bronze Age, with three further subdivisions (1, 2, 3) of each age. The Late Bronze Age phase of the mainland and of the islands (except Crete) is usually called Mycenaean after Mycenae, the chief Late Bronze Age site in mainland Greece. The Troadic culture is subdivided according to the "cities" (or superimposed levels of settlement found by H. Schliemann and his successors) at Troy, ranging from the earliest, Troy I, to Troy VII, the last Bronze Age settlement. Each of these "cities" is subdivided further according to occupation levels labeled a, b, c, etc. Various phases of Neolithic culture have been identified on the mainland of Greece (especially in Thessaly) and in Crete; but not yet for certain in the Aegean islands or in the Troadic area. Traces of Late Paleolithic occupation were found by R. Stampfuss during World War II at Haliartus on Lake Copais, and later by V. Milojevic along the Peneus river in Thessaly.

The first centre of high civilization in the Aegean area, with great cities and palaces, a highly developed art, extended trade, writing and use of seal stones, was Crete. Here from the end of the 3rd millennium B.C. onward a very distinctive civilization, owing much to the older civilizations of Egypt and the near east but original in its character, came into being. This rise of the first high civilization on European territory may have been stimu-

lated by an actual immigration of new peoples into the island in the early part of the Bronze Age, c. 2500–2300 B.C.

The Cretan (Minoan) civilization had begun to spread before the middle of the 2nd millennium across the Aegean to the islands and to the mainland of Greece. During the Late Bronze (Mycenaean) Age (c. 1600–c. 1100), from the middle of the 16th century onward, a civilization more or less uniform superficially but showing local divergencies—with cities, palaces, writing and use of seal stones—is found throughout the Aegean area including Thessaly, the coasts of Macedonia, the rest of central and southern Greece, and the Aegean islands with Crete and Rhodes. Eventually people bearing this civilization spread colonies eastward to Cyprus and elsewhere on the southern and western coasts of Asia Minor as far as Syria; also westward to Tarentum in southern Italy and even perhaps to Sicily. In the latter part of this period, after about 1400 B.C., the centre of political and economic power, if not of artistic achievement, appears to have shifted from Knossos in Crete to Mycenae on the mainland of Greece.

HISTORY OF DISCOVERY AND DISTRIBUTION OF REMAINS

The first great landmark in the development of modern knowledge of the Aegean Bronze Age civilization was undoubtedly the excavation of the 16th century B.C. royal shaft graves at Mycenae by Schliemann in 1876. The second was the uncovering of the Bronze Age Palace of Minos at Knossos in Crete by A. J. Evans from 1900 onward. Mycenae and Tiryns near Argos in the Peloponnese are the two principal sites at which evidence of a prehistoric civilization was remarked. But the Cyclopean walls of the citadel of Mycenae, its gate with heraldic lions, the royal tholos (or beehive) tombs, the so-called Treasury of Atreus and the galleries of Tiryns were supposed by scholars only to point to the civilization represented in Homer (*q.v.*) or, at farthest, the primitive stages of a Hellenic civilization. Not until Schliemann exposed the contents of the shaft graves that lay just inside the gate (see MYCENAE) did scholars recognize the advanced stage of art which prehistoric dwellers in the Mycenaean citadel had attained.

A good deal of other evidence was available before 1876, but it had not been collated and seriously studied. Although it was recognized that certain tributaries—represented, e.g., in the 18th-dynasty tomb of Rekhmire at Egyptian Thebes as bearing vases of peculiar forms—were of some Mediterranean race, neither their precise habitat nor the character of their civilization could be determined. Nor did the Aegean objects that were lying obscurely in museums before 1870 provide a sufficient test of what real basis there might be underlying the Hellenic myths of the Argolid, the Troad and Crete. Both at Sèvres and Neuchâtel Aegean vases had been exhibited since about 1840, one found at Philacopi in Melos, the other in Cephalonia. L. Ross, by his explorations in the Greek islands from 1835 onward, called attention to certain seal stones, since known as "island gems," but it was not till 1878 that C. T. Newton demonstrated that these were not Phoenician products. In 1866 primitive structures were discovered in the island of Therasia by quarrymen extracting *pozzolana* for the Suez canal works. When this discovery was followed up on the neighbouring island of Thera, by excavations of the French School at Athens, much pottery of a class now known to belong to the transition from the Middle to the Late Bronze Age (16th century B.C.), and many stone and metal objects, were found and dated by the geologist M. Fouqué, somewhat arbitrarily, to 2000 B.C. In 1868 tombs at Ialysus in Rhodes had yielded to M. A. Biliotti many fine Late Bronze Age painted vases, but these, bought by John Ruskin and presented to the British Museum, were supposed to be of some local Asiatic manufacture of uncertain date. See also PRE-HELLENIC ARCHITECTURE.

Schliemann's Excavations.—Even Schliemann's first excavations at Troy (Hisarlik in Turkey) did not excite astonishment. But the "Burnt City" of his second stratum, revealed in 1873, with its fortifications, vases and a hoard of gold, silver and bronze objects, began to arouse curiosity. As soon as Schliemann came on the royal shaft graves at Mycenae three years later, the importance of his findings in relation to prehistoric Greece was widely recog-

AREA OF AEGEAN BRONZE AGE CIVILIZATION, c. 2500 B.C.—c. 1100 B.C.

nized. Both the fabric and the decoration of the Mycenaean objects differed from any well-known art. The wide extent in space of this culture was proved by the identification of the "island gems" and the Ialysus vases with the newly discovered style; its wide extent in time was proved by collation of the earlier discoveries at Thera and Troy. A relation between objects of art described by Homer and the Mycenaean treasures was generally allowed, and a correct opinion prevailed that, while Homer was certainly later, the civilization described by him was in many respects reminiscent of the Mycenaean civilization. Schliemann resumed work at Troy in 1878, and greatly increased our knowledge of the lower strata. He did not recognize the Mycenaean remains in his "Lydian" city of the sixth stratum, which were not to be fully revealed till W. Dörpfeld resumed the work at Troy in 1892 after Schliemann's death. But by laying bare in 1884 the remains of a Mycenaean palace on the rock of Tiryns (*q.v.*), Schliemann made a contribution to knowledge of prehistoric domestic life that was amplified two years later by C. Tsountas' discovery of a similar palace at Mycenae. Work at Tiryns was not resumed till 1905, when it was proved that earlier strata dating back to the beginning of the Bronze Age lie below the palace cleared by Schliemann. In 1877 Late Bronze Age sepulchres were found outside the Argolid.

Between this date and the end of the 19th century many isolated tombs of the beehive type and cemeteries of rock-cut chamber tombs were explored in different districts of Greece. Chamber tombs were found in Attica (*e.g.*, at Spata and Markopoulo) and in the Argolid (at Nauplia, and near the Argive Heraeum) and some late graves in Salamis. Beehive tombs, already rifled but retaining some of their furniture, were excavated at Dimini in Thessaly, Thoricus (Thorikon) in Attica, Orchomenus (Petro-magoula) in Boeotia and Kampos in Laconia. The richest tomb of all was cleared at Vaphio in Laconia in 1889, and this produced, in addition to a fine series of engraved gems and miscellaneous goldsmith's work, two splendid golden cups chased with scenes of bull hunting, the famous Vaphio cups. The exploration of classical sites showed that many of these, too, had been important centres of culture in Bronze Age times. Thus the sanctuary at Delphi, the Argive Heraeum and the acropolis of Athens all yielded their quota of Mycenaean remains. A Cyclopean acropolis and palace were explored on the island of Goules (Gla) in Lake Copais in Boeotia, the apparently prehistoric dikes of which were surveyed.

Mycenaean remains came to light in most parts of Greece, but except for Eleusis, the island of Aegina and Thoricus (all in the *nomos* of Attica) few settlements (as opposed to tombs) were excavated. At these last three sites pottery of new types was found dating from the Middle Bronze (Middle Helladic) Age; but

this and the discovery in 1894 in a barrow at Aphidna (Aphidnai) in Attica of burials accompanied by similar early wares remained almost unnoticed. Similarly some rock-cut tombs with Early Bronze Age (Early Helladic) handmade pottery found in the American excavations at Corinth in 1896 did not fall into their right context till the discoveries at Korakou, near Corinth, almost 20 years later.

Excavations Outside the Greek Mainland.—Meanwhile certain of the Aegean islands, Antiparos, Ios, Amorgos, Syros and Siphnos, were found to be singularly rich in remains of the local Early Bronze Age (Early Cycladic). The series of graves on Syros, containing crouching corpses, is most representative. Rich cemeteries in Naxos and Paros contained in addition to early graves some remains of the Middle Bronze Age (Middle Cycladic). Delos too proved an unexpected source of Bronze Age culture, with a settlement on Mt. Cynthus and tombs in the area of the later sanctuary of classical times at its foot. Melos, long marked as a source of early objects but not systematically excavated till 1896 by the British School at Athens, yielded at Philacopi remains of all periods except the Neolithic. Numerous cemeteries with Late Bronze Age pottery were found in Rhodes both in the 19th century and later by Italian excavators.

In Cyprus, where colonists from the Aegean area seem to have arrived during the Late Bronze Age, vast numbers of clay vases of Mycenaean type (mostly of local manufacture, but some imported) have been recovered. Even earlier in the Bronze Age vases and bronze weapons were apparently being imported into the island from Crete. A prolonged campaign of excavations was undertaken in Cyprus by the Swedish Cyprus expedition between World Wars I and II. After World War II the French under C. Schaeffer and the Cypriot Antiquities service under P. Dikaios made fruitful excavations at the chief Late Bronze Age site in the island, Enkomi.

The Troadic Early Bronze Age culture has been found throughout the whole region of the coast of western Asia Minor including the great islands of Lemnos, Lesbos, Chios and Samos. Excavations at sites in Macedonia by W. A. Heurtley and others in the 1920s and 1930s indicated the existence of an allied culture there. At Niletus, on the southwestern coast of Asia Minor, German excavations before and after World War II revealed Late Bronze Age pottery of Minoan and Mycenaean types, evidence of an actual colony of peoples from Crete or mainland Greece or both. In Egypt in 1387 W. M. Flinders Petrie found imported Cretan sherds of about 1750 B.C. at Birkat Qaroun in the Fayum, and in 1889 fragments of hundreds of Late Bronze Age (*c.* 1375–1350 B.C.) vases from the Aegean (thought to be of mainland rather than of Cretan

manufacture) from the rubbish dumps of the palace of the pharaoh Ikhnaton at Tell el-Amarna on the Nile. Vases of the Late Bronze Age imported from the Aegean also were found in tombs near Syracuse in Sicily. Aegean objects were reported from Sardinia and the Balearic Islands.

Crete.—The greatest Bronze Age city of the Aegean and the chief site of the Minoan Bronze Age civilization was Knossos in Crete, which has yielded the most various and the most continuous evidence from the Neolithic Age onward. It was in fact the fountainhead of Aegean Bronze Age civilization and probably for long its political and social centre. The remarkable archaic Greek bronzes found in a cave on Mt. Ida in 1885, and epigraphic monuments of the classical period such as the famous law of Gortyna (*g.v.*), first attracted the notice of archaeologists, but the first undoubted Bronze Age remains reported from it were a few objects extracted from the palace at Knossos by M. Kalokairinos in 1878. These were followed by important discoveries made in the southern plain (Mesara) by F. Halbherr and other Italian explorers. The American W. J. Stillmann and Schliemann both made unsuccessful attempts at Knossos, and Evans, going to Crete in 1893, traveled in succeeding years about the island exploring sites and collecting evidence which convinced him that greater things would eventually be found. He was able to forecast the discovery of written characters, till then not suspected in Aegean civilization. For the subsequent history of Evans' excavations at Knossos see CRETE.

Further Investigations on the Mainland After 1900.—The success of the excavations in Crete naturally caused fresh attention to be paid to Mycenaean remains on the mainland. At Thebes in Boeotia the ruins of the Late Bronze Age palace (the House of Cadmus) were found by A. D. Keramopoulos and yielded many fragments of brilliant frescoes and a store of inscribed vases; close to the city chamber tombs, stored with vases and other funeral furniture, were excavated. At Orchomenus the Mycenaean stratum was explored by A. Furtwängler and the underlying strata, earlier Bronze Age and Neolithic, began to reveal for the first time the pre-Mycenaean history of the mainland. Wares of the Early and Middle Bronze Age were unearthed at Aegina, and imported Cretan ware of the Middle Bronze Age also came to light there and, after World War II, at Lerna. At Tiryns many fragments of frescoes from the palace were found, and in the strata beneath the palace floor, reaching down to bedrock, remains of the Middle and Early Bronze Ages appeared. Further beehive tombs were excavated in Messenia at Kakovatos and Pylos (Pilos) and in the Argolid at Tiryns and at many other sites. More evidence for the Late Bronze Age came from Argos, Achaea, Aetolia, Locris and Cephalonia, showing that culture all over Greece at that time had been more or less uniform.

In Thessaly rich deposits of painted Neolithic pottery were found before World War I at Dimini and Sesklo by Tsountas. Further systematic excavation of other sites in Thessaly, notably by A. J. B. Wace and M. S. Thompson before World War I and after World War II by V. Milojevic and H. Biesantz, and researches by G. Soteriades and later by H. Goldman and S. Weinberg in Boeotia and Phocis, showed that the Neolithic pottery of the Greek mainland was different from that of Crete, having painted designs instead of plain burnished surfaces. Dorpfeld in Leucas (an island off the coast of Acarnania) found mares of all Bronze Age periods (Early, Middle and Late) and Neolithic pottery with painted decoration closely akin to the Thessalian. Euboea produced tombs of the Early Bronze Age, with pottery showing a striking likeness both to the wares of the Cyclades and to those of the mainland, and more Late Bronze Age tombs.

After 1915, American excavations there under C. W. Blegen and others threw light on the early history of the mainland. In the Peloponnesus, Neolithic wares similar to those of Thessaly have been found at Corinth, Nemea, the Argive Heraeum and Lerna. Excavations at Korakou and at Zygouries (southwest of Corinth), at the Argive Heraeum and, near Athens, at Ayios Kosmas have revealed further evidence of the three stages of Bronze Age culture on the mainland. In the Argolid, at Asine near Nauplia and at Berbati near Mycenae, Swedish expeditions under A. W. Persson recovered remains of all periods, and at Midea (Dendra) exca-

vated an unlooted beehive tomb that revealed evidence of the burial ritual and treasures richer than those of Vaphio. There was a splendid gold cup chased with a design of octopuses and dolphins, a gold and silver cup adorned with bulls' heads, silver cups, weapons of bronze, engraved seal stones and pottery dating the tomb to about 1350 B.C. Nearby a chamber tomb, with a hoard of 33 bronze vessels, empty of human remains, seemed to have been a cenotaph. Another tomb produced a bronze helmet, and one found in 1960 contained a bronze corselet.

But the most spectacular discoveries from the mainland of Greece in the 20th century have been at Mycenae itself and at Pylos in Messenia in the southwestern Peloponnesus. At Pylos in 1939 Blegen began to excavate a great Mycenaean palace (the Palace of Nestor) containing archives of clay tablets inscribed with a linear script (Linear B) like those found for the first time by Evans at Knossos about 40 years earlier. No such tablets had been found before this on the Greek mainland, although a few clay jars with painted inscriptions had come to light, for instance, at Thebes and Eleusis. After World War II many more tablets were found at Pylos, and similar tablets were recovered at Mycenae. In 1952 the language of these tablets (both those from Knossos and those from the mainland sites) was deciphered by M. Ventris and J. Chadwick as Greek. Their decipherment has been accepted by many authorities, but is challenged or doubted by others. At the same time more tholos tombs and rock-cut chambers with very rich finds rivaling those from Mycenae itself have been excavated by Blegen at Pylos near the palace and by S. Marinatos elsewhere in the Pylos area. Many other unexcavated tholos tombs and Bronze Age sites are known to exist in this region.

From 1920 to 1923 the British under Wace re-explored the Late Bronze Age palace and the great royal tholos tombs around the city at Mycenae, and cleared new cemeteries of rock-cut chamber tombs there. In 1939 Wace resumed excavations, and continued them again after World War II, excavating important Bronze Age houses outside the walls with a rich harvest of clay and stone vases, ivory inlays and inscribed clay tablets. In 1951 a new circle of royal shaft graves like those explored by Schliemann but in general somewhat earlier in date (they contained imported Cretan pottery of about 1550 B.C.) came to light in the same area outside the Late Bronze Age citadel walls and was explored by the Greek archaeologists J. Papademetriou and G. E. Mylonas. The wealth of gold cups, bronze weapons, vases and objects of rock crystal and jewelry from these graves rivals the treasures from the graves examined by Schliemann.

GENERAL NATURE OF THE EVIDENCE

The internal evidence comprises:

1. Structures: ruins of palaces, palatial villas, houses, built tholos (domed or beehive) tombs, rectangular built tombs (in Crete), cist graves and fortifications (Aegean islands, Greek mainland and northwestern Asia Minor). Large temples like those of Egypt and the near east do not seem to have existed. Small shrine buildings, however, have been noted at many sites in Crete, for instance at Gournia, in the centre of the town, and associated with the palaces at Mallia and Ayia Triada, and on a large number of mountain tops. On the mainland what appears to be a Late Bronze Age shrine has been recognized deep under the floor of the later Hellenic *telesterion* (hall of the mysteries) at Eleusis. Many pictures of shrines appear in fresco paintings, on stone relief vases and on gold plaques, and clay models of them exist. These, mostly of the Late Bronze Age, have been recovered from both Crete and the mainland. From like sources and from faïence and ivory inlays representations of palaces and houses also have been recovered.

2. Structural decoration (*i.e.*, architectural features), such as stone columns, friezes and various moldings; mural decoration, including fresco paintings, coloured plaster reliefs and perhaps mosaic inlay.

3. Furniture including: (a) Domestic, such as vessels of clay, stone, bronze, etc., from huge store jars down to tiny unguent pots; culinary and other implements; thrones, seats, tables, etc., of stone or plastered terra cotta. (b) Sacred, such as models or actual examples of ritual objects; of these there are also numerous pic-

torial representations. (c) Funerary; *e.g.*, coffins in painted terra cotta and occasionally stone.

4. Works of art; *e.g.*, objects carved in stone or ivory, cast or beaten in metals (gold, silver, copper and bronze) or modeled in clay, faïence, paste, etc. Little or no trace has been found of large sculpture in stone or any other material, but many examples exist of small sculpture in stone, bronze and ivory. There is some evidence from Crete, however, that there were larger statues in wood. There are vases of all kinds, carved in marble or other stones, cast or beaten in metals or fashioned in clay, the latter in enormous number and variety, richly ornamented with painted designs and sometimes bearing molded decoration; examples of painting on stone, opaque and transparent; engraved objects in great number, *e.g.*, ring-bezels and gems (seal stones); and an immense quantity of clay impressions, taken from these.

5. Weapons, tools and implements in stone, clay and bronze and, from *c.* 1100 B.C., iron, sometimes richly ornamented or inlaid. Numerous representations of these also have been found. Evidence for the use of body armour (bronze helmets, greaves, cuirasses) has been found, the rare surviving examples of these all being of the Late Bronze Age.

6. Articles of personal use; *e.g.*, brooches (only at the end of the Late Bronze Age), pins, razors, tweezers, etc., occasionally found as dedications to a deity.

7. Written documents; *e.g.*, clay tablets, engraved gems and gem impressions, legends written with ink or paint on pottery or painted on frescoes (rare) and characters incised on stone or pottery.

8. Excavated tombs, of either the pit or the chamber kind, in which the dead were laid together with various objects of use and luxury. The burials are almost invariably inhumations, but rare examples of cremations, mostly Late Bronze Age, have been found both in Crete and on the mainland. The bodies were placed in either coffins of clay or wood (in Crete) or simple wrappings.

9. Public works, such as paved and stepped roadways, bridges, systems of drainage, etc.

A certain amount of external evidence also may be gathered from:

1. Monuments and records of other contemporary civilizations. Among these are representations of alien peoples in Egyptian frescoes; imitation of Aegean fabrics and style in non-Aegean lands; allusions to Mediterranean peoples in Egyptian, Hittite, Semitic or Babylonian records.

2. Literary traditions of subsequent civilizations, especially the Hellenic, such as those embodied in the Homeric poems, the legends concerning Crete, Mycenae, etc.; and statements as to the origin of gods and cults transmitted by Hellenic antiquarians such as Strabo, Pausanias and Diodorus Siculus.

3. Anomalies in customs, creeds, rituals, etc., in the Aegean area in the periods after the Bronze Age, indicating survivals from earlier systems.

4. Philological evidence: survivals in Greek (an Indo-European language) of words of non-Indo-European origin.

GENERAL FEATURES OF AEGEAN CIVILIZATION

From the evidence classified above it is possible to deduce some leading features of Aegean civilization.

Political Organization. — The Cretan palaces, and the fortified citadels of Mycenae, Tiryns and Troy, containing little more than one great residence and dominating lower towns of meaner houses, point to monarchy at all periods. Local variations in the development of Aegean art before the middle of the 2nd millennium B.C. suggest the early existence of independent political units in various parts of the Aegean world, of which the strongest was that at Knossos.

Religion. — The kings were evidently priest-kings, if not themselves regarded as divine, as in Egypt and the near east. Religion in the area may have been essentially the same everywhere from the earliest period, though until the spread of Minoan civilization in the Late Bronze Age the evidence for it is virtually confined to Crete. *viz.*, the cult of divine principles, resident in nature and controlling fertility. This cult in Crete passed through an aniconic

stage, from which fetishes survived to the last, these being rocks or pillars, trees and weapons (*e.g.*, the double war ax, the shield). When the iconic stage was reached, in Crete from early in the 2nd millennium B.C. or before, we find a goddess with a subordinate young god, as in many other eastern Mediterranean lands. The god was probably son and mate of the goddess, and the divine pair represented the genius of reproductive fertility in its relations with humanity. The goddess at times appears with doves, as uranic. at others with snakes, as chthonic. In the ritual, fetishes, often miniature, played a great part. Many plants and animals were sacred; animal sacrifice (but not normally burnt, in Crete at least), invocation and dedication of all sorts of offerings and effigies were practised. The dead may have been objects of a sort of hero worship both in Crete and on the mainland. This early nature cult explains many anomalous features of Hellenic religion, especially in the cults of Artemis and Aphrodite.

Social Organization. — Of the organization of the people under the monarch little is known. There are so few representations of armed men that it seems doubtful if there can have been any professional military class, at any rate until the Late Bronze Age. Theatrical structures, found at Knossos and Phaestus within the precincts of the palaces, perhaps were used for shows of a religious character or for sittings of a royal assize, rather than for popular assemblies. The remains at Knossos contain evidence of an elaborate system of registration, account-keeping and other secretarial work, which perhaps indicates a considerable body of law.

The life of the ruling class in Crete at least was comfortable and even luxurious from early times. In Crete fine stone palaces, richly decorated, with separate sleeping apartments, large halls, ingenious devices for admitting light and air, sanitation and highly developed arrangements for supply of water and for drainage, attest this fact. There, even the smaller houses, after the Neolithic period, seem also to have been of stone, plastered within. After 1600 B.C. the palaces in Crete had more than one story, fine stairways, bath chambers, windows and folding and sliding doors. In the Late Bronze Age palaces of the mainland, the distinction of blocks of apartments has been held to indicate the seclusion of women at least among the ruling class; moreover, frescoes at Knossos show women grouped apart, and they appear alone on gems.

Meat, fish and many kinds of vegetables were evidently eaten, and wine and beer were drunk. There was evidently olive and vine culture on a large scale. Vessels for culinary and table use show an infinite variety of form and purpose. Artificers' implements of many kinds mere in use, bronze succeeding obsidian and other hard stones as the material. Stone seats are found carefully shaped to the human body. Chariots were in use in the Late Bronze Age, as is proved by the pictures of them on the shaft grave steles (tombstones) at Mycenae, on Cretan tablets, and on gems and frescoes. The horse was also ridden, but chariots were no doubt used more than cavalry in war, as in Egypt and elsewhere at the time. Main roads were paved. Sports, probably more or less religious or magical in their object, are often represented; *e.g.*, bull-fighting, dancing, boxing and armed combat.

Commerce. — Trade was practised to some extent from the earliest times, as is proved by the distribution of obsidian from Melos over most of the Aegean area and by the Nilotic influence on early Minoan art. Early in the 2nd millennium Cretan vases were exported to Melos, Egypt, Cyprus and the Greek mainland; Melian vases came in their turn to Crete. After 1600 B.C. there is very close intercourse with Egypt, and Aegean things find their way to all coasts of the Mediterranean. No traces of currency have come to light, unless certain axheads, too slight for practical use, were used as such; but standard weights and ingots have been found. No Aegean written documents have been found outside the area and there is therefore no evidence of epistolary correspondence with other lands. Representations of ships are not uncommon on Aegean gems, gem-sealings and vases. There are also leaden and clay models of boats, of low freeboard, with masts. Familiarity with the sea is evinced in the free use of marine motives in decoration.

Disposal of the Dead. — Little is known about the burial customs of the Neolithic peoples whether in Crete or on the mainland.

In Crete at the beginning of the Bronze Age natural caves were being used as communal tombs by whole families or tribal groups. Somewhat later artificial caves—irregular chamber tombs with one or more compartments—began to be cut in the soft rock at sites such as Knossos. In other parts of the island tombs built of stone above ground, either rectangular with several chambers, or circular, domed in stone, mud or mud brick (remote ancestors of the great tholos tombs of the Late Bronze Age), were also in use. All these were communal tombs used for repeated burials over long periods of years, and they often contain the remains of hundreds of bodies. In the other Aegean islands cist graves (also found in Crete from an early period) and little stone-built tombs containing only one or two bodies were more often the rule. On the Greek mainland in the Early Bronze Age both stone-built communal tombs (at coastal sites such as Ayios Kosmas near Athens) and rock-cut chamber tombs with only one or two bodies are known.

About the beginning of the Middle Bronze Age (Middle Helladic), however, an intrusive culture brought by invaders apparently from somewhere in Asia Minor introduced new burial customs to the mainland. The dead were now buried individually in graves, often lined with slabs (cist graves), either under the floors of the houses or in the streets inside the settlements. Throughout the Aegean area, before this time, burial was always (except in the case of infants) outside the settlement area. In Crete from about 1600 B.C. the custom of communal burial began to give way, at the great centres like Knossos at least, to a practice of burying in small tombs or graves with only one or two bodies in each. But by a curious inversion, with the spread of the Minoan civilization to the mainland of Greece, large chamber tombs used by whole families for repeated burials largely replaced the Middle Bronze Age (Middle Helladic) custom of burial in single graves there.

On the mainland royal burials were at first in shaft graves, and later in tholos tombs apparently descended from the earlier Cretan circular tombs. In Crete the only "royal" tombs that have been identified are at Knossos; and they are either circular beehives or rectangular stone rooms with keel vaults, or (in the case of the Temple Tomb at Knossos) in the form of a regular funerary temple with a rock-cut burial chamber behind it.

In Crete during the early part of the Bronze Age burials were normally contracted (the body being often squeezed head or feet first into a clay store jar), but in the later Bronze Age loosely flexed and extended burials became common. At this time in Crete the bodies often were placed in wooden coffins or in clay imitations of them, or in clay bathtubs (the latter also used, but more rarely, on the mainland). Rare examples of cremation have been found dating from the Late Neolithic period in Thessaly, and from about the 17th century B.C. and later in Crete and on the mainland; but cremation was never a regular form of burial around the Aegean area (except perhaps in the Troad) until the beginning of the Iron Age after 1100 B.C.

In Crete there is evidence of an elaborate cult or tendance of the dead in the shape of vast numbers of vases, evidently once containing food and drink, placed outside the great communal tombs. In the later Bronze Age it became the custom throughout the Aegean area to put such grave goods together with the bodies inside the tombs. The arrangements in the royal Temple Tomb at Knossos, and the funerary scenes depicted on the painted stone sarcophagus found at Ayia Triada dating from about 1350 B.C., suggest an elaborate cult of the dead continuing into the Late Bronze Age in Crete. Above the shaft graves excavated by Schliemann at Mycenae was what appears to have been a circular altar. This and offerings in the form of terra-cotta figurines, bronzes, etc., placed, as well as vases of food and drink, outside the great royal tholos tombs at Mycenae, indicate a similar kind of cult on the mainland as well.

Artistic Production.—Ceramic art reached an especially high standard in its fabric, form and decoration by about 1750 B.C. in Crete. But the high-water mark of the Bronze Age civilization of Crete is in the 17th and 16th centuries B.C. It was during this period that the Cretan civilization spread its influence over the Aegean islands and the Greek mainland. The products of the Aegean gem (seal stone) engravers then probably excelled in fine-

ness anything of the kind made elsewhere at the time. The same may be said of fresco painting, and probably of metalwork. By the end of the 15th century B.C., however, the beginning of a decline in workmanship and style in all branches of the arts is visible. This decline was accelerated during the centuries that followed.

ORIGIN AND HISTORY OF AEGEAN CIVILIZATION

Distinctive Features.—The distinctive character of Aegean civilization is now clear enough. The truth was obscured for a time, however, by prejudices in favour of certain alien Mediterranean races long known to have been in relation with the Aegean area in prehistoric times; e.g., the Egyptians and especially the Phoenicians. Others put forward the Achaeans (*q.v.*) from the north as the people to whom this civilization belongs. But such claims to the authorship of the Aegean remains grew fainter with every fresh Aegean discovery; with the Cretan revelations they largely ceased to be considered.

The Aegean civilization developed these distinctive features:

1. Indigenous scripts expressed in characters of which only a small percentage are identical, or even obviously connected, with those of any other scripts (see CRETE).

2. Art quite distinct in character from any other known art. Its obligations to other contemporary arts (of Egypt and Babylonia, for instance) are many and obvious, especially in its later stages; but every borrowed form and motive is modified in the works of Aegean craftsmen and assumes a new character. In it may be detected the beginning of that naturalism, combined with a striving for the ideal, that afterward animated Hellenic art. The fresco paintings, ceramic motifs, reliefs, free sculpture and metalwork of Crete confirm the impression long ago created by the earlier discoveries on the Greek mainland (Mycenae, Vaphio, Tiryns).

3. Tomb construction of the tholos or beehive type, of which the grandest examples known are at Mycenae. The Cretan type of coffin, also, has no parallel outside the Aegean.

Chronology and History.—The Cretan Bronze Age was divided by Evans, on a basis of changes observable in the style of the pottery, seal stones and other objects, into three main periods, called by him the Early, Middle and Late Minoan after the legendary King Minos of Knossos. Some years later a similar scheme was proposed by Wace and Blegen for the Bronze Age sequences of the mainland (Early, Middle and Late Helladic) and the Aegean islands (Cycladic). These three systems do not by any means necessarily run parallel to each other except during the last (Late Bronze Age) phase from about 1600 B.C. onward, when Cretan civilization had spread its influence throughout the Aegean and over the Greek mainland.

The earlier Bronze Age (Early Minoan period) in Crete had many affinities with the end of the Old Kingdom (6th dynasty) and the First Intermediate period succeeding it in Egypt. There may even have been an influx of settlers from Egypt, and from the coasts of Syria and Palestine, into Crete during this disturbed time between about 2400 and 2200 B.C. But many of the basic elements of the Cretan (Minoan) Bronze Age civilization can be traced back into the local Neolithic civilization. At the same time, the earliest Bronze Age civilization of Crete had much in common with the earliest Bronze Age cultures of the islands and the Greek mainland, although the civilization of Crete from the start appears to have been much more advanced, with a knowledge of writing and extensive use of seal stones in commerce.

The distribution of place names of a peculiar non-Indo-European (see INDO-EUROPEANS) type, notably names with roots ending in *-ss* like Knossos or *-nt(d)* like Korinthos (Corinth) or Tiryns with genitive *Tiryntos*, together with words of the same type surviving in later Greek, suggest that at some point in time a people speaking the same or related non-Indo-European languages occupied the whole Aegean and the western part of Asia Minor. The spread of this language or languages may have been due to immigrations into the Aegean from the direction of Asia Minor at the beginning of the Bronze Age, or may reflect the position in still earlier Neolithic times.

In Crete a high civilization, with great cities and palaces, the arts of writing, fresco painting, stone vase making, gem engraving,

ivory carving, and faience molding, developed without any apparent break throughout the 2nd millennium B.C. On the mainland of Greece, however, the promise of the Early Bronze Age (Early Helladic) culture, apparently connected in many ways with the civilization of Crete, was cut short by an irruption of more barbarous people coming perhaps from the hinterland of central or eastern Asia Minor. These people lived in long houses of a primitive aspect with a main room and a porch in front, and often with a semicircular compartment at the back—a type of dwelling already found in Thessaly during Neolithic times and widespread throughout central Europe and Asia Minor—and they introduced the practice of burying their dead inside their settlements. But the influence of the rich and powerful Cretan civilization, now at its apogee, increasingly made itself felt and spread over the islands and the Greek mainland.

In some of the Aegean islands this spread of Cretan civilization was certainly accompanied by actual colonies of Cretans. Such a colony dating from the 17th or 16th century B.C. has been recognized at Trianda (near Ialysus) in Rhodes, and many others no doubt existed. On the mainland the position is less clear, and it is by no means certain that any part of the mainland was ever politically subject to Cretan rule. The kings of the shaft graves at Mycenae were clearly natives, although many of the fine things placed in their tombs (the gold cups, swords, gems, etc.) were of Cretan origin, either gifts from Cretan kings, or plunder taken by mainland kings in war, or manufactured by Cretan craftsmen, whether prisoners or volunteers, working at mainland courts. Moreover the Cretan civilization, which is best represented at the great centres like Mycenae or Pylos, does not appear really to have saturated the mainland. The use of seal stones, for instance, general in Crete, was evidently confined to a comparatively small class—kings, nobles and officials—on the mainland; for on the mainland seal stones are much rarer than they are in Crete, and the cheap crude seal stones used by ordinary people are almost entirely absent. Above all, the Late Bronze Age palaces of the mainland are of quite a different type from the earlier Cretan palaces. The latter were built around a large open court, while the former were dominated by a great hall or *megaron*, as it has come to be called from its resemblance to the *megara* (halls) that Homer describes, with a huge central hearth and a porch in front, a glorified version, in fact, of the long house of the Middle Bronze Age and earlier times on the mainland. It seems therefore that the kings of the mainland, even if at some point they were tributary to Cretan overlords, were not themselves Cretans.

About 1400 B.C. what Evans called the "Last Palace" at Knossos was destroyed. It may be that both at Knossos and other Cretan sites palaces existed after this time. But if they did they were almost certainly poor and mean compared with the great palaces that had preceded them. The archaeological evidence suggests that in the period immediately before 1400 B.C. Knossos was the centre of a great political power with a highly developed military system, ruling the whole of Crete and many of the islands if not parts of the mainland as well; but that after 1400 B.C. the centre of political power had shifted to Mycenae, which during the following century attained the height of its glory and prosperity. In this period the greatest of the beehive tombs like the Treasury of Atreus and the Cyclopean walls round the citadel were built.

The decline in the civilized arts that had already begun to be visible during the period of the so-called Last Palace at Knossos before 1400 B.C. continued throughout the 14th and 13th centuries. Internal wars or the threat of invasions from outside are reflected in the construction of great fortifications on the mainland of Greece, at Mycenae, Tiryns, Dendra, Athens and Gla in Lake Copais, for instance. There appears also to be a Mycenaean fortification wall crossing the Isthmus of Corinth to defend the Peloponnese from the north. In the course of the 13th century the great palaces of the mainland were destroyed one after another, never to be rebuilt. But at Mycenae itself, and perhaps at Pylos, the final destruction of the city and palace apparently were delayed until 1200 B.C. or later.

About 1100 B.C., according to tradition, the last wave of Greek invaders, the Dorians, entered southern Greece. This period coin-

cides with the ultimate degeneration of the Old Bronze Age civilization. It also coincides with the beginning of the extensive use of iron replacing bronze for tools and weapons in the Aegean area, and the spread of the practice of cremation burial.

When the earliest wave of Greeks had begun to enter the Aegean area is a more open question. If the language of the Late Bronze Age (Linear B) script of Knossos, Pylos and Mycenae is correctly interpreted as Greek, they clearly entered the Aegean before the time that such a script was evolved, in the 15th century B.C. or earlier. Many authorities would place the entry of the first Greeks into Greece at the turn of the Early and Middle Bronze Ages of the mainland, the beginning, that is, of the 2nd millennium B.C. There are many arguments in support of this view; and even if the language of the Linear B script is finally proved not to be Greek, the first Greeks may still have come into Greece then. But if the language of the script is not Greek, they may also have come later in the Bronze Age, during the 13th century B.C., only 100 years or so before the Dorians. See also MINOAN LINEAR SCRIPTS; and Index references under "Aegean Civilization" in the Index volume.

G. H.; A. J. B. W.; M. S. F. H.)

AEGEAN SEA (Gr. AIGAION PELAGOS; Turk. EGE DENIZI), an arm of the Mediterranean sea between Greece on the west and Asia Minor on the east, is connected by the Dardanelles with the sea of Marmara and closed by Crete to the south. The name "archipelago" was formerly applied specifically to the sea. Variouso derivations suggest the origin of "Aegean" from the town of Aegae (modern Limni), or from Aegea, queen of the Amazons, who perished in this sea, or from Aegeus, father of Theseus, who drowned himself there. Structurally the sea is a much-shattered old land block almost entirely submerged, outlined by younger fold mountains (being continuations of ranges of Asia Minor), also partly submerged. Both features have accounted for this island-studded sea with its alternating deeps and shallows. Island chains may be traced through Chios, Psara and Skyros to the northern Sporades; through Samos, Icaria, Mykonos, Tenos and Andros to the southeast promontory of Euboea; and through Rhodes,

Karpathos, Crete and Cerigo to the southeastern promontory of the Peloponnesus. Between the two last chains is the great group of the Cyclades including Naxos, Paros and Melos. Islands in the northern section of the sea include Thasos, off the Macedonian coast, Samothrace, fronting the Gulf of Saros, and Imbros and Lemnos, in prolongation of the Gallipoli peninsula, while Mitylene lies off the coast of Asia Minor. Important sea basins are those of the Cretan sea with depths of over 1,000 fathoms, and the trough between Thessaly and the Gulf of Saros (over 600 fathoms). Many islands are of volcanic formation; and a well-defined volcanic group includes Melos, Cimolus, Thera and Therasia. The larger islands have some fertile and well-watered valleys and plains. The chief productions are wheat, wine, oil, mastic, figs, raisins, honey, wax, cotton and silk. The people fish for coral and sponges, as well as for bream and mullet. Greece owns most of the islands, since a number collectively known as the Dodecanese were transferred to Greece by Italy after World War II. Imbros (Imroz) and Tenedos (Bozcaada) remain Turkish. The storms which cross the sea in the winter months inhibit navigation, but in summer the gentle and regular Etesian winds, setting from the north, make movement by sea safe and easy. In the latter half of the 2nd millennium B.C., the Mycenaean thalassocracy, or maritime supremacy, was centred on the Aegean and controlled its shores. In later antiquity, the Aegean is the heart of the Greek world, and the Greek people lived along its shores, as Plato said, like frogs around a pond; indeed, the island of Delos was traditionally the centre or hub of the world, set between the foreshores of the three continents.

The ethnic unity of the islands and shores of the Aegean was only broken after World War I, with the exodus of a large Greek population from the western coasts of Asia Minor. Now that the frontier cuts the Turkish coast from all but a few minor inshore islands, coastal trade on this side of the sea has declined sharply. Geological changes, too, have affected shipping, for on all the Aegean coasts the accumulation of silt has swamped numerous small harbours since classical times, and traffic has concentrated increasingly in a few large silt-free ports, like Izmir (Smyrna) and Piraeus. There are separate articles on most of the islands; for historic aspects see *AEGEAN CIVILIZATION*; *GREECE*.

(Wm. C. B.)

AEGEUS, son of Pandion and grandson of Cecrops, was king of Athens and the father of Theseus (*q.v.*).

AEGINA (mod. Gr. *AIGINA* or *AIYINA*), a Greek island in the Saronic gulf, lies 20 mi. from the Piraeus. In shape almost an equilateral triangle (each side about 8 mi. long), it has an area of about 33 sq.mi. and a population of (1951) 8,859. In the northwest is a stony but fertile plain which produces olives, figs, vines and almonds; along the east coast stretches a ridge of volcanic trachyte, its highest point the conical Mt. Oros in the south (1,745 ft.). The chief town, Aegina (pop. [1951] 6,217); whose sheltered harbour is now little used, lies at the northern end of the west coast. The island forms an eparchy of the modern *nomos* of Attica (*q.v.*).

Antiquities.—The site of the modern town has been occupied continuously since about 3000 B.C. Excavations on the promontory which shields the double harbour on the north have yielded abundant evidence of Neolithic and Bronze Age occupation. With the extension of the city southward in historical times this acropolis became more exclusively a religious centre and remains have been found of several small sanctuaries (notably that of Aeaecus (*q.v.*), the hero whose mother gave her name to the island) and of a central temple (c. 500 B.C.), now known to be that of Apollo, of which the foundations and one interior column are preserved. Neolithic to late Mycenaean tombs have been discovered near the town, from one of which came the famous Aegina treasure in the British museum (now known to be of Cretan origin). At the northern end of the eastern ridge stands the sanctuary of Aphaea, a primitive local goddess of uncertain origin, associated by the systematic mythographers with Britomartis (Pausanias, II, xxx. 3). The sanctuary was already established in late Mycenaean times and traces of walls, an early temple and an even earlier altar testify to successive improvements before it reached its final form

AFTER FURTWÄNGLER

PLAN OF THE SANCTUARY OF APHAEA, 5TH CENTURY B.C., AEGINA

flanked by groups of combatants before Troy, but stylistically the eastern pediment is markedly more developed than the western, a discrepancy explained by the discovery near the east front of fragments of a third group on the same theme in the earlier style. This, the original east pediment, was probably damaged in the wars of 490–480 B.C. and then replaced by a more modern version (see *GREEK ART*).

The Munich sculptures were discovered by Charles Robert Cockerell (*q.v.*) and others in 1811 and sold to Louis of Bavaria who had them restored, disastrously, by Bertel Thorvaldsen (*q.v.*). Further fragments came to light and the whole plan of the sanctuary was established in the systematic excavations of Adolf Furtwängler (*q.v.*) in 1901. By 1960 the Greek Archaeological service had carried out extensive restoration.

The sanctuary was thought by early writers to belong to Zeus Hellanios; its real identity was proved by Furtwängler while substantial traces of the sanctuary of Zeus have now been discovered toward the summit of Mt. Oros.

History.—The dominating factor in Aegina's early history was trade. Commanding, as it does, the Saronic gulf, it was the natural clearinghouse in any dealings between central Greece and the east. The evidence of literature and archaeology bears witness to the devotion with which it exploited its natural advantages and to the profits which this devotion brought.

Already in the Early Bronze Age (2500–2000 B.C.) Aegina was importing from the Cyclades, Crete and Asia Minor while in the Middle Bronze Age (2000–1600) its own pottery was distributed throughout the neighbouring mainland states. To this period, perhaps, we should ascribe its membership in the shadowy association of Saronic states later remembered as the Calaurian league (Strabo, VIII, vi, 14). During the Mycenaean period (1600–1200) its individual style of pottery disappeared and this may be symptomatic of some more general decline; Homer makes it a dependency of Argos at the time of the Trojan War. As elsewhere the Dorian invasion (c. 1200; see *DORIANS*) brought an end to commerce, culture and history for several hundred years, although the island was not occupied by the invaders until 1000 B.C. or even later. They came in the end, traditionally, from Argos via Epidaurus (*q.v.*) on which Aegina long remained, in some sense,

FROM THE ESTATE OF WALTER HECE

EAST END OF THE TEMPLE OF APHAEA, AEGINA

c. 490 B.C. (see plan). The temple, which is perhaps the finest example of late archaic architecture in European Greece, was a Doric peripteral structure of local limestone, coated with stucco and richly decorated. In the pediments were set two superb groups of marble sculpture, substantial fragments of which are now in Munich, Ger. The theme of each is similar, an Athena

dependent. But this dependence did not hinder a return to pre-Dorian habits of trade; as the Greeks extended their exploration of eastern waters, Aeginetan ships followed close behind, to Syria, Egypt and the Black sea; all this in close collaboration with Miletus and other friendly cities of Ionia and not without opposition from Miletus' enemy Samos. It is a good illustration of its interests and success, public and private, that Aegina was the first Greek state to introduce coinage (c. 620), soon after its invention by the Lydians, and that an Aeginetan citizen, Sostratus, was said by Herodotus (IV, 152) to have made more profit on a single voyage than any other merchant. Little is known of the nature of Aegina's commerce; but without many native resources it must have been chiefly as a carrier and distributor of corn (Herodotus VII, 147). oil, wine and slaves that it earned its profits. By 505 the aristocratic government was faced with a politically unsympathetic and economically formidable neighbour and rival, Athens (*q.v.*), whose new democracy had just survived a combined attack by Thebes, Chalcis and the Peloponnesian league (see SPARTA). Thebes appealed to Aegina, invoking a mythological connection, and Aegina replied, appropriately, with mythological aid. But the loan of statues of the Aeacidae did not help materially and a second appeal followed. This time the Aeginetans began a damaging series of raids on the Attic coast line, the resumption of an old quarrel, says Herodotus, referring to an early war, perhaps of the 7th century; but Aegina had more immediate reasons for wishing harm to Athens. Athens was diverted from prompt reprisals by other preoccupations which culminated, after 494, in the threat of an attack by Persia. Faced with the same threat Aegina decided to submit; with all its former partners and most of its markets in Persian hands, Aegina could hardly reconcile patriotism with profit. The crisis gave Athens a chance of revenge; an appeal to Cleomenes I (*q.v.*) brought the Spartan king to Aegina and, ultimately, ten Aeginetan hostages to Athens. This seems to imply that Aegina was at the time a member of Sparta's Peloponnesian league and we might, perhaps, suggest that Cleomenes' decisive defeat of Aegina's old friend Argos about 494, at a time when relations were strained between Sparta and Aegina's natural rival Corinth (*q.v.*), had brought it under Spartan influence. After Cleomenes' death the Aeginetans, through the Spartans, asked for the return of their hostages and, when Athens refused, reacted by seizing an Athenian ship. So war began—Herodotus implies in 490, the year of Marathon, but many modern scholars prefer a later date (c. 487) when, they argue, Athens would be free to think of revenge. Whatever the date, an Aeginetan nobleman, Nicodromus, was prepared to lead a democratic uprising against his fellow aristocrats and arranged for Athenian help. But by the time the fleet arrived Nicodromus had fled and, in spite of some initial successes, it was defeated and driven off. The war continued, for Nicodromus raided the Aeginetan coast from his base at Sunium, near Athens, and it was against Aegina that Themistocles (*q.v.*) persuaded the Athenians to build their new fleet in 483; but of the course of the war nothing is known. At least Aegina suffered no serious defeat for it was to the decade 490–480 that the ancient chronographers dated its thalassocracy, or rule of the sea.

By the time of the second Persian invasion (480 B.C.) Aegina had realized that collaboration with Persia was no longer practicable; in the crisis the quarrel with Athens was patched up and together they shared the responsibility for the naval defense of Greece. Eighteen Aeginetan ships served at Artemisium and perhaps 40 at Salamis—small numbers compared with the massive Athenian squadrons, but the skill and bravery of their crews earned the first prize for valour after Salamis. This was Aegina's finest period; the wealth of its ruling aristocracy bought luxury and culture (from abroad, for, apart from one or two sculptors in the late 6th and early 5th century, there were few native artists of distinction); their political security won the admiration of less happy aristocrats elsewhere. On both counts Pindar (*q.v.*) found Aeginetan society congenial and some of his finest odes were composed for the well-born athletes of the island. This same aristocratic sympathy brought 20 years of peace with Athens after Salamis. While Themistocles remained popular Athens had other

preoccupations; from about 474 until 462 the pro-Spartan Cimon (*q.v.*) could see no reason to resume the quarrel with his fellow aristocrats in Aegina, themselves Sparta's allies. The end came, however, in 457, three years after the outbreak of the first Peloponnesian War, when the city was besieged and captured by an Athenian fleet. By the terms of the peace treaty (446 B.C.) Aegina was abandoned by the Spartans to be "autonomous" but tributary to Athens. The former was an empty word, the latter meant the vast annual contribution of 30 talents (sufficient evidence of continued wealth). When war between Athens and Sparta was imminent again in 432 B.C., the Spartans chose to make much of Aeginetan complaints about this "autonomy"; the drastic Athenian reply was to expel the whole population and settle their own citizens in its place (winter 431). The exiles were given land by the Spartans in Thyreatis but even there the Athenians pursued them; most were killed in a naval raid in 424 and only a remnant could be restored to their home by the victorious Spartans in 404. Thereafter the impoverished island served only the strategic ends of others; it was used, for example, by the Spartans against Athens in 390 and 378, by Demetrius Poliorcetes against the Piraeus in 307 and by the kings of Pergamum as a base in European Greece from 210 until it passed into the hands of Rome in 133 B.C.

The pax romana brought no great benefits, the collapse of the Roman empire even greater trials. A renewed prosperity under Venetian control (from 1451) was broken by the terrible raid of the pirate Khair ed-Din, another Barbarossa, in 1537. From then, except for a brief Venetian interlude, it remained in Turkish hands until 1826, by which time it was again a modestly successful commercial centre and was chosen by Capodistria to be the temporary capital of independent Greece (1826–28). Since then the increasing concentration of business in Athens had led to a gradual decay until today it is little more than a holiday resort, an Athenian colony again.

AEGIRITE or **ACMITE:** see PYROXENE.

AEGIS (Gr. *aigis*, "goatskin"), a garment, obviously very ancient, worn especially by Zeus and therefore imbued with something of his supernatural power. On occasions he allows his favoured daughter Athena to have it, hence in time it becomes her ordinary dress, as in Aeschylus' *Eumenides*, where she uses it as a kind of sail. Less commonly, some other god has the use of it, as Apollo in Iliad xv, where he employs it to rouse panic in the Achaean host. This terror-producing property recurs in Odyssey xxii, when Athena shakes it against the suitors, and is part of the divine power resident in the garment. As early as Homer, it is something more than the ordinary goatskin cloak of a countryman in appearance, for it is decorated with golden tassels. A stout hide of this sort could turn a blow, like a buffcoat, and thus it often appears as a piece of armour. This no doubt is why Athena casts it about the unarmed Achilles' shoulders (Iliad xviii) and why it protects Hector's corpse (Iliad xxiv). Lastly, as improvised armour of this sort had long gone out of use and

DETAIL OF ATHENA PARTHENOS 1ST CENTURY A D., WEARING THE AEGIS

been forgotten, it is occasionally thought of as a metal corselet; so Horace (in the *Odes* iii, 4) describes it as "ringing" (*sonantem*) under the blows of the attacking giants. (H. J. R.)

AEGISTHUS, in Greek legend, the surviving son of Thyestes, who was driven out with his father after the Thyestean banquet (Aeschylus, *Agamemnon*). He plotted with Clytemnestra to kill Agamemnon. A story first alluded to by Plato (*Laws*), and told with fantastic details departing from all received versions of the legend by Apollodorus and Hyginus, makes him the son of Thyestes by his own daughter Pelopia, exposed in infancy and suckled by a goat (*aix*), hence his name, derived from *aigos*, its Greek genitive form.

See AGAMEMNON; ATREUS.

(H. J. R.)

AEHRENTHAL, ALOYS, GRAF **LEXA** VON (1854–1912), Austro-Hungarian statesman who as foreign minister pursued a policy of short-term success that increased the international feeling of insecurity in the years preceding World War I. The son of an Hungarian landowner, he was born at Gross Skal in Bohemia, on Sept. 27, 1854. He began his career in 1877 as an attaché in Paris, but in 1878 was transferred to Russia, where he was attaché at St. Petersburg until 1883. Sent back to Russia in 1888, he remained there till he was appointed ambassador to Rumania in 1895. In 1899, however, he became ambassador at St. Petersburg.

Aehrenthal's experience of Russian affairs was expected to be of great value when he was appointed foreign minister of Austria-Hungary on Oct. 22, 1906. From the first his policy was more active than his predecessor, Agenor Goluchowski's. His first attempt to extend Austrian influence in the Balkans, by linking the Bosnian railway system with Salonika, miscarried. Then, in Oct. 1908, his diplomatically ill-prepared annexation of Bosnia and Hercegovina (*q.v.*), which had been under Austrian occupation since 1878, provoked an international crisis. Complete understanding had not been reached between Austria and Turkey, and Russia's consent, supposedly obtained in September at a meeting between Aehrenthal and the Russian foreign minister, Count A. P. Izvolski (*q.v.*), at Graf L. Berchtold's house at Buchlau (Buchlovce) in Moravia, was denied by Izvolski when the annexation had been announced. Izvolski's statement contributed greatly to European feeling against Austria. Turkey's consent was withheld until Feb. 1909, Russia's till March (when it was obtained through German mediation). Aehrenthal's policies also damaged the Austrian government's relations with its allies. Italy cooled noticeably toward Austria after the Bosnian crisis and was further alienated by Aehrenthal's conduct on the outbreak of the Italo-Turkish War in 1911, when Austria, despite German advice, maintained a reserved attitude toward Italian claims. The archduke Francis Ferdinand's circle, in particular the chief of staff F. Conrad von Hötzendorf, heightened the tension by demanding a preventive war against Italy, but Aehrenthal then had enough sense of responsibility to secure Conrad's dismissal. Finally, Aehrenthal's critical attitude toward Germany during the Moroccan crisis of 1911 impaired Austro-German relations without achieving any real *rapprochement* between Austria and France.

Recognizing the mistakes of German foreign policy, Aehrenthal tried to dissociate himself from them but could never in fact do so because his own policies depended on German support. He weakened the German and Austro-Hungarian position in Europe, as his rebuffs to Italy prepared the dissolution of the Triple alliance. His apparent foreign successes, however, set the Austro-Hungarian monarchy on a dangerous road. Aehrenthal died in Vienna on Feb. 17, 1912.

Carlgren, *Izvolsky und Aehrenthal vor der bosnischen Annexionskrise* (1955); and general histories of Austro-Hungarian foreign policy from 1908. (K. O. V. A.)

AELFRIC, called GRAMMATICUS. "the Grammarian" (fl. c. 955–c. 1010), English abbot and author, the greatest prose-writer of Anglo-Saxon times, was educated in the Benedictine monastery, the Old Minster at Winchester, under Aethelwold, one of the chief leaders of the 10th-century monastic reform, who was bishop of Winchester from 963 to 984. When the abbey of Cernel (Cerne

Abbas, Dorset) was founded about 987. Aelfric was sent there by Aethelwold's successor, Bishop Aelfheah, at the request of the founder, Aethelmaer, to teach the monks. He was by that time in priest's orders. Aethelmaer and his father, the ealdorman Aethelweard, were enlightened patrons of learning and Aelfric's work owed much to their encouragement. Aethelmaer founded the abbey of Eynsham in 1005, and placed Aelfric as abbot over it. There he remained until his death. The date of this is uncertain, and the assertion sometimes made that he witnessed a document of 1020 rests on shaky evidence. His last datable work is the homily *In natale unius confessoris*, 1006–12.

His major works belong to his Cerne period. In 990–991 he issued the first volume of his *Catholic Homilies*, and the second volume followed a year later. Each volume contained 40 homilies for the chief festivals and saints' days celebrated by the English people, except that the copy of volume one for the ealdorman Aethelweard was to contain an extra four homilies. Only one manuscript contains the prefaces and has the two series arranged in the way Aelfric issued them, for the work proved popular, and the homilies were copied in many different arrangements. Aelfric's aims, to provide the clergy with orthodox sermons, is set out in his English preface to volume one, where he regrets that, except for Alfred's translations, Englishmen had no access to sound doctrine in their own language. His homilies are largely based on Latin writers, especially St. Augustine, St. Jerome, St. Gregory and Bede.

A translation of Bede's *De temporibus* was probably his next work, to be followed by his Latin *Grammar*, *Glossary* and *Colloquy* and then by the *Saints' Lives*, planned to include lives of the saints honoured by the monks, rather than by the people in general. He had doubts, however, regarding the wisdom of placing such translations in the hands of the unlearned, and resolved to translate no more, but pressure from others, especially from Aethelweard and Aethelmaer, caused him to continue. Thus, under protest, he translated at Aethelweard's wish parts of the Old Testament. His chief works written at Eynsham are a Latin *Life of St. Aethelwold*, an abridgement of the *Regularis Concordia* (the general rule of monastic observance in England, drawn up by the synod of Winchester) for the use of his monks, a *Treatise on the Old and New Testament* addressed to an Oxfordshire thegn, Siward of Asthall, a treatise on chastity and one on the Trinity and the Atonement for a Warwickshire thegn, Wulfgeat of Ilmington. Some minor works survive from both the Cerne and the Eynsham periods, as well as some of uncertain date, including a translation of the *Hexameron* of St. Basil.

Aelfric's works reveal great learning in both the Fathers and later theological and canonical writings, and he was largely instrumental in spreading the teaching of the monastic revival of the 10th century. He was recognized as an authority in his own day, and was commissioned to write pastoral letters for Wulfsige, bishop of Sherborne (992–1001), and Wulfstan, archbishop of York (1002–23). Most of his works continued to be copied and studied throughout the middle ages, and he was the first Anglo-Saxon writer whose work was printed. Reformation ecclesiastics interpreted his teaching on the Eucharist as proof that the Anglo-Saxon church did not believe in transubstantiation, and so a *Testimonie of Antiquitie*, a work of religious polemic issued in 1567 under the auspices of Archbishop Matthew Parker, includes Aelfric's Easter homily from the second series of *Catholic Homilies*.

Though much of Aelfric's work is translated and compiled from Latin sources, it includes additions of his own which shed light on contemporary conditions and ways of thought. It is written in a style of singular clarity, variety and grace.

Current editions of his major works are: *Homilies of the Anglo-Saxon Church*, part i. *The Sermones Catholici*, ed. by B. Thorpe (1844–46); *Aelfric's Metrical Lives of Saints*, ed. by W. W. Skeat for the Early English Text Society (1881–1900) with a good study of the author; *The Old English Heptateuch, Aelfric's Treatise on the Old and New Testament and his Preface to Genesis*, ed. by S. J. Crawford for the Early English Text Society (1921); *Aelfric's Grammatik und Glossar*, ed. by J. Zupitza (1880); *Aelfric's Colloquy*, rev. ed. by G. N. Garmonsway (1947) and Eng. trans. by

A. S. Cook and C. B. Tinker, *Select Translations from Old English Prose* (1908) and by S. H. Gem, *An Anglo-Saxon Abbot* (1912); *De temporibus anni*, ed. by H. Henel for the Early English Text Society (1942); Vita S. *Aethelwoldi*, ed. by J. Stevenson, *Chronicon Monasterii de Abingdon*, "Rolls Series," ii, 253–266 (1858), Eng. trans. by D. Whitelock, *English Historical Documents* c. 500–1042, pp. 831–839 (1955); *Aelfric's Hirtenbriefe in altenglischer und lateinischer Fassung*, ed. by B. Fehr, *Bibliothek der angelsächsischen Prosa*, ix (1914).

BIBLIOGRAPHY.—Older incorrect identifications of the author with prelates of the same name were disproved by E. Dietrich, "Abt Aelfric," *Zeitschrift für historische Theologie*, xxv, xxvi (1855–56). Sisam, *Studies in the History of Old English Literature* (1953). For work on sources, and other detailed study, see *The Cambridge Bibliography of English Literature*, vol. i, pp. 89–92 (1940). (D. Wκ.)

AELIAN (AELIANUS TACTICUS), Greek military writer of the 2nd century A.D., resident at Rome. He is sometimes confused with his namesake Claudius Aelianus. Aelian's military treatise, *Taktike Theoria*, is dedicated to Hadrian, though this is probably a mistake for Trajan, and the date A.D. 106 has been assigned to it. It is a handbook of Greek (*i.e.*, Macedonian) drill and tactics as practised by the Hellenistic successors of Alexander the Great. The author claims to have consulted all the best authorities, the chief of which was a lost treatise on the subject of Polybius. Perhaps the chief value of Aelian's work lies in his critical account of preceding works on the art of war and in the fullness of his technical details in matters of drill. Critics of the 18th century thought Aelian greatly inferior to Arrian, but on the Byzantines and on the Arabs, who translated the text for their own use, Aelian exercised a great influence. The emperor Leo VI incorporated much of Aelian's text in his own work on the military art. The Arabic version of Aelian was made about 1350. The copious details in the treatise made it valuable to the army organizers of the 16th century, when translations of it formed the groundwork of many books on drill and tactics. The theory that Aelian wrote most of Arrian's *Tactica* and that the *Taktike Theoria* is a later revision of this original is not generally accepted. The *Poliortetica* of Aeneas Tacticus is wrongly ascribed to Aelian in its manuscript superscription.

A few editions by German editors were published after the *editio princeps* (Italian) in 1552, and an English translation was printed by Viscount Dillon in London in 1814. For a scholarly account with a bibliography see K. K. Müller, "Aelianus," in A. von Pauly and G. Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*.

AELIAN (CLAUDICUS AELIANUS) (c. 170–235), Roman author and teacher of rhetoric, is best known for his stories in *De natura animalium* and *Varia historia*. He was born at Praeneste and flourished under Septimius Severus. His extant writings are in Greek, which he spoke so well that he was called "honey-tongued" (*meli-glossos*) and "honey-voiced" (*meli-phthongos*). The chief of them, both valuable for their many excerpts from earlier writers, are the *De natura animalium*, curious stories of animal life, frequently with moral lessons; and *Varia historia*, mainly anecdotes of men and customs.

His style is simple, and he was, like Lucian, an Atticist; in his views he was a Stoic. Twenty Farmers' Letters, after the manner of Alciphron but inferior, are attributed to Aelian; if this attribution is correct, they were probably composed in his youth.

BIBLIOGRAPHY.—Complete works ed. by R. Hercher (1864–66); for the *Farmers' Letters* with Eng. trans., see A. R. Benner and F. H. Fobes (eds.), *Letters of Alciphron, Aelian and Philostratus*, in the "Loeb Series" (1950).

AELLA (d. 867), king of Northumbria (*q.v.*), succeeded to the throne in 862 or 863 on the deposition of Osbert, although he was not of royal birth. In 867 he and the deposed Osbert joined forces against the invading Danes, whom they attacked in York on March 21 or 23. They were both killed in this attack. Later Scandinavian legend regarded Aella as the king responsible for the death of Ragnar Lodbrok by having him thrown into a snake-infested pit.

omnia, ed. by T. Arnold, vol. i and ii (1882–85); *Rogeri de Wendover Chronica*, ed. by H. O. Coxe, vol. i (1841). (D. Wκ.)

AELLI (d. 588 or 590), first king of Deira (*q.v.*), succeeded in 560. Tradition says that on his death, Aethelric of Bernicia seized his kingdom. Deira was certainly ruled by Aethelric's son Aethelfrith, king of Bernicia from 593 to 616, in the latter part of this period. Aelli was the father of Edwin, later king of the Northumbrians, and of Acha, wife of Aethelfrith. His name gave rise to Pope Gregory the Great's pun on the word "Alleluia," when he saw youths from Deira in Rome.

AELLI (late 5th century A.D.), king of the South Saxons, founder of the kingdom of West Sussex, is said to have landed near Selsey Bill in 477, with his three sons. In 491 he and his son Cissa captured the Roman city of Anderida (Pevensey). His subsequent history is unknown, but Bede reckons him as the first king to be recognized as overlord of all the English peoples south of the Humber, which shows that he must have led the invaders against the Britons in the south. The *Anglo-Saxon Chronicle*, using Bede, puts him as the first *bretwalda* (ruler of Britain).

AELRED (AELRED, ETHELRED), **SAINTE**, OF RIEVAULX (c. 1110–1167), Cistercian abbot, spiritual writer and historian, who exerted a powerful influence on the ecclesiastical affairs of northern England, was born at Hexham. Brought up at the Scottish court with the sons of King David I, he was the royal steward when he entered the monastery of Rievaulx in Yorkshire, probably in 1134. He was abbot of Revesby in Lincolnshire from 1143 to 1147 and then abbot of Rievaulx until his death there on Jan. 12, 1167.

Aelred's works include: *Speculum caritatis*, on the monastic life, written when he was novice master at Rievaulx; *Relatio de standard*—an account of the battle of the Standard against David I in 1138; *De spirituali amicitia*, a Christian counterpart of Cicero's *De amicitia*; a treatise on the questioning of the 12-year old Jesus in the Temple; Vita S. *Edwardi*, written in honour of the translation of Edward the Confessor's body in 1163; *De anima*, Aelred's last work, on the nature of the soul; and various sermons.

BIBLIOGRAPHY.—Most works in J. P. Migne, *Patrologia Latina*, vol. 195, col. 197–796 (1855). Critical editions: *Relatio de standardo* by R. Howlett in the "Rolls Series" (*Chronicles of the Reigns of Stephen, etc.*, 3: 181–199; 1886); *Sermones inediti* and *De anima* by C. H. Talbot (1952); *De spirituali amicitia* with French trans. by J. Dubois (1948), Eng. trans. by C. H. Talbot (1942); *De Jesu puero duodenni*, by A. Hoste, with French trans. by J. Dubois (1958).

Grosjean, "La prétendue canonisation d'Aelred de Rievaulx par Célestin III," in *Analecta Bollandiana*, vol. 78 (1960). (PL. GN.)

AEMILIAN (MARCUS AEMILIUS AEMILIANUS) (d. A.D. 253), Roman emperor in 253. A native of Mauretania, a senator and consul, he commanded the army of Moesia under the emperor Gallus (251–253). In the late summer of 253 he rebelled, invaded Italy, killed Gallus near Interamna (Narni) and was recognized by the senate and both armies. About 12 weeks later he was attacked by Valerian and killed by his own troops, near Spoleto. His wife was named Cornelia Supera. (JN. R. M.)

AENEAS, mythical hero of Troy and Rome, son of the goddess Aphrodite and Anchises. Aeneas was a member of the royal line at Troy and cousin of Hector. He played a prominent part in the war to defend his city against the Greeks, being second only to Hector in ability. Homer implies that Aeneas did not like his subordinate position, and from that suggestion arose a later tradition that Aeneas helped to betray Troy to the Greeks. However, the commoner version made Aeneas the leader of the Trojan survivors. In any case, he came through the war, available to compilers of Roman myth.

The association of Homeric heroes with Italy and Sicily goes back to the 8th century B.C., and the Greek colonies founded there in that and the next century frequently claimed descent from leaders in the Trojan War. Legend connected Aeneas, too, with certain places and families, especially in Latium. As Rome expanded over Italy and the Mediterranean, its patriotic writers began to construct a mythical tradition that would at once dignify their land with antiquity and satisfy a latent dislike of Greek superiority. The fact that Aeneas, as a Trojan, represented an enemy of the Greeks and that tradition left him free after the war made him peculiarly fit for the part assigned him; that is, founding Roman greatness.

It was Virgil (*q.v.*) who gave the various strands of legend related to Aeneas the form they have possessed ever since. The family of Julius Caesar, and consequently of Virgil's patron Augustus, claimed descent from Aeneas, whose son Ascanius was also called Iulus. Incorporating these different traditions, Virgil created his masterpiece, the Aeneid, the Latin epic whose hero symbolized not only the course and aim of Roman history but also the career and policy of Augustus himself. In the journeying of Aeneas from Troy westward to Sicily, Carthage and finally to the mouth of the Tiber in Italy, Virgil portrayed the qualities of persistence, self-denial and obedience to the gods that, to the poet, built Rome.

When Troy fell to the Greeks, Virgil recounts, Aeneas, who had fought bravely to the last, was commanded by Hector in a vision to flee and found a great city overseas. He gathered his family and followers and took the household gods (small images) of Troy, but in the confusion of leaving the burning city his wife disappeared. Her ghost informed him that he was to go to a western land where the Tiber river flowed. He then started on his long voyage, touching at Thrace, Crete and Sicily and meeting with many adventures which culminated in shipwreck on the coast of Africa near Carthage. There he was received by Dido, the widowed queen, to whom he told his story. They fell in love and he lingered there, forgetful of his destiny, until sharply reminded by Mercury, at Jupiter's command, that Rome, not Carthage, was his goal. Guilty and wretched, he immediately abandoned Dido, who committed suicide, and sailed on in obedience to his fate.

When, after being shown the future greatness of Rome by the Cumean sybil, he finally arrived at the mouth of the Tiber, he was well received by Latinus, the king of the region, but other Italians, notably Latinus' wife and Turnus, leader of the Rutuli, resented the Trojan arrival and especially the plan for a marriage alliance between Aeneas and Lavinia, Latinus' daughter. When war broke out Aeneas found some support from Evander (significantly ruler on the site of later Rome), and succeeded in checking Turnus' attacks on the Trojan camp. After Turnus had broken truce negotiations, Aeneas engaged him in combat and killed him, thus ending the war. Aeneas then married Lavinia and founded Lavinium, the parent city of Rome.

Aeneas' character as portrayed by Virgil is not only that of a heroic warrior. In addition he guides his life by obedience to divine command, to which he sacrifices his own natural inclinations. It is in this sense that the epithet *pius*, so frequently applied to him in the Aeneid, is to be understood.

Aeneas' death is described by Dionysius of Halicarnassus. After he had fallen in battle against the Rutuli his body could not be found, and he was thereafter worshiped as a local god, *Juppiter indiges* as Livy reports.

See L. Matten, "Aineas," *Archiv für Religionswissenschaft*, 29: 33-59 (1931); J. Perret, *Les Origines de la légende troyenne de Rome* (281-31) (1942). (Wm. S. A.)

AENEAS SILVIUS, the popular name of the voluminous author Enea Silvio de' Piccolomini (1405-64), who became pope as Pius II in 1458. See **PIUS**.

AENEAS TACTICUS (4th century B.C.), Greek writer. According to Aelian (Aelianus Tacticus) and Polybius, he wrote a number of treatises on the art of war; the only one extant deals with the defense of fortified cities and is chiefly valuable as containing a large number of historical illustrations.

Aeneas was considered by Casaubon to have been a contemporary of Xenophon and identical with the Arcadian general, Aeneas of Stymphalus, whom Xenophon mentions as fighting at the battle of Mantinea (362 B.C.).

Two English translations exist, accompanied by introductory and bibliographical material. They are Aeneas Tacticus, by the Illinois Greek Club, in the "Loeb Classical Library" (1923), and L. W. Hunter, Aeneas on *Siegecraft*, rev. by S. A. Handford (1927).

AENEID, THE, Latin epic poem by Virgil (*q.v.*), relating the adventures of the Trojan hero Aeneas (*q.v.*) who after the fall of Troy voyaged to Latium in Italy as the destined founder of Lavinium, the parent city of Rome.

The Aeneid was the model for the Roman *d'Énéas* (c. 1160), a French poem of uncertain Norman authorship, which in its turn provided the basis for the Flemish *Eneide* by Heinrich von Veldeke (c. 1190), now extant only in a Thuringian version. Another medieval French version was translated into English by Caxton (1490).

See also Index references under "Aeneid, The" in the Index volume.

BIBLIOGRAPHY.—For the Latin poem, see bibliography to **Virgil**, Critical edition of the French romance by J. S. de Grave (1891), of Veldeke's version by O. Behagel (1882) and of Caxton's by W. T. Culley and F. J. Furnival (1890).

AENESIDEMUS (fl. c. 80-60 B.C.), Greek philosopher and leader of what is sometimes known as the Third Skeptical school, was born at Cnossus in Crete and taught at Alexandria. He revived to a great extent the doctrine of Pyrrho and Timon. His chief work was the *Pyrrhonian Discourses*, addressed to Lucius Tubero. Although his work has been lost, its argument can be reconstructed from an analysis by Photius (9th century) and evidence furnished by Diogenes Laertius and Sextus Empiricus.

First, as regards the meaning and criterion of truth, Aenesidemus distinguished himself from other *soi-disant* skeptics of his day, regarding them as tainted with dogmatism. A skeptic is inconsistent if he affirms that he knows that there is no criterion of truth—he believes this, indeed, but his skepticism is a manner of behaviour rather than a sect existing in rivalry to others. The dogmatic philosophers (*i.e.*, principally Epicurus and the Stoics) had found the criterion either in sense perception or in intellectual judgment or in some alliance between these. Aenesidemus showed that no variety of these views is tenable and further drew up the famous "ten tropes," a general statement of reasons why perception must not be trusted, as follows.

Things present a diverse appearance (1) to different species of animals, (2) to different men, (3) to the different senses of one and the same man, (4) to the same sense according to the man's circumstances and physical condition and (5) to the same sense according to distance and perspective. Moreover, perceptions vary (6) on account of mixture with one another in various degrees and (7) on account of their extent. In general, (8) perceptions depend upon the relation of the perceiver to his object, or of things or notions to one another, (9) their strength varies with habituation and (10) the beliefs, laws and customs of men are indefinitely variable.

Next, Aenesidemus proceeded to the criticism of signs and causality. Under the heading "signs" it was not the causal relation itself that was criticized, but the rules laid down by some philosophers for an inference from an observed fact to its concealed cause. But by a parallel line of reasoning he rejected as unintelligible the cause-effect relationship. To name a thing a cause implies that it has some intrinsic productive power, but of this power no intelligible account has been or can be given. In the last part of his *Discourses* he carried his criticism into the region of moral ideas and argued that neither pleasure nor happiness nor knowledge is the *summum bonum*; there is no such highest good. See also **SKEPTICISM**.

AEOLIAN HARP, a stringed musical instrument, played by

the wind, and so-called from Aeolus, god of the winds. It consists of a wooden sound box, usually about three feet long, five inches broad and three inches deep, with raised ends into which are fixed tuning- and hitch-pins, and between which are loosely stretched 10 or 12 catgut strings, usually tuned in unison; these vary in thickness and therefore in elasticity and the play of the wind causes them to vibrate in aliquot parts; *i.e.* (the fundamental note not being heard), the half or octave, the third or interval of the 12th, the second octave and the third above it: in fact, the upper partials of the strings in regular succession. The Aeolian harp is generally placed by an open window or hung out of doors to catch the wind.

The principle of the natural vibration of strings by the pressure of the wind has long been recognized. According to legend King David used to hang his *kinnor* (a kind of lyre) above his bed at night to catch the wind, and Dunstan of Canterbury was charged with sorcery for producing sounds from a harp by allowing the wind to blow through its strings. Athanasius Kircher constructed such an instrument and described it in his *Musurgia universalis* (1650). It became popular in Germany and England during the Romantic movement; and models were made by the poet Robert Blomfield, author of a pamphlet about them (*Nature's Music*, 1808). There have been two attempts to construct keyboard instruments on this principle, using bellows-fed wind: J. J. Schnell's *Anémocorde* (Paris, 1789) and Isouard's *Piano éolien* (Paris, 1837).

AEOLIAN ISLANDS, known in ancient times as the *Aeoliae Insulae*, a group of volcanic islands north of eastern Sicily; also called the Lipari Islands (*q.v.*).

AEOLIS (*AEOLIA*), the name applied collectively to a group of ancient cities on the west coast of Asia Minor founded toward the end of the 2nd millennium B.C. by Greeks from Thessaly, Phocis, Locris and Boeotia, speaking a dialect known as Aeolic. The earliest settlements on the islands of Lesbos and Tenedos and on the mainland opposite, between the Troad and Ionia, including Pitane, Gryneum, Myrina, Cyme, Temnos, Notium and Smyrna (which in the 7th century was taken by the Ionians), were the result of a wave of migration c. 1130–c. 1000 B.C. A wave of secondary colonization, perhaps in the 7th century B.C., gave rise to further Aeolian settlements in the Troad and in the region of the Hellespont. At the end of the 6th century Aeolis was merged in one of the 20 satrapies organized by Darius I. Aeolic was the dialect of the poets Alcaeus and Sappho.

AEOLUS, the name of two figures in Greek mythology.

1. **AEOLUS**, a mythical king of Magnesia in Thessaly, was the son of Hellen and father of Sisyphus. His daughter Canace and son Macareus committed incest and suicide, providing the subject of Euripides' lost *Aeolus*. Aeolus gave his name to Aeolis, a territory on the western coast of Asia Minor.

2. In Homer, **AEOLUS** was the son of Hippotes. He was controller of the winds and ruler of the floating island of Aeolia. In the *Odyssey* he entertained Odysseus, gave him a favourable wind and a bag in which the unfavourable winds were confined. Odysseus' companions opened the bag; the winds escaped and drove them back to the island, whence Aeolus dismissed them with bitter reproaches. Human in Homer, he later became a minor god. This was his status in Latin poetry especially. According to Virgil, in the *Aeneid*, Aeolus dwelt on one of the Aeolian islands to the north of Sicily, Lipara or Strongyle (Stromboli), where he kept the winds imprisoned in a vast cavern.

AEOLIAN HARP

AEPINUS (originally *НОСН*), **FRANZ (MARIA) UL-RICH THEODOR** (1724–1802), German physicist, best known for his researches, theoretical and experimental, in electricity and magnetism, was born in Rostock, on Dec. 13, 1724, and died in Tartu (Dorpat), Estonia, on Aug. 10, 1802. He first studied medicine and then physics and mathematics, his original work in these new fields leading to his election to the Berlin Academy of Sciences and, in 1757 to professor of physics in St. Petersburg, where he remained until he retired in 1798. His principal work, *Tentamen theoriae electricitatis et magnetismi* (1759), was the first systematic attempt to apply mathematical reasoning to these subjects. He designed a type of parallel-plate electrical condenser. He improved the microscope and extended Franklin's one-fluid theory of electricity, which postulated an all-pervading electric fluid of particles which were mutually repellent but which attracted particles of ordinary matter. He studied the relation between electrical conductors and nonconductors and carefully investigated the phenomena of pyroelectricity. His discussion of the effects of parallax in the transit of a planet over the sun's disk excited great interest, having appeared in 1764 between the dates of the two 18th-century transits of Venus.

(D. McK.)

AEPYORNIS, the genus name for "elephant birds," large flightless forms extinct for several centuries. They comprised the family Aepyornithidae and the order Aepyornithiformes. Aepyornis species resembled the moas (*q.v.*) in many particulars, and inhabited the southern half of Madagascar. They are said to have been the origin of the legend of the roc (*q.v.*). Many species were the size of ostriches, but one, *A. titan*, apparently reached a height of 12 ft. Its egg was larger than that of any other bird, measuring more than 13 by 9½ in. and having a capacity of more than two gallons.

AEQUI, an ancient people of Italy originally inhabiting the region watered by the tributaries of the Avens (the modern Velino river in the province of Rieti). Hostile to Rome for centuries (according to Livy), they became a menace in the 5th century B.C., advancing to the Alban hills. The Romans attacked and ejected them from Tusculum c. 484 B.C. and drove them from the Alban hills and the Algidus gap in 431. The Aequi were not finally subdued, however, until the end of the second Samnite War (304 B.C.), when they received *civitas sine suffragio* (a limited form of Roman franchise). Rome established the Latin colony of Carsoli (302 B.C.) in the territory of the Aequi, through which, at about the same date, the Via Valeria was extended. Thenceforward the Aequi rapidly became romanized; before Latin, they had probably spoken Oscan, one of the chief non-Latin Italic dialects.

All that is known of their subsequent political condition is that after the Social War (90–89 B.C.) the people of Cliternia and Nersae appear united in a *municipium* Aequiculorum or *Aequiculanoorum*. This name, which appears as *Cicoli* and *Eiculi* in medieval documents, survives in modern times as *Cicolano*, denoting the district north of the Lago Fucino.

See R. S. Conway, *Italic Dialects*, vol. i (1897); J. Whatmough, *The Foundations of Roman Italy* (1937).

AERARII, in ancient Rome, were citizens subjected to special tax by the censors as a mark of disgrace (from Latin *aes*, money). Theodor Mommsen (*Römisches Staatsrecht*, vol. ii, 3rd ed., pp. 399 ff., [1887]) thought (1) that they were the citizens without the vote and citizens subjected to civil degradation for following professions such as acting, for dishonourable acts or for certain crimes and excluded from the tribes and the centuries, from voting, from holding magistracies and from serving in the army; (2) that the original *aerarii* had been landless citizens excluded from registration in the tribes who were distributed among the tribes by the censor Appius Claudius in 312 B.C. but limited to the four city tribes by the censors of 304; and (3) that the term was later also applied to citizens demoted from a higher (rustic) to a lower (urban) tribe though not deprived of the right to vote or to serve in the army. It has been shown, however, (1) that *aerarii* did hold magistracies and serve in the army; (2) that landless citizens must have been registered in the

tribes from the beginning of the Servian constitution, traditionally in the 6th century B.C.; (3) that the term *aerarii* is not used in connection with landholding, on which the evidence for the censorship of 312 has nothing to say; and (4) that to be moved to a lower tribe and to be made an *aerarius* were distinct penalties, though often imposed together. The term therefore must refer solely to payment of *acs*, and the penalty involved may have been payment of tax at a higher rate.

BIBLIOGRAPHY.—G. W. Botsford, *Roman Assemblies* (1909); H. M. Last, in *Journal of Roman Studies*, 35:30-48 (1945); P. Fraccaro, *Opuscula*, vol. ii, pp. 149-170 (1957). (T. R. S. B.)

AERARIUM, the treasury of the Roman people, was housed in the temple of Saturn at the west end of the Forum and in the adjacent *tabularium* (record office), built in 78 B.C. In it were stored coin and bullion, certain public records (including laws) and the public accounts. Under the republic it was managed by the two urban quaestors with a staff of permanent salaried clerks and controlled by the senate, without whose authorization no payment could be made except to the consuls. In theory all revenues were paid into the *aerarium* by the *publicani* who farmed the taxes or by the magistrates who collected them, and all public payments were made from it. In practice provincial governors were normally authorized to draw their allowances from the local offices of the *publicani* or from the provincial depots (*fisci*) into which local revenues were paid, and money was moved from the provinces to the *aerarium* only if a province produced a surplus, while conversely money was paid out of the *aerarium* only if the provincial revenue did not cover expenses. All magistrates and *publicani* had, however, to balance their accounts with the *aerarium*, which was thus a central clearinghouse.

Augustus in 27 B.C. transferred the control of the *aerarium* to two prefects of praetorian rank, elected by the senate, and in 23 B.C. to two of the praetors. Claudius restored the *aerarium* to the quaestors, who were nominated by himself and served three years. Nero went back to praetorian prefects, who were henceforth nominated by the emperor. Under the principate the *aerarium* gradually waned in importance as the emperors, who were responsible for the bulk of the public expenditure, drew the money from provincial *fisci* and, as they never laid down their office! did not account to the *aerarium*. They built up their own treasury and audit, the *fiscus*.

In A.D. 6 Augustus founded a second treasury, the *aerarium militare* (the old treasury was henceforth distinguished as *aerarium Saturni*). Its function was to pay bounties to discharged veterans or purchase land for them, and it was managed by prefects of praetorian rank, at first chosen by lot, later nominated by the emperor. The *aerarium militare* was initially endowed by Augustus out of his own pocket and fed by two new taxes payable by all Roman citizens, the 5% tax on inheritance and the 1% tax on sales.

See A. H. M. Jones, *Studies in Roman Government and Law* (1960). (A. H. M. J.)

AERIAL, an elevated wire or group of wires or rods forming the principal part of a radio antenna of the open or "condenser" type. See ANTENNA (AERIAL).

AERIAL MAPPING: see PHOTOGRAMMETRY.

AERODROME: see AIRPORT.

AERODYNAMICS, a branch of physics concerned with the study of the motion of air or other gases, and of the forces acting upon bodies passing through the air. In particular, it seeks to understand the principles governing the flight of aircraft through the earth's atmosphere and the flight of rockets and missiles. Aerodynamics has made important contributions to the design and development of modern aircraft and has promoted understanding of the special problems of supersonic flight. Aerodynamics has also been concerned in the design of ships, land vehicles such as streamlined trains and automobiles, and in the construction of tall buildings, towers and bridges to determine their resistance to high winds.

HISTORICAL DEVELOPMENT

Observation of the flight of birds and of projectiles stirred spec-

ulation among the ancients as to the forces involved and the manner of their interaction. These speculations were in general carried on without benefit of what has become known as the "experimental method." The ancients had no real knowledge of the physical properties of air nor did they attempt to study these properties, in the modern sense.

The ideas of the ancients usually involved the concept that the air provided a sustaining or impelling force. These ideas were based to a considerable degree on the principles of hydrostatics (the study of the pressures of liquids) as they were then known or understood. Thus, in ancient times, the view was held that the impelling force of a projectile was associated with forces exerted on the base by the closure of the flow of air around the body. This view of air as an assisting rather than a resisting medium persisted for centuries, even though in the 6th century men recognized that the energy of motion of a projectile was imparted to it by the catapulting device.

Near the end of the 15th century Leonardo da Vinci recognized that air offered resistance to the movement of a solid object and he attributed this resistance to compressibility effects. His theories of bird flight were also related to the compressibility properties of air. In his view, the rapid flapping of a bird's wings created a region of compressed air beneath the wings and thus provided the desired lift.

Using an experimental approach, Galileo later established the fact of air resistance and arrived at the conclusion that the resistance was proportional to the velocity of the object passing through it. The Dutch physicist Christiaan Huygens (*q.v.*), near the end of the 17th century, may have been the first to appreciate that the resistance of air to the motion of a body was proportional to the square of the velocity. Huygens used an experimental approach; at about the same time, Newton reached the same conclusion by deduction.

The work of Newton in setting forth the laws of mechanics marked the beginning of the classical theories of aerodynamics. Newton considered the pressure acting on an inclined plate as arising from the impingement of particles on the side of the plate facing the air stream. His formulation produced the result that the pressure acting on the plates was proportional to the product of the density of the air, the area of the plate, the square of the velocity and the square of the sine of the angle of inclination. Later, by a somewhat different argument, Leonhard Euler produced the same result with the exception that the effect of inclination was proportional to the sine rather than to the square of the sine, a result more in accord with experimental evidence. The arguments, of course, failed to show the important result, to come much later, of the effects of the flow on the upper surface of the plate where low pressures exist and from which a major portion of the lift of a wing is produced. The concept of air as a continuum with a pressure field extending over great distances from the plate was to come much later.

Daniel Bernoulli, a Swiss physicist, made a most important discovery in the middle of the 18th century. Proceeding, perhaps, from the then well-known principle of hydrostatics that the level of a liquid flowing from one tank to another would in the end achieve the same height in both tanks, Bernoulli arrived at the formulation of his well-known theorem

$$p + \frac{1}{2}\rho V^2 = \text{constant}$$

where p is the pressure in the stream, ρ is the density of the fluid and V the velocity of the fluid. This result evolved from the study of the flow of a fluid from a tank through a nozzle. The constant is the height of the fluid above the nozzle. This formulation expresses the interrelation of the pressure and velocity along any fluid streamline for incompressible flow, the constant being the pressure corresponding to that for zero velocity. The simple formulation is, of course, not correct for high velocities because air is compressible.

A somewhat more complicated form proceeding from the same basic considerations but including the compressibility effect is found for high speeds. The effect of the compressibility correction in the Bernoulli equation becomes about 1% of the value of

the term $\frac{1}{2}\rho V^2$ when the Mach number is equal to 0.2 and increases rapidly with the speed.

Also in the 18th century, Jean Le Rond d'Alembert, apparently dissatisfied with the theories for resistance, tackled the problem. Considering air as an incompressible elastic fluid composed of small particles and, carrying over from the principles of solid body mechanics the view that resistance is related to loss of momentum on impact of moving bodies, he produced the surprising result that the resistance was zero. D'Alembert was himself dissatisfied with the result and, largely because of his own comments, the conclusion is known as "D'Alembert's paradox."

BY COURTESY OF NATIONAL AERONAUTICS AND SPACE ADMINISTRATION
 FIG. 1.— SCHLIERENPHOTOGRAPH OF SUBSONIC FLOW FOR A WING SECTION
 Bright area at the leading edge shows region where the impinging streamline is decelerated. Dark regions aft of the leading edge are areas of rapidly increasing speed as the streamline accelerates. The boundary layer is the thin bright region in contact with the wing. (The Schlieren method, widely used for the observation of flow phenomena, makes flow visible because regions of changing density bend light rays. The optical phenomena are similar to the "heat waves" frequently observed above hot surfaces)

The common physical characteristic of both Bernoulli's and D'Alembert's results follows from the law of the conservation of energy: in the absence of a dissipating agent such as friction the potential and kinetic energies of the flow are freely interchangeable. Actually, the body of the classical hydrodynamics that was so highly developed through the 19th century is based on these same assumptions. For many applications, the friction effect is small so that the pressures acting on bodies and the flow fields surrounding them may be calculated with surprising accuracy.

The relationship of resistance to the viscous properties of a fluid was appreciated to some degree by the beginning of the 19th century. Numerous investigators, including C. A. de Coulomb, J. M. H. Navier, A. J. C. Barré de St. Venant, J. L. M. Poiseuille, George G. Stokes and others made important contributions. In the 1880s Osborne Reynolds, experimenting with flows in pipes, demonstrated laminar flows (of a smooth, shear layer nature) and an abrupt transition region to turbulent flows. Only then did modern understanding of viscous effects begin. Reynolds observed that flow which may have started as laminar became abruptly turbulent when a particular value of the product of the distance along the tube and the velocity divided by the viscosity was attained. From this work the "Reynolds number" evolved. Dimensional analysis shows that the Reynolds number expresses the ratio of the mass forces to the viscous forces in a fluid; hence, flows at equal Reynolds numbers (other factors such as surface roughness and Mach number being the same) are similar.

Beginning with Newton and continuing until the end of the 19th century, the foundations of classical hydrodynamics had been developed. The period of modern aerodynamics then began at about the same time that the Wright brothers made their first powered flights. Frederick W. Lanchester in England at the beginning of the 20th century may have been the first to set forth the idea of the circulation theory of lift of an airfoil of infinite span and the idea of the vortex theory of the lift of a wing of finite span. His ideas did not receive wide circulation at the time. At about the same time or shortly thereafter (1901-10) M. Wilhelm Rutta in Germany and Nikolai E. Zhukovski in Russia came independently to the idea of the circulation hypothesis and produced the mathematical theory.

Ludwig Prandtl at Göttingen, who has been recognized as the "father of modern aerodynamics," arrived independently at the

same hypotheses as Lanchester and developed the mathematical treatment. Many feel that Prandtl's mathematical formulation of the results is one of the most useful contributions ever made in the field of aeronautics. The lifting theory is based largely upon Prandtl's work as is the modern recognition that the total resistance of an aircraft is composed of three parts: skin friction (viscosity), form or pressure drag and the production of lift (induced drag).

Following Prandtl, the theoretical basis of modern aerodynamics was developed and expanded by a host of contributors in the first half of the 20th century. Among the most notable were contributions of Max M. Munk in the subsonic area and Theodore von Karman in the area of subsonic, supersonic and viscous flows. Like Prandtl, Karman's contributions embraced the original and applied fields, and as teacher Karman became the founder-leader of modern aerodynamics in the mid-20th century.

SUBSONIC AERODYNAMICS

General.— The forces and moments (tendencies to produce motion) acting on an aircraft are the sum of the forces and moments of its components. Lift, most of which is provided by the wing, balances the weight of the aircraft. It overcomes the force of gravity that tends to pull the aircraft back to the ground. At the same time, the wing and the body usually exhibit unstable moments tending to cause roll, pitch or yaw. The wings themselves are designed to prevent rolling of the plane about its longitudinal axis. The horizontal stabilizer at the tail of the plane, acting at a considerable distance from the centre of gravity, gives a counteracting moment that prevents pitching (rise or fall of the plane's nose or tail). The vertical stabilizer or fin, also at the tail, helps to keep the plane from yawing, or turning about its vertical axis. The drag of the aircraft (the force that resists its motion through the air) is balanced by the thrust from the engine.

FIG. 3.— VORTEX FLOW AT TIPS OF A WING
 A wire grid to which wool tufts are attached is placed in the wake of a delta wing. Examination shows that the vortex extends its effects a considerable distance from the tips. The induced drag is associated with the energy in the vortex shed at the tips

As noted above, the drag of the aircraft is composed of three factors: skin friction, drag due to lift (induced drag) and pressure drag. Skin-friction drag is due to the viscosity of air. Its effects are exhibited in the boundary layer (after Prandtl), the thin layer of air that is in contact with the surface. The boundary layer begins at the surface of the aircraft where the air in immediate contact with the surface is at zero velocity relative to the surface; the outer edge of the boundary layer is at air-stream velocity. There is, thus, a velocity gradient in this layer and a stress is produced in the layer. The skin-friction drag is the result of the stresses produced in this layer. The boundary layer starts as a laminar layer which terminates abruptly in a transition region after which the boundary layer becomes turbulent and increases in thickness. The boundary layer is illustrated in fig. 1.

The drag of the laminar boundary layer is very much lower than the drag of the turbulent layer, hence it is important to design for laminar layers. The transition from the laminar to the turbulent layer occurs at a critical value of the Reynolds number mentioned above. This critical value of the Reynolds number is lowered by the effects of surface imperfections and regions of increasing pressure. The boundary layer in subsonic flow is the only region in the whole flow where kinetic energy of the flow is lost from the main stream. In some circumstances, the kinetic energy lost from the flow in the boundary layer is so great that the flow separates from the body and produces large pressure or form drag. Examples of such separation are the flows for a cylinder and for a wing at high angles of attack, illustrated in fig. 2. In the design of aircraft, care is taken to produce the maximum extent of laminar boundary layer and no separation. Modern subsonic aircraft have insignificant form or pressure drag caused by separation effects.

The drag due to lift is associated with the shedding of vortices from each wing tip. The flow from the lower surface, which is at higher pressure than the upper surface, rolls up over the tip and a vortex trails from the tip (fig. 3.). The drag due to lift, called induced drag, becomes smaller as the span of the wing is increased in relation to the chord (dimension of the wing in the stream direction). This point is important to aircraft designers. Airplanes that travel long dis-

BY COURTESY OF NATIONAL AERONAUTICS AND SPACE ADMINISTRATION
FIG. 4 — DRAWING OF WING CHARACTERISTICS
 The lift increases along a straight line as the angle of attack is increased until separation of the flow when "stall" occurs. Further increase of the angle of attack results in decrease of lift, rapid increase of drag and reversal of the moment curve slope

tances at moderate cruising speeds minimize the induced drag by using long wing spans.

Aircraft Aerodynamics.— The characteristics of airplanes and airplane components may be represented by a system of non-dimensional coefficients. Lift, drag and moment may be expressed as follows:

$$\begin{aligned} \text{Lift, } L &= C_L \frac{1}{2} \rho V^2 A \\ \text{Drag, } D &= C_D \frac{1}{2} \rho V^2 A \\ \text{Moment, } M &= C_M \frac{1}{2} \rho V^2 A c \end{aligned}$$

A is the area of the wing, ρ is the mass density of the air, c is the chord of the wing and V is the velocity. The term $\frac{1}{2} \rho V^2$ is known as the dynamic pressure, one of the terms of the Bernoulli equation. The usual representation of wing characteristics is illustrated in fig. 4.

The lift increases as the angle of attack (the angle included between the direction of the air flow and the chord line of the wing) is increased up to the "stalling angle," after which the lift falls abruptly. At this angle, the flow fails to follow the contour of the wing; it separates from the upper surface (fig. 2), leaving a turbulent wake which is very unsteady. Many examples of loss of aircraft control have occurred at the stall. Because the lift must balance the weight of the aircraft, one can readily see that at high speed the wing or airplane is at a small angle of attack relative to the flight path. The minimum speed at which flight can be sustained is determined by the value of the maximum lift coefficient.

The drag coefficient curve shows a minimum at small values of the angle of attack increasing rapidly as the stall angle is approached. High-speed flight occurs near this minimum value. For good subsonic aircraft, this drag is essentially that due to skin friction.

The principal aerodynamic property determining the range of an aircraft is the maximum lift-to-drag ratio. It has been shown that this occurs for the attitude of the airplane at which the sum of the profile drag (essentially skin friction) and the induced drag is a minimum. The induced-drag coefficient is

$$C_{Di} = \frac{C_L^2}{\pi R}$$

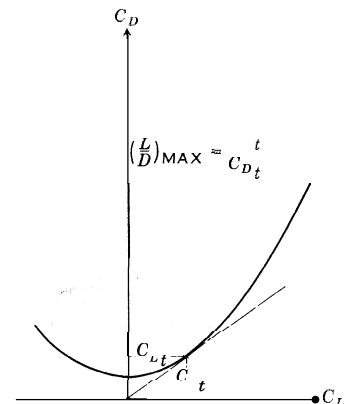

where R , the aspect ratio, is the span squared divided by the area. To minimize this factor, the wings are of large span and small chord.

If the lift coefficient is plotted with the drag coefficient as a parameter, as in fig. 5, the line drawn from the origin tangent to this curve gives the point for which the lift-to-drag ratio is maximum.

The distribution of lift along the chord of the wing is illustrated by the pressure-distribution diagrams, fig. 6.

High-performance aircraft make use of auxiliary devices called flaps to increase the maximum lift so that the landing speed may be kept low. There is a wide range of flap types and the choice depends on the particular application. Frequently, such auxiliary devices are used to improve the climbing properties of an airplane. A simple type is illustrated in fig. 7. The action of such a flap is shown by the lift curves in the figure. At high-speed flight (low angles of attack), the flap is retracted and the low drag of the plain wing is achieved. The flap is extended or deflected for low-speed flight as at landing and the increased lift produced as shown by the upper curve permits the achievement of greatly reduced speeds.

Stability and Controllability.— Stability is that characteristic of a moving body which will cause it to return to its original path or attitude, without the application of control forces, following a disturbance of the original path or attitude. The stability

BY COURTESY OF NATIONAL AERONAUTICS AND SPACE ADMINISTRATION

FIG. 6.— DISTRIBUTION OF LIFT ALONG THE CHORD OF A WING
 The arrows show direction of pressures acting on wing surfaces; arrow lengths indicate magnitude of pressures for (A) high-speed (low angle of attack) condition; (B) low-speed (high angle of attack) condition; (C) "stall" (angle of attack higher than that for the maximum lift coefficient) condition

of aircraft is usually treated in terms of static stability and dynamic stability. Static stability is provided when the summation of the aerodynamic forces and moments is such as to cause a return to the original path or attitude. Dynamic stability treats of the interaction of the aerodynamic and inertial forces.

Aircraft may exhibit static stability, yet be unstable in maneuvers. This occurs when the inertial effects of the mass of the aircraft in the disturbed or maneuvering motions are too great in relation to the aerodynamic restoring forces. Thus, it is not sufficient that the aerodynamic forces and moments have stable rather than unstable characteristics; there must also be a static stability margin. If, on the other hand, this margin is too great, difficulties with control arise. The general stability equations have been well developed and have been used in various simplified forms. Increased speeds which bring about compressibility effects and the flexibility of the structures have required increasingly detailed analysis as well as more accurate knowledge of the aerodynamic, inertial and structural flexibilities of aircraft.

Controllability is that characteristic of an aircraft which permits the operator to fly along desired paths and at desired attitudes for landing, take-off and maneuvers. Increased speeds and weights of aircraft require increasing precision in the flight paths flown and accurate response to a control movement. Small aircraft usually have more or less direct connection of the control column and rudder pedals to the control surfaces of the aircraft. Large aircraft and high-speed aircraft usually require power-actuated surfaces because the control surfaces, even when aerodynamically balanced, require large forces. Mechanisms for actuating control surface sometimes become very complicated and their characteristics have to be taken into account in the stability and control analyses. On the basis of flight research,

FIG. 7.—EFFECT OF FLAP DEFLECTION ON LIFT CHARACTERISTICS
 Deflecting the flap raises the characteristic lift curve and changes the pressure distribution over the whole wing. The increase in the maximum lift coefficient enables an airplane to land at a slower speed

to the vertical fin; and the ailerons, small, hinged outboard rear sections of the wings. Usually, of course, there is interaction of the controls and the motion of the airplane; seldom, if ever, is a maneuver made without simultaneous use of all control surfaces.

lished for safety and ease of control.

Stability of an aircraft is usually fixed by the action of fixed surfaces—wings, horizontal stabilizer, vertical fin. Controllability is provided by control surfaces—elevator, hinged to the horizontal stabilizer; rudder, hinged

SUPERSONIC AERODYNAMICS

Pressure Fields.—The speed of sound (Mach 1.0) is important in aerodynamics because it is the speed at which small pressure disturbances, such as those caused by the shape or lift of a moving body, are transmitted through the surrounding atmosphere. When a body moves at subsonic speed, its pressure field extends far in front of the body. At supersonic speeds, the pressure field is confined to a region extending mostly to the rear and

outward.

The first clear presentation of these phenomena was made by the Austrian physicist Ernst Mach, about 1881. Fig. 8 illustrates the Mach construction. The projectile at point A is assumed to move at twice the speed of sound (Mach 2.0). In a given time, it will have moved the distance AD. In the same time interval, the pressure disturbance at the nose will have traveled one-half of the distance AD, that is, to points on the circle with centre at A and radius a, the speed of sound.

Similarly, at all points along the path AD, the pressure disturbances will travel at the speed of sound and will have reached points on corresponding circles. The line DW is the tangent or envelope of these circles. The total pressure field caused by the projectile passage is, thus, contained within a cone having its vertex at the nose of the projectile with the line DW as its

FIG. 8.— MACH CONSTRUCTION

surface generator. The half angle of this cone is measured by the ratio a/V , which is the trigonometric expression for the sine of the half angle. The angle is called the Mach angle and the cone is called the Mach cone.

When a body moves at supersonic speeds, the pressure field ahead of the body is continuous, with no sharp disturbances or jumps, and shock-free passage of the body occurs. boom, a sound like a clap of thunder which can be heard on the ground but not in the plane that produces it. When such aircraft fly at low altitudes the sonic boom may be of sufficient intensity to cause glass breakage and other damage. When shock waves are present they cause a considerable energy loss which appears as drag in the forces on the body.

Referring to fig. 8, it can be seen that when a body travels at subsonic speeds the pressure disturbances set up along the path precede the body. Because this disturbance is transmitted to every point along the path, the pressure field ahead of the body is continuous, with no sharp disturbances or jumps, and shock-free passage of the body occurs.

Lift and Drag.—The next significant step following Mach's

analysis was development of the theory of the supersonic flow into and around corners. This work, known as the Prandtl-Meyer turn, was first presented in 1908. It demonstrated that the streamlines of the flow turned along a line that began in the corner and had a slope related to the Mach angle of the flow. From this work the calculation of the pressures and forces on the cross section of a wing of large (infinite) span followed directly. This flow is illustrated in fig. 9.

The lift on the airfoil is the net difference between the upper and the lower surface pressures acting on the surfaces. With positive pressures acting on the forward surfaces and negative pressures acting on the rearward surfaces, there is a pressure drag acting on the airfoil section associated with the wave system. When the angle of attack (α) of the airfoil section is zero with respect to the air-stream direction, the pressure diagrams for the upper and lower surfaces become coincident. In this case lift becomes zero, but because of the positive pressure on the forward surfaces and the negative pressure on the rear surfaces, a pressure drag acts on the airfoil. This pressure drag is not experienced at subsonic speeds.

At a given Mach number, the pressure drag due to the shape of the airfoil increases approximately as the square of the thickness; the drag due to lift increases approximately as the square of the angle of attack.

From the method of characteristics and the conical flow theory developed by Adolf Busemann from 1930 to 1935, accurate representation of the flows for curved surfaces and bodies and their shock-wave systems can be made. Numerous investigations have refined and extended the Busemann theory so that general flows are well understood for most examples so long as aerodynamic frictional heating and large boundary-layer effects are not con-

trolling factors.

Interaction of Waves.—The interaction of the shock and expansion waves from bodies in combination, such as wings and fuselages, is of foremost importance in practical applications. By the correct shaping and positioning of adjacent surfaces, shock and expansion waves can be made to interact to reduce drag. This was first illustrated by Busemann's concept of the supersonic biplane about 1935 (see fig. 10).

The Mach waves from the leading edges, when passing into the region between the wings, interact with the expansion waves and theoretically reduce to zero the pressure drag due to the thickness of the airfoil sections, known as shape drag. The outside surfaces, being parallel to the flow, produce no change of direction of the streamlines. Thus no pressure jumps and corresponding drag losses occur. The whole body acts as though it were a plate of zero thickness in the flow.

By increasing the angle of attack, lift and drag due to lift would be produced, but shape drag would still be nullified. Practical difficulties in the application of the biplane occur because the added surface area would increase skin friction as would any internal structure required to support the surfaces. A further restriction occurs in that precise contours could be made for only one value of the Mach number and one angle of attack. Nevertheless, the concept is of the first order of importance in the design of aircraft where the combinations of wings, bodies and air inlets for engines can be and usually must be carefully calculated to obtain favourable interactions.

Sweeping.—A most important contribution to the achievement of supersonic flight in the late 1940s was the recognition of the effect of sweeping the wings back or forward with respect to the line of flight. This work is attributed to Busemann, A. Betz and R. T. Jones, all of whom seem to have arrived at the result independently during World War II. The physical concept may be grasped by considering a wing in an air stream with its span perpendicular to the direction of flow.

If this wing is now moved continuously in the spanwise direction, no increase in the flow velocity occurs, yet the true velocity of a point on the wing is greater than the flow velocity. The resultant velocity of a point on the wing is in a direction different from the flow velocity by an amount determined by the sidewise velocity. This leads to the conclusion that it is the component of velocity perpendicular to the leading edge of the wing that determines whether the flow over the wing has subsonic shock-free flow or supersonic flow with shocks and consequent drag. Fig. 11 illustrates this effect.

The flight velocity is resolved into the components parallel and perpendicular to the leading edge. The Mach angle for the assumed Mach number is shown. The velocity V_{le} being less than the speed of sound a , the flow over the wing is of the shock-free subsonic type.

If the velocity of the wing is increased, the component perpendicular to the leading edge is increased and finally equals or exceeds the speed of sound. Similarly, if the velocity is increased while the speed of sound remains constant, the Mach angle is de-

creased and the Mach line originating at the vertex will eventually coincide with the leading edge. At that time the velocity component perpendicular to the leading edge becomes equal to the speed of sound and supersonic-type flow with shock waves and their consequent drag occurs. In practice, because of the effects of wing thickness and lift, the leading edge of the wing

FIG. 11.—DRAWING OF VELOCITY AND MACH CONE FOR SWEEP WING WITH SUBSONIC LEADING EDGE

must be at a small angle to the Mach cone. Because the Mach angle decreases with increased speed, the sweep angle of the wing must be increased to preserve the beneficial effects of sweep. As there is a limit to the amount of sweep that can be achieved while still preserving some lifting area of the wing, there is a maximum Mach number, in the range of 2.5 to 3.0, for which the beneficial effects of sweep can be maintained. Photographs of the flow for a swept wing are shown in fig. 12.

Boundary-Layer Effects.—The boundary layer introduces special problems at supersonic speeds. Under certain conditions, shock waves from one component surface impinging on another

cause the boundary layer to thicken and even separate from the surface upon which the shock wave impinges (fig. 13). Such types of flow interactions are very complicated and generally produce serious unfavourable effects on the stability and controllability of an aircraft. Knowledge in this field, however, is sufficiently advanced so that such adverse effects can be reasonably minimized by proper shaping and location of the aircraft components with respect to each other.

Surface Heating.—An even more serious problem is surface heating caused by the boundary layer. The simple form of Bernoulli's equation shows the relation between velocity and pressure at points in the flow about a body. At the nose of a body, the velocity of the body in the direction of the stream becomes zero and the pressure at this point, called the stagnation point, is consequently at its highest value. The temperatures at points in the flow are related to the density and the pressure of the gas by the general gas laws. At the nose of the body, the temperature, as well as the pressure, is at its highest value. Physically, what has occurred at this point is that the kinetic energy represented by the velocity of the impinging streamline has been converted to potential energy which is measured by the pressure and tempera-

FIG. 13.—SCHLIEREN PHOTOGRAPH OF SEPARATION OF BOUNDARY LAYER BY SHOCK WAVE

The line along which separation occurs is illustrated by the dark line in the photograph. The sharp line fades as mixing of the boundary layer occurs downstream of the separation region

ture for the zero velocity case.

When air is brought to rest, as at the stagnation point, the stagnation temperature is given by the formula

$$T_s = T \left(1 + \frac{M^2}{5} \right)$$

where T is the temperature of the surrounding atmosphere as measured from absolute zero (Fahrenheit temperature plus approximately 460) and M is the velocity of the flow expressed as a Mach number. Thus, very large local temperatures exist at the stagnation point when the Mach number is increased. The temperature difference ($T_s - T$) is called the adiabatic recovery.

In the boundary layer the velocity is reduced by the friction resulting from the viscous properties of air. The kinetic energy lost by this friction causes an increase in temperature related to the work done in overcoming the frictional resistance. In the idealized example of an insulated body, the temperatures in the boundary layer reach a balance between the frictional heat generated and the conduction in the gas so that the temperature rise in the boundary layer attains a value very near the adiabatic recovery.

For a laminar boundary layer, the temperature increase is approximately 85% of the adiabatic recovery, and for a turbulent boundary layer the recovery factor is about 90%.

At high Mach numbers, then, the surface of the body is subjected to severe heating, requiring the employment of special structural and cooling materials. Extreme examples of surface heating are meteors which are heated to ignition temperatures upon entering the earth's atmosphere and are generally consumed before striking the earth.

Supersonic Aircraft.—The general principles of subsonic aircraft design apply also to supersonic aircraft. The characteristics of the components, however, are different. The centre of lift of the wing is further aft on wings designed for supersonic speeds and the controls are generally less effective for a given angular deflection. The general appearance of the aircraft and the distribution of the main masses, such as engine, fuel and payload, are also different.

The aerodynamic heating due to the boundary-layer frictional effects probably accounts for the most serious difference. When the Mach number exceeds 2.0, the structure and the materials of the aircraft are markedly different. Aluminum, so widely used in subsonic aircraft fabrication, cannot be used and must be replaced by such materials as titanium and special steel alloys. When the Mach number exceeds 3.0, major changes in engine configuration become necessary.

TRANSONIC FLOWS

A special case of subsonic and supersonic flows occurs when the Mach number is near 1.0 and is termed transonic flow. As wings or other bodies approach the speed of sound, the velocities at local points on the bodies are increased in correspondence to the pressures acting at these points so that locally the velocity of sound may be exceeded. Strong shocks then form on the wing or body, usually causing separation of the boundary layer. These

BY COURTESY OF NATIONAL AERONAUTICS AND SPACE ADMINISTRATION

FIG. 14.—SCHLIEREN PHOTOGRAPHS OF TRANSONIC FLOWS FOR A WING SECTION

(Top) At Mach 0.92, a strong shock wave separates the flow. At the point where separation first occurs, a rearward sloping shock starts and terminates on intersection with the single strong shock. (Bottom) When the speed is increased the shock is swept to the trailing edge, becoming a sharply inclined shock. The separated flow disappears and supersonic flow occurs (Mach 1.2)

flows are very unsteady and give rise to severe buffeting and changes in the characteristics of the wings or bodies that may cause serious stability difficulties and losses in control effectiveness. An example of a transonic flow for a conventional wing section is illustrated in fig. 14. These effects are minimized by reducing the thickness of wings, by sweeping and by the proper combination of wings and bodies following a principle called the area rule.

In principle, the area rule combined with reduced thickness of components reduces to a minimum the differences between the flight velocity and the velocities of local points on the surface of the vehicle. Generally, vehicles properly designed for supersonic flight will not have great difficulty in passing through the transonic speed region, the so-called sound barrier. On the other hand, aircraft efficiently designed for subsonic speeds, with comparatively thick, unswept wings, may become extremely dangerous if through a dive maneuver they should enter the transonic speed range.

AERONAUTICS (ARTICLES ON). The history of the intellectual and physical pioneering by which the basic principles of flight were established is summarized in AVIATION. HISTORY OF, and the major applications of these principles are described.

The earliest type of exploration of the air and its modern applications are discussed in BALLOON, which deals with the history and methods of construction of balloons, from 18th-century France to the Skyhook balloons used for the study of cosmic rays. The evolution of modern techniques is described also in AIRSHIP, dealing with self-propelled dirigibles, and in GLIDING and PARACHUTE.

AVIATION, CIVIL surveys the general history of aerial passenger

and cargo transport, and describes the major world airlines.

The theoretical structure on which aeronautical science is built and the technical history of its development are outlined in AERODYNAMICS; AERONAUTICS; and FLIGHT (NATURAL). Some important experimental aspects of aeronautics are covered in WIND TUNNEL. Applications of aerodynamic theory in aircraft design are explained in AIRPLANE; SEAPLANE; and HELICOPTER. The evolution of aircraft power plants and the techniques on which modern types are based are treated in AIRCRAFT PROPULSION. Both the function and operation of basic flight instruments, engine instruments and auxiliary instruments are covered in AIRCRAFT INSTRUMENTS. Landing fields and service facilities for aircraft are discussed in AIRPORT.

AIR WARFARE traces the military use of aircraft, from the balloons used by the French during the siege of Paris in 1870 to the development of the intercontinental ballistic missile, which is treated in detail in MISSILES. AIR FORCES deals with the assimilation of air units into armies and navies, and their evolution as separate military organizations. AIRCRAFT CARRIER surveys the emergence of the floating airfield in World War I, its formidable role in World War II and the Korean war and its subsequent development. Other articles dealing with military applications of aeronautics are AIR DEFENSE; AIR POWER; and AIR-BORNE TROOPS.

Medical and legal aspects of aeronautics are discussed in AVIATION MEDICINE and AIR LAW.

The student who wishes a broader theoretical perspective of the science of which aerodynamics represents a subdivision will find this in MECHANICS, FLUID. Similarly, AIRCRAFT PROPULSION is supplemented by the general article INTERNAL-COMBUSTION ENGINE, and AVIATION, CIVIL by TRANSPORT. Aerial navigation is included in the article NAVIGATION. The reader interested in specialized areas should consult the Index, which refers not only to major articles but to individual topics in them.

The theories on which the possibilities of flight into outer space are based are explained in SPACE EXPLORATION; the methods used in attempting to apply these theories are described in ROCKETS.

Many of the key figures of aeronautical history whose work is described in the articles mentioned above are represented by biographical articles—for example, WRIGHT, ORVILLE; WRIGHT, BILBUR; LANGLEY, SAMUEL PIERPONT; BLERIOT, LOUIS; MITCHELL, WILLIAM, etc.

AERONAUTICS. This term has been used for many years to describe generally the art and science of aerial flight. It included flight in lighter-than-air craft (balloons and airships) as well as in all forms of heavier-than-air machines. With the advent of vehicles capable of flight outside the earth's atmosphere, however, its implications were too limited, and a revision in terminology became necessary. Various combinations have been suggested (e.g., "aero-astronautics"), but most have proved to be too awkward for common use. A combination of "aeronautics" and "space" has resulted in the coinage of the word "aerospace" to describe the regions in which man may now navigate, and the science of aeronautics has become integrated into the aerospace sciences.

Because the aerospace sciences cover a wide range of diversified activities and applications, it is not feasible to treat them all under one entry. A series of articles on various aspects of the aerospace sciences is included in this edition, the major entries being listed in AERONAUTICS (ARTICLES ON); see also Index references under "Aeronautics" in the Index volume. The remainder of the present article deals with those facets of the aerospace sciences that are concerned with aircraft design, and presupposes an elementary knowledge of aerodynamics (*q.v.*). It consists of the following material:

- I. Introduction
- II. Forces Acting Upon Aircraft
- III. Aircraft Lift Systems
 1. Airfoils
 - Boundary-Layer Phenomena
 - Shock-Wave Phenomena
 2. Three-Dimensional Wings

3. Bodies of Revolution

 2. Temperature Considerations

I. INTRODUCTION

To produce a successful aircraft, the airplane designer must blend the sciences of fluid mechanics and aerodynamics with the most advanced engineering techniques available. He must foresee any number of unexpected situations and applications for his machine. He must anticipate emergency situations of wide variety and provide the pilot and crew with systems and techniques for dealing with them. There is no single design that can optimize all factors. The design process is a process of compromise—the exercise of the designer's judgment about the interrelation and relative importance of the various functions that his product will have to perform.

Aircraft of today have become so complex that their design demands a detailed knowledge of physics, chemistry, electronics, fluid mechanics and the various branches of engineering. Frequently basic design decisions are based upon economic or political considerations. The job has become too large for one man and in most companies is handled by design teams ranging in size from a few men to thousands of highly trained specialists. Because each design is different, it is impossible to outline all of the factors that control the final appearance of the aircraft, but the following paragraphs discuss in a general way the major factors that lead to a particular configuration.

II. FORCES ACTING UPON AIRCRAFT

Vehicles moving through the air that are not directly supported from the earth's surface may, in general, be considered as being subjected to a system of body forces consisting of the weight and various inertia forces such as centrifugal forces, etc.; a system of aerodynamic forces arising from the relative motion of the vehicle with respect to the surrounding air; and lastly, the forces generated by whatever method of propulsion is employed. Efficiency of design requires that, for a given amount of power to be used, the maximum load must be carried at a given design speed. Furthermore, the machine must be stable; *i.e.*, must return to its given flight condition when displaced by either mechanical or atmospheric disturbances. It must also be satisfactorily controllable throughout its entire range of possible flight conditions.

The aerodynamic forces acting upon a vehicle moving through the air arise from physical properties of the air such as density, viscosity and specific heat, and from the fact that the pressure throughout the flow is a function of the velocity, decreasing as the velocity increases. By proper design of the shape of the machine, these characteristics of the air can be made to produce sustaining or lift forces many times greater than the retarding or drag forces. In the case of an airplane ($q.v.$) or glider this involves shaping the craft, within the limits set by structural weight and strength, to produce the greatest possible ratio of lift to drag at the design speed. In the case of a lighter-than-air ship, or a missile, efficiency of design involves surrounding the required space within the machine with a structure of adequate strength offering the least possible resistance for the lowest possible weight.

III. AIRCRAFT LIFT SYSTEMS

When considering an airplane or glider it is natural to regard

the wings as the major element of the lifting system, even though appreciable lifting forces may arise from the pressure distributions over the fuselage and control surfaces, as well as from components of the forces produced by the propulsive system. The lift of lighter-than-air craft is generally computed on the basis of the volume of lifting gas contained within the gas bags, even though a large contribution to the craft's over-all lift may result from the pressure distribution about the hull. The sustaining forces acting on a missile may come from many sources, such as the pressure distributions over the body and control surfaces; but the major contribution in the case of wingless designs arises from those components of the propulsive and body forces that act in a direction opposite that of the force of gravity.

To maintain steady level flight, forces must be created that are equal and opposite to the gravitational pull. In addition, the propulsive or thrust forces must exactly balance the aerodynamic resistance tending to retard the machine. The components of the aerodynamic forces created by the relative motion of the air flowing past the machine are related to the direction of the flow. The components perpendicular to the flow direction add to produce the force known as lift. The summation of the components of the retarding forces parallel to the direction of the flow is termed the drag.

Because the lift of a dirigible or blimp arises from the displacement of air by an equal volume of lighter gas, and that of a missile is frequently largely the result of a component of the propulsive force, the discussion of lifting systems will be narrowed to an investigation of the lift of wings. These wings may be either fixed, as is the case with airplanes and gliders, or rotating, as in helicopters or gyroplanes. In either case the fundamental flow mechanisms are much the same.

1. Airfoils.—A cross section of a wing, such as either of those shown in fig. 1, is termed an airfoil section. The operation of such an airfoil is best understood by considering a section such as that shown in fig. 1(A), in which the thickness is distributed symmetrically (*a-a*) about the line joining the leading and trailing edges, the so-called chord line. When the angle of attack α is zero, *i.e.*, when the chord line is parallel to the direction of flow, the particles of air flowing over the upper surface travel the same distance from the point of flow impingement, the stagnation point located on the leading edge, as do the particles of air flowing

FIG. 1.—AIRFOIL SECTIONS: (A) SYMMETRICAL AIRFOIL WITH THICKNESS DISTRIBUTION (*a-a*) SYMMETRICAL ABOUT CHORD LINE; (B) CAMBERED AIRFOIL WITH THICKNESS DISTRIBUTION (*b-b*) SYMMETRICAL ABOUT CAMBER LINE

under the wing. Thus, two particles of air starting on either side of the stagnation point and flowing over the upper and lower surfaces, respectively, will arrive at the trailing edge simultaneously. Under these conditions the flow will leave the trailing edge smoothly, as illustrated by fig. 2(A).

If the angle of attack, the angle between the chord line and the undisturbed direction of the flow, is increased, as shown in fig. 2(B), the stagnation point moves under the leading edge so that the air flowing over the upper surface suddenly has a greater distance to travel to reach the trailing edge than does the air passing under the wing. As a consequence, the lower surface flow arrives at the trailing edge before the flow that started at the stagnation point at the same time but followed the upper surface.

There being no forces to prevent it, the lower surface flow attempts to expand around the trailing edge, as illustrated in fig 2(C). As it flows about the sharp trailing edge, the magnitudes of the centrifugal and viscous forces are such that the flow separates, forming a vortex flow of the type illustrated. Because of the sense of rotation of this vortex, it serves to accelerate the upper surface flow so that the length of time required for a particle of air to move from the stagnation point at the leading edge to the trailing edge becomes the same for either the upper or lower surface routes.

The increased velocity of the upper-surface air produces two significant effects; it eliminates the tendency of the lower-surface air to expand about the trailing edge, and it produces lower pressures at each point on the upper surface than exist at the corresponding points on the lower surface. Each time the angle of attack is changed, an imbalance of velocities and pressure occurs at the trailing edge, producing another vortex which serves to establish the new upper-surface steady-state flow. Thus, as the angle of attack is increased, the upper-surface velocities increase, producing lower and lower pressures.

The summation of the pressures acting over the infinitesimal elements of area that make up the airfoil surface represents the resultant force on the section. The component of this force in the direction perpendicular to the flow is the lift; the component parallel to the flow is the drag. These forces can readily be measured in wind tunnels on models especially designed and constructed for the purpose (see WIND TUNNEL). In order to make the data so obtained applicable to wings of other sizes moving through the air at speeds other than those employed during the test program these data are presented in a nondimensional form. Extensive investigations have shown these nondimensional coefficients to be functions of the airfoil shape, the angle of attack; the Mach number (ratio of the speed of the body to the speed of sound); and the Reynolds number.

Boundary-Layer Phenomena.— The influence of Reynolds number, which is merely the ratio of the inertial forces to the viscous forces within the fluid, becomes important only when the viscous forces become large. Even though air is a fluid of low viscosity, in certain regions within the flow field the magnitude of the viscous forces may become large enough to be the controlling factor determining the nature of the flow. One such region is the boundary layer, the layer of air adjacent to a solid surface over which air is flowing.

To examine the nature of this layer, consider a flow of the type pictured in fig. 3. In this case a thin, flat plate is placed parallel

FIG. 2.— CHANGE OF AIR FLOW WITH CHANGE IN ANGLE OF ATTACK

to the oncoming flow, which has a velocity U . At the extreme leading edge of the plate, the particle of air immediately next to the surface is brought to rest. At each successive point along the plate, the molecules of air immediately adjacent to the surface are bound to the surface by the powerful attractive forces of

FIG. 3.— BOUNDARY-LAYER DEVELOPMENT OVER A FLAT PLATE: A, REGION OF LAMINAR FLOW; B, TRANSITION REGION; C, REGION OF TURBULENT FLOW. U , VELOCITY VECTORS OF UNDISTURBED AIR STREAM; u , VELOCITY VECTORS IN SAME DIRECTION BUT OF SMALLER MAGNITUDE

the molecules making up the solid boundary. This is the so-called no-slip condition, and has been found to exist in air flows up to very high Mach numbers when the energies involved in the flow are so great that the chemistry of the air undergoes a change, with ionization and dissociation taking place.

The molecules of air immediately above those bound to the surface are slowed to a velocity u by their contact with these stationary particles. As they move away from the surface under the influence of their random molecular motions, they collide with other molecules and are slowed, while the latter in turn are speeded up. Thus, a molecular mixing region exists which thickens as the flow proceeds downstream. The existence of this region is indicated by the loss in velocity shown by the typical velocity profiles sketched in fig. 3. Because the decrease in velocity in this region of the boundary layer is produced primarily by molecular action, the flow itself is relatively smooth and tends to move in layers parallel to the surface. This portion of the boundary layer is thus referred to as laminar.

As the flow proceeds along the solid boundary, it loses energy through the molecular action at a rate which depends upon its viscosity. Because of this loss of energy, the stability of the flow (its ability to damp out disturbances) is affected. As a result, slight velocity components normal to the surface, produced perhaps by freestream disturbances or by irregularities in the surface itself, tend to grow instead of diminish. If they grow sufficiently large, the fairly regular motion of the laminar boundary layer is destroyed, and the boundary layer is said to undergo transition; it thickens rapidly, and becomes characterized by large random motions or turbulence.

The sensitivity of the boundary layer to transition has been found to be a function of the amplitude and frequency of the disturbance, the Reynolds number, the freestream turbulence, the surface smoothness and temperature and most important, the pressure gradient along the surface.

If the flow is proceeding from a region of high pressure to one of low pressure (*i.e.*, in a favourable pressure gradient), it can be likened to a stone rolling downhill, and small disturbances are readily damped out; however, if it is proceeding in the other direction (*i.e.*, in an adverse pressure gradient), it is extremely sensitive, and will almost immediately undergo transition to the turbulent state.

One other boundary-layer phenomenon must be understood to appreciate the behaviour of airfoils. This is the tendency of the boundary layer to become thicker and thicker as the flow proceeds against an adverse pressure gradient. The layers of air next to the surface become more and more retarded until, as shown in fig. 4, the velocity above the surface, instead of increasing, remains equal to zero for a short distance. Under these conditions, the air will react to the higher pressure downstream, and will actually

begin to flow upstream along the surface, forcing the freestream flow away. Such a flow is said to be separated, and the point at which it first occurs is termed the separation point.

These characteristics of the flow, arising from the viscosity of the air, have a profound effect upon the behaviour of the air as it passes over the airfoil. If, for the moment, consideration is limited to the type of airfoil pictured in fig. 5(A), in which the leading edge is well rounded and the airfoil is relatively thick (maximum thickness being roughly between 10% and 20% of the chord line length), it will be seen that, at the positive angle of attack illustrated, the flow proceeding from the stagnation point to the minimum pressure point on the upper surface is in a region of favourable pressure gradient, and is, therefore, probably laminar. Once the flow is past the minimum pressure point, the gradient reverses and transition occurs. The boundary layer may thus be considered as turbulent from this point aft to the trailing edge. The flow under the airfoil could remain laminar all the way or might, under the action of large disturbances, undergo transition, but is certainly in a much less critical position than the layer above the airfoil.

As the angle of attack is increased, the depth of the turbulent boundary layer at the trailing edge increases until separation occurs. Further increases of angle of attack cause the separation point to move upstream, as shown in fig. 5(B). Because more and more of the profile is covered by the separated region, the increase of lift for each incremental change in angle of attack after separation has begun is less than for the case of completely attached flow. As the angle of attack is further increased, a point is reached where no further increase in lift results. This is the point of maximum lift, and further increases in angle of attack cause the lift to diminish, in some cases very rapidly. An airfoil in this flow situation, in which most of the upper-surface flow is separated, is said to be stalled.

The characteristics of the boundary layer also have a controlling influence upon the drag of the airfoil profile. The action of the surface molecules in decreasing the velocity of the air flowing past is manifested as an equal and opposite force termed the skin friction. This skin friction is a function of the viscosity of the fluid and the rate at which the velocity increases above the surface. In the laminar portions of the boundary layer in which the change of velocity is accomplished solely by molecular diffusion resulting from the random motion of the air molecules, this rate of change of velocity normal to the surface is relatively small.

FIG. 5.—GROWTH OF TRAILING-EDGE SEPARATION ON THICK AIRFOIL (A) AIR FLOW AT SMALL POSITIVE ANGLE OF ATTACK, (B) AIR FLOW AT INCREASED ANGLE OF ATTACK WHICH LEADS TO TRAILING-EDGE SEPARATION

FIG. 4.—BOUNDARY-LAYER SEPARATION

Once transition has taken place, and the boundary-layer flow has become turbulent, the molecular mixing throughout the layer is much more rapid, molecular diffusion giving way to conduction by means of large turbulent eddies as the primary mixing process. As a result, the rate at which the velocity above the surface increases to nearly the freestream value is much more rapid than in the laminar case.

The difference in shape between typical laminar and turbulent velocity profiles is shown in fig. 3.

The rapidity of the velocity rise normal to the surface being associated with a turbulent boundary layer than with a laminar one.

It would thus be expected that as the region of turbulent flow

over the surface of the airfoil profile increases with angle of attack, the drag of the profile will also increase. In addition, as separation occurs, the change in pressure distribution results in a large increase in the component of force in the direction parallel to the freestream; i.e., a large increase in the pressure drag.

In an attempt that was initially intended to produce a reduction in drag by increasing the extent of the laminar flow areas over the surface of the profile, the so-called high-speed profiles were developed. As shown by fig. 6(A), the geometry of these profiles from their relatively small-radius leading edges to their point of maximum thickness well aft on their chord line is arranged to maintain favourable (or at least zero) pressure gradients over the greater part of the chord for the given range of design lift coefficients.

Figure 6(B) shows typical lift and drag characteristics of such a profile. In this figure C_L , called the lift coefficient, and C_D , the drag coefficient, are nondimensional quantities proportional to the lift and drag, respectively. The most notable feature is the abrupt reduction in drag in the range of low lift coefficients, the so-called drag bucket. This reduction represents the increased region of laminar flow that results when the surface of such a profile is polished and maintained to a high degree of smoothness. Unfortunately, disturbances such as mud, or even scratches, are sometimes sufficient to disrupt the flow causing premature transition and loss of the entire drag advantage.

The second feature of the curves shown in fig. 6(B) that requires comment is the abrupt nature of the stall. Typically, this type of profile displays a flattening of the lift-coefficient vs angle-of-attack curve near the stall, and when stall occurs, the loss of lift is apt to be sudden and severe. Unlike the stall of conventional airfoils, which originates as a trailing-edge separation of the turbulent boundary layer, the stall of a sharp-leading-edge profile originates as a separation of the laminar boundary layer at the leading edge. The exact nature of this separation depends upon the Reynolds number, the curvature of the leading edge and the thickness distribution of the profile.

The mechanism of this leading-edge separation arises from the fact that as the angle of attack increases, the forward stagnation point moves below the leading edge. The air must thus accelerate

FIG. 6.—DESIGN OF HIGH-SPEED AIRFOILS: (A) AIRFOIL PROFILE AND PRESSURE GRADIENTS AT ANGLE OF ATTACK α ; (B) VARIATION IN LIFT AND DRAG COEFFICIENTS AT VARYING ANGLES OF ATTACK

FIG 7 — LEADING-EDGE SEPARATION ON HIGH-SPEED AIRFOIL OF THICK PROFILE (A) LEADING-EDGE BUBBLE FORMS. (B) BUBBLE MOVES FORWARD WITH INCREASED ANGLE OF ATTACK. (C) SHORT-BUBBLE STALL OCCURS WITH FURTHER INCREASE IN ANGLE OF ATTACK

past a region of very abrupt curvature to reach the upper surface. The velocities at such a point can be very high, and although the pressure gradient may be strongly favourable, the centrifugal forces acting on the air as the air attempts to turn around the leading edge become so large that the air is pulled from the surface. The laminar flow leaving the surface moves into a region of adverse gradient as it proceeds downstream. Under the action of this gradient it undergoes transition, and as a result of the growth of turbulence it reattaches to the upper surface, forming a leading-edge bubble, as shown in fig. 7(B).

If the profile is relatively thick and the leading-edge radius large, the separation point and the reattachment point will move forward as the angle of attack increases; therefore, the bubble does not grow appreciably but remains small while moving forward on the profile. Quite abruptly, a point will be reached where the growth of turbulence causes the flow to expand along a line that, instead of intersecting the surface and producing reattachment, becomes merely tangent, thereby producing the abrupt and violent stall associated with the small or so-called short bubble. This sequence of events is shown in fig. 7(C).

In the case of a very sharp leading edge, separation occurs either right at the leading edge or possibly slightly below it. Under these circumstances the separation bubble is large and becomes larger with increasing angle of attack. Final stall occurs when the reattachment point on the downstream end of the bubble reaches the trailing edge. Fig. 8 demonstrates this set of circumstances. Because of the growth of separation over the upper surface, the lift curve of such a profile demonstrates a much more gradual stall than the small-bubble case. The maximum lift coefficient obtainable, however, may be only about one-half that which can be obtained from a thicker wing having a trailing-edge stall.

Shock-Wave Phenomena.—The major reason for employing high-speed profiles, rather than the trailing-edge stalling type of profiles, is to reduce the high-speed drag. Curiously enough, this is not so much to reduce the skin-friction drag which they were originally designed to overcome, but rather the drag associated with the change of flow that takes place when the velocity at some point on the profile approaches the velocity of sound.

Pressure waves move through the air with the speed of sound; thus, as a wing moves along at some velocity well below that of sound, the pressure disturbance it causes is transmitted to the

air ahead, enabling the air to flow smoothly over the surfaces. If at some point the local velocity, *i.e.*, the flow velocity at that point, becomes equal to the speed of sound, the pressure disturbances cannot propagate forward; instead, they build up to form a surface of discontinuity of pressure and density known as a shock wave.

When a shock wave first forms on the wing, it is limited to a relatively small region, as shown by fig. 9(A). Tending to be somewhat unstable, it dances back and forth over the boundary layer, producing large disturbances and leading to premature separation aft of the shock. As previously pointed out in the discussion of trailing-edge stalls, such a separation reduces the lift and increases the drag. Because of the similarity of the effects produced by the shock-induced separation and the trailing-edge stall, this condition is sometimes referred to as a shock stall. The speed at which the shock wave is first encountered is called the drag divergence Mach number, or the critical Mach number, of the section. Because it is a function of the local pressure distribution, the speed at which the condition is first encountered will vary with the angle of attack, and hence with the lift coefficient of the section.

An airfoil designed to avoid high-velocity peaks, *i.e.*, low local pressures, in the range of low angles of attack will have good high-speed characteristics in that the formation of the disruptive shock waves will be delayed. The high-speed profiles have just such peakless pressure distributions at these angles of attack, being so designed in the attempt to avoid boundary-layer transition. These profiles thus delay shock-wave formation until high speeds are attained, and as a consequence have found extensive use on high-speed airplanes. Reducing the thickness of the airfoil also reduces the magnitude of the difference between the local velocities on the surface and the freestream. For this reason the nings of high-speed aircraft are as thin as the demands of structure and fuel storage space will allow.

If the velocity is increased beyond that at which shock waves first appear, the region of supersonic velocities (velocities greater than the speed of sound) increases, the shock wave splitting as shown in fig. 9(B). When the freestream velocity becomes supersonic the shock waves are located at the leading and trailing edges. Further increases of speed merely reduce the angle between the shock wave and the profile surface, but do not appreciably change the location of the waves.

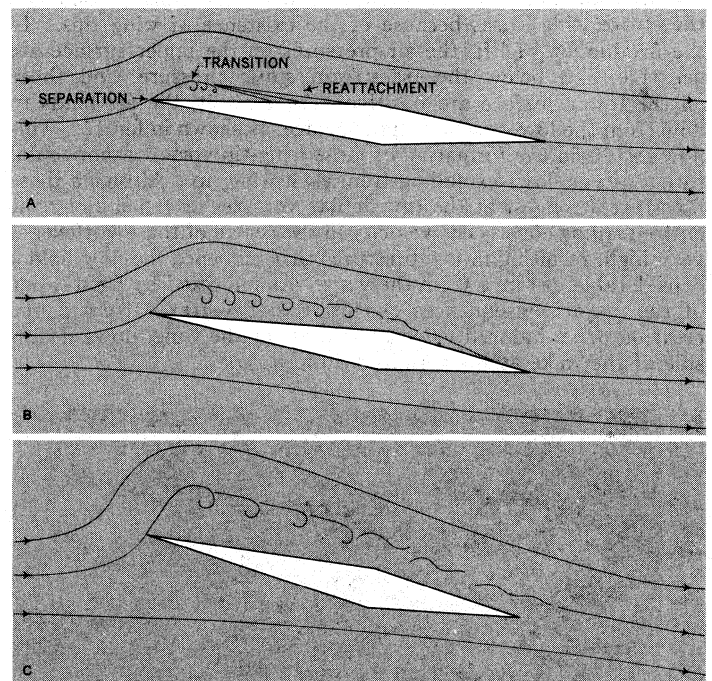

FIG 8 — SEPARATION ON HIGH-SPEED AIRFOIL WITH SHARP LEADING EDGE: (A) LEADING-EDGE BUBBLE FORMS. (B) BUBBLE ENLARGES WITH INCREASED ANGLE OF ATTACK. (C) LONG-BUBBLE STALL OCCURS WITH FURTHER INCREASE IN ANGLE OF ATTACK

With the first appearance of a shock wave, the lift of the profile tends to drop while the drag starts to rise rapidly. This increase in drag arises partly from the induced separation produced by the shocks, but as the flight speed increases, the major contribution arises from the energy necessary to maintain the shock pattern, the so-called wave drag. As shown by fig. 10, which is a plot of the typical variation of drag coefficient with Mach number for constant values of lift coefficient, the drag coefficient ceases to increase once completely supersonic flow has been achieved. This reflects the steadier nature of the purely supersonic shock patterns.

FIG. 9.—SHOCK-WAVE PATTERNS: (A) SHOCK WAVE AS INITIALLY FORMED; (B) SPLIT SHOCK WAVE FORMED AT INCREASED SPEEDS

2. Three-Dimensional Wings.—The preceding discussion has dealt solely with airfoil sections. If the entire wing is considered, still another method of delaying the advent of the drag rise associated with local velocities equal to the speed of sound can be added to the use of thin high-speed sections. This is the utilization of wing sweep as explained in AERODYNAMICS. The importance of sweep decreases as the speed of flight increases to the point at which the component normal to the wing becomes supersonic. Fig. 11 shows the drag coefficient variation of straight, swept and delta wings at various speeds. It will be seen that although there are large differences between the wing types in the region of Mach number one, they become of relatively little significance as the velocity increases beyond Mach two.

FIG. 10.—VARIATION OF DRAG COEFFICIENT WITH MACH NUMBER

One other important difference between the wing section and the entire wing arises because of the existence of wing tips. In the production of lift, the air pressures on the upper surface are negative, *i.e.*, below the freestream static pressure, and those on the lower surface are positive. As a result, the air tends to flow from the lower to the upper surface, as shown in fig. 12. This flow results in the formation of large wing-tip vortices, horizontal tornado-type flows extending from each wing tip. Although these flows are strongest at the tip, similar vortices are shed along the entire trailing edge. The velocity in the centre of these vortices is very high, resulting in low pressures that influence the flow field a considerable distance from the wing. As indicated by fig. 12, one of the major consequences of this trailing vortex pattern is the creation of an induced velocity field about the wing, upward outside of the wake and downward within it.

FIG. 11.—VARIATION OF DRAG COEFFICIENT WITH MACH NUMBER FOR THREE WING FORMS

The downward velocities induced at the wing produce an additional component of drag appropriately termed the induced drag and usually indicated by the induced drag coefficient, C_{Di} . The mechanism by which this occurs is demonstrated by fig. 13, which shows how the resultant of the combination of the freestream velocity vector V_1 and the induced velocity or down-wash V_2 at the wing combine to produce an effective change in the angle of attack. As a result of this change in angle, the lift vector of the wing is rotated backward, creating a component of force arising from the lift but oriented like a drag.

By constructing long slender wings, *i.e.*, wings with a high aspect ratio (ratio of span to chord) the effect of the tip vortices is held remote from the wing sections located on the inboard portions of the span. The induced drag at any given lift coefficient is therefore reduced if the aspect ratio is large.

The shape of the wing and its resultant distribution of pressure along the span also has an effect upon the magnitude of the induced drag. Investigations have shown that a wing planform having an elliptical shape produces a uniform distribution of down-wash along the span, resulting in the minimum induced drag. Because elliptical planforms require both the leading and trailing edges to be curved, modern production practice tends toward accepting the slightly higher induced drag associated with the cheaper and more easily constructed straight leading and trailing edges.

FIG. 12.—VORTEX TURBULENCE PATTERN BEHIND WING

However, use is made of wing taper, *i.e.*, utilizing a tip section that is smaller than the root, so that an elliptical planform is roughly approximated.

3. Bodies of Revolution.—Three-dimensional bodies approximating bodies of revolution in appearance, such as the fuselage and nacelles of an airplane or the body of a missile, are also subject to the four types of drag arising from the skin friction, the pressure distribution, the formation of shock waves and the induced effects resulting from the creation of lift. Because the lift created by the fuselage is small compared to that of the wings, it is generally assumed that the drag contribution arising from the induced drag of the fuselage and nacelles is negligible, and that the total lift of an aircraft arises from the wings.

The design considerations applied to airfoil sections to reduce the skin friction and pressure drags are also applicable to three-dimensional bodies. In order to minimize pressure drag, the body should be designed in a so-called streamline shape to avoid regions of appreciable separation. To reduce skin friction, every precaution must be taken to maintain laminar flow in the boundary layer over as great a portion of the forebody as possible. This includes shaping the body to maintain favourable pressure gradients as far aft as practicable, as well as maintaining at least the forward portions of the body as smooth as possible, using flush rivets, faired windows, etc.

Design Considerations.—To reduce wave drag, it is necessary to produce as little initial disturbance to the flow as possible. This is generally accomplished by the use of a spike- or needle-nose design. In such a design the initial wave created by the spike slightly reduces the velocity downstream of the shock front. The next increase in body diameter downstream of the spike creates

another shock wave, but because the velocity is less than freestream, the strength of this second wave is not as great as would be the case if the spike had not previously formed its shock. This procedure persists until the full diameter of the fuselage is achieved.

Studies have shown the drag created by this successive weak-wave generation to be much less than that associated with a single strong shock wave from the bow.

Interference Drag.—The total drag of the complete aircraft is greater than the sum of the drags of its individual components. This is because of the change in the velocity and pressure fields about one element created by the pressure of another. As an example, consider a low wing attached to a fuselage. The high-velocity air passing over the wing will increase the skin friction of the adjacent portions of the fuselage above that which would be created by only the freestream velocity.

In addition, the presence of the adverse pressure gradient over the aft portion of the wing may produce local separation in the junction between the wing and fuselage with a resultant increase in pressure drag. The creation of these interference drags in the subsonic regime has driven designers to develop fairings and fillets to avoid separation areas at the intersection of a lifting surface and a body.

In addition, attempts have been made to reduce the number of such intersections. These attempts have concentrated on tail design, and have given rise to such arrangements as the butterfly tail, in which the conventional horizontal and vertical surfaces are replaced by diagonal surfaces, and the T-tail, in which the horizontal surfaces are removed from the fuselage altogether and placed at the top of the vertical fin.

FIG 13 — PRODUCTION OF INDUCED DRAG C_{D_i} , BY ROTATION OF LIFT VECTOR L ; V_1 FREESTREAM VELOCITY; V_2 INDUCED VELOCITY; V , RESULTANT VELOCITY; L_1 , LIFT PERPENDICULAR TO FREESTREAM; L , LIFT RESULTING FROM PRESENCE OF INDUCED VELOCITY

In the transonic regime, that range of flight speeds in which the velocity field about the aircraft is mixed (in some portions being supersonic and in others subsonic), the interference drags can have a profound influence on the design. It has been found theoretically, and confirmed experimentally, that in this velocity range the aircraft can be considered as an equivalent body of revolution having at each section a cross-sectional area equal to that of the actual aircraft. The drag of such a body of revolution is a function of the rate at which the cross-sectional area varies along the longitudinal axis. If the variation is smooth and steady, the drag is low; if it is abrupt and sudden, the drag is high.

When moving aft on a conventional subsonic airplane, it is found that the variation of cross-sectional area is likely to be smooth until the location at which the wings are attached is reached (fig. 14[A]). At this point an abrupt change is experienced, due to the fact that the cross-sectional area added by the wing is appreciable. The area of outboard nacelles must also be included, and this tends to make the variation even more abrupt. Highly swept wings somewhat alleviate the situation, but to achieve a truly smooth variation of cross-sectional area it is necessary to reduce the fuselage area to compensate for the increase produced by the wing. This gives rise to designs displaying the distinctive "coke bottle" shape shown in fig. 14(B).

Similar considerations also determine the optimum shape for supersonic aircraft! although additional factors must be considered. Under proper conditions, it is possible to utilize shock-wave interactions to reduce interference drags, the higher pressure behind the shock being employed to increase pressures on bodies in favourable locations. In certain supersonic ranges, it is desirable to keep the leading edges of the wings within the shock cone emanating from the nose spike. For this reason many such designs have a canard or tailfirst configuration, the smaller control surface fitting within the narrow confines of the forward part of the cone, the larger wing filling the more ample space further downstream.

4. Minimum Flight Speeds; High-Lift Devices.—For an aircraft to fly in steady level flight, the lift must equal the weight, and the thrust must equal the drag. If the lift is set equal to the weight for a given weight and altitude, the velocity is controlled by the value of C_L . The pilot controls the value of C_L through his longitudinal control system, the elevators. By deflecting these he is able to pitch the aircraft about its centre of gravity, thereby increasing or decreasing the angle of attack, and hence the lift coefficient, at will. It is thus, with the elevators rather than with the throttle, that the pilot controls the speed of his aircraft.

The minimum speed at which flight is possible is determined by the maximum lift coefficient that can be achieved. This, of course, occurs just before the stall. The equation for the minimum speed obtainable in level flight is

$$V_{min.} = \sqrt{\frac{2W/S}{\rho C_{L_{max.}}}}$$

where W = aircraft weight, S = wing area, ρ = air density and $C_{L_{max.}}$ the greatest value of the lift coefficient obtainable. When applying this expression, it must be remembered that $C_{L_{max.}}$ occurs at a high angle of attack, implying a rather large angle of pitch. If the power plant is producing high thrust under these conditions, an appreciable component of the thrust vector may add to the total lift force. In addition, if the propellers are employed, the slip stream passing over the wings will also result in values of $C_{L_{max.}}$ considerably higher than those obtained in free air, a characteristic that has been extensively employed in the development of short take-off and vertical take-off aircraft.

As the speeds of aircraft have increased, it has become more and more desirable to reduce wing drag by reducing wing area. This means that the wing loading W/S has been increased. Since $C_{L_{max.}}$ is limited by stall, this trend has resulted in the minimum speeds of aircraft, the speeds used for landing and take-off becoming higher. These higher speeds have, in turn, necessitated longer runways. Because the space available for such runways is

FIG. 14.—REDUCTION OF DRAG BY VARIATION OF TOTAL CROSS-SECTIONAL AREA: (A) CONVENTIONAL SWEEP-WING DESIGN SHOWING ABRUPT CHANGES IN CROSS-SECTIONAL AREA AT POINTS OF ATTACHMENT OF WINGS; (B) AREA CURVE SMOOTHED BY ALTERING FUSELAGE TO "COKE BOTTLE" SHAPE

limited. This trend has also produced a search for methods of increasing $C_{L_{max}}$.

Trailing-Edge Flaps.—The most common method of increasing $C_{L_{max}}$ is the deflection of a trailing-edge flap. Although, as shown by fig. 15, there are many varieties of such devices, they all work on the same principle. Deflection of the trailing edge increases the camber or mean line curvature of the profile and thus causes the

FIG. 15.—EFFECT OF VARIOUS TRAILING-EDGE FLAPS IN INCREASING COEFFICIENT OF LIFT AT GIVEN ANGLES OF ATTACK: (A) DOUBLE-SLOTTED FLAP; (B) FOWLER FLAP; (C) SLOTTED FLAP; (D) SPLIT FLAP; (E) PLAIN FLAP; (F) PLAIN WING

very effective.

Because of the success achieved with the slotted flaps, systems have been developed in which the blowing air is supplied at even higher energy levels by using compressed air from a separate blower located within the wing or fuselage (frequently the compressor of a jet engine) which is piped along the wing, ejected through small slots and blown over the flaps. Other systems have been developed which accomplish the same end of energizing the boundary layer by removing the lower-energy air next to the surface by sucking it through slots or holes. This latter arrangement of powered suction has also been used to reduce the skin-friction drag by maintaining the boundary-layer laminar over the entire wing surface. Such arrangements, in which power is supplied to alter the aerodynamics of the boundary layer, are termed boundary-layer control systems.

FIG. 16.—EFFECT OF LEADING-EDGE DEVICES IN EXTENDING LIFT CURVE TO HIGHER ANGLES OF ATTACK

The slat is particularly effective for profiles that display leading-edge stalling characteristics, and is frequently used on such profiles in addition to flaps because the flap alone tends to induce premature leading-edge stall. Other devices which are used for this same purpose are termed leading-edge flaps, two examples of which are shown in fig. 16. The primary purpose of these devices is to increase the effective radius of curvature at the leading edge, thereby reducing both the centrifugal forces and the severe pres-

sure gradients associated with small leading-edge radii.

5. Effect of Sweepback on Lift.—The use of sweepback has a significant effect on the maximum lift coefficient that can be achieved. Experiments have shown that when a transverse velocity is imposed upon a separation bubble such as that at the leading edge, a vortex results. The spanwise component of the freestream velocity along the swept wing provides the required transverse velocity, and a conical vortex is formed. As the angle of attack increases, the magnitude of the vortex also grows.

If the wing under consideration is of relatively low aspect ratio, it is practically buried under these vortices. Although the lift coefficient under these circumstances is not great, it is nearly constant; the maximum lift in some cases is not reached until the angle of attack is nearly 40° , and even then the decrease of lift as the angle is increased is slight. On wings of larger aspect ratio, the vortex grows along the leading edge. When the angle of attack is sufficiently large, the wing tips become completely submerged below the large vortices.

This is an undesirable effect for two reasons. First, it produces thick turbulent flow (in a sense a separated flow) in the region where the lateral control ailerons are customarily located, thereby severely limiting lateral control; for this reason, many swept-wing aircraft have ailerons located well inboard on the span. Second, as the lift on the tips is decreased, the centre of action of the resultant lift vector on each wing panel moves forward, producing a "nose-up moment" or "pitch-up" that is difficult for the pilot to control.

FIG. 17.—SPANWISE FLOW OF BOUNDARY LAYER

An aggravating factor in the so-called tip stall of high aspect ratio swept wings is the outboard flow of the boundary layer. As shown in fig. 17, the low pressure point of an outboard section is located opposite a higher pressure region of an inboard section. The boundary layer, made up of low-energy, low-velocity air, responds readily to such a pressure difference, sweeping along the span and flowing toward the tip. The tip thus develops a very deep low-energy boundary layer and becomes very prone to stall.

It has been found that in some cases this type of flow is decreased by the use of boundary-layer fences, thin strips of metal fastened to the wing in the flowwise direction forming a barrier to the drift of the boundary layer. In other cases, the pressure field created by the presence of underwing-mounted engine pods is sufficient to cause the leading-edge vortex to shed and in the process to block the spanwise flow of the boundary layer.

IV. AIRCRAFT PERFORMANCE ESTIMATION

The general performance of an aircraft is determined from a plot of its thrust (or horsepower) required to maintain level flight versus flight velocity, superimposed upon a plot of the thrust supplied by its power plant. The power plants commonly employed for aircraft propulsion ($q.v.$) are the reciprocating engine; the turbine propeller, or turboprop engine; the turbojet; the pulse jet; the ram jet; and the rocket. The first two, the reciprocating and turboprop engines, are designed primarily for the production of shaft horsepower which is converted into thrust by means of a propeller or rotor. The remainder produce thrust directly by

using chemical energy to exhaust a stream of high-velocity gases. It is the momentum of these gases that creates the thrust force. All but the rocket use atmospheric air as their working fluid. The rocket's fuel and oxidizer are both carried within the rocket, thus permitting the production of thrust in the rarefied atmospheres encountered at great altitudes and in space.

The location of the power plants is an important decision for the designer. If propellers are used, there must be sufficient ground clearance, but the landing gear weight should not be excessive. Low- or mid-wing-mounted engines are generally decided upon for multiengine machines, fuselage mounting being usual for single-engine aircraft. To reduce the high drag associated with the slip stream passing over the nacelle or fuselage, rearward-mounted or pusher propellers have been used on some designs. Usually the slight gain in drag reduction is more than offset by the loss in propeller efficiency arising from its operating in the wake of upstream bodies as well as by the more severe mechanical problems such as engine cooling, etc.

The large air-breathing engines, such as turbojets, must be so located that their performance is not adversely affected by inlet restrictions and obstructions, because much of their ability to produce thrust depends upon achieving appreciable amounts of ram pressure recovery by well-designed inlets and diffusers which slow the flow ahead of the first engine compressor stage. To ensure optimum conditions when the inlet is located next to the fuselage, a diverter plate is used to prevent the fuselage boundary layer from entering the inlet duct. At supersonic speeds, centre bodies, not unlike the spiked-nose body of revolution already discussed as a drag-reduction device, are used to slow the flow with the smallest loss of pressure recovery possible. To maintain optimum conditions at all speeds, the position of these bodies is frequently adjustable.

Mounting such engines within the fuselage can, of course, be accomplished only on relatively special design types such as fighters. The space requirements on other types dictate other mounting locations. Mounting the engines in the wing roots relieves their drag but compromises their performance because of the variable up-wash field which is created as the angle of attack is changed. A location within the fuselage results in high noise levels; and high-temperature jet impingement on other parts of the aircraft downstream of the engine is also a factor that must be considered. Pod mounting below the wing eliminates the flow difficulty and is possibly somewhat safer in the event of violent engine failure, but produces higher drag and creates a control problem should one engine fail. If noise is a problem, as it is for commercial passenger aircraft, a rearward location on the fuselage may be desirable, although the thick fuselage boundary layer may cause a loss in efficiency.

1. Propeller Design Considerations.— A propeller or rotor produces thrust in the same manner as a wing creates lift. A velocity-vector diagram of a typical blade section is shown in fig. 18. The resultant velocity is the summation of the freestream and rotational velocities. The thrust is the summation of the force components parallel to the propeller shaft; the torque is the product of the force components perpendicular to the shaft times the distance from the axis of rotation to the blade element under consideration. Summation of the contributions of each element over the entire disk area gives the total thrust and torque of the propeller.

Because the velocity at each blade section is a function of the radius, the blades are twisted to maintain a reasonable distribution of angle of attack along the span of the blade. Adjustable-pitch propellers are designed to maintain propeller efficiency as the forward velocity changes by giving the pilot control over the pitch angle β (see fig. 18). As the forward velocity increases, this angle is increased in such a manner as to keep each section operating close to its maximum value of L/D , the ratio of lift to drag, or, alternatively, to keep the engine rotating at a constant speed.

An additional complication is introduced when there is a velocity component parallel to the plane of rotation, as in the case of a helicopter rotor. The velocity of the forward-moving blade is

FIG. 18.— VELOCITY-VECTOR DIAGRAM OF SECTION THROUGH A PROPELLER OR ROTOR BLADE: V_1 , FREESTREAM VELOCITY; V_2 , TANGENTIAL VELOCITY DUE TO ROTATION; V , RESULTANT VELOCITY; β , BLADE PITCH ANGLE; D , DRAG COMPONENT; L , LIFT COMPONENT; T , RESULTANT THRUST

greater than that of the retreating blade, and if the blade is rigid and the angle of attack is not changed mechanically, an imbalance of lift results, the lift on the forward-going blade being considerably greater than that on the retreating blade. The result is a large rolling moment tending to bank the machine. It has been found that the most convenient way to overcome this rolling moment is to hinge the blade at the shaft, thereby moving the point at which the load is transmitted to the aircraft from well out on the blade inboard to the shaft axis.

This, of course, eliminates the rolling moment, but allows the blade to tilt or flap about this hinge under the action of this unbalanced load. The exact arrangement used for tilting the axes depends upon the rotor configuration. It may vary from a seesaw scheme used on two-bladed rotors to individual hinges on multi-bladed designs, but in all cases the blade is prevented from merely being deflected to an upright position by the magnitude of the centrifugal forces.

The forces required to move the helicopter in any direction are produced by tilting the rotor in that direction. This is achieved by cyclic pitch control, an arrangement whereby the pilot can increase the pitch of the blades over a portion of the rotor disk, causing the blades in that region to flap upward, while decreasing the pitch over that portion of the rotor disk 180° away, causing these blades to flap downward.

2. Thrust Considerations.— Fig. 19 shows the variation of thrust, T , with velocity for various types of power plants. Fig. 20 shows the variation of thrust required to maintain level flight of a typical aircraft, indicating the relative importance of each of the varieties of drag as the flight speed changes. Fig. 21 gives graphs depicting the thrust available from a typical turbojet engine, with a superposed curve of required thrust. The two points of intersection of each set of these curves represent the minimum and maximum velocities at which level flight can be maintained.

FIG. 19.— EFFECT OF VELOCITY ON AVAILABLE THRUST FOR VARIOUS TYPES OF POWER PLANTS

FIG. 20.— EFFECT OF VARIOUS DRAG FACTORS ON THRUST REQUIRED TO MAINTAIN LEVEL FLIGHT AT DIFFERENT VELOCITIES

under the conditions of engine thrust depicted.

Velocities lying to the left of the intersection of the thrust-available and thrust-required curves represent conditions under which level flight is impossible, the power required being greater than the power available. In most cases, it is likely that a factor contributing to the rapid drag rise in this region is the proximity of the stall, a fact which, coupled with the difficulty of control encountered at these low speeds, makes even nonlevel flight in this region dangerous and undesirable. Velocities lying to the right of the intersections at the right side of the graph also lie in a region in which level flight is impossible because the thrust required is greater than the thrust available; in this case, however, higher velocities can be achieved by placing the aircraft in a dive, thereby adding a component of the weight to the thrust available.

Velocities between the intersections of the curves lie in a region in which the thrust available is greater than the thrust required. If a constant lift coefficient is maintained, the excess thrust available causes the aircraft to climb. If the throttle setting is such that there is less thrust available at any given speed than the thrust required for level flight, the rate of sink of the machine can be computed from the deficiency of thrust.

Both the thrust available at a constant throttle setting and the thrust required are affected by a change in altitude: the curve representing the thrust available lowering with increasing altitude and the thrust-required curve moving upward and to the right. As a result, the excess thrust available for producing climb falls off with altitude, lowering the rate of climb. The altitude at which the rate of climb falls to 100 ft. per second is termed the service ceiling, and the altitude at which it falls to zero is called the absolute ceiling.

FIG. 21.— THRUST AVAILABLE FROM A TURBOJET ENGINE AT THREE POWER SETTINGS AND THRUST REQUIRED TO MAINTAIN LEVEL FLIGHT AT VARIOUS SPEEDS

3. Range of Flight.— A major performance item that exerts an influence on the design of an aircraft is the range over which it is desired to fly. The factors that contribute to the range are the airframe efficiency, as reflected by its lift-to-drag ratio; the engine efficiency, expressed by the specific fuel consumption, which relates the pounds of thrust produced per unit time to the pounds of fuel consumed; the weight of fuel carried; and the speed at which the flight is conducted.

It was formerly believed that the influence of the lift-to-drag ratio, L/D, which is high at low speeds and falls off with velocity together with the specific fuel consumption, would limit truly long-range aircraft to relatively low speeds. These low speeds correspond to relatively large values of C_L and hence to a large induced drag. To overcome this, high aspect ratios are used and have become a characteristic of long-range transports and bombers. Developments have shown, however, that it is possible to obtain acceptable lift-to-drag ratios at supersonic speeds by making full use of the possibilities of favourable supersonic interference drags. Much the same has proved true of the specific fuel consumption. As a result, it appears that it will be possible to achieve long ranges at supersonic speeds because the increase of speed more than compensates for the loss of airframe and engine efficiency. This is the major reason why the development of supersonic transports is considered both feasible and desirable.

V. AIRCRAFT STABILITY AND CONTROL

Stability may be defined as the ability of a system, when disturbed from its equilibrium position, to create forces and moments that tend to restore equilibrium. The control characteristics include both the aircraft's response to a given control movement and the force required of the pilot to produce such a desired response.

As applied to aircraft, stability can be defined as the machine's tendency to return to a trim speed if it is disturbed. If, for example: the airplane encounters an upward gust of air, its angle of attack will be increased. Because the speed of flight does not change instantaneously, this increment in angle of attack will result in an unbalanced lift force which will start to curve the flight path upward. Both this upward motion and the increase in induced drag will tend to slow the machine below its trim speed. If the airplane is neutrally stable, it will reach a new equilibrium point, but will generate no forces or moments tending either to slow it further or speed it up. If it is unstable, slowing the machine will produce the tendency to slow it more. If it is stable, slowing it will create the forces and moments necessary to speed it up. In a like manner, if the aircraft were inadvertently to increase its speed without a corresponding change in angle of attack, a stable machine would tend to slow down.

If the pitching moment about the centre of gravity is considered, nose-up moments are, by convention: referred to as positive and nose-down moments as negative. To provide stability, a sudden increase in coefficient of lift should produce a nose-down pitching moment, tending to reduce the angle of attack; or it should produce a nose-up pitching moment, should the initial disturbance be a decrease in angle of attack. This means that the change in pitching moment, or of pitching moment coefficient C_m , as defined in fig. 22, should be of a sense opposite to the lift coefficient; a decrease in lift, or negative lift increment, should produce a positive or nose-up moment, and a positive lift increment, a nose-down moment.

The major components contributing to the pitching moment of an airplane are the propellers, the fuselage, the wing and the tail. A propeller ahead of the centre of gravity produces a nose-up moment; one behind, a nose-down moment. The contribution of the fuselage is always nose up. The major contribution of the wing arises from the lift vector acting on a lever arm about the centre of gravity; it may be either nose up or down depending upon whether the point of action of the lift force, termed the aerodynamic centre, is ahead or behind the centre of gravity. The magnitude of the wing's contribution varies directly as the distance between these two points.

The greatest nose-down effect comes from the horizontal tail.

Tailless airplanes can, of course, be stable, but this can be achieved only by a careful balance between the location of the aerodynamic centre and the centre of gravity. Not only does this serve to limit severely the amount of travel permitted the centre of gravity, but, in general, these machines are unable to trim out the large moments associated with high-lift devices, such as flaps, etc. If care is taken to avoid the stall, a tailforward, or canard, configuration can also be made stable. A stall of the forward trimmer, however, can produce dangerously severe nose-down pitching moments and must be avoided. A stall of the main lifting surface prior to the stall of the trimmer produces an unstable nose-up moment, and stalling both simultaneously produces a dangerous controlless situation. The canard and tailless configurations are thus used only if the performance gains to be achieved by employing them outweigh their stability disadvantages.

The horizontal tail is so designed that its position and size serve to produce a change in stabilizing moment greater than the destabilizing contribution arising from the change in lift coefficient. Thus stability can be assured about a given equilibrium position. A change in the position of the centre of gravity, by changing the arm between it and the aerodynamic centre, changes the magnitude of the stability contribution of the wing. If the centre of gravity is too far behind the aerodynamic centre, this destabilizing contribution becomes equal to the stabilizing contribution of the horizontal tail, canceling it out and producing neutral stability. The centre-of-gravity position at which this occurs is termed the neutral point and forms the aftmost limit of centre-of-gravity travel, for to go aft of this point will cause the machine to become unstable.

1. Longitudinal Control Systems.—Although, as can be seen from fig. 22, a change in the centre of gravity changes the equilibrium trim point, it does so by changing the slope of the C_m v. C_L curve, the so-called stability level of the aircraft. This is an unsatisfactory system of achieving control, because it produces a change of stability at each speed. For this reason, elevators that are merely controllable trailing-edge flaps located on the horizontal tail are employed. These elevators change the tail lift coefficient, and hence its pitching moment contribution, forcing the machine to pitch about the centre of gravity. This produces a change in angle of attack and lift, resulting in a new equilibrium speed.

The application of such a control deflection, unless the system is completely powered, will require the pilot to exert a control force on the stick. Because this force is required continuously to maintain trimmed equilibrium, it can become most fatiguing. To avoid this, the control surfaces are equipped with small trailing-edge flaps, termed tabs, which the pilot can deflect (in a manner exactly analogous to a wing flap) to produce a small force opposite in direction to that produced by the main control deflection. These forces are small enough so they do not appreciably affect the overall control effectiveness, but being remote from the hinge line they allow the total hinge moment to be reduced to zero, thereby relieving the pilot of the necessity of applying a constant correcting force.

Just as the neutral point forms the after limit on the permissible centre-of-gravity travel, the forward limit is set by the elevator's ability to produce a large enough control force to maintain flight at a speed corresponding to $C_{L_{max}}$. If the centre of gravity is too far forward, the rate of change of pitching moment with lift coefficient becomes so large that at high values of C_L the elevator cannot create a sufficiently large counteracting moment. The forward limit on the centre-of-gravity travel is set so that the elevator not only can trim out $C_{L_{max}}$ in flight, but has some reserve power to provide proper control during landing.

Other limits, possibly more severe than the ones described above, restrict the centre-of-gravity travel. These arise from the character of the air loads on the control surfaces and from the necessity of keeping the control forces within certain predetermined bounds, and will not be discussed here. The examples just given serve to demonstrate the extreme importance of designing the machine in such a way that all permissible loading arrangements keep the centre of gravity within well-defined limits.

2. Lateral and Directional Control Systems.—No less important than the longitudinal stability and control of the aircraft are its lateral and directional stability and control characteristics. In this case, there being no large side loads corresponding to the wing lift, the exact location of the centre of gravity is of minor importance. The vertical tail and rudder operate in a manner completely analogous to the horizontal tail and elevator: producing yawing moments tending to force the airplane back to a condition in which the freestream approaches from directly ahead (zero sideslip). The size of the rudder is generally determined by the most severe conditions anticipated for the given design; for example, the need to hold zero sideslip at low speeds on a multiengined aircraft when one engine is inoperable.

Lateral control: *i.e.*, control over the angle of bank or the rate of roll, is achieved by means of ailerons, which are differentially acting flaps located on the trailing edges of the wings. Whereas the rudder is employed to maintain zero sideslip angle, the ailerons are used to bank the airplane, thereby tilting the lift vector and producing a component of lift at right angles to the flight path. It is this component of lift that turns the airplane; the steeper the angle of bank, the steeper the turn.

In the lateral-directional modes of motion, the directional stability, *i.e.*, the ability of the aircraft to return to a condition of zero yaw when disturbed, corresponds to the longitudinal stability level, dC_m/dC_L . This stability is produced by the vertical tail in a manner exactly analogous to the horizontal tail's role in the longitudinal case. There is no equivalent stability laterally, but there is a coupling between sideslip and roll known as the dihedral effect. As a sideslip is produced, the geometry of the aircraft is such that a rolling moment is also produced. If this rolling moment is in such a sense that the forward-going wing is raised, it is said to be a positive dihedral effect.

VI. AIRCRAFT STRUCTURES

Aircraft structural technique differs from structural practices in other fields primarily in the emphasis placed upon weight. In order to minimize weight, extensive testing of sample elements of the aircraft, in many cases to failure, is resorted to in an effort to eliminate all unnecessary structural weight. Because of this extensive testing it is possible to design to much smaller margins of safety than in most other fields. Unlike other structures, for which the maximum anticipated loads are multiplied by a safety factor and the resulting product required to be less than the proportional limit of the material, aircraft design practice merely requires that the maximum anticipated loads shall be less than the proportional limit of the material, and that these loads when multiplied by a safety factor of the order of 1.5 shall be less than

FIG. 22. — STABILITY CRITERIA

the ultimate strength of the material.

1. Wing Design.—The aircraft wing is probably the most difficult structure to design, because of the fact that air loads produce large bending moments while aerodynamic considerations require that the beam carrying these loads be thin, the maximum depth being limited by the maximum thickness of the airfoil section employed. In addition to the lift loads it carries, the wing is also subjected to drag loads in the chordwise direction, and to a torsional load arising from moments created by the basic section and by any high-lift devices that might be employed.

In order for the wing to carry these loads, design techniques have been developed which concentrate the main structural load-carrying members as far from the neutral axis as possible. This means that the skin giving the wing its aerodynamic shape must be highly stressed. To keep it from deforming under load, particularly under compressive loads, use is frequently made of stiffeners or stringers running in the spanwise direction.

Another method which has found considerable application is the use of sandwich construction, in which the material actually withstanding the applied loads is stiffened by a low-density core which might be constructed of balsa wood, plastic or thin aluminum sheets formed into a honeycomb-type structure placed edgewise between the two cover plates. The bond between the core and cover plates may consist of any one of a number of high-strength resins.

Irrespective of the type of construction employed, the designer has to exercise great caution to ensure that the mass distribution of the structure and its elastic constants are adjusted in such a way as to damp any vibrations that might arise from unsteady or vibratory aerodynamic loading. The study of the deformation of the aircraft structure under load comes under the heading of aeroelasticity, and its response to vibration comes under the heading of flutter.

Although the wing is probably the most critical element of an aircraft structure, the same general structural techniques are employed for all other elements, and the search continues both for better materials and for better ways of operating higher-strength structures.

2. Temperature Considerations.—Another problem which has become of increasing importance as the speeds of aircraft have become higher is that of temperature. The temperatures associated with the very high energies dissipated during re-entry of a missile are frequently above the melting point of most materials. Even the temperatures associated with the leading edge of airplanes in supersonic flight are high enough to reduce severely the strength characteristics of the structural materials.

Three methods have been used to overcome the temperature problem. For certain missile re-entry applications, it is possible to construct the body with a shielding of material that is designed to absorb the heat generated during the re-entry maneuver by merely melting or burning away the shielding, leaving the main structure undamaged. In cases where such an approach would be unsatisfactory, efforts have been made to combat the temperature by utilizing cooling systems such as bleeding water under pressure through the leading edge and absorbing the excess heat by converting it to steam. At lower speeds, merely switching to temperature-resistant materials, such as stainless steel or titanium or even certain aluminum alloys, has proved to be a very satisfactory approach.

AERONOMY, the study of that part of the earth's atmos-

phere in which ionization and dissociation are important phenomena; *i.e.*, the part above about 20 mi. The word gained in usage after 1954 when it was incorporated in the name of the International Association of Geomagnetism and Aeronomy. It has been justified as a science distinct from conventional meteorology because it involves techniques of astrophysics, physics, chemistry, radio propagation and rocket and missile technology as well as meteorology. See also ATMOSPHERE; IONOSPHERE. (H. R. B.)

AEROPLANE: see AIRPLANE.

AEROSOL, a system of very finely subdivided liquid or solid particles dispersed in and surrounded by a gas. The earth's atmosphere, in which minute particles of many kinds are suspended, is an aerosol. In common parlance, however, an aerosol denotes a product dispensed from a pressurized container. Food products are pressurized with a compressed gas such as nitrous oxide or carbon dioxide. Nonfood products are generally packed with a propellant gas, usually a fluoro-hydrocarbon, in two-phase or three-phase systems.

In a two-phase system, the propellant gas in liquid form is mixed with a product, such as an insecticide or room deodorant. Released to the atmosphere, the liquid propellant vaporizes, causing the product to disperse in minute particles. Such dispersions in space are true aerosols. However, increasing the quantity of the product to between 20% and 75% of the total content produces a spray of material on a surface.

In a three-phase system, the product is contained between a layer of vaporized propellant occupying the top, or head space, of the dispenser, and a layer of liquid gas propellant at the bottom. When the actuating button is pressed, vapour pressure in the head space forces the product up the dip-tube and out the valve. The increase in head space resulting from the loss of product is filled by vaporization of the liquid gas. Powders and foams are pressurized in three-phase systems. In foam packs, however, the liquid propellant and the product, such as a shaving cream, are present as an emulsion. Upon reaching the atmosphere, the liquid gas immediately vaporizes, whipping the whole into a foam.

AERSENS (AERSSSEN), FRANÇOIS VAN (1572–1641), Dutch statesman influential in his country's foreign affairs in the later phases of the war of independence against Spain, was born in Brussels, in the Spanish Netherlands, but went with his parents to the United Provinces. Educated at Leiden university, he was sent in 1598 to be the agent of the states-general at the court of France, where he was subsequently accredited ambassador. He favoured Johan van Oldenbarnevelt's policies until 1607, but supported Prince Maurice of Nassau in his fruitless opposition to the signing of the Twelve Years' truce in 1609. His position in France became so difficult after the death of Henry IV (1610) that he was recalled in 1613. He sided with Prince Maurice against Oldenbarnevelt in the bitter struggle which led to the latter's execution in 1619. Thereafter as a member of the states of Holland and of their delegation to the states-general he exercised a decisive influence on foreign policy, and was instrumental in concluding the Franco-Dutch treaty of 1635. He also took part in the negotiations for the marriage of William II of Orange and Mary Stuart (1641). He died at The Hague on Dec. 27, 1641. (E. H. K.)

'AERTSEN (AERTZEN, AARTSEN), PIETER (1508?–1575), Dutch painter, known for his meticulous renderings of still life and genre, nas called "long Peter" because of his height. He was born and died at Amsterdam. When a youth he distinguished himself by painting homely scenes, in which he reproduced articles of furniture, cooking utensils, etc., with marvelous fidelity. An excellent specimen of his style on a small scale, a picture of the Crucifixion, is in the Antwerp museum. Aertsen was a member of the Academy of St. Luke, in the books of which he is entered as *Langhe Peter, schilder*. Three of his sons attained to some note as painters.

AESACUS, a Trojan seer, son of Priam. He learned the interpretation of dreams from his grandfather Merops, by which he foretold that Paris would cause the destruction of Troy and argued

that the infant be exposed (which was unsuccessful). He committed suicide by jumping into the sea, grieving for the death of his wife, but Thetis changed him into a diving bird.

(T. V. B.)

AESCHINES (5th–4th century B.C.), Athenian writer of Socratic dialogues which were praised for their authentic portrait of Socrates, came from the Athenian deme of Sphettus and was still a boy or young man at the time of Socrates' death at which he was present (Plato. *Apology*, 33 e; *Phaedo*, 59 b). After an interval into which presumably the composition of his dialogues falls, he was attracted to Syracuse (c. 368–356 B.C.) by the temporary enthusiasm of Dionysius II for philosophy. He gained his livelihood by teaching rhetoric and writing speeches.

Of the dialogues passing under his name, seven were singled out by ancient critics as genuine; these were entitled *Miltiades*, *Callias*, *Axiochus*, *Aspasia*, *Alcibiades*, *Telauges* and *Rhinon*. At least four of them were in the form of a reported dialogue with Socrates himself as the narrator (a form perhaps imitated from Plato). The titles confirm the impression given by Plato that Socrates consorted on terms of familiarity with Athenians of high rank and members of the Periclean circle. Aeschines seems to have agreed with Plato rather than with Xenophon in his presentation of Socrates' tenets and manner of life. But the extant fragments are so scanty that any attempt to reconstruct the dramatic situation or argument of his dialogues is conjectural.

See Diogenes Laertius, ii, 60–64; editions of the fragments of the dialogues by H. Krauss (1911) and by H. Dittmar (1912); and A. E. Taylor, *Philosophical Studies*, ch. i (1934).

(D. J. A.)

AESCHINES (389–c. 314 B.C.), Athenian orator who advocated peace with Philip II of Macedonia and was a bitter political opponent of Demosthenes (*q.v.*). His father Atrometus lost his property during the Peloponnesian War, and Aeschines was brought up in humble circumstances. During his early career he held minor posts in the state service and was a professional tragic actor. He is first heard of as prominent in public life in 338 B.C., when he served on a mission sent by the Athenians to Arcadia. Two years later he, like Demosthenes, was a member of the embassies to Philip II of Macedonia which resulted in the peace of Philocrates (see GREECE: *History*). During the negotiations he changed his policy in favour of Macedonia, and after the peace had been concluded Demosthenes together with a certain Timarchus prepared to prosecute him for treason. He retaliated by successfully indicting Timarchus for gross immorality. Aeschines' trial took place in 343 B.C., when he was acquitted by a narrow majority.

In 339 B.C., by provoking the Amphictyonic council to declare a sacred war against the Locrians of Xmphissa, Aeschines enabled Philip to enter central Greece as champion of the Amphictyonic forces. The bitter hostility between Aeschines and Demosthenes culminated in the years following the defeat of Athens and Boeotia at Chaeronea. In 336 B.C. Aeschines brought an action against a certain Ctesiphon for illegally proposing the award of a crown to Demosthenes in recognition of his services to Athens. The case was not heard until 330 B.C., when Aeschines was overwhelmingly defeated, largely, no doubt, because of Demosthenes' brilliant speech for Ctesiphon ("On the Crown"). He left Athens for Rhodes, where he is said to have taught rhetoric.

Aeschines was a political opportunist rather than a statesman. His own speeches suggest that he had little understanding of Philip's intentions or the wider implications of the struggle with Macedonia. There is, however, no evidence to support Demosthenes' accusation that he was a paid agent of Philip.

Three speeches by Aeschines are extant: (1) in accusation of Timarchus; (2) in defense of his own conduct on the embassies to Philip; and (3) in accusation of Ctesiphon. These appear to have been the only speeches which he wrote as opposed to those which he delivered extempore. They show a tendency to superlative expression and exaggeration, free use of rhetorical figures, variety of sentence construction, fondness for poetical quotations and ready wit. As a literary stylist he has imperfections, although there are fine passages. The effectiveness of his oratory was enhanced by his impressive voice and dignified bearing.

There are editions of the speeches by F. Blass, 2nd ed. in the

"Teubner Series" (1908); by C. D. Adams with Eng. trans. in the "Loeb Series" (1919); and by V. Martin and G. de Budé with French trans., 2 vol. in the "Budé Series" (1927–28).

(H. L. H.-W.)

AESCHYLUS (?525–456 B.C.), the earliest and perhaps the greatest Greek tragic poet of whom completed plays have survived. Without abandoning the lyrical and ritual character which can be assumed for early tragedy, he added the second actor (according to Aristotle), developed the possibilities of dialogue and pioneered the characteristic forms of the 5th century. The first-known writer to express in dramatic form that vision of life which is recognized as "tragic," he may well merit Gilbert Murray's description of him as "the creator of tragedy."

Life.—Son of Euphorion, a landowner of aristocratic family, Aeschylus was born at Eleusis in Attica. The known facts of his life are few. He fought at Marathon, where his brother Cynegeirus fell; and in his own epitaph, which he probably wrote himself, Marathon is mentioned to the exclusion of his poetic achievements. He doubtless fought at Salamis, a battle brilliantly described in his *Persae*, and perhaps also at Plataea. In his poetry the miseries of war are more prominent than its glories, though both were known to the full by his generation. Between 472 and 468 he visited the court of Hiero I at Syracuse, where he is said to have revived the *Persae* and to have produced in honour of the newly founded city of Aetna a play (*Aetnae* or *Aetnaeae*), part of the argument of which may be preserved on a papyrus. He revisited Sicily in 458 or later, and died there at Gela in 456. It is possible that among the western Greeks he became acquainted with the philosophy of Pythagoras. But this influence has not been demonstrated, nor has that of the famous mysteries at Eleusis, his birthplace. It is related on fair authority that, when he was accused of having violated their secrecy, he pleaded successfully that he had done so without knowledge. If in fact he was initiated, it seems unlikely that his thought was greatly affected by ceremonies mainly concerned with the life after death, a theme not prominent in his plays.

Plays.—Aeschylus won his first victory in 484, and was victorious not less than 13 times. The figure of 28, also given, may include victories won after his death, when he was granted the unique honour that his plays might be revived in subsequent competitions. One authority puts the number of his plays at 90, including satyr plays as well as tragedies; about 80 titles are known. Seven tragedies only have survived entire.

The *Persae* was produced in 472; the *Septem contra Thebas* (Gr. *Hepta epi Thebas*, "Seven Against Thebes") in 467; the *Agamemnon*, the *Choephoroi* ("Libation bearers'!) and the *Eumenides*, which together constitute the trilogy of the Oresteia, in 458. The dates of the other surviving plays are unknown. Most scholars are now inclined to place the *Prometheus Vincetus* (Gr. *Prometheus desmotes*, "Prometheus Bound") late. The *Supplices* (Gr. *Hiketides*, "Suppliant Women"), because of archaic features in its technique, was generally regarded as the earliest extant play, until the publication in 1952 of a fragmentary argument on papyrus which implies that the trilogy of which the *Supplices* formed part was produced in competition with Sophocles, who first competed in 468; there is an indication that 463 may be the date. Though doubts still remain, it can no longer be assumed that this is an early play. There is thus no certain knowledge of the early work of Aeschylus.

Persue.—This play is unique in two important respects. (1) Each competing poet was required to produce three tragedies and a satyr play. It was evidently the practice of Aeschylus, at least in his later period, to link his three tragedies closely in subject matter and treatment—to write, that is to say, trilogies or (including the satyr play, which took its subject from a related myth) tetralogies. The trilogy, which may have been his own invention, enabled him to transcend the temporal limits imposed on each single play by the chorus: to achieve a grand architecture and to explore the problems of human destiny upon an extended scale. How he handled this form at the height of his powers can be seen in the Oresteia. The *Septem*, the *Supplices* and the *Prometheus* all formed part of trilogies; and various lost tragedies

can be grouped together in this way. But between the tragedies of 472—(asterisk indicates a lost play) Phineus*, Persae, *Glaucus Potnieus**—there is no obvious link of any kind. (2) The Persae is the only extant Greek tragedy on a theme taken from contemporary history. Phrynichus had produced his *Miletou halosis** ("Capture of Miletus") about 493; his Phoenissae* of 476 (?) had dealt with the defeat of Xerxes at Salamis, and it was to this theme that Aeschylus returned in 472.

Aeschylus treats his historical subject with some freedom; and patriotic exultation takes second place to a broad religious view. The action is of archaic simplicity. The play opens with the chorus of Persian councilors. Concerned that no news has come from the great expedition, they declaim and sing for 150 lines before the entry of the first character—the mother of Xerxes. She tells them of an ominous dream. A messenger brings news of the disaster of Salamis. The return of the humiliated Xerxes and the lamentations between king and chorus with which the play ends are delayed, while the spirit of the dead Darius is evoked from his tomb. The use by Aeschylus of overwhelming spectacular effects was noted by ancient critics. Such an effect is the evocation of Darius, but it is not used for mere sensation: Darius is central to the play, for it is his function to expound the moral order of Zeus and so give meaning to the events.

Septem contra Thebas.—This play was the third of a trilogy dealing with the well-known legend of Laius, Oedipus and his sons. It is uncertain how the earlier events were distributed between the first two plays, *Laius** and *Oedipus**, but, clearly, after Laius had disobeyed the oracle and begotten a son, the family had been doomed and the city endangered. When the Septem opens, Oedipus is dead; Thebes is besieged by an army of Argives come to place Polynices on the throne; his brother Eteocles leads the defenders. The action is again extremely simple, but, unlike the Persae (and the *Supplices*), the play opens with a prologue scene. This difference in technique may be connected with the fact that, whereas in the Persae there is little interest in individual personages as such, the dramatic issues are here focused upon Eteocles, both "captain of the ship of state" and son of Oedipus, whose decision to fight his brother is the climax of the play. It is to this decision that the earlier scenes lead up. When the chorus of frightened women break in tumultuously, Eteocles, to calm their fears, promises to fight as one of the seven champions at the gates; and at the seventh gate he is to meet his brother in fratricidal combat. Toward this combat dramatic tension is built up in the most striking—and archaic—scene of the play. In seven pairs of speeches, a scout describes the enemy champions and Eteocles posts a defender against each. But at the seventh gate the foe will be no Argive, but the Theban Polynices. Eteocles recognizes the fulfillment of the curse of Oedipus, that his sons should divide their inheritance with the sword. Soon the messenger reports that the brothers have killed one another, but the city has been saved. (There is grave doubt whether the end of the play in the extant text is genuine; most scholars think that the decree forbidding the burial of Polynices has been imported for a revival subsequent to the *Antigone* of Sophocles.)

Supplices.—Of the Danaid trilogy the first play alone is extant. The archaic features which led to belief in its early date are evident. The play opens, like the Persae, with the chorus, to which well over half the lines belong. The dramatic interest is in their fate, and the dramatic tension is largely generated through their songs. They are the 50 daughters of Danaids, who have fled with their father from Egypt to Argos, home of their ancestors, to escape a hated marriage with their cousins, the sons of Aegyptus. They appeal for protection to the king of Argos, who is confronted with a dilemma: war, if he protects them, or the wrath of Zeus, if he rejects the suppliants. He decides to commend their case to the people of Argos, who have the final word. This word is favourable, but a herald lands from the Egyptian fleet and with barbarous violence seeks to drag the suppliants from the altars at which they have taken refuge. They are saved by the king; and the play ends with the Danaids and their handmaidens on the way to safe quarters in Argos, the Danaids singing to Artemis, their handmaidens (surprisingly) to Aphrodite. The *Supplices* was followed by the

Aegyptii* and Danaides*. It is probable that after a battle in which the king was killed the city was besieged. It is certain that the Danaids were given as brides to their cousins, but on the counsel of Danaus slew their husbands on the wedding night, with the exception of Hypermestra, who spared Lynceus and by him became the ancestress of the Argive kings. In the Danaides*, Aphrodite appeared, proclaimed her universal power, justified Hypermestra and (it may be) reconciled her sisters to the state of marriage.

Prometheus Vincetus.—Prometheus, who in defiance of Zeus has saved mankind by the gift of fire, is riveted to a Caucasian rock. There he is visited by the chorus of ocean nymphs, by their father Oceanus, by the "cow-headed" Io (another victim of Zeus) and finally by Hermes, who vainly demands from him his knowledge of a secret threatening the power of Zeus. At the end of the play Prometheus sinks into Tartarus for further torture. A motionless hero, and a minimum of action; much of the play is taken up with long expository speeches, as he recounts to the chorus his services to mankind or prophesies to Io her future wanderings (there is a strong geographical interest in Aeschylus) and her glorious destiny. The drama resides in the clash between the irresistible power of Zeus and the immovable will of Prometheus, rendered more stubborn still by Io's story. It has been doubted whether this is the first or second play of a trilogy, though the former is more likely, and whether the trilogy was ever completed, though this play was certainly followed by the *Prometheus Iyomenos* ("The Loosing of Prometheus") and perhaps by the *Prometheus pyrrhoros* ("Prometheus the firebearer"). (Few have accepted the view, advanced on stylistic and other grounds, that Aeschylus was not the author of the play.) It appears that in the sequel Heracles, descended from Io, shot the eagle that feasted on the liver of Prometheus and loosed him from his bonds. Zeus and Prometheus must have been reconciled, but it is not known how this was achieved, nor how Aeschylus developed the most controversial feature of the *Prometheus Vincetus*—that Zeus is there presented as a tyrant.

Oresteia.—This trilogy deals with the criminal history of the house of Atreus. In the Agamemnon the conqueror of Troy returns to Argos to be killed by his wife Clytemnestra in vengeance for the sacrifice of their daughter Iphigenia before the Trojan war. In the *Choephoroi* his son Orestes avenges his father by an act of matricide. In the Eumenides Orestes is pursued by the furies (Erinyes) of his mother, first to Delphi, where he is purified by Apollo, then to Athens, where he is acquitted before the court of the Areopagus. (Such a change of scene is uncommon in Greek tragedy.) The trilogy forms a single artistic whole unified by the themes which run throughout its length, but each play has its own dramatic action, its own tone and character.

The Agamemnon is the most complex, as it is the longest, of the plays of Aeschylus. It is complex in exposition; and, as facts and implications are gradually revealed through the speeches of the watchman, of Clytemnestra, of the herald and above all through the songs of the chorus of elders, so foreboding accumulates, up to and beyond the entry of Agamemnon. Though Aeschylus now has three actors at his disposal, he is still using in the main an old technique. The choral odes bulk large; scenes are often between one actor and the chorus; genuine dialogue is rare—the greater, therefore, the effect when Clytemnestra persuades her husband to enter the palace treading on scarlet draperies. In no scene are there three speaking parts; Cassandra the prophetess is silent while Clytemnestra and Agamemnon are on the stage. Alone with the chorus, she weaves past, present and future into a single fabric as the poet weaves them in his trilogy: it is the masterstroke of Aeschylus. But the play is dominated by Clytemnestra. Characterization in Aeschylus is and remains austere and limited, but he can now place a person vividly in the centre of the stage with a power that foreshadows Sophocles. Minor characters are now naturally portrayed: the watchman, the herald—and the nurse in the *Choephoroi*.

The *Choephoroi* contains a recognition and an intrigue: Electra recognizes her brother Orestes on his return from exile, and with him plots the deaths of Aegisthus and Clytemnestra. The action moves more rapidly, and the old nurse of Orestes is used to make

it go forward. But, compared with the wide horizons of the *Agamemnon* (which embrace the sack of Troy), the interest is sombrely concentrated upon the theme of vengeance through matricide. The most elaborate and impressive feature in the play is lyrical, when son and daughter join with the chorus of palace slaves in invoking the aid of the dead Agamemnon from the earth.

The *Eumenides* is a play of gods; even the chorus is divine. It is a play of brilliant variety and scenic effect: at Delphi, where Orestes is disclosed in the shrine of Apollo surrounded by sleeping furies; at Athens, when the furies dance round Orestes and sing their binding song, when Athena empanels the Areopagus and Apollo enters to conduct his defense. After Orestes has gone free, Athena persuades the furies to accept worship at Athens, and the play ends with a procession, as, scarlet-robed and singing good songs, they are escorted by torchlight to their new home in the rock.

Staging. — Apart from the *Oresteia*, no play certainly demands a substantial edifice in the background. Visual attention was then concentrated upon costume and grouping, upon the chorus in the orchestra, for whom Aeschylus devised new dance movements. There were often large numbers to be deployed in and behind the dance floor, when supplementary choruses, as in the *Supplikes* and the *Eumenides*, and other supernumeraries, were employed. The *Oresteia*, however, not only requires a solid structure in the background to represent palace and temple fronts, but Aeschylus there seems to have used the *eccyclema* or wheeled platform to expose an indoor scene. His use of other stage devices, e.g., the crane, particularly concerns the staging of the *Prometheus*, on which there is little agreement.

Style and Structure.—Aeschylus can write with great simplicity, and to humbler characters he sometimes gives colloquial turns of speech. But in general his style, both in lyric and dialogue, is grand. His vocabulary owes much to his epic and lyric predecessors, though he was doubtless a bold innovator in his own right, particularly in the coinage of those compound epithets which are characteristic of his diction. But the richness of his style is seldom, if ever, used for mere decoration. The firm dramatic control being most evident in his later work. In the bold use of metaphor Aeschylus has no peer but Pindar. While he can elaborate a single figure, he does not hesitate to combine different metaphors and may sometimes be felt to have strained figurative language almost to its breaking point.

It is characteristic of Aeschylus to sustain an image or images throughout a play: the ship of state in the *Septem*, the birds of prey in the *Supplikes*, the snare in the *Agamemnon*. Such sustained images perform a structural function, but are only a special case of a more general aspect of his art, which is the deployment throughout a play or trilogy of leading themes, often associated with a particular word or group of words. In the *Oresteia*, for instance, such themes as wrath, mastery, persuasion and the contrasts of light and darkness, dirge and triumph song, run throughout the trilogy. Another point of style and structure is the use of symmetry and correspondences. A minor aspect of this artistic method shows itself in the way that speeches, odes and scenes constantly recur at the end to a word or theme from the beginning (sometimes called ring composition). But major symmetries are visible in the shaping of whole plays. In the *Persae*, themes from the earlier part of the play recur toward the close with the effect of isolating the Darius scene (from which they have been absent) and establishing its dominance in the thought structure of the play. The same pattern of action and emotion is repeated from the *Agamemnon* to the *Choephoroi*; and there is reason to suppose that a similar correspondence existed between the *Prometheus* and its sequel. Such principles of construction have been traced in Homer and, thanks to Pindar, can be inferred for the earlier lyric poetry: they are wholly consonant with the sense of form which the Greeks displayed in their visual art. The appreciation of them is a valuable aid in the interpretation of the dramatic thought of Aeschylus.

Dramatic Conceptions.—Aeschylean tragedy deals with the plight, decisions and fate of individuals, but the destiny of the community is also at stake; both individual and community stand in close relation to the gods. Personal, social and religious

issues are integrated, as they still were in the Greek civilization of the poet's day.

The concern of Aeschylus with the events of his own time is most obvious in the *Persae*, where he interprets a contemporary event as though it were myth. In dealing with the mythical subject matter of the *Oresteia*, he is not without thought for the political circumstances of his own day. That he hints in passing at a recent alliance between Athens and Argos is a minor matter: more important is the establishment of the Areopagus as a court to try cases of homicide. To this function the ancient council had been all but confined by the democratic reforms of 462; in dignifying it Aeschylus may well be accepting and commending the new order in the state. But if so it was not mere propaganda; murder and feud might be incidents in political strife, and it was essential that the state should control the punishment of homicide—a primary issue of the trilogy. Again, it was in the lifetime of Aeschylus that the reforms of Cleisthenes had sought to reduce the political power of the clans; and it has been plausibly suggested that the Theban trilogy dramatizes the disentanglement of the fortunes of clan and state, the guilty family being annihilated without bringing ruin on the city.

A different social question occupies the mind of Aeschylus both in the Danaid trilogy and in the *Oresteia*: marriage, and the right relationship of man and woman in society. This issue arises naturally out of the myth in the former trilogy; it is given stress in the *Oresteia* by the portrayal of Clytemnestra as a woman of manly and dominating character. It is hard to believe that Aeschylus treated this theme without thought of the social conditions of his time. To later generations he has often seemed to deal in a remote and awful way with the problems of theodicy in terms of strange and even barbaric myths. But, though the myths provided him with symbols, his thought was firmly rooted in his own experience of life, which for him as a Greek was political and social life. The gods were still at work in the world he knew; and to him a contemporary reference would in no way detract from the solemnity of his tragedy.

Theodicy, the justifying of God's ways to men, which was the concern of Milton, was in some sense also the concern of Aeschylus, though it might be truer to say that he aimed through dramatic conflict to throw light on the nature of divine justice. The Greeks had pondered much upon the operations of the gods. Though Homer had established the Olympian family with clear anthropomorphism, popular belief tended to think of divinity in vaguer terms; but in either case it was power rather than goodness that characterized the divine. It was commonly believed that the gods grudged human greatness, sent infatuation upon a man at the height of his success and so brought him to disaster. But his infatuated act was one of impiety or pride (Gr. *hubris*), for which his downfall could be seen as a just punishment. Thus the jealousy and the justice of heaven fought a battle in the Greek mind. The more articulate thinkers wrestled with this problem. Hesiod saw in Zeus, supreme among the gods, the guardian of a just moral order. But the unjust are not always punished in their lifetime: it is upon their descendants, according to Solon, that the punishment may fall. Aeschylus received a tradition of thought from Hesiod and Solon—belief in a just Zeus and in hereditary guilt. The simplest case is that of Xerxes and his Persians, who, as Darius says, were punished for their own offences. (*Persae*, 827 ff.) But in the *Agamemnon*, where the chorus explicitly rejects the doctrine of divine jealousy (750 ff.), Agamemnon is punished not only, through Clytemnestra, for his own slaying of Iphigenia, but also, through Aegisthus, for the sin of his father Atreus at the Thyestean banquet. Guilt haunts the house; and in the next phase Orestes, who kills his mother to avenge his father, is the sinner-victim, saved only at the last by divine interposition.

That divine justice punishes pride and impiety is certain for Aeschylus, but is not the end of the matter. Troy was punished for the sin of Paris; but the innocent suffered with the guilty; Iphigenia died as the inescapable preliminary to an act of justice. As for such a sinner as Eteocles or Agamemnon! how can he be responsible, if he is not free? How can he be free, if he is bound by evil heredity and divine compulsions? How can he be justly

punished, if he is not responsible? Early Greek thought had hardly clarified these issues; and the opinions of interpreters differ as to the insight with which they are handled by Aeschylus. To some it seems that he has envisaged with clarity and presented with power contradictions which still baffle the human intellect. The nearest perhaps that he comes to a formulation is when the chorus of the *Agamemnon* (1505 ff.) refuse to allow that Clytemnestra is without responsibility, while admitting that the avenging spirit of Atreus may be lending her his aid. Human action is both responsible and determined; and the same action can, as in Homer, be seen on two planes, divine and human. The divine justice uses human motives to carry out its decrees: among these motives is the desire for vengeance, basic to the ancient Greek scheme of values.

In the one complete extant trilogy the notion of retaliation is dominant. Retaliation is a motive of Agamemnon, Clytemnestra, Aegisthus and Orestes. Upon Orestes there is no human being to take vengeance, and it is the Erinyes—divine avengers—who seek to enforce upon him the *lex talionis*. But even before these grim earth boogies take up their role, *talio* has been seen as a principle of divine justice and human avengers as incarnations of an Erinyes. It was Zeus who sent Agamemnon as an Erinyes against Troy to do indiscriminate justice, and Apollo who commanded Orestes to kill his mother under threat of persecution by Erinyes. Justice is done, but crime is punished by crime, until at last we see the hideous aspect and hear the odious words of the divine avengers themselves. Here we touch the essence of the tragic thought of Aeschylus, but do not exhaust it. For the poet must not only end his trilogy, but solve his problem, must show that divine justice is more than the perpetuation of evil and that the Zeus to whom the chorus of the *Agamemnon* prayed does really teach by suffering (176 ff.). To this end the acquittal of Orestes upon an equal vote may be less significant than the institution of the Areopagus; more important still may be the reconciliation of the Erinyes by the persuasions of Athena and their transformation into Eumenides ("spirits of good will"). It will be more important, if those scholars are right who see in the contrast of force and persuasion a significant category of Aeschylean thought and find the most original product of his religious genius in the demonstration that the divine power operates through persuasion no less than through force. It may be that the solution of the problem of the Promethean trilogy was upon the same lines, that the Zeus first presented as the master of might and force was reconciled to his intransigent opponent by persuasion. It seems certain that in the Danaid trilogy sexual passion, which under the mode of violent pursuit gives rise to deeds of violence, was presented by Aphrodite toward the end of the trilogy as a persuasive influence. But it is in the *Oresteia* alone that the full facts can be studied. The trilogy ends with reconciliation and with joy in the triumph of good. That good could triumph was not the conclusion of a mystic or a metaphysician, but something based upon the poet's experience of life, in which perhaps the defeat of Xerxes counted for less than the fact that society showed some sign that its problems could be solved without violence. By setting up the Areopagus, Athena had shown a better way. She persuaded the Erinyes, and persuasion is the cardinal democratic virtue.

In writing tragedy which, for all its power in depicting evil and the fear of evil, ends with joy and reconciliation, Aeschylus has found few, if any, imitators. But this is only one of several conjunctions which make him unique. Master of an intricate verbal technique and an elaborate architectural structure, he is no less the master of spectacular effect and emotional crisis. Heir to the archaic poetry of Greece with its direct physical apprehension of emotion, living at a time when men could still feel themselves surrounded by gods, he had a capacity for general thought which was typically Greek and, in the judgment of many, treated the problem of evil with singular honesty and success.

Finally, this tragedian of superhuman stature was known as the best writer of satyr plays. It is astonishing that the sublime close of an Aeschylean trilogy could be followed by a grotesque treatment of myth, with a chorus of satyrs, as the *Oresteia* by the

*Proteus**, the Theban trilogy by the *Sphinx**. These plays are now lost, but papyrus finds of the *Diktyoukoi* ("Net-fishers") and the *Isthmiastae* show what lightness of touch Aeschylus could use in this genre, with what charm he could invest the traditional obscenity.

AESCULAPIUS: see ASCLEPIUS.

AESOP (d. ? 564 B.C.), famed as the composer of short animal fables, was regarded throughout classical antiquity as the exponent of fables par excellence. He used them to carry his point in debating or pleading with others in the conflicts of real life, but it is improbable that he wrote anything for publication. Similar fables had been employed in the wisdom literature of the Sumerians, Babylonians and Assyrians throughout the second millennium B.C., as well as by other Greek authors before him.

A slave most of his life, Aesop lived on the island of Samos in the early part of the 6th century B.C., being a contemporary of Solon and the so-called Seven Wise Men of Greece, with whom he is closely associated by writers from the 4th century B.C. onward. An inscription of 16 A.D. and the chronicle of Eusebius (fl. 4th century A.D.) fix his death at Delphi in 564 B.C. Since this was four years before Croesus became king of Lydia, it is probable that the tradition, known chiefly from Plutarch, which represents Aesop as adviser and diplomatic courier to Croesus originated in Alexandrian times by assimilation with stories about the Seven Wise Men at Croesus' court. The oldest information about Aesop comes from Eugeon (5th century B.C.) who according to the Suda lexicon said that he was a Thracian. It is probably Eugeon also, in his lost chronicle of Samos, who was the source for Herodotus' statement (2:134) that Aesop was put to death unjustly by the Delphians, whom he had offended or insulted, and for the tradition that he became the slave of Xanthus in Samos and later of Iadmon, who freed him. Aristophanes (*Wasps* 1446–48) relates that Aesop was accused by the Delphians of stealing a goblet from Apollo's temple, and told the fable of the eagle and beetle to the Delphians in pleading for his life, and Aristotle (*Rhetoric* 2:20) that he used the fable about the fox's ticks in defending a politician on trial for embezzlement at Samos.

A romantic biography of Aesop, written in Egypt in the first century A.D., has many stories about him: describing his outwitting of his master, Xanthus the philosopher, his sojourn with

Croesus, his career as minister and riddle-solver for King Lycurgus of Babylon (taken from the Assyrian story of Ahikar, *q.v.*), and his death at Delphi. This biography, of which the Byzantine scholar Maximus Planudes (c. 1300 A.D.) made a truncated edition, was first printed entire in 1952 from the only manuscript (10th century). Herein originated the idea of Aesop as physically ugly and deformed, on the analogy of Socrates. Demetrius Phalereus (fl. c. 320 B.C.) is probably the source of the statement widely made by later rhetoricians, and in the biography, that Aesop was a Phrygian by birth. There is no evidence for the improbable theory that a folk book about Aesop was written in the 6th or 5th centuries B.C.

The first-known collection of fables ascribed to Aesop, published in one short book by Demetrius Phalereus, has not survived, but it was extant in the 9th century, was apparently well known to the Greek rhetoricians as the official Aesop, and was probably the chief source used by Phaedrus for his Latin versification. The next oldest collection of Greek fables in prose, ascribed by an anonymous collector to Aesop and written probably in the 2nd or 1st century A.D., consists of about 230 fables and is known as the *Augustana* (first printed entire in 1812). This is independent of Babrius, who versified a number of Aesopic fables in the 2nd century A.D. and probably antedates him. In Byzantine times the prose fables of the *Augustana* passed into various shorter and slightly reworded recensions, which, together with a prose paraphrase and a few metrical adaptations of Babrius, constitute the entire corpus of Greek fables fancifully ascribed to Aesop in more than a hundred manuscripts. This corpus has not been influenced in any way by the Fables of *Bidpai* (*q.v.*) or any other Indian sources. The contents of modern editions have varied widely according to the manuscripts on which they were based. Planudes' selection, first printed in 1479, was long the standard one.

In antiquity the Aesopic fable was never popular literature. Normally it was told very briefly in a learned context for the sake of its metaphorical meaning. Fable collections in prose were made originally as repertoires for the use of writers and speakers. Phaedrus (fl. 1st century A.D.) was the first to publish fables in verse meant to be read consecutively as literature; and this classical precedent, together with that of Avianus (late 4th century A.D.), both very popular authors in medieval and early modern times and much used in the schools, sanctioned and made fashionable the publication of fable books as belles-lettres in the hands of such able stylists as Jean de La Fontaine, and as moral instruction addressed by writers of lesser artistic claims to both children and elders in innumerable translations, adaptations and imitations of "Aesop" throughout Europe. Like fairy tales told purely for entertainment, amusing stories about the clever or stupid actions of animals have always been popular in oral folklore, and never more so, perhaps, than in early modern times; but the recognition in intellectual circles of the Aesopic fable as wisdom literature—Luther reckoned it next to the Bible—gave it a far greater proliferation in literature than was possible for the fairy tale, which had no such sanction. See also *FABLE*.

BIBLIOGRAPHY.—All the Greek proverbs and fables ascribed to Aesop together with Latin translations as well as the lives and the references to him in classical literature are ed. by B. E. Perry, *Aesopica*, vol. 1 (1952). The Eng. trans. by S. A. Handiord (1954) is closest to the Greek text of the *Augustana*. See also B. E. Perry, "Fable," *Studium generale*, 12:17-37 (1959). (B. E. Pe.)

AESOPUS, CLAUDIUS, Roman tragedian, flourished in the 1st century B.C.

Cicero was on friendly terms with him. Aesopus made a last appearance in 55 B.C.—when Cicero tells us that he was advanced in years—on the occasion of the splendid games given by Pompey at the dedication of his theatre.

Horace (Sat. iii, 3, 239) mentions his taking a pearl from the eardrop of Caecilia Metella and dissolving it in vinegar, that he might have the satisfaction of swallowing £8,000 worth at a draught.

AESTHETICS (Gr. *aisthesis*, "sense perception") is the theoretical study of the arts and related types of behaviour and experience. Traditionally regarded as a branch of philosophy, con-

cerned with the understanding of beauty and its manifestations in art and nature (see *AESTHETICS, HISTORY OF*), it is still so classed by some writers. In the 20th century, however, there developed a tendency to treat it as an independent science, concerned with investigating the phenomena of art and their place in human life. The data for such study consist of (1) works of art in all media, to be analyzed, described and compared; (2) human behaviour and experience directed toward works of art.

Aesthetics studies all the arts, including music and literature, theatre, dance and film, as well as painting, sculpture, architecture, landscape design and town planning. It deals with the "useful" as well as the "fine" arts insofar as they appeal to aesthetic taste. When covering so broad a field, it is sometimes called general or comparative aesthetics. Some writers specialize on theoretical problems within a single art.

Modern aesthetics collects information from the older sciences and from every other source which may contribute to a fuller understanding of the arts and their changing roles in civilization. It makes especial use of psychology (including psychoanalysis and depth psychology) for the light it throws on the processes of artistic creation and appreciation, including the symbolic meaning and emotional effects of various images. It looks to the social sciences, such as anthropology, for information on the ways in which the arts have fitted into the cultural patterns of different peoples and periods. It draws upon the histories of the various arts and on cultural history in general, but differs from them in organizing its materials and conclusions in theoretical rather than chronological order. General theories of art history are on the borderline between aesthetics and history. Aesthetics is also closely related to art criticism, but differs in emphasizing general principles and problems in that field, rather than the merits of particular artists or works of art. It examines the standards used in evaluation and criticism. As an empirical subject, it is regarded as primarily descriptive; *i.e.*, concerned with discovering and generalizing on the facts of art and related human activities. It does not abandon the problem of value, but approaches it more indirectly through a search for fuller understanding of the actual nature, functions and effects of art, which need to be considered if evaluation is to be more than a mere dogmatic assertion or expression of personal taste. Modern aesthetics makes no claim to proving universal laws of value, but seeks to provide relevant knowledge and methods which may help to make evaluation more informed and intelligent. It does not ignore the subject of beauty, but is less narrowly devoted to the task of defining "the beautiful," "the sublime," "the ugly," etc., than traditional aesthetics. Instead, it tries to describe the many specific processes and configurations involved in aesthetic experience, both in the observer and in the work or other object which stimulates it. Defining such terms as "beautiful" is seen as partly a semantic problem for which there is no one right answer; the main task is to analyze the various phenomena to which such terms are applied and then to seek more adequate ways of describing them verbally. The concept of beauty holds a less pre-eminent place in modern than in traditional aesthetics, being only one of many aspects of art and aesthetic experience which calls for investigation. This reflects the tendency of contemporary artists to aim at other qualities and of critics to put less emphasis on beauty in judging the value of art.

Origins and Development.—Some disagreement about the proper definition of aesthetics survives from the conflict of rival schools of thought in philosophy and art criticism during the 18th and 19th centuries, when it first achieved recognition as a distinct field of knowledge and inquiry. In France and England during the Enlightenment (*q.v.*), theories of art and beauty followed a naturalistic, empirical approach, but toward the end of the 18th century, beginning with Immanuel Kant's *Critique of Aesthetic Judgment* (1790), this empirical approach was temporarily overwhelmed by the powerful influence of German idealism, and the approach to beauty and art became more metaphysical and transcendental, more devoted to the search for a priori, universal principles of beauty and aesthetic value.

The empirical study of works of art continued along other lines,

however, and that of aesthetic psychology revived soon afterward. The former continued in the researches of 19th-century anthropologists and archaeologists on primitive and prehistoric art and in those of art historians on historic styles, especially in architecture, painting and sculpture. A leader in this renewed attempt at a science of art was Hippolyte Taine, who in 1864 proposed that styles of art should be studied in the same way as the kinds of plants are studied by the botanist and as subject to evolutionary development. In Germany the name *Kunstwissenschaft* was applied to the historical writings of Gottfried Semper, Konrad Fiedler, Jacob Burckhardt, Alois Riegl and Heinrich Wölfflin on the history of styles in the visual arts. These writers strove for objectivity in comparative analysis, through the avoidance of personal value judgments, and sought to understand each style as the expression of a certain way of seeing, thinking and feeling. They also sought to explain, in various ways, the causation of stylistic change: some attributing it to economic or technological factors; some (especially Riegl) to a collective will or striving toward some type of form; some to factors inherent in art. Such *Kunstwissenschaft*, restricted to a certain art or group of arts, was both historical and theoretical; it aimed at a grasp of underlying trends and principles rather than a superficial account of individual artists and their works.

In the meantime aesthetics in the narrow sense, as the study of aesthetic experience rather than of art, was also being recalled to scientific aims and methods. It gradually became not only the "philosophy of beauty" but also the empirical psychology and sociology of artistic creation and appreciation. Chief leader in this revival was G. T. Fechner (1801–87), whose *Vorschule der Ästhetik* (1876) proposed an approach to aesthetics "from below" — that is, by observation of particular phenomena — rather than "from above." — by deduction from metaphysical assumptions. His so-called "experimental aesthetics" (also called "laboratory" or "biometric" aesthetics) emphasized the statistical study of individual aesthetic preferences for standardized types of object, such as rectangles of certain sizes. Because of its reliance on exact measurement it has sometimes been regarded as equivalent to scientific aesthetics in general; but it is only one of many approaches in that general direction. It was actively developed early in the 20th century by such psychologists as C. W. Valentine and Edward Bullough in England, Lightner Witmer in the United States and Charles Lalo in France, but declined in activity after World War II. An initiator of another main line of psychological investigation was F. T. Vischer (1807–87), who formulated the theory of empathy (*Einfühlung*) in his *Ästhetik oder Wissenschaft des Schönen*, first published in 1836. It describes how the observer of a work of art or other aesthetic object tends to project his own feelings into it, exploring its form imaginatively and deriving therefrom an enjoyment similar to that of play. (Schiller, Herbert Spencer and others also noted the analogy between art and play.) Theodor Lipps developed this hypothesis in detail (*Ästhetik*, 1903–06), showing how the process of empathy is not purely subjective but dependent for its satisfaction on the nature of the work of art. Hence both subjective and objective phases in aesthetic experience must be studied in their interrelation. Other important contributions to aesthetics were made from the standpoint of psychoanalysis (notably by Sigmund Freud and C. G. Jung) and from that of Gestalt psychology (for example, in K. Koffka's *Problems in the Psychology of Art*, 1940).

Most important of all is the general, naturalistic account which modern psychology has provided of human nature in all its integrated functions, including those which operate in art. This includes the evolutionary account of the human species with its innate perceptual, mental and affective functions, predispositions and aptitudes, especially man's power to learn and to accumulate culture. It includes the unconscious and preconscious realms of human experience as revealed by depth psychology, with the light it throws on dreams and creative imagination. General psychology provides a framework within which aesthetics can focus its special studies on the creation and appreciation of art and related varieties of experience.

The social sciences, especially anthropology, sociology and cul-

tural history, have provided another framework for aesthetic theory in their accounts of the various culture patterns which man has developed in successive periods in different parts of the earth. In these, the arts are more fully understood as 'interacting with economic, technological, social, political, religious and intellectual factors, as well as with natural conditions and resources. Art is shown as profoundly influenced by these and as expressing aspects of them in its varied forms, but also as affecting them in return, especially in advanced civilizations.

Early in the 20th century Max Dessoir, professor at the University of Berlin, sought to enlist the co-operation of many different approaches under the double name "aesthetics and general science of art." This implied that aesthetics was still to be understood in the early, narrow sense as philosophy of beauty, but that a new, empirical science of art was to be recognized as allied and parallel with it. A more synthetic and general (*allgemeine*) kind of *Kunstwissenschaft* was to be formed through integrating the specialized historical and critical studies. The "double-barreled" name was used as the title of a society and a quarterly review, the *Zeitschrift für Ästhetik und allgemeine Kunstwissenschaft*, which Dessoir edited from 1906 until the time of Hitler. However; it did not find favour outside of Germany, and since World War II the single term aesthetics has been more commonly used instead, in a sense broad enough to include all the various lines of research and schools of thought.

The work of synthesizing the prerequisites for a broadly scientific study of art, that had been accumulated since the latter years of the 19th century, was undertaken by scholars in the field with the aid of universities, museums, libraries, research foundations, professional societies and periodicals. One of the most important comparatively new resources was the greatly increased supply of works of art for observation and comparative analysis. Until the late 19th century, there was little opportunity in Europe or in the United States for intensive study of oriental, archaic and primitive types of art. European aesthetics was accordingly restricted to generalizing mainly on the styles and guiding principles of European art from the classical Greek and Roman through the Renaissance and baroque styles which had been deeply influenced by the classical. In the 20th century, however, a flood of art works in all media from China, Japan, India, Indonesia, Iran, Arabia, Egypt, Negro Africa, the Pacific islands and the western hemisphere became available to scholars. This vastly greater sampling of the world's art profoundly affected the theories of aesthetics. Confronted with such diversity, western scholars became more modest and more relativistic in their standards of value. They saw that modern western art, though possessed of many important values, is not the only good or important kind; that the rules and standards developed by western philosophy and criticism cannot be assumed as valid for art in general; and that each style of art had to be understood and appreciated in terms of the aims and value system of the group wherein it was made. It was learned, moreover, that nonwestern as well as western civilizations had much to say on the philosophy of art: for example, the theory of *rasa* (aesthetic flavour) in Indian aesthetics.

The Scope of Modern Aesthetics.—As a result of the convergence of these many approaches, each providing new materials and concepts, aesthetics gradually developed new divisions and subdivisions as a large, diversified science. Among theoretical studies focused on the arts, there are (1) systematic classifications of the arts (the arts and their interrelations); (2) aesthetic morphology (the descriptive study of form and style in the various arts); (3) theories of art history (evolutionary and other hypotheses about the main trends, patterns and causal influences in the sequence of styles with the study of the relations between art and other cultural factors). Among studies focused on human behaviour and experience in relation to the arts are: (1) aesthetic psychology, the subjects of which include the nature of the artist and the processes involved in artistic production, the relations between art and personality and children's art expressions; (2) the sociology of art, including the economics, anthropology and cultural history of art; (3) the logic, semantics and semeiology of

art, dealing especially with language, signs and symbols, concepts, propositions and inferences used in discussing art; and (4) the epistemology and ontology of art, which examine the nature of the work of art or other aesthetic object in relation to existence and to human knowledge. A third main division must be recognized for the subject of aesthetic value theory or axiology, since it requires attention to both the work of art and the observer or user in almost equal degree and involves (1) a knowledge of the various types and styles of art and of their relations to human nature, individual and social; (2) of the kinds of effect that they tend to have on various types of person under various conditions; and (3) of the relation of such effects to various ideal goals and standards of value, including moral and practical as well as aesthetic.

Principal Exponents.—The theories of past and present philosophers still provide enlightening hypotheses. Idealism as developed from Plato through Hegel and Emerson and dualism as set forth by St. Thomas Aquinas, Descartes, Jacques Maritain and others still hold many followers especially in Germany, France and Italy. These traditional philosophies maintain that art is essentially spiritual and supernatural; that the work of true art is a sensuous manifestation of eternal ideas; and that it can reveal divine truths and point the way to higher values in the next life. Naturalistic and empiricist philosophers stress rather the natural basis of art in man's animal origin and evolution, its sensuous forms and the impossibility of separating it from man's practical, social activity. At the same time, they recognize its value in serving ideal goals through the improvement of experience in this life on earth. The empiricist trend toward science in aesthetics, strong in the United States, France and England, is derived from the humanism of Aristotle's *Poetics*, Lucretius, the naturalism of the French Enlightenment, Hume, Edmund Burke, Auguste Comte, Herbert Spencer, Taine, George Santayana and Lalo. The pragmatism of John Dewey has also helped to shape it. Long overshadowed by the prestige of German transcendentalism, this tradition revived in Europe toward the end of the 19th century and now dominates American thinking in the field.

In England, Herbert Read, a leading writer on aesthetics, approached the subject mainly as a poet and critic of the visual arts. In British philosophy and in American philosophy under its influence, the school of thought known as logical positivism (*qv*) achieved wide influence after World War II. Its occasional discussions of aesthetics were highly specialized on semantic, logical and epistemological problems—not so much on the phenomena of art or aesthetic experience as on the language used for discussing them and the logic of inferences made about them. In Europe and South America, the phenomenology of Edmund Husserl and the existentialism of Soren Kierkegaard, Martin Heidegger, Karl Jaspers and Jean-Paul Sartre were applied to aesthetics, most explicitly by Sartre in his philosophic and literary writings. Aesthetics and criticism in the U.S.S.R. and other Communist countries were dominated by the theories of art developed by Marx, Engels, Georgy Plekhanov, Lenin and others. They emphasized the economic determination of styles in art as a phase in the dialectical process of cultural evolution and the role of art in strengthening (or sometimes undermining) the current socio-economic order at various periods of history. Selected aspects of the Marxist or sociological approach are accepted in modified form by many noncommunist writers, in stressing the influence of socio-economic factors in art history.

General Characteristics.—Modern aesthetics does not expect to discover exact, permanent laws like those of physics, but only approximate accounts of recurrent types and tendencies, correlations and causal connections. The phenomena of art and taste are obviously among the most variable, complex and often intangible of those presented to scientific inquiry. They vary somewhat from person to person, from culture to culture, from period to period; their changing and unique aspects are often among their most important. They cannot be reduced to fixed, numerical formulas, but they are not completely unique or chaotic, and it is the business of aesthetics to describe both their constant and their variable aspects. Where direct sensory observation is im-

possible, as in the case of past events and inner experiences, all available clues to their nature can be examined, including those of introspection. Along these lines, aesthetics is trying to achieve the status of an empirical science in spite of the serious difficulties involved in interpreting the data.

Opinions differ as to whether aesthetics is now a science or can ever become one, in the strict sense of that word. If the concept of science is limited to subjects in which exact measurement and logical proof are highly developed, as in mathematics and physics, then aesthetics cannot be a science. Attempts at the measurement of aesthetic phenomena by laboratory and statistical devices have achieved comparatively little of importance. Much of the central subject matter of aesthetics remains inaccessible to exact measurement. But there is a broader sense of science which includes the rational pursuit of knowledge by other means where measurement is impossible; that is, by controlled, systematic observation and logical inference, eliminating guesswork, personal bias and subjectivism as far as possible; by testing hypotheses and comparing results to achieve the utmost objectivity and a gradual increase in the reliability of generalizations. As an attempt to set up absolute laws of value and beauty, traditional aesthetics could not achieve even this modicum of scientific status; but as an attempt to discover the facts about art, modern aesthetics has made considerable progress.

Two other criteria of scientific status are also, in some degree, within the reach of empirical aesthetics: namely, prediction and control. Through systematic observation and experiment, we can gradually learn the effects of certain types of art on certain types of persons under certain conditions. Understanding these general tendencies, even in a rough, approximate way, enables one to predict with some reliability what the effect will be in a particular case. Such knowledge has been applied for centuries in the use of art for political, military and religious propaganda and, in modern times, for commercial advertising. Only a slight beginning has been made toward the scientific investigation of the psychological and social effects of art. Education, both general and artistic, is one potential laboratory for testing the effects of different kinds of art and activity on different kinds of persons.

Obviously the power to control the human mind by art may be used for bad ends as well as good: for destructive or mercenary ends or far-reaching benefit. It is part of the task of contemporary aesthetics to consider how the power of art and of knowledge about art can be devoted to the best possible ends, such as the enrichment of experience, the development of mental powers and better social and material conditions. It is not assumed that art should be actively used or regulated by governments or other social agencies as a means of social improvement, but as pressures grow to use its resources for commercial, political and other interests not always consistent with public welfare, society is forced to take more careful note of them and to decide the extent to which it wishes to adopt collective policies in the realm of art—perhaps only to protect individual freedom and initiative, as through laws of copyright and free press.

Organization.—The international leadership in aesthetics which had long been exercised by German scholars ceased with World War II. The *Zeitschrift für Ästhetik und allgemeine Kunstwissenschaft*, edited first by Max Dessoir and later by Richard Miiller-Freienfels with the co-operation of a distinguished list of writers, ceased publication in 1943, though steps toward revival in Germany were taken in the series of yearbooks on aesthetics, edited by Heinrich Lutzeler from 1951. Meanwhile, other countries carried on more actively. French aestheticians, led first by Victor Basch, then by Charles Lalo and then by Étienne Souriau at the Sorbonne, organized before the war an Association pour l'Étude des Arts et les Recherches Relatives à la Science de l'Art. Revived in 1945 under the simpler name Société Française d'Esthétique, it began publishing a quarterly *Revue d'Esthétique* in 1948. In the United States, the quarterly *Journal of Aesthetics and Art Criticism* first appeared in 1941, being edited from 1945 by Thomas Munro. The American Society for Aesthetics, founded in 1942, publishes it under the auspices of the Cleveland Museum of Art and Western Reserve university in

Cleveland, O. The British Society of Aesthetics was founded in 1960, with Sir Herbert Read as president. It publishes the *British Journal of Aesthetics*, with Harold Osborne as editor. In Tokyo there is a Japanese Society for Aesthetics and a quarterly, *Bigaku* ("Aesthetics"), sponsored by the faculty of letters of Tokyo university. In Spain the Instituto Diego Velázquez (Madrid) publishes its *Revista de Ideas Estéticas*. In Italy, at the University of Turin, the Instituto di Estetica publishes a quarterly *Rivista de Estetica* (1956 ff.) under the editorship of Luigi Pareyson. A congress on aesthetics was held in Berlin in 1913 by Dessoir and his group; a second, more international in scope, in Paris in 1937 under the leadership of Paul Valéry, Paul Claudel, Victor Basch and Charles Lalo; a third in Venice in 1956, with Luigi Pareyson as chairman of the executive committee; and a fourth in Athens in 1960, with P. A. Michelis as chairman. A standing executive committee was appointed to further international co-operation, with Étienne Souriau as chairman.

AESTHETICS, HISTORY OF. The history of aesthetics (*q.v.*) puzzles the student by its paradoxes. Aesthetics as a branch of philosophical inquiry was constituted under its now familiar name as late as 1750 by Alexander Baumgarten (1714–62), author of *Aesthetica*, a book in Latin which was never reprinted or translated into a modern language. If aesthetics is regarded as beginning with the publication of this highly successful but little-read treatise, it will seem to be a modern invention and its history a relatively short one. But the long preparatory stage before Baumgarten's book is at least as important to the study of aesthetics as its historical life under its own name. For most of the ideas developed by the modern science of aesthetics were conceived before by earlier thinkers ignorant of the name and possessing no terminological equivalent to it. Even after the unpremeditated start of 1750 the unity of aesthetics as a philosophical discipline was by no means taken for granted. The first important journal in the field, *Zeitschrift für Ästhetik und allgemeine Kunstwissenschaft*, founded in 1906 by Max Dessoir, suggested by its dual title that the theory of our perception of beauty and the theory of the principles of art were kindred but independent studies. Yet Baumgarten was apt with his name-giving precisely because for him aesthetics embraced both the study of beauty and the theory of art. The unsolved problem underlying the dynamic pattern of the history of aesthetics throughout the ages was this duality, which there were many attempts to resolve, as unity could only be effected if art could be interpreted as that type of human creativity whose purpose is to embody beauty.

CLASSICAL ANTIQUITY

Plato.—The great author whose work was to become the fountainhead of aesthetic thought down to modern times spoke disparagingly of works of art—including the Homeric poems—which we are accustomed to exalt. Plato (*q.v.*) was of course not blind to the grandeur and loveliness of Greek poetry or sculpture. But his own writing extolled a beauty unknown to previous poets, painters and sculptors. Their failure, in Plato's judgment, was to have missed the true object of poetic praise. The essential nature of beauty, in Plato's *Symposium*, reveals itself to the enraptured beholder who, guided by love (*eros*), has ascended from the admiration of physical perfection to the discovery of inward beauty and thence to an ultimate vision. The beautiful as such, hardly distinguishable from the good as such, a nonsensuous transcendent splendour, was characterized by Plato with a series of negations: not subject to growth and decay, not like a bodily frame, not mutable or enmeshed in relativities, but "being itself by itself

with itself sempiternally uniform." This negative science of beauty was counterbalanced by a theory of participation: everything is beautiful through participating in the "beautiful as such," and love, though a yearning after transcendent beauty, is kindled by visible loveliness. So the attempts made in Plato's dialogue *Hippias Major* at defining sensuous beauty were not unrelated to the subject matter of the *Symposium*. There was at least no contradiction between Diotima's lofty teaching and the more empirical definition of the beautiful in *Hippias Major* as that which is "pleasing to the eye and ear." Both the straining of later occidental art after "the light that never was, on sea or land" and the ever-repeated attempts to interpret this urge in terms of aesthetic theory were to testify to the fruitfulness of Plato's discovery.

For Plato love, inspired by beauty, especially by the beauty of a human being, and yearning after immortalization, was in its turn creative of beauty: the lover desires to "engender in the beautiful." But among the fair works and deeds which, according to the *Symposium*, bear testimony to love's creative power, "works of art" (in the modern sense of this term) were not explicitly included. And this is all the more noteworthy as the theory of art, in the sense of man's rational productivity, played an important part in Plato's thought. At the same time, Plato did view poetry as closely linked to the erotic vision of beauty. The poet, Plato made Socrates say in the *Phaedrus* and the *Ion*, chants his praises in a sacred madness, and no sober speech can compete with the words inspired by enthusiasm. But the "fine frenzy" which Plato attributed to the poet—another concept which was to echo through centuries of occidental civilization—did not belong to him as to a representative of art in general. On the contrary, in Plato's mind this distinction of poetry, which disabled the poet from giving a rational account of his own works, set it apart from the rest of those arts or crafts which through their purposive structure furnished to both Plato and Aristotle a model of rationality. The good poets, Plato affirmed in the *Ion*, do not compose their poems "by art" but under divine inspiration. Just as the Greek language knew of no word which corresponded to our "art" with its aesthetic overtones, so we shall look in vain for an aesthetic theory of art in Plato. Yet an approach to this modern concept was effected through an association of art with imitation (*mimesis*)—a word which in Greek is closer to "re-enactment" than to "copying." The idea of an "imitative art" might seem peculiarly apt to suggest a generic likeness between poetry on the one hand and sculpture and painting on the other, while at the same time hinting at an analogy between the human artificer and the divine demiurge who, in the *Timaeus*, fashioned the world by copying an ideal pattern. For Plato, the opponent of naturalistic tendencies in contemporary sculpture and painting and the critic of traditional poetry, this concept generally served to disparage all copy-making on account of the distance separating the copy from the ultimate original, the "form" or *eidos*. But again *mimesis* meant also a kind of participation, and Socrates, drawing the picture of a blessed city, was cast by Plato in the role of a painter. In addition, Plato was heir to the Pythagorean theory of music, based as it was on the conviction that the same numeric harmony which becomes audible through music determines the order of the universe as well as that of the soul. So the constructive power of *mimesis* was evident especially in the eminence assigned to music in the educational process: "rhythm and harmony sink into the innermost recesses of the mind."

Aristotle.—Plato objected to tragedy on the ground that tales of weepings and wailings weaken rational self-control through their appeal to passion. Aristotle (*q.v.*), while following to some extent the argument of Plato's *Republic*, book iii, in writing his *Poetics*, turned his teacher's verdict into a defense. The high hopes which Plato, a believer in divine justice, cherished for the just man's destiny after death were not entertained by his pupil, and therefore tragedy, which in Aristotle's opinion was largely concerned with the incongruity between the relative slightness of the hero's guilt and the awful magnitude of the disaster visited upon him, had to be recognized as true to life. Thus the two passions of fear and pity, arising out of sympathy, were according to Aristotle not only stimulated but also cleansed by tragedy. At

the same time, the divine madness as a source of poetic inspiration was replaced by a natural talent, the ability of the poet's sensitive mind to adopt the gesture and attitude of his fictitious characters. So, together with a rationally justifiable purpose, the title of art could be restored to poetry. In spite of being anti-Platonic in some respects, Aristotle's *Poetics* served as a vehicle for other Platonic concepts and so helped to pass on Plato's notion of the poem, or more generally of speech, as an integrated whole like a living creature to later books of poetics, of which Horace's *Ars Poetica* (*Epistula Ad Pisones*) was the most celebrated example.

The Later Classical Writers.—Thought on aesthetics in late antiquity was rich and varied. Fresh insights were gained less through clarifying the theoretical principles than through direct knowledge of a variety of creative processes. A unity existed in aesthetic thought, but it was concealed by a multiplicity of *artes* with their sets of rules, which were continually revised and enriched by new observations. A number of classic works emerged as a result, and the authority of some of them survived antiquity. Horace (*q.v.*) wrote his epistle to the Pisos (an "Art of Poetry"), Vitruvius his *De Architectura*, Aristoxenus his *Harmonics*. Rhetoric, the most productive member in this family of aesthetic technologies, found its lawgivers in Quintilian and Cicero (*qq.v.*). While the authors of these writings generally made no claim to speak as philosophers, the pervasive influence of the Platonic theory of beauty remained noticeable in most of them. The observation that the sculptor Phidias wrought his statue of Zeus on a model visible only to the eyes of the mind rather than after a man of flesh and blood was a commonplace with Hellenistic writers on the arts. When at last Plotinus, in the 3rd century A.D., repeated this well-worn affirmation it once more regained some of its authentically Platonic ring. With him the repudiation of a bare reproduction of things visible was a move involved in the mind's ascent toward a vision of "the beautiful." But this Platonic vision as renewed by Plotinus had no longer the dignity of an ultimate consummation: it was the prelude to a mystic union in which the seer and the seen became indistinguishably one (*see* NEOPLATONISM). The fine essay *On the Sublime*, wrongly attributed to Longinus, which established the idea of sublimity as an aesthetic counterpart to the ethical notion of magnanimity or greatness, was a product of the combined influences of the art of oratory and Neoplatonism.

THE MIDDLE AGES AND THE RENAISSANCE

Augustinian Platonism.—The beginning of the Christian era was less of a break in the development of aesthetic ideas than in some other fields of philosophical thought. To be sure, Christian asceticism deepened the distrust of the arts and their effects on the human mind, and there were frequent complaints about those who pleased congregations by their music while displeasing God by their lives. But the Christian criticism of aesthetic pleasures merely continued a line of thought traced before by Plato. At the same time the fight against Gnostic and Manichaean heresies helped to make it clear that hostility directed against sensuous delight as such was alien both from the Christian idea of the world as bearing imprinted upon it the vestiges of its creator and from the spirit of the divine Master who put man's idle worries to shame by letting him "consider the lilies." The Platonic idea of poetry as praise gained a wider bearing and a fresh radiance in minds familiar with the Psalms. "*Ore canunt alii Christum, canit arte fabrilis Hugo*" ("Others sing of Christ with their mouths, I with my craftsmanship") read the inscription by a medieval sculptor, Hugo d'Oignies. Thanks to educated and sensitive leaders of the early church such as the Cappadocian fathers in the east and, above all, St. Augustine in the Latin world, the aesthetic culture of ancient Greece was, after severe scrutiny and not without grievous omissions, preserved for Christendom. Accordingly the approach to the aesthetic problem continued to follow a path mapped out by classical philosophy. On the one hand, beauty was made the object of analysis and of a speculation which, while taking its departure from its sensuous appearance, tended to veer toward the beautiful as a purely spiritual brilliance. This was the

Platonic or Augustinian strain. On the other hand, the theory of the arts, an Aristotelian heirloom, was appropriated and, especially during the 12th and 13th centuries, developed, systematized and refined far beyond what could be found in Aristotle. Art (*ars*) for these thinkers, and here again they followed an ancient tradition, signified invariably a knowledge of how to make something, in other words, a "poietic" knowledge as distinguished from both theoretical knowledge (*i.e.*, knowledge for knowledge's sake) and practical knowledge. The medieval thinkers eagerly studied Plato's *Timaeus*, substituting for the mythical figure of the demiurge the God who spoke through the prophets. So man the maker was viewed in the light of the humbling idea of God the Creator. This analogical view was instrumental in conferring a higher degree of systematic consistency upon the theory of the arts, especially in the school of Chartres in the 12th century, but otherwise the principles laid down by Greek philosophy were maintained. The more science there was in an art, and the less its work required the services of the body for its execution, the higher it ranked and the better founded was its claim to be classed as "liberal." It is quite true that medieval painters, sculptors, architects, illustrators and goldsmiths attained to high personal fame and developed a great professional pride; it is also true that a lofty idea of the perfect craftsman-artist was held out for admiration and emulation. Furthermore, the medieval theorists were not unaware of the difference that existed between useful arts and those which simply aimed to give pleasure or to satisfy a desire for purposeless play. Yet for all that they remained, like their ancient predecessors, ignorant of the idea which in modern times was expressed by the term "fine arts." To them it seemed evident that all arts, weaving or agriculture no less than painting or sculpture, strove after beauty as one form of perfection. So the idea of singling out certain arts as "fine" (*i.e.*, as specifically designed for materializing beauty) did not enter their scheme of thought.

Plato was the mastermind that dominated aesthetic theory throughout the history of occidental civilization. But in the Christian era this influence was exercised largely through the medium of later authors, especially through the Pseudo-Dionysian writings and through St. Augustine (354-430). In the chapters of *De Trinitate* that dealt with the Word, Augustine defined the transcendent basis of all beauty. He sought the principle of beauty in unity, from which its further characteristics, order, harmony and proportion, were to flow, and found the paragon of this unity in the Word as the perfectly adequate expression of the Father. At the height of scholastic philosophy in the 13th century St. Bonaventura and St. Thomas Aquinas reaffirmed this aesthetic doctrine, and the latter developed it into the well-known triad of marks of things beautiful: integrity or perfection, due portion or consonance and finally clarity (understood as the radiation of the form). On the one hand beauty was held to subsist in God, on the other it was discovered through the ear and the eye, as sound and colour. But whether transcendent or sensuous, it was covered by the general formula: beauty is that which pleases the beholder. This definition set a clear distinction between the beautiful and the good, relating the beautiful to cognition and the good to appetite; and, again, this dual conception of beauty as of a perfection both sensuous and supersensuous derived from Augustinian Platonism.

Of the six books of St. Augustine's *De Musica*, five were devoted to questions such as metre, rhythm, scale and the like, all treated with an eye to discovering numerical relationships as the basis of musical delight. But the sixth book of the fragmentary treatise purported to show the fruits of the preceding argument by lifting the reader "on the wings of charity" from the visible and audible and mutable numbers to the immutable numbers through which the invisible things of God became clearly seen, "being understood by the things that are made, even His eternal power and Godhead." What began as a dialogue on one of the liberal arts ended as a Pythagorean-Christian version of the Platonic ascent of the love of beauty toward a beatific vision.

This Augustinian appraisal of beauty was to predominate throughout the middle ages, and it by no means vanished with

the beginning of the modern era. The mind of St. Augustine—and that is generally true of those who followed him—was open to the glory of the created world, to the loveliness and grandeur of nature as well as to the majestic and awe-inspiring spectacle of human history, the *ovdo saeculorum*, which he likened to a most beautiful poem composed of antitheses. Man's predilection for fair things offered him through eye and ear appeared to him not only legitimate but good: it could provide steppingstones for the spiritual ascent of the mind. Yet it held also a temptation. For because of the depravity of man the love of sensuous beauty might exceed the place assigned to it within the order of things, with the result that the inferior love would turn against the love of divine beauty. Accordingly the praise of beauty had to be kept in balance by words cautioning the lover of beauty against the perils of disorderly affection. This was the twofold lesson taught by Augustine, Christ's follower and a pupil of the Greeks, to the theologians and philosophers of subsequent centuries: while knowing that only an obtuse and ungrateful mind will blind itself to beauty, we must also bear in mind that even after his rebellion Lucifer retained the fair aspect of his celestial origin. How else could he tempt the proud and the high-minded?

The Renaissance.—When Petrarch (*q.v.*), who is usually considered one of the early embodiments of post-medieval man, had ascended Mont Ventoux, he stood long transfixed by the grandeur of the panorama. Then it occurred to him to open the copy of St. Augustine's *Confessions* which he used to carry with him, and the first lines to catch his eye were those which exhorted the reader not to forget the beauty of the soul in seeking external beauty: "*Et eunt homines admirari alta montium . . . , et relinquunt se ipsos*" ("And men go to wonder at mountain heights . . . and leave themselves behind"). On reading these words aloud the poet, abashed and silent, began to descend with his companions: "*Tunc vero . . . in me ipsum interiores oculos reflexi*" ("Then indeed . . . I turned my inward eyes on to myself"). The story has a symbolic significance. Great though the artistic achievements of the Renaissance were, the pattern of ideas by means of which this burst of aesthetic creativity was interpreted showed no great departure from classical tradition. A period of relative philosophical sterility had intervened between the breakdown of medieval philosophy and the Cartesian renewal. Consequently the idea of beauty at the same time sensuous and supersensuous lingered on in the minds, though the framework of medieval metaphysics to which it belonged had less importance. Humanist philosophers like Marsilio Ficino (1433–99) became Platonists by reading all or most of Plato's dialogues instead of reading St. Augustine and Pseudo-Dionysius. But what they found in Plato's dialogues differed surprisingly little from what others had found in St. Augustine and in *De Divinis Nominibus*. Platonism, in the minds of the educated, eclipsed Aristotelianism. But while astronomy and physics were to reap marvelous benefits from this turning of the philosophical tide and while the influence of Platonism as a spiritual atmosphere was all pervasive, the philosophical insight into the nature of beauty was not much advanced.

The general theory of the arts, so important a part of ancient and medieval philosophy, had likewise come to a standstill. All the greater was the theoretical vitality exhibited by the special theories devoted to poetry, the pictorial arts, architecture and music. Boccaccio, Lodovico Castelvetro and J. C. Scaliger wrote on the art of poetry, Leon Battista Alberti on architecture and painting, Cennino Cennini on painting, and then came the long procession of authors of "defenses of poetry," headed by Sir Philip Sidney. The title suggested a program: the Platonic theory of inspiration was invoked for a refutation of the verdict passed on poetry by Plato. The evaluation of this vast literature is the business of historians of the various arts concerned rather than that of the historian of aesthetics, yet certain ideas and tendencies of general import stood out. There was a novel insistence on the value of artistic mastery measured by the magnitude of the difficulties overcome; and the pride of human achievement expressed itself in other ways also. To relate man the maker to God the Creator was a commonplace with medieval theologians and philosophers. When, however, Scaliger dared to describe the

poet as "another god" he seemed to view this analogy in a light more flattering to human self-esteem than might have seemed permissible in the middle ages. The new consciousness of man's power and dignity involved liberation from the shackles of tradition. The artist was bidden to seek his models in nature rather than in art: "He who can go to the fountain does not go to the water vessel," wrote Leonardo da Vinci. But nature, the artist's fountain, was for Leonardo something recondite rather than the surface aspect of things met with in everyday life. The limited antitraditionalism of the Renaissance is not to be confused with 19th-century naturalism. Michelangelo, for instance, frowned upon Flemish painting, with its records of the contemporary scene, as a sort of pictorial heresy. As a rule the exaltation of nature went hand in hand with an equally enthusiastic admiration of antiquity. A recognition of the authoritative greatness of Greek and Roman art, feeding as it did on archaeological discoveries and on the translations of the ancient classics multiplying in the 16th century, did not seem to contradict the idea of nature as the fountain of art. The ancient masters, closer to nature than the artists of the middle ages, were believed to be nature's true interpreters. Yet this duality of authorities—nature and classical antiquity—was to become the source of the "quarrel of the Ancients and Moderns," the great theme not only of French criticism in the 17th century but also of classicist and romantic aesthetics at the turn of the 18th and 19th centuries. "We are greater than the ancients," asserted Giovanni Pico della Mirandola, writing to Pietro Bembo, a man of letters and a Platonist! on Sept. 19, 1512. At the end of the 17th century this battle cry was raised again by Charles Perrault and by Fontenelle in their onslaught against classical orthodoxy as represented by Racine and Boileau.

A historian writing about a Renaissance theory of art (taking this word in its modern sense) would still be guilty of an anachronism. There were arts and theories relating to these various arts, and there were, of course, mutual influences and interdependencies combining these theories into a vaguely circumscribed whole. But the idea of art as such, the indispensable counterpart to aesthetics as a unified field of study, was as yet unknown. An important step, however, was taken toward forming this decisive concept. The idea of the artist began to take shape. This was not a discovery of philosophers but rather the fruit of a theoretical self-consciousness developing in some of the great painters and sculptors of the time. Certain sociological elements were involved in this process. The Greek civilization, with the contempt for manual labour characteristic of a slaveholding society, celebrated the works of Phidias and Zeuxis but paid very little attention to Phidias and Zeuxis as persons. Again, in the feudal society of the middle ages, the *artifex*, or artisan, was by and large kept in a lowly though respected position roughly corresponding to that of the artisans in Plato's ideal state. With the disintegration of feudalism and the growth of a new urban society, at first in the Italian city-states, the artist was given a chance to throw off the social limitations placed upon him by his membership in a guild and to demand for himself the dignified place which antiquity had freely granted to the poet and which Dante had regained for him. However, the social change favoured but did not produce the decisive event—the discovery, or rediscovery, of the fundamental truth that there is a poetry not only of words but also of colours and lines, of sculptural and architectural forms. If the poet is moved by "love" to feel a sensual-spiritual aspiration in which his mind has to be fructified by an immediate contact with transcendent reality, so also is the pictorial artist. This idea, though never developed by Plato, was yet touched upon by him in a sentence which, in his suggestive brevity, taxes the understanding of the modern interpreter. Love, so Diotima taught Socrates, is a desire "to engender in the beautiful." While some are creative in their bodies, others are pregnant in their souls and give life to what is proper for the soul to beget and bring forth: wisdom and virtue in general. "And such creators are all poets and those of the artificers who are called inventors." It took two great inventor-artificers, Leonardo da Vinci and Albrecht Dürer (*qq.v.*) to revive this insight, the idea of a poetical power

shared by the poet with his brother-artists—a revival due primarily not to a study of Plato's words but to encountering, through personal experience, the very reality with which Plato had been confronted. This was the deeper significance of Leonardo's struggle after winning for painting a rank equal to or even above poetry. Beauty, Diirer affirmed, "stands firmly fixed in nature," and nature in God. Therefore a painter must study God through science and observation, for only by such submission—which entails imitation—shall a man ever be able to make a beautiful figure. Here, at long last, the point was discovered at which the essential kinship not only of poet and painter but of all "artists" in our sense of the word became clear—a discovery that made it possible to advance from the ancient theory of art as "knowledge of how to make things" toward aesthetics as a philosophy of art. This point, moreover, was found to lie not in the sphere of art itself but in that of religion.

THE CARTESIAN ERA AND THE 18TH CENTURY

Classicism.—The enthusiastic appraisal of man's eminence as expressed in the Oration on *the Dignity of Man* by Giovanni Pico della Mirandola (1463–94)—"to him is granted to have whatever he chooses, to be whatever he wills"—seemed to be borne out in the following centuries by an achievement of staggering greatness: the modern technological civilization began to take shape. The philosophical guidance needed for the development of a science which made man the master of nature was provided by Descartes (1596–1650), and the new science itself reached a first apogee in Newton's *Philosophiæ Naturalis Principia Mathematica* (1686–87). Philosophers, bent on co-operating in this enormous enterprise, were, on the whole, not too much concerned about art and its problems. Leibniz (1646–1716), critical though he was of some aspects of Cartesianism, could quote with approval the tsar Peter the Great confessing that "he admired more certain pretty machines than all the beautiful paintings in the king's palace." Enthusiasm was frowned upon in the Age of Reason, and John Locke (1632–1704) in the role of an educator offered advice for combating it in young people. In this dry intellectual atmosphere the French developed their classic literature, which succeeded in attaining to poetic greatness by pleasing in accordance with rules. Paradoxically, these rules, thought through and applied in a Cartesian spirit, were borrowed from Aristotle. But whereas Aristotle had been looking back upon a period of poetical creativity which in his time had already spent its force, Corneille (1606–84) rewrote Aristotle's *Poetics* in three prefaces ("On the Function and Parts of the Dramatic Poem," "On Tragedy" and "On the Three Unities") as a set of interconnected precepts at a time of vigorous poetic creation in France. So Corneille's code of rules was more nearly an "art" in the traditional sense (*i.e.*, knowledge of how to write a dramatic poem) than his ancient model. The premise of this normative theory was belief in the ultimate identity of nature and reason. The rationality exhibited in coherent rules was conceived as an expression of the very nature of things themselves and especially of man, and a poem obeying these rules could not fail to give pleasure to the audience while benefiting it morally. For Descartes the clarity and distinctness of our ideas produced the conviction of truth. Not only that, said Boileau (1636–1711) in *L'Art poétique*, but they are likewise productive of poetic beauty.

The forceful elegance of versification attained by the French classics and successfully emulated in England by Dryden and Pope was a short-lived triumph. When G. E. Lessing (1729–81) in his *Hamburgische Dramaturgie* (1767–68) attacked the artificiality of the French rules in the name of "untrammeled" nature (which supposedly spoke through Greek tragedy and had been listened to by Aristotle), the classical code had already lost its sway. The postclassic generation, encouraged by critics and theorists like Jean Baptiste Dubos, Charles Batteux and Diderot, looked for the unaccountable charm, the *je ne sais quoi*, the surprising departure from the expected norm, the emotional impact which can do without mediating concepts. French classicism had shown how far it was possible to go in contravening Plato's statement that the good poets do not write their poems "by art." The limit was

reached and a small host of avenging Platonists stood in readiness biding their time. But first we must look at the contribution made by the Cartesians toward forming a body of aesthetic thought.

The Subjective Approach.—The Cartesians' contribution to aesthetics was an important one. But its significance consisted less in throwing a fresh light on the twin problems of beauty and art than in providing a psychology of aesthetic experience. Descartes himself, in his *Compendium of Music* (1618) and in his correspondence with Marin Mersenne, found the basis of beauty in agreeableness, which in its turn he explained as resulting from the adaptation of stimulus to response. The human voice impressed him as more agreeable than other sounds, "because it holds the greatest conformity to our spirits." The aptness of sensation to the recipient he conceived furthermore as a mean between extremes: that is pleasing which neither bores nor fatigues. There was nothing really new in all this. The idea that the pleasure which we take in beautiful objects involves a harmonious relationship between man who perceives and the object perceived was part of the Platonic teaching and was reaffirmed by Thomas Aquinas. Again, the idea of a mean between extremes was clearly derived from Aristotle's functional theory of pleasure and pain. The novelty, however, was in the emphasis placed upon the emotional response. "Beauty pleases"—this was a truism conceded by everyone, and attempts had been made to show why its pleasingness is an essential rather than an accidental attribute of beauty. But Descartes and his followers turned the self-evident assertion around so as to read: "Whatever pleases in a certain way is beautiful." Pleasure, hitherto understood as the mark by which beauty can be known, was now considered the fundamental fact, mental or physiological, from which beauty derives. For the new kind of investigation the centre of theoretical interest had shifted from the beautiful object as perceived and enjoyed by the mind to the subject; *i.e.*, to the perceiving and enjoying mind.

The subjective approach won, and along with it there developed a new vocabulary. Imagination, fancy, taste, sense of beauty, sentiment and the like became the cardinal words of an emerging science. The influence of Locke, in England and also in France, combined with and generally outweighed that of Descartes. Psychological hypotheses abounded. The abbe' Jean Baptiste Dubos (1670–1742) regarded our instinct to be always in motion and to avoid ennui as the source of our love of the beautiful. For the abbe' Charles Batteux (1713–80) "imitation of nature" was the key to artistic perfection, and that might suggest a concentration of analysis on the object. Yet Batteux believed the artist's concern with nature to be through sentiment rather than through the intellect, and this view leads back to that of Dubos with his fear of boredom. Lord Kames (1696–1782) moved in the same direction when he connected aesthetic pleasure with readiness of apprehension, liking for novelty and social sympathy. Similarly Edmund Burke (1729–97), not quite able to disentangle his sentimental and amorous experiences from among his aesthetic ones, asserted: "I call beauty a social quality" (*A Philosophical Inquiry Into the Origin of Our Ideas of the Sublime and Beautiful*, 1756). David Hume (1711–76) finally brought to a logical conclusion the process by which beauty self-subsistent and real was dissolved into the mental life with its throng of ideas and impressions: pleasure and pain, he maintained, "are not only necessary attendants of beauty and deformity, but constitute their very essence" (*A Treatise of Human Nature*, 1739–40). One may well sympathize with the "common-sense" philosopher, Thomas Reid (1710–96), who was dismayed at seeing his contemporaries "resolve all our perceptions into mere feelings or sensations"; or with the obstinacy of William Hogarth (1697–1764) who, in the face of psychologically inclined critics, clung to his "precise serpentine line" as the standard of beauty.

The psychological analysis was in danger of explaining away its object: the sense of beauty, under the scrutiny of the psychologist, turned out to be something else in disguise—human sympathy or desire for change or self-assertiveness or a longing for emotion. Against these aberrations the great influence exercised by the 3rd earl of Shaftesbury (1671–1713) and his disciple Francis Hutcheson (1694–1746) served as a counterweight, not only in England but also on the continent of Europe and especially in Germany. It

KANT AND LATER AESTHETICS

was largely through Shaftesbury that sense, inner sense and sense of beauty became key words in the language of literary and artistic criticism. But though the method that he promoted had been initiated by Locke, Shaftesbury was also a Platonist and, as such, was bitterly critical of the "physiologist" Locke. By Shaftesbury the way into the inward life was once again understood as part of a movement ultimately raising the mind to the vision of spiritual beauty.

Vico, Herder and Winckelmann.—The analysts of the mind had generally adopted the point of view of the receptive rather than of the creative mind—another weakness of their theories. Thomas Hobbes (1588–1679), who spoke of the architectural and philosophical nature of poetical fancy! was one of the exceptions to this rule. Then Giambattista Vico (1668–1744) sought to remind his contemporaries—who were tastefully dallying with things that flattered a refined sense of beauty—of a forgotten truth. He stepped forth as a witness to the power of imagination, whose heroic strength was manifest in ancient poetry, especially in Homer. The dormant potentialities of St. Augustine's idea of the Word, perfect expression of the Godhead and thereby source of all beauty, came to life in Vico's concept of a poetical wisdom which, in the early phase of human civilization, acquainted man with truth through language and myth. So he anticipated J. G. Hamann (1730–88), for whom poetry was "the mother-tongue of the human race" and who exalted the archaic simplicity of the language of the Pentateuch and the New Testament above Greek tragic poetry. At the same time, the life of poetry was viewed by Vico in a historical context, as exercising an important function in the growth of human civilization. A deep affinity rather than effective influence connected Vico with J. G. Herder (1744–1803), the rediscoverer of folk poetry of many languages and the visionary who surveyed the history of mankind as the epic of humanity triumphant. With all his fondness for national and historical colour and character, Herder aspired with the ardour of a Platonist toward the idea of beauty which is one and the same for all men and for all times. Also a Platonist, or rather a Plotinist with Stoic leanings, was J. J. Winckelmann (1717–68), who with his *Geschichte der Kunst des Altertums* (1764) laid the foundations of the modern study of the history of art. At the same time, Winckelmann's book became the bible of the classicist dogma which was to dominate aesthetic thought for more than a century. In the majesty and repose of Greek sculpture he saw the unique revelation of beauty pure and unalloyed, the incarnation, as it were, of a Platonic form.

The New Notion of Art.—The subjective approach, first conceived in the spirit of Cartesian and Lockian psychology, broadened into a genetic or historical study of man's artistic creativity. The new emphasis placed on man the spectator or the creator or, finally, the genius (the Platonic inspiration transfigured into a talent) helped to decrease the distance which to earlier thinkers separated activities such as the writing of verses, painting, play-acting, building, dancing and others. "Art" was now more and more frequently coupled with the predicate "fine;" but the prevailing use of the plural showed that the minds did not yet have a firm hold on the essential unity of "art as such." The current expression read: *les beaux-arts*, the fine arts, *die schönen Künste*, sometimes with the addition of sciences (*und Wissenschaften*), which provoked Herder's vigorous protest. In fact it showed that the ancient idea of art as "poietic knowledge" was still abroad. The work of two great poets and critics, Goethe and Schiller, finally succeeded in firmly establishing the modern usage, now accepted by all European languages, which leaves no doubt about the primary meaning of "art." Only by keeping in mind this development can one understand the limited but real importance of Alexander Baumgarten's idea of beauty as a "phenomenal perfection," corresponding to the lower form of apprehension. Though by no means original or profound; it was instrumental in furthering the growth of the concept of art with its new unified meaning. Baumgarten's two books, a thesis *Meditationes philosophicae de nonnullis ad poema pertinentibus* (1735) and the first volume of *Aesthetica* (1750), foreshadowed the beginning of a new epoch. Posterity paid Baumgarten the not undeserved compliment of accepting the name he had chosen for a philosophical science both old and new.

Kant.—Immanuel Kant (*q.v.*) in his *Critique of Judgment* (1790), the third of his three fundamental works, applied the transcendental method of philosophical analysis to the problem of aesthetics. What are the conditions, he asked, implied by the existence of the phenomenon of beauty? What are the presuppositions which give validity to our aesthetic judgments? The *Critique of Pure Reason* had outlined the realm of phenomenal necessity, determined by the a priori laws of creative understanding (*Verstand*). Then the *Critique of Practical Reason* had granted a glimpse into the realm of freedom where reason (*Vernunft*) holds sway in the role of moral legislator. The dualism of the phenomenal world on the one hand and the noumenal world on the other (or of the corresponding faculties of the mind) required a mediation, and beauty as analyzed in the first part of the *Critique of Judgment* furnished the connecting link. Through the harmonious design of a shell or a melodious sequence of sounds the effectiveness of reason in the phenomenal world is borne in upon the mind which intuitively recognizes in these forms a "purposiveness without purpose"; *i.e.*, they appear to be designed to fit our needs and desires although there is no rational ground for supposing this. This recognition gives a peculiar pleasure at the harmonious interplay of our cognitive faculties, and it expresses itself in a judgment which, though incapable of demonstration, can claim universal validity.

As against the confusion of aesthetic pleasures with other pleasurable feelings which had marred the theories of the 18th-century psychologists, Kant sharply distinguished the disinterested pleasure, fruit of the contemplation of the beautiful, from "agreeableness." At the same time, he restored to beauty the dignity of a power mediating between two worlds. But the mediating function assigned to beauty by Kant characteristically differed from the classical or Platonic mediation. Instead of inflaming the passionate yearning of love and thus initiating an ascent toward beauty as a transcendent form, beauty was now conceived as healing an otherwise incurable wound by reconciling the intelligible to the sensuous, freedom to necessity. Beauty, in this view, became an essentially and exclusively sensuous phenomenon, though one of great spiritual significance. Kant's followers, however much they modified the master's theory, generally maintained this his fundamental thesis, thereby justifying the title of "aesthetics," derived as it is from *aisthesis* or sense perception. Beauty is "the ideal informing the real," as Schelling (1775–1854) asserted; or "the sensuous appearance of the idea," in the formula of Hegel (1770–1831). The conception of an "aesthetic at-one-ment" as envisaged by Kant became the germinating idea which, at the turn of the 18th and 19th centuries, gave rise to a breath-taking wealth of intellectual creations. System after system was forged, and almost all of those philosophical constructs included aesthetics as an essential part of the systematic whole—a novelty in the history of philosophy. Moreover, though most of these systematic treatises on aesthetics dealt separately with beauty in nature and with artistic beauty, they were all animated by the conviction that man holds commerce with beauty chiefly through art.

Goethe.—Kant himself, by taste and culture a man of the Enlightenment, was out of touch with the new creative movement heralded by the early phase of romanticism. Yet his *Critique of Judgment* ushered in a new epoch of aesthetic thought because those who felt the impact of his teaching were influenced by another master as well—one who taught them less through his arguments than through his presence and his poetical work. Goethe (1749–1832) seemed to his contemporaries the incarnation of poetical power and wisdom. The lesson that he taught was all the more impressive as neither as an artist nor as a thinker did he start from the Kantian experience of an ultimate duality: the harmony symbolized, according to Kant, by the beautiful form seemed to be the principle animating both his life and his thought. He, too, used Platonic language, knowing that he received "the veil of poetry out of the hands of Truth." But the spiritual significance of beauty appeared to him in the light of a formative ascent rather than as the healing of a fatal breach—the roots of his thinking reached more deeply into the past than those of his philosophizing

contemporaries. Their idealist aesthetics was, to a large extent, an attempt to understand art and the artist, typified by Goethe and his work, with the help of concepts derived from Kant.

Schiller and the Notion of Play.—Friedrich Schiller (1759–1805) took up and transformed Kant's idea of an interplay of faculties in his *Letters on the Aesthetical Education of Man* (1793–94). Man's inner life, composed, as he thought, of the two basic drives *Stofftrieb* ("sensuous instinct") and *Formtrieb* ("formal instinct"), can attain to balanced unity only through a third force, the play-impulse which constitutes beauty and art. Hence art appeared to him an indispensable instrument for fashioning man into the kind of harmonious personality which he admired in Goethe. A little less than a century later, Herbert Spencer (1820–1903) read Schiller's essay, forgot the name of the author and made the idea of play the cornerstone of his sociological aesthetics. The theory was then adopted and variously modified by psychologists such as Karl Groos (1861–1946) and Konrad Lange (1855–1921), until a growing realization of the importance of the festival as a matrix out of which the arts developed reminded scholars of the religious and metaphysical significance of play.

Later Romantic Aesthetics.—Friedrich Schlegel (1772–1829), the master theorist of the romantic movement in Germany and one of the representatives of Christian idealism, combined the idea of play with another element of Kant's aesthetics, the notion of freedom, interpreting the latter as the freedom of the creative mind to rise by means of play above the limitations imposed by fixed form. Thus he arrived at his concept of irony, which then furnished to S. A. Kierkegaard (1813–55) the dominant trait for characterizing the aesthetic type of life and served K. W. F. Solger (1780–1819) as an axis around which he constructed his system of aesthetics. The climax of romantic thought was finally reached by Novalis (Friedrich von Hardenberg, 1772–1801), with whom poetry, philosophy and life came to be fused in the ecstatic vision of a "magic universe." A curious reversal of the preceding development took place. Through the constitution of aesthetics, an area of its own had been set aside for man's artistic creativity. Now autonomy turned into hegemony, and the tendency toward differentiation gave way to desire for total inclusiveness. Art, after liberating itself from service under alien powers, aspired in its turn to embrace life in its entirety. In German romantic thought, especially in Novalis and E. T. W. Hoffmann, we find the seeds of 19th century aestheticism—the movement which tried to raise beauty to the rank of the sovereign good. Edgar Allan Poe, Gustave Flaubert, Théophile Gautier, Charles Baudelaire, Walter Pater and Oscar Wilde—all had undergone, directly or indirectly, the influence of German romantic aesthetics.

The Creative Imagination.—The harmonious attunement of the cognitive faculties as a natural gift was for Kant the mark of genius. Schelling, carrying the idealist principle beyond the limits of Kantian phenomenalism, took a further step by developing the idea of a creative imagination as a faculty analogous to the power of intellectual intuition. Both imagination and philosophical vision, he asserted, achieve a reconciliation of the finite and the infinite—imagination in the sphere of the real, philosophical vision in the sphere of the ideal. Art, like philosophy, discloses metaphysical truth, not under the form of concepts but by the imaginative creation of symbols. The spread of the concept of the symbolizing imagination, however, owes much to Samuel Taylor Coleridge. It is reflected in his distinction between fancy on the one hand, which plays only with fixities and definites, and imagination on the other. a "living Power and prime Agent . . . a repetition in the finite of the eternal act of creation in the infinite I AM." Largely through Coleridge, the same idea was carried to America, where it inspired Emerson and the New England transcendentalists.

The "Naïve" and the "Sentimental."—One may wonder how an aesthetics spellbound by Winckelmann's classicist dogma and looking backward to ancient Greece as to the unique revelation of absolute beauty could give guidance to the forward-going creative movement of German classical and romantic poetry. An answer to this question was first suggested by Schiller. Through him the problem that had agitated the combatants in the quarrel of the Ancients and Moderns gave rise to a scheme boldly conceived as

the outline of a philosophy of history. This scheme achieved the seemingly impossible: a justification of modern art which left to the ancients the prize of unmatched perfection. All poets, he held, are nature or seek nature: in the "naïve" poet, the perfect accord between imagination and understanding is the source from which his creation springs; the "sentimental" poet strives after this accord which to him is a remote ideal. Naïve poetry and art in general were typified for Schiller by the Greeks and among his contemporaries by Goethe; sentimental poetry by the moderns in general and especially by his own works. Of the Greeks he wrote: "They are . . . what we must be again some day . . . We perceive eternally in them that which we have not, but which we are continually forced to strive after; that which we can never reach, but which we can hope to approach by an infinite progress." Friedrich Schlegel appropriated and reinterpreted this scheme in broadening its historical basis and in replacing Schiller's "sentimental poetry" with his idea of a "progressive universal poetry" and of the "characteristic" as a hallmark of the modern artistic achievement.

Hegelian Aesthetics.—The scheme of a universal history of artistic creation yielded a program for the romantic school of poetry. In a revised form it was adopted by G. W. F. Hegel (*q.v.*; 1770–1831), the beneficiary and at the same time the adversary of romanticism. In his famous *Lectures on Aesthetics* he distinguished three phases: (1) in the "symbolic" as produced by the nations of the ancient orient, the idea is still recalcitrant in its relation to form; (2) Greek art alone attains a perfect equilibrium of the ideal and the sensuous form ("Nothing more beautiful can ever be"); and (3) in the Christian era, the aesthetic achievement of antiquity is surpassed by a spiritual comprehension of the idea as such, which gives rise to a new form of art, called "romantic" by Hegel. This art may still rise to its peculiar kind of greatness, though art has outlived its former vitality: "For us art is no longer the highest form under which truth can become real." Nevertheless, Hegel firmly established the place of art in the highest sphere of the creations of the mind. In the sphere of the "absolute spirit," "the identity eternally subsisting in itself and returning to itself," art comes first, and it is surpassed only by revealed religion and philosophy. Long after the decline of idealism, Hegelian aesthetics, in one form or another, continued to survive, in Germany chiefly through the magisterial work of F. T. Vischer (1807–87), whose *Ästhetik oder Wissenschaft des Schönen* first appeared in 1846, and in England through Bernard Bosanquet (1848–1923), who published a *History of Aesthetic* in 1892.

Schleiermacher.—Through art a fundamental duality is resolved into a happy consonance—this was the conviction shared by all the representatives of German idealist aesthetics. F. D. E. Schleiermacher (1768–1834) developed this idea of reconciliation through art with an unparalleled analytic subtlety. He showed that expression and imaginative play are two aspects of the same peculiar semblance which characterizes the work of art—a semblance which lifts the artistic image out of the context of reality and confers upon it a symbolic significance. So the aesthetic *via media* between construction and experience leads the mind to a vision of the absolute.

Schopenhauer and Nietzsche.—Art became an instrument of liberation rather than of reconciliation in the system of Arthur Schopenhauer (1788–1860), who inherited the riches of the Platonic-Kantian tradition and out of them erected a towering metaphysical structure. At the same time he vitiated the meaning of it all by putting a blind will as the ultimate reality in the place of the absolute as understood by his brother-idealists. Art, within this strangely inverted idealist scheme, was viewed as a substitute for religion. In the creations of art, Schopenhauer taught, the mind intuits Platonic forms, thus freeing itself for a while from the curse of existence and "keeping the Sabbath of the penal servitude of milling."

Friedrich Nietzsche (1844–1900) recognized Schopenhauer as his true master: the idea of a liberation through art was at the core of his famous essay on *The Birth of Tragedy From the Spirit of Music*. In a luminous symbolic dream-picture an Apollonian vision of life redeems the primordial pain of Dionysian ecstasy—such was for Nietzsche the essence of Greek tragedy. Again art

was conceived as a road toward salvation, but this saving power was not only distinguished from but opposed to reason.

Conclusions. — In Plato's dialogues Socrates is depicted as the true lover, the only one worthy to receive out of the seer's mouth the disclosure of the mystery of the love which, through beauty, creates wisdom. In Nietzsche's view the same Socrates appears as a fiendish character who destroys the heroic wisdom of the early Greeks by propagating a reason hostile to art. Thus the path which has been traced here through the centuries has come full circle. First, the two lines of thought — the one which pursues the idea of beauty and the other trying to determine the nature of art as a form of human productivity — will not fit into a harmonious pattern: the essence of beauty appears to be a transcendent entity, and art seems much more, and again much less, than "fine art." Then a *rapprochement* takes place, and finally, in the heat engendered by an overwhelming experience, a fusion is effected: a unified idea of art emerges, modeled, roughly speaking, on a Platonic concept of poetry. But the solution, hardly achieved, creates fresh difficulties. Art, placed in the neighbourhood of religion and metaphysics, reveals its innate dignity but also a tendency toward beguiling the mind into an idolatry of beauty, whereupon, defeated in its attempt to dominate life, it becomes divorced from life, and writers on aesthetics spread the false gospel of "art for art's sake." So the history of aesthetics is in fact a guide to aesthetic truth. But the art of interpreting the guide's language must be acquired through a renewed study of the phenomena. One lesson, however, stands out and, as formulated by Franz Baader (1765–1841), has a direct bearing on the difficulty under which 19th-century aesthetics laboured: "The deeper the mind of an artist and the more intensely he lives in ideas and ideals, the more certain it is that, even in the moments of supreme enthusiasm, the idea will flash through his inward life: alas, I have only painted pictures, and yet I feel I am created for realities."

For later developments see AESTHETICS.

AETA, a collective name by which the Negritos (*q.v.*) in the Philippines are known. They are short (pygmoid) with woolly hair and dark skin, believed to be an early land-migrating people related physically to the Semang of the Malay peninsula and to the Andaman Islanders. Comparisons of blood types contradicted an earlier assumption that they have a common origin with the African Pygmies. The Aeta are semisedentary and continue to derive a major part of their subsistence from hunting, fishing and food gathering. They inhabit the remote upland regions of the larger islands. The basic social unit is the extended patricentric family. The bow and arrow are used by all groups. Personal ornamentation includes scarification, teeth chipped to a sharp point and unusual bamboo combs. Though technologically primitive, they possess a phenomenal knowledge of plant and animal life. Religious beliefs and practices centre on a complex of potentially helpful or harmful spirits, *anitu*, whom they believe inhabit the proximate environment.

Survey of the Philippines*, II (1904); Schebesta, *Die Negrito Asiens* (1952); Vanoverbergh, *Negritos of Northern Luzon Again*, *Anthropos* (1930).

AETHELBALD (ETHELBALD) (d. 757), king of the Mercians from 716 to 757, succeeded Ceolred after some years in exile, during which he visited St. Guthlac, the hermit of Crowland. By 731 all the provinces south of the Humber were subject to his overlordship. He occupied Somerton in Wessex in 733 and controlled Berkshire some time between 740 and 757. He held London by 733. He made war on Northumbria in 737 or 740 and on the Welsh in 743. Though defeated by the West Saxons in 752, one of his charters shows that he could dispose of land in Wiltshire in 757. He made many gifts to the church, and Boniface and other Anglo-

Saxon missionary bishops in Germany praised his generosity in almsgiving and his strong, just rule in a joint letter written primarily to dissuade him from loose living and from violating ecclesiastical privileges. His charter of 749, freeing the church from public burdens except bridge repair and fortress building, may be a response to this letter. His charters use the regnal style "king of Britain." He was murdered in 757 by his followers.

AETHELBERHT (ETHELBERT) I (d. 616), king of Kent from 560 to 616, was son of a certain Eormenric. Bede attributes to him an imperium over all England south of the Humber, a position which he probably obtained only late in his reign, for he was defeated by the West Saxons in 568 at a place called Wibbandun. He married Berhta, daughter of Charibert, king of Paris, and she brought with her Bishop Liudhard, but they seem to have made little attempt to convert the people of Kent to Christianity. This marriage may, however, account for the tolerant reception that Aethelberht gave to the missionaries sent by Pope Gregory the Great. These landed in Thanet in 597. The king gave them a dwelling in Canterbury and later accepted Christianity himself, though he did not attempt to force it on his subjects. A second see for Kent was established at Rochester in 604; and one also at London, where the king, Saebert of Essex, was Aethelberht's nephew. Aethelberht's conversion of Raedwald of East Anglia had only a temporary effect. Aethelberht issued the first code of Anglo-Saxon laws, which established the legal position of the clergy and put into writing many secular regulations.

AETHELBERHT (ETHELBERT) (d. 865), king of the West Saxons, an elder brother of King Alfred, succeeded to the under-kingdom of Kent, Essex, Surrey and Sussex on the death of his father Aethelwulf in 858 and to the whole kingdom of Wessex (*q.v.*) after his brother Aethelbald's death in 860. A great force of Vikings stormed Winchester in that year, but were later defeated. In 865, the year of his death, a Viking force raided Kent.

See *Anglo-Saxon Chronicle*; also King Alfred's mill, in *English Historical Documents*, vol. i, ed. by D. Whitelock (1955). (D. Wk.)

AETHELFLAED (ETHELFLAEDA) (d. 918), "lady of the Mercians," played an important part in the struggle against the Scandinavians during the reign (899–924) of her brother Edward the Elder (*q.v.*). Daughter of Alfred the Great and wife of Ealdorman Aethelred of the Mercians, she became effective ruler of Mercia (*q.v.*) some years before Aethelred died in 911.

Her fame rests chiefly on her close and successful co-operation with Edward against the Danish armies of eastern England. To supplement Edward's fortified enclosures (boroughs) in the south-east midlands, she built fortresses at "Bremesburh" (910), "Scergeat" and Bridgnorth (912), Tamworth and Stafford (913), Eddisbury and Warwick (914), and Chirbury, "Weardburh" and Runcorn (915). She also restored the defenses of Chester (907). The joint attack on Danish positions was launched in 917. Aethelflaed captured Derby and in 918 occupied Leicester. Edward had advanced to Stamford but before the campaign could be successfully completed Aethelflaed died at Tamworth on June 12, 918, and he at once rode there to claim Mercian allegiance. Within a few months he was formally accepted as lord by all Danes and Englishmen south of the Humber.

Aethelflaed ordered at least one expedition into Wales, against Brecknock (916), and she probably compelled the princes of Wales to recognize her overlordship. She also intervened in Northumbria, and Irish annals suggest that she led a temporary alliance of Picts, Scots, Britons and Anglo-Danish Northumbrians against raids by Irish-Norse adventurers. She made possible Edward's reconquest of the Danish midlands, she facilitated his integration of Mercia and Wessex and, by extending her influence into Wales and Northumbria, she ensured that he was accepted as the most

powerful ruler in Britain.

See F. T. Wainwright, "*Aethelflaed Lady of the Mercians*," in *The Anglo-Saxons*, ed. by P. Clemoes (1960). (F. T. W.)

AETHELFRITH (ETHELFRITH) (d. 616), king of Northumbria (*q.v.*), succeeded his father Aethelric as king of Bernicia (*q.v.*) in 593 and later ruled Deira (*q.v.*) also. He married Acha, daughter of Aelli of Deira. His advances against the northern Britons brought him also into conflict with Aedan, king of the Dalriad Scots, whom he defeated at a place called Degsastan in 603. Between 613 and 616 he routed the Britons at Chester, killing a host of monks from Bangor Iscoed who had come to pray for the British army. He extended his authority so far southwest that by the end of his reign the Britons of Wales had become separated from those of Strathclyde. He tried to persuade Raedwald (*q.v.*) of East Anglia to surrender or kill Edwin, the refugee heir to the Deiran throne, but Raedwald refused and restored Edmin, after killing Aethelfrith at the battle of the Idle in 616.

AETHELNOTH (ETHELNOTH, EGELNODUS; called THE GOOD) (d. 1038), archbishop of Canterbury from 1020 to 1038, son of the ealderman Aethelmaer (a descendant of King Alfred's brother Aethelred), was a monk at Glastonbury and then dean of Canterbury before being consecrated archbishop on Nov. 13, 1020, by Archbishop Wulfstan of York. He translated the relics of St. Alphege (Aelfheah) from London to Canterbury. The *Encomium Emme* has a story that he refused to crown Canute's son, Harold Harefoot. He died on Oct. 29, 1038.

AETHELRED (ETHELRED) (d. 716), king of Mercia (*q.v.*) from 674 to 704, succeeded his brother Wulfhere (*q.v.*) as ruler not only of Mercia but also of Middlesex and the once West Saxon area north of the Thames, where he placed a Mercian see at Dorchester-on-Thames in Oxfordshire. He also had influence in Wiltshire and Berkshire. He married Osthryth, daughter of King Osmiu of Northumbria, but this did not prevent warfare against her brother King Egfrith, over whom he won a great victory at the Trent in 678, by which he obtained Lindsey. Peace was made by Theodore, archbishop of Canterbury, and Aethelred paid a wergild for Egfrith's brother Aelfwine who was killed in the battle. Meanwhile, in 676 Aethelred had raided Kent, and he had some power there about ten years later. But he lost to Ceadwalla of Wessex the control in Surrey and Sussex which Wulfhere had held. He was a protector of Bishop Wilfrid (*q.v.*) in his exile and was a benefactor of churches. In 704 he retired to the monastery of Bardney, where he died in 716.

AETHELRED (ETHELRED) I (d. 871), king of Wessex from 865 to 871, was the fourth son of Aethelmulf (*q.v.*) and succeeded his brother Aethelberht (*q.v.*) in the year when the great Danish army began its attempt to conquer England. Aethelred went with his brother Alfred (*q.v.*) to help Burgred of Mercia against the Danes, who were in Nottingham in 868, but the Danes refused battle and the Mercians made peace. Late in 870, the Danes invaded Wessex, and Aethelred and Alfred unsuccessfully attacked them at Reading. The brothers won a victory on the Berkshire downs, then called Ashdown, where Aethelred refused to begin battle until divine service was over. Defeats followed at Basing and a place called Merton. Aethelred died in 871 and was succeeded by Alfred.

BIBLIOGRAPHY.—*Anglo-Saxon Chronicle*; Asser, *Life of Alfred*, ed. by W. H. Stevenson (1904); *King Alfred's Will*, in *English Historical Documents*, vol. i, ed. by D. Whitlock (1955). (D. Wk.)

AETHELRED (ETHELRED) II (968?-1016), king of the English from 978 to 1016, surnamed "the Unready" (originally *unraed*, "evil counsel"), was the son of King Edgar and his second

wife Aelfthryth. His accession after the murder of his half brother Edward (*q.v.*) the Martyr in 978 was an inauspicious beginning responsible for much of the distrust and disloyalty prevalent during his reign. Danish raids recommenced in 980. In spite of some heroic defense, especially of London, bad leadership and mismanagement made the history of his reign a sad tale of defeat. The attackers were bought off in 991 and at ever-increasing price on many later occasions. Almost the whole country was ravaged. The massacre of the Danes on St. Brice's day, Nov. 13, 1002, provoked a great invasion by Sweyn of Denmark in 1003, and another great army arrived in 1009. St. Alphege (Aelfheah), archbishop of Canterbury, was captured by the Danes in 1011 and martyred in 1012. By the end of 1013 Sweyn was accepted as king and Aethelred fled to Richard of Normandy, whose sister he had married. When Smeyn died early in 1014, Aethelred was invited back on condition that he would rule better, but Sweyn's son Canute returned with an army and war was raging when Aethelred died at London on April 23, 1016.

The reign is disfigured by the treachery of English leaders and by murders instigated by the king, such as that of Aelfhelm, a Northumbrian ealderman, in 1006 and of the northern thegns Sigeferth and Morcar in 1015. Aethelred was unhappy in his dealings with the north. Yet the picture in the *Anglo-Saxon Chronicle* may be one-sided. Archbishop Wulfstan of York strove for reform and composed several law codes for the king, and numismatic evidence suggests a high degree of administrative efficiency. The reign saw a great production of literary and artistic works.

See *English Historical Documents*, vol. i, ed. by D. Whitlock, pp. 210-226, 293-297, 318-321, 401-414, 525-547, 823 ff., 854-859 (1955); F. M. Stenton, *Anglo-Saxon England*, 2nd ed. (1947). (D. Wk.)

AETHELSTAN (ETHELSTAN OF ATHELSTAN) (d. 939), king of the English from 924 to 939, son of Edward the Elder, was the first Saxon king to have effective rule over the whole of England. He called himself *rex totius Britanniae* ("king of all Britain"), on his coins attested charters with the same title, and used flamboyant styles such as "*basileus* of the English and in like manner ruler of the whole orb of Britain." He was brought up at the court of his aunt! Aethelflaed, lady of the Mercians. On his father's death (924): he was elected king by the Mercians and then crowned king of the whole country at Kingston on Sept. 4, 925. He gave his sister in marriage to Sihtric, Scandinavian king of York, on Jan. 30, 926, but when Sihtric died in 927 he seized control in Northumbria and on July 12 received at Eamont near Penrith the homage of Constantine of the Scots, Owain of Strathclyde, Howel of Dyfed, Owain of Gwent and Ealdred, the English high reeve of Bamburgh. Welsh princes and Northumbrian magnates attended the great courts which he held between 931 and 935. At a meeting at Hereford he forced Welsh rulers to promise tribute and fixed the river Wye as a boundary. He made the river Tamar the boundary for the Britons of Cornwall, refortifying Exeter after evicting the British population. He established the see of St. Germans for the region beyond the Tamar. In the north, he bought the district of Amounderness (north Lancashire) from the Scandinavians, no doubt in order to prevent attack from the northwest. He attacked Scotland in 934, when he reached Fordoun (in Kincardineshire) by land, and Caithness by sea. Constantine of the Scots, Owain of Strathclyde and Olaf Guthfrithson, claimant of the kingdom of York, combined against him in 937 and invaded England with a large force, but were utterly routed by the West Saxons and Mercians at a place called Brunanburh. The *Anglo-Saxon Chronicle* enters a poem on this battle and later Anglo-Saxon writers regarded it as the main event of Aethelstan's reign. He died on Oct. 27, 939.

Aethelstan played a part in continental politics. His father had given one of his daughters in marriage to Charles III the Simple, king of the West Franks, and their son Louis was brought up at Aethelstan's court until recalled to his father's throne in 936. Aethelstan married his sisters to continental rulers including the emperor Otto I and Hugh the Great, duke of the Franks. He had stood godfather for Alan of Brittany, who was brought up at his court and won back Brittany by his support. A third foreign prince reared at his court was Haakon, son of Harald Haarfager, who sailed with English men and ships to win Norway and to at-

tempt its conversion to Christianity.

Aethelstan was a generous donor to churches, both in England and on the continent. His gifts included relics, of which he was a famous collector, and books, some imported from abroad. Six of his law codes are extant and show him active in suppressing theft, in removing to other districts men too overbearing in their own and in punishing corruption. An unusual note of leniency is found in his concern to mitigate the punishment of young offenders. His reign is important in numismatic history, for he pronounced that one coinage should be current throughout the realm, and that money should not be minted outside a town.

AETHELWEARD (ÆTHELWERD) (d. 998?), English chronicler and ealdorman of the western provinces (probably the whole of Wessex; *q.v.*), was a descendant of King Alfred's brother Aethelred. He wrote, in elaborate and peculiar Latin, a chronicle for his continental kinswoman, Matilda, abbess of Essen. In the printed version of the text, the chronicle stops in 975, but fragments of the burned manuscript show that it continued in this into the reign of Aethelred (978–1016). Up to 894 it is based on a version of the *Anglo-Saxon Chronicle* (*q.v.*) more ancient than any now surviving; thereafter it is an independent authority. Aethelweard was the patron of Aelfric the homilist. The last certain mention of him is in 998.

BIBLIOGRAPHY.—H. Petrie, *Monumenta Historica Britannica* (1848) gives a text of the chronicle. See also E. E. Barker, "Cottonian Fragments of Aethelweard's Chronicle," in *Bulletin of the Institute of Historical Research*, vol. xxiv (1951); F. M. Stenton, "The South-Western Element in the Old English Chronicle," in *Essays in Medieval History Presented to T. F. Tout* (1925); "Aethelweard's Account of the Last Years of Alfred's Reign," in *English Historical Review*, vol. xxiv (1909) and "The Danes at Thorney Island in 893," in vol. xxvii (1912); K. Sisam, "Anglo-Saxon Royal Genealogies," in *Proceedings of the British Academy*, vol. xxxix (1953). (D. Wk.)

AETHELWULF (ÆTHELWULF) (d. 858), king of the West Saxons from 839 to 858, was the son of Egbert and father of Alfred the Great. On his accession he relinquished to his son Aethelstan the subkingdom of Kent, Essex, Sussex and Surrey which he himself had ruled since 825. He was constantly at war with the Danes and his great victory in 851 at a place called Aclea in Surrey against a large force, which had stormed Canterbury and London and put Beorhtwulf of Mercia to flight, was widely acclaimed. But it did not prevent further raids and the Danes wintered in Sheppey in 855. Aethelwulf showed wisdom in his dealings with Mercia. He helped King Burgred (Beorhtwulf's successor) against the Welsh in 853 and gave him his daughter in marriage. During Aethelwulf's reign the long struggle for the possession of the lands on both sides of the Thames was amicably settled. Aethelwulf receiving Berkshire, and presumably renouncing all claim on the lands north of the upper Thames. He was a religious man, who freed one-tenth of his demesne from secular dues and services for the benefit of churches, and in 855 he took his son Alfred to Rome. On his way back he delayed at the Frankish court to marry Judith, the daughter of Charles II the Bald. Under pressure from a faction in Wessex he agreed to relinquish that kingdom to his son Aethelbald, retaining only his previous subkingdom in the east.

AETHRA, in Greek legend, was the daughter of King Pittheus of Troezen, who married her to Aegeus, king of Athens, who had previously been childless. She became mother of Theseus by Aegeus or by Poseidon, who had attacked her in Troezen. (The two versions may reflect the antique confusion of Aegeus with the sea-god; *e.g.*, the Aegean sea.)

Many years later she guarded Helen when she had been stolen from Sparta by Theseus; in retribution Aethra was carried to Sparta by the Dioscuri to be Helen's slave, thereafter following her to Troy. Freed after the ten years' war, Aethra later killed herself in grief for her son. (T. V. B.)

AETIUS (FLAVIUS AETIUS) (d. 454), Roman general and statesman, the commander of the imperial army at the battle of the Catalaunian plains, was born at Durostorum (Silistra in Bulgaria), probably toward the close of the 4th century. He was the son of Gaudentius, the magister *equitum* ("master of the cavalry"), and of his Italian wife. As a youth Aetius spent some time as a hostage with Alaric, leader of the Visigoths, and later with the Huns, thus acquiring valuable knowledge of the leading barbarian peoples of his day. He supported the usurper John in Italy in 423–425 and brought to Italy a force of Huns, alleged to number 60,000 to help him. Although John died three days before his arrival, Aetius forced the government to grant him an amnesty. After successful battles in Gaul against the Visigoths and the Franks, he was appointed in 430 as magister utriusque militiae ("master of both services"). His rival Bonifacius having died in 432, he soon gained almost complete control over the young emperor Valentinian III, and from this time until the end of his life he was the dominating personality in the western empire. He became consul three times (432, 437 and 446), a unique distinction for a commoner; and it was said that envoys from the provinces were no longer sent to the emperor, but to Aetius. He was given the title of patrician in 433 and for several years thereafter fought continuously and successfully in Gaul against rebels and barbarians. In 435–437 his general Litorius crushed the Armoricans, who had revolted. In the same years, aided by Hunnish troops, Aetius mercilessly destroyed the Burgundian kingdom at Worms, an event which made a deep impression in the barbarian world and is remembered in the Nibelungenlied (*q.v.*). In 437–439, despite the defeat and death of Litorius, he checked the Visigoths of Toulouse. He returned to Italy in 440. In 443 he transferred the remnants of the Burgundians from Worms to Savoy, where their kingdom survived until 534. In 446, during his third consulate, the Britons appealed to him for help against the barbarian invaders of their island, but there is no evidence that he was able to do anything to aid them. In 451 he joined with the Visigoths in defeating Attila and the Huns at the battle of the Catalaunian plains (*q.v.*), but when Attila invaded Italy in the following year, Aetius could do little to oppose him. He next secured the engagement of his son to Placidia, the emperor's daughter; but on Sept. 21, 454, at the height of his power, he was assassinated at the instigation of Petronius Maximus, the future emperor. Valentinian III struck him down at an audience.

See J. B. Bury, *History of the Later Roman Empire*, vol. i (1923). (E. A. T.)

AETOLIA (AÏTOLIA), a district of ancient Greece, directly north of the Corinthian gulf, bounded on the west by the Achelous river, on the north and east by the western spurs of Mt. Parnassus and Mt. Oeta. The land falls into two divisions. The basins of the Ioner Achelous and Euenus (Evinos) form a series of alluvial valleys intersected by detached ridges which mostly run parallel to the coast, the hinterland being the rich agricultural country of the central Aetolian plain north of Lakes Hyria (Lisimakhia) and Trichonis. Northern and eastern Aetolia is a complex of chains and peaks, whose rugged limestone flanks bear only stunted shrubs and leave scarcely room for a few precarious mule tracks. These heights often rise in the frontier ranges of Tymphrestus, Oxia and Corax (Vardhousia) to more than 7,000 ft.; snow-capped Kiona attains to 8,235 ft.

In early legend Old Aetolia, with its cities of Pleuron and Calydon, figures prominently. During the great migrations (see GREECE: History), the earlier inhabitants were largely displaced. Those who were left long remained backward; in the 5th century some tribes still lived in open villages under petty kings, addicted to piracy and hardly recognized as Hellenes. But the successful repulse by their archers and slingers of the Athenian invasion of 426 indicates a fairly advanced organization, and by 367 the Aetolian league (*q.v.*) was in existence. The subsequent history of Aetolia is the history of this body. In 27 B.C. Augustus included Aetolia in the province of Achaëa. In the 15th century it passed first under the rule of Skanderbeg and the Venetians and later under Turkish rule, in the reign of Mohammed II. In the War of Greek Independence it saw much severe fighting, including the

sieges of Missolonghi. In modern Greece it is linked with the ancient Acarnania in the department (*nomos*) Aetolia-Acarnania with its administrative centre at Missolonghi.

See W. J. Woodhouse, *Aetolia* (1897). (F. W. WA.)

AETOLIAN LEAGUE. The tribes of ancient Aetolia (*q.v.*) possessed some degree of central organization by 426 B.C., when they repelled an Athenian invasion; by 367 they had united in a federal state or "sympolity," perhaps under Theban influence (see GREECE: History). In return for helping Epaminondas (367) and Philip II of Macedonia (338) they recovered their seaboard, including Naupactus, later adding Oeniadae (*c.* 330). Aetolia thus became one of the four leading military powers in Greece. Its subsequent prosperity depended partly on the wealth and influence acquired by Aetolian mercenaries in Hellenistic courts! but chiefly on the strength of the confederacy which, after successfully resisting the punitive invasions of Antipater and Craterus (322) and of Cassander (314–311), grew rapidly during the ensuing period of Macedonian weakness. By *c.* 300 (the exact date is uncertain) Aetolia, expanding eastward, had gained possession of Delphi and formed an alliance with Boeotia. This led to war with Demetrius Poliorcetes, but in 280 the Aetolians fought beside Antigonos Gonatas against the Peloponnesians led by Areus of Sparta and successfully extended their influence in central Greece, where Heraclea furnished a strong point against northern invaders and their control of the Amphictyonic council provided a useful political instrument. Aetolian valour was conspicuously displayed in 279, when it broke the strength of the irruption of the Celts and played a leading part in preserving Delphi. The commemorative festival of the Soteria ("Salvation"), which the league established at Delphi (246), obtained recognition from many leading Greek states. In 245 the Aetolians brought the Boeotians into subjection after defeating them at Chaeronea, thus gaining control of all central Greece. They then joined Antigonos Gonatas against the Achaean league (*q.v.*) and Sparta and made acquisitions in the Peloponnesus for their allies in Elis, Megalopolis and Messene.
