Later in the century their power was attenuated by Macedonia. From 239 to 229 they combined with Achaea against Demetrius II of Macedonia and in 230–229 against the Illyrian pirates, who outdid them in unscrupulousness and violence. Although by this time their power extended to Cephalonia and several Aegean islands, the provinces of Thessaly which they seized on Demetrius' death were promptly recovered by his successor, Antigonos Doso, and eastern Phocis and Boeotia detached themselves from the confederacy. Moreover in 229 Cleomenes of Sparta annexed several Arcadian towns which the Aetolians had recently acquired from Achaea. Aetolian raids on Achaean territory (220) led to a war with Philip V of Macedonia and many members of Antigonos Doso's Greek league. Philip displayed great energy, expelling the invaders from the Peloponnesus and even marching into Aetolia, where he sacked the federal capital, Thermum (now Thermon); but when he was lured by the war between Hannibal and Rome he made peace with Aetolia on the basis of the *status quo* (217). The Romans solicited Aetolian help against Philip in 211; the subsequent war against the Greek league ended with a separate peace in 206. In the second Macedonian war (200–197) the Aetolians again fought with Rome against Philip, and their cavalry largely secured the victory at Cynoscephalae (197). The Romans handed over Dolopia, Phocis and eastern Locris to the Aetolians in return but excited deep resentment by withholding Aetolia's former Thessalian possessions. The Aetolians then (192) invited Antiochus III of Syria to European Greece, thus precipitating a conflict with Rome. In this they wasted their chances. Sparta refused support, and the Aetolians' failure to hold Thermopylae (191) rendered Antiochus' position untenable. His defeat at Magnesia left the Aetolians in isolation, and despite their fierce resistance the Romans refused all compromises and after their surrender in 189 B.C. restricted the league to Aetolia proper and assumed control of its foreign relations. The importance of the league as an independent state was at an end, and by the time of Sulla its functions mere purely nominal.

The federal constitution closely resembled that of the Achaean league, for which it doubtless served as a model. The primary

assembly was normally convoked twice a year, at Thermum each autumn to elect officials, and at various cities to transact other business in early spring. Apparently all adult males voted, though in practice the richer citizens controlled affairs. A council ("boule," "synedrion") of about 1,000 members, in which cities were represented in proportion to their population, met more frequently to supervise administration. But, especially in wartime, many essential duties fell to a smaller body of at least 30 *apokletoi*, who were perhaps a committee of the council. An annually elected general ("strategos"), assisted by the *apokletoi*, had complete control in the field and presided over the assembly. Leadership within the league was always kept in Aetolian hands, since the more distant states were linked to the confederacy by "isopolity," a "potential" citizenship which gave full civil but no political rights unless one migrated to a community enjoying full Aetolian citizenship. The Aetolians deservedly enjoyed an evil reputation for lawless violence; hence their grants of *asylia*, a guarantee against seizure of property, were highly valued. But as champions of republican Greece against foreign enemies no other Hellenistic power rendered greater service.

Walbank, *Historical Commentary on Polybius* (1957). (F. W. WA.)

AETOLUS, in Greek mythology, was the son of Endymion (*q.v.*), king of Elis in northwestern Peloponnesus. To determine the succession to the throne of Elis, Endymion ordered a foot race at Olympia between his sons Aetolus, Paeon and Epeius, of whom Epeius won the race and crown. Paeon left Elis in a rage, moving "as far away as possible" (Pausanias), to that part of northern Greece to which he gave his name, Paeonia. Aetolus remained in Elis but later fled the Peloponnesus after accidentally running over and killing a spectator during a chariot race. He took refuge in Aetolia, so called after him. The whole myth represents the historical fact that in Greek prehistory dissensions in the Peloponnesus forced some of its people to migrate northward. (T. V. B.)

AFAR: see AFRICA: *Ethnography*; Northeast Africa.

AFER, DOMITIUS (d. A.D. 59), a Roman orator and advocate, was born at Nemausus (Nîmes) in Gallia Narbonensis and was among the first men of provincial birth to enter the Roman senate. A prominent delator (*q.v.*) under Tiberius, he was consul under Caligula (39) and superintendent of the water supply from 49 to 59, when he died. Quintilian calls him the greatest orator of his age, but only a few mots are preserved. (P. A. BR.)

AFFIDAVIT, a written statement of fact signed before an officer empowered to administer oaths. It recites the place of execution, that the person making the affidavit (affiant or deponent) states certain facts: that he appeared before the officer on a certain date and "subscribed and swore" the statement, and a jurat (*q.v.*). See OATH AND AFFIDAVIT. (R. E. DE.)

AFFILIATION, in law, the procedure by which paternity of an illegitimate child is determined and responsibility for its support is fixed. In England and the United States affiliation statutes provide the chief means of securing support for the illegitimate child from its putative father. See BASTARD; CHILDREN. LAWS CONCERNING. (M. K. R.)

AFFINE GEOMETRY: see DIFFERENTIAL GEOMETRY.

AFFINITY, in law, denotes relationship by marriage as distinguished from blood relationship (consanguinity; *q.v.*). The subject is important chiefly because of legal prohibitions against marriages between certain persons closely related by affinity, such as marriage between a widower and the sister of his deceased wife. See MARRIAGE: LAW OF. (B. CE.)

AFFIRMATION, in law, is the special form of safeguard against false testimony allowed to those who cannot because of conscience swear an oath and, increasingly, to those who have no religious faith. Affirmation is appeal to the penalties of perjury rather than to eternal damnation. See OATH AND AFFIDAVIT. (R. E. DE.)

AFFRAY is the misdemeanour of breaking the peace in public to the terror of the public. Fighting in public is an affray, but no actual violence is necessary, and the offense is committed even where a man arms himself with weapons so as to cause terror to the public. However, abusive and threatening words alone will not amount to an affray. In the United States the English common law concerning affray applies, subject to certain modifications by the statutes of particular states. See CRIMINAL LAW.

AFFRE, DENIS AUGUSTE (1793–1848), French prelate, the first of the three archbishops of Paris to die by violence between 1848 and 1871, was born at St. Rome-de-Tarn (Aveyron) on Sept. 28, 1793, and was educated at the seminary of St. Sulpice in Paris, where he was for a time professor of theology. He became archbishop of Paris in 1840. Opposed to the July monarchy of Louis Philippe, he welcomed the establishment of the second republic in 1848. When, on June 23, 1848, the Parisian workers rose in revolt, Affre was led to believe that by intervening in person he might be able to restore order. Accordingly, on June 25, he mounted a barricade at the entrance to the Faubourg St. Antoine, but had only spoken a few words when, in a moment of confusion, firing broke out and he was struck by a stray bullet. He died on June 27. On June 28 the national assembly issued a decree expressing their sorrow at his death. His immediate successor, M. D. A. Sibour, was killed by a mad priest in 1857, and Georges Darbois (*q.v.*) was shot during the commune.

See *L. Alazard, Denis-Auguste Affre, archevêque de Paris (1905)*.

AFFREIGHTMENT. The contract of affreightment is a contract for the carriage of goods by water, "freight" being the price paid for the service of carriage. Such contracts are of immense importance in the world's economy; they make up the legal structure governing the arterial traffic of the oceans. Contracts of affreightment are highly standardized, both by the requirements of law and by custom. Their terms are considerably complex, but the basic arrangement is very simple. There are two parties: (1) the carrier (or, by familiar personification of maritime law, the ship); and (2) the shipper and his successors in interest, the persons (if any) to whom he transfers his title to the goods in transit and his rights in the contract of carriage. The fundamental undertakings are that the carrier will carry the goods to a specified destination and that the shipper (or his successors) will pay the freight. The entire contract of affreightment consists in such qualifications and additions as the parties may expressly make to this simple arrangement or as the law may read into it irrespective of the expressed intention of the parties.

The formation of the contract is usually evidenced, and its terms stated, by one or both of two documents: the charter party (often shortened to charter) and the bill of lading. The charter party engages the whole capacity of the ship for a single voyage or for a period of time. The bill of lading is a receipt for goods taken on board for carriage and (if it is an "order" bill) functions also as a negotiable document of title, *i.e.*, its endorsement and transfer puts title to the goods in the transferee, the ship being obliged to deliver the goods at destination to the person presenting a duly endorsed bill. In the text of the charter or of the bill of lading (usually a printed form) are embodied any special terms on which the parties may have agreed. For reasons which will be made clear, many shipments are documented both by charter party and by bill of lading, but in numerous other cases (principally the less-than-shipload shipment) the bill of lading alone covers the shipment, and in some cases the charter party alone expresses the contract of carriage. It is evident from what has been said that consideration of the contract of affreightment amounts in effect to considering the content and import of these two documents.

The Bill of Lading.—As stated above, this document is first of all a receipt for goods taken aboard for carriage. As such, it names the vessel and the ports of loading and destination, describes the cargo, with needful particulars as to measure, weight and apparent condition, and states the freight payable on delivery (if freight has not been prepaid). Though no modern bill of lading stops with this, the legal position can best be clarified by reference to the rights that would arise if no further contractual

terms were added and if no statutes modified the old law of public carriage.

There are no problems, of course, if all goes well, *i.e.*, if the goods are delivered to the right person in the right place at the right time and in good condition, and if freight and other charges are duly paid. The most important part of the law pertaining to the carriage of goods concerns the allocation of responsibility when the goods are lost or damaged. In the absence of a special contract or statute (and it must be emphasized that in modern times this is a hypothetical situation) the public carrier is said to be responsible as an "insurer" for the safety and due delivery of the goods, by which is meant that, entirely without reference to any fault of his, he must pay the shipper or consignee for any loss unless it occurs through a catastrophic happening without human agency ("act of God"), through an act of the public enemy, through some defect in the goods themselves or through some negligence or misconduct of the shipper. (There is also a special arrangement, known as "general average," for dealing with the deliberate sacrifice of goods to save other goods and the ship; this will be touched on later.)

It could hardly be expected that shipowners would be satisfied to rest under this drastic liability if means were available for avoiding it. Accordingly, they sought to contract out of it by the insertion of exculpatory language in their bills of lading. (It is normally the carrier and not the shipper who prepares the printed bill.) During the 19th century, with the advent of steam, the shipping lines (dominantly British) attained a degree of economic power that enabled them to go very far in inserting clauses that exempted them from liability for loss or damage to cargo; shippers, relatively weak and unorganized, had to accept the terms offered on the carriers' printed forms or let their goods rot on the dock. The result was that, by "contract," the legal position was virtually reversed; instead of being responsible for almost all cargo loss and damage, the carrier came to be responsible for almost none, insofar as his exculpatory clauses, shortly referred to as "exceptions," were effective.

Shippers were dissatisfied with this situation, and their dissatisfaction was focused on bill-of-lading clauses that exempted the carrier from liability for the negligence of his employees. As a concrete example of the operation of such a clause, a shipper might ship farm machinery, and the carrier's sea personnel might through sheer negligence fail to close ports near this machinery, with the result that it was ruined by rust; but, with an appropriate negligence clause in the bill of lading (and a willingness by the courts to enforce the clause), the shipper or consignee could not recover damages. The U.S. federal courts refused to honour these negligence clauses, on the ground of inequality in the bargaining position of the parties, and of the clauses' repugnance to public policy. But the British courts and some U.S. state courts gave them full effect as valid terms of a contract. The position was therefore confused as well as oppressive to the cargo interests, and since the United States was then dominantly a cargo-shipping rather than a cargo-carrying nation, while British ships did most of the carrying, some international feeling was aroused.

In 1893, in the United States, the Harter act tried a compromise. The act followed the federal decisions by outlawing the negligence clause, insofar as that clause related to the carrier's duty to furnish a seaworthy and properly outfitted ship and to his duty to care properly for the goods. But it made a concession to the carrier interests by giving them (if due diligence had been used to furnish a seaworthy vessel) a positive immunity from liability for the negligence of master and crew in the navigation and management of the ship. For example, if a ship carrying goods that required refrigeration were to sail with its refrigerating gear in a defective state, proper inspection having been neglected by the carrier, or if the carrier's employees (ship's crew) negligently failed, during the voyage, to keep the refrigerating equipment turned on when needed, then the carrier would be liable for any cargo damage resulting from either of these causes. But if, due diligence having been used to make the vessel seaworthy, she struck a reef through negligent navigation and was stranded, with consequent spoilage of the goods, the carrier would not be liable. Doubt-

less the thought behind this compromise was that, where navigation or management of the whole ship was concerned, the carrier was sufficiently motivated by his interest in his own property, while the spur of liability was necessary to make him see that the ship was fit to receive cargo and that the cargo was properly handled.

This compromise seemed to work well and commended itself to the leading maritime nations of the world. In 1912 the Hague rules, adopting the substance of the Harter act compromise (as well as other provisions), were proposed for general voluntary inclusion in bills of lading, and in 1924 these rules were embodied in a proposed international convention. Ratification has been widespread though not universal. The United States and Britain have adhered; the U.S. version is the Carriage of Goods by Sea act of 1936, which may be taken as typical of the law of bills of lading throughout most of the world.

It is this act that governs and prescribes the terms of the bill of lading in the U.S. with respect to the vital matter of responsibility for cargo loss or damage; the contract of affreightment, in this regard, is no longer a bargained-out contract but one read into the bill of lading by law. Every bill of lading in foreign trade is required to embody a "clause paramount" subjecting it to the act, but the act would govern even if this requirement were not obeyed. (In domestic water carriage—from one U.S. port to another—the Harter act still governs unless the Carriage of Goods by Sea act is expressly stipulated for, as by its own terms it may be.)

Essentially, the act does two things: (1) it imposes on the carrier (and forbids him to avoid by contract) the obligations of using due diligence to furnish a proper ship, properly equipped and manned, and of carefully caring for the cargo while it is aboard; (2) it immunizes the carrier entirely from liability for all losses which do not result from his negligence and that of his employees, and even exonerates him in some cases of negligence (*e.g.*, in the navigation and management of the ship—the Harter act formula). Besides this basic distribution of responsibilities, the act regulates various other matters; it forbids, *e.g.*, the insertion of clauses placing a valuation on the goods lower than \$500 per package or customary freight unit, and on the other hand limits the carrier's liability to that amount unless a greater value is agreed on.

Thus, there is little left for the bill of lading to do, as pure contract: with respect to this vital matter of cargo damage; its terms are laid down by law. Outside the ambit of the act, however, the parties may still contract with some freedom, though the freedom, it must be emphasized, is largely a freedom of the carriers to insert terms they feel to be advantageous to them. The act generally forbids any stipulations lessening the carrier's obligations under the act.

Implied in the contract of carriage is a "warranty not to deviate," *i.e.*, the carrier undertakes to proceed on his voyage by a customarily direct route; the deviating carrier becomes liable for subsequent cargo damage. The Carriage of Goods by Sea act allows "reasonable" deviation but no more. Modern bills of lading have sought to avoid the deviation rule altogether by defining the "voyage" in extremely broad terms. The courts have in turn indicated that they will not give effect to these clauses where the result would be to defeat altogether the obligation not to deviate.

Reference has been made above to the functioning of the bill of lading as a document of title, the ownership of the carried goods following ownership of the bill of lading. Doubtless the most important use resulting from this characteristic of the bill is its employment as security in the financing of the sale of goods. In the most common transaction, the buyer of the goods opens a letter of credit, directing a bank to pay the seller's draft for the purchase price "against documents." *i.e.*, on presentation, along with the draft, of a bill of lading, an insurance policy and perhaps other less important documents. The seller thus gets paid at the time of shipment, and if the bank has extended credit to the buyer it is secured by the fact that it holds the bill of lading, which carries title to the goods. The use of the bill of lading in this and similar transactions principally motivated the passage of

the Harter act and the Carriage of Goods by Sea act; under the older bills of lading, with their broad negligence clauses, neither bank nor buyer could have much idea of the value of the bill of lading as security, though their positions were softened by the partial protection of insurance. (See also COMMERCIAL PAPER.)

The Charter Party.—Basic commodities (corn, oil; coal; iron ore, as well as many others) move in shipload lots, and the charter arrangement is the typical one. Leaving out of account the demise or "bareboat" charter, which amounts to the lease of a ship and is not a contract of affreightment at all, there are two types: the voyage charter and the time charter. In both, the shipowner continues to control the navigation and management of the vessel, but its carrying capacity is engaged by the charterer.

The voyage charter is a simple engagement for the carriage of a whole cargo from one port to another. Such charters are fixed by the activity of brokers, and their terms are highly standardized for each trade. For example, there is a form known as the Chamber of Shipping Australian Grain Charter 1928 (code name "Austral" for use in cable negotiations); most grain shipments from Australia will move under such a form; in which the principal matters shown by experience to give rise to dispute will be dealt with. Freight under a voyage charter may be a lump sum or may be calculated on intaken or delivered quantity.

The time charter places the capacity of the ship at the charterer's disposal for a definite period. He may order the ship to go any here not forbidden in the charter and to carry any cargoes that are not excluded by the charter's terms. Payment under such a charter is by the month or other unit of time.

By operation of law (absent special agreement) the shipowner is absolutely bound to furnish a seaworthy ship, properly equipped and manned and fit for carriage of the particular goods, and is also under an obligation to use care in the stowing and custody of the cargo; he must pay for damage ensuing from breach of either of these obligations. His obligation not to deviate is similar to that resting on the carrier under a bill of lading. But the disparity of bargaining position that led to judicial and legislative protection of the bill-of-lading recipient against too drastic contractual modification of these obligations has not been thought to exist in the charter relation; charters may therefore freely alter the shipowner's liabilities, though in fact, precisely because the shipper of large bulk cargoes is likely to have a good bargaining position, typical charters are by no means the one-sided documents that bills of lading were in the pre-Harter act days.

The Carriage of Goods by Sea act has no application to charter parties as such but does apply to bills of lading issued for goods carried under charter. This leads to the consideration of the problem of the simultaneous coverage of a shipment by charter and by bills of lading. This is the typical situation when goods move under charter, for the charter is not a document of title and cannot be used in the financing transaction discussed above. The shipper of coal, *e.g.*, who has a voyage charter wants bills of lading for the coal so that he can get his money at once by using the bills as security. Most charters expressly provide that bills of lading shall be issued by the master of the vessel on loading. In most charter shipments, therefore, two documents are extant expressing the contract of affreightment, and since the Carriage of Goods by Sea act fixes the terms of one but not of the other they are likely to differ in the legal obligations they embody, the bill of lading (under the act) being usually somewhat more favourable to the cargo interest than the charter. While the decisions are confusing, some points seem fairly well settled: (1) as long as the bill of lading remains in the hands of the charterer, the charter is the governing contract and the bill of lading is a mere receipt; (2) if the bill of lading is transferred without notice to the transferee of the existence or terms of the charter, then the bill of lading alone governs; (3) subject to the reservation in the next sentence: effective notice to the bill-of-lading transferee of the terms of the charter (usually by some form of stamped or type-written clause on the bill of lading) makes them effective against him; (4) in no case, regardless of notice, may a bill of lading, in the hands of a party to whom it has been transferred for value, import obligations less than those imposed by the Carriage of

Goods by Sea act; this point, though dealt with confusedly in the decisions, seems clear on the face of the act.

The interest of the shipowner, in the voyage-charter situation, lies in finishing the voyage as quickly as possible so that he can start another; thus he gets the most income from his ship. Hence such charters always put a penalty (demurrage) on the cargo owner for delay in loading or unloading; elaborate provisions in the charter govern this subject. In the time charter, on the other hand, it is the charterer who is interested in speed; hence such charters make detailed provision for the allocation of loss in the event of the disablement of the ship or of any of its essential gear.

General Average.— There is a distinctively maritime term in every contract of airtightment to the effect that, if either the ship or the cargo makes a sacrifice for the purpose of rescuing the entire venture from peril, the saved interests will contribute pro rata to equalize the loss; this system of loss distribution is known as general average (see AVERAGE for more detailed treatment). The most important contractual modification of general-average rights, now found in virtually all bills of lading and charter parties, is the Jason clause, so called from the name of the ship involved in the case that established its validity. Under maritime law, a ship could not recover general average from cargo when the peril that led to the ship's sacrifice arose through the ship's fault. The Jason clause changed this rule; under it, *e.g.*, a ship that has negligently run astrand and that deliberately damages her engines in order to get free can enforce a general-average contribution from cargo.

Obligations of the Shipper.— The obligation to pay freight, unless there is a contractual agreement to some other effect, does not become complete until the goods reach their destination. In modern practice, freight is often prepaid by small shippers. In voyage-charter carriage, the older rule is more usually adhered to.

The shipper may also make himself liable to the carrier, in accordance with normal legal principles, by his own negligence or misconduct. If, therefore, he negligently ships dangerous goods, without notice to the carrier, he may be held to pay for consequent damage to the ship.

Remedies.— Generally speaking, the obligations arising under the contract of carriage may be enforced by suit against the responsible person or corporation, either in admiralty or in the ordinary law courts. Besides this personal remedy applicable to all contracts, breach of the contract of carriage gives rise to a maritime lien, either on the cargo or the ship. Thus the carrier not only may sue the shipper (or, in some cases, the consignee) for such freight, demurrage, or general-average payment as may be owing but may also hold the cargo until the amount due is paid or procure its sale, under an order of the admiralty court, for satisfaction of the claim. Similarly, the shipper or consignee to whom the carrier is liable for cargo damage not only may sue the carrier but may libel the ship (*i.e.*, procure her seizure by an officer of the admiralty court) and enforce his claim against her directly, by sale under court order and by the satisfaction of his claim out of the proceeds. In practice, in most such suits against the ship, the owner posts a bond to cover the claim and so procures the release of his vessel. See also MARITIME LAW.

See T. G. Carver, *Carriage of Goods by Sea*, 10th ed. revised by R. P. Colivaux (1957); G. Gilmore and C. L. Black, Jr., *The Law of Admiralty*, ch. iii and iv (1957). (C. L. B.)

AFGHANISTAN (DOWLAT E PADSHAHI YE AFGHANISTAN), a kingdom of central Asia, is bounded on the north by the U.S.S.R. (the Turkmen, Uzbek and Tadzhik Soviet Socialist Republics), on the west by Iran (Persia) and on the east and south by West Pakistan; in the northeast it touches the Sinkiang Uigur Autonomous Region of China and Hunza in Kashmir. For information about border disputes and agreements see History, below. Area: 250,000 sq.mi. Pop. (1954 est.) 12,615,146; (1959 est.) 13,260,000. The capital is Kabul.

I. PHYSICAL GEOGRAPHY

1. **Physiography.**— The dominant feature of Afghanistan is the great central range of mountains which divides the country approximately from east to west. This range, known in its eastern portion as the Hindu Kush (*q.v.*), takes off from the Little Pamir in the extreme northeast, and after forming the boundary between Chitral (in northwest Pakistan) and Afghanistan to a point south of the Dorah pass turns westward, and spreads across central Afghanistan in a series of deep ravines and broken ridges gradually diminishing in height from the eastern peaks of 25,000 ft. Opposite Kabul and about 100 mi. to the north of it, the main ridge rises to peaks of about 20,000 ft. Farther west it spreads out fanwise in a series of subsidiary ranges, such as the Paghman range (15,500 ft.), while the main ridge continues westward under the names of the Koh-i-Baba (16,900 ft.), the Band-i-Bayan (12,300 ft.) and the Safed Koh (10,400 ft.) and finally the Paropamisus mountains (11,800 ft.) which continue as a series of low ridges in a northwesterly direction until they reach the valley of the Hari Rud.

Around the central structure the country is divided into four main divisions depending on the four principal river systems. In the north the gorges of Badakhshan and the high pastures of Mazar-i-Sharif and Kataghan descend to the valley of the Amu-Darya (*q.v.*) and the rich lands of Afghan Turkistan with its principal city, Mazar-i-Sharif. In the west the valley of the Hari Rud (*q.v.*) contains the city of Herat and the fertile surrounding country. In the southwest the Helmand and Arghandab with their tributaries water the provinces of Kandahar, Ghor and Farah. In the centre and east the Kabul river (*q.v.*) system, which includes among its tributaries the Logar, Panjshir and Kunar rivers, waters the Kabul plateau, the rich valleys of Chahardeh and Koh-i-Daman, and at a lower altitude the country of Nangrahar province around Jalalabad. Subsidiary to these main divisions are the valley of the Murghab river in the northwest, the plains of the Harut Rud (Adraskan), Farah Rud and Kash Rud in the southwest and the area around the headwaters of the Kurram, Tochi and Gumal rivers in the southeast.

2. **Climate.**— Three main traits are characteristic, namely, extremes of temperature (both seasonal and diurnal), wind and dryness, in respect of which elevation rather than latitude is the chief deciding feature. In Seistan and in the north along the valley of the Amu-Darya temperatures may rise to more than 115° F. in the summer, while in the highlands of Kabul and Ghazni on the southern side of the main range the maximum shade temperature rarely rises above 100° F. The minimum temperature in these areas falls as low as -10° to -15° F. in February. Jalalabad (2,000 ft.) and Kandahar (3,500 ft.) have a subtropical climate; *i.e.*, the

mean temperature of the coldest month keeps above 50° F.

The heat of summer is aggravated by hot winds, particularly on the western frontier from Herat to Seistan where a wind with a velocity which reaches 110 m.p.h. blows continuously from June to September. In winter periodic blizzards from the northwest bring heavy falls of snow at altitudes of more than 5,000 ft.

The average yearly rainfall varies. In Seistan and in Wakhan it is 2 in. along the lower Kabul river and along the lower Amu-Darya it is 5 in.; in Kabul it is 12 in., the greater part of which falls between December and April. An occasional shower falls in summer, but the influence of the southwest monsoon hardly extends beyond Jalalabad in eastern Afghanistan.

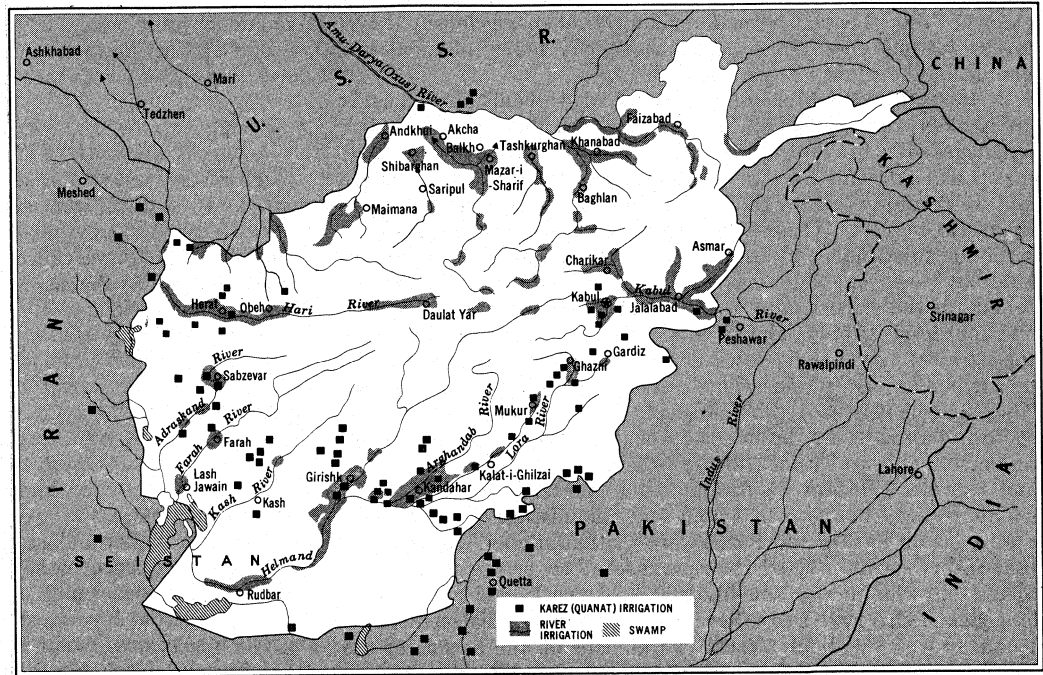

In the central highlands the climate is brisk. The spring and autumn are particularly fine, with clear, cool days and nights and a dry, invigorating atmosphere. At lower altitudes, below 3,000 to 4,000 ft., winters are pleasant but the heat in summer is intense.

3. Vegetation. — On the main ranges at 6,000 to 11,000 ft. grow large forest trees, among which the most prominent are conifers, such as deodar (*Cedrus deodara*), weeping spruce (*Picea smithiana*, *Abies webbiana*) and pines (*Pinus griffithii*, *P. gerardiana*). Yew, hazel, juniper, walnut, wild peach and almond are also found. Growing under the shade of these are several varieties of rose, honeysuckle, currant, gooseberry and hawthorn, and luxuriant herbage—the Ranunculaceae being abundant and rich in genera. The lemon and wild vine are commonest on the northern mountains. The walnut and oak (*Quercus ilex ballota*) descend to the secondary heights, where they become mixed with alder, ash, arborvitae, juniper (*Juniperus seravt-schanica*), *Indigofera* and dwarf laburnum, with species of *Astragalus*, etc. Lower again and down to 3,000 ft. grow wild olive, species of rockrose, wild privet, acacias and mimosas, barberry and *Zizyphus*, trumpet flower (*Bignonia*), sissou, mustard tree, verbena, acanthus and species of *Gesneria*. The lowest terminal ridges, especially toward the west, are naked in aspect. Their scanty vegetation is almost wholly herbal, shrubs are only occasional and trees almost nonexistent. Labiate, composite and umbelliferous plants are most common. Ferns and mosses are almost confined to the higher ranges. On the dreary Kandahar tablelands grow many vigorous plants, such as the camel's-thorn (*Alhagi pseudalhagi*); *Zygophyllum*; *Artemisia*; *Astragalus* in several species; spiny restharrow, the fibrous roots of which often serve as toothbrushes; mimosa; also certain orchids and several species of *Salsola*.

Many plants are used domestically for medicinal purposes. The chief cultivated trees are mulberry, apricot, willow, poplar, ash and occasionally the plane.

Of some commercial value is the gum resin of *Ferula assafoetida* of the high and dry plains of western Afghanistan, especially between Kandahar and Herat. In the highlands of Kabul edible wild rhubarb is a local luxury. Walnut and edible pine kernels are both found wild and are exported. The *sinjid* (*Elaeagnus angustifolia*), common on the banks of watercourses, furnishes an edible fruit. A subspecies of *Pistacia terebinthus*, called *khinjuk*, affords a mastic. The pistachio is found along the northern slopes of the Hindu Kush and is an important article of export. Mushrooms and other fungi are also used as food.

4. Animal Life. — Wild animals include the wolf, fox, hyena, wild dog, wildcat, common leopard, mongoose, wild sheep, mole, shrew, hedgehog, bats, several species of jumping mouse, jerboa

JOHANNES HUMLUM

RIVER SYSTEMS AND IRRIGATION OF AFGHANISTAN

and pica hare. Bears are found in the forests and the Mongolian tiger is said to inhabit the thick reed country of the Amu-Darya.

Of the goat family the markhor, urial and ibex are found in the central ranges, while the wild sheep (*Ovis poli* and *O. ammon*) inhabit the Afghan Pamirs. Two types of deer are said to exist.

There are more than 100 specimens of birds, including several varieties of pheasant, goose, duck, teal, crane, pelican, snipe, woodcock, partridge and chikor. Smaller birds include the garden oriole, magpie, bulbul, swallow, quail and sparrow. Brown trout (*Salmo oxienis*) are plentiful in all streams north of the Hindu Kush; mahseer and snow trout or *chush* are found in the rivers of the Indus watershed. (J. P. C. N. H.)

II. THE PEOPLE

The origin of the name Afghan is obscure, but it has been in consistent use since its first known appearance in a Sanskrit text of the 6th century.

1. Anthropology. — The inhabitants of the modern state are divisible into four main ethnies, or cultural groups: the Pashtun (*anglice* Pathan; *q.v.*), the Tajik, the Uzbek and the Hazara (*qq.v.*). The Pathans, *i.e.*, the Afghans proper, form about 60% of the population. The Tajiks or Tadziks represent the next largest ethny, 31%, followed by the Uzbeks or Usbeqs, 5%, and the Hazaras, 3%. The remaining 1% comprises Hindus, Jews, Sikhs and a congeries of central Asian tribal elements. Members of the four principal groups are scattered throughout the country, but the bulk of the Pathans occupy its eastern and southeastern parts as well as Herat and Seistan. Most Tajiks live in the provinces of Herat and Kabul; the Uzbeks in northern and central Afghanistan; and the Hazaras in the mountainous district of Hazarajat, south of the main range of the Hindu Kush, and in the region west of Anardarra (Gandarra) bordering Iran. In physical type the Pathans belong to the Caspian branch of the Europiform Mediterranean race. They have sallow skins and dark hair and eyes, are of medium stature with very long, high heads, prominent occiputs, well-developed brow ridges, and large, moderately broad aquiline noses depressed at the root. The Tajiks are pale-skinned hirsute Europiform Pamirians with lighter hair (10% blonde) and eyes (15% blue) than the Pathans. Their stature is medium, their heads are short and high with flattened occiputs, receding frontal bones, and pronounced brow ridges, and their narrow noses straight in profile with curved wings. The Uzbeks, of recent mixed Europiform Mongoliform descent, are on balance Mongoliform. The Hazaras, also, are part of the far-flung Mongolian race. They are

glabrous, short-headed, of medium stature, and have elongated oval faces, jutting cheekbones, straight salient noses of moderate breadth and eyelids with an epicanthic fold.

2. Languages. — Most of the 20 or so Afghanistan languages are inadequately studied in their form and distribution. The major languages — Pashto (see PUSHTU. PAKHSTO, PAKKHTO), with its many dialects, and Persian — belong, respectively, to the eastern and western divisions of the Iranian branch of the Indo-European linguistic family. These two languages are the mediums of instruction in schools and are spoken by more than 75% of the inhabitants, who in some areas are bilingual. Pashto is the mother tongue of the Pathans and is therefore most common in the east and southeast, from Jalalabad to Kandahar. In 1936 it was made the national language by royal decree and efforts have been made to further its use in educational establishments and in the press. The movement is backed by an active Pashto academy (Pashto or Pakhtu Tolena). As the lingua franca, however, an archaic form of Persian akin to Tajiki still prevails, not only among the Tajiks and Hazaras (Hazaras being the last to preserve relics of Mongolian speech) but also in Kabul and administrative circles generally. Both Pashto and Persian are written in modified forms of the Arabic script. The Uzbeks, whose urban centre is Mazar-i-Sharif and who number roughly 1,000,000, speak Uzbek, a Turkish language. There are two other important Turkish dialects: Turkoman, spoken by about 200,000 Turkomans on the border of the Turkmen S.S.R. and in the town of Maimana; and Kirghiz, spoken in northern Wakhan by a few thousand Kirghiz who wander across the Afghan, Chinese and Soviet frontiers. Dardic languages (*q v*), the precise status of which is disputed, but which appear to belong to an undifferentiated stage of Indo-Iranian, are spoken by 50,000 or so Nuristanis who occupy the remote and inaccessible valleys draining into the northern affluents of the Kabul river. The Indians of eastern Afghanistan and Kabul, principally traders, speak Lahnda, a Panjabi dialect. The few immigrants from Baluchistan, living as nomads in the frontier regions southwest of Quetta, speak both the Balochi and Brahui languages (*qq.v.*).

3. Culture and Beliefs. — Two million Afghans, mostly Pathans, are pastoral nomads and practise transhumance, changing the grazing grounds of their cattle and sheep with the seasons. The sedentary Tajiks are agricultural and irrigate their crops. They also engage in business and form the main urban communities north of the Hindu Kush. A group of Pamirian *Galchas* ("mountaineers"), speaking ancient Persian, live in the alpine regions of Badakhshan and Wakhan; these people rarely leave their villages. The Hazaras are both agriculturalists and pastoralists. In winter they are often snowbound and their cattle and sheep, which are pastured during the short summers, have to be stabled and fed. Different forms of the vendetta exist, and even the settled Afghan is often very much a warrior. Women still occupy a subordinate position in society but they are no longer required to wear the veil and increasing numbers are employed outside the home.

Among favourite sports is a kind of team wrestling (*ghosai*) in which the protagonist hops on one leg to reach a goal while protected by supporters against opponents, all similarly handicapped. *Buzkashi* involves the attempt to retrieve a decapitated calf's body from a ditch, on horseback, and carry it to the goal, hundreds of riders participating in the contest. Polo is also an Afghan game. The national dance, *Attan*, is performed in a circle by 50 or more persons singing in chorus to the accompaniment of native instruments, steps becoming progressively faster as the tempo of the music increases.

Although Afghanistan was once among the main centres of Buddhism, Islam has predominated since the 10th century and is the state religion, being professed by an overwhelming majority of the inhabitants. Most Afghans follow the Hanafi rite and belong to the Sunni sect. The Hazaras, apart from those of the west, and a few other minorities are Shi'as (see ISLAM). The peoples of Nuristan (*i.e.*, "land of light") were forcibly converted to Islam when the amir Abdurrahman Khan sent a military force to their mountain valleys in 1895. Before that they were known as Kafirs and their area as Kafiristan (*i.e.*, "land of the infidels").

Traditional proselytizers of peninsular India, the Afghans are intolerant of Christian evangelism in the kingdom, but freedom of belief is constitutionally accorded to its resident non-Muslims.

(J. C. Tr.)

III. ARCHAEOLOGY

Afghanistan forms the northeastern portion of the Iranian plateau. Its political frontiers include several natural regions. In the north is the narrow plain of loess and alluvial sand lying between the Amu-Darya (ancient Oxus) and the Hindu Kush, the ancient Bactria; in the centre is the mountain mass of the Hindu Kush and its subsidiary ranges, which may be further subdivided historically in terms of the watershed and drainage pattern; the southern extensions of the mountains are little explored and their archaeology is little known, but they extend to a line from Kandahar to Farah; in the south and west of the country are areas of desert and near-desert extending to the hills of Baluchistan, Seistan and the Iranian desert.

The earliest trace of human activity so far discovered is in Bactria (*q v*) where a Mousterian-type flake industry is suggested by finds near Balkh and at Haibak. At Kara-kamar cave near the latter a sequence of several industries was discovered, the earliest having blades and steep-ended scrapers of Upper Paleolithic type and the uppermost being described as Mesolithic. This suggests a sequence similar to that reported at Teshik Tash and other sites in Uzbek S.S.R. north of the Amu-Darya. In the south the earliest sites are Chalcolithic. At Mundigak, northwest of Kandahar, a prolonged occupation is attested. The earliest settlement produced painted pottery with affinities to Quetta ware, while the pottery of the middle periods suggests relationship with the Harappa culture. At this time (middle of the 3rd millennium B.C.) a great mud brick platform was constructed about the central mound. Finally in the upper levels plain gray and buff pottery are found with the first iron. Slightly later in time may be the site at Nad-i-Ali in Seistan. In the north no Chalcolithic sites are yet known and the sequence begins again with evidence of an Iron Age settlement at Balkh with plain buffware akin to that of Anau IV and many other sites in Soviet territory. This culture was associated with an eastern Iranian-speaking people who settled widely in the area during the 1st millennium B.C. No Achaemenid sites have yet been identified in Afghanistan, but at least part of the "treasure of the Oxus" and the coin hoard of Chaman-i-Hazouri near Kabul are certainly pre-Alexandrine. Again, archaeologists cannot yet identify any traces of Alexander's invasions, although the edicts of the Mauryan emperor Asoka in Greek and Aramaic versions discovered near Kandahar (ancient Alexandria Arachosiorum) about 1956 and in Aramaic near Jalalabad at Pul-i-Darunta, discovered about 1936, testify to these territories having fallen into Indian hands soon after. It is certain that in Bactria the vast mounds at Balkh (*q.v.*), Kunduz and Khulm must contain monuments and relics of the Greek cities constructed at that time; while the ancient city of Kapisa at Bagram must indicate, with its hoards of Indo-Greek coins, the Greek campaigns south of the Hindu Kush and the centre from which the Greeks invaded north India.

The last two centuries B.C. witnessed an extension of the Parthian influence, at least in the north and west, while at the same time the barbarian Yue-chi (*q.v.*) were establishing themselves in Bactria. At Balkh and other sites pottery and architectural fragments recall the Parthian influence. In the 1st century A.D. the Kushans (a branch of the Yue-chi) followed the Greeks through the mountains and into India, and under Kanishka established a vast power that straddled the mountains. The temple at Surkh-Kotal near Baghlan in the Hindu Kush, excavated between 1952 and 1957, with its Bactrian inscription of Kanishka, commemorates this power, as does the treasure of Indian and Mediterranean *objets d'art* discovered at Bagram. The succeeding centuries produced many monuments of a Buddhist character in which Indian influence is strongly felt. These are found mainly in the north and east, particularly around Hadda, near Jalalabad and around Kabul. The earliest show typical Gandharan influence, but by the 6th century a powerful new hybrid style developed

which had its contacts with the caves of the Takla Makan and the frontiers of China. Foremost among these later sites are the caves at Bamian (*q.v.*) with their two colossal Buddha figures and rich frescoes. The main political forces at this time were the Hephthalite and Chionite princes and the western Turks, all apparently recent invaders from central Asia, but the main cultural influences were still from Iran. To this period must belong the great brick fortress of Zohak near Bamian, so evocative of Sassanian work, and the many other ruined forts of the valleys of the Hindu Kush and Bactria.

Few remains of the early Muslim invaders survive. Of the Ghaznevid period, however, the great palaces of Lashkari Bazar (Bust) southwest of Kandahar form a splendid monument, and many others must await discovery or description.

Again many monuments of the Ghorids survive, including a minaret near Djam, a village in the valley of the Hari Rud, 150 mi. E. of Herat, discovered in 1957, and the neighbouring city of Firoz Koh, the Ghorid capital whose site was identified in the same year. Many of these monuments bear traces of the Mongol invasions, but sufficient remains to indicate the wealth that yet awaits study. Of the Timurid period mention may be made of the fortifications and mosques at Balkh and Herat.

IV. HISTORY

1. Early Period. — The earliest recorded use of the name Afghan is by the Indian astronomer Varaha Mihira (of 6th century A.D.), in the form "Avagana." The Afghans proper form a group of tribes speaking an Iranian language, Pashto, and centred since first they are recorded in the Sulaiman mountains in the east of modern Afghanistan. Their legendary history survives in traditional forms of which none is more than 500 years old. While it throws some light upon their tribal dispersion, it holds little historical interest for the country as a whole. There is no evidence that the Afghans anciently occupied any areas of modern Afghanistan other than those in which Pashto is spoken, and only in modern times have they settled in the parts occupied by peoples such as Tajiks and Hazaras over whom they hold feudal domination. The previously recorded distribution of Pashto as the predominant local language is from a little north of Jalalabad in the northeast, southward to Kandahar and thence westward to Farah and Sabzevar. Pashto extends also into the Northwest Frontier region of West Pakistan and thence southward through the Sulaiman ranges as far as Quetta.

Geographically and culturally Afghanistan forms the northeast portion of the Iranian plateau through which passed the routes which anciently linked India with the middle east, and both these regions with China and central Asia. It is thus to be expected that while the main cultural influences were those of Iran, others from India and central Asia have been constantly in evidence. The area enters history with the Achaemenid rulers of Iran, and although it is not easy to locate all the names derived from their inscriptions or from Herodotus (whom the inscriptions remarkably confirm) and other sources the principal regions are recognizable. Thus Bactria must have included the plain of the Amu-Darya, Arachosia the neighbourhood of Kandahar and Aria the country of the Hari Rud valley around Herat, while the Drangiana of the inscriptions and later Greek sources must have been a region of southwestern Afghanistan including perhaps parts of Seistan. Sindhu and Gandhara may be taken as the Sind and Northwest Frontier regions of West Pakistan and probably did not include lands of Afghanistan. There are also problematic names: Herodotus mentions in the seventh satrapy of Darius, along with the Gandharians, the Sattagydae, Dadicae and the Aparytae (?Afridi, an Afghan tribe), and one of these may indicate tribes occupying the country around Kabul and the ancient Kapisa, which was included from the time of Alexander with the Hindu Kush mountains in Paropamisus, whence arose the satrapy of Paropamisadae. Mention must also be made of the Pactyes of Herodotus, for it has been sought to connect them with the Pathans, speakers of Pashto with the modern dialectic variant Pakhtun. Linguistically, however, this presents difficulties; nor is Herodotus clear regarding their location, for while he includes their country in the 13th satrapy with Arme-

nia and the Euxine (the Black sea), he elsewhere states that its people were the northernmost of the Indians, following the way of life of the Bactrians, and that from their city of Caspatyrus Scylax set out on his memorable journey down the Indus.

Achaemenid rule was first established in the regions of Afghanistan by Cyrus (559–530 B.C.) and consolidated by Darius I (522–486 B.C.). It survived until Alexander the Great (*q.v.*) overthrew the dynasty. After Alexander's death his empire broke up and the eastern satrapies passed to the Seleucid dynasty (*q.v.*). Already by 322 B.C. Chandragupta Maurya (*q.v.*) had gained control of northern India, and after his defeat of Seleucus (c. 305 B.C.) he gained also the eastern provinces of Afghanistan, Paropamisadae and Arachosia. Confirmation of the Indian hold over these two provinces half a century later is provided by the Asokan edicts discovered at Kandahar and Pul-i-Darunta. By c. 250 B.C. the local Greek ruler in Bactria, Diodotus, broke away from the Seleucids and established an independent kingdom. At the same time the Farthians also broke away. Probably Seistan and Aria were in dispute between Bactria and Parthia, finally falling to Parthia. The Bactrian Greek dynasty, famed for its coins, flourished for about a century (see BACTRIA). Soon after 175 B.C. its ruler Demetrius moved south through the mountains to capture the region of Kabul and thence to invade northwestern India and establish the Indo-Greek dynasty there. Parthian power, however, was increasing along the western frontiers of Bactria, and to the north beyond the Oxus, some time before 125 B.C., the barbarous Yue-chi appeared in Sogdiana. This tribal group, who spoke an Iranian dialect (after leaving their homeland but possibly not before), was driven from the Chinese frontier region by a non-Iranian group, the Hsiung-nu. Before or with them came other Iranian tribes of nomadic Saka (*q.v.*) who seem, before 130 B.C., to have made a pact with the Parthians and to have moved south into Seistan (Sakastan) to settle there. Thence they spread east through Arachosia and in the 1st century B.C. extended their power into India. Meanwhile the Yue-chi had wrested Bactria from the Greeks and settled there.

At the beginning of the Christian era one group, henceforward known as the Kushans, followed the Greeks into the mountains and shortly after emerged as conquerors of northern India. The zenith of Kushan power was reached under Kanishka (*q.v.*),

whose rule stretched from beyond Mathura (see MUTTRA) to Kabul and thence from Bactria to the frontiers of China. During this time (2nd century A.D.) Afghanistan may have been momentarily united under one rule. The Kushans were patrons of the arts and of religion, and under Kanishka Buddhism flourished. The empire did not long survive Kanishka, but for centuries Kushan princes continued to rule in the various provinces. During the 4th century the Sassanids offered a growing challenge from Iran, while in the latter half of the century fresh incursions of northern tribes, the Little Kushans under their leader Kidara, closely followed by or associated with the White Huns or Chionites, took place. These latter are generally associated with a branch of the Hsiung-nu, the Mongolian tribes who centuries before had driven forth the Yue-chi. Two branches were discerned. The northern settled in Bactria and the Hindu Kush and were known eponymously as the Hephthalites (*q.v.*) (after their hero Hephtha), while the second (*Zavula*) branch moved south through the mountains to Kabul and Arachosia. There they, too, came under Sassanid influence and formed the centre for their raids of India between 455 and 510 under their rulers Toramana and Mihiragula. In India they were long remembered for their barbarity and Hunas, as they were called, became a name to be regarded with horror. At about the same time, A.D. 484, their victory over the Sassanid king Firuz marks the beginning of a period in which they were more the masters than the vassals of Iran. The Hephthalite domination lasted for a century until in 565 the western Turks, another newly arrived tribal group from central Asia, made an alliance with the Sassanid Khosrau Anushirvan and destroyed their power. For the next century the Turks ruled Afghanistan until their defeat by the Chinese in 658, when already Arab armies had reached the area.

2. The First Muslim Dynasties.—The advance of Islam into Iran and central Asia was rapid, but in the mountain fastnesses of the Hindu Kush it was much slower, and it was not until the 9th and 10th centuries that the last non-Muslim dynasties disappeared from Kabul. The initial control of the caliphate soon declined in these remote areas and the 9th and 10th centuries also witnessed the rise of numerous local dynasties, both Turkish and Iranian. One of the earliest of these was the Arab Tahirid dynasty, which included Balkh and Herat in its kingdom of Khorasan. They were succeeded there by a native Iranian dynasty, the Saffarids, of whom Yakub ibn Laith (867–870) made a series of whirlwind campaigns throughout Afghanistan. In the north, soon after, the local princes became feudatories of the powerful Samanids, also an Iranian house, under whose rule Bukhara, Samarkand and Balkh enjoyed a golden age. In the middle of the 10th century the former Turkish slave Alptigin seized Ghazni from its former ruler and built up for himself a principality. He was succeeded by another former slave, Subuktigin, who extended the conquests to Kabul and the Indus. His son was the great Mahmud (*q.v.*) of Ghazni who came to the throne in 997. Mahmud not only made extensive conquests in the north and west, thus bringing all Afghanistan under his sway, but also conquered the Punjab and Multan and carried his raids into the heart of India. The hitherto obscure town of Ghazni (*q.v.*) became a splendid city, as did the second capital at Bust (*Qala Bist*). Mahmud's descendants continued to rule from Ghazni over a gradually diminishing empire until 1152, when Ala-ud-din of Ghor, a mountain-locked region in northwestern Afghanistan (see GHOR), descended upon the city, sacked it and drove the last Ghaznavid out to India, thereby earning the cognomen of Jahansuz ("World Burner"). The Ghorids appear to have been of Iranian origin. The nephew of Ala-ud-din, Muizz-ad-din Mohammed, commonly known as Mohammed of Ghor, drove out Ghuzz-Turkoman nomads from Ghazni and in 1175 invaded India. After his death in 1206 his general Qutb-ud-din Aibak became the first sultan of Delhi.

(F. R. A.)

3. The Mongol Invasion.—Shortly after Mohammed of Ghor's death the Ghorid empire fell apart and Afghanistan was occupied by Sultan Ala-ud-din Mohammed, the Khwarizmshah or shah of Khwarizm (Khiva), an incapable ruler who was merely a tool in the hands of his mother, Turkan Khatun. The Khwar-

izmshahi dynasty was at this time at the zenith of its power, its territories extending from Chinese Turkistan in the east to the borders of Iraq in the west, but Ala-ud-din Mohammed planned also to take the place of the Abbasid caliphs and early in 1219 (616 *anno* Hegirae), marched with a large army against Baghdad. Hardly had he reached his destination, however, when news was brought that Mongol hordes under Genghis Khan had invaded the eastern part of his empire, seizing some of the most important cities of Transoxiana and everywhere spreading death and destruction. Hurriedly he turned back to repel them but, though he had no less than 400,000 horsemen under his command, he was not equal to the occasion. Shirking a battle, he retreated hastily to a small, deserted island in the Caspian sea, where he died shortly afterward (1220).

Soon after Ala-ud-din's death, his energetic son Jalal-ud-din Munkabirni decided to wage a war of liberation against the Mongols. With Ghazni as his military headquarters, he allied the Afghan highlanders and at Parwandarah near Kabul inflicted a crushing defeat on the Mongols under Kutikonian. Genghis Khan, who was then at Herat, hastened to avenge the defeat and laid siege to Bamian, a place of great strategical importance in the Hindu Kush. Here Mutugen, his grandson, was killed and this so infuriated Genghis Khan that when he captured the citadel he ordered that no living being was to be spared. The beautiful city of Bamian was utterly destroyed.

Advancing on Ghazni, Genghis won a great victory over Jalal-ud-din, who then fell back toward the Indus (1221). Here he made a final but unsuccessful stand. Seeing that all was lost, he threw his family into the river to save them from the wrath of the Mongols and then, with a few faithful adherents, jumped in the river on horseback, still exchanging arrows. Thereupon Genghis Khan gave up the pursuit, thus permitting Jalal-ud-din to escape into India. Genghis Khan returned to Afghanistan through Peshawar and the Afghans' gallant resistance then brought a dreadful retribution. The whole country from Herat and Balkh to Kandahar and Ghazni was turned into a wilderness, and many thousands of people were butchered.

After his death in 1227 Genghis Khan's vast empire fell to pieces. In Afghanistan some local chiefs succeeded in establishing independent principalities, while others acknowledged Mongol princes as suzerains. This state of affairs continued until the end of the 14th century, when Timur (*q.v.*) conquered a large part of the country. The horrors of the Mongol invasion were then repeated, though on a lesser scale.

4. The Timurids of Herat.—Timur's successors, the Timurids, were great patrons of learning and the arts and enriched their capital city Herat (*q.v.*) with fine buildings. Under their rule 1404–1507) Afghanistan enjoyed peace and prosperity. The first Timurid king, Shahrukh Mirza, Timur's fourth son, was an enlightened monarch of literary taste. He was greatly assisted in his work by his queen, Gohar Shad Agha. During his reign Herat became an important centre of Islamic civilization.

Sultan Husain Bayaqa, another Timurid king (1468–1506), was also, with his minister Amir Ali Shernawai, a patron of scholars and artists. Jami (*q.v.*), the great Sufi poet, and Behzad, the painter, flourished at his court.

5. The Moguls.—Early in the 16th century the Usbeks, under Mohammed Khan Shaibani, rose to power in central Asia and when Mohammed Khan Shaibani entered Herat triumphantly in 1507 the rule of the Timurids was practically at an end. Babur (*q.v.*), a direct descendant of Timur and the founder of the Mogul dynasty in India, was at this time in possession of Kabul. Driven from Fergana by the Usbeks, he had crossed the Hindu Kush in 1504 and established an independent principality in central Afghanistan with Kabul as its capital. When he heard that the Usbeks had captured Herat he joined forces with the Safawid shah Ismail against Mohammed Khan Shaibani. In 1510, when Mohammed Khan was killed in battle near Merv, Babur thought that the time was opportune to re-establish his authority in central Asia, but again he was defeated and forced to quit the country. Falling back on Kabul, he decided to make it a base for conquests in the east and south. He took Kandahar in 1522 and

then turned his attention toward India. A series of expeditions enabled him to seize the Punjab and in 1526 he marched on Delhi. Ibrahim, the last of the Lodi Afghan kings of India, came out to meet him at Panipat, 80 mi. N. of Delhi. After a hotly contested battle in which Ibrahim was killed, Babur was victorious. He could then lay the foundations of the Mogul empire, which lasted until the middle of the 19th century. Babur made Agra his capital and the whole of eastern Afghanistan right up to the Hindu Kush became a part of the Mogul empire. When he died (1530), Babur's body, in obedience to his wishes, was taken from Agra to Kabul to be buried in his favourite garden.

For the next 200 years Afghanistan lost its political entity and was parceled between the Moguls of India and the Safawids of Persia. The former holding the regions south of the Hindu Kush, while the latter held Herat and Seistan. Kandahar was for many years in dispute between them.

6. The National Awakening.—Although it was not until later in the 18th century that Afghanistan emerged as a united nation under Afghan rule, the national awakening may be said to have started when, in 1709, Mir Vais Khan, an influential leader of the Hotaki Ghilzai tribe, led a rising against Gurgin Khan, the Persian governor of Kandahar. The Persians, caught unawares, could offer no effective resistance and were slaughtered. Mir Vais Khan governed Kandahar until his death in 1715. In 1716 the Abdalis of Herat, encouraged by this example, took up arms against the Persians and under their leader, Asadullah Khan, succeeded in liberating their province.

Mahmud, Mir Vais's young son and successor, was not content with possession of Kandahar. He resolved to invade Persia and, in 1722, at the head of about 20,000 men, marched on Isfahan. The degenerate Safawid government could offer no effective resistance and after a siege of six months, Shah Husain surrendered.

Mahmud was a man of talent and energy and immediately set himself to reorganize the Persian administration and economy. He was not destined to see the fruits of his labours, however, for he died in 1725 and was succeeded by his young cousin Ashraf. Ashraf, too, was energetic, but he came to power at a critical time. The Afghans in Persia were threatened on all sides. The Russians were advancing from the north, while the Ottoman Turks seized part of western Persia. Internal strife and jealousy among the Afghan chiefs made the situation worse. Shah Ashraf met the dangers with courage and determination. He halted the Russian advance at Darband and in 1726 inflicted a crushing defeat on the Turks, who were marching on the capital. Meanwhile news was brought to him that a brigand chief, Nadr Kuli Beg, had attacked Tus and was on his way to take Meshed and Herat. Collecting all available troops Ashraf hastened north to meet him, but after a fierce encounter was defeated at Damghan on Oct. 2, 1729. The Afghan position in Persia was thereafter untenable, and during the retreat Ashraf himself was murdered by a Baluchi chief in Seistan.

7. Nadir Shah.—After consolidating his position in Persia, Nadir turned his attention to the east, against Herat. The Abdali chief Zulfikar Khan appealed to Kandahar for help, and Saidal Khan, a Ghilzai chief of repute, was sent to his aid. In an engagement at Kafir Kila, near the Afghan border, the Afghans inflicted a crushing defeat on the Persians (1731). Nadir himself, with only 80 men, was cut off from the rest of the army, but made good his escape and, in 1732, on receiving reinforcements, marched again against Herat. The besieged fought desperately, but dissension in their ranks forced them to sue for peace. Impressed by their valour, Nadir treated them with courtesy and recruited many of them into his own army. He was elected shah of Persia, with the name Nadir Shah, in 1736.

In 1737 Nadir Shah advanced with an army of 80,000 men against Kandahar. The city fell after a year's siege and Nadir then came into conflict with the Mogul empire of India. He seized Ghazni and Kabul and, advancing into India, defeated the Mogul army at Karnal, north of Delhi, in 1739. Then having seized the jewels and treasure of the capital, including the famous peacock throne, he returned through Afghanistan to Persia. He was assassinated at Khabushan in 1747.

8. Ahmad Shah and the Durrani Dynasty.—After the

death of Nadir Shah his empire fell to pieces. In Afghanistan, Ahmad Khan Abdali, with a contingent of 4,000 Afghans, entered Kandahar and there, in 1747, was elected king of the Afghans by a tribal assembly. Ahmad Shah (*q.v.*) was a member of the noble Sadozai clan of the Abdali tribe of Afghans. He changed the tribal name from Abdali to Durrani. Though barely 25 years old, he soon proved himself a capable ruler. Securing the affection of his people and welding them into a strong nation, he was able in 25 years not only to liberate Afghanistan from foreign rule but also to lead conquering armies from Meshed to Kashmir and Delhi and from the Amu-Darya to the Arabian sea. He defeated the Marathas at the third battle of Panipat (Jan. 14, 1761). His popular manners, combined with indomitable courage and other martial virtues, won him the title of Baba ("Father of the Nation").

Ahmad Shah died about 1773 and was succeeded by his son Timur, who bore no comparison with him. He received but nominal homage from the feudal chieftains and much of his reign was spent in quelling their rebellions. It was Timur who, seeing how the people of Kandahar hated him, decided to shift his capital to Kabul.

After the death of Timur in 1793, his fifth son, Zaman, seized the throne with the help of Sardar Payenda Khan, the influential chief of the Barakzai. Zaman was from the beginning of his reign beset with difficulties, both external and internal. His elder brothers, Humayun and Mahmud, governors of Kandahar and Herat, respectively, took up arms against him. At first Zaman was successful, Humayun being defeated and blinded and Mahmud forced to take refuge in Persia. Zaman then turned to India with the object of repeating the exploits of Ahmad Shah. This alarmed the British, whose Indian possessions were now threatened both by the French and by the Afghans. After the way had been paved for him by the dispatch of a Persian agent in 1798, Capt. John Malcolm was sent in 1800 as envoy to Persia to induce Fath Ali Shah to bring pressure upon the Afghan king and to divert his attention from India. The shah went a step further, helping Mahmud, the ex-governor of Herat, with men and money and encouraging him to advance on Kandahar. Mahmud, assisted by Fath Ali and by his vizier Fath Khan, eldest son of the Barakzai chief Sardar Payenda Khan, took Kandahar after a 42-day siege and then pushed on toward Kabul.

Zaman was at this time in India but learning of Mahmud's activities, he hurried back to Afghanistan. There, after various vicissitudes, he was betrayed by an old adherent, Ashiq Khan. He was handed over to Mahmud, blinded and imprisoned in the Bala Hissar fort at Kabul (1801).

Mahmud was an incapable, selfish and indolent ruler. He took no interest in the welfare of his people, squandered the nation's treasure on his personal pleasures and left all affairs of state in the hands of his vizier Fath Khan. Jealousies between Fath Khan and his rival Akram Khan Alizai caused unrest throughout the country, and finally some of the chiefs, who had grievances against the king or one of his ministers, joined forces and invited Shah Shuja, a full brother of Zaman, to Kabul. The intrigue was successful. Shah Shuja occupied the capital, and Mahmud sued for peace. His life and eyes were spared, but he was imprisoned in the Bala Hissar.

The new king, Shah Shuja, who ascended the throne in 1803, was unable to restore peace. The chiefs had become too powerful and unruly, and the outlying provinces were trying to assert their independence. The Sikhs of the Punjab were encroaching upon Afghan territories from the east, while the Persians were threatening from the west, and the shah could not conciliate Fath Khan.

At this time Napoleon, the French emperor, was at the zenith of his power in Europe. After the signing of the treaty of Tilsit in 1807 he and Alexander I of Russia decided on a combined invasion of India. This once more aroused the British to action, and a mission, headed by Mountstuart Elphinstone (*q.v.*), was sent to meet Shah Shuja at Peshawar to discuss mutual defense against this threat. The mission was warmly received by Shah Shuja and a treaty of friendship was concluded (June 7, 1809), the shah promising to oppose the passage of foreign troops through his

dominions. Hardly had the mission left Peshamar, however, when news was received that Kabul had been occupied by the forces of Mahmud and his vizier Fath Khan. Shah Shuja's troops were thereafter routed in a brief encounter near Gandamak and Shah Shuja himself withdrew from Afghanistan. In 1810, after making some ineffective efforts to recover his throne, he was captured and imprisoned in Kashmir. He escaped in 1812 and came to Lahore, hoping to receive help from Ranjit Singh, the ruler of the Punjab, but instead the Sikh ruler robbed him of the famous Koh-i-Nor diamond. Finally Shah Shuja found asylum under the British at Ludhiana.

9. **Dost Mohammed and the Rise of the Barakzai.**—The Barakzai were now dominant throughout Afghanistan. This incited the jealousy of Kamran, Mahmud's eldest son, who had a grudge against Fath Khan and who now sought for an opportunity to ruin him and his influential brothers. His chance came in 1816 when Fath Khan and his younger brother Dost Mohammed Khan, who had been sent to defend Herat against a Persian army, insulted Kamran's sister, who was the daughter-in-law of the governor of Herat. When she called on her brother to avenge the insult, Kamran seized and blinded Fath Khan. Retribution immediately followed this outrage. The vizier's brothers, 21 in all including Dost Mohammed who had escaped to Kashmir, took up arms. Shah Mahmud asked Fath Khan to write to his brothers and order them to submit. Fath Khan replied that he was blind and had no control over them. Enraged by this answer, the shah ordered the unfortunate minister to be cut to pieces. Fath Khan met his death calmly and died as he had lived—dauntless and resolute. The end of the vizier was the death knell of the Durrani dynasty.

The first of the Barakzai brothers to enter the field was Dost Mohammed. Advancing from Kashmir in 1818, he took Peshawar and Kabul and drove the shah and Kamran from all their possessions except Herat, where they maintained a precarious footing for a few years. The rest of Afghanistan was parceled out among the Barakzai brothers. In the confusion that followed, Afghanistan suffered heavily. Balkh was seized by the ruler of Bukhara; the trans-Indus Afghan districts were occupied by the Sikhs; the outlying provinces of Sind and Baluchistan assumed independence. In the partition which took place in 1826, Ghazni, Kabul and Jalalabad fell to the lot of Dost Mohammed, who thus became the most powerful of the Barakzai Sardars.

It was Dost Mohammed who established the Barakzai or Mohammedzai dynasty in power. As soon as his position was secure at Kabul, he decided to recover Peshawar by force from the Sikhs. Declaring a jihad or holy war in 1836 he collected an army of Moslems from far and wide and advanced on Peshawar confident of victory. But the shrewd Sikh leader, finding himself too weak to meet Dost Mohammed in the open field, sowed dissension in his camp, so that the invading army melted away and Peshawar was permanently lost to the Afghans.

In Nov. 1837 Mohammed Shah of Persia laid siege to Herat, which was looked upon by the British as the key to India. The Russians supported the Persians in their designs, and the British, fearful that Persia was falling completely under Russian influence, determined to stem the tide by entering into alliances with the rulers of Herat, Kabul and Kandahar. A British mission to Kabul under Capt. (later Sir) Alexander Burnes (*q.v.*) in 1837 was welcomed by Dost Mohammed, who hoped that the British would help him to recover Peshawar. Burnes, however, would not give him the required assurances, and when a Russian agent, Capt. P. Vitkevich, appeared in Kabul, the British broke off negotiations and were ordered to leave at once.

The failure of Burnes's mission gave the governor general of India, Lord Auckland, a pretext for the invasion of Afghanistan, with the object of restoring Shah Shuja to the throne. This was the origin of the first war between the British and the Afghans (1838-42). A British army assembled at Ferozepur in Dec. 1838, and Shah Shuja was supplied with funds to raise an army of his own. As the Sikhs did not allow the British to pass through their territories, the British army had to take a circuitous route to the Bolan pass in order to advance on Kandahar. In April 1839, after

suffering great privations and guerrilla attacks on the way, the British army under Gen. Sir John Keane, entered Kandahar. Shah Shuja was then crowned in the mosque next to the mausoleum of Ahmad Shah. Ghazni and Kabul were captured in the following July and August, Shah Shuja being crowned again at Kabul. Dost Mohammed escaped first to Balkh, then to Bukhara, where he was treacherously arrested. The Afghans, however, could tolerate neither a foreign occupation nor a king imposed on them by a foreign power and insurrection broke out on all sides. Hearing of the risings, Dost Mohammed escaped from prison and returned to Afghanistan to lead his partisans against the British. In a battle at Parwandarrah on Nov. 2, 1840, Dost Mohammed had the upper hand but it was found the next day, to the astonishment of the Afghans, that he had surrendered to the British in Kabul. He was honourably treated by the British and deported to India with the greater part of his family.

After Dost Mohammed's departure the situation did not improve. Outbreaks continued all over the country and, when winter set in, the British garrison in Kabul found their position untenable. Terms for their withdrawal were discussed with Akbar Khan, Dost Mohammed's son, but the negotiations were delayed by the tactics of Sir William Hay Macnaghten (*q.v.*), the British political agent, who was in no mood to quit Kabul. His attempts, however, to sow dissension among the Afghan chiefs were frustrated, and finally he was invited to a meeting by Akbar Khan, who killed him with his own hands.

On Macnaghten's death the British garrison decided to leave the city at once. On Jan. 6, 1842, in severe cold, approximately 4,500 British and Indian troops, with 12,000 camp followers, marched out of Kabul. Bands of Afghans swarmed around the line of their retreat, and the retreat ended in a massacre which few survived.

Though in the summer of the same year British forces under Gen. William Nott and Gen. George Pollock reoccupied Kabul, the new governor general, Lord Ellenborough, decided on the immediate evacuation of Afghanistan. In 1843 Dost Mohammed was released and allowed to return to his country, which was now without a ruler, as Shah Shuja had been killed by his own subjects after the British had left the capital. Thus ended the final phase of the war, which left bitter memories behind it.

Dost Mohammed reigned until 1863. During the last 20 years of his reign he occupied Kandahar, Mazar-i-Sharif, Kataghan and, at last Herat, but died thirteen days after capturing the last-named city.

10. **Sher Ali.**—Sher Ali Khan, Dost Mohammed's third son, then became amir, but his elder brothers Afzal and Azam rose against him. For five years fratricidal war went on until, in autumn 1868, Sher Ali was finally able to establish his authority. The British again became apprehensive of Russian designs on Afghanistan, and Sher Ali's reception of a Russian mission at Kabul and his refusal to receive a British one, intensified their suspicions and led directly to the war of 1878-81. On Nov. 21, 1878, the three great passes leading into Afghanistan were entered by British armies. They met stiff resistance, but by the end of the year Jalalabad and Kandahar had fallen. Sher Ali, leaving his son Yakub Khan as his regent in Kabul, went to Mazar-i-Sharif to seek help from the Russians, but the Russians advised him to make peace. Worn out by disease and worry, Sher Ali died at Mazar-i-Sharif on Feb. 21, 1879.

11. **Yakub Khan.**—By the treaty of Gandamak (May 26, 1879) Yakub Khan agreed to receive a permanent British embassy at Kabul; to conduct his foreign relations with other states in accordance "with the wishes and advice" of the British government; and to allow such rectification of the frontier as was demanded by the advocates of a "forward policy" for the British in India. In return he was promised help against foreign aggression. This British triumph, however, was short-lived. On Sept. 3, 1879, Maj. Sir Pierre Louis Cavagnari, the British envoy, and the whole of his escort were murdered in the Bala Hissar. British forces were again dispatched, and before the close of October Lieut. Gen. Frederick (later Field Marshal Earl) Roberts had occupied Kabul. Yakub abdicated and was sent to India (where he died in 1923.)

12. Abdurrahman Khan.—The British remained in Kabul during the winter of 1879–80. In the meantime Lord Lytton, a supporter of the "forward" policy in Afghanistan, was succeeded by Lord Ripon who had instructions to bring about a speedy but peaceful settlement of the Afghan question. Accordingly, when Abdurrahman Khan (*q.v.*), a grandson of Dost Mohammed, appeared on the scene in July 1880, the British recognized him as amir of Kabul and undertook not to require the admission of a British resident anywhere in Afghanistan.

As the British were preparing to leave Kabul, news reached them that at Maiwand, near Kandahar, a British force had been annihilated by Ayub Khan, Yakub Khan's brother. Roberts, with 10,000 picked men, at once started for Kandahar and on Aug. 31, 1880, attacked and defeated Ayub at Baba Wali, 3 mi. W. of the city. The British then handed over Kandahar to a governor deputed by Abdurrahman and evacuated Afghanistan. After the departure of the British, Ayub, from his base at Herat, once more seized Kandahar, but he was decisively defeated there by Abdurrahman, who thus won possession of both Kandahar and Herat. Ayub fled to Persia.

With great energy and determination Abdurrahman then set about establishing peace and a strong central government in Afghanistan. In this he was entirely successful. It was during his reign (1893) that the Durand line (named after Sir Mortimer Durand) was laid down to fix the boundary between Afghanistan and the North-West Frontier province of India. He died in Oct. 1901 and was succeeded by his eldest son Habibullah Khan.

13. **Habibullah Khan.**—Habibullah was an enlightened amir. In his reign the foundations of the Habibia school were laid, roads were constructed and steps were taken to introduce machinery and other modern appliances. A weekly Persian paper, *Siraj-ul-Akhbar*, was started and entrusted to the well-known Afghan writer, Mahmud-i-Tarzi. This paper infused new life into the country and played a great part in the national awakening. In Feb. 1919, having observed strict neutrality during World War I, Habibullah wrote to the viceroy of India demanding recognition by the Paris peace conference of Afghanistan's "absolute liberty, freedom of action and perpetual independence." But on the night of Feb. 20, 1919, he was assassinated.

14. **Amanullah Khan.**—After Habibullah's death his third son Amanullah Khan (*q.v.*), seized the throne and proclaimed himself king, displacing Habibullah's younger brother Nasrullah Khan. Amanullah's first act after his accession was to proclaim Afghanistan's complete independence in both internal and external affairs. He communicated his decision to the viceroy of India, and it was the reluctance of the government of India to recognize this independence that led to the third war between Great Britain and Afghanistan. Hostilities began on May 3, 1919, but the fighting was inconclusive and when peace was signed at Rawalpindi on Aug. 8 (supplemented by further agreements signed Nov. 22, 1921) the complete independence of Afghanistan was recognized. Amanullah then established diplomatic relations with the outside world.

Having achieved his first purpose, Amanullah started to introduce internal reforms on European lines with a view to preparing his people for the responsibilities of modern international life. This brought him into conflict, however, with a group of reactionaries who were rigidly opposed to the modernization of Afghanistan. Civil War broke out and in Jan. 1929 a brigand chief Habibullah took advantage of the confusion to seize Kabul. Amanullah abdicated and left for Kandahar. In the spring of the same year, having made an unsuccessful attempt to recover the capital, he left the country and went into exile. Habibullah declared himself king, and ushered in a reign of terror which lasted for nine months.

15. Nadir Khan.—Sardar Mohammed Nadir Khan, Amanullah's cousin, was serving in France as Afghan minister. He was not in good health, but on hearing the news from Afghanistan decided to return home at once. There he and his brothers played a leading role in the struggle against Habibullah, who was finally driven from the capital in Oct. 1929. In a tribal assembly held shortly afterward in the Salaamkhana (audience hall) at Kabul, Moham-

med Nadir Khan was unanimously elected king.

The first aim of the new king was to restore peace. Habibullah and his accomplices, who were still at large, were arrested, court-martialed and executed. Thereafter the king ruled without challenge and devoted his attention to internal reforms. New schools, a literary academy, a military college and a medical college were established; some Afghan graduates were sent abroad for higher education; and, as the crowning achievement of the reign, a constitution was introduced in 1930 providing for a bicameral legislature. Unfortunately, this steady progress was interrupted by the murder of the king during a prize distribution for schoolchildren on Nov. 8, 1933.

16. **Zahir Shah.**—Nadir Khan was succeeded by Mohammed Zahir, his only surviving son, then 19 years of age. On the day of his accession the king declared that he would scrupulously follow in his father's footsteps and fulfill his program. Internal peace was maintained and steady progress in all walks of life continued. Neutrality was observed in World War II as in World War I. In the years following Pakistan's achievement of independence (1947) there was friction between Afghanistan and Pakistan over the establishment of an independent Pathan state. The disputed area, based on the "Durand line," originally comprised the free tribal territory bordering the North-West Frontier province, afterward incorporated in the province of West Pakistan. In 1956 a five-year plan for the construction of better roads and better means of communication and for the development of mines, industry, education and agriculture was drawn up under the guidance of the prime minister, Sardar Mohammed Daud, and in the early 1960s this was being successfully carried out. To finance this vast development, the Afghan government signed agreements with certain foreign governments, notably the U.S.S.R. and the U.S., for loans and financial assistance. In this the intent was to serve the national interest without endangering national independence or security. Afghanistan also had recourse to the services of foreign experts and foreign construction firms and welcomed specialists and educationists who were able to help advance its modernization.

A border agreement was signed with the U.S.S.R. in 1958. A goodwill visit was paid to Afghanistan in 1959 by Dwight D. Eisenhower, president of the U.S., and in 1960 by Nikita S. Khrushchev, premier of the U.S.S.R. (Md. A.)

V. ADMINISTRATION

Until 1919 the government of the country was an absolute monarchy. King Amanullah, however, introduced a system of democratic government, but evolution was inevitably slow. Although, after the accession of Zahir Shah in 1933, the king no longer took any direct part in the administration, much power still rested in the hands of the royal family, who continued to fill many of the most important offices of state. The constitution, based on Moslem law and on a constitutional code promulgated in 1931, provides the framework of a constitutional monarchy.

Legislation is effected by a national assembly (*majlis-i-shura-i-milli*) composed of approximately 172 members elected from the various provinces at three-year intervals, and by a senate (*majlis-i-aiyan*) of 50 members appointed by the king; the administration is carried on by a cabinet consisting of the prime minister and about 15 other ministers, including ministers of defense, the interior, foreign affairs, planning, commerce, finance, justice, education, communications, public works, mines and industries, agriculture and public health. In addition there is a grand council (*loa jirga*) consisting of more than 1,000 delegates from all provinces which meets only at times of great national emergency.

Afghanistan is divided into seven major and eight minor provinces. The major provinces are Kabul, Mazar-i-Sharif, Kandahar, Herat, Nangrahar (formerly Samt-i-Mashriqi), Paktia (formerly Samt-i-Junubi) and Kataghan. The minor provinces are Parwan, Farah, Maimana, Girishk, Shibarghan, Badakhshan, Ghor and Ghazni. Each province is in charge of a governor and is subdivided into districts (*hukumat*). The governor is assisted by local officials in charge of revenue, justice, communications, health and so on. The larger towns are controlled by municipal committees under a president (*rais-i-baladiyah*).

All Afghan subjects, and foreigners without diplomatic status, are subject to Muslim religious law (*shnrint*). The courts range from the police (*huqziq*) court to the high court of appeal (*tamiz*). Punishments vary from the death sentence, which requires confirmation by the king, to fines.

Primary schools exist throughout the country but there are secondary schools only in the larger cities. In Kabul there is a university known as Puhantun, founded in 1932, a teachers' training college and facilities for technical education. There is also a teachers' training college in Kandahar. The Afghan academy consists of two organizations—the Pashto Tolena (see *The People*, above) and Anjumane Tareekh, a historical society.

The organization of the army is based on a scheme that was formulated with the help of Turkish advisers in 1937. The strength of the army in the early 1960s was increasing from 60,000 to about 90,000. There are army corps in Kabul and Paktia provinces, and infantry division headquarters at Ghazni, Kandahar, Herat, Mazar-i-Sharif and Jalalabad. In addition there are brigades of armed police in Kabul and the chief provincial towns. Approximately 300,000 to 400,000 armed levies can also be called upon in times of emergency. The regular forces are armed with modern weapons including a few tanks, armoured carriers and anti-aircraft guns. A considerable amount of motor transport is maintained in Kabul for the rapid movement of troops in case of trouble.

A small air force, mostly equipped (1960) with Russian aircraft, provides a useful means of carrying out reconnaissance in a country where communications are difficult and tribesmen unruly.

VI. THE ECONOMY

Afghanistan is self-supporting in food (except for tea and sugar) and in cotton and wool, the two raw materials most important to its industries. The national income is obtained chiefly from land taxes and customs duties, and to a lesser extent from the profits of state trading and the Afghan National bank. This pays for defense and for development. A plan for the economic development of the country was adopted by Nadir Shah and his advisers in 1932, and was steadily pursued. It was based on the partial industrialization of Afghanistan, and included the installation of hydroelectric works, the erection of textile factories, of machinery for the extraction of sugar from beets, of cotton gins and of other plants. The principal object of these schemes was to enable Afghanistan to be self-supporting so far as possible in certain essential commodities, and so to avoid the necessity for extensive importation of basic requirements. At the same time state-controlled companies were formed to regulate the purchase and sale of the principal imports and exports, the financial equilibrium of the state being maintained by the establishment of a national bank with branches at home and abroad. In 1956 a five-year development plan was announced.

Until 1947 the bulk of Afghanistan's export trade was with, or passed through, the undivided Indian subcontinent; in that year it was seriously disturbed after the two independent countries of India and Pakistan were created. Lambskins continued, however, to go principally to the United States and a barter agreement with the U.S.S.R., first negotiated in 1943 for the exchange of Afghan wool for Soviet gasoline, piece goods, etc., was renewed in 1950 and afforded some relief to the country's economy. Under the Point Four program an agreement with the U.S. was signed in Kabul in Feb. 1951 to assist the Afghan government in the economic development of the country. A similar agreement was later signed with the Soviet Union and some of the east European states.

The principal export commodities are the Afghan lambskin, of which 1,500,000 to 2,000,000 are exported in a normal year; wool; cotton; fruit, both fresh and dried; nuts; hides and skins; cattle felts; sheepskin coats (*poshtins*); carpets; *asafetida*; and timber. Imports consist principally of textiles, piece goods, sugar, petroleum products, machinery, motor vehicles, hardware and manufactured rubber goods.

The chief commercial centres are Kabul, Kandahar, Herat, Mazar-i-Sharif and Jalalabad.

1. Agriculture and Animal Husbandry.—Afghanistan is

mainly a pastoral country. Of a total area of about 250,000 sq.mi. probably not more than 30,000 sq.mi., or about 12%, are under cultivation. The remainder consists of desert land in the south and southwest and of highland country providing seasonal grazing. On the whole the soil is fertile, particularly in the wide loess plains north of the Hindu Kush and in the eastern and southern areas. In these places and along the valleys wherever irrigation is possible good crops are obtained.

Irrigation is carried out by means of a network of channels, often many miles in length. The cultivators are skilled irrigators, utilizing every fragment of profitable land. Some of the Ghilzai are specially skilled in building underground water channels called *karez* (see *KANDAHAR*). Modern irrigation works have been constructed at Pul-i-Khumri, Baghlan and Kunduz in the north and at Girishk near Kandahar. Dry farming is also practised in certain areas.

The principal crops are wheat, the staple food of a large portion of the inhabitants, rice (particularly in the valleys), barley and lucerne for fodder, cotton, sugar beets, sugar cane, Indian corn, millet, lentils and mustard seed. Vegetables are extensively cultivated and include potatoes, carrots, turnips, onions, chilies, tomatoes, beans, peas and cabbages.

Horticulture is largely practised, particularly around Kabul and Kandahar where the Sardas melon is famous. Grapes, of many varieties and excellent quality, and dried apricots are exported in large quantities. Other fruits include all well-known European varieties. The mulberry is grown extensively and in some localities forms the staple food of the inhabitants. Dried and crushed with walnuts it is made into a cake (*talkhan*) and stored for winter use.

Domestic animals include sheep; horses, of which the northern variety (Turkoman) is the best-known; donkeys, extensively used for light transport; camels of two types for heavy transport (the dromedary south of the Hindu Kush); goats; and poultry.

The principal wealth of Afghanistan lies in the immense flocks and herds which roam the great pasture lands below the mountains. From the pastures around Andkhui, Akcha and Shibarghan come the highest-quality lambskin or astrakhan (*karakul*): while from the southern sheep come wool, mutton and butter (which is used in the clarified form of ghee). The cattle are kept chiefly for milk and also provide a considerable quantity of skins and hides.

2. The **Helmand River Project**.—After World War II the Afghan government invested a great part of the economic resources of the country in the construction of a multipurpose project in the regions of the Helmand and the Arghandab, its main tributary. In addition a large part of the necessary capital was obtained from the U.S. and the International Bank for Reconstruction and Development. The aim of the Helmand River project (carried out by an Afghan subsidiary company of an American firm) is to enlarge the irrigated area, increase and modernize agricultural production and at the same time to make the settlement of a great number of nomads possible. Further, the plan is to enlarge the road system in the Helmand region, produce hydroelectric power through two large dams on the Helmand and the Arghandab, and develop trade and industry.

The Kajakai dam on the Helmand is 360 ft. high and forms an artificial lake 50 mi. long, with a capacity of 1,498,000 ac.ft. This reservoir ensures the irrigation of about 355,000 ac. divided into eight districts along the Helmand. It has a power potential of 120,000 kw. About 1,000 nomad families and other landless Afghans have been settled; but beside difficulties of adaptation there have been problems with regard to the unfavourable soil (too salty or too alkaline), bad drainage, the tendency of the farmers to use too much water (when it is available), etc. In the Arghandab region difficulties have been considerably smaller, chiefly because there it is the water supply of already existing holdings that is being increased and regulated. The Arghandab dam is 230 ft. high with a reservoir of a capacity of 388,000 ac.ft. After the final extension it will provide water for 154,000 ac., about half of which will be new land, while the rest formerly had an uncertain and strongly seasonal supply from primitive canals. Its power potential is 7,000 kw. The growing of grapes, peaches, apricots,

almonds and other fruits is particularly important for the Arghandab region, while the produce in the Helmand regions consists mainly of wheat, alfalfa, cotton, melons and vegetables.

The town of Kandahar, where the principal trade is in fruit, has suffered badly from the industrial weakness of the region, and in 1960 there was a pronounced need for an increase in the production of electricity and for a reduction in its cost. Until completion of the dams this need was met by byilding smaller power stations in the Arghandab dam and on some main canals.

3. Minerals.— Much work was done on the geological survey of the country by various agencies after 1930, but although Afghanistan is rich in minerals, its mountainous nature and its remoteness from the sea make the profitable exploitation of this source of wealth a matter of extreme difficulty.

Extensive coal-bearing strata were located in the Hindu Kush north of Bamian, but the only mines sufficiently accessible to work are at Ishpushta on the north road near Doab and at Karhar south of Khanabad, though the coal is not of the highest quality. A survey of the country in 1937-38 and later surveys in the 1950s located oil in the north. In 1960 there was some production of oil for experimental purposes.

Large deposits of rock salt in Badakhshan, supplemented by brine deposits in Andhkui and Herat supply the greater part of the country's needs. There are alluvial gold deposits in the Amu-Darya and a disused gold mine in Kandahar. However, these are not rich enough for profitable exploitation, and neither is the silver that exists in the Hazarajat and the Panjshir valley. There is also a ruby mine in the Jagdalak pass, east of Kabul, and lapis lazuli of a high quality is found in Badakhshan and has been utilized for thousands of years.

Plentiful supplies of lead, zinc and iron ore of excellent quality have been proved near Kandahar and in the Ghorband valley, which also contains copper and manganese. Chrome ore has been found in the Logar valley about 35 mi. S. of Kabul, beryl in Nangrahar province and talc in Shinwari tribal territory adjoining Pakistan. Sulfur, gypsum, alabaster and saltpetre are also found.

4. Communications.— There are no railways and virtually no navigable rivers in Afghanistan. Main roads connect the principal centres of the country and link up with the road system of Pakistan: from Kabul via the historic Khyber pass (*q.v.*), and from Kandahar via Chaman and the Khojak pass. From Ghazni old trade routes lead through the Gumal pass and Kurram. A road links Herat with Iran via Islam Qala. Principal connections with the U.S.S.R. are by ferry across the Amu-Darya to Termez and from Herat to the Soviet railhead at Kushka. A road driven through the passes of the Hindu Kush to connect Kabul directly with the northern provinces was opened in 1933, and in the following 12 years fair-weather roads to all the larger towns were constructed. In the early 1960s a tunnel was under construction below the Salang pass in the Hindu Kush to allow the main road from Kabul to Mazar-i-Sharif to be shortened by 125 mi. The main roads, though usually metaled, are rough and liable to be blocked by snow or damaged by floods in the winter and spring. Bus services ply on these with fair regularity. Merchandise is still frequently conveyed by camel caravans and pack animals.

Ariana Afghan Airlines was founded in 1955, and Afghanistan has regular air services between all major towns and between Kabul or Kandahar and several airports in the U.S.S.R., Iran and India, as well as direct lines to the near east and Europe. In the 1960s fairly large and modern airports were constructed near Kabul and Kandahar.

Afghanistan is a member of the International Postal and Telegraph union. Post offices have been established in the principal towns and regular motor mail services are in operation. A telegraph and telephone system links the provinces with the capital, while a world-wide radio installation connects Kabul with the outside world. There are subsidiary radio stations at Kandahar, Herat and Mazar-i-Sharif.

AFONSO, the name of six kings of Portugal.

AFONSO I (Afonso Henriques) (1109?–1185), the first king of Portugal, was the son of Henry of Burgundy and Teresa, an illegitimate daughter of Alfonso VI of León and Castile. Henry, a grandson of Duke Robert I of Burgundy, had become count of Portugal in 1095, and on his death in 1112 Teresa took charge of affairs. On Afonso's coming of age, Teresa refused to surrender her powers, but Afonso defeated her forces on June 24, 1128, and took over the government. After a period of conflict with Alfonso VII of León, he obtained the latter's recognition of his title as king of Portugal at the conference of Zamora (Oct. 4–5, 1143). Subsequently he extended the Portuguese frontier southward by expeditions against the Muslims, capturing Santarém and Lisbon (1147), Beja (1162), Évora (1165) and Juromenha (1166). He had securely established Portuguese independence by the time of his death (Dec. 6, 1185).

AFONSO II (1185?–1223), king of Portugal from 1211 to 1223, was the son of Sancho I and Dulcia, daughter of Ramón Berenguer IV of Barcelona. His reign was distinguished by his army's share in the victory over the Muslims at Las Navas de Tolosa (1212) and by the conquest of Alcácer do Sal (1217) but was also marked by conflict with the clergy and the nobility, who resented Afonso's policy of strengthening the crown to their detriment. He was excommunicated in 1220 and died on March 25, 1223.

AFONSO III (1211?–1279), king of Portugal from 1248 to 1279, was the son of Afonso II and Urraca, daughter of Alfonso VIII of Castile. He became regent after the deposition of his brother, Sancho II, in 1245, and king on his death in 1248. He conquered Faro in 1249 and established his dominion over Algarve, thus securing to Portugal the natural limits of its southern frontier. The first known meeting of the *curia regis*, in which the municipalities were represented, dates from his reign (1254). Afonso III died on Feb. 16, 1279.

AFONSO IV (1291–1357), king of Portugal from 1325 to 1357, was the son of King Diniz, whom he succeeded, and Isabella, daughter of Peter III of Aragon. He was at war (1336–38) against his son-in-law, Alfonso XI of Castile, but later allied himself with him against the Muslims to win the battle of the Salado river (1340). In 1355 Afonso ordered the assassination of Inez de Castro (*q.v.*) and so provoked his son and heir, Pedro, into rebellion. Afonso IV died on May 28, 1357.

AFONSO V (1432–1481), king of Portugal from 1438 to 1481, was born at Sintra in Jan. 1432, the son of King Duarte and

Leonor, daughter of Ferdinand I of Aragon. He succeeded his father at the age of 6, under his mother's regency. This she was obliged to yield, in 1440, to Afonso's uncle, Pedro, duke of Coimbra. At the end of his minority, in 1448, Afonso embarked on a series of campaigns in north Africa. He conquered Alcácer Ceguer in 1458 and, after subduing Arzila in 1471, occupied Tangier. Ambitious of achieving the union of Castile with Portugal, he invaded Castile in support of the claims of his wife Joan, daughter of Henry IV of Castile, against those of Isabella I. In this same cause he went to France in 1476, hoping to enlist the support of Louis XI. When he failed to win this, he abdicated in favour of his son John, who, however, restored the crown to him on his return to Portugal in Nov. 1477. Afonso died on Aug. 28, 1481. (V. R. R.)

AFONSO VI (1643–1683), king of Portugal from 1656, when he succeeded his father John IV, to 1683, was born in Lisbon on Aug. 21, 1613. In fact he ruled only from 1662, when he came of age, until 1667, when his brother Pedro (afterward king as Pedro II) seized power, keeping Afonso prisoner until his death at Sintra on Sept. 12, 1683. The reign was marked by internal disputes between partisans of the king and of his brother, and by a series of victories against Spain, including the battles of Ameixial (1663), Castelo Rodrigo (1664) and Montes Claros (1665) which led to the recognition of Portuguese independence by Spain in 1668. (D. A. P.)

A FORTIORI (Lat. "from a stronger [ground]"), a type of argument in which the conclusion is supported by a ground stronger than one that has already been accepted in a previous argument as sufficient justification for a similar conclusion about a subject of the same kind. For example, when it has been accepted that in a right-angled triangle the side opposite the right angle must be greater than either of the other two sides because the right angle is greater than either of the other two angles, then it can be argued that in an obtuse-angled triangle a fortiori the side opposite the obtuse angle must be greater than either of the other two (an obtuse angle being even greater than a right angle).

AFRICA, the second largest of the continents, has an area (including offshore islands) of approximately 11,759,000 sq. mi. and a population exceeding 230,000,000. Though stretching for about the same distance north and south of the equator (from Ras ben Sekka near Cape Blanc, Tunisia; 37° 21' N., to Cape Agulhas, South Africa, 34° 51' S., about 5,000 mi.), two-thirds of the continent lies north of the equator, while nearly four-fifths is within the tropics. The west-east extent is 4,600 mi. from Pointe des Almadies, 17° 32' W., on Cape Verde, Senegal, to Ras Hafun, 51° 25' E., near Cape Guardafui, Somali Republic. It is joined to Asia in the northeast by the Sinai peninsula, cut by the Suez canal, and its nearest contact with Europe is across the Strait of Gibraltar. Some areas have long been known to Europeans, notably in north Africa, a part of the Mediterranean world! but western contact with much of Africa is relatively recent and accounts for the great international interest in territorial expansion during the 19th century as well as for the upsurge for political independence after World War II. (L. C. KG.)

I. PHYSICAL GEOGRAPHY

It is sometimes suggested that the physical characteristics of Africa—its climate, vegetation and soils as well as its relief and drainage—help to explain why Africa remained the "dark continent" for so long and until so recently. Certainly the physical environment has presented mankind in Africa with many obstacles and challenges. There are no deep bays or gulfs penetrating far inland and comparatively few rocky headlands to afford shelter to adjoining bays. Beaches are often surf bound, and sometimes backed by large though shallow lagoons, frequently with mangrove forests in them. Large rivers are relatively few and, apart from the Congo, end in deltas or are blocked by sand bars. Rapids and falls comparatively near the coast have discouraged penetration upstream, and navigation on most African waterways is inevitably restricted both by the grading of the river and by the often great seasonal fluctuations of volume. It is doubtful whether these difficulties would have proved insuperable had the resources of the continent been sufficiently attractive to encourage men to overcome them: but it is almost certainly true that they long discouraged, even where they did not actually prevent, European penetration. The realities of the limitations imposed on development by physical conditions must also be recognized today, and several large-scale projects carried out following World War II have failed largely because adequate attention was not given to the facts of physiography, climate, water supply and soils. (R. W. SL.)

A. GEOLOGY

Africa is a plateau. Except in the north where the continent stands lower and was occasionally flooded by transgressive seas, it has remained stable and emergent practically since Pre-Cambrian time. Upon a basement of Archean rocks, highly metamorphosed and much intruded by granites of various ages, rest numerous sedimentary rock sequences, mostly nonmarine in origin. The materials of sequences such as the Lubilash of the Congo and the Karroo of South Africa were derived in part from beyond the borders of the present continent. This fact, with the truncation of older structures at the coasts and the similarity with late Paleozoic and Mesozoic formations in South America, India, Australia and Antarctica, led to the conception of a formerly vast southern land mass, Gondwanaland, of which Africa formed a part.

The existing outline of the continent, including Arabia, which is geologically a part of Africa, dates from the earliest Cretaceous as is shown by the occurrence of seaward dipping marine Cretaceous rocks in many maritime provinces.

Few severe orogenic movements have affected Africa. The Atlas mountains, which geologically and biologically resemble Europe more than they do the rest of Africa, are the only example of Tertiary mountain making, while the Cape ranges at the opposite end of the continent were crumpled during the Triassic. Paleozoic folds in the Sahara are apparently not as extensive as Eduard Suess formerly suspected; but if the Serie des Mines and allied systems of south-central Africa are of Cambrian age as some authorities suggest, their deformation also would be early Paleozoic. Not all instances of folding and metamorphism in the basement are orogenic. A. M. Macgregor defined in Southern Rho-

desia a number of mantled gneiss domes closely crowded together. Between these domes the Archean rocks crop out as arcuate or triangular areas wherein the foliation is parallel to the curving edges and gneissosity of the intruding domes. Such assemblages are likely to prove widespread in the African basement.

Deformation has generally taken the form of broad basins separated by axial upwarps: Congo cuvette, Kalahari basin, Chad depression. Such features are of all ages from Pre-Cambrian to modern times. Most are occupied in part by sedimentary accumulations. Spectacular are the Rift valley troughs extending from Jordan to Mozambique. In their present form dominantly of mid-Pleistocene age, the Rift valleys are sited upon earlier rift structures of the Cretaceous, the Paleozoic and possibly also the Pre-Cambrian which were probably equally impressive. Despite the general rise of adjacent country toward the rifts so that the sides frequently rise to (or near) 10,000 ft. and the floor of the rift stands perhaps above the general elevation of the African plateau, the origin of the rifts is usually ascribed to tensional forces.

Volcanism has been endemic throughout geologic time. Scarcely any rock system exists but has its quota of associated intrusive or extrusive rocks and some of the phenomena are on a magnificent scale. The Lebombo basalts and rhyolites concluding the Karroo sequence are estimated at 29,000 ft. in thickness by A. L. du Toit, who also calculated the volume of magma in Karroo intrusions as between 50,000 and 100,000 cu.mi. At Calvinia and Hopetown in the Republic of South Africa individual dolerite sheets are quoted as 3,500 and 5,000 sq.mi. in area, respectively. Plateau-making floods of phonolite welled out in Kenya during the late Cretaceous, contemporary with the Deccan traps of India.

Recent and subrecent volcanism in central Africa has been aligned closely along the Rift valleys. Mt. Kenya (17,058 ft.) is a denuded cone, the summit of which projects as a neck; Kilimanjaro (19,340 ft.) was formerly in the same state but a new cone with a semiaactive crater, Kibo, now makes the highest eminence. Ruwenzori (the Mountains of the Moon) is nonvolcanic, consisting of a huge upwarped mass of basement rocks differentially elevated to 16,763 ft. Volcanic emissions along the eastern rift are strongly sodic in composition, those of the western rift through the Congo are strongly potassic. Mt. Oldonyo Lengai of Tanganyika and Mt. Nyamagira and Mt. Niragongo of the Congo have been active of recent years, the 1939-40 outflows of basalt from Nyamagira being among the largest witnessed by man. Recent volcanicity is also displayed in the Cameroons and at Emi Koussi and Tibesti in north Africa.

Stratigraphy. — Correlation among formations is usually based upon stratigraphic criteria. Fossils are scarce and of limited value for correlation before the late Paleozoic. The absence of fossils from formations such as the Transvaal and Waterberg systems does not prove them Pre-Cambrian as they accumulated within continental basins of Gondwanaland.

In the Pre-Cambrian rocks radioactive age determinations are beginning to be useful. A. Holmes and L. Cahen indicate seven Pre-Cambrian geological cycles besides others extending into or belonging to the Paleozoic. Only a few minerals are older than 3,000,000,000 years; the Witwatersrand uraninite is 2,100,000,000 years, the Kibara-Karagwe-Ankole rock systems are indicated at about 1,400,000,000 years and there is abundance of ore deposits in the 630,000,000 years age group.

The solid foundation, exposed over about a third of the continent, is a mixed assemblage of Archean schists and paragneisses everywhere intruded by granites of various ages. Upon this lie thick Proterozoic sequences in which strikes are variable, while folding and metamorphism are in some places intense, in others relatively weak. The most complete subdivision of the Archean is established for Southern Rhodesia where three accumulative phases are followed, respectively, by three intrusive phases. The Sebakwian system comprising several thousand feet of rock, originally sediments and basic volcanics (now converted to hornblende schist), is intruded by serpentines and Older Gneiss with an age of 2,900,000,000 years. The Bulawayan, which includes all the

larger gold belts of the colony, is a monotonous greenstone succession of 30,000 ft of onetime basic lavas. It is intruded by the Younger Gneiss. The Shamvaian is mostly fine-grained arkoses (separated by unconformities into three series), and is intruded by younger (Matopo) granite dated as 1,900,000,000 to 2,150,000,000 years old. The threefold subdivision of the east African Archean into Basement, Nyanzian and Kavirondian shows several lithological parallels with the Rhodesian classification. The Basement is heavily migmatized, the Nyanzian consists mainly of acid and basic volcanics and the Kavirondian resembles the Shamva grits.

Archean rocks in a series of major anticlineals make a chain of inliers along the tropic of Cancer from former French West Africa to Egypt and Sudan and appear also about Ghana, Nigeria and the Cameroons region, but detailed correlation with the Archean systems of Rhodesia is not yet possible.

Proterozoic rocks may be divided into older and younger groups, represented in South Africa by the Witwatersrand and allied systems, and the Transvaal and related systems respectively. The first group finds few extensive correlatives farther north, but the latter assemblage has representatives in almost every African territory to beyond the northern tropic. Arkoses, quartzites, shales, mica schists, limestones and dolomites are the typical rock types, and ore deposits due to abundant intrusions are often associated.

Early Paleozoic rocks are scarce in Africa. In the north, the Cambrian is identified only in Morocco, near Tetuán, and Ordovician is restricted to a small area within the Sahara. Marine Silurian, with fossils including *Spirifer cf. rousseaui* and *Leptostrophia oriskania* and crinoids, is, however, encountered at intervals right across north Africa. Post-Silurian folding was mild. In the south, the fossils *Rangia schneiderhöhni*, *Pteridium simplex*, *Orthogonium parallelum* may indicate a Cambrian age for part of the Nama system, but no Ordovician formations have been identified. Reddish Silurian sandstones and conglomerates of continental facies are widespread (see *List of Formations*, below) from the Cape to the Republic of the Congo and Tanganyika. Only in the Congo are these fossiliferous (fish scales, Crustacea, hexactinellid sponge spicules and Radiolaria), and only in the Congo and Cape Province have they undergone severe folding.

The Devonian is widely fossiliferous. It includes the Bokkeveld series of the southern Cape, and is extensive in the Sahara, Libya and the western Sudan. On the Ghanian coast it reaches the Atlantic; marine representatives occur of the lower, middle and upper divisions. The Carboniferous of north Africa is widespread and generally continental. Between Ennedi in Chad and Uweinat (Libya-Egypt-Sudan border) the change of facies began in late Devonian time with the appearance of plant fossils—*Lepidodendron*, *Archaeosigillaria* and *Stigmaria*; but in Mauretania terrestrial conditions did not supervene until the mid-Carboniferous. In Egypt marine intercalations from the north appear in a predominantly continental sandstone series which continued to accumulate probably until the mid-Mesozoic. Central and southern Africa display the continental Karroo system over vast tracts of country. The lowest series is late Carboniferous in age and includes the glacial Dwyka tillite, 2,000 ft. thick in Cape Province but thinning northward to the Transvaal. Patches of it occur as far afield as the Congo and Madagascar.

The succeeding Ecce series (Permian) contains the rich coal deposits of South Africa, Southern Rhodesia and Tanganyika with the fossil frond *Glossopteris*; while the Beaufort series (Triassic) of the Cape is famous for its fossil reptiles (*Pareiasaurus*, *Dicynodon*, *Cynognathus*). Equivalent formations in the Congo basin make the Lukuga series. The Stormberg series contains a Triassic flora (*Dicroidium*, *Baiera*, *Dadoxylon*) with the dinosaurs *Gryponyx*, *Plateosaurus* and the early mammal *Tritylodon*. Aeolian sandstones commonly conclude the Karroo sedimentary sequence before the extrusions of Drakensberg basaltic lava (Liassic). Totalling 4,500 ft. thick in the Drakensberg, these eruptives extended from the east coast to the west, and from the Cape mountains to Victoria falls. Immediately following the extrusions the residual magma invaded the subjacent Karroo sediments as the largest network of associated dikes and

sills extant. Except along the Atlas and in southern Tunisia no marine Trias is established in Africa.

Outside the Congo (Lualaba series), continental Jurassic sediments are scarcely known in Africa; instead, a phase of erosion was ubiquitous and virtually the whole continent was reduced to a plain. Remnants of this plain may still be identified in existing landscapes. The breakup of Gondwanaland was begun by penetration of the Jurassic sea from Somalia to Tanganyika, whence from Tendaguru come marine shells and fossil reptiles of which *Gigantosauros* is the largest known animal. Madagascar was separated from the mainland. The isolation of Africa was completed during the early Cretaceous, when arms of the sea passing down the east and west coasts respectively met around the southern Cape. The faunas of these seas were Indo-Pacific and Mediterranean respectively; e.g., Cretaceous faunas of Zululand and Angola. All stages of marine Cretaceous are known along the east coast, most widely distributed being the Neocomian and Senonian. Cretaceous epicontinental seas spread widely over north Africa reaching to latitude 24° N. up the Nile valley and in Libya. Cenomanian seas spanned west Africa, from Tunis and Morocco to the Gulf of Guinea. Limestones are typical in north Africa, for little terrigenous waste was supplied to the epicontinental sea from the low, smoothly planed Gondwana landscape. About emergent areas in the Saharan Ahaggar, Tibesti and the Sudan accumulated continental and lagoonal sandstones with plants and crocodile remains.

After the Cretaceous the sea shrank, leaving a number of Eocene relicts of much smaller dimensions upon the rising land. Chief areas of sedimentation are the lower Nile valley, central Libya, the Niger valley from Tombouctoo (Timbuktu) to the river mouth, thence Sokoto and the interior of Senegal. Across the northern Sahara retreat was rapid, leaving the Cretaceous hamadas to be covered by various continental Tertiary and Quaternary deposits, including the *ergs* or sand seas. Tertiary basins (e.g., Chad) have received appropriate sedimentation. The Faiyum (Fayum) sequence of Egypt contains the earliest fossil elephants and ancestral apes.

In the western Sahara there was no Eocene sea, only Algerian and Moroccan bays, for a convulsion of the Tethyan geosyncline created an early phase of the Atlas mountains. The Miocene sea covered only Cyrenaica and Degardaia in Algeria. The Pliocene sea was even more restricted. Elsewhere north Africa was land throughout the Neogene. Erosion carved a set of cyclic erosional bevels that can be correlated with similar features in the south.

Marine Tertiary formations are strictly coastal about east, south and west Africa. Lower Miocene occurs at Mombasa (Kenya), Lindi (Tanganyika), Inharrime (Mozambique) and St. Lucia (South Africa) along the east coast and in Angola in the west. Pliocene is best known in Zanzibar and Angola. Marine faunas are again of contrasted Indo-Pacific and Mediterranean types on the east and west coasts respectively.

In southern Africa the correlation between (1) cyclic erosional landscapes, (2) sedimentary sequences of continental type and (3) coastal marine sequences which rest upon marginally downward warped land surfaces is tabulated in Table I. The same scheme may be extended, with slight modifications, to most of the continent.

TABLE I. — Correlation of Sequences, South Africa

Continental erosional stages	Succeeding continental deposition	Succeeding coastwise deposition
Congo cycle . . .	Pleistocene and Recent sands and terrace deposits with implements	Beaches and dunes
"Post-African" cycle (later Tertiary)	Kalahari-type sand, chalcidonic, with abundant fauna including Australopithecine-Late Pliocene Plateau sands (chalcidonic)	Late Pliocene sands (Zanzibar)
African cycle (early Tertiary)	Grès polymorphes, Botletle beds (late Cretaceous-Oligocene)	Early Miocene (Uloa and Inharrime)
"Post-Gondwana" (late Cretaceous)	Serie de Kwango	Senonian-Eocene
Gondwana landscape (Jurassic)		Neocomian-Cenomanian

The South African Pliocene preserved in caves has yielded Australopithecine man-apes and associated fauna; and the Pleisto-

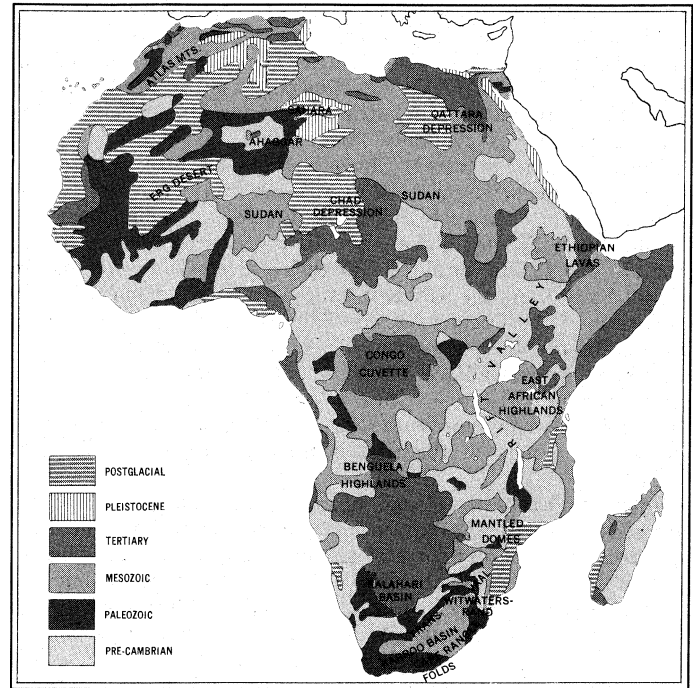

FIG. 1.—GEOLOGIC AGE OF SURFACE ROCK FORMATION OF AFRICA

cene throughout the continent is rich in stone tools and other evidences of early man.

List of Formations

QUATERNARY

Alluvia, raised beaches, desert sands, etc., with neolithic and palaeolithic implements. **Lavas** and tuffs of recent volcanoes.

CAINOZOIC

Pliocene . . Marine beds in Algeria, Tunisia and Egypt. Limestones of Zanzibar and Mombasa. Bone beds of Omo valley and South African caves (with Australopithecines). Older lavas of central African volcanoes.

Miocene . . Marine limestones of northern and eastern coasts. Rusinga Island beds of Lake Victoria; plateau sands of Congo and Kalahari.

Oligocene . . Marine limestones in Algeria, Tunisia, Egypt, Somalia and Tanganyika. Lake beds of Fayum.

Eocene . . Nummulitic limestone of north Africa, Somalia and Mozambique. *Aturia* beds of South-West Africa, Niger valley and Sokoto. *Grès polymorphe* of the Congo and Angola. Widespread eruptions in Kenya.

MESOZOIC

Cretaceous . . Almost complete marine sequences in former French West and north Africa, Mozambique and Zululand. Coastal Angola and Benue valley. Kwango series in Congo and Angola. Continental intercalary and Nubian sandstone of north Africa; dinosaur beds of Nyasaland. Kapitan phonolites of Kenya.

Jurassic . . Late Jurassic marine and continental facies of Somalia and coastal Tanganyika. Lualaba series of Congo basin. Liassic effusion of Drakensberg lavas.

Triassic . . Upper Beaufort and Stormberg series of South Africa, terrestrial Trias of Tunisia and Atlas.

PALEOZOIC

Permian . . Ecca and Lower Beaufort series of South Africa, Tanga beds, Lualaba sandstones of Congo.

Carboniferous . . Dwyka series (with tillite), Witteberg series of Cape, terrestrial and marine sandstones of Egypt.

Devonian . . Bokkeveld series, marine and terrestrial beds of Sahara, Libya and Sudan.

Silurian . . Table mountain, Umkondo, Upper Kundelungu and Bukoban series. Sandstones of central Sahara.

Ordovician . . Sahara.

Cambrian . . Northwest Morocco, Gulf of Aqaba. ?Nama system (in part).

?LATE PROTEROZOIC OR TRANSITIONAL

Transvaal system, Lomagundi, Serie des Mines, Bwana Mkubwa series; arkoses, mica schists and limestones of Tibesti and Ahaggar.

?EARLY PROTEROZOIC

Witwatersrand system, Frontier system, Kibara system; Lépi formation, Ankolean system; ?bankets of Ghana.

ARCHEAN

Onverwacht, Figtree and Moodies systems of the Union, Sebakwian, Bulawayan and Shamvaian of Southern Rhodesia, Tugela-Mfongozisystem of Zululand, Basement, Nyanzian and Kavirondian of east Africa, Benguela gneiss, Nigeria, Tibesti and Egypt.

(L. C. Kg.)

B. PHYSIOGRAPHY

Relief.—The physiography of Africa is largely a reflection of the geological history and geology described in the previous section. The continent, largely composed of a vast rigid block of ancient rocks, has geologically young mountains at its extremities in the highlands of the Atlas mountains in the north and the Cape ranges in the south. Between them are series of plateau surfaces, with huge areas that are level or slightly undulating, above which stand occasional harder and more resistant rock masses. Surrounding these plateaus is a zone of plateau slopes below which are narrow coastal belts widening along the Mediterranean coast, the coastlands of Tanganyika and Mozambique, a narrow belt between the Kunene and Niger rivers, and an area northward of the Gambia and Senegal rivers.

In proportion to its size Africa has less high mountain and less lowland plain than any other continent. The limited areas above 8,000 ft. are either volcanic peaks or resistant massifs. All the land below 500 ft. occurs within 500 mi. of the coast, except for two small basins in the Sahara.

The relief map (fig. 2) shows a contrast between the higher plateau areas of the south and east (to which the name "High Africa" is sometimes given) and the generally lesser elevation of "Low Africa" in the west and north. South of a line drawn from near the mouth of the Congo river to the Gulf of Aden most of the land lies 1,000 ft. or more above sea level, and much of it exceeds 3,000 and even 4,000 ft. North of the line there is relatively little land above 3,000 ft., most of the area being between 500 and 1,000 ft. above sea level; there are also broad coastal lowlands, except in the northwest and in the east beyond the Nile.

These contrasts between High and Low Africa are not only important physical differences, they are also full of consequences for economic development, for European settlement and for political status. An effect of elevation is to modify temperature conditions and, in a tropical area, generally to ameliorate the climatic environment so that the majority of the permanent white settlers in Africa, apart from those of the northwest, live either near or southward of the equator. The highest extensive areas are in Ethiopia, parts of which exceed 15,000 ft. Southward the east African plateau is highest in Kenya, where it is often 8,000 ft. or more above sea level, with occasional volcanic peaks that are much higher, such as Kilimanjaro (19,340 ft.), Kenya (17,058 ft.), Meru (14,979 ft.) and Elgon (14,178 ft.). Ruwenzori or the Mountains of the Moon (16,763 ft.), on the borders of the Republic of the Congo (former Belgian Congo) and Uganda is not volcanic in origin. From east Africa, the plateau extends southward, often with a well-defined, though by no means continuous, escarpment which is particularly noticeable in the Drakensberg mountains of southern Africa (Thadentsonyane 11,425 ft. and Mont aux Sources 10,822 ft.). There the plateau edges are especially marked because the rock formations are hard and horizontal, whereas in Ethiopia they are conspicuous because of recent faulting. Where the rocks are softer and less resistant the escarpment is not so pronounced and so forms less of a barrier to climatic influences and to human movement.

Northward and westward of the plateau area of High Africa there is a decline in altitude to the lower areas of the basins of the Congo, Niger and Nile (*qq.v.*). The only large areas above 3,000 ft. are in the folded ranges of the Atlas mountains and in the central Sahara where resistant granites form the massifs of Ahaggar (Hoggar) and Tibesti. The interior uplands of west Africa and of the Cameroons consist of ancient crystalline rocks, reaching

considerable heights only in the Fouta Djallon plateau in Guinea and on the borders of Sierra Leone and Liberia, and in Nigeria in the Jos plateau, and Adamawa and Cameroon highlands. There are extensive low-lying areas near the coast and in the basin of rivers such as the Senegal, Gambia, Volta and Niger Benue. The high areas of Darfur in the Sudan (over 10,000 ft.) and of Mt. Cameroon (13,350 ft.) are volcanic in origin and are evidence of the same tensions that have resulted in rifting and vulcanism in east Africa.

The ancient crystalline Archean base (or Basement complex) is exposed at the surface over vast areas amounting in all to about one-third of the surface of the whole continent. Sometimes granites are predominant: elsewhere there has been much metamorphism, and schists and gneisses are common. Where erosion is vigorous, surfaces may be very uneven, since the granitic rocks erode rapidly while the metamorphosed rocks, which are often highly folded, form irregular and rugged ridges. In drier areas the more resistant rocks stand up sharply above their surroundings to give the inselberg (*q.v.*) or island-mountain topography so characteristic of much of the Rhodesias and of Tanganyika. Parts of the Basement complex are highly mineralized, as are some of the sedimentaries that rest on it, and there are important mineral-producing areas in southern Africa, on the Congo-Zambezi watershed and in western Africa (see *Mining* below).

Over very extensive periods of time, the African land mass has been subject to vertical movements of elevation and depression, but there has been relatively little folding. Exposure to atmospheric weathering resulted in the reduction of practically the whole land area to an almost level surface or peneplane in Miocene times. Subsequent elevation of this surface through thousands of feet led to the faulting and fracturing responsible for the formation of the great east African Rift valley and to the associated volcanic activity. It also created huge inland seas and lakes in shallow basins on the uplifted surface, and in these areas were deposited large quantities of Quaternary and Recent alluvium. In some areas, however, the older rocks have remained hidden beneath a thick cover of aeolian or wind-borne deposits, as in parts of the Sahara and in the Kalahari.

Vast areas of Africa are characterized by uniformity and monotony of landform and natural vegetation. Level or slightly undulating surfaces occur widely and sometimes give the impression of being a lowland plain, even though lying at a considerable elevation above sea level. Much geomorphological investigation remains to be done, and more precise correlation is needed between the surfaces recognized in different parts of the continent. There is a fair measure of agreement for the view that at least three major cycles of erosion have been completed and are represented by well-marked surfaces; certainly in southern Africa where most work has so far been done. The oldest of these is a high-level erosion surface of late Jurassic age at between 7,000 and 8,500 ft. above sea level. It has been recognized in the Cape ranges, the Basuto mountains and, farther north, in the Nyika plateau of Nyasaland. The second surface (of Miocene or mid-Tertiary age) stands at about 4,500 ft. and is best preserved where rivers like the Orange and Limpopo and, to the north, the Zambezi and Congo have carved out great valleys in troughs that were filled with easily erodable Karroo sedimentary rocks. The third well-developed surface, occurring at between 2,500 and 4,000 ft. is Pliocene or late Tertiary and is most marked where the sedimentary rocks are weaker and in the Cretaceous beds of the Luangwa valley and of the Lake Nyasa trough. In other parts of the continent detailed studies are progressing. They may help to elaborate and perhaps to modify the sequence of the geomorphological history of Africa.

The Rift valleys of east Africa, though directly affecting only one part of the continent, are nevertheless most striking and distinctive features of the relief of Africa (fig. 2). Numerous theories have been advanced for their formation. They probably came into existence in Cretaceous or late Tertiary times and were contemporaneous with the separation of the island of Madagascar from the mainland of Africa. Associated with their formation was the volcanic activity responsible for most of the higher peaks of

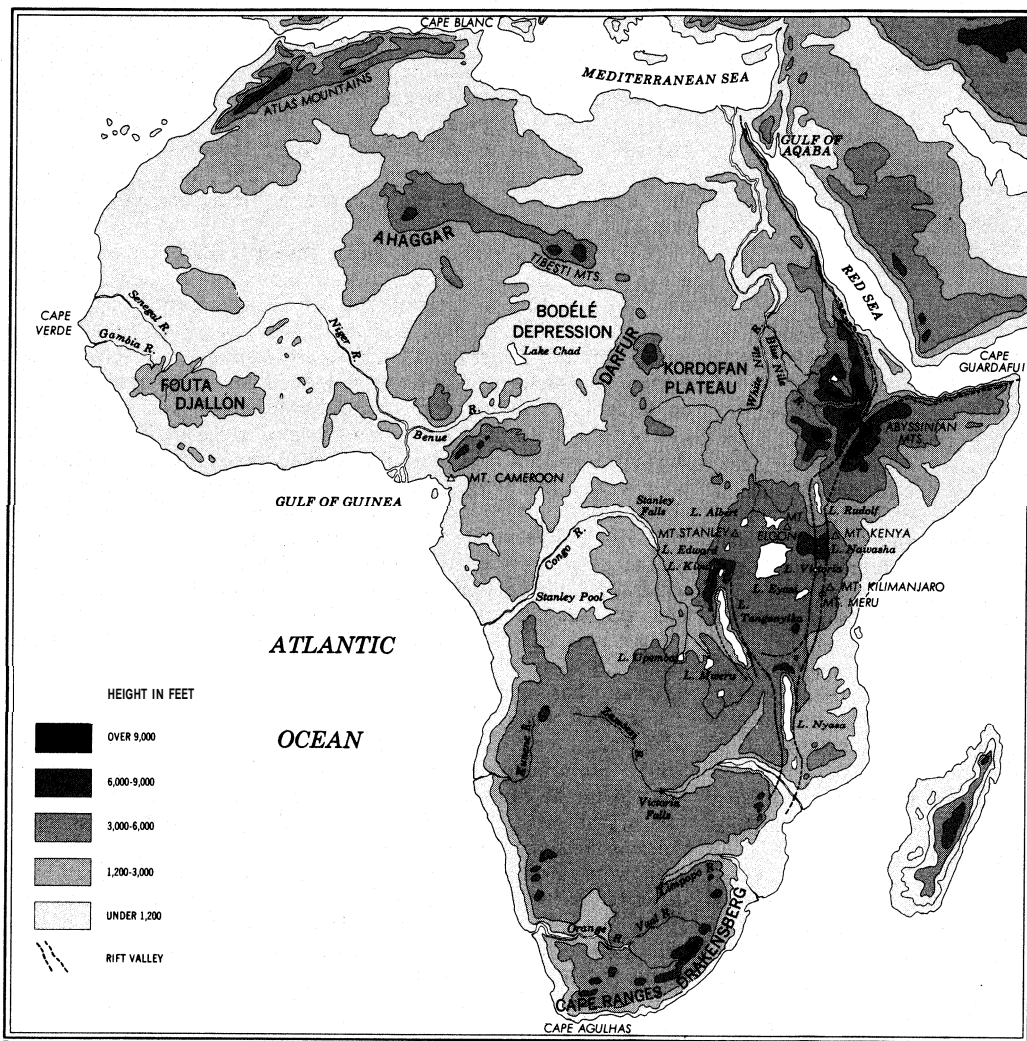

FIG. 2.— TOPOGRAPHY OF AFRICA

east Africa, including Kilimanjaro, Africa's greatest mountain which is always snow-capped, near though it is to the equator. Seismic and volcanic disturbances are still recorded in the western portions of the Rift valley system. In the Mfumbiro or Virunga mountains northeast of Lake Kivu there are periodic outbursts every 10 or 12 years which have created a series of lava flows of known dates. One of these volcanoes dammed the Rift valley and converted a large area, formerly drained by a tributary of the Nile, into Lake Rivu.

The Rift valley extends for about 4,000 mi., its course being clearly marked out by many of the lakes of east Africa as well as by the adjacent volcanic peaks. From the Gulf of Aqaba it can be traced southward along the Red sea and into the Ethiopian massif to the lakes Rudolf, Naivasha and Magadi in Kenya. Farther south the line is less obvious through Tanganyika. The walls that constitute the eastern rim have been more easily eroded, while the lakes are generally smaller and not in line and some of them are only waterless salt beds: the largest lakes are Natron and Manyara, with Eyasi in a side branch of the main rift. The edges are obvious enough to the south in Nyasaland where a huge crusted block collapsed along the parallel faults that constitute the steeply rising slopes of Lake Nyasa. The lake is 360 mi. long but never more than 50 mi. wide, and has a maximum depth of 1,226 ft. The rift then follows the line of the Shiré valley to reach the coast of the Indian ocean near Beira, Mozambique.

The western branch or Western Rift valley extends from the northern end of Lake Nyasa in a great arc taking in the lakes Rukwa, Tanganyika (after Lake Baikal [*q.v.*] the deepest lake in the world with a sounding of 4,708 ft.), Kivu, Edward and Albert.

Subsidiary branches of this valley include the basins in which lie Mweru and Upemba.

Most of the Rift valley lakes lie well below the general level of the plateau, ranging from 1,300 to 3,000 ft. above sea level. They are generally very deep and fiordlike, and some, though with surfaces many hundreds of feet above sea level, have their floors well below sea level.

In complete contrast is Lake Victoria, the greatest of all east Africa's lakes. This occupies a shallow depression on the plateau, 3,717 ft. above sea level, between the major branches of the Rift valley. Its greatest depth is only 270 ft. but its size (26,828 sq.mi.) makes it the third of the world's great lakes after the Caspian sea and Lake Superior.

Drainage.— Both High and Low Africa are similar in that they consist of blocks elevated to form saucerlike depressions surrounded by land higher than their centres. On the seaward side the blocks generally slope steeply down and are deeply cut by relatively short but rapidly flowing streams. On the inland side the descent is usually gradual, except in the cases of the Atlas mountains, the Drakensberg and the Ethiopian massif. The drainage pattern of the continent is determined by the nature and extent of these depressions and of their surrounding uplands. Formerly there were, as a result

of uplift of the plateau surface, numerous vast inland lakes and seas. These have now either disappeared or been much reduced in size, through being drained by streams that have cut back through the plateau rim. Thus the Niger and Congo now drain the lake basins of the upper Niger and the central Congo, the rivers meandering across the huge stretches of Quaternary and Recent alluvium before tumbling over the plateau edge to reach the sea. Yet despite the evolution of the drainage system, nearly one-third of the continent (3,750,000 sq.mi.) still consists of areas of inland drainage with no outlet to the sea. Apart from the many short, and often seasonal, streams that are usually limited to the coastal zones, there are only nine major river systems, and one of these (the Lake Chad system) fails to reach the sea. Even these main rivers have not yet had time to grade their courses, and falls or cataracts occur where the rivers descend from the interior basins across the hard rocks of the plateau rim to the narrow coastal plain below. Energetic, short coastal streams are actively cutting back by headward erosion into the plateau, especially in the better watered areas, and in due course will drain to the sea areas that are at present inland drainage basins. Part of the explanation of the apparent drying up of some inland lakes like Ngami, Makarikari and Chad since Europeans first saw them may be at least as much concerned with changes in drainage as of climate.

The Congo— This river has the largest drainage system (1,425,000 sq mi. drained, 2,918 mi long). It lies entirely within the tropics, the main river running at times astride the equator. Thus most of its basin experiences the heavy and fairly evenly distributed rainfall of equatorial latitudes, so that all the main rivers are perennial, with many of them available for navigation during

most of the year in those stretches between falls and rapids. Much of the basin of the central Congo is 1,000 ft. or more above sea level tilting gently from southeast to northwest. It is surrounded by uplands such as the Ratanga-northern Angola plateau on the south, the Rift highlands of east Africa to the east, and the uplands of the watershed between the Congo and the Niger-Chari in the north. The alluvial plain is crossed by ill-defined channels with numerous lakes, marshes and swamps—parts of the basin that have never yet been fully drained.

All the tributaries join the main stream before breaching the Crystal mountains in a long series of 32 rapids and cataracts known as the Livingstone falls which take the river down 700 ft. in a stretch of 220 mi. immediately below Stanley pool. By contrast the difference in height between Stanley pool and the Stanley falls farther upstream (on the eastern edge of the former inland lake) is about 800 ft., spread over more than 1,000 mi. The Congo, unlike the other great African rivers, has an estuary and not a delta.

The Nile.—Though with a smaller drainage area (1,110,000 sq.mi.), the Nile is one of the world's greatest rivers, comparable with the Mississippi and the Amazon, with a total length of 4,157 mi. It maintains its volume during a passage across a wide rainless desert area because much of its water comes from the equatorial regions of the east African plateau where it is stored in the huge natural reservoir of Lake Victoria. Its tributary, the Blue Nile, brings the seasonal rainfall of the summer monsoon from Ethiopia and is thus mainly responsible for the great fluctuations in the amount of water in the lower parts of the valley. Navigation on the river is checked by six cataracts between Khartoum and Aswan as well as by the irrigation barrages and dams constructed since the mid-19th century.

The Niger.—This river drains 580,000 sq.mi. and, while rising only 200 mi. from the Atlantic ocean in the Fouta-Djallon plateau, has a total length of 2,600 mi. before reaching the sea in the Gulf of Guinea. The lower Niger, formerly a separate stream, has cut back into the plateau to drain the middle basin, a former inland lake, which still floods very easily during the rainy season in the area above Tombouctou. The Niger's main tributary, the Benue, is gradually working back, in the same manner, into the Lake Chad basin, by cutting its way through the upland area linking the plateaus of northern Nigeria to the mountains of the Cameroons.

The Zambezi.—The Zambezi is 1,700 mi long and its basin covers 513,500 sq mi. Its upper course drains a huge shallow alluvial basin more than 4,000 ft. above sea level: many of its tributaries there are intermittent because of the highly seasonal nature of the rainfall and the intensity of evaporation. The falls and rapids are in its middle course, the most spectacular being the Victoria falls, 355 ft. high (cf. Niagara, 167 ft.). Below the falls the river follows a narrow zigzag course developed along successive fault lines. Farther downstream the Kariba dam has formed a huge lake in the section known by the Matabele people as Gwembe. Nearer the Indian ocean the river becomes 5 mi. or more wide in places, and the railway bridge (3,775 yd.) which spans the river between Sena and Dona Ama is one of the longest in the world.

The Orange.—This river, with its single important tributary, the Vaal, is 1,300 mi. long but has a relatively restricted basin of 170,000 sq mi. It drains some of the higher parts of the South African plateau westward to the Atlantic: but it loses so much of its water through evaporation and, in the 20th century, through withdrawal for irrigation, that in drought years it carries very little water and may even be dry. Much of the rainfall never reaches the main river but collects in shallow lakes (vleis) and is evaporated so that they become salt encrusted.

Other Rivers.—Three other rivers deserving individual mention are the Limpopo, draining an area between the Zambezi and the Orange, and the Volta and Senegal rivers of west Africa, but none has a catchment area comparable with the five larger systems already described.

The great desert areas of northern Africa contain several basins with no outlets to the sea. Lake Chad is a shallow body of water

whose volume and area fluctuate greatly from year to year largely because of the highly irregular seasonal discharge of the Chari river. Northeastward lies the lower-lying Bodélé depression, into which Chad water occasionally overflows. From the Gulf of Gabes in southern Tunisia there is a line of depressions extending southwestward across the desert from the Chotts or salt lakes (some of which are below sea level) to the salt desert of El Djouf. The few streams that flow in the Sahara all lose themselves in the desert and fail to reach the sea.

See also articles on the main geographic features.

(R. W. SL)

C. CLIMATE

Africa extends from 37° N of the equator to 35° S. and hence the climates of the continent are largely tropical and subtropical in character. Temperate climates are found on the Mediterranean shores in the north, in the southern and southwestern Cape province and on the higher parts of the great inland plateau. The cold ocean currents flowing equatorward on the western side of Africa cool the climates of the coastal zones for a few miles inland. In the east the climatic influence of the warm ocean currents is stronger and warm humid air penetrates far inland.

The amount of rainfall and its distribution throughout the year vary greatly. The outstanding feature of the rainfall is its seasonal distribution; almost everywhere, apart from the equatorial lowlands, there are marked wet and dry seasons, wet seasons as the sun passes overhead and dry seasons in the intervening periods. (See fig. 3.)

Air temperature is about as variable as rainfall. From the human point of view the climates of most of Africa are warm, though cold weather is common in the deserts, on the plateau and in the mountains. At times some regions are uncomfortably hot but only the deserts are too hot for active life. Statistics of average temperature for some representative stations are included, but the great differences of temperature between day and night make these figures difficult to interpret in the light of experience in temperate countries. (See fig. 4.)

There are seven major types of climate which occur in zones roughly symmetrical about the equator corresponding in a general way to the major zones of natural vegetation.

Equatorial Climate.—This is the climate of the basin of the Congo river west of Ruanda-Urundi, the Central African Republic, part of the Guinea coastlands extending to southern Nigeria,

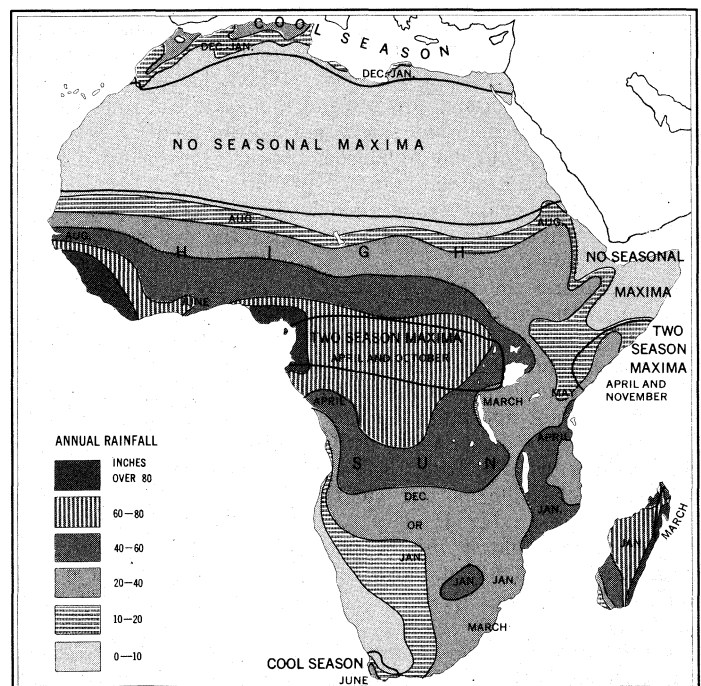

FIG. 3.—TOTAL ANNUAL RAINFALL OF AFRICA

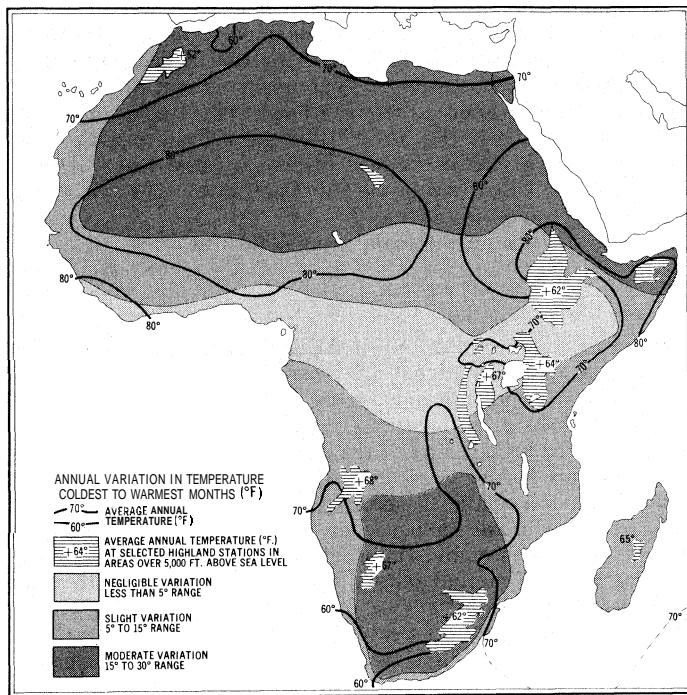

FIG. 4. — AVERAGE ANNUAL TEMPERATURE RANGE OF AFRICA

Ivory Coast and a small part of Ghana. The heavy convectional rainfall has no marked dry season but an interruption in the rains between two periods of maximum. Rains are heaviest when the sun is overhead; near the equator the equinoctial months are the wettest, but farther from the equator the two maxima merge into one: in midsummer — January in the southern hemisphere and July in the northern. The change from a southern hemisphere regime of rainfall to a northern hemisphere one takes place about 3° N. of the equator. At Abidjan (77 in.), the first rains come from March to July; August and September are relatively dry and the second rains occur in October and November. At Leopoldville, June to August is a dry season and the rains occur from October to May with maxima in November and April. The average rainfall over most of the Congo basin is 60–70 in. a year, but some areas on the west coast receive 150–200 in. The hill slopes in the Cameroons are exceptionally wet. These heavy rains are influenced by the moist southwesterly monsoon wind that blows inland in the hot season, May to October. When this wind augments the ordinary convectional processes of the equatorial zone there is no interruption in the rainy season and no dry months. (Douala 156 in., Port Harcourt 98 in., Harbel 154 in.) On the other hand, where the influence of the monsoon predominates, as at Conakry (169 in.) in Guinea, there is a single, though long, rainy season followed by five months of drought when the dry northeasterly harmattan blows.

Temperatures in the equatorial region do not vary much throughout the year. The annual mean for the basin of the Congo is about 80° F. with only a small difference between the means of the warmest and coolest months. The daily range (approximately 12°–20°) exceeds the annual range; in fact, cool though humid evenings are not uncommon on the banks of the Congo. Where there is a dry season the mean daily range may be as much as 30° even a short distance from the coast. (Mean monthly temperature: Coquilhatville, hottest month March 78° F., coolest July 74° F.; greatest range January 20°, least July 16°; Stanleyville, hottest month March 79° F., coolest August 76° F., greatest range January 20°, least range July 14°; Douala, hottest month March 82° F., coolest July 77° F.; greatest range April 16°, least July 9°.)

Tropical Climates.— These are found in the savanna lands which enclose the equatorial regions. Precise definition of their extent is difficult but, taking the 30-in. rainfall line as a rough limit, the northern boundary would be somewhere between the

parallels of 12° N. and 14° N. and the southern boundary near the parallel of 16° S. The rainfall varies from 30 to 60 in., except on the windward slopes of high mountains like Mt. Kenya and Kilimanjaro and in favoured situations like the northwestern shores of Lake Victoria (Entebbe 66 in.). Tropical climates are distinctly drier than the equatorial climates and are characterized by a rainy season in the summer of either hemisphere and a dry season in the winter. Rainfall decreases fairly rapidly in the direction of the tropics and the vegetation of tall trees and high savanna deteriorates into scrub.

The relatively cool highlands of east Africa which lie across the equator have a tropical rather than equatorial climate because of their altitude. Rainfall in the wetter parts of Kenya and Uganda is about 60 in., with local variations due to relief; the Rift valley, for example, is notably dry with only about 30 in. and densely populated Ruanda-Urundi has about 45 in. Temperatures in the warm months are higher than in the equatorial regions. But these climates are not always oppressive; relative humidity is usually low in the daytime when the temperature is high, and there is considerable range of temperature between day and night; in the warm weather before the rains day temperatures are above 80° F., but with a range of 20°–30° the nights are comfortable. Uganda, at a somewhat lower altitude than the highlands of Kenya and with a similar rainfall: has a warmer climate.

The region of tropical climate stretches westward from Uganda through Chad to west Africa. There the prevailing southwest winds, from the Gulf of Guinea, carry moist air inland. The months April to October are rainy. The rest of the year, when the northeast winds blow, is dry and hot; temperatures are above 90° F., but the daily range is about 20° and on the hottest days the relative humidity is below 50%. The discomforts of the hot season are often exaggerated. (Mean temperature: Kano 87° F. in April and 71° in January. Jos 77° in April, Nairobi 65° in March and October and 59° in July, Kampala 74° in January.)

The corresponding tropical climate of the southern hemisphere is in the Federation of Rhodesia and Nyasaland and in Angola. With the exception of the deep Zanibesi valley, the whole of this area lies above 3,000 ft. and in the east some of it is above 6,000 ft. Rainfall is moderate (30–50 in.) and the temperatures are lower than in the tropical region north of the equator. The daily maximum temperature in summer at about 5,000 ft. is approximately 80°–85° F. The hottest areas are in the deep valleys of the Zambezi (Luangwa and Kafue) where temperatures of over 100° are common, and the coolest near the eastern mountains.

On the desert side of the tropical climates is a dry region with the same essential characteristics forming a zone of transition from the savanna to the deserts. The northern Sudan, the northern frontier district of Kenya, the Karamoja district of Uganda, the Nyika zone in east Africa, southern Tanganyika, northern Kalahari and southern Angola all belong to this dry region. Rainfall is low (15–30 in.) and the rainy season lasts only three to five months (Kays 30 in.; Niamey 23 in.; Dodoma 22 in.; Maun 17 in.). Temperatures are high throughout the year (Kays, mean maximum in May 108° F., daily range 26°; Niamey, mean maximum in May 106° F., daily range 31°; Dodoma, mean maximum in November 88° F., daily range 24°; Maun, mean maximum in October 95° F., daily range 31°). The seasonal range of temperature is small (Niamey 9°, Dodoma 9°, Maun 18°) and there is no real winter. The hot weather at the end of the long drought is uncomfortable and despite the rise in humidity the arrival of the rains brings relief from the heat.

Desert Climates.— These are found in both hemispheres — the Sahara (*q.v.*) in north Africa and the smaller deserts of the Kalahari and South-West Africa in the south. The former extends across the continent from the Atlantic to the Red sea and, for the most part, is a true desert. Except in the mountain massifs years may pass without rain; vegetation is sparse and stunted and the surface consists largely of sand and broken rock. Apart from the lack of rain, one of the most interesting features of the climate is the great range of temperature: dry northerly currents of descending air prevail most of the time and the sky is hazy as even a light wind raises the dust. There is no cloud and the sun scorches

the ground. Summer temperatures are among the highest in the world; day after day the thermometer rises above 110° F. But as the air is dry the ground cools rapidly when the sun begins to set and the night seems cold. Daily ranges of over 50° are usual. In the winter, on the other hand, the days are pleasant; the temperature is about 60° F. but severe frosts follow at night. There are occasional violent dust storms known by local names like *simoom*, *sirocco* and the *khamisin*.

The Kalahari desert in the southern hemisphere extends from the Orange river to the Zambezi and has a summer rainfall varying from 10 in. in the south to over 25 in. in the north. Practically the whole area supports a natural vegetation of some economic value. Normal summer maximum temperatures are close to 90° F. and days with temperatures as high as 105° can be expected only about once a month. The winter temperatures are over 70° in the daytime with light frosts at night and occasional severe frosts at altitudes above 3,500 ft. The Namib and the southern end of the plateau in South-West Africa, Namaqualand, the drier parts of the south African Karoo and the lower reaches of the Orange river valley, where the rainfall is less than 5 in. (Goodhouse 2 in.), also belong to this region of desert climates. Though the rainfall (5–15 in.) is meagre, nearly half of it falls in winter and the vegetation of low scrub provides grazing for sheep and goats. Summer temperatures are similar to the Kalahari but winters are somewhat colder.

The coastal zone of the Namib is a narrow sandy desert, cool and almost rainless, stretching from Angola to Cape Province. True desert begins some distance south of Luanda where the mean annual rainfall is 13 in.; Mossâmedes has only 3 in. of rain and the coast of South-West Africa almost no rain at all. The upper air over the coast is warm but the surface air is cooled by the Benguela current and the coast is liable to frequent low cloud and fog. Called *cacimbo* in Angola, it occurs mainly in the cool season, spreading inland from the sea in the early morning and dispersing a few hours later. In South-West Africa, however, it becomes a thick layer of stratus cloud about 1,000 ft. high extending from the seaward limit of the cold water to about 30 mi. inland. Almost every morning in summer and on many days in winter the sky is overcast and a fine drizzle falls and wets the ground. Toward afternoon the sky clears and a strong, almost violent, sea breeze comes up to raise the loose sand of the desert into clouds of dust. The hottest days are in the winter months when the cool weather is occasionally disturbed by the familiar berg of south Africa—a hot dry wind from the direction of the interior of the plateau which makes the temperatures on the cool coast rise to over 90° F.

Mediterranean Climate.—This occurs on the coast of the Mediterranean sea, beginning in Morocco and extending eastward through northern Algeria and Tunisia, and in southwestern Cape Province. Both areas are mountainous and the rainfall, which is cyclonic, varies considerably with altitude and exposure. The characteristic feature of the Mediterranean climate is winter rainfall (15–30 in.) and a long dry summer.

In north Africa the Mediterranean region includes the coastal strip, a plateau 3,000–4,000 ft. high and the wooded ranges of the Atlas mountains in which there is abundant rain in both summer and winter. The climate of the Atlantic coast is moderated by the cool Canary current. Summer is cool and the low cloud and fog are the cause of high humidity and a small range of temperature. Summer temperatures increase eastward along the north African coast (Mogador 68°, Algiers 79°, Tunis 91°) and the contrast between summer and winter becomes much more pronounced. The extreme maximum temperatures in the hottest months may exceed 100° (Algiers, mean August maximum 88°). Winter depressions with their westerly winds and clouds bring cool weather (Algiers, mean January temperature 56°); frost is rare on the coast but common on the drier steppe-covered plateau of the Shotts between the Atlas ranges. There the winter climate is severe and the summer is as hot as it is near the coast.

The Mediterranean region of Cape Province is small in comparison with the coast of north Africa but has large variations of rainfall and temperature. Winter is cool and wet and the sum-

mer dry and warm near the coast, though at times the weather may be uncomfortably warm only a short distance inland (Wellington, mean January maximum 88°). Both seasons suffer from strong winds—in winter the northwesterly gales and in summer the monotonous and regular "Cape southeaster" which, in the neighbourhood of Cape Town, may blow gale force for two or three days at a time. Rainfall varies greatly with exposure. The city of Cape Town has a rainfall of about 25 in. but the mountain slopes receive 60–70 in. The rainfall decreases rapidly northward and inland toward the Karoo where the Mediterranean climate merges into semidesert (Saldanha bay 12 in., Garies 5 in., Worcester 9 in., Laingsberg 4 in.). In the warm summer (mean January temperature: Cape Town 71°, Stellenbosch 70°, Worcester 73°) weeks may pass without rain; the southeaster blows persistently, covering the mountains with whitish clouds like the "table cloth" on Table mountain.

Humid Subtropical.—The plain in the southeast of Mozambique and its continuation in the narrow coastal strip in South Africa have a warm and humid climate which is distinctly subtropical in the north but temperate in the south where it becomes cooler and merges into the region of year-round rainfall found on the south coast and on the forested southern slopes of the mountains of Cape Province (Harkerville near Knysna, mean annual rainfall 43 in., wettest month September 5 in., driest month April 3 in.). The extent of the region is restricted by altitude, losing its subtropical character above 2,000 ft. Rainfall occurs mainly in summer and varies from about 30–50 in. (Lourenço Marques 32 in., St. Lucia bay 51 in., Durban 45 in., Port St. Johns 48 in.) The warm Mozambique current exerts a strong influence on the temperature of the whole coastland of Mozambique and Natal and daily maxima in summer vary between 80° and 90°. (Mean January maximum: Lourenço Marques 86°, St. Lucia bay 83°, Durban 81°, Port St. Johns 79°.) These temperatures combined with a relative humidity of about 65% are uncomfortably warm, but in the winter the climate of this coast is the most genial in southern Africa. (Mean July maximum. Lourenço Marques 76°, Durban 72°, St. Lucia bay 72°, Port St. Johns 71°.)

The rainy season in Mozambique (November to April) corresponds to the season of the northern monsoon which is a southern extension of the Asian circulation into the Mozambique channel. The southern monsoon which blows in winter is part of the trade wind circulation of the southern hemisphere and does not usually bring rain. The coast of Natal, however, does not experience these winds and the most notable feature of the wind there is the fresh northeasterly sea breeze relieved occasionally by stray southwesterly bringing clouds and rain. East London has a high frequency of southwest winds and there the average velocity for the year is 14 m.p.h.

Temperate Plateau.—This is the grassland plateau, 3,000–6,000 ft. high, and includes the high veld on which the Witwatersrand gold fields and the principal farming lands of South Africa are situated. The main features of the climate are low rainfall, cloudless skies and large diurnal changes in weather. Local differences of rainfall and temperature are due to relief and exposure, and a number of isolated areas of wet, cool and misty mountain climates are found on the prominent eastern escarpment. Seasons are sharply contrasted: summer is warm and the rains, mostly convectional, occur then; winter is cool and dry. Mean annual rainfall varies from about 20–40 in., decreasing from east to west (Standerton 28 in., Johannesburg 30 in., Bloemfontein 22 in., Kimberley 16 in.). Moisture for the summer rains appears to come from the Indian ocean in a deep northerly to northeasterly current which becomes unstable and produces convectional showers with only a small ascent. Most of the plateau is cool in summer. (Mean January maximum: Ermelo 78°, Johannesburg 79°, Bloemfontein 86°.)

The winter weather is fine and warm in the daytime followed by cold nights, and in the mornings the thick haze in the valleys and depressions reveals the inversions of temperature. In winter outbreaks of cold air from the south sweep across the plateau now and then bringing snow and rain to the mountains. Severe frosts are not unusual, as at Bloemfontein in July when this occurs on

about one night in four.

Highland Climates.— These climates occur, in small areas, throughout eastern Africa where the altitude exceeds 6,000 ft., notably on the mountain slopes of Ruwenzori, Kilimanjaro, Kenya and Elgon. The Ethiopian plateau is an extensive area of highland climate—a rugged massif in which difference of altitude and exposure are responsible for important local differences of climate. But for the mountain peaks reaching 15,000 ft. the general level of the plateau is about 8,000 ft. The land between 6,000 and 8,000 ft. has a pleasant climate. The rain (Addis Ababa 49 in.) is monsoonal and falls mainly from June to September.

In the southern hemisphere the Basuto highlands with their natural vegetation of mountain grass should be included in the region of highland climates. The higher mountain slopes are cool, misty and often wet; in the winter they are snow-covered and intensely cold. The population is therefore concentrated in the valleys where conditions are less severe. (Mokhotlong 7,800 ft., rainfall 22 in., mean July maximum 25° F.) (S. P. JN)

Effects of Climate.— Climatic conditions, particularly rainfall, have very important effects on other aspects of the physical environment and on economic and settlement possibilities. There is a direct correlation with vegetation types and with hydrographic conditions, especially in relation to the regime of rivers. Navigability, the possibilities of irrigation and the generation of hydroelectricity are all affected by the markedly seasonal nature of most African rivers. The Congo benefits in that its catchment area extends both north and south of the equator so that the volume of water in the main river fluctuates relatively little from season to season, while the Nile has the advantages of year-round rainfall over much of its upper basin and of the vast storage capacity of natural reservoirs like Lake Victoria.

The types of agriculture practised in different parts of Africa (fig. 4) are closely influenced by climatic conditions, and the predominance of crops or livestock in the rural economy is determined largely by rainfall. In areas with considerable altitudinal differences, with consequent variations in temperature, such as the uplands of Ethiopia, the east African plateau, and the Atlas mountains, there is usually a well-marked correlation with vegetational belts, and a wide range of products can be grown.

The links between climatic conditions and human activities are also revealed by a study of the distribution and incidence of disease. The effects of malaria, carried by the *Anopheles* mosquito,

and of trypanosomiasis or sleeping sickness, which is spread by the tsetse fly (*Glossina*) are seen in the health of humans and of animals and in the nature of the farming systems practised (see Natural Resources: Land Use, below). Climate has also been a leading factor in determining those areas in tropical Africa that are suitable for permanent European settlement. Thus the hot, humid and relatively unhealthful conditions of the coastlands of the Gulf of Guinea for long gave west Africa its not wholly deserved reputation as "the white man's grave." In contrast Europeans were attracted to the healthful inland areas of east Africa, especially above 5,000 ft., and to the high veld areas of the Rhodesias at a rather lower altitude. In subtropical Africa (e.g., Algeria and South Africa) there are continuous areas in European occupation; but within the tropics the European-settled areas generally form relatively small islands of white settlement in the midst of predominantly African areas. The extent and nature of white settlement have an obvious relevance to the problems of interracial co-operation and political progress.

Rainfall Probability Forecasting.— Since World War II the shortcomings of mean annual rainfall figures have been recognized by economists as well as by agriculturalists and climatologists, partly as a result of costly failures in agricultural planning, such as the East African Groundnut scheme of 1946–51 for the raising of peanuts in Tanganyika. What matters from an agricultural point of view is not average conditions but actual totals of rainfall during a particular year or growing season. In general, variability from year to year appears to be greatest in those districts where total rainfall is generally low, as for example in arid and semiarid areas. Under less dry conditions, the variations may be smaller, but they can have vital consequences, especially in areas of intermediate average rainfall (20–40 in. per annum).

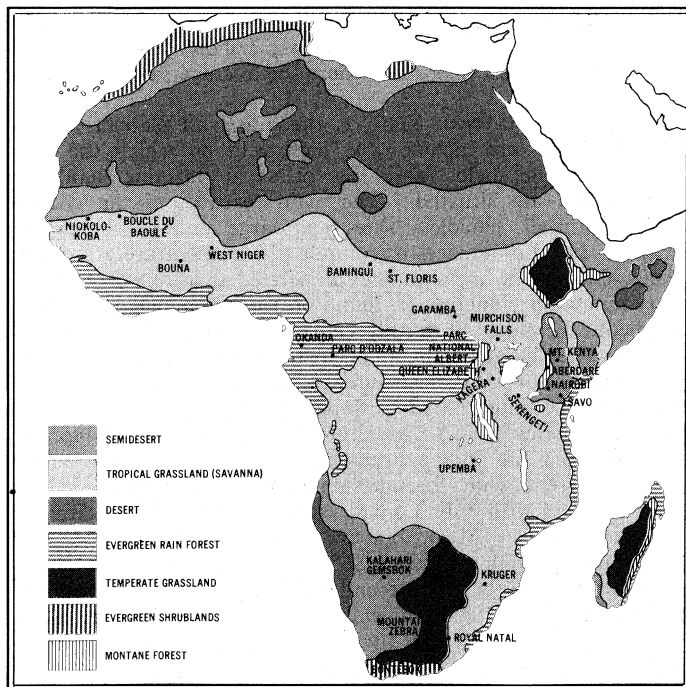

Investigation carried out in east Africa, and closely studied by the East Africa Royal commission of 1953–55, showed that there was a very close relationship between rainfall reliability and the various ecological zones. Less than a quarter of the total area of east Africa was found to have reasonable prospects of receiving 30 in. of rainfall in a year (and much of this was already rather more densely peopled than most other areas). Although similar studies are not yet available for most parts of the continent, it is now widely accepted that it is essential to have accurate measurement of rainfall probability if the future planning of agricultural development is to be sound and realistic. (R. W. SL.)

D. VEGETATION

The greater part of Africa is covered by desert and by grasslands with or without trees; dense forest and thickets cover less than a tenth of the continent. The extratropical regions of north and south Africa both have a Mediterranean type of vegetation, but they are very different from each other floristically. The intertropical regions have belts of vegetation ranging from desert to luxuriant lowland rain forest, while the high mountains have their own special varied and exceptionally interesting vegetation. (See fig. 5.)

African vegetation is constantly being modified or destroyed by man, his animals and the fires he starts. The most striking change is when humid forest is degraded to savanna, but a more widespread, though less dramatic, change has also occurred in the broad-leaved woodlands. In these a shrubby understory has been replaced by tall grass and the trees have become more widely spaced. Many changes have undoubtedly taken place within living memory but certain features are probably the result of more ancient changes. In particular, the alternating humid and arid phases of the Quaternary seem to be responsible for the disjointed distribution of many genera and species. Fires have been prevalent in most areas at least since the last humid phase of the Quaternary, so that the climax vegetation may never have had a chance to become continuously established.

North African vegetation contains a considerable proportion of European genera and species, besides certain endemics in and south of the Atlas mountains. Forests of cork oak (*Quercus suber*) and of Atlas cedar (*Cedrus atlanticus*) occur in Morocco, Algeria and Tunisia. Mediterranean maquis, composed of ever-

R. W. HAYMAN

FIG. 5.— VEGETATIONAL ZONES AND NATIONAL PARKS OF AFRICA

green shrubs with hard leathery leaves, occurs in these countries and also in Libya. High plateau steppe is extensive in the Atlas mountains and subdesert steppe is found in the western desert. The Egyptian farmlands depend entirely on the Nile waters, while the rest of this country is arid desert. Plants of European affinity are found in scanty fragments of vegetation in the Saharan mountains and in oases with their characteristic date palms. The southern edge of the Sahara is wholly tropical in its flora.

Cape maquis occupies a narrow strip in the extreme south. The flora of the Cape is extraordinarily rich and resembles certain features of the Australian flora, the peculiar families Proteaceae and Restionaceae and certain groups of Leguminosae being common to the two areas but rare in other parts of the world. Many of the maquis shrubs contain oil or resin and have a brown or grayish appearance, such as many species of heather and Compositae (e.g., *Elytropappus rhinocerotis*). The few trees, such as *Callitris juniperoides* (a conifer) and the silver tree (*Leucadendron argenteum*), are thought to be remnants of more extensive forests. There are many beautiful herbs such as ground orchids, oxalis and members of the geranium and lily families.

Behind the maquis lies the vast subdesertic Karroo which extends to the northwest and merges with the coastal desert of South-West Africa and Angola. The Karroo vegetation is extremely well adapted to the arid climate and is very rich in species. Among the commonest shrubs and shrublets are *Pentzia*, *Chrysocoma* and *Euryops* and, on saline soils, *Salsola* and *Atriplex*. North of the Orange river the commonest shrub is *Rhigozum trichotomum*. In certain areas low succulent plants are abundant, especially the genus *Mesembryanthemum* and its segregates, which sometimes have strange leaves which can easily be mistaken for stones. Heathlike shrublets and taller succulents such as aloes and euphorbias also occur. *Acacia karroo* and *Rhus viminalis* are often abundant along watercourses; trees also occur on mountain slopes.

On its eastern side the Karroo type of vegetation has invaded degraded areas of temperate and subtropical grassland. The latter, known as high veld, occupies vast areas above about 3,500 ft.; *Themeda triandra* is a widespread and abundant grass there, as on certain tropical mountains.

Evergreen forest in Cape Province is confined to small areas of which the Knysna forest is the largest. Although growing in a temperate or subtropical climate, these forests have close floristic affinities with the montane evergreen forests of the intertropical regions. Trees include the conifers *Podocarpus* and *Widdringtonia* as well as wild olives (*Olea*) and stinkmood (*Ocotea*).

The eastern coast of south Africa is much wetter than the western, and the plains are occupied by savanna and patches of forest, both of distinctly tropical aspect and affinity. This savanna, composed of tall rank grasses which are nutritious only in their early stages, is called "sour veld" in contrast with the "sweet veld" of higher altitudes where the grass remains nutritious even when dry.

Mangroves grow in brackish swamps by river estuaries. Those of eastern Africa have a strong Asiatic affinity and are found in small patches from the Red sea to south of Durban. On the west coast they are found from the Senegal river to the Longa river in Angola; the dominants are three species of red mangrove (*Rhizophora*) which also occur on the Atlantic shores of America.

The coastal areas of west Africa are more or less humid from the Senegal to the Congo rivers; the coastal areas of Angola and South-West Africa are, however, extremely dry. The position is reversed on the east coast where there is a relatively humid strip all the way from South Africa to the equator, but farther north in the Horn of Africa the coastal area, as well as the interior, is very dry.

The equatorial forests of the Congo basin do not extend east of the great lakes, except for outliers such as the Kakamega forest in Kenya. A broad tract of dry country separates these forests from the moister coastal areas. The latter have patches of dense forest rather different in floristic composition from that of the main equatorial block which extends as far west as western Nigeria. A relatively dry area of savanna vegetation in Dahomey and Togo separates the main forest block from the western block

which extends from Ghana to Guinea.

The largest trees in the lowland rain forest are about 200 ft. high; many of them have buttresses and some yield valuable timber, such as African mahogany (*Khaya*), iroko or mvule (*Chlorophora*) and obeche (*Triplochiton*). In the moister areas the Leguminosae (e.g., *Bmchystegia*, *Cynometra* and *Gilbertiodendron*) are the most important family of large trees. The Sterculiaceae, Clmaceae, Moraceae and Meliaceae are more important in the peripheral areas.

Understory trees and shrubs include many Rubiaceae, Euphorbiaceae, wild kola nuts (*Cola*) and ebonies (*Diospyros*). Lianes and epiphytes, including many ferns, orchids and begonias, abound.

Farmed areas have many oil palms (*Elaeis*), kapok or silk-cotton trees (*Ceiba pentandra*) and secondary growth trees, such as the umbrella tree (*Musanga*). Plantations of rubber, cocoa, kola and robusta coffee are found in the forest regions.

Although the belts of vegetation surrounding the humid forest are not arranged symmetrically, there is a fairly uniform sequence of types as one moves toward the desert. Immediately surrounding the forest regions are belts of tall grass savanna with relic patches of forest. This savanna has been formed by the destruction of forest for cultivation and the consequent incidence of fire. Elephant grass (*Pennisetum purpureum*) is characteristic of this type. In places where there is some protection from fire it is possible to observe the recolonization of the savanna by forest species.

In somewhat drier regions there is broad-leaved woodland, often known in east Africa as "myombo." The genera *Brachystegia*, *Isobornia*, *Julbernardia*, *Monotes*, *Combretum* and *Terminalia* have numerous tree species typical of this woodland. Much of it has been modified by fires to a savanna type with a continuous layer of tussocky grass 3-7 ft. high (especially *Andropogon* and *Hyparrhenia*), with rather widely spaced and often gnarled trees 20-60 ft. high. Farmed areas usually have native fruit trees, such as baobab (*Adansonia*), shea nut (*Butyrospermum*), locust bean (*Parkia*) and tamarind (*Tamarindus*). The streams are fringed by evergreen forest in these moister savanna regions.

In the more arid regions there is an increasingly large proportion of fine-leaved and thorny trees, and the grass is shorter. A dry type of deciduous forest dominated by Rhodesian teak (*Baikiaea plurijuga*) is found in Barotseland (Northern Rhodesia) and neighbouring districts. The forest has a dense deciduous understory which is readily burned, and with increasing human activity big areas are being degraded by fire to an open savanna type. Woodland of mopane (*Colophospermum*) is extensive in the hot dry valleys of the Zambesi and Limpopo. Dense thickets are found in central Tanganyika and in Ethiopia; in the latter area, as in parts of western Uganda, candelabralike euphorbias are conspicuous. Vast tracts, including the Kalahari and a long belt extending from Senegal into most of east Africa, are covered with thorn woodland. The genera *Acacia*, including gum arabic (*A. senegal*) and myrrh (*Commiphora*) are by far the commonest trees. The grass is short and feathery and is often regarded as steppe rather than savanna. This type gradually merges into subdesert steppe, which has widely spaced low perennial plants, as well as annual herbs which flourish for only a few weeks after rain. The extraordinary *Welwitschia bainesii*, unique in the plant kingdom, occurs in this type from Walvis bay to Mossamedes.

Mountain vegetation includes evergreen forest, woodland, grassland and bamboo (*Arundinaria alpina*) brakes. The forest at lower elevations is usually richly draped with mosses, ferns and other epiphytes (e.g., *Begonia*, *Impatiens*, *Peperomia*); tree ferns (especially *Cyathia*) are also characteristic. The trees in this type of forest include the gymnosperms *Juniperus* and *Podocarpus* and dicotyledons such as *Olea*, *Ocotea*, *Schefflera* and *Pittosporum*. At higher altitudes the woodland of such trees as *Hagenia*, *Gnidia*, *Erica*, *Phillipia* and *Hypericum*, is festooned with lichens and is rather easily destroyed by fire. Grassland of species such as *Themeda triandra*, *Andropogon distachyus* and *Lozidetia simplex*, covers considerable areas at altitudes between about 5,000 and 7,000 ft. Higher up the grassland is often quite short and is composed of genera such as *Festuca*, *Agrostis* and *Pentaschistis*.

A characteristic and highly interesting feature of the mountain flora is the presence of numerous European genera and some species, which are absent from vast areas of intervening hot lowlands. Good examples of these genera are violet (*Viola*), dock (*Rumex*), cranesbill (*Geranium*), wood sanicle (*Sanicula*), buttercup (*Ranunculus*) and scabious (*Succisa*). Above about 10,000 ft. on the east African mountains are remarkable communities of tree lobelias and tree senecios, as well as shrubby *Alchemilla* and everlasting flowers (*Helichrysum*).

There is a strip of rain forest on the eastern side of the Malagasy Republic (Madagascar) and a strip of dry deciduous forest on the west. Forest has, however, been destroyed by fire in the centre of the island, and there is now a wide expanse of almost treeless grassland. There are extensive thickets containing many succulents in the southwest. The flora of Malagasy is very rich and is strikingly different from that of the mainland. (R. W. J. K.)

E. ANIMAL LIFE

Several factors, geographical, climatological, evolutionary and historical, have contributed to the extraordinary richness of animal life on the African continent (including the island of Madagascar). The enormous area of the land mass, the fact that the greater part lies within the tropics and has benefited by a stable equatorial climate since the earliest times, and its long connections with the Eurasian land masses, from which successive faunal waves have invaded Africa, have combined to produce a remarkably favourable environment for the evolution and development of many and varied forms of animal life, a good proportion being endemic groups. Historically, Africa was the last of the old world tropical regions to experience the impact of agricultural and pastoral man, in the form of Bantu and Hamitic invasions from the north. These replaced the sparse aboriginal hunting tribes, whose economy was based on the harvesting of the game animal surplus. By bigger populations competing directly with the animal life for living space. The effect of European settlement and development has speeded up enormously the process of change: the disastrous results will be referred to later.

The open country south of the Sahara provides food for the great herds of grazing and browsing herbivores, accompanied by their attendant predators. In complete contrast, over an enormous region of immense equatorial rain forest no herds of grazing animals can exist and the ground fauna is sparse and solitary rather than gregarious. Only in the treetops, where monkeys roam in large troops, is there obvious evidence of animal life.

North of the Saharan wastes, which constitute an effective northern barrier for most of the Ethiopian forms of life, the north African territories have a Mediterranean type of climate and vegetation, and the fauna is largely of the south European-Mediterranean type, with a strong admixture having southwest Asian affinities. In northeast Africa, the great tableland of Ethiopia shows some affinities with its eastern neighbour Arabia, across the Red sea gulf. Finally, apart from the continent lies the great island of Madagascar, where a very high proportion of endemic groups and a lack of many of the continental types give evidence of a remote separation and subsequent isolation.

The once teeming African animal life has been disastrously affected by rapid economic and political changes so that possibly only precarious relics of its former glory may survive.

Among the mammals, no less than 13 orders out of the 17 recent orders listed for the whole world (excluding the purely marine Cetacea) are represented. Of the Insectivora, four of the six families are endemic: the tenrecs (*Tenrecidae*) of Madagascar, the golden moles (*Chrysochloridae*) of south Africa, the elephant shrews (*Macroscelididae*) from north Africa to the Cape, and the primitive otter shrews (*Potamogalidae*) of the equatorial forest streams. Many shrew and hedgehogs are also found.

The bats (*Chiroptera*) are richly represented, but not one of the ten families is peculiar to Africa, all having Asiatic affinities, although many of the genera are endemic. Among the abundant fruit bats is the largest in Africa, the grotesque hammerhead (*Hypsignathus*) of west Africa; it is noteworthy that the most important and wide-ranging genus in the Indo-Malayan region

(*Pteropus*), has never reached the African continent although it has colonized Madagascar and the east African coastal islands. There are no vampire bats in Africa.

The order Primates is abundantly represented. In Madagascar alone, all the Primates are lemurs (*Lemuridae*) in great variety. None of the continental groups is found on the island, but in Africa the pottos of the forests and the bush babies of the savannas are widespread, forming part of the oriental family *Lorisidae*. The true monkeys of the old world (*Cercopithecidae*) are represented by many species of guenons, mangabeys, baboons, colobus and, in northwest Africa only, one species of macaque, the Barbary ape. It is particularly in the forest regions that the monkeys have reached their peak in variety and numbers. Finally, Africa is noted for the two great anthropoid apes (*Pongidae*), the chimpanzee and gorilla. Both are confined to the forest regions.

A very primitive order, *Pholidota*, contains only the toothless scaly anteaters or pangolins, an oriental group; and another small and primitive order, *Sirenia*, contains only the manatee and dugong of coastal waters and estuaries.

The *Lagomorpha*, containing rabbits and hares, has many representatives, but it is in the order *Rodentia* that Africa is particularly rich. Of the 11 families, only 4 are endemic, the most notable being the scaly-tailed flying squirrels (*Anomaluridae*) and the Cape jumping hares (*Pedetidae*). Tree and ground squirrels, tree rats, grass rats, banana mice, mole rats, porcupines and scores of others make up a great variety in many different habitats. Jerboas, an Asiatic group, are found only in north Africa.

The predators and scavengers forming the order *Carnivora* are numerous. On the plains, lions and cheetahs, hyenas, jackals and hunting dogs follow the game herds, while in forest and bush the leopard, genets, civets, mongooses and others pursue the smaller prey animals. No wolves or bears are found in Africa. Madagascar has only one family of carnivores, all *Viverridae* of genera confined to the island.

A peculiar Ethiopian order, the *Tubulidentata*, contains a single genus and species, the termite-eating aardvark (*Orycteropus*) a primitive type known also as a fossil from southeast Europe.

It is among the hoofed animals, now divided into *Proboscidea* (elephants), *Hyracoidea* (hyraxes), *Perissodactyla* (zebras, asses, rhinoceroses) and *Artiodactyla* (antelopes, pigs, hippopotamuses and giraffes) that Africa's greatest glory lies. More families, genera and species have evolved on the continent than in any other region of the earth. The African elephant of savanna and forest, the rock or tree hyraxes, the three species of zebra, with the wild ass of northeast Africa, and above all the fantastic variety of the antelopes, together with the unique giraffe and okapi of the thornbush plains and the equatorial forest respectively, added to the three genera of pigs, the hippopotamus of the rivers and great lakes, and the black Cape buffalo, all make up a big-game fauna that has never been excelled in variety and numbers. The former immense numbers of antelopes such as wildebeeste, hartebeeste, waterbuck, gemsbuck, gazelle and many others, which so astonished the early travelers on the plains of south and east Africa, have now unfortunately dwindled to a mere relic of their earlier numbers. The inevitable march of human development in most of their former territory has now wiped them out in most areas, so that it is only in the national parks and reserves that the visitor today can glimpse something of the real Africa of former days. Even in these reserves the need for constant struggle by the authorities against native poaching, competing cattle, threats of economic development and the general pressure of the rapidly increasing human population of the surrounding territories, allied to the political uncertainty for the future maintenance of the reserves, all give grounds for deep misgivings as to the eventual fate of the finest forms of animal life on the African continent. Two further families of hoofed animals, widespread elsewhere in the northern hemisphere, the deer and the wild sheep and goats, are barely represented in Africa, with one small population of north African red deer in Tunisia, one species of wild sheep and two forms of ibex also in north Africa. (For livestock see Land Use: *Agriculture—Tropical*, below.)

The bird life is no less rich and varied, in its way, for in addi-

tion to the great variety of groups native to the continent, a large part of the migrant Palearctic species spend half their lives in east or south Africa, traveling by several routes of which the Nile valley is one of the most important. Of the 67 families recorded in the region, 53 are of much wider distribution and only 7 are peculiar to Africa. These include the ostrich, the secretary bird, the whale-headed stork, the touracou or plantain eaters, the mouse birds or colies, the helmet shrikes and the sugar birds, while several subgroups such as guinea fowl, oxpeckers and honey guides are predominantly Ethiopian. An interesting recent discovery in the Congo forests is the African peacock (*Afropavo*), but such traditionally tropical birds as parrots are scarce. The Madagascar avifauna is much more restricted, and has greater affinity with the orient than with Africa, on the whole. For instance, 20 Ethiopian families are absent.

The reptiles and amphibia are largely representative of groups widespread in the old world tropics, with some South American affinities in some groups. Among the snakes, a python is the largest, up to 20 ft. in length, the large family Colubridae contains a great many types, including the cobras and mambas; the Viperidae include the puff adder and horned adder, while the primitive Typhlopidae or earth snakes are well represented. No poisonous snakes are found in Madagascar. Lizards in many forms, from geckos, skinks, chameleons to the large Nile monitor (*Varanus niloticus*) abound, Madagascar being particularly rich in chameleons. Frogs and toads swarm wherever there is sufficient moisture and contribute a major share of the vocal sounds which enliven the African night. Most belong to groups widespread outside Africa, but one of the most remarkable, the clawed frog (*Xenopus*), is confined to south and tropical Africa.

Tortoises and turtles exist in suitable habitats, and the best known and most feared of all the reptiles is the Nile crocodile (*Crocodylus niloticus*), growing up to 16 ft. long and living in most of the rivers and lakes. Three smaller types inhabit the forest regions of west Africa and the Congo basin. (See also NATIONAL PARKS.)

The fresh-water fish are also numerous but can only be briefly mentioned here: the extraordinary lungfish (*Protopterus*) which burrows into the mud as the pools dry up, to wait for the next rains, has South American affinities. Finally mention must be made of the enormous class of invertebrates including the vast insect life of tropical Africa, which, particularly in the form of the malarial mosquito and the disease-carrying tsetse fly, has in the past been largely responsible for preserving much of the region from human development.

II. NATURAL RESOURCES

The preceding sections on *Physical Geography* suggest that much of Africa is a difficult and harsh environment for human occupation and development. Some areas have quite a variety and range of resources, but in only relatively few agricultural commodities and minerals is the continent in an outstandingly strong position: cocoa, gold and diamonds are examples but there are not many similar cases. It is sometimes said, with truth, that Africa needs overseas capital and enterprise much more than overseas capital and enterprise need Africa. In the years between World Wars I and II, it was estimated that Africa's share of the world's trade was 4.5% of total exports and 4.8% of total imports, while in 1935 Africa was thought to be responsible for 2.8% of the world's primary production (rather more, 3.2%, in agricultural but substantially less, only 1.3%, in nonagricultural production). Africa's economic development is still in a very early stage and the limits imposed on its future expansion by the nature of its natural resources must always be remembered.

A. WATER

Perhaps more than any other single factor, water supply controls the habitability of an area, for plants and animals as well as for human beings. In many of the wetter parts of the continent, water supply is not a matter of great concern (drainage, on the other hand, may well be). But it clearly is a problem of vital significance in the many and extensive arid and semiarid areas of Africa. Furthermore, investigations made in east Africa and elsewhere have shown that availability of water can present real problems even where average rainfall totals might seem to be adequate for agricultural or pastoral needs; and in the section above on *Climate* reference has been made to the need for forecasting of rainfall probability in such areas. Generally there is a reasonably close connection between rainfall and the availability of water. Areas receiving a fair total of rainfall not confined to one season in the year are generally well supplied with both surface and underground water. Where, however, the rainfall is distinctly seasonal, as it frequently is, the availability of water may depend largely upon underlying geology. The nature and type of the soil may also be significant: granitic soils, for example, hold water comparatively well and are often capable of supporting a considerable agricultural population.

Prospects for irrigation on any scale are fairly limited in Africa, outside of the Nile valley in Egypt and some of the oases of north Africa. Egypt presents special conditions that are found nowhere else in Africa: it is the classic example of flood plain and delta irrigation, and the lower Nile valley is thus able to support the highest density of agricultural population in the continent. Of a total cultivable area of 9,000,000 ac., 5,250,000 ac. are in fact in cultivation; entirely under irrigation. About four-fifths is supplied with water controlled by barrages and the remainder depends upon the traditional basin system.

The French have given great encouragement to the establishment of irrigation schemes in Algeria, Morocco and Tunisia. In the Saharan oases and in the Niger Basin project. In the Sudan the Gezira scheme has been successfully carried through as an enterprise of the state in partnership with private capital. But elsewhere irrigation possibilities are very limited, even in countries like South Africa where the capital for the development of large schemes such as the Vaal-Hartz undertaking is available. Attention is, therefore, being increasingly directed more to the small-scale water storage project, by the digging of wells in preference to the building of dams, to provide domestic supplies or to water stock. More care is also being taken to conserve water supplies and to prevent the excessive use of particular water points, especially in stock country during the dry season. This is singularly difficult among communities where overstocking is common.

The hydroelectric potential of Africa exceeds that of any other continent, even if estimates of future developments are accepted with considerable reserve. One such estimate puts the potential water power at 190,000,000 h.p.; i.e., three times the estimated potential of Europe. Another estimate credits Africa with two-fifths of the world's potential or four times that of North Amer-

ica: one-quarter of this is stated to be in the Congo basin alone. As yet, however, only 0.1% is used. Major power schemes in operation or nearing completion in 1960 included the various installations in Katanga, the Owen Falls dam at Jinja where the Nile leaves Lake Victoria, and the Kariba dam on the Zambezi designed to supply both the copper belt of Northern Rhodesia and the rapidly growing manufacturing industries of Southern Rhodesia.

B. SOILS

In tropical Africa the exuberance of the natural vegetation has sometimes been taken as an indication that the soils are rich; whereas in fact they are usually rapidly exhausted under cultivation. More recently there has been a tendency to emphasize the poverty of African soils, especially those within the tropics. Reference is made, for example, to the leaching that takes place in heavy rainfall conditions, and to the absence of elements essential for plant growth, such as calcium and phosphorus. In arid and semiarid regions there is usually a shortage of humus and sometimes a tendency for sodium salts to form layers that are harmful to plant life. As the scientific knowledge of Africa's soils increases, however, their potentialities as well as their shortcomings may be recognized. Some workers now stress that many soils appear to be of at least average fertility, especially as they rarely receive additional fertilizers of any kind. They suggest that the abundance of energy from the sun, together with the range of root systems and water storage, permits plant growth of greater rapidity and bulk than in temperate areas.

Maps of the major soil groups of Africa closely resemble the main climatic belts. In a continent like Africa soils are generally more closely related to the climates in which they have evolved than to the rocks from which they are derived. This is because weathering is able to continue throughout the year, unchecked by frozen ground, and because so much of the surface has remained horizontal and undisturbed for long geological periods. The wetter areas are characterized by red and red-brown tropical soils (the colour resulting from oxidization of their iron content): the top soil is leached of its plant food and underlain by a lateritic hardpan of fine particles. The desert soils of the arid and semiarid areas are brown, coarse and undifferentiated, with a variety of minerals including the salts needed for plant food. In the intermediate areas between the generally wet and the always dry regions

there are intermediate types of soil, including chestnut soils, chernozems and black soils.

Two exceptions to the general poverty of African soils should be noted, though they are limited in the area covered. They are (1) those formed from recent alluviums (so that they are neither leached nor oxidized), as in the lower Nile valley and in the frequently flooded middle reaches of the Niger, Congo and Zambezi; and (2) the young soils derived from volcanic rocks as on the slopes of the peaks of east Africa or of Mt. Cameroon. In both cases they are highly valued by farmers, as for example for cotton cultivation, with the aid of irrigation in Egypt and for coffee growing by the Chaga (Chagga) people on the fertile, well-watered lower slopes of Mt. Kilimanjaro.

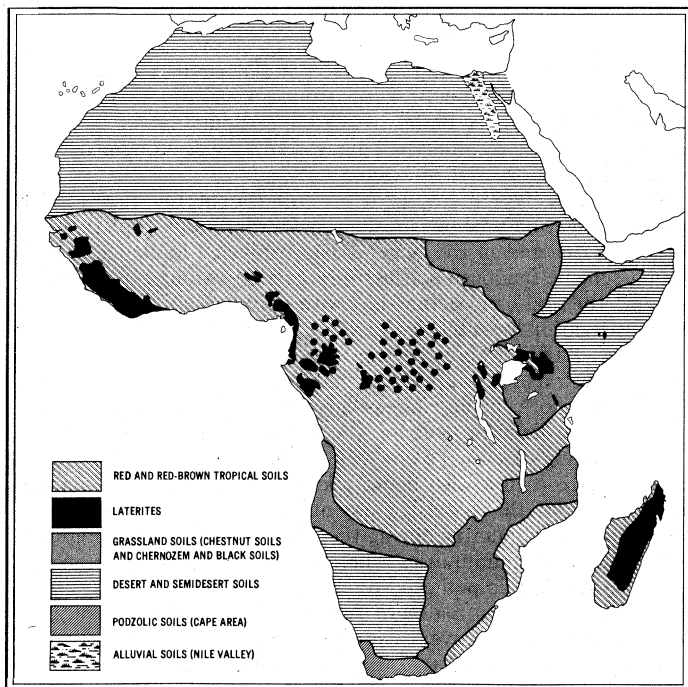

Soil Erosion.—The downward washing of soil is a normal geomorphological process in most parts of the world, but it can be greatly accelerated by the activities of man. Thus the excessive clearance of natural vegetation from the surface, the cultivation of very steep slopes or the overstocking of a grassland area can result in the complete removal of the soil cover over wide areas. The liability to erosion is especially great where torrential rains mark the beginning of the wet season following a period of drought lasting several months.

Three main types of erosion are commonly recognized: (1) sheet erosion, which causes the removal of a film of soil from the surface over a wide area especially during heavy rainfall; (2) gully erosion where this destructive work is concentrated along stream beds, footpaths or shallow depressions in the surface to such an extent that these lines become such deep gorgelike gullies that communications across the area are made difficult and plowing is rendered impossible; and (3) wind erosion, characteristic of most arid landscapes where exposed areas may be swept bare to bedrock with the blowing away of the finer particles.

During the 20th century and particularly since the 1930s, soil erosion has been recognized as a major problem of several African territories, and immediate action has been taken wherever possible. The problem is especially serious in a continent where the areas of good soil are generally so restricted and where farming remains the chief occupation of most of the inhabitants. It is particularly unfortunate where soil loss affects countries with rapidly increasing populations that are, at the same time, attempting to improve their standards of living.

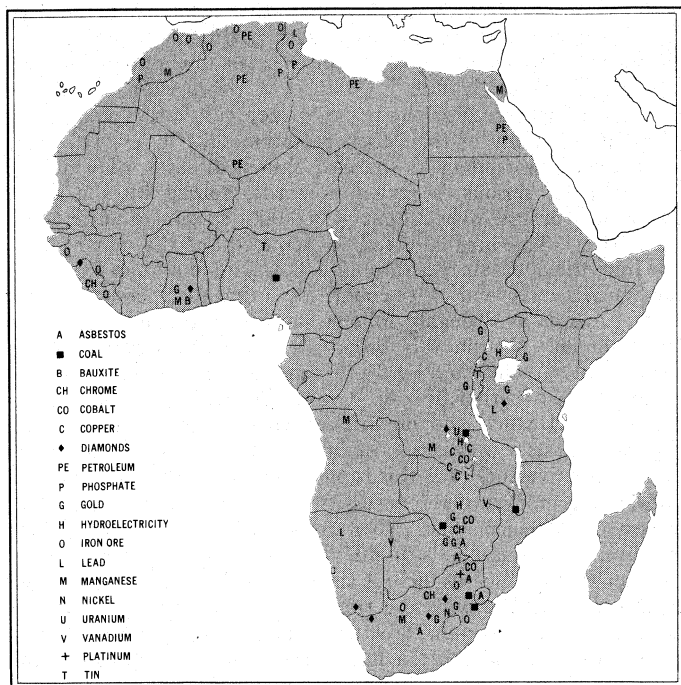

Apart from desert areas, South Africa is as much affected by soil erosion as any part of the continent. It is estimated that 200,000,000 tons of soil are removed from the surface every year and deposited in the Indian ocean. Though European farmers are by no means blameless, Africans by their careless agricultural method and their tendency to overstock their farms are chiefly responsible for soil erosion, partly because they are rarely allowed sufficient land to support themselves by cultivation and stock raising. The contrast between well-tended European pastures and overgrazed, exhausted and eroded African areas is often very striking in many parts of South Africa. There are similar contrasts between many of the European farms in the highlands of Kenya and conditions in the adjacent African areas of the Nairobi district. Other areas that are relatively overpopulated and where soil erosion can be seen include parts of Ruanda-Urundi, Uganda, southern Nyasaland and the Eastern Region of Nigeria.

Remedies adopted, often with considerable success, include the reservation of forests to prevent further clearance by cultivation and the destruction of deep-rooted trees that help to bind the soil together; the training of farmers to cultivate along the contour rather than downslope; and the planting of trees, grasses and other crops on steep bare slopes to check further erosion. The whole appearance of the Kigezi district of southwestern Uganda has been altered by the measures introduced by the government to check soil erosion, to encourage contour farming, to consolidate scattered farm holdings and to resettle people on the land. As a result Kigezi is able to support a density of population that is, by common African standards, surprisingly high, and the exodus of its inhabitants to find work elsewhere in Uganda has been reduced.

FIG. 7. — MINING AND HYDROELECTRIC SITES IN AFRICA

C. MINERALS

Precious metals gave rise to the first Arab contacts with Africa, and the Portuguese were mining gold in Ghana before the end of the 15th century and numerous expeditions were sent to the kingdom of Monomotapa because of the accounts of the wealth of the gold available at Sofala. Mineral discoveries in the southern parts of the continent have transformed the modern economic history of Africa by bringing in both capital and European settlers. Exports of minerals play a leading part in Africa's external trade and dominate the economy of certain territories such as Northern Rhodesia. Minerals have also been the reason for much of the initial railway construction in countries like Ghana, Nigeria and the Rhodesias.

About 5.5% of the annual value of the world's mineral products comes from Africa. All but a very small proportion is exported, since minerals can generally bear the fairly high cost of transport to a consuming centre. Unfortunately the production of heavier minerals is slight—coal, less than 2% of the world's tonnage; petroleum, as yet only 0.25%; salt 1.5%; bauxite 1.5%; and iron ore 2%. In contrast, Africa leads easily in the production of certain precious and rare minerals. About 98% of the world's diamonds come from various African territories, especially the Republic of the Congo (85% are used in industry and only 15% as gem stones). The Congo also had the world's first important uranium mine and was the only source of radium for several years.

Over half the world's gold comes from Africa, a high proportion still from South Africa. Africa produces substantial supplies of those minerals that are used to strengthen steel, including cobalt (70% of world output, chiefly from Katanga and Northern Rhodesia), chrome ore (40%, South Africa, Southern Rhodesia), manganese (30%, Ghana, Congo) and vanadium (20%, South-West Africa, Northern Rhodesia). Three nonferrous minerals are important—platinum (24%, South Africa), copper (about 24%, Northern Rhodesia, Katanga) and tin (15%, Nigeria). One-fifth of the world's asbestos comes from South Africa. Southern Rhodesia and Swaziland, and more than one-third of the phosphate rock from Morocco! Algeria and Tunisia.

Important oil strikes were made in the Sahara at mid-20th century and pipelines to the Mediterranean were constructed. Several new mines were developed after World War II, some in old established mining districts and others in new areas to which rail-

nays have been built. These include the Orange Free State gold fields in South Africa, the Kilembe copper deposits in Uganda (to be refined at the Owen Falls dam), the Mpanda lead mine in Tanganyika and the Bomi hills iron field in western Liberia.

Mining creates many social and political problems of its own, such as the migration of labour, detribalization, housing and food supply difficulties, and the question of whether labour should be encouraged to settle permanently or not. Difficult though these problems always are, the countries concerned value the revenue and the prosperity that comes from mining, and the contrast between mineralized and other territories in material terms is often great.

D. LAND USE

Land use covers a whole range of the ways in which mankind takes advantage of the natural resources of an area: it thus includes agriculture, forestry, fisheries, manufacturing industry and the growth of towns and villages together with certain activities, such as mining.

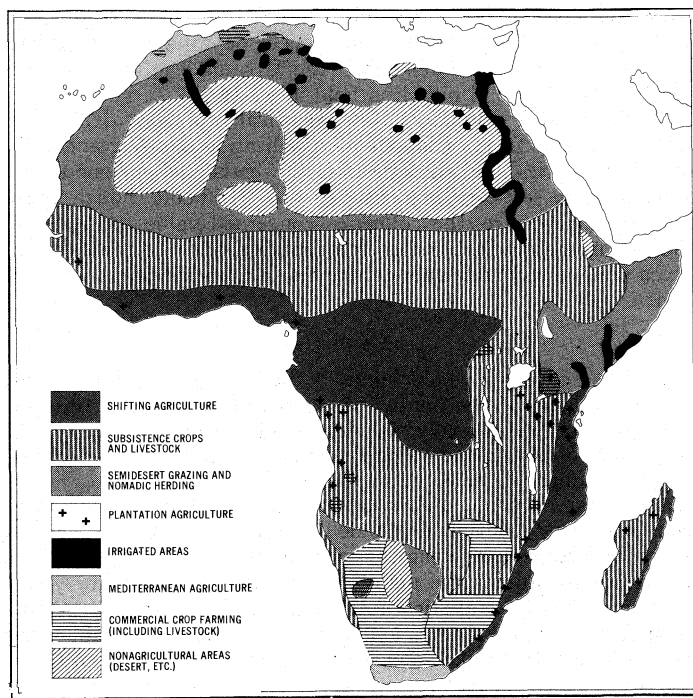

A summary account of the agricultural activities of the mixed races of a vast continent can do little more than note certain major features, emphasizing the more unusual among them. It is impossible to present the main facts about agriculture in Africa in a comprehensive statistical form because of the extreme paucity or inaccuracy of the figures available, especially for certain territories where nothing like an agricultural census has yet been taken and where often no real records are available even for individual farms or districts.

Agriculture in Africa can better be studied in two main groups, tropical and extratropical, than by any division into, for example, agricultural and pastoral or African and European.

Agriculture—Tropical.—Large areas within the tropics are used for shifting agriculture, for subsistence cultivation and livestock, and for semidesert grazing and nomadic herding. By comparison the areas that are irrigated or farmed intensively or commercially are only small, and these are characteristic of European rather than African farming. Even though it is not easy to draw a clear line of distinction between crops grown by Europeans and those grown by Africans, since some are produced by both, there is nevertheless a great difference between the two types of farming. The African is nearly always a peasant cultivator, still interested mainly in subsistence cropping; even if he has extended his activities to produce certain cash crops, his methods are still largely determined by the needs of subsistence cultivation. The European, by contrast, is usually a farmer employing paid labour or the manager of a company that has adequate capital both for cultivation and for marketing and processing of the commodities grown: he must, therefore, depend greatly upon the availability of a supply of relatively cheap African labour or upon the possibility of the introduction of some sort of mechanization to replace such labour.

Shifting Agriculture.—Nearly all the traditional systems of agriculture practised by the indigenous peoples of Africa are on too small a scale for efficient production. Shifting agriculture, the prevalent system of much of tropical Africa, is any form of farming in which a piece of ground is cultivated for a period of one, two, three or more years until the soil shows signs of exhaustion or the land is overrun by weeds. The plot is then abandoned to the regrowth of the natural vegetation while another patch is cleared and brought under cultivation. The original plot will be farmed again, after a period of some years, when natural growth has restored fertility and checked the growth of weeds: the longer the fallow period, the better for the subsequent cultivation.

At one time it was customary to regard shifting cultivation as a relic of barbarism and an indication of the primitive organization of the society that followed the system; but it is now generally recognized as basically a concession to the nature of tropical soils that require long periods for recovery and regeneration. Indeed in areas where the density of population is low, so that there is plenty of land available for farming and adequate fallow periods are possible, the system is in effect a rotational method of farming, a system of bush fallowing, and has much to be said in its

R W STEEL

FIG. 8 — AGRICULTURAL REGIONS OF AFRICA

favour. Details for individual tribes differ widely, as do conditions in forest and in savanna areas. Methods and the types of crop vary according to the nature of the topography and the quality of the soil, to the availability or otherwise of livestock and to the dietetic habits of the community concerned. But everywhere it is seen to be a farming system in which groups cooperate to produce some of the necessities of life: and in an empirical way there is recognized the value of crop rotation, the use of different soils, the importance of the maintenance of fertility and even the prevention of soil erosion.

Unfortunately circumstances have so changed that shifting cultivation is no longer an adequate farming system for much of the tropics. No longer is there an abundance of land, for populations are increasing, often very rapidly. Many of the young men who used to clear the forest are away for long periods earning wages at the mines or in the towns. An increasing amount of land may be needed to grow crops for sale as well as for subsistence. It is vital, therefore, that farming methods should be improved and crop yields increased. Scientific research has not been very successful in finding easily applied solutions to these problems of subsistence farming, apart from the greater use of livestock to graze and fertilize the crops, and this, as will be seen shortly, is not possible in many areas because the tsetse fly makes impossible the keeping of most domestic animals.

Plows have been introduced in some districts, though as they go more deeply into the soil than the common implements, the hoe and the ax, they sometimes cause soil erosion. The crops grown vary widely with environmental conditions. In the wetter forest country root crops predominate—yams, sweet potatoes, cassava (manioc) and coco yams—supplemented by plantains or bananas.

In drier areas cereals are commoner, including maize (introduced by the Portuguese from America) and the indigenous sorghum and bulrush millets.

Livestock.—In the early 1960s Africa had about 26% of the world's goats, 15% of the sheep and 11% of the cattle on 23% of the earth's surface. Animals, especially cattle, often have great social and religious significance. A man's status in society will be judged by the size of his flocks and herds. Quantity, therefore, tends to be regarded as more important than quality and there is a strong preference for keeping animals alive rather than slaughtering them. (See Ethnography below.)

In certain areas, particularly in eastern and southern Africa,

pastoralism has often dominated the native economy in the past. It is probably no longer so except with particular tribes like the Masai who depend wholly upon their cattle for subsistence and who despise all cultivation. Today even tribes with strong pastoral traditions recognize the value of crop cultivation as a means of satisfying many of their food requirements.

Africa has more than its share of animal diseases, of which by far the most serious is trypanosomiasis, spread by the tsetse fly, which occurs over about 4,000,000 sq. mi. of intertropical Africa. The area affected is bounded on the north by a line from the Senegal river through Lake Chad and Lake Rudolf to the Somalia coast and on the south by a line that passes through central Angola and roughly follows the course of the Zambezi to Mozambique. Within this broad area between two-thirds and three-quarters is infested by fly to a greater or less extent. Five-eighths of Northern Rhodesia, two-thirds of Tanganyika, three-quarters of Uganda and one-fifth of Kenya are affected. The presence of tsetse makes almost impossible the successful rearing of domestic livestock, and this is particularly unfortunate with the growing recognition of the necessity for mixed farming to replace exclusive dependence upon either crops or animals. It also hinders improvements in methods of shifting cultivation, as already seen.

Other animal diseases include rinderpest, East Coast fever, contagious pleuropneumonia and tuberculosis. Veterinary work has been successful in certain directions, but constant vigilance is necessary, and epidemics often have serious and widespread consequences, affecting both European-owned and African beasts. The common breed of cattle in the tropics is the indigenous, often humped "zebu" type, except for the introduced European breeds on some upland farms in areas such as the Kenya highlands.

Cash Crops.—In many parts of tropical Africa there is increasing production of crops for sale and for export by African farmers as well as by the Europeans who have settled in countries like Kenya, Tanganyika and the Rhodesias. At one time Africa produced little besides gold dust, spices and human slaves. The cessation of the slave trade and the abolition of slavery during the 19th century coincided with an increased demand in Europe for west African palm oil as an ingredient of soap. Later, with advances in industrial chemistry, palm kernels became valuable as a constituent of margarine. Peanuts and other oilseeds were also in demand and cotton cultivation and rubber plantations were established in some areas. Coffee, tea and sisal production was usually in European hands, at least in the early stages, but cocoa growing was, from the first, an essentially African enterprise which transformed the economy of southern Ghana and southwestern Nigeria. The consequences of these developments have been tremendous, affecting methods of land use, standards of living, the provision of communications, the pattern of population and indeed every aspect of the lives of the peoples concerned. These results must be remembered along with the statistics of production which, by world standards, may not be very spectacular. Africa is, however, the source of more than nine-tenths of the world's supply of palm kernels and nearly two-thirds of its palm oil and cocoa, together with substantial quantities of cotton, sisal, tea, coffee and peanuts. More commercial use is also being made of tropical African livestock, and meat-packing stations have been established in several countries.

Much useful study has been given to the problems of commercial crops and considerable success achieved in plant breeding, in increasing yields, in minimizing the effects of disease and in the general improvement of farming methods. Even financially unsuccessful projects like the East African Groundnut scheme (established without adequate preliminary investigation in Tanganyika shortly after World War II) have subsequently produced valuable information about the prospects of the application of mechanization to African farming conditions.

The principal plantations owned and managed by Europeans within the tropics are in Kenya (formerly known as the "white highlands"), Tanganyika, the high veld areas in Northern and Southern Rhodesia, the higher parts of the Republic of the Congo and occasional districts in west Africa (though not generally in the former British west African territories). These areas have an im-

portance to the economy of these countries which bears no relation to their size or to the scale of their contribution to world supplies. It must, however, be admitted that the resulting social and political problems are sometimes very great.

Agriculture — Extratropical. — Relatively small areas occur outside the tropics but some of them are very important farming lands. There are some extensive areas of desert and semidesert which are agriculturally useless. In the more favoured, better-watered and cooler parts of South Africa and of north Africa, particularly Algeria and, to a less extent, Morocco and Tunisia, European farming has been established on a large scale.

The basis of the agricultural and pastoral economy of South Africa consists of livestock, especially sheep with cattle in the less dry areas, associated where possible with maize production; but there are also special features such as dairying in the Transvaal, sugar production in Natal and citrus and vine growing in the southwestern Cape. Southern Rhodesia, with many similarities to South Africa even though it lies within the tropics, has good cereal and pasture country and is a leading producer of tobacco. North Africa's principal crops, grown by non-Europeans as well as Europeans, include wheat, barley, olives and vines.

Scattered around the edge of the Sahara are numerous intensively cultivated oases, while the Nile valley in Egypt is able to support a very high density of population by the provision of irrigation and the abundance of the Nile waters and by the successful commercial growing of cotton.

Forestry. — The botanical aspects of the forests of Africa have already been described (see *Vegetation*). Forests now occupy only about one-eighth of the total area of the continent. Even the tropical rain forest or high forest of equatorial districts has been vastly reduced in area, largely because of the deforestation that is an inevitable consequence of the widespread use of the system of shifting cultivation for agriculture. There are extensive areas of the more open type of woodland known as savanna, while temperate forests occur at higher elevations in east and southern Africa, and there are limited forests in Mediterranean north Africa.

In the early 1960s reservation of forests by government legislation was widely practised (though not as widely as it should have been) for soil and water conservation in watershed areas, for Africa subsistence farming and for local fuel and timber needs. Exploitation of timber resources for export proved difficult, except from certain areas such as Gabon, because of the diversity of species, the problems of transport and the uncertainties of overseas demand. World War II greatly stimulated activity and flourishing timber industries have been established in the Ivory Coast, Ghana, Nigeria and the Republic of Congo. In addition to the export of sawn timber, integrated industries are being developed, and experiments carried out in the manufacture of paper pulp. Most of the trade is concerned with 30 or 40 of the 300 or more species of marketable size.

Outside tropical Africa certain forest products have long been of commercial value, particularly the cork oak forests of north Africa and the hardwoods of Knysna in South Africa.

Fisheries. — Africa has little continental shelf. There is usually a sharp drop of 2,000–3,000 fathoms to the ocean depths, quite near to the mainland, so that there are no prospects of large-scale commercial fisheries such as have developed off northwest Europe or eastern Asia. But many forms of aquatic life abound along Africa's seaboard as well as in its large lakes and long rivers. So far, however, most attempts to develop the fishing industry have failed, despite the repeated efforts of the Colonial Development corporation (*q.v.*). Fish farming, especially that based on a species of Tilapia, has proved successful, notably in the Congo basin. The marine fisheries of South Africa are growing steadily, in trawling and in catches of pilchard. South Africa with about 650,000 tons of fish per annum is easily the principal producer in the southern hemisphere.

Manufacturing Industry. — Only in the extreme north and south of Africa had manufacturing industry made much progress before World War II, in both cases in close association with a fair-sized settled European population and with the exploitation of

mineral resources (see *Minerals* above). A few, relatively minor, secondary industries were established in the bigger of the tropical African towns before 1939. World War II provided a tremendous stimulus by creating large overseas demands for certain African primary products and by cutting off the supply of many manufactured goods from Europe for several years. Industries started then have been maintained and some have expanded since, while new concerns are being established elsewhere, particularly in the newly independent countries. The problems of industrialization (including mining) are closely associated with those of the increasing movement of people into towns (see *Population* below) and are engaging the close attention of the governments concerned. The proposed solutions range from the extreme of apartheid (*q.v.*), with no permanent African town dwellers, to that of integrated multiracial communities which would have considerable stabilized populations of all races living in all industrial towns.

See also the *Economy* sections of the articles on the individual countries. (R. W. SL.)

III. ETHNOGRAPHY (ANTHROPOLOGY)

Since the African continent is ethnographically most diverse in all respects the more detailed characteristics of its peoples can only be satisfactorily grasped by a consideration of its various regions. No such regions are, however, homogeneous or completely distinctive in character. It is therefore necessary to consider the nature and distribution of some prominent features that are significant over wide areas.

In physical or racial type most of the peoples of Africa south of the Sahara and the Ethiopian highlands are predominantly Negroid and there are Negroid enclaves in northern Africa as for example in the Tibesti highlands, the Nuba mountains and along the middle Nile. On the other hand, it would appear that the basic racial stocks of northern Africa, which are generally regarded as part of the Mediterranean or "brown" race, have been the source of many incursions into tropical Africa. These may have given rise to distinctive local types by Negroid admixture as among the pastoral Fulani (Fula) of the Western Sudan, the Galla and some of the Nilo-Hamites of East Africa. Lighter skin colour, tall stature and absence of marked prognathism and platyrrhiny among other East and West African peoples have also been attributed to mixtures of northern and Negroid elements and subsequent southward migrations. But there is little documentary or biological evidence concerning these.

Both the supposedly mixed stocks and the Negro peoples themselves have expanded over long periods in the past at the expense of other older stocks in central and southern Africa that once occupied extensive areas as hunting populations. In the tropical forest areas there are a number of enclaves of pygmoid groups while the ancient Bushman stock, now confined to a semidesert area in the southwest, appears to have been formerly more widespread in central and eastern Africa.

The languages of Africa also show a general cleavage between the various Hamito-Semitic languages on the one hand, which are spoken in North Africa, much of the Sahara and the eastern Horn, and the several major language groups associated with Negroid peoples to the south. The classification and the determination of the genetic relations of these African languages, many of which are still little known, is by no means definitive. In particular, the question of Hamitic elements in some East African languages has, in the 1960s, still been debated. But apart from the survival of the distinct Bushman and Hottentot (Khoisan) languages in the southwest and among one or two small East African peoples, the greater part of central and southern Africa is occupied by peoples speaking a large number of clearly related languages known collectively as Bantu. These in turn are held to be more remotely related to another large family of languages spoken in West Africa commonly labeled as Western Sudanic. But not all the Negro peoples of Africa speak Bantu or related languages. Those of the Negroid populations from the region of the upper Nile westward to Lake Chad belong to several distinct and apparently unrelated linguistic stocks such as Nilotic (to which the Nilo-Hamitic tongues of East Africa are closely related). Eastern Sudanic and

Central Saharan. Finally, Hamitic languages are found among them to the west of Lake Chad; e.g., Hausa over much of northern Nigeria.

Modes of life over most of North Africa, the Sahara and much of the Ethiopian highlands are continuations of patterns characteristic of southwest Asia and range from fixed plow cultivation of temperate cereals and irrigated gardening in oases, to nomadic pastoralism often based mainly on camel herding but including the rearing of goats or sheep and in some regions cattle.

The economies of the tropical and southern African peoples have been less directly affected by northern techniques. Those of the Bushmen and Pygmies retain archaic modes of hunting in a food-gathering economy. But most of the Negroid peoples, while they formerly engaged extensively in hunting, are predominantly agriculturists. Since primitive forms of iron smelting have been long established in many areas, nearly all have iron tools and in particular hoes for cultivation. But the rapid exhaustion of tropical soils with shallow cultivation and limited means for regularly restoring fertility has nearly everywhere imposed a pattern of shifting cultivation in which tracts of forest, bush or grassland are cleared afresh by felling and burning for each year's crops and are left to recover indefinitely or for a period of years, according to the conditions and the pressure of population, before being brought under cultivation again. But within these general limitations, to which there are also exceptions such as the permanent cultivation of banana groves in the East African highlands, there is considerable diversity of farming methods and efficiency.

Root crops predominate as food staples over most of the forest areas and their fringes in central and western Africa, while coarse

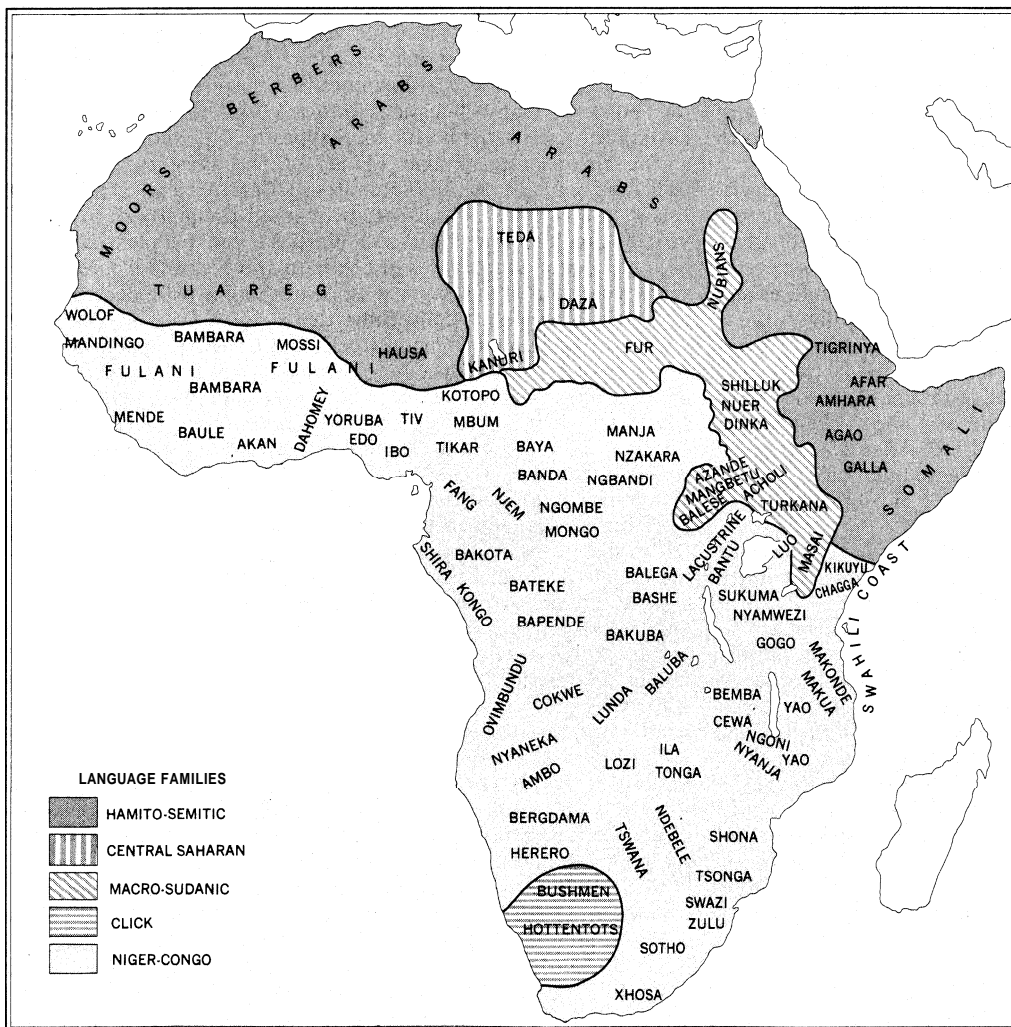

grains are characteristic of the wide arc of tropical woodland and grassland with its long dry season that extends from Senegal in West Africa eastward to the southern Sudan and thence southward through East Africa to the southern plateaus of the Rhodesias, Bechuanaland and Angola. Techniques range from the dibbling of a catch crop on patches of charred forest or burned grass to the systematic provision of fertilizer, e.g., by pollarding trees for supplies of ash as in the *chitemene* system of Northern Rhodesia, or the hoeing of high ridges for grain planting as among the Hausa of Nigeria and of large hills for yams as in southern Nigeria to secure an adequate depth of soil for large crops.

The grain and root staples include both African and introduced crops *Eleusine* and *Pennisetum* (bulrush millet), which are widespread savanna grains, may have been first cultivated in the Ethiopian region; while *Sorghum* (Guinea corn) includes both Asiatic and perhaps indigenous West African varieties. Several of the varieties of the forest root staple, the yam, are Asiatic in origin but indigenous varieties are also cultivated in West Africa. The banana or plantain which is widespread and forms the staple in parts of eastern Africa was, like one species of coco yam (*Colocasia*), also introduced from south Asia. The antiquity of agriculture in tropical Africa and the periods at which the various Asiatic cultivated plants were introduced have not yet been determined. But some plants which have become staples over wide areas are known to be recent since they are of new world origin and could not have been introduced before the end of the 15th century. These include the root crop cassava or manioc which has been adopted at the expense of yams in more densely populated areas of western and central Africa a second species of coco-

yam (*Xanthosoma*) and maize, a staple over the subtropical grasslands of the south and east.

Domestic goats and chickens, which are ubiquitous among the tropical cultivators, were an early introduction from Asia. Cattle were introduced many centuries ago from the north and have become an important element in the economy over wide areas. Small short-horned cattle resistant to fly-borne and other diseases are reared in small numbers by some forest cultivators, especially in West Africa, but the larger long-horned cattle are confined to the fly-free savanna in the north east and south. Among some of the peoples of these regions cattle are the central element of the economy and hence of major social and religious importance. Pastoralism has been variously combined with agriculture according to circumstances. Although in West Africa many of the Fula-speaking peoples from Senegal to Lake Chad have specialized almost exclusively in cattle rearing, formerly depending on serfs and now on the trading of milk for supplies of grain, the agricultural populations rarely keep cattle for milking. Most of the eastern and southern African pastoral peoples combine grain farming with cattle rearing and prize milk highly as food.

The scale and complexity of political organization in Africa has depended only to a limited degree on the character of the econ-

LLOYD A. FAILERS

FIG 9 — MAJOR PEOPLES AND LANGUAGE FAMILIES OF AFRICA

omy. While Pygmy and Bushman organization has been limited to small scattered and independent bands, among both the agricultural and the pastoral peoples the foundations of organization are usually enduring kin groups united according to a definite principle of descent, usually either patrilineal or matrilineal. Among many such peoples there were traditionally no formally political offices or central organization. Kin groups, fluctuating in scale according to the circumstances, co-operated and competed under their leaders, while religious sanctions reinforced by priesthoods and recurrent rituals supported a moral order among them. Such chiefless or segmentary societies are to be found in all regions among both agricultural and pastoral peoples. Well-known examples are the Tiv of northern Nigeria, the Nuer of the southern Sudan and the Cewa of Northern Rhodesia. Some peoples, notably certain pastoral tribes of East Africa such as the Nandi and the Masai, have a territorial age-set organization through which limited political power is exercised in turn by the sets as they reach certain grades. But political centralization under a hierarchy of chiefs and their councils has long been developed among many peoples. Many of these in West Africa (*e.g.*, Yoruba and Akan) and in East Africa (*e.g.*, Nyoro and Ganda) have traditions of ancient foundation under sacred rulers who came with their followings from farther north. But strong chiefdoms were also early developed in the western and southern Congo basin and later among the Bantu of southeastern Africa. In many cases there is evidence of the peaceful incorporation or forceful domination of earlier peoples in the formation of these states.

While in Ethiopia early monophysite Christian kingdoms have persisted, political organization over most of North Africa, among both sedentary and pastoral peoples, has received the imprint of the Islamic Arab conquests which began in the 9th century A.D. Islamic principles of government and law as well as religious doctrine have also been superimposed in varying degree on the political life of many of the chiefdoms of the savanna belt to the south of the Sahara from the Senegal to the middle Nile.

The foregoing and other aspects of the indigenous cultures and social life of African peoples, including religion and art, are considered in more detail below within the framework of a series of major regions. These regions, while severally manifesting considerable internal diversity, have each some degree of coherence with respect to certain predominant cultural patterns or the historic movements and interrelations of peoples within them.

There are separate articles on the main groups; *e.g.*, ASHANTI; BUSHMAN; HAUSA; NILOTES, etc.; see also AFRICAN LANGUAGES and the main language groups; *e.g.*, BANTU LANGUAGES; BUSHMAN LANGUAGES, etc. The sections on The People of the articles on the various countries may also be consulted. (D. F.)

A. NORTH AFRICA

North Africa extends from the Atlantic to the Red sea and from the Mediterranean to the northern bend of the Niger river and a line from the peak of this bend to the Red sea. This vast region is divided into numerous territories which do not correspond to the simple lines of relief or population. In the north the mountain folds from Morocco to Tunisia are continuations of the Mediterranean chains. In the south the Sahara extends the great artery of nomadism from the steppes of central Asia as far as Africa. Two isolated mountain massifs have particular populations: the Ahaggar (Hoggar) at the very heart of the Sahara, and Tibesti farther southeast. Neither relief nor natural resources have profoundly marked the life of the people. The great invasions of the past came from east to west, but constant exchanges have occurred from south to north and from north to south, with less obvious, but slower and deeper effects.

Physical Types.—The northern mountain chains are inhabited by the Berbers, a fair Mediterranean race of varied lineage. The Sahara artery is peopled by the same Semitic nomads as the near east, mixed in greater or less degree with Negroid blood. The oases of the south are inhabited by Negroids; the Tuaregs of the Ahaggar are so mixed with Negroids that their original type cannot be distinguished. Tibesti and Borku are also inhabited by Negroids under various names: Tilda on the massif itself,

Daza in the north and south of Borku; the Bideyat and Zaghawa from the south of Ennedi to the north of Wadai and Darfur extend eastward to the south of the Libyan desert. (See BERBER; TUAREG.)

Languages.—The spoken Arabic is noticeably different from classical Arabic, a difference which increases from east to west. Subject to modification by regional accents, it is the language of the majority. Berber is also a Semitic language, spoken especially in the massifs of the Moroccan Atlas, and in Algeria in the Zakkar, Kabylia and Aures. In Tunisia it is spoken by the 11 villages of the Matmata to the south of Gabes. In the Sahara Berber is spoken in most of the oases from Tabelbala to Agades, with a significant centre in Mzab. Farther south it is represented by the important group of the Mauritanian tribes: Tekura, Rigibat and Arusigin; and by the Tuaregs of the Ahaggar. To the east, in Egypt, it is practically confined to the oasis of Siwa.

In Tibesti the languages of Teda, Bideyat and Kanuri are the heart of the Sudanese languages. But Arabic has infiltrated across the whole of the Sahara, from Fezzan and northern Libya to Chad, through the migration of the Awlad Sliman about 1840 and, after 1850, by the religious brotherhood of the Senusi (Sanusi). (See ARABIC LANGUAGE; SEMITIC LANGUAGES; SUDANIC LANGUAGES.)

Population **Movements**.—In North Africa these are independent of the linguistic situation. There are arabicized Berbers where tribes of the latter have come under Arab cultural influence; on the other hand, there are berberized Arabs where the reverse has been the case. In the heart of Kabylia are found important Arab elements, the Beni Thour and the Beni Sliyam on the Kabylia coast and the Beni Husain in the Azazga region, who have become entirely Berber-speaking. The Arab tribes of Djedjelli region are partly berberized and speak, indifferently, a corrupt Arabic.

Living Conditions.—There is a clear distinction between the settled peoples and the tented nomads. Houses with double-sloped roofs cover a region stretching from the mountain chains of Morocco to the Krumirian mountains in Tunisia, and from the littoral to the high plains. The flat-roofed and terraced house covers all the rest of the northern area and the whole of the central area of North Africa. The domed house is often a stage toward permanent settlement of the nomads. Dugout dwellings or adapted caves are sometimes used by nomads in the process of settlement, as for example the Beni Bahdel near Tlemcen in Algeria, the inhabitants of the Jebel Ussalet settlement of Kairouan in Tunisia and those of the Jebel Nefusa in Libya. In Tunisia the Matmata have dwellings deeply dug into the ground.

The tents of North Africa are similar to those of the east, from where they were brought by the Bedouin tribes, made of bands woven from wool and goats' hair. Often the tent is surrounded by a dry stone wall, against which came to be erected domed storehouses; this is the beginning of the settled life. In eastern Morocco and western Algeria tents are often made of plaited matting. In Mauritania and the Ahaggar are found leather tents. Palm huts are used by the seminomad Teda in Tibesti and Borku and by the settled people of Kufra.

Mode of Life.—The settled peoples of the northern mountains are cultivators of trees and grain. The Ksuri of the south live essentially on their dates. The nomads throughout the Sahara raise sheep entirely for food; their main resources derive especially from their role as navigators of the Sahara, formerly by camel caravan, but now more and more by the organization of motor transport. The cycle of life depends on the production of resources. Among the settled peoples of the north, after the tillage, the men leave the mountain villages and go to work in the cities of the coast and more frequently in the industrial towns of France, Belgium and Germany. The high rewards of European industry cause this emigration to become intensified and prolonged. The money sent back to the villages provokes a veritable inflation because the necessities of life remain underdeveloped as the fields are increasingly deserted. The men return at the beginning of summer for the harvest, when a relative abundance reigns in the villages.

For the Ksuri of the Sahara dates provide a sufficient basic

food so that the men do not seek to emigrate. The new oil industry attracts labour (formerly restricted) from the north. Among the nomads of the Sahara movement begins in mid-November after sowing the barley at the foot of the palm trees. Their route covers more than 500 mi. and the journey takes two or three months with halts which combine pilgrimages to the tombs of saints. The duration of the nomadic movement never exceeds nine months. In Tibesti and Borku the nomadic cycle covers about 300 mi. in the irrigated valleys during the wet season from August to January. The true nomads of Tibesti, Mauritania and the Sahara have no agriculture but live alongside the settled inhabitants of the oases.

Social Organization.— Among the settled and nomad peoples alike the family is patrilineal and patrilocal. It is basically a cult community. The father is head of the family. Polygamy is little practised and is found more in the cities than outside; but where it occurs the mistress of the house is always the first wife or the one whose first child is a boy. The husband's mother plays a pre-eminent part. Families sharing a communal life form a clan; thus communal life may derive from a common ancestor or from an alliance made by a sacrificial contract. The nomads throughout the high plains and the Sahara have the same social organization. The sons live a communal life with the father, and he has the sole right to allow them to pitch their tents near his, when they are married, to form a *duwar* or group of tents.

Families who share the same food cooked on the same fire may not intermarry. The *horma* ("sanctity of the house") forms an obstacle to the marriage of close cousins, but this obstacle disappears between families living under separate roofs. The bride preferred is usually a cousin on the mother's side.

Every human community, family, village or tribe, is basically a sacrificial community; it is also linked directly or by alliance with a common ancestry. Every year, generally in the autumn at the first plowing among the settled peoples and before the annual movements among the nomads, the members of a village or group repeat the ceremony that marked the arrival of their founder ancestor: a sacrifice of cattle in the north, of sheep and camels in the south.

The quarters of a village are grouped in *sof* ("halves"), opposed and complementary. These *sof* have a matrimonial significance: the men of the upper *sof* take their wives from the lower *sof*; the men of the lower *sof* seek wives among the lower *sof* of a neighbouring village. "A man does not climb the village hill to seek his wife" is the first and plainly expressed principle; "every village is also the upper *sof* of another village" is the second. Every family has its special tabus concerning food or clothing, as does every *sof*, and sometimes the villages and the tribes.

Among the nomads is found the same structure and the same idea of opposed and complementary clans. The founder ancestor is reputed to have come from Arabia and his descendants have formed numerous groups of tents arranged in *fevqa* of 15 to 20 tents which journey together. The different *ferqa* are divided into *sof*, distributed according to the direction of movement, e.g., northern *sof* or southern *sof*, and they form matrimonial categories as with the settled peoples. The 40 clans of Tibesti have much the same organization.

Administration.— Among the settled peoples of the north authority is exercised by the assembly of heads of families, the *Jema'a*. Executive power is delegated for one year to an *amin* or sheikh, chosen alternatively from the two *sof*, who is assisted by *tamen*, the responsible heads of the quarters. The executive sees to the application of the customary law, the *kanun*, which is the expression of the will of the *Jema'a*. Among the nomads power resides with the eldest male descendant of the family of the founder ancestor, assisted by the assembly of heads of groups. There are also more complex structures involving several villages or tent groups; the alliance of divers of these larger groupings constitute a tribe and several tribes may form a confederation.

Technical Trades.— Skilled workers in North Africa form castes: they include butchers, potters, stonemasons, hunters, blacksmiths and, in the Sahara, well cleaners. The blacksmith's skill includes magic as well as technique, as he is often the healer of

heat disorders, fevers, etc. He also plays a social part: it is often his task to inaugurate the plowing, and among the northern settled peoples he was formerly war leader. In the Ahaggar, blacksmiths are frequently Hausa. In Tibesti they also form a separate nomad caste, and no observer has yet been able to say whether this caste is of different racial origin from the rest of the population. The existence of hunting clans appears to establish that a ritual chase once preceded the plowing. In Tibesti the blacksmith has the privilege of hunting the antelope with hounds.

Economic Activity.— The existence of groups with their particular tabus has entailed the existence also of complementary productive castes; exchange in its simplest form of barter has long been the only means of bringing these human groups together. The market, the place of exchange, is consecrated with magical rites; like the house, it has a sacred character which assures its protection, and men belonging to different clans can meet there unarmed to exchange their products. Barter has an important place in the economic life and makes it impossible to evaluate family budgets in terms of money. Earthenware vessels, for example, are exchanged for one or several times their content of grain; two or more goats are exchanged for one sheep and so on.

Towns.— The large towns have been founded on the sites of the Phoenician wharves and the Roman garrison quarters. Like all Mediterranean cities they have separate ethnical quarters. The gates which formerly pierced their walls were always placed under the protection of a saint whose sanctuary has often survived. Craftsmen occupy particular streets or quarters (*sugs*), which conform to the same tabus as in the rest of the country.

Arts and Handicrafts.— The arts and domestic crafts are part of the cycle of the life of the fields. Weaving is linked to plowing and to marriage. Women weave in winter, for then "the fields are covered with vegetation as the loom with wool." The two beams of the loom form a couple; the woven cloth is regarded like a living being and the ritual for separating it from the loom when it is finished is the same as that which attends the cutting of the umbilical cord of a newborn child. The striped blankets decorated with lozenges, common in the Berber regions, recall according to tradition, the skin of serpents and the parallel bands of the fields. In the high plain region the women weave pile carpets designed to cover the ground of the tent. Some, such as those of Kairouan in Tunisia, have achieved renown.

Domestic pottery is made by all women, provided they have learned the art before puberty. Pottery is the object of many tabus and many groups may not make it. The patterns of Berber pottery symbolize the world and social organization: water, clouds, houses, the reed of a loom, or the fields are their principal elements. Pottery is made in springtime when the ears of corn are forming; it dries in the shade while the ears ripen and bakes under the open sky when the harvest is ended and there is no more fear that fires will parch the earth.

Remarkable pottery has long been made at Fez and Meknes in Morocco; at Nabeul and Djerba in Tunisia production has almost reached industrial scale. Leatherworking has given rise to corporations, especially in Morocco. The making of silver and gold jewelry has long been an activity of the blacksmith caste.

The music of North Africa can be clearly differentiated according to whether it is Berber music, which is related to the popular music of the northern Mediterranean, or Arab music, which is the mark of eastern influences. The latter may be divided into rural music, represented principally by the songs of the nomads to the accompaniment of the flute, of which the rhythms are the same from Syria across all the Sahara to the Atlantic, and urban music where the chief instrument is the lute, which is also the sign of eastern influences, doubtless from Iran. This music has undergone a considerable Spanish influence. There are groups of professional men singers whose social standing varies with their type of singing, sacred or secular. They move from village to village at the time of plowing, when obscene jokes are customary. The broadcasting of thoroughly arabicized songs over the extensive radio system is a great threat to rural music.

Religious Life.— The basis of the religious life of the people is the linking of society with the invisible world. The dead an-

cestor is at the root of a family cult. It is his duty to bring fertility to the earth, especially for his direct descendants, who in return must carry out funeral rites at fixed times. Among the people ancestral tombs take the place of martyrs' tombs among Christians and those of holy men among Muslims. At the mercy of desecrators, their name is often unknown or forgotten; they are simply *jedna* ("our ancestor") to the peasants. Religious life is thus composed of rites intended to propitiate and strengthen the spirit of the ancestor within the framework of the agricultural year.

Pilgrimages, the expression of popular piety, are seasonal rites. In spring they are accompanied by prayers for rain; in summer by offerings of first fruits after the harvest; at the beginning of autumn they are a consecration of the plowing and a reminder of the alliance between the descendants of the same ancestor and their relations by marriage. The family house is the principal temple, sanctified from the time of its construction by foundation sacrifices. Every domestic object is regarded as the abode of a guardian spirit and ritual offerings are placed by each at the time of every festival.

"Rites de Passage."—These rituals are parallel to the agricultural rites, and they also sanction entry into the family conceived of as a cult community. Birth is surrounded by ceremonies which aim at fixing the human spirit in a body and protecting the mother and the newborn baby from evil influences—evil spirits and the evil eye. Circumcision is practised throughout North Africa. The traumatic experience of the operation brings the child out of the world of women into the world of men. The age of circumcision varies from 1 year or less to 12 years: in the first case it is the survival of a very old Jewish custom. Female excision is practised in Egypt and Tibesti; it has not been noted in the rest of North Africa. Marriage is the keystone of all fertility rites: by virtue of this it assumes many of the aspects of the plowing rites. It is also the sign of alliance between two families, with the exchange of gifts of food and presents. The escorting of the bride to the conjugal home may be preceded by a pretense of abduction. Her departure from her paternal home is surrounded with ritual signaling the abandonment of her father's authority and her passing under that of her husband. Her arrival at her conjugal home is marked by a series of fertility rites which are repeated seven days after consummation of the marriage.

The rites connected with death are governed by the rules of orthodox Islam. A very ancient past, however, controls the tabus and the mourning obligations, which are in fact relative tabus to those connected with germination in the plowing season—the forbiddance to cut the hair, beard or nails.

Agricultural Rites.—Plowing is accompanied by the same rites all over North Africa. After the sacrifice at the tomb of the founder ancestor, the eldest of his descendants or "a man with a lucky hand" cuts the first furrow, having placed an offering of multiple-seeded fruit on the soil, an offering often made in marriage rituals. Spring rites are especially for the protection of the green corn and of milk; by extension they have also become rites for the protection of the young and of the flocks. Harvest rites are essentially parallel to funeral rites. Special rituals surround the reaping of the first ears or the last sheaf.

The solar year was undoubtedly formerly divided into two seasons and began with the heliacal rising of Sirius at the beginning of August. The different phases of plant growth were calculated by the moon. Later the Arabs brought into use the Julian calendar borrowed from the Egyptian Copts, and their religious lunar calendar. The solar year has retained the names of the months of the Julian calendar and of festivals common to all Europe. The new year is marked by rites designed to avert famine and to foretell the fortune of the months to come. For the nomads this festival, called the festival of the tent pegs (*Bu inian*), marks their departure on their nomadic journey. June 24 (Julian) is celebrated throughout North Africa by the fires of *'ainsara* which, according to tradition, perpetuate the memory of a sinful "pagan" woman who was burned alive. In reality these fires are an extension of the solstice fires which are found all over Europe.

Islam.—Officially Islam is practised in North Africa according

to the Malikite rite, but there is a strong Ibadite community in Mزاب and some Hanifites in the towns formerly occupied by the Turks. The Islamic religion of the people has had to take into account the essential facts of North African thought, the ancestor cult and the cycle of the fields. Islam penetrated North Africa in the Shi'ite (Shi'ah) form of the Omayyads in the 8th century, and later of the Fatimids. The memory of the Shi'ite faith is kept alive by the "hand of Fatima," an old symbol known to the Phoenicians but which Shi'ite Islam made the symbol of "the five most precious things in the world."

The principal Islamic festivals in North Africa are: 'Ashura, Mulud, Sha'aban, Ramadan (or the Little festival which marks the end of the fast of Ramadan) and the Great festival 40 days later. These festivals have borrowed numerous rituals from the ancient festivals of the solar year. 'Ashura, the first feast of the lunar year, has drawn on many new year rituals. Mulud, the birthday of the Prophet, has become a festival of lamps all over North Africa, the flame being the symbol of the return to earth of the spirits of the dead. The 15th night of Sha'aban is the anniversary of the ascension to heaven of the Prophet, on al-Mihraj. Peasants regard this night as one of destiny, in the course of which God allots the goods of this world for the year to come.

The *Mrabtin*, whose name comes from a root meaning "to bind," form a sacred caste of intermediaries and conciliators between this world and the next. They are forbidden to carry arms. Their villages are often situated on the plain, since they have no fear of any attack. Their weapon is the *da'a* or "power to curse." Among the Tuaregs of the Sahara they form special tribes. *Mrabtin* all over North Africa claim descent from the Prophet through Idris, and a common place of origin, Ssguia al-Hamra in the Rio de Oro.

Brotherhoods.—Dey Obayd Allah, who came from Iran to Little Kabylia about the 9th century, brought with him the idea of a secret mystical society. It is not surprising to see appearing much later, in the 17th century but in the same region, the first Muslim brotherhood, the *Rahmaniya*, founded by Si Abd-ar-Rahman, with seven degrees like the mystical Persian order of the deys. Other brotherhoods have followed, all borrowing their ritual from the first. The most popular is the *Qadiriya*, the most important politically the *Senusi*, which for long held all the Sahara and converted Tibesti, Borku and the Ahaggar to Islam. The part played by these brotherhoods, important up to the beginning of the 20th century, has waned with the development of Muslim Reformism, and especially with the growing disaffection of the masses for the mystical aspects of Islamic thought.

Evolution.—At the beginning of the 20th century the social ideal was the western *petit bourgeois*, an official or member of a liberal profession. After World War I the Muslim Reformists of Cairo inspired a renewed idealism and the hope of a rebirth of Muslim civilization. In fact the achievement of independence by the states composing North Africa (Egypt before World War II and Libya, Tunisia, Morocco and Mauritania after) has seen the continuance of the European administrative structures and the domination by an intellectual minority of a peasant population still faithful to its traditional systems. Reformism has shaken the cult of the saints and with it Islam, which was scarcely known to the masses except through the tombs and holy places. In its turn Reformism has been abandoned by the young, leaving only a great vacuum in the minds of nearly 40,000,000 persons. (J. H. SE.)

B. NORTHEAST AFRICA

This region, usually taken to include the Republic of the Sudan and the Horn of Africa (in its widest use Eritrea, Ethiopia, Somalia and French Somaliland), is one where political frontiers bear particularly little relationship to ethnic divisions. The Sudan embraces an area of 965,491 sq.mi. and, like the Horn to its east, has a long and varied history. The earliest name of the country is the vague Egyptian *Ta-Nehesu* which like the *Bilad as-Sudan* of the early Arab geographers means "land of the blacks." In fact, however, although Negroid features are widely diffused in the Sudan they are particularly pronounced only in the physical characteristics of the inhabitants of the south, and it is usual to recognize a general division between the predominantly Arabic-speaking and

Muslim desert regions of the north and the Negroid and largely pagan areas of the less arid south. The Arab and Muslim influence which is dominant in the north has been superimposed upon earlier Hamitic cultures which survive little changed in the Red sea and Kassala provinces of the east. The earlier Hamitic populations were first influenced by Arab penetration in the middle of the 7th century when the Egyptian amir Abdullah ibn Sa'd led a well-equipped expedition into Nubia, reaching as far as Dongola, and concluded a treaty of peace with the Nubian king. But the first considerable Arab incursions came three centuries later when armies largely composed of Arab nomads were sent from upper Egypt and many Arabs settled among the Nubians and among the Beja. Christianity, which had been implanted about the 6th century, began to wane, especially after Arab immigration through Egypt reached a peak in the 13th century.

The Sudan.—The peoples of the Sudan whose culture and physical features represent the admixture in varying proportions of the three basic stocks, Negroid, Hamitic and Arab, can be classified as follows:

Nubian-Speaking Peoples.—The Nubians, who probably number more than 200,000, live along the Nile in Egyptian territory of Aswan to Halfa, and in the Sudan in Halfa district and Dongola as far south as Debba. The earliest inhabitants of this region were of the same stock as the predynastic Egyptians, but through assimilating successive waves of Negroid immigrants have come to speak a language (Nubian) which is regarded as belonging to the Sudanic (Negro) family. In physical type the population is a fairly homogeneous Negroid cross. The Barabra, who may be taken as representative, are fairly tall with a medium- to dark-bronze skin, thick lips and black hair which is curly rather than kinky. They are essentially an agricultural riverain people dependent upon the Nile for their livelihood and forced by the poverty of their habitat and pressure of population to travel widely as traders and seek work in the towns of the Sudan and the Egyptian Region. Occupational groups are organized into guilds under a sheikh. Descent is generally patrilineal and tribes have a segmentary lineage structure akin to that of the Arabs. (See BARABRA; NUBIA.)

Beja Tribes—Beja is the name given by Arabic writers to the large group of Hamitic-speaking, nomadic and seminomadic peoples who inhabit the eastern district between the Nile, the Atbara river and the Red sea, and who number about 300,000. Their largest group is the Haden Dowa (Hadenoa) who number about 70,000 and are known popularly as the "fuzzy wuzzies" from the wavy character of their hair. The Beja are essentially pastoralists wandering over wide distances with their flocks and herds of cattle and camels on whose produce (milk, butter and meat) they subsist almost entirely. There is a complex of attitudes surrounding milk which is regarded as in a sense sacred. Although there is evidence that in the past descent was matrilineal, it is now patrilineal and the tribes have a segmentary lineage organization similar to that of the Arabs. Authority is vested in the heads of kin groups, and in the case of larger groups which hold territorial rights in sheikhs. As Muslims, polygyny is permissible but usually only the rich have several wives. Following the Shariah, father's-brother's-daughter marriage is preferred and bride wealth is paid generally in livestock. Boys are circumcised and girls subjected to clitoridectomy, but age sets are lacking. War and feud are common with such a virile and independent people and only recently has the Muslim Arab custom of paying blood compensation (dzya) been introduced. Most of the Beja still speak the Hamitic To Bedawi although some have adopted Arabic, and in the case of the Beni Amer the Semitic Tigre. (See BEJA.)

Arabic-Speaking Peoples.—The term Arab has in the modern Sudan the vaguest connotation, and many of the Hamitic Beja and the Nubian tribes as well as Negroid groups (such as the Fung) have Arab pedigrees and claim Arab ancestry. Nevertheless it is possible to distinguish a congeries of peoples who descend from the earlier Arab invasions and preserve their Arab characteristics in varying degrees. These have been divided by Sir H. A. MacMichael into two groups: the Ga'alín-Danagla (Ja'aliyyin-Danaqla) and the Guhayna (Juhaina). Together they are

estimated to number about 5,000,000 and constitute the largest element in the population of northern Sudan.

The Ga'alín-Danagla, who include most of the riverain and Kordofan sedentaries, have less Arab blood than the predominantly nomadic Guhayna. Some have been completely negritized. They are distributed in cultivating villages under headmen ('umdas) who hear and try cases. A characteristic feature is the numerous markets (suqs) which are held regularly and permit the grain, sugar, dates, etc., of the cultivators to be exchanged for the livestock and livestock produce of the pastoralists, for both groups are economically interdependent. The larger *suqs* have developed into market towns where trades are organized in guilds each under its own sheikh. Descent is patrilineal and the sedentaries, who are generally despised by the proud nomads, have a weaker tribal structure than the latter.

There is not, however, a complete division between the sedentaries and the Guhayna nomads, for some tribes have nomadic and sedentary sections, and true nomadism often gives place to transhumance where a tribe cultivates in oases in the autumn and then moves out into the pastures with its livestock until the spring. But it is the Guhayna nomads who preserve the highest proportion of Arab blood. They comprise the camel-owning nomads of Kordofan (the Kababish, Dar Hamid and Hamar), those of the Butana and Jezira (the Shukriya and Rufa'a) and the cattle-owning Baggara (Baqqara or Bakkara). The Baggara cattle people are less mobile than the camel pastoralists and are more mixed in ethnic composition. They have evolved a distinctive dialect and distinctive customs and are among the most warlike of the Arabs in the Sudan, being good horsemen. Their tribes, which like those of the other Arabs have a genealogical structure, are large and organized under nazirs whose lieutenants ('umdas) lead their segments.

The less heterogeneous camel people (or Ahl Ibl as they are called) move over wider distances than the Baggara. Each tribe (qabila) has its own grazing area (dira) and wells. The tribal head (sheikh or, in administrative terminology, nazir) is a *primus inter pares* ("first among equals") whose office is not necessarily hereditary. The tribal war drum (nahas) is the traditional symbol of tribal unity and sheikhly authority. War and feud are common, friction over grazing and water rights being a frequent source of conflict, and blood compensation (diya) is regularly paid by all the nomads. Descent is patrilineal. (See also BAGGARA.)

Muslim Negroids.—Many Negroid groups chiefly in central and western Sudan have become Muslim, but most have retained their own languages and cultures. They may be divided into the following: (1) Fallāta: colonies of West Africans settled in eastern Sudan, mainly immigrant Hausa, Fulbe, Kanuri and Borku. They probably number a few hundred thousand. (2) Fung (*q.v.*): groups of semi-arabized Negroids of mixed ethnic composition known to the Arabs as Hameg living in Darfung. (3) Non-Arab peoples of Darfur, including seminomads such as the Tebu (Tibbu) and the sedentary agricultural Fur. (4) the Nuba (*q.v.*) of southern Kordofan, a heterogeneous group numbering several hundred thousand, mainly engaged in cultivation in terraced fields. They have many cattle and other livestock. They live in small sedentary hamlets united in larger hill communities. There are religious leaders (*kujurs*) and secular leaders (mek). All the Nuba have descent groups; the Tumtum of the south are exclusively matrilineal while the northern and central Koalib are patrilineal; others have dual descent. Age sets are common but not universal.

Pagan Tribes of Southern Sudan.—These have been classified by C. G. Seligman as follows: (1) Xilotes: those living in the Sudan have a total population of almost 1,000,000, the chief peoples being the Dinka, Nuer, Anuak and Shilluk. Although all engage in some cultivation and in fishing and other activities, they are predominantly pastoralists possessing large herds of cattle. All are patrilineal. There is considerable variation in political structure from the extremely egalitarian Nuer, who have a segmentary lineage structure, to the Shilluk who were united under a divine kingship. The Nuer and Dinka have strongly monotheistic religions centring in the cult of spirit and differ markedly in this

respect from most Negroid peoples. (2) The Nilo-Hamites: the Bari, Mandari, Kuku, etc., and Lotuko and Luluba stocks (numbering scarcely more than 100,000) among whom pastoralism seems generally less important than agriculture. All are patrilineal and most are divided into small political units among whom ritual "earth chiefs" and rainmakers play an important role. An age-set organization is a general feature. (3) The Fung-Nuba peoples mentioned above. (4) The southwestern peoples: of whom the Azande of the Ironstone plateau, with their conquest state political organization and numbering about 200,000 in the Sudan, are the best known. They are a conglomerate people welded together under the political ascendancy of the Ambomu whose ruling clan is the Avungara. They have a hierarchical system, are patrilineal in descent, and perhaps best known for their preoccupation with magic and witchcraft. They are agricultural, and have no cattle. (See also BARI; DINKA; NILOTES; NUER.)

The Horn.—Most of the peoples of Sudan's eastern frontiers extend into the Horn giving this region considerable ethnic and cultural continuity with the Sudan. The pastoral Hamites of northeastern Sudan reach far into Eritrea; the Arabic-speaking Shukriya and other peoples to the southeast of Khartoum extend into central and western Ethiopia; and the pagan peoples (Beni Shangul, Nuer and Anuak) of southern Sudan spread into southwestern Ethiopia. As in the Sudan the physical characters and cultures of the present inhabitants are the result of the mixing of Negroid, Hamitic and Semitic stocks over a long period. This has led to a remarkable diversity of peoples and cultures, such indeed that Ethiopia has been described as a "museum of peoples" (Conti Rossini). The aboriginal population of at least part of Ethiopia was probably Negroid. But there is nevertheless a considerable uniformity of physical type due especially to the Hamitic strain which predominates and is assumed to date from several milleniums B.C. This absorbed a later population introduced by Semitic migrations from southern Arabia probably in the 1st millenium B.C. The population may conveniently be divided into the following main groups:

Semitic-Speaking Peoples.—(1) Tigre-speaking communities: the Beni Amer (60,000) of eastern Sudan extend into Eritrea along the Red sea coast. Contiguous Tigre-speaking peoples are the Bait Asgade (including the Habab and the Marea (Marya) and Mensa, the total Eritrean Tigre-speaking population numbering about 260,000. Most of the Bait Asgade are pastoral nomads; the Marea combine pastoralism with cultivation; and the Mensa are sedentary cultivators. All are Muslims, patrilineal in descent, and constitute tribal federations with a ruling and a serf class. The serfs (Tigre) are in most cases the descendants of various earlier communities upon which the present aristocracies imposed their dominion. Among the Mensa, who still preserve traces of their former adherence to Christianity, each tribal section is under an elected chief (kantebai) whose position is symbolized in the possession of a tribal drum. (2) Tigrinya-speaking peoples: these are mainly Christian, although some are Muslim, and number about 1,150,000 of whom 430,000 (the Akkele-Guzai, Hamasien and Serae tribes) live in Eritrea. The majority, however, live on the northwest Ethiopian plateau. They are mainly cultivators, using the ox-drawn plow common in Ethiopia, and grow a wide range of crops. Livestock are also reared, milk being an important item of diet. Descent is patrilineal. Their social and political organization is similar to that of the neighbouring Amhara. (3) The Amharic-speaking community (the Amhara) is the ruling Christian aristocracy of Ethiopia and numbers at least 3,000,000. In contrast to the Tigrinya-speakers, to whom they are otherwise similar, descent is apparently bilateral. Both groups are settled in villages on the central Eritrean plateau and in the northern highlands of Ethiopia where the fundamental political unit is the large kinship group (*enda*) which is a territorial unit with hereditary land rights. Society is traditionally divided into landholders (restenyatat) and tenants (sedbi). In the Amhara feudal system of government the village headman has authority under the local chieftain and local representative (ras) of the emperor. The traditional hierarchy presided over by the emperor (negus), whose dynasty claims descent from the queen of Sheba, has only been

slightly modified by recent reforms and, although parliamentary government has been introduced, the Amhara political system conserves much of its feudal character. (4) The Gurage are a patrilineal people numbering about 350,000 who live as sedentary cultivators with large herds of livestock in the fertile mountains south of the Awash river and west of Lake Zwai. They are partly pagan, partly Christian, partly Muslim and, although they speak a Semitic language, are closely related to the Cushitic-speaking Sidama.

Cushitic-Speaking Peoples.—(1) The Bogos (Bilen), who number about 20,000, inhabit the northern part of the high plateau north of the Gash (Marab) river and are predominantly Muslim. They are mainly agriculturists, living in small hamlets, and have a hierarchical political structure in which the ruling class (*simgager*) derive from Agao immigrants, the serfs (*mikeru*) descending from the earlier Tigre-speaking inhabitants. (2) The Agao, who represent a distinct strain of Cushitic stock, are scattered in several small pockets to the northwest of Addis Ababa in Ethiopia and probably number 100,000. Most are Muslim and sedentary cultivators with a social structure similar to that of the Amhara and Bogos. Of particular interest are a northern group, the Falasha (or "black" Jews), who number about 50,000 and live scattered in the northwestern provinces of Ethiopia practising primitive Judaism. They have no knowledge of Hebrew and their priests use the canonical and apocryphal books of the Old Testament in Ge'ez. (3) The Saho-Afar: two Muslim and predominantly pastoral peoples (Afar 100,000, Saho 50,000) who live south of the Bait Asgade along the Red sea coast of Eritrea extending for a considerable distance into northeastern Ethiopia and French Somaliland. Both are patrilineal and have a segmentary lineage structure with chiefs, the Afar having rigid class divisions. (4) The Somali, who number between 2,500,000 and 3,000,000, are a Muslim and essentially pastoral people closely related to the neighbouring Afar and Saho, although their social organization differs from that of the latter in several respects. There is some cultivation in northern Somalila, but agriculture is most developed in the region between the Juba and Webi Shibeli rivers in southern Somalia. Descent is patrilineal and the Somali have a clearly defined lineage structure in which political contracts play an important role. Although many clans have sultans, the northern Somali particularly have an egalitarian and nonhierarchical political structure. (5) The Galla peoples who, with the exception of the Boran group of the northern province of Kenya, call themselves Oromo, dominate most of south and southeast Ethiopia and are the largest single ethnic group in the Ethiopian population. It is possible to make a rough division in economy and way of life between the eastern Galla or Baraytuma, who are mainly agricultural, and the western Galla or Boran, who are essentially pastoral. Some Galla have adopted Christianity but the majority are Muslim or pagan preserving much of their Cushitic monotheistic religion centring in the cult of the sky god (*Waq*). Descent is patrilineal and all the Galla have a highly developed cyclical system of age sets (*gada*) with important political functions and presided over by the Abba Boku or "father of the sceptre." This type of organization is entirely lacking among the Somali to whom the Galla are closely related. (6) The Sidama are a congeries of peoples representing an early Cushitic stock which, prior to the Galla incursions of the 16th century, occupied most of southern Ethiopia. They number about 1,500,000 and are concentrated in southwestern Ethiopia, bordered to the west by the Nilotes and to the north and east by the Galla. Agriculture is strongly developed, the ox-drawn plow being generally used, and in some places there is irrigated terrace cultivation. Descent is patrilineal and marriage mainly virilocal. Most of the Sidama have a monarchical type of political system which is most elaborate in the traditional structure of the Gibe, Janjero and Kafficho states which were ruled by divine kings.

Negroid Groups.—(1) The Baria (Barea) and Kunama: these groups situated in the Barentu region of southwest Eritrea number about 15,000 and are sedentary agriculturists who were formerly regularly raided by the Beja and other neighbouring peoples. The Baria are patrilineal and solidly Muslim, while the Kunama are matrilineal and mainly pagan. (2) Beni Shangul: this term is used

by the Arabic-speaking tribes of the Sudan to refer to a group of agricultural tribes living in Ethiopia between the Blue Nile and the Sudan frontier. They are called by the Ethiopians *Shanqela* (a term applied to Negroes in general) and are an islamized segment of the Berta of the Sudan. (3) Bantu and Swahili-speaking communities of southern Somalia: these are predominantly Negroid but partly hamiticized tribes living among the Somali, especially in pockets along the Webi Shebeli and Juba rivers. They are Muslims like their stronger Somali neighbours, to whom they are allied, and are essentially cultivators. They number about 80,000 and represent the remains of the pre-Hamitic population which before the Galla and Somali invasions formerly occupied this region. See FALASHAS; GALLA; MENSA. (I.M.L.)

C. WEST AFRICA

South of the western Sahara desert from Dakar on Cape Verde (Senegal) to Lake Chad about 2,500 mi. to the east, West Africa extends southward for about 1,000 mi. to the Guinea coast of the Atlantic ocean. This extensive region, which is divided among many territories, is far from uniform in physical conditions or in the culture and social organization of its peoples. But, as will be seen, important and widespread internal developments, often under the impact of prolonged external influences, have given it a character of its own. The greater part of the interior (generally known as the Western Sudan) is tropical savanna or orchard bush, covered with waist-high grass during the summer rains and studded with low trees. To the north along the lower Senegal river, the bend of the middle Niger and in the region of Lake Chad, trees give place to thorn bush. The grass is thin and short-lived, and disappears in the sands and bare rock of the Sahara. But 700 mi. farther south the savanna merges insensibly into the rain forests of the coastal belt which, but for human intervention, would extend almost continuously for a depth of about 200 mi. behind the surf-beaten shores and mangrove swamps.

This north-south gradation of climate and vegetation gives a beltlike character to the West African environment. Between the open interior and the forested coastlands there have been marked contrasts in opportunities for human settlement, external contact and cultural development. To the north the Sahara has been no complete barrier. For at least 2,000 years there has been continuous, if restricted, communication between the Western Sudan and the ancient and later Muslim cultures of North Africa. On the south from the end of the 15th century, the hitherto empty beaches and mangrove swamps of the coast, which had so long been ultimate limits to movement and settlement in West Africa, became the sites of European trading posts, through which direct contact with western mercantile civilization has been established for over 400 years. Thus on both the northern and southern flanks the lure of gold, ivory, tropical products and slaves has long sustained external trade and political relations, stimulating complex but very different cultural and social developments in the two zones.

Peoples and Languages. — There are, however, common features which indicate long prehistoric periods of internal development, diversification and expansion. Thus, despite very considerable variation in physical types, the overwhelming predominance of Negroid characters ultimately links all the peoples of this area with the rest of tropical Africa. Moreover, the great majority of the hundred or more languages of West Africa appear to have been diversified from a common stock generally known as Western Sudanic. Only to the east in the country from the Niger bend to Lake Chad have languages like Hausa, which belongs to the Northern Hamito-Semitic group, and Kanuri, which is similar to the Saharan languages of the central oases, spread deeply into the Western Sudan. The internal groupings of the Western Sudanic languages suggest an early cultural separation of the populations which spread into and through the forest belt from those occupying the savannas to the north. Among the former, over a distance of 1,000 mi. from Liberia to beyond the lower Niger, although individual languages unintelligible to outsiders are sometimes confined to a few thousand people, linguistic studies have revealed underlying similarities of vocabulary and structure that

justify their grouping into a single family known as Kwa languages. This in turn suggests the proliferation through the forest belt of early communities stemming for the most part from a single stock. It points also to the obstacles which the forests presented to large-scale penetration from the north. Although later intrusions of far-reaching cultural importance occurred in some areas, these appear to have been confined to small if dominant groups that were absorbed linguistically by the local populations. Only in the west did northerners penetrate in large numbers to establish petty chiefdoms like those of the Mende of Sierra Leone, which carried Mande languages from the Western Sudan right down to the coast.

Most of the Western Sudanic languages of the wider savanna zone also fall into a few major and divergent groups; broadly speaking each occupies a block of country extending across it from the desert to the forest margin. In the upper basins of the Senegal and Niger, the widespread group of Mande languages predominates. Linguistic and other cultural distributions show that the Mande-speaking peoples such as the Mandingo (*q.v.*) and Bambara of Senegal and Soudan, most of whom share a tradition of military organization under strong chiefs, have in the course of time expanded at the expense of other stocks to the west and east. This expansion, which was still in process at the time of European pacification, corresponds to the main sphere of influence of a vigorous civilization that the medieval Arab chroniclers described as long established in the Western Sudan. (See also AFRICAN LANGUAGES; SUDANIC LANGUAGES.)

Forest Belt, Mode of Life. — An early and important cultural differentiation between these zones is also reflected in modes of subsistence. The forest peoples were and have remained hoe cultivators depending basically on root crops, yams and coco yams and fruits, especially varieties of the cultivated banana, supplemented by semicultivated tree crops, notably the oil and raffia palms and the cola tree. Hunting and trapping, although now much reduced, were prominent in the traditional economy but livestock was confined to small numbers of fowl, goats, pigs and in a few areas dwarf cattle attached to the household. There was no continuous loom weaving, fabrics being made of raffia and pandanus matting and beaten bark cloth. Iron tools were scarce but available to most peoples by traffic from scattered centres of ore smelting. On these depended not only more efficient forest clearing and cultivation, but also well-developed woodworking crafts, the products of which included massive assembly houses, stools, slit gongs, drums, statuary and masks for which distinctive aesthetic canons developed among different peoples. Pottery, which was also generally available, was often traded over considerable distances from specialized centres of production.

The development of this forest economy appears to have depended on early introductions from the east since the main crops, the domestic goat and fowl and the crafts of barkcloth and raffia matting are also widespread among the forest people of central Africa and most are ultimately of south Asiatic origin. But some important local additions were made; notably the cultivation and improvement of two local species of yam. In the west, from Gambia to Liberia, rice was also established as both a rain and swamp crop, a development which is perhaps explained by the fact that rice had early been introduced, possibly across the Sahara, as a riverain crop along the upper Niger, where it could have been carried south into the wet forests.

Social and Political Organization. — Apart from a few more complex state organizations ascribed by their own traditions to incursions from the north and some later developments of trading oligarchies on the coast in response to commerce with Europeans, indigenous political organization in the forest belt has been small in scale, remaining rooted in ties of neighbourhood and kinship. Communities of only a few hundred strong were often virtually autonomous each with its own organization of groups of kinsmen in an internal system of authority. Their relations with one another were not regulated from above but depended on mutual obligations and alliances maintained by traditions of common descent and intermarriage, ratified by collective ceremonies and feasts and economic exchange. Such ties were liable to disruption and re-

alignment by rivalries and mutual suspicions that could lead to hostilities.

A system of lineages, whereby a body of kinsmen in one line of descent maintained collective claims to resources, co-operating and competing with similar groups for various ends, appears everywhere to have provided the first order of political organization within a locality. Among some peoples, like most of the Ibo and Ibibio of eastern Nigeria who were dispersed in small compounds or hamlets, this lineage grouping operated to unite smaller or larger bodies of kin according to the activity or issue involved. There were often fertility and other cults whose priests had ritual and moral authority to declare, and prescribe remedies for, breaches of custom in an area. But the larger groups which were united on occasion in defending their rights against more distant kin, themselves dissolved into ever smaller units on narrower issues; so that the authority of elders to mobilize and represent a following and to settle disputes among them by arbitration or threat of retaliation varied according to circumstances and size of groups which opposed or competed with one another.

Among peoples who congregated in compact villages separated geographically and socially from one another, there was usually a more definite local organization, including a village council variously composed of the priests of village cults; the leaders of local men's associations or of senior age groups, which directed village affairs and settled disputes between the kin groups holding rights in land and other resources. Political relations between such villages were often those of give and take between independent groups. But whether the social organization was one of proliferating lineages or of independent villages, communication through trade, intermarriage and ceremonial exchanges could maintain common speech, custom and pattern of organization over populations of several thousands. Despite the small size of the independent political units, technical skills, aesthetic styles, beliefs and rituals, as well as valued commodities: could be and were transmitted over wide areas.

Thus, while most of the forest peoples lived in small self-contained communities, persistent if slow diffusion of techniques and ideas, as well as territorial expansion under favourable conditions, can account for the fact that their cultures show many common elements in technology, art, beliefs and institutions.

But in some parts of the forest belt, notably among the Akan-speaking peoples of Ghana and the Ivory Coast and the Toruba and Edo (Benin) of southwest Nigeria, both technical skills and the form and scale of political organization were far more elaborate. Thus the Xkan, as the records of travelers from the 18th century show, had long been organized in states with a hierarchical organization and complex ritual focused on a sacred chief in whom political as well as religious authority was vested. Prompted by the opportunities for enrichment by control of trade to the north, and later with Europeans on the coast, some states secured dominance over others which they organized in military confederations. Of these, Ashanti, which united the greater part of the forest belt of Ghana, in the 18th and 19th centuries was the best known and most powerful. The Akan languages belong to the Kwa group of the forest belt and most of their crafts and religious beliefs are characteristic of that zone. But the older Akan states lay on the savanna borders, and all ascribe their origins to the successive hiving off of state after state from more northern centres.

Before the arrival of Europeans in West Africa, chiefdoms had also been established among the Yoruba in the forests right down to the Guinea coast, and among the Edo to the east in the kingdom of Benin. According to their own traditions these too had been formed by the repeated hiving off of members of the chiefly houses and their followers to found new chiefdoms on the model of the old. The old capital of Oyo, which was paramount in the 18th century, lay north of the forests and the founders of the first chiefdoms were believed to have come from the north.

Despite variations in detail, whether in craft or social organization, the techniques and skills characteristic of such chiefdoms present a remarkable contrast to those of the rest of the forest belt. Cotton was usually grown for weaving, the high status of the chief and other officeholders was marked by elaborate robes,

ornaments and headgear. Bronze, brass, gold and precious stones were used to fabricate ceremonial objects, extensive buildings were erected for the court. Towns were protected by wide ditches and walls, armies were raised for conquest and defense. The subsistence economy and many elements of the ancestral and other spirit cults among their peoples were similar to those of other forest communities and there was some diffusion of particular crafts, customs and beliefs among other groups who were not fully incorporated into state organizations. Nevertheless, the association of these centralized political systems in the forest zone with sacred chiefship and new crafts justifies acceptance of their traditions of northern origins, even though archaeological and documentary evidence is so far lacking.

Western Sudan, Modes of Life and Political Organization.—The peoples of the savannas of the Western Sudan are predominantly grain cultivators as contrasted with the root- and fruit-growing peoples of the forests. Their essential agricultural tool (the broad-bladed, short-handled hoe) is the same, but their food staples and patterns of farming belong to a different tradition. Cereals, including *Sorghum*, *Pennisetum* and *Eleusine*, are their food staples, although a wide range of subsidiary held and tree crops is obtained. These two West African farming traditions were combined in some areas along the forest margins. This may well be the result of later interpenetrations such as the extensive but comparatively recent northward expansion of the Tiv into the orchard bush of the Benue valley in Nigeria. Originally, however, they appear to have been separate. Thus the early linguistic divergence of the language families of the forest belt and the savannas may well have been associated with these two distinct patterns of cultivation and the separate westward expansions of agricultural populations that they made possible.

Moreover, there appear to have been several phases of agricultural development within the savanna zone as additional crops and associated crafts were established in some areas. Thus there is great variation among its peoples in technical skills. Among some there persisted until recently a more primitive economy with a less productive agriculture, lacking textiles and dependent on sporadic trade for iron tools. Some of these people grew only inferior grains such as *Digitaria*. Others, although they cultivated several kinds of the better-yielding millets, merely dibbled in the seed and weeded with light hoes. Such peoples living dispersed in small hamlets or clustered in hill villages for protection, had no central organization of government. As in the forest belt the kin groups or the village communities of a locality allied themselves or disputed with each other on equal terms as occasion arose. Societies of this type are to be found in the more remote areas in many parts of the Western Sudan, as for example in the interior of Guinea and Liberia, the northern territories of Ghana, the north of Dahomey and the hill country of northern Nigeria and the Cameroons region.

Many other peoples, however, such as the Hausa and Kanuri of northern Nigeria or the Mandingo and Bambara of Mali (former French Sudan) and other territories, have practised a much more elaborate agriculture. With deep hoeing and ridge cultivation they raised a wide variety of grain and other crops, sometimes by irrigation. The level of agricultural production was correspondingly higher and could normally provide a surplus for trade and tribute. Cotton was generally grown to supply the weavers who were but one among a variety of specialist craftsmen. These populations have also long been organized in centralized chiefdoms which, while varying greatly in size from extensive empires to much smaller areas, shared many basic features of organization and ceremonial. Authority was concentrated in the ruler who, with his councilors and nobles, constituted a hereditary aristocracy often by tradition of conquest. The ranking and subordination both of offices and of classes was expressed in an elaborate etiquette. Slaves, whose numbers were continually augmented by periodic raiding of the more primitive peoples and by warfare between states, were important as a class not only for providing farm labour on the big estates, but as trusted and often powerful agents of their masters at all levels from the chief downward. The more primitive tribes of dispersed kin groups and isolated villages had

for centuries been subject to conquest, slave raiding and incorporation by expanding chiefdoms. In many areas only small remnants had survived in independence at the time of European intervention at the end of the 19th century.

Impact of Islam. — The rulers and most of the populations of many chiefdoms have been at least nominally Muslim for many centuries. But both the chronicles of medieval North Africa and of the Western Sudan itself and modern ethnographic studies show that while the adoption and promotion of Islam have been potent factors in the growth of later chiefdoms, many of the basic ideas and customs associated with chiefship and other social relations are much older, and that in varying degrees, elements of pre-Islamic rituals and social codes have persisted. The earliest accounts of these ancient chiefdoms and empires are those of Muslim Arabs who crossed the western Sahara in the 10th and 11th centuries to report vivid if fragmentary impressions of the empire of Ghana which already extended from the Senegal to the upper Niger and to an unknown extent southward into the gold-bearing highland and forest. It claimed a history of many centuries at that time and its ruler was a sacred figure possessed of supernatural powers and the centre of elaborate ritual. The authority of the state was extended over a wide area by means of a standing army and control of vassal chiefs. Tribute was collected from its provinces, dues were levied on trade and there was a state monopoly of the traffic in gold from the south which appears to have been all important in sustaining the trans-Saharan caravan traffic. The early Muslims who came from North Africa were welcomed as merchants and advisers but were kept apart from the political and ceremonial life of this pagan kingdom. It was not until late in the 11th century that the Almoravid Berbers immediately to the north conquered part of Ghana and began the imposition of Islam. By the early 14th century, when this region was visited and described by Ibn Khaldun, Mali or Mande (Mandingo) had replaced Ghana as the centre of empire with an essentially similar but Muslim state organization. Many of the rulers of Mali made the pilgrimage to Mecca and it maintained diplomatic and scholarly as well as commercial relations with the Arab world until it in turn dwindled to a vassal chiefdom in the 17th century after the rise of the Songhai (Sonrhāi) empire based on the middle Niger.

Although contemporary records do not go back so far, pre-Islamic foundations for states that were early established on the Niger bend and in the region of Lake Chad are claimed in later chronicles. The traditions of Kanem-Bornu in the latter area ascribe its foundation to northern immigrants at least two centuries before the introduction of Islam in the 11th century. By the 13th century this empire controlled the chiefdoms that had been established among the Hausa to the west and extended northward into the Saharan oases of Fezzan (in Libya). An established route by way of the Bilma oases was regularly used by North African caravans and provided the main link with the outside world until the end of the 19th century. For, despite many vicissitudes, the kingdom of Bornu maintained itself until it became part of Nigeria.

The widespread adoption of Islam in the many chiefdoms and successive empires that controlled different parts of the Western Sudan strengthened commercial and cultural links across the Sahara. But the first development of more productive agriculture and elaborate crafts, the specialization of occupations and the development of trade, is likely to have been associated with an earlier establishment of ruling aristocracies and administrative government before the Arab conquest of North Africa and the subsequent penetration of Islam into the Western Sudan. This is consistent too with the character and traditions of chiefdoms of the southern margins of the savanna and the forest belt. The Akan, the Yoruba and the chiefdoms of the southern Cameroons region knew of Islam only through traders and later military incursions from the north. But they ascribed their founders to earlier arrivals from older centres there.

Thus the emergence of the more complex cultures and political systems of the Western Sudan and of parts of the forest belt is linked with the early practice of superior crafts as well as elaborate doctrines whereby the authority of chiefs is derived from

their supernatural powers as incarnations of gods or ancestors. Some of these traditions have individual parallels in the crafts and rituals of the ancient east whose beginnings go back before the 2nd millennium B.C. Although evidence of the processes of early cultural diffusion from the ancient east to western Africa is meagre in the extreme, such clues as are available point to intermittent incursions and traffic by way of North Africa and the oases of the central and western Sahara. And it is probable that early in the 1st millennium A.D., if not before, large chiefdoms had already been established in several parts of the Western Sudan. The domesticated camel, which was first introduced into North Africa at this time and provided the means of carrying men and goods in large numbers across desert country may have greatly reinforced this development. The introduction of the horse and donkey were also of key importance for political organization and long-distance trade within the Western Sudan. Horses provided the means for the concentration and rapid movement of military force, administrative control over provinces and vassals and raiding into distant areas for slaves. The modern ceremonial horse-riding displays in the northern chiefdoms and the elaborate Yoruba carvings of chiefs on horseback amid their wives and dependents are still symbols of chiefly power and recall the former importance of the horseman as the key to political control. The economical donkey afforded a great advance on human portage for the transport of harvests and goods from farm to granary and from villages to central markets and storehouses.

The Hausa chiefdoms in northern Nigeria came under the control of local leaders of a remarkable and alien people at the beginning of the 19th century. Known there as the Fulani, they conquered and united in an empire based on their new capital Sokoto the Hausa states and several other peoples of this region in the course of a holy war (*jihad*) for the purification and re-establishment of Islam. These ancestors of the chiefs and nobles of the Nigerian emirates who are of Fulani descent, came from tribes of a distinctive pastoral people who are found dispersed across the Western Sudan from Senegal to the Cameroons region where most of them have lived for centuries in small scattered groups. Their initial expansion was not by conquest but through a slow dispersion of migrant cattle-herding groups keeping to the outskirts of the chiefdoms to whose peoples they were often linked in the exchange of products. Lighter-skinned and non-Negroid in appearance, their common language (Ffulde) suggests that they began to spread less than 1,000 years ago from the region of the lower Senegal river. As pastoralists they long remained pagans, but some groups in the west embraced Islam with fanaticism in the 17th century. From among these, Muslim teachers and leaders gained influence in several areas to capture or found Fula-governed chiefdoms on the Senegal, the Niger and in the Futa highlands of Guinea, as well as in Nigeria. They were outstanding among the great chieftains which the French and British encountered in the interior at the end of the 19th century. But their pastoral cousins have continued to herd their cattle from migrant camps in the remote bush.

European Influence on Coastal Chiefdoms.--Quite independently of the trans-Saharan stimulus, the European trading posts established on the Guinea coasts also from the 16th century onward offered new opportunities which profoundly affected cultural patterns and political organization along parts of the coastal belt. The traders provided muskets and gunpowder which, with the European demand for slaves, fostered the growth of larger and militarized chiefdoms there. Slave raiding and trading became the new means to power. Inland chiefdoms like Akwamu, Ashanti, Dahomey and Oyo fought for control of routes from the interior to the coast and sought to dominate its peoples. Benin temporarily achieved hegemony over most of the coast of western Nigeria. In the lagoons of the Niger delta, on the Calabar river and elsewhere small fishing communities were slowly transformed by leaders who built up bodies of kinsmen and slave dependents for their fleets of canoes to monopolize the creeks and organize the traffic in slaves and later in palm oil. Thus there grew up miniature trading empires composed of wealthy and competing houses as in Bonny and Old Calabar in Nigeria and Grand Bassam

in Ivory Coast, which carried commerce and new forms of political organization into the forested hinterland.

Among such peoples as the Efik and Ibo of eastern Nigeria and also among some forest chiefdoms, such as the Yoruba and Mende in Sierra Leone, religious cult groups (into which some or all of the men were initiated) developed considerably under the stimulus of increasing wealth from raiding and trade as political forces that both supported and curbed the authority of elders or chiefs. At the same time these secret societies organized elaborate rituals that included dramatic public performances in which ancestral and other spirits were portrayed by elaborately masked dancers. Masks used in such rites are among the better-known examples of West African woodcarving. This art, which also includes statuary and other forms and played a great part in chiefly ceremonial, had, as is clear from Yoruba and Benin, a long history. Indeed it is part of an older and more widespread African tradition that existed to the east throughout the Congo basin and to the north in the savannas. Although some conventions, symbols and decorative elements are widespread: a multitude of highly distinctive local styles have developed among different peoples, giving a character of great richness and diversity to the West African art which has so greatly influenced styles and theory in European art of the 20th century.

Many features of the older cultures and forms of social organization in West Africa are now, at the insistence of its own peoples, being superseded by new patterns that reflect its increasingly rapid incorporation into the economic and political life of the modern world. But some of the traditional elements are still vigorous in all spheres of village life, and are manifest in periodic rites and festivals which express underlying beliefs and values.

D. EAST AFRICA

East Africa has been the meeting place of many ethnically diverse groups, most of them immigrants from the west and north. The environment varies considerably, and high population densities are found in only a few favoured areas where intensive agriculture can be practised; these are especially the northern and western shores of Lake Victoria and the highland areas near Mounts Kenya, Kilimanjaro, Elgon and Ruwenzori. Over most of the remainder of the region only shifting agriculture or herding is possible with traditional techniques.

The remnants of aboriginal non-Negro peoples are found in a few scattered and unfavourable places, to which they have been driven by later immigrants. A few thousand people known as Dorobo or Okiek still live in the forests of the mountainous parts of Kenya and eastern Uganda, gathering forest products and speaking the language of their more powerful neighbours (usually Nandi and Kikuyu). In western Uganda there are a few hundred Pygmies, and in the Lake Eyasi basin in northern Tanganyika there are about 600 hunters called Hadzapi or Tindiga. They speak a Bushmanlike language and have been thought to be a northern remnant of the Bushmen of whom only those that migrated to southern Africa survive in large numbers (see *Southern Africa* below).

The aboriginal tribes were probably once dispersed over wide areas of East Africa, and were driven into their present habitats (and also absorbed by intermarriage) by immigrants. Most of the latter were Negroes from the west and north, although there have been non-Negro invasions from the northeast and Arab, Indian and European contact from the coast. The history of early immigration into the region is confused and uncertain, resulting from lack of adequate archaeological and documentary information. Most knowledge comes from linguistic studies and from traditional oral legends which provide little sound material for historical reconstruction.

The earlier immigrants were almost certainly Bantu-speaking Negroes from the west or northwest. They are primarily agriculturists, usually with grains as their staples (traditionally millets and sorghums, but later maize in most areas); they keep livestock where this is possible. They certainly brought a knowl-

edge of ironworking with them. It seems likely that most of their differences, in both culture and social organization, are caused by differences of ecology and to the influences of later invaders, mainly from the north. The first of these later immigrants were probably Sudanic-speaking peoples from the region of Lake Chad, now represented only by the Lugbara (183,000) and Madi (63,000) of northwestern Uganda. They have had little influence on the rest of East Africa, although some observers have detected a substratum of Sudanic culture among many southern Uganda tribes. The Sudanic tribes are agriculturists, with little interest in cattle, and lack any developed form of political authority. Later came the Nilotic-speakers, known generally as Lwoo, who moved southward up the Nile valley from the Sudan. In the vanguard of the movement were the Lwo (Luo) of western Kenya (757,000), who were followed by the various Nilotic groups in Uganda (Lango, Acholi, Alur, etc., in all 654,000); and there are others still in southern Sudan. They are traditionally cattle keepers, with great cultural emphasis on the values associated with cattle, although the modern southern Nilotes of East Africa are all agriculturists. All those in East Africa, with the exception of the Alur, lack any formal political authority and are organized largely in strongly patrilineal descent groups (lineages and clans). Both Sudanic and Nilotic Negroes are tall and extremely dark people, renowned for their physical strength and generally regarded as "savages" by their Bantu neighbours to the south.

A further immigrant grouping consists of the many tribes speaking Nilo-Hamitic languages. These peoples are clearly physically of mixed Negro and non-Negro origin; they are often said originally to have been Hamites, although the precise ethnical connotation of "Hamite" (a linguistic rather than a racial term) is open to doubt. Traditionally all were transhumant pastoralists, despising agriculture. They occupy the floor of the Rift valley in Kenya and northern Tanganyika (Masai, Nandi, Kipsigis, Turkana, etc.) and the drier regions to its west in northeast Uganda (Karamojong, Teso, etc.) and in southeast Sudan (Bari, Lotuko, etc.). In all they number almost 2,000,000. They all lack formal centralized political authority, but possess prophets such as the famous Masai *laibons*; all have an elaborate age-set system, based upon the initiation of boys by circumcision, the age sets providing the basis for an extremely efficient military organization. Some of them are settled agriculturists (especially the Teso, Nandi and Kipsigis) but most of them have turned their backs on European influence, preferring to retain their traditional dependence upon cattle herding. Many of them are dying out.

In northern Kenya there are a few tribes of Hamitic speakers, especially Galla and Somali, numbering about 100,000; their influence has been negligible. And lastly, on a plateau in the Rift valley in northern Tanganyika, is a cluster of tribes of which the largest is the Iraqw (103,000) whose language is said to show strong Semitic affinities and who seem ethnically to be quite unrelated to other peoples in the region.

The early history of East Africa is thus one of displacement of aboriginal tribes by Bantu peoples and then of the Bantu agriculturists by northerners, the Nilotes and Nilo-Hamites being the most important. The Bantu tribes near the invaders show differing degrees of influence. To the north and west of Lake Victoria is a cluster of kingdoms, the Lacustrine Bantu states, with a population of about 1,500,000 in Uganda. There something approaching a caste system is found, the state consisting of, originally, a non-Negro king and aristocrats exercising power over subordinate Bantu and Pygmy servile classes. The aristocrats, known as Hima in the northern kingdoms (Nyoro, Toro, Ankole and Ganda, although they are no longer a distinct group in the last) and as Tutsi in the southern (Ruanda, Rundi and others) are tall fair-skinned people, keeping cattle of a type not found elsewhere in Africa and scorning the agriculture of their servile peasants. The peasants are Bantu, known in the north as Iru and in the south as Hutu, who provide tribute through a hierarchy of Hima-Tutsi chiefs set over them.

In some kingdoms Pygmies known as Twa are found; they are

hunters and gatherers and also provide bodyguards and soldiers for the aristocrats. The classes do not intermarry, although aristocrats take peasant concubines. All speak the Bantu languages of the peasants. It is generally accepted that the aristocrats came from the north, probably by the 12th century and before the Nilotic invasions mentioned above; they probably came from the region of the Ethiopian state of Kafa. There is some evidence of Nilotic influence in the royal lines of the northern kingdoms, although the neighbouring Nilotic tribes do not possess kingship themselves. The influence of these invasions spread southward in an attenuated form to the peoples south of Lake Victoria (Ha, Nyamwezi, Fipa, numbering in all 750,000).

The Nilo-Hamitic invasions, down the line of the Rift valley, have affected the neighbouring Bantu peoples considerably. These are mainly tribes of agriculturists who have lived in uneasy relationship with their warlike pastoralist neighbours. Some, such as the Kikuyu (1,250,000) and Kamba (612,000) of Kenya, have adopted the age-set systems of the Masai. Clothing decorations and other features have also been affected: especially among the Gogo (271,000) who have intermarried with Masai and are in many ways similar to them (except in language).

All the Bantu peoples of East Africa are culturally fairly similar, although there are marked differences in some aspects of social organization and in size and density of population. Except for the Lacustrine kingdoms and the small tribe called Wanga in western Kenya, all lack traditional kingship, although the Chagga (237,000), the Sukuma (559,000) and several other tribes had a form of chieftainship. Almost all reckon descent patrilineally, but there are a few groups in southeast Tanganyika (Makonde 281,000, Makua 95,000, etc.) which trace descent matrilineally, through women only. These are part of a belt of matrilineal peoples stretching across Africa from Mozambique to Angola. There are a few matrilineal tribes on the coast (Digo, Bondoi, etc.).

The influence of the outside world has always been felt at the coast. Arab city-states were founded at many places from Cape Guardafui to Kilwa in the early centuries of the Christian era, and persisted until weakened by the Portuguese in the 16th century. Later, Arab influence from Muscat became important as the power of the Portuguese waned, and in the 19th century Arab influence was considerable as far as the great lakes, as Zanzibar became the seat of the East African slave trade. The modern coastal population is distinct from that of the hinterland, and is known as Swahili, or in Zanzibar as Shirazi. It is ethnically and culturally mixed, with many Arab and Indonesian features, the latter from Madagascar; its language, Swahili, is basically Bantu but with much Arabic influence in its vocabulary. The coastal tribes are also mainly Moslem, which has further distinguished them from the peoples of the interior.

Indians have been settled in the coastal towns throughout their history and are found throughout East Africa, mainly as traders. Europeans are administrators, missionaries, settlers and traders, with an influence out of proportion to their relatively small numbers. The region has been administered by European powers since the late 19th century. Intertribal warfare and raiding, such as that by the Masai of their neighbours, have been stopped. Non-traditional chiefly authorities have been created, with new roles and new sanctions for their position; where there were traditional rulers the basis of their authority has been changed and they have tended to become bureaucrats rather than primarily ritual leaders.

Much in traditional religion has been changed: either tribes have become Christian or indigenous religious beliefs and practices have died out without being replaced. The introduction of cash crops (especially of cotton and coffee), of cash markets for livestock and for labour in new enterprises, and the possibility of movement between tribal areas, have all affected the traditional economic and social systems. A formerly egalitarian standard of living, with few marked differences of status, is giving way to a situation in which there are considerable differences of wealth and of political power. An incipient class system is emerging, based mainly upon the larger towns.

The over-all picture is one of a few wealthy, densely populated

and "progressive" areas, interspersed with areas of comparative poverty and social stagnation. The progressive and wealthy areas include southern and parts of eastern Uganda where wealth is based largely upon cotton and coffee; the Kavirondo area of Kenya; the Kikuyu highlands; the Chagga area of Kilimanjaro; and to a less extent parts of the coast. In all these what is usually called detribalization is taking place, with loss of narrow tribal loyalties and the appearance of new political and class movements. From the poorer and more rural areas there is often considerable emigration, especially of men who move away for a year or two as labourers in the industrial centres and then return to their homes; this has led to a degree of breakdown of traditional tribal life. These are all features characteristic of rapid social and economic change, part of the process of change from tribal subsistence small-scale societies to a wider-scale society based upon a cash economy.

E. WEST CENTRAL AFRICA

The following areas may be included in this region: the Cameroons region; Chad, the Central African Republic (Ubangi-Shari), Gabon, Republic of Congo (former Middle Congo), Republic of the Congo (former Belgian Congo), Angola north of the Kalahari. Northern Rhodesia and Nyasaland. The habitat ranges from semidesert in northern Chad and southern coastal areas in the west to open woodlands (savanna) and tropical rain forest. The northern limits of dense forest are situated toward the 5th parallel, but there are grasslands and savanna in the eastern and southern Congo, Angola and Rhodesia. The peoples of this diverse area are heterogeneous. They include pastoral or agricultural Arabs in the north; pastoral seminomad or sedentary Fulani living as minorities or as dominant groups in the Cameroons region; Pygmies in Gabon and the Congo republics; Sudanic-speaking tribes, including some Nilotes, in the northeast of the Republic of the Congo; and to the south and west many subdivisions of Bantu are found. Moreover, there are numerous ethnic mixtures which often make strict classifications difficult, while linguistic groupings do not coincide with racial or cultural ones.

Agriculture is of primary importance throughout the area; but hunting, fishing, food gathering and herding are also widely practised. Pure hunters survive among the Pygmies; elsewhere, though dependent on an agricultural economy, some tribes have strongly preserved the outlook of hunters. The staple crops cultivated in different habitats are: millets and maize, roots (yams, manioc or cassava, taro and sweet potatoes), bananas and peanuts. The oil and the raffia palm are important in the forest regions. Bows and arrows, spears, throwing knives, knives, clubs and shields are found as weapons of war and the chase. Dwellings range from tents in the north and rudimentary shelters in the forest to quadrangular or round huts and rectangular houses. Settlements may be small and dispersed or large and compact; royal capitals and other towns occur among some tribes.

Social groupings often depend on descent systems that range from patrilineal to matrilineal and double; but residence is generally patrilocal although the practice of bride service may result in the temporary residence of husbands with their wives' families. Marriage payments (in iron, cattle and sheep) are common. In some areas exchange marriages predominate. Some societies are organized into larger or smaller chiefdoms; while in others, small autonomous village groups with a segmentary structure form the ultimate political units. Associations may have great political significance. Tribal or village initiation is general and may be accompanied by widely different forms of body markings. Besides a general belief in a supreme being, ancestral, skull and spirit cults are much developed. Islam has spread among certain northern tribes. Many of the tribes are renowned carvers and craftsmen practising ironworking, plaiting, basketmaking and weaving.

The Cameroons Region. — The people of the northern Cameroons are subdivided into numerous small groups: some are culturally similar to the plateau tribes of northern Nigeria, whereas

others are linked with groups from Chad or the Central African Republic. The Kirdi (pagan sedentary tribes), Bata, Bura, Vere, Mumuye, Chamba, Namshi, Kotopo, Mbum and Wute are the better-known peoples. Most peoples speak languages of the Adamawa-Eastern branch of the Niger-Congo family. Fulani are also present everywhere and are politically dominant in Adamawa. Shifting hoe cultivation is practised; some groups also keep cattle and milk them. Bride service and elopement are very common. Most tribes have patrilineal descent, but some also stress matrilineal ties. Some groups have been incorporated by the Fulani into their chiefdoms.

The central Cameroons highlands are inhabited by peoples of diverse origins, such as Tikar and Nsaw, Bamum, Bamileke, Banen, Bafia, Bali. Linguistically some of them are Bantu (*e.g.*, Bafia); others are Sudanic (Bali). Most of those that have been called semi-Bantu have been shown by modern research to belong to the Bantu group. Culturally many are complex groups in which different elements have been combined. Thus the Bamum invaded some of the Bamileke and their ruling clan is said to be of Tikar origin. Agriculture is important, millet, maize, cassava and coco yams being the staples. A few groups have small cattle, but these are not milked. Nearly all tribes of this area are patrilineal and patrilocal. Marriage payments are common, but simple marriage gifts with bride service do occur. The social organization is based upon a lineage system. Most people live in small compact villages or dispersed in neighbourhoods, but there are some large settlements. They are organized in chiefdoms of varying size, with sacred chiefs and special status attributed to queen mothers. Men's associations, often important, exercise military or police functions or are mainly religious in character. Cults of ancestors, twins and skulls are widespread. Some of these peoples (Bamum, Bamileke) are well-known artists and craftsmen working in wood, bronze and terra cotta. King Njoya of the Bamum invented a system of ideographic and pictographic signs for writing.

The coastal area of the Cameroons is peopled by various Bantu-speaking groups, such as Kpe-Mboko, Duala, Limba, Tanga-Yasa, which are linked by common myths of origin. They are fishermen, but cultivation and cattle keeping are not unknown. Settlements may be small and dispersed or concentrated. The Duala are famous traders. There is generally some stress both on patrilineal and matrilineal descent and some tribes have a clear-cut double descent system; virilocal residence is general. Marriage payments (goats) are common. The social organization is of the segmentary type and leaders are often merely village headmen. But some groups (Duala) have developed larger chieftaincies. Dance associations are prominent and there are cults of ancestors and water spirits.

The southern Cameroons are inhabited by Bakoko, Ngumba, Mabea, Bulu, Beti and the larger Fang (*q.v.*) group which also extends into Gabon. There are also some Pygmies. The progressive expansion of the Fang has often disrupted earlier tribal organization and Fang influences have been profound. (See also BAMILEKE; BAMUM; DCALA.)

Chad.—In the Republic of Chad a large number of groups which present varied aspects of language, origins and modes of life may be distinguished. A mosaic of small tribes of Negro origin was overrun and broken up by waves of invading peoples, including Arabs, Fulani and Kanuri-speakers. The northern parts are inhabited by people of Kanuri linguistic stock, such as Teda, Daza, Bideyat, who are seminomadic herders (camels and cattle). Agriculture (date palms, millet) is left to the descendants of ancient captives, and hunting to some specialized groups. Descent is either bilateral or double, but residence is virilocal. Political organization does not extend beyond autonomous local communities or small chiefdoms. They are partly pagans and partly Muslims.

More or less pure Arab groups (Ouled Sliman, Ouled Rashid) are dispersed throughout the Teda area. Farther south are the heterogeneous peoples of the old kingdoms (Kanem, Bagirmi, Wadai, Bulala, Kotoko). Some speak independent languages, others belong to Chadid, Kanuri and Central Sudanic linguistic stocks. They practise hoe cultivation; most groups keep cattle

and fishing is important along the rivers. Descent is patrilineal and residence patrilocal. Social stratification is complex and the political organization is strongly centralized. There are compact villages and towns. Arab groups (Ouled Rashid) are particularly numerous in Wadai and Bagirmi. On the Lake Chad islands, in the marshy regions and in the mountainous areas there are also isolated groups of heterogeneous origin which have been forced back by conquest. The Yedina are fishermen and herders; the Kinga and Dadjo are agriculturists and herders. They are patrilineal and seem to be organized in small chieftaincies. The southern areas of Chad are inhabited in part by Logone populations (Mbum, Mundang, Masa) and by the more numerous Sara group. The term Sara refers to a mosaic of agricultural patrilineal tribes who also keep cattle and camels.

Central African Republic.—The Central African Republic (formerly Ubangi-Shari) is peopled by Sudanic-speaking groups that suffered heavily from slave raiding during earlier centuries. There are some Sara and Wadai groups to the north and some Azande, Nzakara and riverain groups (Banziri, Buraka, Ngbaka, Ngbandi) along the Cbangi to the south. But the bulk of the population is formed by Mandja-Baya groups to the west and Banda to the east. The former are related to the Mbum and Wute of the Cameroons region; the Banda are composed of a large number of small tribes which settled in these countries during the 19th century. Hoe cultivation (millet, maize) is developed throughout the area, but hunting, fishing and gathering have considerable importance. Descent is patrilineal and residence is virilocal. There are dispersed exogamous totemic clans, but the patrilocal extended family is basic to the social organization. Living generally in small dispersed settlements, they are subdivided into autonomous village groups with headmen and elders. Among the Azande, however, there are strong chiefdoms. Circumcision is not widely diffused, but girls' initiations are common. Ancestral cults, beliefs in semihuman fabulous heroes and closed associations are very general. (See AZANDE.)

Gabon.—In northern Gabon live the Fang, who seem to constitute a special group within the Bantu linguistic family. They migrated from the northeast in mid-19th century and settled in forest areas which were occupied by Pygmies (Babinga) and Bantu groups (Mekae, Ngumba, Njem). These and other surrounding tribes are strongly influenced by Fang culture. To the south of the Fang there are the Mpongwe who, with other smaller tribes, form the Omyene cluster. The other major groups are the Bakota to the northeast, the Shira to the southwest, the Okande to the centre and the Mbede-Nzabi to the east. The Fang and the other tribes which have been influenced by them are agriculturists (manioc, bananas, maize, palm trees) and gatherers, but hunting is important. Fang are renowned carvers in wood and steatite. They are patrilineal and patrilocal. Settlements are small; there is no central political organization. Fang are both egalitarian and competitive; rich people are looked upon with suspicion. Their associations have a marked religious or magical character.

Republic of Congo.—In the Republic of Congo (formerly Middle Congo), the following clusters may be noted: the Sanga, the Njem (Bakwele) who are influenced by the Fang; the Bangi; the Bateke and Bakongo, including many subdivisions; there are also Pygmies. Some links between Bakongo and Bateke exist; Shira have come under the influence of Bakongo. Some of these tribes are also largely represented in adjoining parts of the Republic of the Congo (former Belgian Congo). They are agriculturists (manioc, bananas, palm trees, peanuts), but hunting and fishing are prominent among some of them. Most of them are very good carvers. Descent is patrilineal among the northern but matrilineal among the southern groups, and notably the Bakongo among whom residence was formerly avunculocal. The social organization is segmentary in type; there are no large chiefdoms, although the Bakongo once formed part of the powerful Kongo chiefdom and the Bateke have small chieftaincies.

All these tribes belong to different groups of the Bantu linguistic stock.

Republic of the Congo.—The savannas, grasslands and rain

forests of the former Belgian Congo are peopled by well over 200 tribes which claim widely different origins. Many of those on the margins are closely related to peoples of the former Middle Congo, the Central African Republic and the Sudan or of Angola, Northern Rhodesia, Ruanda-Crundi and Uganda. The larger part of the tribes speak various Bantu languages, but there are also in the northern regions people of Sudanic linguistic stock and in the east and northeast a very few groups of Nilotic and Hamitic stock. The tribes may conveniently be grouped into a number of cultural clusters the most important of which are: (1) Bakongo, Bateke and groups of Lake Leopold II, Bayaka-Basuku and Bapende clusters mainly in Leopoldville province; (2) Mongo, Kgombe, Ngbaka and Kgbandi clusters in Equator province; (3) Azande. Meegy-Mangbetu, Mamvu-Balese, Bakumu-Babira, Babua, Balendu, Lugbara, Alur clusters in Oriental province; (4) Banande, Bahunde-Banyanga, Bashi-Bahavu, Balega-Babembe and lubaized clusters in Kivu province; (5) Baluba, Lunda-Cokwe, Babemba in Ratanga province; (6) Atetela, Bakuba-Bashilele, Baluba-Bambo, Bakete and Asalampasu clusters in Kasai province. It should be noted, however, that these clusters do not correspond exactly with the boundaries of the provinces. The various Pygmy groups, who may in all number up to 300,000 persons are found in the rain forests, mainly in Ituri, Kivu, northern Kasai and along the large belt of the Congo river.

Shifting hoe cultivation is practised everywhere by the other peoples, the staple crops according to the area being bananas, manioc (cassava), yams, millet and maize. But food gathering, hunting and fishing continue to play a very important role in the economic, social and religious life of many tribes. In the highlands of the eastern Congo there are some peoples with a mixed pastoral-agricultural economy. Most of the Congo peoples are organized by patrilineal descent and patrilocal residence. In the southwestern Congo, particularly in Leopoldville and Kasai provinces, several tribes have matrilineal descent groups with avunculocal or virilocal residence. A few tribes too show features of double descent grouping. The Lunda have complex descent groups of bilateral composition. Ritually important clans which may be dispersed in varying degrees, and corporate localized lineages are common. Minor lineages and extended families play a foremost part in the social organization. While all tribes accept polygyny, this may be very restricted or, as among Kuba, Luba or Azande chiefs, very elaborate. Widow inheritance is widely practised, as are the sororate and sororal polygyny. Cross-cousin marriage is less frequent. High marriage payments occur in most tribes, but exchanges of women, elopement and true purchase of women are also known.

Political organization ranges from small autonomous states with petty chiefs of a sacred nature and larger kingdoms with divine kings (Bakuba, Lunda) to states of the feudal type (Bashi) and military conquest states (Azande); from complex segmentary structures with or without special functions vested in lineages or closed associations (Xtetela, Balega, Mayumbe) to small band organization (Pygmies) and small autonomous villages or village groups (Bakumu, Mongo). Some tribes too, which are of the segmentary type were once organized in powerful states (Bakongo, Luba). Circumcision, tribal and youth initiations, closed associations and corporations are very widespread. Most tribes have a belief in a supreme being and in heroes; ancestral, twin and spirit cults are very general.

Most Congo peoples are exceptional craftsmen. Ironwork (knives, spears, arrowheads, bracelets) attains an extraordinary variety. Masks are made in wood, ivory, bone, gourd and wicker; statues are made from the same materials, but some are also made in pottery or steatite. Outstanding carvings are known from the Luba, Bakuba, Bapende, Bayaka, Cokwe, Bakongo-Mayumbe, Balega, Benalulua and Asalampasu. (See also AZANDE; PYGMIES.)

Angola.— In Angola the large Ovimbundu tribe occupies a central position on the Benguela highlands. North of them are the Ambundo and Kongo tribes which are related to groups of the southern Congo. To the east live the Imbangala, Songo, Cokwe, Lwimbe and Luchazi who are linked to tribes of the southern Congo and Northern Rhodesia. To the south are localized

cattle-owning tribes, like Nyaneke, Cipungu, Cilengi, Ambo. Many customs and institutions of the Angola peoples are comparable to those described for the Republic of the Congo. All groups speak various Bantu languages. They practise hoe cultivation, but hunting is important. Long-distance trading, especially between the coast and the interior, played a prominent role in the past centuries. Some tribes keep small herds of cattle.

Marriage payments are not usually high; polygyny is common and cross-cousin marriages are allowed. Descent is either matrilineal or double; residence is patrilocal. Some groups, like Cokwe, are organized in autonomous villages; others like Ovimbundu, are divided into a number of independent or tributary chiefdoms under the control of paramount chiefs. Youths' initiations and circumcision masks are common among Cokwe, Luchazi and Ovimbundu. Earth and celestial gods are worshiped; the cults of ancestors are much practised. (See also AMBO.) (D. P. BI.)

F. CENTRAL AFRICA

Central Africa as here defined includes Northern Rhodesia and Nyasaland. Most of the inhabitants of this region belong to the ethnic group known as the Central Bantu, although in Barotseland in northwestern Rhodesia or the Ngoni districts of Nyasaland there were intrusions of warrior bands from Basutoland and Natal respectively in the 19th century.

Northern Rhodesia.— The inhabitants of the northeastern plateau of Northern Rhodesia and the swamps of Lake Bangweulu include the dominant Bemba (*q.v.*) (150,000), widely dispersed over an area of around 20,000 sq.mi.; the Bisa, their neighbours on the west, south and east; the Cnga and Twa, small tribes living in the swamps and islands of Lake Bangweulu; and the Ushi on the plateau between Fort Rosebery and Kawambwa. The ruling group of the Lunda of the Luapula area south of Lake Mweru were also originally of the same stock as the Bemba. South of the Bemba country where the high plateau land begins to slope to the Zambezi plain are the Lala (50,000) and the Lamba (20,000). Similar in culture are the Kaonde (38,000) of northwestern Rhodesia and the Senga of the upper Luangwa valley. Groups of Lamba, Lala and Ushi are to be found over the border of the Republic of the Congo.

This group of tribes claim to be of Congo origin. They speak dialects so similar that they are all classed as Bemba at the Northern Rhodesian copper mines where they go to work in large numbers. Like the peoples of the west central region they are predominantly agriculturists and, though stock are occasionally kept in the regions free of tsetse fly, the ritual attitude to cattle found in parts of East and South Africa does not exist. Hunting was formerly an important activity but game is now nearly extinct. The soil of the northeastern plateau is poor and finger millet and cassava are the staple crops. The people are shifting cultivators, moving their villages every four to five years and sowing their millet in the ash beds formed by the burning of piled-up branches lopped from the savanna forest trees (*chitimene* system). No cash crop has been found for the area and the people now make money in the copper mines farther south. The emigration rate for adult males is 40%–60% in Bembaland.

The Central Bantu are predominantly matrilineal. Descent, clan affiliation and succession to office follow the matrilineal line. Marriage is matrilineal, at any rate initially, and the labour given by a bridegroom to his father-in-law is a more important element of the marriage contract than the passage of goods. The period of service varies from tribe to tribe and is now often replaced by money. The Bemba and kindred tribes are divided into matrilineal clans with totemic names. Girls' initiation ceremonies (*chisungu*) are characteristic of this group. All these people acknowledge the rule of hereditary chiefs, although only in the case of the Bemba (who dominated the region in the 19th century) and of the Luapula Lunda is there anything like a centralized state with a king or paramount chief ruling over lower chiefs. The *chitimukulu* ("paramount chief") of the Bemba had a court with titled councilors, army captains and executioners. Chiefs were believed to have supernatural powers by virtue of access to the ancestral spirits of the tribe and the *chitimukulu* must be classed

as a "divine king" in Sir James Frazer's sense.

Other matrilineal tribes in Northern Rhodesia are the plateau Tonga south of Mazabuka, a people without chiefs and organized on the basis of villages linked to rain shrines. They have girls' initiation ceremonies and also rites for boys. The Ila-speaking peoples on the Kafue river follow matrilineal clan descent but combine this with patrilocal marriage and patriarchal authority, a combination due, it is thought, to southern influences. Girls' initiation ceremonies are practised. The Ila are a cattle keeping people formerly renowned as warriors.

In marked contrast to the organization of the Central Bantu is the kingdom of the Lozi (Barotseland) on the upper Zambezi plains, which has special treaty rights with Great Britain. The Lozi nation (296,000) is formed of many ethnic groups. The original inhabitants, Aluyi, were conquered in 1810 by Kololo of Basutoland origin and, though the Aluyi ousted the Kololo chiefs in 1864, they continued to use their language. The kingdom is ruled by a paramount chief associated with a chief princess established in a secondary capital. The organization of titled ministers and councilors is elaborate. The country is divided into neighbourhoods centred around royal villages. There is no clan system but names are inherited by patrilineal descent. The Lozi follow a unique system of cultivation on mounds raised above the plains which are annually flooded by the Zambezi.

A group of Ngoni is settled in the Fort Jameson area of Northern Rhodesia (see Nyasaland below) and there are two patrilineal cattle keeping peoples, the Mambwe and the Lungu, in the Abercorn area.

Nyasaland.—Inhabited by a complex mixture of tribes, the Arab influence was very marked in this region in the 19th century. Some tribes such as the Nyanja and some of the Cewa were decimated by slave raids; others, such as the Yao, adopted Arab culture, became Muslim and engaged in slave raiding themselves. In 1835 the Ngoni, a group of Nguni (Zulu) scattered by Shaka's wars in Zululand, moved north and crossed the Zambezi. They raided the indigenous inhabitants and finally settled in what is now Nyasaland in a number of separate districts.

With the exception of these recent Ngoni immigrants, most of the Nyasaland peoples follow matrilineal succession and resemble the Bemba-Bisa-Lamba group in Northern Rhodesia. They tend, however, to be organized in small independent village units under headmen rather than in chiefdoms. They can be roughly divided into the following groups: (1) The inhabitants of southwest Nyasaland! which have been called the Maravi group. These include the Nyanja (312,500), who are much interspersed with Ngoni and Yao; the Cewa (576,000), who constitute more than 60% of the population in five districts; the Nsenga (45,000) of whom the majority live in the Petauke district of Northern Rhodesia; and the Cikunda (47,500) scattered among Nsenga and other peoples. This group is said to be of Congo origin and to have migrated earlier than the Bemba. Like them they are divided into matrilineal, totemic clans and practise matrilineal marriage. They hold elaborate girls' initiation schools (*vinyau*). (2) The peoples of northwest Nyasaland, such as the Tumbuka (110,000) and Tonga (50,500) who live on the western shores of Lake Nyasa; the Tonga are mainly fishing people. The history and ethnography of the area is confused and there has evidently been much movement of groups, mainly as the result of Ngoni raids. These are, however, all matrilineal peoples practising matrilineal marriage. They differ from the Maravi group in having no girls' initiation schools. (3) The peoples of eastern origin, such as the Yao (281,000) who are akin to the Makonde in Tanganyika. The Yao had evidently achieved a dominant position in Nyasaland when missionaries arrived in 1876. They now live in the upper Shire and south Nyasa districts, the Blantyre and Zomba districts, at Domira Bay on the west coast of the lake, and north of Dedza and in the east of the Ncheu district. The Yao were converted to Islam in the middle of the 19th century and took to trade and slave raiding. They are divided into matrilineal clans, practise matrilineal marriage and organize elaborate initiation ceremonies for girls, but they also circumcise boys. They grow maize and tobacco as cash crops. (4) The

Ngoni (193,500) live in three chiefdoms in Nyasaland: Mombera in Tumbuka country, Ciwere in the Dowa district and Gomani in Dedza and Ncheu; but Mpeseni's Ngoni live around Fort Jameson in Northern Rhodesia and there are further groups in Tanganyika. The Ngoni language has now been adulterated or forgotten, but the Ngoni remember much of the historic tradition of their journey from the south and their military exploits. Their clan organization is patrilineal and they are strongly patriarchal. The political system is an adapted form of the old Zulu organization. All these areas of Nyasaland form labour reserves for Northern and Southern Rhodesia and South Africa but the rate of emigration among the Ngoni is particularly high. (5) The northern Nyasa group of people including the Ngonde and the Nyakusa who live mainly over the Tanganyika border. These people appear to be immigrants from the east. The Ngonde of Nyasaland numbered 62,000; they live in the mountainous country between Lake Nyasa and the Misuko hills. Their staple crop is the plantain but they now cultivate coffee. Cattle take a foremost place in the economy. The Nyakusa peoples were divided into a number of independent chiefdoms. Among the Ngonde a paramount chief with divine powers was recognized. Characteristic of these cultures is the system of age-villages by which young boys build villages with their own age sets in adolescence and continue to live in them all their married lives. Descent and succession are patrilineal but there are no clans. See also NGONI; YAO. (A. I. R.)

G. SOUTHERN AFRICA

Grouping and Distribution.—The natives of Southern Africa are conventionally classified into four major divisions: Bushmen, Hottentots, Bergdama and Bantu. The Bushmen, originally scattered throughout the region, are now found chiefly in the Kalahari desert and adjacent areas to the north and west. Numbering about 50,000, they are divided into many linguistic groups; the best known are the Xuen, Naron, Kung and Heikum. The Hottentots are represented only by the Nama (30,000) in the southern half of South-West Africa. Farther south and east there were formerly three other groups: Cape Hottentots, Eastern Hottentots and Korana. These have disappeared almost completely, partly because of the effects of war and disease but mainly as a result of absorption into the Cape coloured and other mixed-blood communities of which they were a basic element. The Bergdama (40,000) live chiefly in the centre and north of South-West Africa, to which in historical times they have always been confined. The Bantu, far more numerous and widespread, consist of the following four subdivisions:

Eastern.—Located in the coastal regions east of the Drakensberg mountains and south of the Sabi river, the Eastern division comprises two main clusters, Nguni and Tsonga. The Nguni includes the Cape Nguni (2,380,000) of the Ciskei and Transkei (Xhosa, Tembu or Thembu, Mpondo, etc., also the Fingo, fugitive remnants of tribes broken up in Natal during the great intertribal wars at the beginning of the 19th century); Natal Nguni or Zulu (2,048,000) of Natal and Zululand, with their offshoot the Ndebele (Tebele) of Southern Rhodesia; Swazi (410,000) of Swaziland and eastern Transvaal; and Ndebele (144,000) of central and northern Transvaal. The Tsonga (1,369,000), subdivided into Tsonga, Ronga and Tswa, are found chiefly in Mozambique, with offshoots in eastern and northern Transvaal.

Central.—This subdivision occupies most of the interior plateau north of the Orange river and west of the Drakensberg. It also comprises two main clusters: (1) Sotho, including the Southern Sotho of Basutoland and adjoining districts (1,391,000), Tswana (Thaping, Rolong, Hurutshe, Kwena, Ngwaketse, Ngwato, Tswana, Kgatla, etc.) of Bechuanaland and western Transvaal (816,000) and Northern Sotho (Pedi and many others) of central and northern Transvaal (772,000). (2) Venda (133,000), a homogeneous cluster inhabiting the Soutpansberg district of north-eastern Transvaal.

Shona Peoples.—These groups (over 1,000,000) of Southern Rhodesia and Mozambique are subdivided linguistically into Zezuru, Manyika, Karanga, Kalanga, Korekore and Ndau.

?Yestern.—The fourth group comprises the Ambo (150,000) in northernmost South-West Africa and the Herero (45,000) in central South-West Africa and northwestern Bechuanaland. The Ambo consist of several distinct tribes, notably Ndonga, Kwanyama, and Kwambi; the Herero are customarily divided into Herero, Mbanderu and Tjimba.

Physical Characteristics.—The classification given above is based partly on physical differences. As commonly visualized, the Bushmen are short and yellowish-brown, with wrinkled skin, "peppercorn" hair, low heads, broad flat faces, poorly developed bodies, slender limbs, small hands and feet. These features are especially typical of the southern groups (mostly extinct). The northern groups, mainly because of Bantu admixture, tend to be taller, darker, more muscular, longer and higher in head and face. The Hottentots closely resemble the southern Bushmen in colour and build, skin, hair and facial features, but are taller in stature, longer and narrower headed and somewhat more prognathous.

The Bergdama, in contrast, are of true Negro type; they are mostly very dark (often blue-black) and stocky, with woolly hair, long heads, broad flat noses, thick everted lips and strong prognathism. The Bantu are also basically of Negro stock, but because of early inbreeding with other African peoples vary greatly in appearance. They are, on the whole, taller and less sturdy than the Bergdama and often lighter in colour. Many Tswana, especially, are little darker than Bushmen. Sometimes too, notably among Zulu and Herero, they have narrower and higher noses, thinner lips and other more refined facial features.

Mode of Life.—Cultural distinctions do not coincide with either racial or linguistic divisions. (See AFRICAN LANGUAGES; BUSHMAN LANGUAGES; etc.) Bushmen and most Bergdama live entirely upon the natural resources of their environment. The men hunt mild animals and birds, the women gather edible wild plants; other foods include many kinds of reptiles, rodents and insects (especially locusts and termites). Some Bergdama, however, also keep goats and grow tobacco and dagga (*Leonotis leonurus*), used mainly for barter. Hottentots and Bantu likewise eat many kinds of wild vegetables and fruits and depend largely upon hunting for meat. But they also keep cattle, sheep and goats, whose milk, either fresh or fermented, is part of their staple diet. The animals are seldom slaughtered except on ceremonial occasions, although all animals dying of disease or other causes are eaten. Everything connected with them is normally done by men and boys—Hottentots and Herero are exceptional in entrusting the milking to women. With the outstanding exception of the Herero, all Bantu (but not Hottentots) further cultivate sorghum, millet, maize and such minor crops as pumpkins, melons, peas and beans. From the cereals they make porridge (their usual daily food) and beer; the others are eaten either raw or cooked in various ways. Agriculture, done by means of hoes, is essentially women's work, though men clear new fields and occasionally help in other strenuous activities.

Because of the nature of their food supply. Bushmen and Bergdama are nomadic; whenever game and edible plants fail in their immediate vicinity, the group must move somewhere else. Their dwellings, often erected in a wide circle around a large tree! are usually flimsy bush screens or at best small hemispherical huts made of branches and grass. Hottentots and Herero are also nomadic, their arid environment forcing them to trek periodically in search of new grazing and water for their stock. Settlements among both peoples are circular in form, the huts surrounding a large open space in which the animals are kept at night. The Hottentots live in beehive huts made by covering a framework of slender poles with reed mats, and whenever camp is moved these are dismantled and transported on ox-back until needed again. Herero huts, abandoned when the owners move, are similar in shape but more solidly constructed. All other Bantu have relatively stable villages which, except sometimes among Tswana, are close to or even (as among Ambo) amid the fields cultivated by the inhabitants. The Nguni live in beehive huts, made typically of wattle and daub or wattle and thatch; elsewhere huts normally have a circular wall of wood or earth and a conical roof of thatched poles. The basic settlement pattern is generally

similar to that of Hottentots and Herero. Kraals for livestock usually form part of the central enclosure, though in Bechuanaland and other arid regions the animals are kept mostly at grazing posts out in the veld.

Clothing varies considerably in detail, but is everywhere made chiefly of skins. All peoples also make household utensils of wood, skin and bone. Metalwork, in iron and copper, is confined to Bantu and Hottentots, though early writers say that some Bergdama also practised the art. Each household as a rule builds its own home and makes its own clothing and most of the other goods it uses. However, all metal objects are produced by specialist smiths, who barter them for cattle, grain, etc. Most ornaments and implements can also be exchanged for other commodities and are freely traded, both internally and between different communities. Among Bantu and Hottentots poor persons serve others as herdsmen, receiving milk and an occasional heifer in payment. Among Bantu beer and porridge are used widely as payment for labour and to satisfy social obligations toward kinsmen and neighbours. But nowhere do people depend solely on manufacture and trade for their livelihood; even smiths, magicians and other specialists carry on the same subsistence activities as the rest of the community, their special craft being an additional source of income.

Social and Political Organization.—Every major division consists of many independent political communities, each with its own territory and government. Bushman and Bergdama communities (bands) seldom contain more than 80 persons and often, especially among Bergdama, 30 or even fewer. Hottentot communities (tribes) generally have between 500 and 2,500 members each. Many Bantu tribes are no bigger, but in others, notably among Sotho, Nguni and Ambo, the population exceeds 50,000. The members of a band are as a rule all related closely by kinship or affinity; those of a tribe are invariably of diverse origins and, as among Tswana, may even differ in culture, language and race.

The Bergdama band is a compact residential group. A Bushman band likewise camps together for at least part of each year. Hottentot tribesmen are, however, permanently dispersed over their territory, the men of each local group belonging typically to a single clan. The members of a Bantu tribe are also dispersed. Venda and most Sotho live in compact villages of from 10 to 50 different households; elsewhere each household normally occupies its own hamlet. The Tswana are unique in having relatively large settlements, some with more than 5,000 inhabitants; these are divided into wards under local headmen.

The basic social unit everywhere is the household, consisting typically of a man with his wife or wives and dependent children. Except among Bushmen, married children (especially sons) and their families are often also included. Polygyny is customary everywhere, though only Bantu practise it extensively. Few polygynists have more than two or three wives; among Bantu, however, four to six are not uncommon and some chiefs have many more. Marriages are usually arranged by parents in consultation with close relatives; several groups of Bantu formerly practised infant betrothal. Marriage among all Bantu except Ambo is legalized by a special "gift" of cattle to the bride's parents. There is no corresponding payment elsewhere. A wife normally settles in her husband's local group, though among Bushmen, Bergdama, Hottentots and some Tswana, he must live with her own people for a year or so immediately after marriage.

Hottentots and Bantu, but apparently not Bushmen and Bergdama, also have unilateral descent groups of various kinds. The most widespread is the lineage. The Ambo are matrilineal: all others patrilineal except the Herero, who have a double descent system. Bantu (but not Hottentot) lineages are often subdivided into localized sections, which rank according to seniority of descent. Among Hottentots, Nguni and Tsonga lineages are all component units of exogamous nontotemic clans, whose members (except among Hottentots) are usually widely dispersed. Sotho and Venda lineages belong to much larger totemic groups, which cut across tribal boundaries; among Venda, but not Sotho, people with the same totem are considered relatives and formerly could not intermarry. Shona and Ambo lineages are similarly grouped

into clans that are exogamous, totemic and dispersed. Herero lineages are also subdivisions of totemic clans, and every person belongs to both his father's patriclan (*oruzo*) and his mother's matriclan (*eanda*). The former functions chiefly in religious and political life, the latter in inheritance of property. The patriclan is exogamous and so is the matrilineage (but not the matriclan).

The only other major kinds of social grouping are the age sets characteristic of all Central and Eastern Bantu except Cape Nguni. These are created periodically by the tribal chiefs, at intervals of say four to seven years, when all the adolescent boys are initiated simultaneously. Each set has its own name and leader (always of the chiefly family) and membership is for life. In most tribes there is a parallel grouping of women. The sets, ranked according to priority of creation, feature prominently in tribal affairs. They are often used by the chief for various kinds of public service, and those of able-bodied men fight as separate regiments in the army. Members usually live at home. But among the Zulu, in the heyday of their power, the younger regiments each had its own village, close to the chief's, where its members remained continuously for several years before being released and allowed to marry. The Swazi have a somewhat similar but less comprehensive residential system. The Bergdama are said to have age sets too, though little is known about them. They do not occur anywhere else in the region.

Systems of government differ widely. Each Bushman and Bergdama band has a hereditary headman, but public issues are decided by all the men in council. The headman has no judicial powers, the principal remedy for wrongs being self-help. His main task is to direct migrations and other collective activities, though among Bergdama and some Bushmen (*Kung* and *Heikum*) he is also the band's priest. Every Hottentot clan also has a headman, who with the help of its other men judges internal disputes, punishes criminals and decides on such matters as seeking new pastures. The clan heads together constitute the tribal council, the head of the senior clan presiding as chief. The council deals with intertribal relations and other matters of common concern, and also adjudicates upon disputes between people of different clans. The chief cannot act independently of its other members.

Every Bantu tribe also has a chief. He rules with the aid of several confidential advisers and a large formal council including all heads of major local segments; among Sotho, especially Tswana, he must also habitually consult a mass meeting of tribesmen. But his authority is supreme. He has both legislative and judicial powers, and although local subchiefs and headmen also try cases he only can impose the death penalty. He is the tribal priest and rainmaker and (like his Hottentot counterpart) often the leader in war. He regulates the distribution of residential and cultivable land, controls such other aspects of economy as the cycle of agricultural activities and receives tribute from his subjects in both kind and labour. In return he rewards his assistants with gifts of cattle and other commodities, supports the destitute and on great public occasions provides meat and beer for all who assemble at his village. One quality always required of him is generosity, failing which he soon becomes unpopular.

Religion and Magic.—The Bushmen pray to the moon and other celestial bodies, about which the southern groups especially have a rich and extensive mythology. They also recognize a supernatural being known variously as *Cagn*, *Huwe*, *Hische* or *Tora*. He controls rain, thunder and lightning; he is invoked for abundance of plant foods, good luck in hunting, recovery from illness, protection, etc. The northern groups also speak of *Gaua*, a being associated primarily with the ghosts of the dead and, like them, considered a source of illness and death. He is apparently not worshiped nor are the spirits of deceased ancestors.

The Hottentots similarly connect the ghosts of dead persons with a being named *Gaunab*. Both are greatly feared as causing sickness or death. In mythology *Gaunab* features as an evil chief always in conflict with *Tsui-Goab*, the creator god who is invoked for health, prosperity, abundance and above all rain. Another leading figure in ritual and belief is *Heitsi-Eibib*, the central per-

sonage of a great mythical cycle in which he and members of his family have many wonderful adventures. His "graves," large heaps of stones, are found all over the country, and whoever passes by adds a stone or twig, usually with a prayer for good luck. Some early writers say the Cape Hottentots also prayed for food and rain to the moon, which among all Hottentots figures prominently in myths about the origin of death.

The supreme being of the Bergdama is *Gamab*, whose home in the sky is also the afterworld of the dead. His name, and the belief that he-causes death, are reminiscent of Bushman "*Gaua*" and Hottentot "*Gaunab*," but unlike them he stands alone and is worshiped. His cult is connected with the sacred fire kept burning perpetually in every band. All game killed in the chase and all plant foods as they ripen are brought to it for the headman to bless before they are eaten. Whenever the band moves he also prays there to *Gamab* for abundance and good fortune. Scarcity of food, drought and other ills, are ascribed to the pollution of the fire, which the headman must then extinguish and renew with elaborate ceremonial. On certain occasions he also deposits offerings and prays at the grave of a deceased ancestor.

Among Bantu the dominant religious cult is ancestor worship. Every family and descent group worships its own ancestors, the head of the group conducting the rites. On important tribal occasions the chief also prays to his ancestors on behalf of all his subjects. The spirits of the ancestors are believed to guide the destinies of their living descendants, who propitiate them with prayers and offerings both whenever they reveal themselves through dreams or calamity, and on such occasions as birth, marriage or the start of some new enterprise. The Herero link ancestor worship with the cult of the sacred fire. Every household has its own fire: kindled originally from that of its *oruzo* head. This fire, which should burn perpetually, is the domestic altar. At it the family priest prays to his ancestors and blesses the daily yield of milk before it can be consumed.

The Bantu also have some conception, often rather vague, of a universal power apart from the ancestors. It is variously known by such names as *Tilo* (*Tsonga*), *Unkulunkulu* (*Zulu*), *Modimo* (*Sotho*) and *Raluvhimba* (*Venda*). The beliefs and practices relating to it differ considerably. The Sotho, for example, regard *Modimo* as the creator of all things and the molder of destiny. He is associated with the phenomena of the weather, and punishes innovations or departures from custom by sending mind, hail or heat and withholding the rain. But he is considered too remote from the world of man to be directly approached in prayer, though at times the ancestral spirits may be implored to intercede with him. The *Tsonga*, in contrast, think of *Tilo* as an impersonal power presiding over all unaccountable and inevitable phenomena of the atmosphere, of the fields and of human existence, and try to propitiate it in times of drought or other extreme distress. There is little to suggest that these universal powers play as intimate a part in everyday religion as the spirits of the ancestors.

All South African peoples further make considerable and frequent use of magic. Certain individuals, women as well as men, are specialists in the art and are paid for their services. Their main activity everywhere is treatment of the sick; they also practise divination, charm people for success and protection from misfortune, officiate at puberty and similar ceremonies, and perform rainmaking rites in time of drought. Among Hottentots and Bantu they likewise "doctor" cattle (and among Bantu also fields) to insure fertility and other blessings. Any misfortune, especially sickness or death, may be attributed to the malevolent use of magic and the culprit if discovered is punished severely, sometimes by death. All peoples also have much faith in omens, of which there are many kinds. The wearing of amulets is likewise common everywhere; hunters, warriors, herdsmen and others tie around their necks small pieces of wood, bone and similar objects obtained from the magicians and believed to ward off danger, maintain health or deliver the possessor from evil.

Major Population Movements.—The Bushmen, because of their linguistic and other affinities with such peoples as the *Hadza* and *Sandawe* of *Tanganyika*, have generally been held to have entered southern Africa from the northeast. By the 1960s, observers

had come to maintain instead that they evolved locally from pre-existing and now extinct types of Stone Age man, subsequently spreading north of the Zambezi. It is, however, generally agreed that they have occupied southern Africa since the beginning of the Late Stone Age (about 8,000 years ago) and possibly earlier, and are the oldest of its modern inhabitants. Their relics (*e.g.*, skeletal remains, stone implement industries, pictorial art and place names) are found widely scattered throughout the region and furnish good evidence of their former presence in areas where they are no longer seen—notably Cape Province, Orange Free State, Basutoland and Natal.

The Hottentots have similarly been thought to have originated in East Africa from a mixture of Bushmen and early invading Hamites, to whom were attributed also their language, livestock and other cultural peculiarities. The modern view is that they developed in southern Africa by "hybridization between three basic strains—the small Bushman, the long-headed Bushmanoid (Boskop) type and a long-headed non-Bushmanoid form represented by the Kakamas type" (J. D. Clark). It is to the last-named, immigrants of Caucasoid or Erythriote stock who "probably originated somewhere in northeast Africa," that they are said to owe the distinctive features of their culture, brought into the country about 1,500–2,000 years ago.

The Bergdama are a mystery. Because they speak the same language as the Nama Hottentots, one view is that they were subjected by the Nama somewhere in central Africa and brought to the south as servants. It is generally and more plausibly assumed that in fact they represent an old Negro stock which, with the possible exception of the Bushmen, preceded all other inhabitants of South-West Africa. It is certain also that by the end of the 18th century many had become serfs of Nama, Herero and Ambo. But how and when they acquired their language is still a moot problem, since when first seen by Europeans (1792) they were living north of the Nama tribes, not in their midst.

The Bantu are universally held to have moved into South Africa from the north, the lake region of East Africa often being regarded as their centre of origin. They apparently came in many separate bodies and along diverse routes, each of their main groups representing a different series of migrations. Archaeological evidence, notably from Zimbabwe (*q.v.*) and similar ruins, suggests that the ancestors of the Shona were already in Southern Rhodesia by the 8th century A.D. Other evidence indicates that the Nguni and Sotho had reached their present habitats by the 14th century A.D., that the Venda migrated from Southern Rhodesia to the Soutpansberg about A.D. 1600, and that the Ambo and Herero entered South-West Africa from the upper reaches of the Zambezi about the same time. More cannot be said with much plausibility, and even the dates mentioned are hypothetical.

The impacts upon one another of different native peoples, and the later advance inland from the Cape of European settlers, resulted in many local upheavals, during which various groups of Bushmen and Hottentots ceased to exist and the Bantu also were greatly affected. In particular, the wars of conquest initiated by the Zulu chief Shaka (Chaka; 1816–28) led to widespread devastation and enforced migration. One sequel was the creation of several other strong native states. Mzilikazi, after dominating central and western Transvaal (about 1821–37), went on to conquer the Shona in Southern Rhodesia, where he established the Matabele (Ndebele) kingdom. Soshangana subjugated most of the Tsonga in Mozambique and founded the Gasa (Shangana) kingdom, while Zwangendaba and others founded Ngoni kingdoms north of the Zambezi. Moshesh from the remnants of many scattered tribes similarly created the modern Basuto nation in Basutoland. Thulare and his son Sekwati brought many northern (Transvaal) Sotho tribes under the rule of the Pedi; Sebetwane, leading a horde of Sotho refugees from the south, established in far-off Barotseland the great Kololo kingdom. The wholesale destruction of life and dispersal of people resulting from these upheavals facilitated the subsequent extension of European settlement over the country. By the end of the 19th century, European armies had destroyed most of the new kingdoms, but such large tribal states as the southern Sotho (of Basutoland), Swazi and

Ngwato still survive as examples of the political development to which the Bantu could sometimes attain.

IV. ARCHAEOLOGY

The first factor which must be taken into consideration in discussing the archaeology of Africa is the vast size of the continent, which stretches from the equator to the edge of the temperate zone in both the northern and the southern hemisphere. This wide expanse is interrupted by few geographical barriers except those created by changing climate. Northward from the equator there is a steady transition from tropical rain forest to more open forests and rich grasslands, then to drier grasslands, woodlands and thorn scrub and so to semidesert and the extreme desert conditions of parts of the Sahara. Northward again the extreme

aridity of the desert decreases and there is a fairly rapid transition to more hospitable conditions along much of the southern shore of the Mediterranean. From the equator southward this pattern is repeated, but in a somewhat modified form as a result of the eastern mountains and plateau, which extend from Ethiopia to the Cape of Good Hope and cause a considerable increase of rainfall down the entire southeastern part of the continent. Similarly, the Nile valley forms a bridge across the desert conditions of the northern half of the continent, locally upsetting the absolute regularity of the climatic pattern.

In general outline, this pattern has remained constant throughout the period of man's existence in Africa, but from time to time it has been considerably modified. Thus there have been periods when the desert has become the habitat of grazing animals, which now live only on its fringes, and of the men who hunted them. There have also been times when the tropical forests have extended or receded beyond their present limits. Thus any particular area may form a barrier to human contact at one period and quite the reverse at another.

Sub-Saharan Africa has yielded a wide variety of early human and near-human skeletal remains, extending well back into geological time, and also what is probably the most complete series of Early Stone Age hand-ax industries known anywhere in the world. Taken together these strongly suggest that it was one of the centres of early human evolution, possibly even the region in which the all-important change from animal to man took place—a change signalized by the appearance of deliberately made tools which reflect developing manual and intellectual skills.

The fact that during much of this stage of human development the Sahara desert enjoyed a more humid climate than it does in modern times; and therefore was not such an obstacle to the movement of animals and man as it later became, may to some extent account for the remarkable uniformity of the hand-ax industries throughout Africa, southern Europe, western Asia and India. Later the climate of the desert belt became more intensely arid and human cultures in different regions, both in Africa and outside, began to develop along their own lines of local specialization. From then on, with certain notable exceptions, African culture tends to be more and more diversified. The climax comes with the final intensification of desert conditions in the Sahara and the early rise of civilization in the Nile valley. From that point onward Egypt and the north African littoral tend to form part of the Mediterranean world and Sub-Saharan Africa to go its own way.

Stone Age cultures succeeded one another in the various regions south of the Sahara. In the savanna regions of the south and east these were clearly based upon hunting the numerous species of larger game animals, and the diet was augmented by vegetable foods. In the forest regions vegetable foods must have played a more important part in the inhabitants' diet, but at what stage they began to encourage and then to cultivate the plants they found most palatable is not clear. Nor is it clear how far the change to food production was a spontaneous development or was due to direct or indirect influences from outside. Egyptian and Mediterranean influences are apparent around the fringes of the Sahara, but farther southward their traces tend to disappear.

During the Late Stone Age, Sub-Saharan Africa was a region of relative cultural and physical diversity; ideas spread from group to group and occasional movements of population no doubt took place, but the general trend was toward regional continuity. No Bronze Age revolution cut across this pattern as it did in Europe and northern Asia. The two factors which brought the whole region back into contact with the outside world might be summarized as iron and trade. In the last centuries before the beginning of the Christian era the knowledge of iron smelting and ironworking began to reach the Sudan, probably from Nubia, and then to spread southward, taking with it the possibility of numerous agricultural and technological advances and all that these implied. Following the Arab conquest of North Africa, Arab traders began to cross the Sahara and to sail down the east coast, chiefly in search of gold and other minerals, which they

found in plenty. Partly no doubt as a result of these stimuli large tribal groups, kingdoms and empires emerged in many parts of Africa, like those described by Arab geographers and Portuguese travelers in West Africa and the Sudan, and those which have left evidence of their presence in the extensive ruins of East and Southern Africa. It is with the Iron Age also that the expansion of Bantu peoples in East and Southern Africa may be associated. Unfortunately the Iron Age has hitherto been one of the most neglected periods of African prehistory.

The study of African archaeology has naturally tended to be approached from two directions. The archaeology of Egypt and North Africa has been studied in relation to that of the Mediterranean, Europe and western Asia, and is described in similar terms; that of Sub-Saharan Africa has developed its own terms, as an independent field. The whole continent falls naturally into a number of major geographical units each of which can be further subdivided, and these generally correspond to cultural groupings at different periods. Naturally these vary somewhat from time to time, but the pattern is sufficiently persistent to justify discussing the archaeological sequence in terms of these regions.

(B. AL.)

A. FOSSIL HOMINID REMAINS

Africa is a part of that old world land mass which contains some of the earliest-known protohuman fossils as well as extremely ancient cultural traces of man. It was regarded by Charles Darwin as the continent which probably first witnessed the appearance of man, a view later revived by prehistorians of such distinction as P. Teilhard de Chardin. Moreover, Africa contains two of man's closest primate relatives, the gorilla and chimpanzee, as well as a variety of more distantly related monkey and lemuriform forms. In spite of Darwin's views, however, the weight of conservative opinion for long tended to view Asia as the more likely centre of human origins. Partly this was the result of earlier historic and philosophical ideas, partly the natural outcome of the discovery of Miocene and Pliocene apes in the Siwalik fossil beds of northern India. In addition, the late 19th-century discovery of a primitive type of man, *Pithecanthropus erectus*, in Java and, beginning in 1929, the uncovering in China (near Peking) of a number of specimens of an almost equally primitive fossil form of man, designated as *Sinanthropus pekimensis*, tended to strengthen the view that man had arisen in Asia and only later reached the African continent.

This ancient controversy was revived by two dramatic events: first, the discovery of a remarkable group of upright-walking man-apes classified taxonomically as the family Australopithecinae; second, the discovery in Kenya of an older and remarkably unspecialized ape, *Proconsul africanus*.

"**Proconsul africanus.**"—In old lake deposits of Lower Miocene age have been located the remains of primitive anthropoid apes known under the generic name of *Proconsul*. These finds include a reasonably complete skull, the most complete so far recovered of any ape of this period, as well as other bones including femurs, a humerus and numerous teeth and jaws. In *Proconsul* the upper canine tooth is large and the dentition is related to that of the later great apes as well as showing certain more human features. The skull lacks the heavy brow ridges associated with many early human skulls and with the great apes. All in all, *Proconsul* suggests a fairly primitive ape, gracile and slender bodied with quadrupedal as well as brachiating habits. There can be no doubt that it represents an early, generalized type of anthropoid ape. It may therefore stand close to the point of divergence of the protoape and protohuman lines of descent. There are altogether three species that have been described under the generic name *Proconsul*.

Australopithecinae.—In 1924 the first of a series of discoveries made in the neighbourhood of the Vaal river in the Union of South Africa revealed a creature so intermediate in character between ape and man in many of its anatomical features that its clear assignment either to an anthropoid or early human status is beset with difficulties. The Australopithecinae, as these crea-

tures have been named, come close to satisfying the idea of what the earliest "half men" looked like. They have been classified as members of the Hominidae, the family to which man belongs, and are described in separate articles. (See MAN. EVOLUTION OF.)

Fossil Men.—From 1954 onward, fossil human remains were discovered associated with Acheulian hand axes at Palikao near Ternifine in Algeria and at Sidi Abderrahman in Morocco. They consist of lower jaws and a piece of parietal. The chin region is receding and this feature, as well as the teeth, recalls *Pithecanthropus* of Java and Peking. These fossils all belong to one type, known as *Atlantropus mauritanicus*, which apparently represents the African form of the Asiatic *Pithecanthropus* and could well be the next stage in hominid evolution after the australopithecines.

Other early forms of man which are known to have inhabited Africa during the Pleistocene fall into two main categories. The first is a gerontomorphic group of hominids with heavy facial bones and large brow ridges, which belong to the widespread type known as Proto-Australoids; and the second is a remarkably pedomorphic *Homo sapiens* type apparently preceding and related to the existing Kalahari Bushmen.

The Proto-Australoids are known from three specimens: (1) the famous Broken Hill skull from a mine in northwestern Rhodesia; (2) certain fragmentary remains originally classified under the title *Africanthropus* (*Homo njarensis*); and (3) a skull from Hopefield near Saldanha bay, Cape Province.

Homo rhodesiensis.—Often termed Rhodesian man, he is represented by one of the most complete Pleistocene crania discovered by the mid-20th century. The skull and a few bones included with it was found in an old cave 60 ft beneath the surface during the course of mining operations carried on by the Broken Hill company in 1921. Unfortunately, no anthropologist was present at the time of discovery, so that the exact circumstances of the skull's position in regard to other cultural and faunal levels in the cave were not recorded. The skull itself, save for breakage in the region of the right parietal bone and the right side of the occiput, is complete, the face being in perfect condition. The mandible was never recovered. The salient feature of the cranium is its great size and massiveness. The supraorbital torus is exceptionally large, measuring 139 mm. across, a width greatly in excess of that of recent man. The skull is low and of great length (208.5 mm.) being rather similar to the European Neanderthals in this respect, and the occipital torus is heavy and pronounced. The cranial capacity is about 1,300 c.c., a lower figure than that observed for some European Neanderthals of similar size. The palate is much larger than in modern man and the face was undoubtedly huge and of a formidably primitive aspect. Morphologically the skull seems to belong to roughly the same level as European Neanderthal skulls, though its physical characters do not permit ranging it in an identical position with the Neanderthals, and it perhaps approximates a little more closely to the *Homo soloensis* form from Java. Its geological dating is early Upper Pleistocene.

Africanthropus.—The discovery of *Africanthropus* was made in the Eyasi lake basin of northern Tanganyika in 1934. Remains of three crania were recovered, but in an extremely fragmentary condition, from a lake deposit of early Upper Pleistocene age. A cranial capacity of around 1,100 c.c. is claimed, with a low basi-bregmatic height. Fragments indicate a heavy supraorbital torus, said to be thinner and more delicate than in the Neanderthals or *Homo rhodesiensis*. This, however, might represent only a sex difference as the small and delicate mastoid also suggests. Some authorities regarded the form as lying on the *Pithecanthropus-Sinanthropus* level, but the fragmentary character of the remains and the difficulties of restoration make a detailed study impossible.

Saldanha Man.—In 1951 pieces of a fossilized human skull were found on the farm of Elandsfontein near Hopefield, 9 mi. inland from Saldanha bay, Cape Province. The skull, as well as fossil fauna and two different stone industries, came from lime-impregnated sand which probably represents the dried up floor of an old pan. The skull is very similar to Rhodesian man, with heavy brow ridges, receding forehead and a low vault. The fauna includes some extinct forms, notably the giant buffalo *Homoioceras*; fluo-

rine tests have shown that the human skull is contemporary with this Cpper Pleistocene fauna and so presumably with the earlier Fauresmith industry rather than with the Stillbay industry found on the surface of the site.

Neanderthal Man.—Save for a few fragmentary hints of the presence of North African Neanderthal men in the neighbourhood of Tangier, at Rabat on the North Atlantic coast and at Haula Fteah in Cyreniaca, there is no further knowledge of this form. The African equivalents of *Homo neanderthalensis* appear to be the Proto-Australoid types discussed above. The finds which remain to be discussed fall into the category of *Homo sapiens*.

Early Forms of "*Homo sapiens*."—*Kanam Man.*—Very much earlier than the Proto-Australoids and Neanderthals described above, according to its discoverer L. S. B. Leakey, is a fragmentary human mandible from Kanam on the shores of Kavirondo gulf of Lake Yictoria. Not only was it said to be associated with pebble tools and a Lower Pleistocene fauna, but it is claimed to be of *Homo sapiens* form due principally to the fact that it does not have a receding chin like, for instance, *Atlanthropus*. The individual, however, had a tumour of the bone which may make the chin appear more prominent than it would otherwise be. If the fossil is really of Lower Pleistocene age, the possibility of its being an australopithecine should not be ruled out; some of these creatures had fairly prominent chins.

Kanjera Man.—At Kanjera not far from Kanam, fragments of four human skulls were found; one of these includes the brow region, which is quite smooth as in modern man. The skull is ultradolichocephalic. The fossils were in the same state of mineralization as Middle Pleistocene fauna from the site and were associated with Acheulean hand axes. Recent tests have revealed a similar uranium content in the human skulls and the extinct fauna, which supports the view that they were contemporaneous.

Florisbad Cranium.—A remarkable specimen is the Florisbad cranium discovered by T. F. Dreyer. It has been called *Homo helmei*. The bones were recovered in 1932 from an old spring deposit at Florisbad, 25 mi. N. of Bloemfontein. Several extinct animals were found in general association with the skull. These included the giant African buffalo, *Homoioceras*, and two extinct species of horse. Dreyer regarded the remains as those of an early and primitive Bushman. M. R. Drennan, on the other hand, insisted that its characters are those of a South African variety of Neanderthal. This controversy arose in part because of the incomplete nature of the specimen. The fragments consist of part of the frontal, the right parietal, maxilla and molar.

The skull has the immense minimum frontal width of 120 mm. as contrasted with an average Caucasian width of about 99 mm. The breadth across the supraorbital process approaches very close to *Homo rhodesiensis*, measuring as it does 136 mm. In spite of being pronounced, however, the brow ridge is divided in a manner resembling *Homo sapiens*. Unlike Neanderthal man, who had round and open orbits, the Florisbad orbital height is much less than the width. The skull must have been huge, perhaps as much as 210 mm. in length, but there are indications that it sloped rapidly away from a high point at the bregma toward the occiput. This feature suggests that the brain was rather low and flat in the occipital region. The face is extremely prognathous. The majority opinion regards the skull as a primitive form of *Homo sapiens*, probably an ancestral Bushman type. It is curious and unique, and can be better understood only as more complete specimens are obtained. Its date is probably early Upper Pleistocene. The age of the peat in which the skull was found has been dated by the radiocarbon method to more than 40,000 years.

Boskop Cranium.—In 1913 a human calvarium of quite remarkable size was turned up in a drainage ditch near Boskop, in the Transvaal. It is 205 mm. in length with a basibregmatic height of 140 mm. The cranial capacity was probably about 1,700 c.c., which is markedly above the modern average. A single stone implement found with the skull shows Middle Stone Age affinities and may indicate the approximate age of the human remains. The most striking features of the skull, apart from its size, are the pentagoid shape when viewed from above, the bosses on the sides and the bulging forehead. It has been found that remains of

Boskopoid individuals turn up with considerable frequency in the lower strata of cliff shelters and seashore middens in various parts of Southern Africa. The term Boskopoid has come to be applied to a pedomorphic type showing some trace of Bushman characters. The other finds are probably very late Pleistocene to early Recent. In the words of Sir Arthur Keith the type "outrivals in brain volume any people of Europe, ancient or modern . . ." The cranium to face ratio is almost five to one; and the face is quite orthognathous. In other words, this is a human type in which the retention of infantile characters is more marked than in other varieties of *Homo sapiens*. Along with this pedomorphic tendency, a marked trend toward high cranial capacity is observable.

Singa Cranium.—A skull from Singa on the Blue Nile is of the pre-Bushman stock so well represented in South Africa and bears a marked resemblance to the Boskop cranium. An accompanying industry is of Middle Stone Age type, described as Proto-Stillbay, and the skull is dated to the early part of the Upper Pleistocene.

Insofar as the skeletal material so far described has any cultural associations they are with Early or Middle Stone Age industries. It is noteworthy that as in Europe the Mousterian industries are so often associated with the heavy-browed Neanderthal man, so in Africa the early Middle Stone Age industries are frequently associated with the large-faced Proto-Australoids. How far this parallelism is significant it is as yet too early to say. With succeeding cultural developments of the Middle and Late Stone Age in East and Southern Africa there is a tendency for more and more specialized Boskop and Bushmanoid types to be associated. This adds to the considerable ethnographic evidence which shows that the immediate ancestors of the modern Bushmen of Southern Africa were the makers of the final phases of the Late Stone Age industries in many parts of the region. (L. C. E.; S. M. C.)

B. SOUTHERN AFRICA

The study of archaeology in Southern Africa grew up in much the same way as it did in Europe—that is to say, through the collection of objects and their arrangement first in groups and then in a sequence of related groups. Later this sequence was altered or confirmed as similar objects were found stratified in river gravels or cave deposits which indicated their chronological relationship to one another in geological terms. Following the Pretoria conference of 1927, a systematic account of these findings was put forward by A. J. H. Goodwin and C. van Riet Lowe in "The Stone Age Cultures of South Africa" (*Ann. S. Afr. Mus.*, xxvii [1928]). Here they make it clear that in South Africa at any rate the stone industries fall into three major groups, which they called Early, Middle and Late Stone Age respectively. As the established European terminology, involving the use of Paleolithic and Neolithic cultural groupings with their subdivisions is patently unsuitable, their terminology has now been generally accepted and their system of classification, with certain minor modifications, has been extended to much of Sub-Saharan Africa.

Early Stone Age.—This includes a series of hand-ax industries closely comparable to those found in Europe, western Asia and India. This is best represented in collections from the gravels of the Vaal river, where the evolution from simple pebble tools to finely worked hand axes and clearers can be clearly seen. By general consent the term Chelles-Acheul is now used to describe these industries, as it is for their European counterparts. In the later stages the Levallois technique of making tools on flakes struck from prepared cores is seen to develop from the original core technique and to continue alongside it. Technically these industries are close to those of the Lower Paleolithic of Europe, but in Africa the proportion of cleavers to hand axes is much higher, as it is in India, and the core and flake aspects of the industries are more closely integrated than in Europe. The dating of these industries and the question of the existence of Pre-Chelles-Acheul pebble industries is discussed in the following section on the archaeology of Central and West Africa.

Middle Stone Age.—This age follows after a transitional period, known as the first intermediate phase, which is represented in Southern Africa chiefly by the Fauresmith industry in which the

hand axes of the Early Stone Age continue to be made but in much smaller sizes, and an increased range of small flake tools and points makes its appearance. The Fauresmith is widely distributed in Southern Africa, and is evidently associated with fairly open country; in places variants of the related Sangoan industries of the more thickly wooded country to the north also appear for the first time. In the industries of the Middle Stone Age proper, which correspond to a period of generally increased rainfall, the tendency to reduction in size and refinement of technique continues; they are characterized by the production of flakes from small carefully prepared cores, and of finely worked points of various kinds. These are accompanied by an increasing range of scrapers, blade flakes, large crescents and so on, like the tools of the Stillbay industries of Central and East Africa. There are a number of local variants which include the Rhodesian Stillbay, the Pietersburg and Hagenstad variants of the Transvaal and Northern Free State, the Mazelspoort and Alexandersfontein variants farther west, and the Mossel bay variant in the extreme south.

The meaning of the reduction in size which began in the preceding intermediate phase is clear: the tools of the Middle Stone Age industries were intended for hafting and not simply for use in the hand, as was the case with those of the Early Stone Age. At this period also man began to inhabit caves and rock shelters with increasing regularity. This may have been partly as a result of climatic reasons, but it was undoubtedly due also to a knowledge of the use of fire, and an increasing ability to control it. During the greater part of the Early Stone Age fire was clearly unknown, and living sites are always in the open, but in the final stages of this period in South Africa there are indications both of its use, and of the regular habitation of caves. Only when he had fire at his command was it possible for man to live in caves and defend himself from the attacks of large carnivores. Fire also made possible the hafting of stone tools in mastics such as resin and similar substances, a practice for which there is considerable evidence from Southern Africa and from many other parts of the world, and it also opened up many new possibilities in all directions.

As the Middle Stone Age drew to a close its final expression is to be found in the Magosian industries, which are also widely distributed in Southern Africa, and which are in many ways transitional between the Middle and Late Stone Age. For this reason they are regarded as occupying the second intermediate phase, which corresponds with an interpluvial or dry phase in the climatic sequence. This possibly accounts for the fact that the majority of Magosian assemblages have been found in the open, and not in caves or rock shelters like the industries which came before and after them. The assemblages include not only small, highly developed Middle Stone Age forms, but also small blades and geometric microliths, which distinctly foreshadow succeeding developments. Whether the bow and arrow also made their first appearance at this stage is uncertain, but a good case can be made for their having done so, as for the first time stone points appear which are light enough to be used as arrow heads.

Late Stone Age.—The age of the bow and arrow and of the final refinement of both hunting and stoneworking techniques, the Late Stone Age was the high period of the arts of rock painting and engraving. Both arts probably began in earlier periods but now reached their zenith in Southern Africa with a richness and variety, particularly in the case of the paintings, which has been attained by hunting people in few other parts of the world. The use of arrow poisons, which made fatal the smallest puncture of the skin, allowed bows and arrows to be extremely small and light; a great variety of small delicate tools of both stone and bone characterize this period.

The Late Stone Age industries of Southern Africa may be divided into two major groups, which are known as Smithfield and Wilton. The latter are similar to the Wilton industries of Central and East Africa in general respects, including a considerable range of geometric forms (among which lunates are the dominant type), thumbnail scrapers, hollow scrapers, awls, backed blades and other stone tools, often accompanied by bone tools, ostrich eggshell beads, large globular stones with hourglass-shaped perforations (used among other things as weights for digging sticks), grooved

stones for straightening arrows and hollow stones for mixing arrow poison. Assemblages of the Smithfield group of industries are substantially similar, but lack the geometric forms. The Smithfield industries appear to be centred upon the interior plateau, but sometimes extend into the surrounding Wilton provinces. The line of demarcation between the two groups is nowhere clear-cut.

The immediate ancestors of the Bushmen were responsible for a great part of these Late Stone Age industries and there are abundant records of their making or using such tools after the middle of the 18th century. A number of stone tools of this period have also been found hafted with mastic in wood or bone handles, and the use of others is clearly shown in the rock paintings. Consequently it is possible to gain a much fuller insight into this period than into those which preceded it.

The Iron Age is a somewhat elusive term in Southern Africa, for when Jan van Riebeeck established a permanent foothold for the Dutch East India company at the Cape of Good Hope in 1652 it appears that both the hunting Bushmen and the cattle-keeping Hottentots were entirely ignorant of techniques of iron smelting, but they quickly made use of any scrap metal which came their way, hammering it into arrow- or spearheads as the Kalahari Bushmen do today. Iron-using agriculturists had arrived in the northern part of the region several hundred years earlier and built massive stone structures, which still can be seen in Rhodesia and the northern Transvaal. From these places they carried on trade with the inhabitants of the east coast and ultimately perhaps with Arabia and India. How soon the hunting people of surrounding regions obtained iron in a similar manner from them is at present impossible to know. At Zimbabwe (*q.v.*) and other sites a series of Iron Age cultural levels has been distinguished, but their relationship to similar cultures farther north, although generally established, has not yet been worked out in detail, and neither has their relationship to existing ethnic groups in Southern Africa.

(B. AL.)

Rock Painting and Engraving.—Two broad periods are discernible in the prehistoric rock paintings. The earlier antedates the appearance of the Bantu-speaking invaders whose vanguard probably reached South Africa about 1,000 years ago; the later postdates this invasion. In the earlier period the art is natural and restful, the work of men of leisure and peace. It is seen developing from single animal studies in monochrome in the order yellow, red, maroon, black and white, through bichromes where perspective and composition first appear and finally to shaded polychromes often showing remarkable grouping and perspective. The paintings give an idea of the dress, arms, occupations, ceremonies and beliefs of the artists. It was during the earlier monochrome phase of this development that Stone Age men in South Africa passed through a stage of artistic expression which shows such striking affinities with the paleolithic art of eastern Spain and East Africa. So alike indeed are certain of the rock paintings of eastern Spain, Tanganyika, Rhodesia and South Africa that parallel evolution does not seem to afford a wholly satisfactory solution.

The latter portion of the earlier period (*i.e.*, bichrome and polychrome phase) is notable first for the emphasis on a variety of gazelles and then on the eland, paintings of which are found superimposed on those of gazelles. Paintings of gazelles such as impala, rhebok, steenbok and springbok are usually small but always beautifully executed; those of eland are usually large individual pictures sometimes reaching a few feet and more in length. The gazelle phase might be referred to as micrographic art; the eland phase as macrographic. These two phases can be said to represent the acme of prehistoric rock paintings in South Africa.

The later period of prehistoric rock paintings is characterized by a restlessness which had a profound effect on the artist. He continued with the knowledge which he had previously gained and certainly maintained the tradition of his ancestors, but he never seems to have had either the leisure or the inclination to paint as easily, skilfully and restfully as did his predecessors. This period of restlessness is characterized by the first appearance in paintings of men with shields and spears, of cattle, sheep and other

objects first brought to the south by Iron Age agriculturists, and the paintings occur as palimpsests over the works of the earlier period. Colour and style sequences and superimpositions are gradually unfolding the fuller story of the dramatic sequence of events. On the grounds of style and subject matter as well as technique there appears to be a general division into cave paintings, and petroglyphs or rock bruising, which are generally found in the open. While many of the petroglyphs, whether pecked or engraved into the rock, reveal remarkable affinities with the rock paintings, many others do not. A close study of the petroglyphs has revealed an interesting sequence of styles and subjects. The oldest are finely incised line engravings where single animal studies in profile appear over finely engraved but crudely drawn figures of triangles, zigzag lines, ladders, chevrons and so on. The finely engraved figures of animals include most of the forms which are still living. Composition or grouping and perspective are very rare. Superimposed over these engravings is a vast array of figures, both animal and schematic, the profiles of which were pecked into the rock by a crumbling as opposed to a cutting process. Rarely are the two styles combined in a single figure. Although both rock painting and rock engraving were extensively practised by Bushmen during the Late Stone Age, the inception and earlier practice of these arts seem to have taken place toward the close of the Middle Stone Age. It is therefore possible that the age of these arts may go as far back in time as that of similar arts in Europe. (S. M. C.)

C. CENTRAL AND WEST AFRICA

It would be convenient to view the progress of African prehistory against a chronological backdrop of climatic change just as one does in northern latitudes, where a series of four major periods of ice-sheet formation can be recognized by the deposits they left behind, as well as by their effect on relative levels of land and sea and on river valley formation. Such a scheme has in fact been proposed for Africa in which four major pluvials (periods of increased rainfall) provide the counterpart of, and have been tentatively correlated with, the northern ice advances. The names proposed, Kageran, Kamasian, Kanjeran and Gamblian, were based on sites in East Africa where evidence was believed to exist for former relatively wet periods, and by tacit agreement these names had been extended throughout the continent wherever evidence of a wetter climate of the right order of age had been found. The validity of such long-distance correlation, based on climate rather than stratigraphy, has, however, been challenged by R. F. Flint and H. B. S. Cooke, as also has the climatic interpretation of the deposits themselves. At the fourth Pan-African Congress on Prehistory in 1959 it was agreed that the notion of a Kageran pluvial should be discarded, while Flint recognized evidence of only a Gamblian and a pre-Gamblian pluvial and two post-Gamblian minor wet phases (Makalian and Nakuran).

In Central and West Africa the evidence for past climatic change is meagre and not easily interpreted. The major river valleys such as those of the Zambezi and Congo and lesser rivers (Kalomo, Bembesi and Volta) display terrace formation which may, in part, be a result of climatic fluctuations. Evidence of former higher rainfall is to be found in the distribution of ferricretes in areas where the rainfall required for their formation is now inadequate, while considerably drier conditions are suggested by the successive redistributions of wind-blown sands. At Kalambo Falls in Northern Rhodesia, examination of fossil pollen grains has shown that part of the lake deposits containing Acheulian camping sites was formed when conditions were considerably cooler and wetter than today. In the present state of knowledge, however, there is a general tendency not to attempt long-range correlation, particularly on the basis of climatic fluctuation which, even when clearly established in one area, does not necessarily hold good for other regions at the same time.

Pre-Chelles-Acheul Pebble Cultures.—A culture stage, preceding the great hand-ax complex, in which the surviving tools consist solely of simply split or flaked pebbles, was first recognized by E. J. Wayland in 1919. Its distribution is now known to be very wide in Africa, sites occurring sporadically from Ain

Hanech in Algeria as far south as Durban in Natal and the Vaal river. Two forms of the culture have been identified: the Kafuan and the Oldowan. The first, which is generally considered to represent an earlier stage than the Oldowan has been subdivided into four stages showing a development from the simplest form of split pebble to more complex forms in which several flakes are removed to provide a sinuous cutting edge; but it is doubtful if such a subdivision is really justified. At Olduvai gorge in Tanganyika Leakey has shown that the Oldowan pebble culture is truly ancestral to the Chelles-Acheul stages that follow.

In Southern Rhodesia pebble tools have been found in the 40–50-ft. terrace of the Hunyani river at Lydiate, clearly stratified above a terrace containing fresh hand axes and derived pebble tools. In the Zambezi valley near Livingstone, pebble tools of Oldowan type and large thick flakes occur heavily abraded in the older gravels I alongside hand axes in a fresher state of preservation. This suggests that the former have been derived from still earlier deposits which have been completely eroded away and incorporated in the older gravels. Other sites exist in Northern Rhodesia at Ngwezi and Kalomo.

Farther north in the Katanga province of the Republic of the Congo, G. Mortelmans has recorded rich sites on the Kundelungu plateau, west of Lake Mweru and in the Kafila river basin. To the west, specimens are recorded by Leakey from the region of the diamond workings at Dundo in Angola. Northward one enters the region of tropical forest which seems to have been avoided by earliest man. If pebble tools exist along the northern fringe of the forest belt they have not yet been recorded with the exception of rather dubious reports from Ghana. Fossil remains of this period are known only from north Nyasaland and southeast Angola, and no human remains are known. The evidence of the Transvaal caves and Olduvai gorge suggests that the makers of the pebble tools may have been of the Pithecanthropine type.

Chelles-Acheul Culture.—The human workmanship of some of the earlier stages of the Kafuan has been questioned by certain authorities, but there is no doubt that the Oldowan-type tools are the work of man or that they are an early stage in the development of the hand-ax cultures. The transition is clearly seen at Olduvai and less clearly in the Vaal river; Kalomo in Northern Rhodesia has also yielded what may well be transitional types, though good stratigraphical evidence is lacking at this site. From the fine stratigraphy of Olduvai and the Vaal it is known that a number of valid stages of the Chelles-Acheul culture exist, though in Central and West Africa no such long stratigraphic sequence is known and the best that can be done is to assign individual sites to early middle or late Chelles-Acheul on typological grounds.

The environment favoured by these early hunter-gatherers seems to have been that of the major and minor river valleys in reaches that cut across fairly open savanna country. Thus the equatorial forest belt is again lacking in finds of this period and even the more densely wooded savanna of the plateau regions appears to have been generally avoided. The period is well represented in Southern and Northern Rhodesia and in the eastern regions of the Congo. Northeastern Angola has yielded a few sites, and a few specimens are known from the lower Congo. In Nigeria Acheulian sites are as yet only known from the mines field area within 80 mi. of Jos. It is quite likely that the environment of the Guinea coast was unsuitable for occupation by hand-ax man, but as little or no field work has been done in this area it would be unwise to say more.

The most important site of Early Stone Age date from the area is undoubtedly that at Kalambo falls discovered by J. D. Clark in 1953. There an almost unbroken succession of camping sites is preserved in the accumulated lake deposits covering the period from an evolved stage of the Acheulian almost to the present. The Acheulian floors uncovered have yielded vast quantities of hand axes, cleavers, cores, hammerstones and flake tools in almost mint condition. But the greatest value of the site lies in the quantities of vegetable remains preserved in the waterlogged deposits. These include a number of wooden implements and sufficient plant remains to be able to reconstruct in remarkable detail the environment in which the hunters lived—an environment then

apparently somewhat cooler and wetter. Careful plotting of the distribution of artifacts on one floor has revealed actual working spots and what may be sleeping places as well as a semicircle of large stones marking the edge of a windbreak—the oldest artificial dwelling known anywhere in the world. Carbon 14 dates from this site give an age of greater than 52,000 B.C. for the Acheulian living floors.

First Intermediate Period.—There is no reason to suppose that there is anywhere more than a purely local break in the sequence of African Stone Age cultures. In fact the evidence strongly supports the notion of a series of evolutionary developments in different regions out of the previously existing cultures. Such changes may be the response to new needs and new potentialities arising from changes imposed by nature on the environment, or the result of pure invention in a relatively static environment. Such a widespread and general change as marks the close of the Chelles-Acheul tradition in Africa, however, suggests strongly that the causes were largely environmental. In Southern and East Africa the first intermediate period is marked by the appearance of the Fauresmith culture in which more refined and smaller versions of the Acheulian continue alongside an increased industry of flake tools and new techniques of stoneworking, in which carefully prepared cores play an important role.

In Central Africa, however, in country that is believed to have been more heavily wooded, a culture appears to which the generic name Sangoan has been given. A few hand axes and cleavers continue the tradition of the Acheulian, but there is a tendency for workmanship to become somewhat coarser. Heavy triangular picks and flat-bottomed choppers, of rostrocarinate form, in which the ventral edges and ends formed the working parts, become important and characteristic elements. Much of the tool kit of Sangoan man appears to be designed for woodworking. Various regional variants appear partly due to the form in which raw material was available, and partly dictated by varying environment and traditions of toolmaking; culture contact no doubt played its part in marginal and outlying regions. In Southern Rhodesia the Bembezi variant has fewer typically Sangoan elements, while in Northern Rhodesia the Zambezi and Luangwa variants appear to be due to differences in the form of the raw material. In Angola and the lower Congo the early manifestations of the Sangoan are remarkably similar to those of the type area in Uganda, but in successive stages these areas develop along very different lines from the Rhodesian Sangoan. Fine lance heads evolve (formerly East African Tumbian) as well as slipper-shaped chisels and woodworking tools. There is a marked encroachment toward the forest areas, until then unoccupied. Little is known of events in Nigeria and the Guinea coast, but B. Fagg makes no mention of Sangoan or Fauresmith tools from Nigeria, and it may well be that the sequence of events in these areas is considerably different. At Kalambo falls the Sangoan has been carbon dated to between 38,000 and 43,000 B.C.

Middle Stone Age.—Moving upward through the cultural succession in Africa, the number of regional variants increases until in the Middle Stone Age there are something like nine or ten throughout the continent. In the area of Central and West Africa there are two, and perhaps three, such variants which to some extent reflect the nature of the underlying Sangoan. In the Rhodesias the form is known as Rhodesian Stillbay. In this the heavy elements of the Sangoan disappear except for a few pebble choppers, and there is a general tendency toward reduction in the size of artifacts. The prepared disk-shaped core is perfected and neat leaf-shaped points appear, both uniface and biface, often displaying some pressure flaking. These were almost certainly hafted as missile heads. Various scrapers and stone balls (possibly missile stones) of reduced size complete the assemblage. The culture has been found in good stratigraphical relationship to other cultures in Southern Rhodesia at Bambata cave and the Khami waterworks site, and in Northern Rhodesia at the Mumbwa caves. The younger gravels in the vicinity of the Victoria falls have also yielded good assemblages. At Kalambo falls the industry shows an interesting blend of Rhodesian Stillbay elements and Lupemban forms more at home in the more northerly and western

regions. This is presumably a reflection of the geographically intermediate position of the site. The famous Broken Hill skull was associated with an industry of the earliest stage of the Rhodesian Stillbay referred to as the Proto-Stillbay. This stage is tentatively dated by Clark to about 38,000 B.C.

To the northwest, in Angola and the lower Congo, as well as in the eastern Congo, the Middle Stone Age is represented by the Lupemban, a culture subdivided by Leakey and Mortelmans into several stages. The stratigraphical evidence for the stages is not good and the division is based mainly on typology. In the early stages a strong element of the Sangoan survives in the form of picks and a few hand axes. These gradually decline in importance and there is a development and refinement of new forms such as chisels, gouges and specialized adzes as well as tranchet axes, scrapers and narrow lanceolate points finely worked on both faces. The later stages of the Lupemban mostly represent a refinement of these various elements. Pressure flaking is used and true blades, sometimes backed, appear. Foliate points are deliberately serrated along to the edges, particularly toward one end, and true tanged points appear. Tranchets assume proportions which suggest their employment as transverse arrowheads. These special refinements appear in the final stage of the Lupemban which in Angola has been carbon dated to about 12,500 B.C.

To the north of the equatorial forest, in Nigeria and the Guinea coast region, information is again scanty. Fagg mentions an undifferentiated Middle Stone Age industry from the mines field area; O. Davies speaks of a "quasi-Magosian" but mentions no true Middle Stone Age from Ghana. He has also spoken of tanged points of Aterian appearance. In 1940, R. Delcroix and R. Vaufray described an industry from Guinea which they compared with the "Tumbian" of Cganda and the Congo. This industry, however, contained a mixture of early and late forms, and cannot be taken as typical of the Middle Stone Age stage in that region.

Second Intermediate Period.—As the Gambian wet phase comes to a close, and during the ensuing dry period about 10,000 B.C. a number of variants of a culture intermediate between the late Middle Stone Age and the true Late Stone Age appear. The tendency toward reduction in size noted in the Rhodesian Stillbay is carried still further in the succeeding Magosian culture to an extent where it clearly indicates that a number of tiny artifacts or microliths were being hafted together in groups to form barbs to spears (and possibly arrows) and to produce composite knives of the kind found at Mt. Carmel in the Natufian. True burins of the kind associated with the Upper Paleolithic and Mesolithic of Europe occur in small numbers, and small punch-struck blades form another new element. These latter are frequently worked into various kinds of microlith such as crescents and backed blades. Two types of special woodworking tool are present: the thick crescent adze and the so-called *outil écaille* ("a gouge" or "flake tool"). The uniface and biface points, triangular and leaf-shaped, continue the tradition of the Stillbay but are generally smaller and often finely shaped with the aid of pressure flaking. Scrapers, drills, mullers and grindstones and the occasional bored stone complete the assemblage. It has been suggested that the culture is the result of a mixture of the indigenous Rhodesian Stillbay, and blade and burin and microlith makers infiltrating from East Africa. Whether this is true or not the Magosian, with minor variations, is the ensuing culture in those parts of Central Africa formerly occupied by the Rhodesian Stillbay. The known distribution appears to be somewhat more restricted than the Stillbay, and this may indicate a greater degree of concentration of population resultant on the deterioration in climate suggested by the redistribution of aeolian sands in and below which the Magosian is frequently stratified.

In those areas in which the Middle Stone Age is represented by the Lupemban the second intermediate period is represented by the final expression of that culture, generally known as the Lupembo-Tshitolian. In a diminutive and refined state many of the ancestral forms of the Sangoan and Lupemban are present. The significant elements are the denticulated and tanged points, backed blades, crescents and trapezes and true punch-struck

bladelets.

Late Stone Age.—In those areas occupied by the Lupembo-Tshitolian the final expression of the full Stone Age is the Tshitolian; a culture which, from its distribution and industrial content, was well adapted to life in the forest regions. The laurel leaf points of Lupemban type remain and leaf-shaped arrowheads, some denticulated, and tanged points are common. There are no true microliths, but tranchets of various sizes, probably transverse arrowheads designed to leave a good blood spore, are abundant. Chisels and gouges reflect an interest in woodworking. In the later stages polished stone axes, adzes and grindstones occur. Occasional finds of pottery suggest contact with food-producing communities. The term Neolithic applied to assemblages with polished axes is inappropriate as this implies food production which is by no means certain. To the south, in Angola, there are differences in that microliths form part of the assemblage, and bored stones are present, probably as digging stick weights, whereas the polished ax is absent. In Katanga the culture shows a blending of Tshitolian and Nachikufan elements. A most important site at Ishango, on the shore of Lake Edward, has yielded a rather crude quartz industry associated with quantities of bone harpoons and barbed points, as well as simple bone points.

Southward over the plateau country of the major part of Northern Rhodesia the culture is known as Nachikufan, the earliest stage of which has been carbon dated to about 4350 B.C. Three stages were established stratigraphically at the type site. In the earliest very small nongeometric microliths are abundant and are associated with trapezes, semicircles and double-backed microliths. Larger elements include grindstones and rubbers, numerous bored stones, bone points and ochre pencils. In the second stage the very small microliths are rare while to the other elements are added hollow and strangulated scrapers and numbers of polished stone adzes and axes. The number of bone points also shows a marked increase. In the final stage the microliths show a closer similarity to the Wilton forms, and the presence of pottery suggests the arrival of immigrant farmers into the area.

In the Zambezi valley the industry is known as Rhodesian Wilton and more closely resembles that of the type site in Cape Province. The forms are mostly rather rough-backed blades, neat lunates and semicircles, some double-backed microliths and a few trapezes. *Outils écailles* and small scrapers are present and polished axes and bored stones are very rare. Two stages are recognized by Clark, the earlier with generally larger microliths and the later with a high percentage of crescent adzes, ostrich eggshell beads and occasional sherds of pottery. A date of about 240 B.C. has been obtained for this later stage. In Southern Rhodesia, in areas close to the Zambezi, the industry is similar to that just described. But farther south an open grassland variant is recognized for Matabeleland and a woodland variant with axes and chopping tools for Mashonaland. The abundant naturalistic rock art of Southern Rhodesia is generally attributed to the Late Stone Age, while in Northern Rhodesia there is some evidence for associating the geometric art of the northern and eastern parts of the territory with an early stage of the Nachikufan culture. In Ghana the Late Stone Age is best represented from the cave of Bosumpra at Abetifi, with a microlithic industry in quartz with lunates, backed blades, burins and simple points. Pottery and polished axes occur in the later stages. Biconically bored pebbles which are abundant in Ghana were also associated. From Rop rockshelter in Nigeria, Fagg has described a similar industry, including a polished ax with hourglass perforation.

Iron Age.—All the cultures thus far described were based on a hunting and food-gathering economy. There is some evidence that Late Stone Age man was taking a marked interest in vegetable foods, but none to suggest that agriculture had been independently discovered. This state of affairs was brought to an end by the movement into West and Central Africa of primitive farmers who brought with them the arts of metal working and pottery manufacture. Evidence for the physical type of these people is not incontrovertible. There is no doubt that in a number of areas the Negro element was strong, and it is probably this which has contributed so much to the make-up of the present Bantu-speaking

tribes. But at Bambandyanalo in the Transvaal a culture of early Bantu type is associated with a very definitely non-Negroid population. This may, however, be an example of culture borrowing by an indigenous stock.

In Southern Rhodesia the earliest Iron Age tradition, which precedes the great ruins complexes, is marked by the fairly widespread occurrence of thick but well-made pottery decorated predominantly by comb impressions. Other elements in the culture are clay figurines, mainly human, but with some animals, clay spoons and possibly some very rough terracing in the Inyanga area. Storage pits have been located and fragments of the walls of pole and daga huts, but the houses themselves had not, by the early 1960s, been identified. From the exclusive occurrence of stamped ware in many of the ancient mines in Southern Rhodesia it would appear that these people were responsible for the mining of gold, and possibly copper and tin also. Recent work in Northern Rhodesia suggests strongly that, over much of the southern part of the territory at least, the same stamped ware tradition forms the substratum of the Iron Age there. Sites in the south of Barotse-land have produced carbon 14 dates of around 400 A.D. for this stage. In the north of the territory, at Kalambo falls, the earliest pottery is more closely allied to the "dimple-based" tradition which is widespread throughout Ruanda-Urundi, in Kenya and as far west as the lower Congo basin. The stage is carbon dated to the 11th century A.D. at Kalambo falls.

In the northern Transvaal and throughout Southern Rhodesia there exists a great complex of stone ruins. These mark the beginning of a new phase in the Iron Age. The earliest of these are probably Zimbabwe and Mapungubwe, whose origins have been carbon dated to approximately the 8th and 12th centuries A.D. respectively; though the date for Zimbabwe is questionable and a date nearer the 14th century may be more accurate. Zimbabwe itself, despite the romantic tales that have grown up about it, is probably the kraal of a paramount chief, possibly connected with the Monomatapa empire. Buildings of different periods are distinguished and the latest of these probably dates from the 17th century A.D., approximately contemporary with the ruins complexes of Inyanga, Khami, Dholo-dholo and Nalatali. Little is known of the origins of the ruins builders, but they possibly represent the first of a series of migrations whose epicentre may have been in the southern Congo basin.

In West Africa the earliest Iron Age culture, the Nok figurine culture, is best known from the tin mines of the plateau mines field area. The most striking features are the beautifully naturalistic clay animal figurines and the more stylized human figurines, mostly heads. These appear to have been made in clay molds possibly formed around a wax model as in the *cire perdue* method of bronze casting. With the figurines are found evidence of iron smelting, polished stone axes and one iron ax, pottery, stone ornaments including ground quartz beads, and bored stones (possibly digging stick weights). The current estimate of its chronology, based on radiocarbon measurement, is that it flourished from soon after 1000 B.C. to around 200 A.D. Its origins and its influence on subsequent events are obscure.

To the west of Nok the finds of finely cast brass, and terracotta heads and figurines at Ife and Benin appear to belong to related kingdoms ancestral to the modern Yoruba. The differences in style between the Ife and Benin products are considerable and support other lines of evidence suggesting that Ife is the earlier and probably ancestral to Benin. The Ife bronzes are probably to be dated to between A.D. 1000 and 1500, and those of Benin to the 16th, 17th and 18th centuries. (R. R. IN.)

D. EAST AFRICA

Much information about the Stone Age sequence of East Africa is derived from studies of the Rift valley. High terraces above the Rift valley lakes point to their extended area in Quaternary times. Partly from this evidence it has been deduced that there was a series of pluvial periods during the Pleistocene, followed by two postpluvial wet phases, each separated by a period of drier conditions. Prehistoric industries and cultures have been correlated with these climatic phases, but attempts at wider cor-

relations throughout Africa and with glacial and interglacial phases in Europe must still be regarded as tentative.

Pebble Culture.— The existence of the Rafuan pebble culture in East Africa, as well as in other parts of the continent, has been questioned; it seems probable that some of these crude pebble tools were fashioned by natural agencies. The later Oldowan pebble tools, however, are undoubtedly of human workmanship. First recognized in the lowest bed of Olduvai gorge (Tanganyika), they date from the Kamasian pluvial period in the early part of the Middle Pleistocene. The pebble culture occurs also in the Kagera valley and other parts of Uganda, as well as in western Kenya, notably at Kanam on the Kavirondo gulf of Lake Victoria, where pebble tools were said to be associated with the Kanam jaw.

Chelles-Acheul Culture.— During the third or Kanjeran pluvial, the Chelles-Acheul hand-ax culture is found in Kenya, Uganda and Tanganyika. Its evolution, including its development from the Oldwan pebble culture, is clearly shown at Olduvai gorge, where thousands of implements as well as numerous fossil mammal remains are preserved in successive lake beds. In 1959 the skull of an australopithecine was found together with Oldowan tools, and associated with the following Chellean stage was a butchering site where the gigantic fauna had been driven into a swamp and dismembered with hand axes and cleavers. Hand axes reached their peak during the Acheulian stage, represented at many sites in East Africa besides Olduvai. Among these are Nsongezi in Uganda; Isimila Karongo in Tanganyika; Kariandusi and Ologesailie in Kenya. At all of these sites implements exist in great profusion; and at Ologesailie they are accompanied by fossils of extinct mammals similar to the gigantic fauna of Olduvai.

The Chelles-Acheul was succeeded by the Fauresmith culture during the first intermediate period in Kenya as it was in Southern Africa. The Fauresmith appears to be confined to high altitudes; it is supposed that the camps belonging to this culture were situated beside streams that would continue to flow during the drier period which followed the Kanjeran pluvial.

Middle and Later Stone Age in Kenya.— During the time of the Gamblian pluvial, the regional specialization of Middle Stone Age times is as noticeable in East Africa as in other parts of the continent. In Kenya two main industries are said to have existed side by side. One is the Stillbay, which is found over most of the drier country of eastern Africa; the other is a blade and burin industry named the Kenya Capsian, which is exclusive to the Rift valley but similar in certain respects to the supposedly much later Capsian industries of North Africa. At Gamble's cave near Elmenteita human burials associated with an Upper Kenya Capsian industry are said to be of Caucasoid type. The implements include backed blades, lunates (crescent-shaped arrow or harpoon barbs), burins, scrapers and other tools all made of obsidian, as well as hone awls and harpoons. It is also claimed that two small fragments of pottery found in the excavation were associated with this industry. The whole assemblage would be regarded as typically Mesolithic in Europe; the bone harpoons are similar to those of the Ishangian culture of Lake Albert, which is dated on extrapolated radiocarbon evidence to about 6000 B.C., a date much later than that previously suggested for the Upper Kenya Capsian but more convincing if the association of pottery with the industry is accepted.

In Uganda the most widespread culture of Middle Stone Age times is the Sangoan, first discovered at Sango bay on Lake Victoria. At Nsongezi on the Kagera river it immediately succeeds the Chelles-Acheul culture and is characterized by rough hand axes and heavy picks. During the succeeding Lupemban and Tshitolian stages of the Later Stone Age, beautifully flaked lance heads and tranchets appear both in Uganda and in the Kavirondo district of western Kenya. The Magosian of the second intermediate period was also first discovered at a water hole named Magosi in Karamoja, eastern Uganda. The industry includes points of the Stillbay type, little tortoise cores and microlithic tools of various kinds as well as grindstones and a perforated stone.

During Late Stone Age times tools tended to become increas-

ingly smaller, notably in the Wilton industries which are widespread in East Africa, particularly in less heavily forested areas. Some Wilton sites are found in the open, others in rock shelters and others again accompanied by huge shell middens beside the shores of Lake Victoria! where they are associated with heavily built skeletons with skulls of Bushman type. In parts of Tanganyika Late Stone Age industries have been found which are clearly closely related to the Nachikufan of Northern Rhodesia.

Rock Paintings.— Little in the way of rock art has been discovered in Kenya and Uganda other than very late paintings and engravings. In Tanganyika, however, there are a large number of painted shelters, particularly in the neighbourhood of Kondoa. Many different styles have been distinguished and some are associated with an industry similar to Northern Rhodesian Nachikufan. Some of the naturalistic animal paintings are comparable to those of the Rhodesias and South Africa.

Neolithic.— The earliest Neolithic culture so far discovered in East Africa stems from the Elmenteitan, which includes long, two-edged blades and sophisticated pottery. It developed during the first postpluvial wet phase into the Hyrax hill variant of the stone bowl culture, of which three other later variants have been distinguished: Gumban A, Gumban B and Njoro River cave. The last has been dated by radiocarbon to about 960 B.C. These cultural variants are distinguished by different forms of stone bowl, ranging from shallow platters to deep basins, and by distinctive methods of burial. At the Njoro River cave cremation was practised. The skulls are all of Caucasoid type and show no trace of Negroid features. The assemblage includes many beads, a carved wooden vessel, pestles and grindstones, bone pendants and awls, basketwork and plaited cord.

Iron Age.— Few Iron Age sites in East Africa had been excavated by 1960 and problems of dating had yet to be resolved. At Hyrax hill near Nakuru (at the same site where the earliest variant of the stone bowl culture was distinguished) an Iron Age village and cemetery was excavated. The village included large horse-shoe-shaped enclosures and hut circles: cowrie shells and water pipe bowls in the midden show that trade with the coast had been established. In Uganda there are remarkable earthworks of which the most extensive is Bigo on the Katonga river. These constructions, which were presumably large cattle kraals, are attributed to the legendary Bachwezi, probably a Hamitic tribe which established an empire in Uganda. Nearby at Ntusi, are huge middens containing animal bones and potsherds— some of which are predated. Other large middens with innumerable potsherds occur at Kibiro on the eastern shore of Lake Albert. (C. V. R. L.; S. M. C.)

The Horn.— Since the earliest evidence of man's presence in the Horn (Eritrea, Ethiopia and Somalia) the climate at its best seems never to have been more than semiarid. Doubtless the more even distribution and small increases of rainfall during the pluvial periods had an important effect on the vegetation pattern and the surface water supply, yet only the Ethiopian high plateau was ever especially inviting to permanent settlement and food production. This predominantly dry ecology, therefore, had an important effect on the human population, and before the end of the Middle Pleistocene the Horn appears to have been unoccupied by man and was probably heavily covered with thicket vegetation. About 100,000 years ago, however, groups practising a stone culture (Acheuleo-Levallois) intermediate in form between that of the Early and the Middle Stone Age are found in the northern parts, particularly in former British Somaliland. Finely made hand axes, both pointed and pear shaped, cleavers and stone balls are found associated with numerous flake tools struck from large, circular, radially prepared Levallois-type cores. From then on there was continuous occupation and many stone implements have been collected from the widely eroded Pleistocene deposits. The material most commonly used was a fine chert but sometimes quartzite was employed and, in the Danakil rift and on the Ethiopian high plateau, fine-grained lavas and obsidian from volcanic rocks.

By the falling out of the heavier hand-ax elements, human culture, during the more favourable conditions pertaining in the Horn during the last or Gamblian pluvial, passed through an unspe-

cialized Middle Stone Age (Levalloisian) using flakes with little secondary trimming and comparable to the contemporary form in Egypt. There followed from this a fully bifacial phase (Somaliland Stillbay) where the flakes were worked by controlled percussion and pressure on one or both sides to form projectile points, knives and scrapers of various kinds. The points, scrapers and crudely backed flakes are similar in technique of manufacture and typology to those from East and Southern Africa, as also is the prepared core technique employed for striking the primary flakes. This culture phase shows affinities with the eastern and southern parts of the continent and it may be that the onset of drier conditions had severed the link with northeast Africa though still preserving that to the south.

By the end of Pleistocene times, about 10,000 years ago, there is evidence of a blade and burin (chisel) element in the north, particularly in the former British protectorate and the Mijiurtein, which was probably derived from southwest Asia via the Red sea hills. Large as well as microlithic blades were struck from cores of black Eocene chert, and finished implements were angle and *bec-de-flûte* burins, single and double end scrapers and straight-backed microliths often with basal retouch. This industry was contemporary with a diminutive and evolved form of Middle Stone Age (Magosian) in the Danakil rift and the southern parts of the Horn. Perhaps this intrusive culture (Hargeisan) was brought by long-headed Hamitic peoples, whose fossil remains have been found in Kenya in association with similar Stone Age cultures both contemporary and earlier than this time. Unfortunately in the Horn no human fossils except comparatively recent ones have been discovered, with the exception of a jaw fragment said to show Neanderthal characteristics and to be associated with a final Middle Stone Age industry in the Porc Epic cave near Diredawa.

After the end of the Pleistocene, connections seem to lie essentially with northern Africa. The so-called Neolithic wet phase in the Sahara, probably lasting from the 5th to the 3rd millennium B.C., permitted Saharan forms of hollow-based and other types of pressure-flaked arrowheads to enter the Horn, probably brought by immigrants from the eastern desert who settled in central and southern Somalia. It is not impossible, on the other hand, that the hollow-based Neolithic arrowheads with shallow hollowing (not the deeply notched and winged forms) may have developed in the Horn from the triangular points of the later Middle Stone Age but, whether this is so or not, the existence of these hollow-based and other forms in both the Sahara and the Horn points to clear connections between the two regions at this time.

There is nothing as yet to show that these people were food producers and they must still have relied on hunting and collecting for their food supply. At a time not yet determined but perhaps in the 3rd or early 2nd millennium B.C., when the drying up of the pastures in the central Sahara drove cattle-owning peoples there to seek fresh country for their stock, pastoralists entered the eastern parts of the Horn. Rock paintings near Harar and Diredawa in Ethiopia and in former British Somaliland depict herdsmen with long-horned, humpless cattle. The style of painting is similar to the later Saharan styles and the people seem to be of Hamitic stock with similar weapons and clothing to those seen in the Sahara paintings.

No settlements of these people have yet been found, unless they can be associated with some of the microlithic industries in the rock shelters in the northern part of the Horn. This is hardly surprising since they were nomadic pastoralists, but some of the "Galla graves" (stone cairns for burial and other purposes that are found throughout the dry areas of the Horn) may date back to these times, though the majority are undoubtedly much later. Some of these people may also have practised a simple form of millet agriculture but the majority are likely to have been purely nomadic as are most of the modern Somali Danakil-speaking peoples. The Egyptian expedition of Queen Hatshepsut (1501-1479 B.C.) to the land of Punt, which most writers are agreed is the northern Somali or Eritrean coast, shows that Hamitic and Negroid peoples, long- and short-horned cattle and evidence of cultivation were present there by that date.

Little is known of the prehistoric archaeology of the Ethiopian

high plateau and Eritrea but it is likely that it was there that cultivation of food plants was first introduced south of the Sahara. Barley, millet and sorghum may have gone south down the Nile (the Khartoum Neolithic dates to 3253 ± 415 B.C., by radiocarbon dating) or across the southeastern desert during the 3rd millennium or possibly even the late 4th millennium B.C., but this is not yet proven.

Obsidian blade industries with pottery exist in the Tigre (at Quiha and elsewhere) but their date is unknown. Polished axes and adzes have been found in western Ethiopia. Similar forms associated with maceheads, stone palettes and pottery having affinities with the C group culture of Nubia have been described from Agordat in Eritrea and would seem to be the products of a sedentary and fully agricultural economy for which an early to middle 2nd millennium B.C. date is suggested.

By the early centuries of the Christian era, however, the camel and zebu or humped cattle (which have now quite superseded the long- and short-horned breeds in the Horn) are believed to have been introduced by Himyaritic peoples from southern Arabia, depicted in most of the later paintings and engravings there.

These Arabian peoples crossed the Red sea during the 1st millennium B.C. and gradually occupied the northern part of the highlands, intermarrying with the Hamitic peoples and forming the kingdom of Aksum (Axum) which apparently covered what is now the Tigre province. The earliest record of this kingdom is in the first century A.D. Ironworking probably spread to the Horn from the kingdom of Meroe on the upper Nile sometime after 500 B.C., but it is not known whether bronze or copper was smelted there prior to that time. Greek sailors from Egypt had reached the Eritrean coast in the 3rd century B.C., probably in search of elephants for the Ptolemaic army. By the 1st century A.D. the king of Aksum controlled the ivory, and probably the incense trade also, on that coast and by the 3rd century most of the northern part of the Horn seems to have been conquered. It may have been this process of subjugation of the indigenous Ethiopian peoples to the kingdom of Aksum that set off movements of Hamitic and Negroid peoples into the southern parts of the continent. While, therefore, during the later Pleistocene the cultural connections of the Stone Age peoples in the Horn were with East Africa, from the end of that time onward they have been linked more particularly with northeast Africa and southern Arabia. See ETHIOPIA, ANCIENT. (J. D. CL.)

E. NORTH AFRICA

In recent years the archaeology of North Africa has assumed a detailed aspect and general importance in human history unsuspected heretofore, and as a result in part of its geographical position as a link between Asia, tropical Africa and southwestern Europe. Ecologically it subdivides into well-defined territories whose geographical pattern in turn has conditioned both its history and its prehistory.

The most important territory for human occupation is the Maghreb, the Africa Minor of the ancients. This comprises the western half of the Mediterranean littoral and consists essentially of the Atlas massif and coastal plain from Morocco to Tunisia. The mountains cause the Atlantic westerlies to drop their moisture mainly on the northern slopes and narrow coastal plain, where under natural conditions the vegetation would be of Mediterranean evergreen and maquis type, as surviving patches show. Rainfall on the southern slopes of the massif is sufficient to maintain desert scrub fading into true desert in the Saharan plain to the south. A small appendage of the Maghreb area of fertility is formed by the high ground of northern Tripolitania, but eastward for about 600 mi. along the shores of the Gulf of Sidra (Sirte) the desert reaches practically to the sea. A second small coastal area comparable in fertility to the Maghreb is the Jebel Akhdar of northern Cyrenaica. Though much smaller in extent it is of importance ecologically as providing a natural staging post halfway between the Maghreb and the Nile.

A quite different ecological role is played by the Nile valley which constitutes the only permanent corridor of access between central Africa and the Mediterranean. A much more tenuous line,

revived in classical times by the introduction of the camel. runs from northern Tripolitania to the Niger bend via the central Saharan highlands. The latter consist of a system of volcanic outcrops and tectonic ridges extending from the Ahaggar in the centre southeastward along the Tummo ridge to Tibesti and ultimately to Darfur. At the present time this feature has only minor climatic consequences. but its importance in the past during periods of over-all increased precipitation is proved by a remarkable relict fauna and flora including such species as crocodile, Asiatic cobra and a conifer that could not possibly spread to the area under prevailing conditions. One such period of greater rainfall certainly occurred during the Middle Acheulean and enabled human settlements to extend far over regions now totally uninhabitable for lack of water; and a second of less pronounced character during the diffusion of pottery and other traits associated with the Neolithic of the 4th and 3rd millenniums B.C.

Signs of other fluctuations of minor and perhaps regional importance have been reported, but the attempt made by some investigators to construct an ambitious scheme of pluvials and interpluvials, and to correlate it with European glaciations must be regarded as quite hypothetical as yet. However, some more direct indications of such correlation can be derived from the combined study of ancient marine shorelines and vertebrate paleontology along the northern littoral. The most ancient certain traces of man in northern Africa consist of cores (possibly tools) and flakes accompanied by a rich Lower Pleistocene (Villafranchian) fauna, discovered at Ain Hanech, Algeria, in 1948. Their age is thus as great as that of the earliest certain human industries in any part of the world, and in particular may be compared with the oldest horizon (Bed I) at Olduvai gorge in East Africa of comparable typology and associated with the remains of *Zinjanthropus*, the most primitive probable hominid known by the early 1960s. The second stage in the North African archaeological succession is represented by a somewhat archaic Middle Acheulean, in which the usual pointed types of hand axes are associated with true cleavers of central African type. The absence of any traces of the earlier precleaver stages in the hand-ax tradition such as those recorded at Olduvai (Bed II) and elsewhere south of the Sahara may well be taken to indicate a severance of the western trans-Saharan route at this time; although such industries do occur in the Nile valley, they are unknown farther west.

The most notable occurrence of the Middle Acheulean in question is at Ternifine in northern Algeria, where it is dated by an early Middle Pleistocene fauna with Villafranchian survivals including sabre-toothed tiger, a giant wart hog and an extinct cynocephalous ape. Also associated are the only known human fossils definitely attributable to this culture stage. They comprise three admirably preserved mandibles and a parietal, and show anatomical affinities to *Pithecanthropus*, the earliest human strain of the far east. They also exhibit some novel features especially in the dentition, on the strength of which their discoverer C. Arambourg proposes separate generic status under the name *Atlantropus*, though most authorities agree that no more than specific differentiation from *Pithecanthropus* is indicated.

Apart from the character of the associated fauna, the age of the Ternifine stage is supported by geological evidence from the Sidi Abderrahman quarries near Casablanca, Morocco. There an identical industry is included in a beach deposit underlying an apparently unwarped strand line at +30 m. attributed by most authorities to the Tyrrhenian I or great interglacial stage. If this correlation is correct it would follow that Ternifine belongs at latest to the equivalent of a Rindel interstadial or more probably the preceding (antepenultimate) interglacial. This date, if transferred to East Africa on the basis suggested above, would suggest a Lower Pleistocene date for *Zinjanthropus*, as his evolutionary status would seem to demand if he is to be regarded as a true human ancestor. It would also be in accord with a recent reassessment of the Bed I fauna at Olduvai as of Lower Pleistocene (Villafranchian) rather than Middle Pleistocene, as previously supposed.

The final stages of the Lower Paleolithic in the western Maghreb are represented at Sidi Abderrahman also by an evolved

Acheulean associated with human fossils believed to indicate a later, more developed form of *Atlantropus*. They are dated stratigraphically as post-Tyrrhenian I (most probably the equivalent of Riss) and paleontologically by the presence of some intrusive Eurasian species. The latter were absent from the Acheulean fauna, which had been of purely African character, but are a regular feature of the biotope associated with the subsequent Middle Paleolithic culture stage. In eastern Tunisia the great length of duration of the hand-ax tradition is shown by the inclusion of typical hand axes in deposits which were warped by tectonic movement on a large scale before the beginning of the Middle Paleolithic. While the fauna associated with the Middle Paleolithic of the Maghreb and Cyrenaica clearly indicates that the east-west corridor along the coast was still biologically viable, there are indications that movement of men and animal species across the Sahara from north to south was considerably less than in Lower Paleolithic times. It is interesting to note that detailed observations in the Nile valley give geological evidence also that desiccation of the later Pleistocene made itself first felt in the south. The apparent effects of this change can be seen in several ways.

In Kharga oasis in the extreme southeast of the Sahara the passage from the final Acheulean hand-ax tradition to the most evolved Middle Paleolithic flake tradition, with a highly evolved technique of cores prepared in the Levalloisian style, is a gradual process with many terms of transition and spread over a long period of climatic change. The same type of gradual evolution is a regular feature of tropical Africa and the Nile valley. Farther north in the Jebel Akhdar the later terms only of this sequence are known, and have recently been shown to be superimposed, not on an Acheulean substratum as at Kharga, but on an early horizon otherwise unique in the African continent, consisting of flake blades and burins. This newly discovered tradition finds its nearest affinities with a flake-blade culture in the Levant known as the Pre-Aurignacian and geologically dated there to the last interglacial. Marine shells associated with the Cyrenaican variant suggest a similar date.

The overlying Middle Paleolithic in both Cyrenaica and Palestine is similar and known as Levalloiso-Mousterian from the combination in it of the two traits of a miniature type of Levalloisian core technique together with various tools finished by unifacial trimming like those of the Mousterian of Europe. This complex tradition is associated both in Cyrenaica (at the cave of Haua Fteah) and Palestine with fossil human remains of Neanderthaloid type sharing a number of peculiarities not known elsewhere, and incidentally contrasting in almost every detail with the corresponding features of *Atlantropus*. It is dated by radiocarbon in both areas to between 35,000 and 50,000 B.C.

The situation in the Maghreb is different again. Earlier facies of the Middle Paleolithic have left few if any certain traces, and there is so far no clear indication of a parallel evolution of this stage out of the preceding final Acheulean. The overwhelming majority of Middle Paleolithic finds belong unquestionably to a single pattern termed the Xterian. This contains all the main features of the Levalloiso-Mousterian coupled with additional elements of a still more specialized kind, above all the device of a carefully contrived hafting projection or tang, clearly implying that many of the tools and weapons were mounted in handles and shafts. A significant feature is the sporadic use of bifacial trimming, sometimes for the manufacture of small hand axes, but sometimes so fine as to indicate a true pressure-flaking technique comparable with that of the Solutrians of Europe. Over a restricted area in the extreme west of the Maghreb the application of this method to the production of tanged points led in the very latest Aterian to a form virtually indistinguishable from Neolithic or Bronze Age arrowheads. Remarkably similar forms occur in the Solutrian of southeastern Spain and it seems not improbable that culture contact in some form was established across the Straits of Gibraltar at this time. If so we have an implied date of about 16,000 B.C. for the final Aterian in the Tangiers-Morocco region. An earlier stage of this tradition in the same region (at the cave of al-'Aliya) is associated with fragmentary human fossils which

appear still to show some of the peculiarities of *Atlanthropus* in attenuated form; and are almost certainly distinct from the Neanderthaloids of Cyrenaica.

A working theory might be postulated on the strength of these observations as follows: The final Lower Paleolithic in both Cyrenaica and the Levant during the last interglacial is characterized by the appearance in both areas (sporadically in the latter and in isolation in the former) of flake blades. This stage is overlaid in both areas by an identical variant of evolved Middle Paleolithic, the Levallois-Mousterian, most probably of ultimate Central African origin and spreading northward along the Nile valley to fan out east and west along the Mediterranean coast. During this time a residual Acheulean may well have survived in the Maghreb, cut off by growing desiccation from the south, and undisturbed until reached by the westward spread of the Levallois-Mousterians along the coast. Culture contact between these and the final Acheuleans to produce the Aterian would not contradict the typological evidence as it stands, and would accord well with such elements as the bifacial technique. Finally, it may be noted that both in Cyrenaica and in Kharga the final term of the Middle Paleolithic succession is in fact supplied by Aterian of a moderately evolved kind.

In eastern North Africa the earliest true blade and burin assemblage of undoubted Upper Paleolithic type occurs in the form of an industry with both primitive backed blades and steep scrapers comparable to the corresponding initial stage of the Upper Paleolithic in the Levant, the Emiran. It is found in the Haua Fteah where it abruptly succeeds the Levallois-Mousterian at or shortly before 32,000 B.C. according to the radiocarbon dates. In the Maghreb not only are all traces of this early tradition lacking but it has been seen that the final Aterian may well have survived as late as the 18th millennium. True blades and burin industries there fall into two classes known respectively as the Oranian (or Ibero-Maurusian) and the Capsian. Contrary to what was at first suggested on purely typological grounds, the Oranian now proves to be very much the older, as well as by far the most widely spread. It is found along the whole coastline and penetrates some distance inland in both Morocco and Tunisia, and has been identified in Cyrenaica where it replaces the earlier Emiranlike tradition about 14,000 B.C. Typologically it is distinguished above all by the immense preponderance of small backed blades over all other tool forms. The date of its substitution for the Aterian in the Maghreb is not yet precisely known but certainly antedates the 10th millennium, a date obtained for an evolved variant at the cave of Tatoralt in Morocco.

Human remains are relatively common with the Oranian and extremely uniform in character; they belong to the Mechta al-Xrbi type. The sudden appearance of the Oranian clearly indicates an incursion into northern Africa on a large scale, and the recent discovery in eastern Spain of a skull dated to the Solutrian showing all the peculiar features of the Mechta al-Arbi type provides a clue to the source of this immigration. In many traits the Oranian closely resembles an impoverished version of the Magdalenian IV of southeastern Spain, for which a date in the 15th millennium B.C. is probable.

The Capsian, once thought to typify the Upper Paleolithic of northern Africa, is now known to be wholly postglacial in date and is only certainly known from a very restricted area in southern Tunisia. It differs from the Oranian in displaying a far more varied tool kit distinguished by large, backed blades and burins in its earlier phase and a gradual development of geometric microliths later. These become its leading feature by the 6th millennium B.C. when they seem to have been transmitted to the final Oranian groups along the coast. Its origin is still obscure but has been sought in an Epi-Gravettian tradition which seems to have survived down to a late period in Sicily and the Sicilian islands.

In Cyrenaica the final Oranian is replaced by 5300 B.C. by a blade and burin tradition resembling an impoverished Capsian without the microlithic element, which shortly afterward, by 4000 B.C., displays signs of contact with the early Neolithic (Fayum A) cultures of Egypt in the form of pottery, pressure-flaked tools of distinctive types and domestic goats or sheep. The pottery is

for the most part plain self-coloured and burnished, and doubtless ultimately of Levantine inspiration.

West of the Gulf of Sidra the earliest evidences of pottery and domestic animals, accompanied by certain changes in the flintwork, follow a different pattern. Widespread adoption of final Capsian microlithic forms, notably the trapeze and scalene triangle, are coupled with small pressure-flaked types such as stemmed arrowheads. This Neolithic of Capsian tradition has a wide extension in space and time; it occurs far south of the Maghreb into the western Sahara and down the Atlantic littoral to tropical West Africa. Its earliest dated occurrence in the Sahara goes back to the 4th millennium B.C. (Meniet) and echoes of its influence can still be detected at the time of the earliest introduction of iron into West Africa.

In the Maghreb itself two distinct provinces can probably be detected: (1) a northern coastal variant with undecorated pottery and virtually lacking in arrowheads and (2) a southern variant with impressed pottery of a type found virtually throughout the Sahara, abundant arrowheads and above all associated with a remarkable style of rock engraving. The latter generally takes the form of large-scale figures of animals or scenes with human figures grouped on slabs near water holes or shelters. Many of the human figures show details of dress, hairstyle, etc., reminiscent of those of the ancient Libyans in contact with Egypt during the 2nd millennium B.C. These occur in a well-studied cluster of sites in southern Algeria; sometimes in connection with curious figures of a ram wearing a round object on its head with snakelike projections recalling the well-known symbol of Amon. In a second large group of sites in the Fezzan district of southern Tripolitania further evidences of Egyptian influence include copies of the Bes design. Scattered finds of a seemingly degenerate version of this style occur as far south as the Ahaggar, but more characteristic of this southern area is a different style of remarkable rock paintings showing numerous human figures engaged in hunting, herding cattle, dancing, etc. The distribution of these overlaps with the engravings in the Fezzan and vicinity to the west. There a clue to the age of the former is afforded by representatives of chariots of almost certainly first millennium date, not improbably to be identified with the Garamantes of Herodotus.

Southeastward the distribution of these paintings can be traced along the high ground to Tibesti, and thence via Aweinat and the Gilf Kebir to the southern confines of Egypt and Nubia. Impressed pottery of Saharan type was in use there during the middle kingdom but an earlier centre of diffusion of pottery making of probable 4th millennium dates occurs in the Old Khartoum culture of the Sudan. The latter shows some possible signs of influence from the Neolithic of Capsian tradition in the flintwork but elsewhere, along the southern Sahara as far west as the Air, Egyptian influence is evident in the stonework generally.

Egypt.—The earliest phases of Egyptian prehistory are recorded in the system of ancient terraces of the Nile which reflect its geological history from late Tertiary times to the present. The earliest cultural remains belong to an early stage of the hand-ax tradition comparable to the remains from Olduvai (Bed II) in East Africa, before the first appearance of the cleaver. It is remarkable that this latter form so common in the later stages in East Africa and western North Africa should be virtually unknown in Egypt throughout the long development of the hand-ax tradition there. While an explanation may be sought in part in local peculiarities of raw material, almost exclusively flint, it seems also to be in part a reflection of the cultural autonomy which characterizes the Egyptian sequence in general.

Hand axes make their first appearance in the 100-ft. terrace of upper Egypt together with rarer pebble tools, and last through the period of the 50-ft. down to the 30-ft. stage when Middle Paleolithic flaking techniques begin to be associated with them. In lower Egypt a pure Acheulean occurs in a terrace at about 80 ft above the Nile which can probably be equated with the Tyrrhenian I stage, but no earlier occurrence is known. The gradual emergence of Middle Paleolithic out of an Acheulean industrial context resembles the normal sequence south of the Sahara rather than that of farther west. The general pattern is that of a gradual

reduction in size culminating in a Levallois-Mousterian contained in a terrace of fine silty character which appears to correlate with a low sea level in all probability of Würmian age.

Several workers have sought in the past to distinguish a final stage of all in the upper parts of the silt terrace and subsequently, during which this refined Middle Paleolithic was supposed to have given rise directly to a microlithic blade industry by a process of independent evolution. The reality of this Sebilian industry may now be seriously doubted in view of the pattern of normal Upper Paleolithic spread and development known from the rest of North Africa. Thus it is practically certain that the bearers of the Emiran type of tradition must have passed from Palestine to Cyrenaica across the delta region shortly before 30,000 B.C. A number of undated surface sites of a blade industry, almost certainly a marginal variant of the Oranian, have been recorded from the Faiyum (Fayum) depression in lower Egypt; and there is evidence of acculturation between this indigenous hunting culture and the Faiyum B Neolithic sometime during the early 4th millennium B.C. or perhaps slightly earlier. The latter is clearly a final stage of the Neolithic A tradition established in the area by the 5th millennium and almost certainly ancestral to the initial Neolithic of middle Egypt represented by the Tasian culture. Both derive their principal culture traits in all probability from the somewhat earlier coastal Neolithic tradition of the Levant dated to the 6th millennium B.C. and connected with still earlier food-producing societies in that area. See also *Archaeology* and *History* sections of EGYPT. (C. B. M. MCB.)

F. CARTHAGINIAN AND CLASSICAL

Carthagian. — The Lebu (Libyans) of Cyrenaica were known to the Egyptians and there are traces of Egyptian influence in prehistoric North Africa. But enduring contact between the older civilizations and western North Africa was due to the Phoenicians. The central point of the North African coast, commanding the passage between the continent and Sicily, was bound to attract sea traders opening up the western Mediterranean, and the position of Carthage, on a peninsula offering good opportunities for defense and with a fertile hinterland, had special advantages. The available evidence agrees with the traditional date (814 B.C.) for the foundation of Carthage. Utica, farther northwest, was believed to have been founded about 1100 B.C.

The development of Punic Carthage is indicated by the position of its successive cemeteries. The two lagoons which lie toward its southern end represent the ancient outer and inner harbours and the foundations on the islet in the northern one may be those of the Carthaginian admiralty building. The hill of St. Louis, farther northwest, is the ancient citadel Rysa; there too Punic foundations and a few remains of Punic houses have been found. However, structural remains are rare, not only because of the celebrated destruction by Scipio in 146 B.C., but because of the great Roman city that rose above the earlier debris and which endured for 700 years before its own destruction and abandonment by the Arabs in A.D. 698.

Pottery found in an ancient sanctuary discovered in 1922 west of the southern lagoon confirms the conclusion that the earliest settlement was near this point and that it was in existence at the beginning of the 8th century B.C. The site is a sacred enclosure of Canaanite type in which young children were sacrificed to Baal Hammon and his consort Tanit, the tutelary goddess of Carthage. The calcined bones of the victims were placed in urns which were buried in the holy place. At first small cairns and then simple memorial stones were set up over the urns, giving place in their turn to larger stelae carved to represent small shrines. Inscriptions on the stones contain the word MLK (molk), meaning "sacrifice," which is the origin of the biblical Moloch. As the temenos filled up, the earlier stelae were covered with soil so that fresh urns might be accommodated above them. More than 1,000 urns have been excavated, the highest (2nd century B.C.) at a point about 4 metres under the level of subsequent Roman buildings. Analogous shrines are known at several other places, including Sousse (Hadrumetum) where, however, the later urns contain animal bones.

The common funerary practice was inhumation, until cremation came in with Greek influence in the 3rd century B.C. Many Punic tombs are chambers cut deep in the rock, reached by vertical shafts. Most knowledge of Punic culture is derived from tomb offerings of pottery, jewelry, etc. Punic pottery has been found at sites all along the coast from Tripolitania to Morocco and is in general inferior to Greek or Italian wares. Grotesque terra-cotta masks were made to be placed in graves as protective amulets. Knowledge of Punic architecture has to be deduced from the sculptures on votive stelae, from rare fragments of decorative elements such as cornices or capitals and from a few Numidian tombs. In the early days the predominant influence was from the east, especially Egypt, and the shrines depicted on the stelae have the concave Egyptian cornice, decorated with rows of uraei and flanked by lotus capitals; from the 4th century B.C. contacts with Greek architecture appear. The final Carthaginian style (if such it can be called) was a florid mingling of elements culled from Egypt, the orient, the Greek and the Hellenistic worlds. In such sculpture as has survived there is similar development. At first sacred stones (baetuli) are shown within the shrines but certain images were adopted quite early, including an Egyptian-looking Baal at Sousse. Greek influence followed and finely sculptured effigies are found on sarcophagus lids of the 4th and 3rd centuries. These are regarded as the work of Greek sculptors settled in Carthage, though the subjects, especially a Tanit encased in wings, are Punic. Many symbols are engraved on the votive stelae, including the triangle with circle and two arms at the top, the sign of Tanit.

Numidia.—Punic culture did not disappear with the fall of Carthage. Other Punic cities had come to terms with the conquerors, and survivors of the siege, scattered through Africa and Numidia, carried their customs with them. Sanctuaries of Punic type later than 146 B.C. have been found at the Numidian cities of Constantine (Cirta) and Dougga (Thuggaj. Their votive stelae exhibit a further proliferation of the old motifs, with the Neo-Punic alphabet gradually ousting the earlier Punic one. The Libyan alphabet appears on the mausoleum at Dougga, persisting on tombstones in outlying areas of Roman Africa, to survive as the *tifinagh* of the Tuareg.

Four tombs afford evidence of the influence of mixed Punic-Hellenistic architecture, the huge cylindrical mausoleums with conical tops of the Medracen, near Batna (3rd century), and the Kbor Rumia (late 1st century B.C.) near Tipasa, and the towerlike 2nd-century B.C. tombs of Dougga and Al-Khroub near Constantine. The Medracen (18 m. high, 59 m. across) is encircled by engaged Doric columns with an Egyptian cornice above. The tomb at Dougga, three stories topped by a pyramid, is the ancestor of the tower tombs with slender pyramids which are characteristic of Roman Africa. Numidian territory has also long been noted for its many megalithic tombs. Their date can rarely be determined, but some overlap with the Roman period. It may also be appropriate to mention two groups of late Iberian tombs: the Djedar of the *département* of Oran near Tiaret. These are large tumuli on square bases, 30–40 m. across, strongly reminiscent of the old royal tombs; they appear to be monuments to the Christian kings of the independent Moorish dynasties of the 5th and 6th centuries A.D.

Roman Africa.—The prosperity of Roman Africa is reflected in the quantity and splendour of its ruins. Their remarkable state of preservation is due in part to the climate, in part to the fact that so many of them were deserted after the Arab invasions. They have yielded many thousands of inscriptions which have furnished material of the highest importance for the history of the empire.

Under the republic a vast scheme of land survey was undertaken. As a result huge areas of Tunisia are still marked with the boundary lines of the Roman centuriation, which show up strikingly in aerial photographs. In the Augustan age the cities began to blossom with all the paraphernalia of municipal adornment, exhibiting an ever-increasing prosperity which reached its climax in the early 3rd century. The impressiveness of their ruins has been enhanced in many places by a partial restoration of fallen columns and other elements. The classic Roman colonial founda-

tion is Timgad (A.D. 100) in Algeria, built by Roman legionaries from Lambaesis. Within the square of its ramparts is a chess-board pattern of 12 insulae each way, those south of the centre being occupied by the forum and civic buildings. The town outgrew its original plan and a large suburb arose to the west. The old Numidian town of Dougga retained its primitive appearance, with narrow streets winding up and down the hillside and with houses adapted to the terrain by having their stories stepped down the hill. Ports, generally very ancient, are again more individual in pattern. The oldest quarter of Sabratha, close to the shore, has the irregularity of the old Punic colony, whereas the newer Roman quarters are regularly laid out.

Buildings throughout Roman Africa are frequently constructed of a framework of large dressed stones, with smaller masonry or rubble and concrete in between. This is found in many public buildings (Dougga capitulum), in houses (Timgad, Djemila) and in farms (Bir Sgaoun in Algeria and Sidi Hamdan in Tripolitania). Houses were built around patios of Hellenistic type, and nearly every house and public building had its cistern.

Standard Roman temples, generally pseudoperipteral and Corinthian, arose in honour of many gods, especially for the official cults of the Capitoline deities and the deified emperors. The capitulum usually stood in or near the forum, as at Sabratha, Dougga or Volubilis, though in Timgad it is on a low hill outside the original colony. The temple of the Severi at Djemila typifies the widespread building programs undertaken in Africa under this dynasty. The temple of Caelestis (Tanit) at Dougga is peripteral, set within a remarkable semicircular portico, and is a link with a group of temples which have preserved features derived from the old Punic sanctuary. This was essentially a court shielded from the outer world by a temenos wall, with perhaps a few small shrines in it. The court was maintained in the Roman period, generally with an internal portico, or there might be, as at Thinissut, a succession of courts, with several shrines in each; and an inner holy of holies. The temple of Saturn at Dougga, on the site of the sanctuary of Baal Hammon, his Punic equivalent, has a monumental propylaeum or gateway at the northeast end and a porticoed court, with three chapels in a row, at the west end.

The forum of Carthage has disappeared, but many others can be studied, from the standard type at Timgad, with its curia, tribune for orators, porticoes, shops and basilica and its many statue bases, to the magnificent imperial forum built by Septimius Severus in his native city of Leptis Magna in Tripolitania. This forum is part of a monumental new quarter of the city, on a slightly irregular site, and is so ingeniously contrived that no impression of irregularity is given. Its architecture departs in certain ways from previously accepted practice, notably in the use of arcading for its porticoes instead of the classical architraves. Its basilica was of exceptional splendour, largely the work of Greek masons brought to Leptis for the purpose.

The public library at Timgad is the only one of its kind discovered in Africa, but other public monuments are repeated from town to town. The four-way triumphal arches at Tripoli (Marcus Aurelius), Leptis (Septimius Severus) and Tebessa (Caracalla) are particularly notable; immense public baths were built, innumerable fountains and many theatres and amphitheatres. The amphitheatre at Al Djem, one of the most complete surviving examples in the empire, dominates a wide expanse of country. Remains of circuses are rarer, but that at Leptis is still impressive.

Nowhere was the Roman concern for the water supply better displayed than in thirsty Africa. The greatest of the aqueducts is that of Carthage, 50 mi. long, of which the collecting basin survives in the hills of Zaghuan. There are long stretches of the arches carrying the channel across the plain, with massive cisterns at its point of arrival at the city. The aqueduct of Cherchel is carried across a valley by a bridge (128 ft. high) of tall arches with two lower tiers of supporting arches. In the country districts farms and grazing areas were provided with numerous large cisterns. Maximum use for agriculture was made of the spates which periodically flood the wadi beds, and numerous concrete dams were built to hold back the water and retain the silt. In the

shallower, broader wadis dry stone walls were regarded as adequate for water spreading. Aerial photographs have revealed vast networks of these wadi walls and of hillside terracing. A huge darn was built to divert the channel of the wadi Lebda above Leptis to prevent silting up of the port.

The sites of olive farms can be recognized by the remains of presses, notably by the upright stones constructed to hold one end of the pressing beam. Large areas in Tripolitania, Tunisia and Algeria, where now there is little or no cultivation, have many presses, attesting their former prosperity. Morocco also has its Roman olive farms.

The garrison of Roman Africa was the Legio III Augusta and a force of auxiliary regiments. The legion, from the end of the 1st century, had its headquarters in the fortress of Lambaesis. Large parts of the site have been excavated and the standard barracks and other buildings, including a hospital, identified. The chief structure still to be seen is the entrance hall of the headquarters building. Outside the fortress was a large town. A section of the *fossatum* mentioned in the Theodosian code survives in the Segua Bent ai-Khass, a ditch 37 mi. long south of Biskra. It resembles other *lintites* of the empire, with a line of fortified posts along it. Aerial photography in the 1940s revealed new lines of *fossata*, from the Al-Kantara pass northwest to Tobna. In association with these works, which are dry stone walls or sometimes earthworks, is a series of forts. Gemellae and Ad Majores are of the standard rectangular form with rounded corners; others with projecting towers (Aequae Herculis) are of a type built under Diocletian or later. An advance post, Castellum Dimmidi (198–238), has been found far to the southwest toward Laghouat. An interesting complementary system, without a *fossatum* as far as is known, has been observed in Tripolitania where a deep frontier zone is guarded by fortified farms along the wadis and by advance oasis forts at Bu Ngem, Gheria al-Gharbia and Ghadames on the routes to the Sahara. The reality of trade with the south is attested by the large quantity of Roman pottery and glass found in the tombs of the Garamantes in Fezzan near Jerma where also there is a solitary Roman tomb, and Roman objects have been found at the tomb of Tin Hinan in the Ahaggar. In the far west the Moroccan frontier still presents some problems, but there appear to have been posts south of Volubilis and a short stretch of frontier ditch south of Sala.

African museums have many art treasures, some acquired through strange chances. Thus, the philhellene king Juba II filled his capital at Caesarea with the finest copies of Greek masterpieces then to be had and some of these are now in the Cherchel museum; and a wreck of the 1st century B.C. found off the coast at Mahdia has yielded a collection of Greek works for the Bardo museum. Of greater interest, however, are the works of art made for Africa itself. An altar from a temple of the Gens Augusta at Carthage has some of the quality of the work on the Xra Pacis. The finest work of the Severan period is to be found, not in Rome, but in Leptis Magna; much of this is the work of sculptors trained in the school of Aphrodisias in Asia Minor. From the 3rd century onward there is a resurgence of indigenous Berber influence, related to the earlier Punic carvings. This is found on pagan tombs, such as those of Ghirza in Tripolitania, and on the Christian churches which spread all over the country districts in the 4th and 5th centuries.

The mosaics are the special glory of Roman African art. Outstanding work is found throughout the Roman period and into the Byzantine age, and the museums at Tunis, Tripoli, Hippo, Cherchel and elsewhere abound with splendid examples. In these are subjects common to the Roman world and others which reflect the African scenes which the artists saw about them. Particularly remarkable are the mosaics of country life—the great demesnes of the rich landowners and their fine towered houses, chariot racing, hunting, scenes from the amphitheatre.

The fame of the Church of Africa in history and patristic literature is equaled by the abundance of its material remains. The Christian quarter of Hippo (Bône), the city of Augustine, is rising from the dust, Carthage has several fine basilicas, Timgad has a Donatist cathedral. The favourite type of church was the three-

aisled basilica, with deep chancel and altar well forward in the nave, and with a raised apse which, especially in Tripolitania, is frequently in the west end of the church. A church of this type is shown on a mosaic found at Tabarka. Djemila has a particularly fine 5th-century baptistry. One of the most imposing Christian buildings is the basilica of Tebessa and its dependencies. The main church is probably to be assigned to the 4th century; later a great square was built out in front, and around the edge of the church itself cells were constructed for members of the religious community established there.

The monuments of the Byzantine period are mainly fortifications and churches. Cities, depopulated and impoverished, were given walls which only enclosed a fraction of their old areas. The centre of modern Tebessa is still enclosed by the Byzantine walls with large projecting towers. A smaller fort was built outside Timgad. The Byzantine walls of Leptis enclose the Severan forum as a citadel. (See also AFRICA, ROMAN PROVINCE OF.)

Greek and Roman Cyrenaica.—The eastern end of the Greater Syrtis marks a natural boundary the effects of which can be observed in the Neolithic period and earlier, as already noted. There also the Carthaginian territory marched with the lands of the Greek colonies of Cyrenaica, of which the earliest and most august was Cyrene founded by Battus about 631 B.C. Although most of the visible monuments date from the Roman period, much is nevertheless known of the Greek buildings which preceded them, and the Greek layout has left its character imprinted strongly on the remains of later ages. The Greek agora of Cyrene was retained and further embellished by the Romans as part of the monumental civic centre of the city. Cyrene suffered two major catastrophes, the wanton destruction wrought by the Jews in A.D. 115, and the earthquake of 365. Nevertheless the archaeological finds are of extraordinary variety and richness. Rome has the Venus of Cyrene (found in 1013) and the museum of Cyrene has many fine Greek treasures. The royal and imperial inscriptions, notably the constitution of Ptolemy I and the edict of Augustus, are of great historical value.

It has been possible to trace the history of the precinct of Xpollo below the sacred spring which was the life of the settlement. The long rectangular Greek altar to the god, with a covering of marble added in the 4th century B.C., stands in the centre. Beside it is the temple of Xpollo, the most venerated shrine in Cyrene. The foundations of the 6th-century temple lie below the second and third temples which were built on the same site in the 4th century B.C. and the 2nd century A.D. West of the precinct is a Greek theatre of which the plan can be clearly distinguished, though the building was made over as an amphitheatre in the Roman period. The largest temple is that of Zeus. Its enormous Doric columns were destroyed in A.D. 115. When the cella was restored a colossal statue of the god, copied from the Theidian statue at Olympia, was introduced. The massive base of the throne is in *situ* and a number of small fragments of the statue have been recovered. The Greek agora contains some interesting monuments. One is a circular shrine marking the traditional tomb of Battus, probably rebuilt in the Roman period; another is a naval monument, representing a trireme's prow, of Hellenistic date. Near the Agora is the public record office, identified by inscriptions and by the numerous clay seals which survived the fire that destroyed the documents. Farther along the central street the Romans built a large new forum, the Caesareum, which was rebuilt by the Italian excavators in 1935–38. Cyrene is also notable for its vast Greek cemeteries, with thousands of tombs, many of them cut in the cliff face.

Cyrene is the most interesting of the sites, but its port Apollonia (Susa) has fine churches, a Byzantine wall and the palace of the Byzantine governor. Its harbour, now mostly submerged, was surveyed by underwater explorers in 1958–59. Ptolemais, farther west, is another fine Hellenistic city with a Roman overlay. The site of Euesperides, predecessor of Berenice (Benghazi) was revealed by aerial photographs taken during World War II.

Outside the cities many country sites are known. Among these, the rural temple of Aesculapius near Beda (discovered in 1958) and the church of Gasr Lebia with it; rich mosaics, deserve special

mention. The defensive system of Cyrenaica, comparable in many respects with that of Tripolitania, consisted of a network of roads and fortified farms and strong points. (O. P. F. B.)

V. HISTORY

A. NORTH AFRICA

Evidence has been uncovered in east Africa suggesting the great antiquity of man in Xirica (see *Archaeology* above). However, the continent's history begins with the gradual development of Egyptian civilization in north Africa.

The western part of north Africa, comprising modern Morocco, Algeria and Tunisia, is often conveniently known as the Maghreb or Barbary and forms a well-marked zone completely surrounded by sea or desert. To the east of this, from Tunisia to the Nile, the Sahara extends northward almost to the Mediterranean sea, and the Cyrenaican plateau is the only substantial area of non-desert character in this stretch. The history of north Africa as thus understood, together with the distinct history of Egypt, which is excluded from this survey, belongs rather to the Mediterranean world than to that of the rest of Africa.

Native history until the arrival of the Muslims late in the 7th century A.D. is practically nonexistent, so that information is chiefly derived from the accounts of the peoples who successively conquered or colonized the region. The oldest inhabitants, who have been there since the dawn of history, are the Berbers (*q.v.*), from whom the name Barbary is derived, a people of diverse physical and cultural types whose only clear unity is that of language. Their own traditions accord them an eastern Mediterranean origin, but it is difficult to detach the genuine Berber elements in the legend from additions resulting from the Berbers' desire to assimilate themselves to their Phoenician and Arab conquerors.

Phoenicians and Greeks.—The earliest settlements from outside were those of the Phoenicians, who arrived in Tunisia, according to some, as early as the 16th century B.C. Their most famous settlement was the city-state of Carthage, founded probably in the last quarter of the 9th century B.C. on a site with many natural advantages at one of the few sheltered points of the Barbary coast. Carthage commanded the passage between the

eastern and western Mediterranean and so controlled the western Mediterranean for more than 600 years. The Carthaginians were interested primarily in maritime trade and made little attempt to penetrate far from the coast. Their activities were concentrated in a series of trading posts along the coasts of the Mediterranean and the Atlantic to where the desert again comes down to the sea in southern Morocco. Isolated expeditions pushed on much farther than this; the *Periplus* of Hanno (6th–5th century B.C.) records a voyage which must have taken him at least as far as Sierra Leone.

During the heyday of Carthage, Greek power began to grow. A Greek colony settled in Cyrenaica (see CYRENE) about 630 B.C. and the first dispute between Greeks and Carthaginians arose out of the settlement of the boundary between the Greek colonies in Cyrene and those of the Carthaginians to the west. Wars with the Greeks continued for centuries all over the Mediterranean, but especially in Sicily and southern Italy. About 300 B.C. the Carthaginians were supreme in the Tyrrhenian sea and Sicily, but by this time they were threatened by the growing power of Rome, and it was in defense of these interests that the Carthaginians found themselves at war with the Romans.

Romans.—The three Punic Wars (*q.v.*), from 263 to 146 B.C., destroyed the power of Carthage and Barbary became absorbed into the Roman empire, under which it remained until the coming of the Vandals. At its best the Roman government ran the country well and endowed it with a good system of communications. The southern frontier of the territory which it controlled, the *limes*, roughly corresponding with the boundary between desert and cultivated land, was guarded by a series of forts which kept the inhabitants of the "granary of Rome" free to follow their occupations under the *pax Romana*. The numerous and magnificent Roman remains still visible (Dougga, Bulla, Timgad), not to mention less conspicuous but ubiquitous traces in areas which are now often uncultivated steppe, bear witness to the prosperity under Roman rule. Apuleius, St. Augustine of Hippo and the emperor Septimius Severus were all born in north Africa. (See AFRICA, ROMAN PROVINCE OF; NUMIDIA; MAURETANIA.)

Vandals.—The Vandals invaded Barbary from Spain in A.D. 428. The decadent Roman regime gave way before them, and for a century they ruled the country. Hostility between them and the romanized natives led to the collapse of orderly government and they could not resist a renewed onslaught from the Byzantine empire.

Byzantines.—By the 6th century the centre of gravity of the Roman empire had shifted from Rome to Constantinople. The Byzantine general Belisarius, sent from Constantinople in 533, landed in Africa, routed the Vandals and re-established the Roman empire in eastern Barbary. Central and western Barbary passed into a period of obscurity of which little is known, though it is evident that Christianity and the Latin language continued vigorous in many places. Though the Byzantine government was oppressive, archaeology shows that it brought to the land an economic and artistic revival.

First Muslims.—The romanized order in Barbary was swept away by the Muslim invaders of the latter half of the 7th century. Their first expeditions were mere raids from bases in Egypt, and it is a moot point whether pillage or proselytization was the dominant motive. The definite establishment of the Muslims may be considered to date from the foundation of Kairouan (in modern Tunisia) by Uqba ibn Nafi about A.D. 680. Tradition credits Uqba with two extensive expeditions, one as far as Kawwar (about 300 mi. N. of Lake Chad) and the other to the Sous (southern Morocco), but these may be legendary. Tradition also describes the whole of Barbary as rapidly Islamized, but in fact it seems to have taken nearly a century for all the Berber tribes to become even nominally Muslim, and the Berbers tended to express their national feeling by the adoption of the Khawarij (Kharijite) heresy of Islam as in Roman times they had adopted Donatism (see DONATISTS).

The first wave of Arab invaders was numerically small and had little ethnic or linguistic effect. Barbary remained overwhelmingly a Berber country until the Bedouin invasion of the 11th century.

The Muslim government was based on Kairouan and was at first under amirs subject to the caliph at Damascus or at Baghdad, but these were succeeded in 800 by the independent dynasty of the Aghlabids. Aghlabid rule covered what is now Tunisia and eastern Algeria. In 788 a descendant of the prophet Mohammed, Idris the Elder, fleeing from Abbasid persecution, set himself up in the far west and founded the Idrisid dynasty, whose capital his son established at Fez. In the central Maghreb the Rostemids formed a small but successful Khawarij state based at Tahert (modern Tiaret). Thus, by about 900, Barbary was more or less completely under the control of Muslim governments, and so it remained until the advent of the Europeans in the 19th century.

The Muslim states, however, did not live at peace with one another, and the history of Barbary is a depressing recital of wars, rebellions, misgovernment and anarchy only rarely relieved by short periods of peace and good management. It is remarkable that Barbary, so clearly a geographical unit, was only once unified politically under a single regime of native origin. Nevertheless, the deeply ingrained traditions left by centuries of Roman rule were not yet obliterated. The sedentary elements of the population still predominated and were capable of resisting the disruptive and anarchical tendencies of the nomads. The country, especially the eastern part, seems to have remained prosperous.

The Aghlabids were succeeded in 909 by the Fatimids (see FATIMITES). The first Fatimid was an easterner of the Shiah (Shi'ite) persuasion of Islam. Despite their successful political and military career in the Maghreb, the Fatimids had no success in converting their subjects to their faith, and their ambitions from the beginning appear to have been directed toward the east. In 912 they moved their capital to Cairo, leaving the Zeirids as their vassals in Tunisia. The Zeirids soon declared their independence, and in revenge the Fatimids let loose upon them the nomad hordes of Beni Hilal, Beni Sulaim and Beni Maqil. This is the received account, but it is permissible to wonder whether the Fatimids did not so much plan and organize this emigration as take advantage of a movement over which they had no real control. At all events these Bedouin fell upon the Maghreb, as Ibn Khaldun says, "like a swarm of locusts."

This catastrophe had profound effects. It brought about a great contraction of the settled areas with a consequent sharp decline in cultural life and prosperity. The turbulent and destructive Bedouin made government extremely difficult and large areas were administered only sporadically when a government was able to mount an armed expedition to extort taxes. What is now Algeria remained virtually without central government until the French arrived in the 19th century. The Bedouin invaders were far more numerous than the few thousand of the first Arab invasions, and they greatly affected the demographic situation of the country. The Berbers, with their language, were driven into the more inaccessible regions while the open country became the domain of Arabs and Arabic. The arabization of Barbary, greatly helped by the prestige of Islam but also hindered by the fiercely independent spirit of the Berbers, remained incomplete even in the 20th century. If language is taken as the criterion, arabization is virtually complete in Tunisia but not far beyond the half-way mark in Morocco.

Berber Dynasties.—In the 11th century, just before the advent of the Hilali at the eastern end of Barbary, a new and powerful dynasty was growing in the west. The veiled Almoravids (*q.v.*), emerging from the western Saharan deserts, quickly took control of Morocco and crossed the Straits of Gibraltar to breathe a new life into the flagging Islam of Spain. Meanwhile the Hammadids had split off from their cousins the Zeirids and instituted in central Barbary a regime remarkable for its unusually tolerant attitude toward Christians and its diplomatic relations with the pope.

The Almoravids, crude Saharans debilitated perhaps by a too sudden introduction to the degenerate ways of Spanish Islam, gave way in less than a century to the Almohads (*q.v.*), a Berber dynasty having its roots in the High Atlas mountains of southern Morocco. These remarkable people not only checked the slow but sure progress of the Christian reconquest of Spain but, for

the first and only time, by clearing away the decrepit remnants of Hammadid and Zeirid authority and carrying out a skilful policy of force and alliances against the Arabs, united all the Maghreb from the Sous to Tripoli under one effective administration (1159).

In course of time the Almohad empire too began to break up. In Morocco their successors the Marinids pursued essentially the same policy with the same administrative machinery. In western Algeria the Abd-al-Wadids of Tlemcen led a precarious and turbulent existence between their more powerful neighbours. In Tunisia the Hafsids, legitimate heirs to the Almohad authority, succeeded on the whole in keeping the Arabs at bay and maintaining the country in a state of reasonable prosperity until the arrival of the Turks.

After the disappearance of the Almohads a gradual decline in the capacity of Barbary to remain impervious to the outside world was matched by the growth of interest from outside. The Spaniards and the Portuguese were eager to extend their conquests into Africa. The Portuguese founded fortresses along the Atlantic coast. The Spaniards did the same along the Mediterranean coast, but in the east they collided with the expanding power of the Turks.

Turks.—The first Turkish establishment in Barbary dates from 1514, when the corsair Aruj established himself at Djidjelli in Algeria. This originally private enterprise later received official recognition from the Ottoman government in Istanbul, and the regency of Algiers was born, to be followed 70 years later by that of Tunis. Two other corsairs, Dragut and Sinan, established themselves at Tripoli in 1553. The Turkish settlements in the Maghreb were only nominally dependent on the central Ottoman government.

The Turks were interested solely in piracy. Though they claimed authority over an area stretching well inland and had garrisons in some of the towns, most of the country in fact escaped their rule entirely and they made only half-hearted attempts to impose it. So long as they were accorded the minimum co-operation necessary for the pursuit of their "trade" they were ready to leave the indigenous inhabitants to their own devices. The activities of the corsairs brought retaliation from Europe, but the Europeans were too divided among themselves to act effectively. Piracy could thus be carried on successfully right up to the 19th century, although united action by the European powers could probably have easily suppressed it. (See BARBARY PIRATES).

Sharifian Morocco.—Sa'adi Dynasty.—The decline of the Marinids led to the establishment of the first of the Sharifian dynasties of Morocco, that generally known as the Sa'adi or Hasani. Tradition has given to their reign an aura of splendour, as one in which Islam was revived and the jihad (holy war) against the infidel renewed, but historical appraisal does not confirm this tradition. Their jihad was a defensive one: the great "battle of the three kings" at Kasr al Kebir (Alcázarquivir) in 1578, in which the sultan 'Abd ul-Malik, the sultan Mohammed XI (whom he had deposed) and King Sebastian of Portugal were all killed, though a victory for the Muslims, was fought on Moroccan soil; and in fact they even entered into an alliance with the infidel Spaniards against the Muslim Turks. Their splendour was that of courtly pomp supported at the people's expense by an alien apparatus of renegade officials and mercenary troops. The Sa'adi sultans managed skilfully on the limited resources at their disposal to maintain a precarious independence despite lack of moral support from within and pressure from Spaniards, Portuguese and Turks. The great expedition of the sultan Ahmad el-Mansur to the Niger in 1590–91 was a costly failure in spite of the prestige which it brought.

Filali Dynasty.—The second Sharifian dynasty, that of the Filali or Alawi, dates from the middle of the 17th century. Their history up to the middle of the 20th century was also one of gradual decline. Though occasionally checked by an energetic sultan such as Mulai Ismail (1672–1727), internal anarchy increased until much of Morocco (the bled *es-siba*), while nominally under the central government's control, was in practice governed by tribal or religious leaders (marabouts). The country began a

life turned in on itself, hopelessly archaic, and by the middle of the 19th century was incapable of resisting the covetousness of Europe.

Return of Europe.—The intention behind the French occupation of Algiers in 1830 was ostensibly a desire to stamp out piracy, but it was complicated by Charles X's need to distract attention from events at home. The French exhibited much indecision as to their aims and were baffled by the nature of the resistance. Nurtured under European conditions, they imagined that the submission of the dey of Algiers entailed the submission of all Algeria. They did not appreciate that the country had not been united under an effective Turkish administration but owed such stability as it had to an intricate interlocking of numerous interests (Turkish, tribal, religious, etc.) which had to be brought one by one under a single control. Thus the conquest of Algeria was prolonged, though the issue was never in doubt. In spite of the valiant efforts of Abd-el-Kader (*q.v.*), who managed to organize opposition by a call to Islam, the conquest is generally reckoned to have been complete by 1857.

Tunisia and Morocco were then threatened by the same fate. In Tunis, after years of increasing European intervention, the bey formally submitted to a French protectorate in 1881 (confirmed 1883). In 1912, likewise, the sultan of Morocco was obliged to accept a French protectorate over the southern part of his empire and a Spanish one over the northern zone. France exercised a form of indirect rule in the two protectorates, but Algeria was administered as far as possible as if it were part of metropolitan France.

The Italians entered late into the race for the partition of Africa, but in 1911 they took Tripoli from the Turks and proceeded to annex Fezzan and Cyrenaica (see ITALO-TURKISH WAR). The ancient name Libya was revived to designate the union of these three territories. In Cyrenaica the Italians met fanatical resistance from Bedouins, the Senusi religious brotherhood.

World War II ushered in a period of ferment in north Africa. The problems facing France and Italy, coupled with the liberal professions of the victorious powers, encouraged independence movements which were difficult to resist. In 1951 Libya, ravaged by war, totally lacking in resources (oil was not discovered in Cyrenaica until 1959) and without a government, was given independence, with the leader of the Senusi movement as king. Morocco attained independence with its sultan as constitutional monarch in 1956. Tunisia also attained independence in 1956 and, by the deposition of the bey the next year, became a republic. Both in Morocco and in Tunisia a lively national feeling and the survival of Muslim institutions allowed these transformations to take place fairly smoothly.

In Algeria, however, the long duration of direct French rule and the policy of integration with France had given rise to a substantial European population so that when the Muslim movement for independence developed into rebellion in 1954 it was long impossible to see how the conflict could be resolved. As warfare continued, France's relations with Morocco and Tunisia, whose economies were still closely linked with France, were strained to the utmost because these two countries felt obliged to give moral and even material support to the Algerian rebels.

See also History sections of ALGERIA; LIBYA; MOROCCO; TUNISIA. (J. F. P. H.)

B. SAHARA AND SUDAN

The name Sahara is derived from the Arabic *as-sahra* ("the waste") and the name Sudan from the Arabic *bilad as-sudan* ("land of the black men"). The Sudan, in fact, being the savanna country between the southern limits of the Sahara desert in about 17° N, and the northern limits of the tropical African forest in about 8° N., is the region in which north African peoples came most directly into contact with Negroes. The Sahara, moreover, has become desert only since Quaternary times, when it was well-watered grassland supporting a rich fauna preyed on by hunters of Negro and Mediterranean stock alike. Subsequent desiccation drove the population outward into the Sudan, into the Mediterranean coastlands and into the Nile valley. In this way the Ne-

groes tended to become separated from the Mediterranean peoples. The desiccation of the Sahara was doubtless a factor in encouraging the Neolithic revolution, in which the growing populations of the better-watered peripheral regions learned first to domesticate animals and then to grow crops. In the Nile valley the Neolithic revolution proceeded rapidly, and led to the emergence by the end of the 4th millennium B.C. of Egyptian dynastic civilization, but in the Sudan south of the Sahara the development of the isolated Negroes was slower. However, through commerce and colonization, Egypt exercised a significant influence on the mixture of brown and black peoples higher up the Nile in Nubia (*q.v.*), which resulted in the development there of the independent Sudanese kingdom of Cush, centred first on the region of Napata (*q.v.*) and later: further south, on Meroë (*q.v.*).

In the middle of the 8th century B.C., Cush was strong enough to conquer Egypt and to establish there the 25th dynasty, which ruled until expelled by the Assyrians in the 7th century B.C. Thereafter the Egyptian-inspired divine monarchy of Cush continued to rule the mixed population of the Nilotic Sudan. Meroë became one of the earliest centres of ironworking in Negro Africa, and the Negroes went straight from the use of stone tools to those of iron without passing through a copper or bronze stage. Meroitic civilization declined when the increase in population and in the number of cattle began to denude the land of vegetation, and the incorporation of Egypt in non-African empires caused north-south trade to be diverted from the Nile route to the Red sea. In the early centuries of the Christian era, Meroë was superseded as a centre for trade with interior Africa by the Semitic kingdom of Aksum. About A.D. 350, Meroë was sacked and Cush finally destroyed by Aksum.

Farther west, the influence of Phoenician, Greek, Roman and Jewish civilizations emanating from their colonies in north Africa seems to have penetrated into the Sahara toward the Sudan only indirectly, through the activities of pastoral Libyan Berber tribes on the steppes fringing the settled coastal regions. Some of these tribes (*e.g.*, the Garamantes described by Herodotus) early developed the habit of crossing the desert in horse-drawn chariots in search of such commodities as gold dust, ostrich feathers and slaves, for sale in the coastal towns. The evidence of prehistoric rock drawings in the desert suggests that two major trans-Saharan routes developed leading toward the headwaters of the Niger and Senegal rivers: a region rich in alluvial gold, later known by the Arabs as Wangara.

Kingdom of Ghana. — By about the 5th century A.D. there had emerged in the savanna bordering the desert just north of Wangara the kingdom of Ghana, founded apparently by Libyan Berber migrants, possibly possessing some Semitic strain, who had established an ascendancy over the Mandingo-speaking Negro clans of the area. Later rulers of Ghana were undoubtedly Negroes themselves, and it has been suggested that the alien element in early Ghana was expelled westward into Tekrur and Futa (Fouta Tovo) on the lower Senegal. There intermarriage with the local Tukulor eventually produced the Fulani, a pastoral people, who subsequently spread eastward throughout the Sudan to the Cameroons, infiltrating among, but keeping themselves separate from, the predominantly agricultural local Negroes.

By the time of the arrival of the Arabs in the Maghreb in the 7th century, Ghana was already renowned there as "the land of gold." Its wealth and greatness, however, seem to have stemmed less from actual possession of gold mines than from its role as a centre where the products of the western Sudan, of which gold was the most important, were collected to be exchanged for exports from north Africa and salt from the Sahara brought to Ghana's markets by the Berber tribes who controlled the desert trade roads.

Spread of Muslim Influence. — The pattern of trans-Saharan relations thus established was confirmed by the introduction of the camel and by the coming of the Arabs and Islam. The camel, established in the Maghreb before the end of the Roman period, secured the Berber nomads in their mastery of the desert. It increased their mobility and made them less dependent on oases tillied by Negro agriculturalists, and the frontier of Negro agri-

culture in the Sudan itself was pushed southward, perhaps as much a result of the destructive propensities of the desert nomads' camels and goats as of deliberate aggression.

Arab penetration of the Maghreb (7th–11th centuries) drove southward some of the fringing Berber tribes most determined to maintain their independence and also, through their eventual islamization, perhaps gave them a new impulse toward southern conquests. Saharan and Sudanese history between the 5th and the 13th centuries was thus one of considerable movement of peoples, except in Nubia, where the adoption of Christianity in the 5th century by the rulers of the Nobatae, of Mukurra and of Alwa added new strength to the culture they had inherited from Cush (*see* DONGOLA). These kingdoms, however, were eventually undermined by the growing infiltration of Muslim traders and Bedouin tribesmen from Egypt and finally disappeared in the 14th century. The advent of the Bedouin meant the arabization of the peoples of the eastern Sudan and the replacement of centralized government by tribal rule, except in the south, where the "black sultans" of the Fung maintained their kingdom of Sennar from the 16th to the 19th century.

Elsewhere in the Sudan the effects of the coming of the camel and of Islam were rather different. Migrants from the desert infiltrated among the sedentary Negro agriculturalists and, possessing organized cavalry and a hierarchical social order, were often able to incorporate the native Negro kinship groups into tribute-paying territorial states. As information on these developments depends mainly on remote oral traditions often surviving only through their incorporation in later Arabic texts (which tend to put an Islamic or at least a Semitic gloss on them), it is not easy to be precise as to the origins of these state-founding immigrants. However, it can be said that, although they inspired Negro clans to imitate their methods and, once established as rulers, became themselves increasingly Negro through intermarriage; they were not Negroes in origin. It may also be affirmed that they were not Muslims: if their coming into the Sudan is to be associated with Islam, it seems rather to have been in reaction to its advent elsewhere. Probably they were connected with the Berber tribes and confederations who dominated the Sahara; *e.g.*, the Sanhaja in the west, the Lemta and Ahaggar toward the centre and the Zaghawa farther east. About this time such tribes were developing into the people later known as Tuareg.

There seem to have been two main streams along which successive waves of alien influence reached the central and western Sudan during this formative period of its history: one from the Maghreb, the other from the Nile valley and the Red sea. These two streams met and intermingled, in overlaps which are difficult to disentangle, in the region which is now Nigeria. The state of Kanem and its successor Bornu — respectively to the north and to the west of Lake Chad — after their conversion to Islam claimed to have been founded by the Sefawa, thought to have arrived from the east before the 11th century. On the other hand, the traditions of the Sonrhāi (Songhai), who in the 14th century created the great empire of Gao, suggest that on an earlier influence from the east was imposed that of Lemta Berbers from the north, the latter having settled among the clans of the eastern Niger bend from about the 8th century. The intervening Hausa states seem certainly to have been the product of at least two major waves of immigration, from the north and the east, between about the 7th and the 11th centuries. The legends of peoples farther south (*e.g.*, the Jukun of the Benue valley and the Yoruba in western Nigeria) suggest that they too felt at least a reflection of these great influences. Farther east, the origins of states like Darfur can perhaps be more confidently associated with the Zaghawa and with echoes of Meroitic culture.

Empires of Mali and of Gao. — In the west meanwhile, the kingdom of Ghana, by then essentially Negro, had come into conflict with the Sanhaja tribes. The imposition on the latter of a puritanical Islamic code gave them a temporary unity, and the Almoravids used this unity to grasp at the wealth which lay at either end of the desert trade road which they controlled. The kingdom of Ghana was eventually conquered in 1076, but the Almoravids as a whole were more strongly attracted by the Magh-

reb. Ghana soon regained its freedom, but not its former greatness and prosperity. The incursion of the Almoravids had disrupted Ghana's trading system, and their flocks and herds brought about a disastrous deterioration of marginal agricultural land. Subject clans asserted their independence of the capital, which declined in commercial importance. The Muslim merchants retreated northward to Walata, while political power in the western Sudan eventually passed to another Mandingo group farther to the south, whose leader Sundiata had by 1240 destroyed Ghana and laid the foundations for a new and greater Mandingo empire, that of Mali. Mali reached its apogee in the time of Mansa Musa (1307-32), who received tribute from the borders of Tekrur eastward to the growing commercial emporia of Tombouctou and Gao, and from Wangara in the southwest far into the desert in the north.

The commercial and cultural influence of Mali reached even farther afield and was enhanced by its rulers' adoption of Islam, which secured recognition from the north African states at a time when the merchants of Mali were developing the trade of a wide area, reaching toward the gold- and kola-producing areas of the southern forest and eastward into Hausaland, whose conversion to Islam they initiated. On the basis of the exchange of north African exports and desert salt for gold, kola nuts and slaves, Mali, Tombouctou and Gao achieved great prosperity, and Tombouctou became recognized as a centre of Islamic learning and culture. Only the emergent Mossi-Dagomba states of the upper Volta, offshoots of the impulses which had produced the Hausa states and Bornu, stood out against the power of Mali.

In the 15th century, the empire of Mali began to decline. Its political power had been extended over many peoples, including the Sonrhai', who had no natural bonds of allegiance to the ruling Mandingo group and would remain subject only so long as Mali's supremacy went unchallenged. Succession disputes weakened the military supremacy of Mali at a time when its commerce was suffering from the decay of the western trans-Saharan trade roads caused by the political weakness of Morocco and by the rise of the more central route which led to Tunis. The Tuareg began to encroach from the north and the Mossi to raid from the south. In the east the Sonrhai' regained their independence and, controlling the navigable middle Niger at its junction with the central caravan roads, began to build up the empire of Gao which, because of the military genius of Sonni Ali (c. 1464-92) and Askia Mohammed (c. 1493-c. 1528): reduced Mali to insignificance and more than took its place as the dominant power of the western Sudan.

The power of the new empire, however, was even shorter lived than that of Mali. Islam had been a source of strength for Mali, but among the Sonrhai' it provoked pagan reactions which Askia Mohammed's heirs, unable to agree on an orderly succession of power, either failed to control or used for their own selfish ends. This proved fatal, since the Sonrhai's control of the Saharan salt mines provoked a series of interventions from Morocco, now united and strong under the Sa'adi sultans, who were anxious to exploit the trans-Saharan trade. In 1590-91, in the time of the sultan Ahmad al-Mansur, a small Moroccan expedition crossed the desert, and its discipline and firearms secured the defeat of the massed cavalry and bowmen of the Sonrhai' emperor. But the Moroccans were strong enough to occupy only the three principal centres of Gao, Tombouctou and Jenne, which they held with difficulty against the remains of the Sonrhai' state in Dendi, against Tuareg raiders from the desert and against a renaissance Mandingo power in the west in the form of the pagan Bambara kingdom of Segu and its offshoot Kaarta. The coveted gold-producing regions of the forest proved far beyond the Moroccans' reach and, in the absence of any strong central government for the Sudan, their victory brought no lasting economic gain.

Decline of Trans-Saharan Commerce.—The great days of the trans-Saharan trade and of the Sudanese empires that it fostered were passing. From the 15th century onward, the Portuguese and their western European rivals had been developing the Atlantic approach to western Africa. The trade which had flowed northward from the Guinea forest lands began to find new outlets in European entrepôts on the coast. The Barbary states, which

were the northern termini for the trans-Saharan trade, became involved in struggles for power between Portugal and Spain, Morocco and the Ottoman Turks. Access to Turkish firearms and military ideas proved an important element in the rise of Bornu under Idris Alooma (c. 1580-c. 1617). But Bornu had less commercial wealth than Ghana. Mali or Sonrhai' had had and so was less significant internationally, though it remained a local centre for an Islam inspired from Egypt rather than from the Maghreb, as had been the case with Mali. Such trans-Saharan trade as remained flowed mainly to the city states of the Hausa, small in size but growing in agricultural and industrial wealth. Freed from the pressures of the blandingo and Sonrhai' empires and with attacks from the pagan Jukun of Kwararafa checked by the advance of Bornu, the Hausa extended their economic and cultural influence to the south and west through their itinerant Muslim traders, who joined with those of the Mandingo as the principal purveyors of commerce and Islam to the peoples of the forest.

Extension of British and French Authority.—In the 19th century, the Sudan experienced a political resurgence which, despite its ostensibly religious colour, seems ultimately to have been a reaction against the pressures which foreigners were exerting on African trade and territory. The French were well established on the Senegal river, and the British, despite their abolition of the slave trade, were diverting coastward the trade of the Gold Coast-Nigeria region. Mohammed Ali's successors in Egypt had embarked on the conquest of the Nilotic Sudan and, through the slave and ivory trades, on its exploitation.

In Nigeria the Fulani rose in a *jihad* against the corrupt and weakening rule of the Hausa amirs and, between 1804 and 1810, incorporated their states in the twin empires of Sokoto and Gando. Checked in the east by the equally righteous Muslim rulers of Bornu, they then began to sweep southward into Yorubaland. Farther west, the Fulani in Massina also set up a new state. A Tukulor from Futa, el-Hadj Omar, launched another *jihad*, conquered the Bambara kingdoms, absorbed Massina and, by 1863, had created an empire reaching from the French outposts on the upper Senegal to Tombouctou. In 1881, Mohammed Ahmed, the blahdi, led a rising which cleared the Nilotic Sudan of its Egyptian oppressors.

These movements naturally came into collision with the advancing power of the British and French, whose explorers from about 1788 had been penetrating the Sudan and stimulating their countries' economic ambitions. The western empire of el-Hadj Omar, weakened by internal revolts, was systematically conquered from 1879 onward by the French, who advanced against it from the Senegal. By the 1890s the French were eroding the hinterland of British trade from the Gold Coast and lower Nigeria and threatening the upper Nile, vital to British interests in Egypt and Uganda. Conflict between the two European powers was narrowly avoided as the British conquered northern Nigeria as far as Sokoto and the southern approaches to Lake Chad (1894-1906) and, in association with Egypt, defeated the Mahdists on the Nile (1898). The French and the British, however, co-operated to defeat the self-appointed Mandingo leader Samory and the slave-raiders Babatu (of the upper Volta region) and Rabah (of the Chad). During the first three decades of the 20th century, the French, overcoming bitter resistance from the Tuareg tribes, became masters of the greater part of the Sahara, and so linked their west African colonies with the Maghreb, where they were already established. In the east, the British had established their rule throughout the Anglo-Egyptian Sudan by 1917.

C. GUINEA

Attempts have been made to derive the name Guinea from Ghana or from Jenne, but it would seem to be a version of the Berber word *Aguinaw* or *Gnawa*, meaning "black man" or Negro. *Akal-n-Iguinawen*, equivalent to the Arabic *Bilad as-Sudan* ("land of the black men"), was the Berber name for Negro Africa. Western Europe's earliest knowledge of Negro Africa came through its

relations with Barbary, and the name Guinea, in forms such as Guinua, Ginya, Gheneoa and Ghinea, began to appear on maps drawn in the Mediterranean lands of western Europe in the 14th century. When the Portuguese explorers of the west coast of Africa first sailed beyond the region of Berber or Moorish dominance and came to the Senegal river and Cape Verde and so to country inhabited by Negroes, they applied to both people and land the name that they had learned in Morocco. Since the Portuguese, together with their European successors until the 19th century, were almost entirely concerned with trade at the coast, the name Guinea came to mean the west African coastlands and the forest adjacent to them.

The history of Guinea before about the 11th century is almost totally unknown. Archaeology has done little to compensate for the absence of written records among the Negroes of Guinea, and the value of oral traditions varies with the degree of political organization of their possessors. The traditions of the best-organized Guinea states may sometimes provide an acceptable historical record reaching back up to 500 years, but beyond this they tend to require considerable interpretation before they can be made to yield useful information. Fortunately, some of these legends have affinities with similar legends of the Sudan which can be more readily placed in a historical setting, since, from the 8th century onward, the western Sudan became increasingly well known to Arab geographers, chroniclers and travelers. By reference to the Sudan it is thus possible to attempt a tentative historical framework for Guinea which may go as far back as the 11th century, about 600 years before European sources begin to afford an increasing amount of reasonably intelligible information about the peoples of the Guinea coast.

This is particularly true of the region lying between the Ivory Coast and the Niger, apparently because its inhabitants were more forward than others in setting up organized states. A state cannot exist without some conscious record of its origin and subsequent history, and the rulers of this part of Guinea took special care to preserve intact the formal traditions of their states. Examination of these suggests that the process of state formation in Guinea was generally begun by emigrants from the Sudan.

The influences from east and north which resulted in the emergence of the states of the central Sudan continued southwestward. Throughout middle Nigeria, from the upper Benue to Bussa on the Niger, there are legends of Kisra, usually represented as a Persian king who fled with his men from Egypt to Napata and then moved westward, followed by the Napatan king and his supporters. Beyond Lake Chad they are remembered as founding a series of states, including Nupe and Borgu, the Jukun state of Kwararafa, some of the states (notably Gobir) which became Hausa states and perhaps the earliest Yoruba states. The historical basis for this story is difficult to assess, but the name Kisra seems to be an echo of Khosrau II, the Sassanid king who conquered Egypt and ruled it during 616-628. Names remembered in connection with the Napatan king, notably Issa (Jesus) and Ylesi (Messiah), together with some other evidence, suggest an emigration about the 7th century from the Christian kingdoms which succeeded Cush in the Nilotic Sudan.

Analysis of Yoruba legends suggests that the Yoruba states were formed by two main waves of settlement. The first was the Kisra migration, which gave rise to a number of small independent agricultural colonies. A later and better-remembered immigration, associated with the name of Oduduwa, the Yoruba god of creation, caused the settlement at Ife to branch out and dominate the others. This Oduduwa migration may be linked with the second major movement into Hausaland about the 10th century. These events in Torubaland had their repercussions in neighbouring territories. The tradition of Benin, immediately to the southeast, makes it clear that it experienced the same two formative influences. Farther along the coast, the traditions of the Adja, Fon, Ewe, Adangbe and Ga indicate a westward expansion from Uorubaland which reached its limit in the southeast of modern Ghana only about the 15th century.

The problem of Yoruba origins is complicated by theories concerning the exceptionally fine sculpture, particularly in brass,

found chiefly at Ife and reflected in the art of Benin. The art of Benin is unquestionably an offshoot of the art of Ife, but the magnificent craftsmanship of the earliest-known Ife heads has given rise to the idea that the art must have originated in the work of some non-Negro artist. Since the evidence from Benin makes it plain that the origins of the art must precede the first arrival of Europeans in the area by sea in the 15th century, it was suggested that some Greco-Roman influence reached across the Sahara. However, finds associated with the Nok culture, on the Jos plateau, which may be dated between about 900 B.C. and A.D. 200, show that early inhabitants of the Nigerian region had already reached a very high standard in the making of figures in terra cotta, and the only innovation of Ife need have been the introduction of the lost-wax method of casting.

This tends to confirm evidence implicit in the early legends and traditions that the migrations which gave rise to the eastern Guinea states were not generally mass invasions of uninhabited land, but that comparatively small numbers of immigrants brought new ideas and techniques to already established Negro kinship groups, fused these groups into political units and in the course of time largely merged with them. There is indeed an underlying cultural continuity throughout the region. A similar picture emerges farther west, among the Akan-speaking peoples of modern Ghana and the eastern Ivory Coast. There the external influences were not from the northeast, from the direction of Lake Chad, but from the north or northwest, from the direction of Mandingoland. The earliest Akan states seem to have been set up on the northern edge of the forest by emigrants from the Sudan by about the 13th century. By the 14th century, states such as Bono and Banda were beginning to prosper on the proceeds of a trade in gold and kola nuts with the Ylandingo emporia. Later waves of pioneers pushed south through the Volta gap to the coast and also to some extent infiltrated into and through the forest. At two points, in what is now northeastern Ghana (where the Xkan touched the Mossi-Dagomba) and by the Volta mouth (where they came into contact with the Ga and Adangbe), this movement of state-formation stemming from the northwest met the similar movement from the northeast.

There is little positive evidence to indicate the motives for these migrations from the Sudan into Guinea. While the movement from the northwest may have been connected with the expansion of trade from the ancient kingdom of Ghana and from Mali, the survival of the horse as a symbol of chieftaincy even in such unsuitable regions as Benin suggests that the migrations from the northeast were the products of the political revolutions which created the states of the central Sudan. From the 15th century onward, however, the Sudanic influence on the Guinea peoples began to be eclipsed by the more readily discernible influence deriving from the establishment on the Guinea coast of European trading posts.

First European Trade and Its Effect.—By 1445 the Portuguese, aiming to outflank the trans-Saharan trade of the north Africans, reached the Senegal by sea. Forty years later they were establishing trading posts on the Gold Coast (later Ghana) and at Benin. Except in what ultimately became the colony of Portuguese Guinea, a region naturally exploited by the colonists of the Cape Verde Islands, the Portuguese largely neglected the coast between the Gambia and the Gold Coast, and the pattern thus established was also followed by other European countries trading with west Africa during the next 400 years. One reason for this seems to have been that the peoples of the region from the Gambia to the Gold Coast were still organized in simple kinship societies, which were economically self-sufficient and possessed none of the surplus of wealth required for international trade. Such surpluses, however, did exist in the Senegal region (on the edge of the Sudanese trading system) and in the more complex state systems of the region from the Gold Coast to the lower Niger. In particular the Gold Coast provided substantial quantities of gold dust, and the Portuguese built a number of strong stone forts on its shores in an attempt to exclude their rivals from this trade.

Portugal's near monopoly of maritime trade with west Africa was broken during the first half of the 17th century by the Dutch,

who concentrated on providing slaves to meet the ever-growing demand for labour on the European plantations in tropical and subtropical America. In the latter part of the 17th century, however, the Dutch met with increasing competition from French and English slave-trading interests and by the beginning of the 19th century, when efforts were being made to stop the transatlantic slave trade, the British had become the most important agents in the west African trade except around the Senegal river, where French influence was dominant.

The European slave traders concentrated their activities on those parts of the Guinea coasts where earlier traders in gold, ivory, gum, pepper, etc., had already created a demand for European exports (cloth, hardware, raw metals, spirits, arms and ammunition) and where native trading systems were consequently well developed. The bulk of the slaves taken to America were in fact purchased from African middlemen on the coasts east and south of the Gold Coast. Though politically the power of the Europeans hardly extended beyond their forts and factories on the coast, the trade that they brought engendered a political as well as an economic and social revolution. Whereas hitherto the main centres of wealth and power in west Africa had been in the Sudan, greater wealth was now coming in from the sea, and attempts to control and to exploit it led to the emergence of Guinea states similar in many respects to earlier Sudanese states and empires.

As the coastal entrepôt for Yorubaland in the 16th and 17th centuries, Benin experienced a period of great prosperity during which it expanded its territory by conquest and colonization. Then, while Benin decayed, one of the more northerly Yoruba states, Oyo, began to advance southward, establishing a political primacy over its fellows comparable with the spiritual primacy of Ife and so coming to control the foreign trade of the whole productive region. Oyo itself did not reach to the sea, but found outlets through small coastal states like Lagos and Badagry. Farther west, however, the Fon state of Dahomey, pursuing similar aims, succeeded in the early years of the 18th century in swallowing up its small kindred on the slave coast, and a similar policy was adopted by Akwamu, an Akan state which between 1670 and 1730 established a short-lived empire over the Ga, Adangbe, and Ewe peoples of the coast from Accra to Ouidah. Akwamu's imperial experience was drawn on to aid in the organization of the Ashanti union, in which a group of small Akan forest states joined together to impose their will on their neighbours in the forest and north of it. By the end of the 18th century the Ashantis were seeking direct access for their trade to the European forts on the coast.

European Government Intervention.—During the early years of the 19th century, the various European nations concerned with trade to west Africa outlawed what had been its most valuable element, namely the slave trade. There followed a period of confusion which lasted until the end of the 1870s. Many European merchants withdrew from west Africa altogether, either because they could not find a successful staple to replace slaves or because, continuing to deal in slaves, they came into conflict with the antislavery trade patrols maintained by the British navy. The French and the British remained, however—the French mainly because they hoped that their foothold in Senegal could be expanded to give access to the wealth of the Sudan, the British partly because some of their merchants found the palm-oil trade of the coasts east of the Gold Coast an acceptable substitute for the slave trade, and partly because of their continuing interest in the fight against the slave trade, which still went on inland after export by sea had finally been suppressed (about 1880). Explorers and missionaries joined the traders, and the British government sent out consular agents briefed to try and induce local rulers to abjure the slave trade and to protect the interests of "legitimate" British traders. All these groups tended to conclude that west Africa could not be peacefully opened to Christianity, commerce and civilization without direct intervention in Africa by the British government.

The troubles resulting from Ashanti invasions of the coastal states of the Gold Coast, Dahomey's continuing activity in the slave trade, and the anarchy and civil war in Yorubaland following

the decline of Oyo power and the invasions of the Fulani, all lent force to the views of the traders and missionaries, but showed at the same time that government intervention was bound to involve Great Britain in responsibilities and expense which it would be very difficult to limit. On the whole, therefore, the British government gave little consistent support to the interventionist cause until the 1880s, when German imperialism and the success of the French in conquering the western Sudan and linking up with hitherto weak and isolated French *comptoirs* in Guinea, the Ivory Coast and Dahomey made action essential if any hinterland was to be preserved for British trade.

Thus while the French were creating the eight colonies which became the federation of French West Africa and the Germans were establishing their colonies of Togo and the Cameroons, Great Britain acquired, besides Gambia and Sierra Leone, the two commercially most attractive territories in west Africa—the Gold Coast and Nigeria.

When after World War I the former German colonies were mandated to Great Britain and France, these two countries ruled all west Africa except for Portuguese Guinea and the republic of Liberia, which, like Sierra Leone, had its origin early in the 19th century in colonization by freed slaves. French policy was in essence to rule directly and to expect the Africans gradually to assimilate French ways. The British allowed somewhat more freedom to indigenous ways of life and hoped for an eventual synthesis which might lead to autonomy under local parliamentary governments. However, the opening up of the colonies by railways and roads, the vast expansion under government auspices of the education systems initiated by the Christian missions and the great increase of wealth resulting from the production for the world market of crops, such as cocoa, palm oil and kernels, coffee, peanuts, bananas and cotton, led eventually to the growth of nationalist movements which found the programs mapped out by the British and French too limited.

After World War II these movements were able to make rapid headway and the colonies began to secure self-government. The Gold Coast led the way, achieving independence as Ghana in 1957; it was followed by former French Guinea (which became the Republic of Guinea), Nigeria, the French Cameroons (which became the Republic of Cameroun), Togoland and by the other former French West Africa territories.

D. CENTRAL AFRICA

Apart from a few insignificant groups, such as the Pygmies of the Congo forests, the indigenous inhabitants of central Africa are Negroes speaking Bantu languages. Comparative study of these languages suggests that somewhere in central Africa close by the Zambezi valley was the centre from which the Bantu-speaking Negroes, themselves probably originally an offshoot of the west African Negroes whose languages are classified as Sudanic, spread out to occupy the greater part of central, eastern and southern Africa south of the Bantu line, absorbing or displacing earlier inhabitants akin to the modern Bushmen and Hottentots. This expansion of the Bantu cannot be accurately dated, but it seems likely that it began early in the first Christian millennium. It was certainly still in progress in southern Africa during the 18th century (see *Southern Africa* below), and there is also evidence for the northward expansion of the Bantu during the last few centuries in the great lakes region of east Africa. This rapid settlement by the Bantu of so large an area was probably facilitated not only by their Iron Age technology but also by their acquisition and development of new food crops of East Indian origin, such as the banana, yam, coco yam and sugar cane, which proved well suited for cultivation in equatorial Africa. The introduction of these crops to Africa was probably in some way associated with the East Indian settlement of Madagascar, which, on both linguistic and cultural grounds, seems likely to have taken place between the 5th and the 8th centuries.

Bantu States.—The earliest historical references to the cen-

tral Bantu are in Arabic accounts of the east coast from about the 10th century A.D. onward. These accounts are scanty and not easy to interpret, but it is clear that from the hinterland of Sofala (Mozambique) Arab traders received gold for which they exchanged Asiatic products. When the Portuguese arrived in the Congo and Angola (from 1483) and in Mozambique (from 1505), in both regions they made contact with a number of well-organized Bantu kingdoms. Those on the west coast—Kongo, Kakongo, Loango, Ndongo, etc.—may have been relatively recent foundations, for the traditions of the not dissimilar Kuba kingdom farther in the interior (which was not known to the Portuguese) suggest that it was formed about 1570, after a period of migrations. Beyond Sofala, however, on the highlands between the Zambezi and Limpopo rivers, Portuguese explorers and missionaries discovered an impressive complex of states commonly referred to as the empire of Monomotapa (*q.v.*). The numerous dry stone ruins (*zimbabwe*) of this region, the best-known and most impressive of which is Great Zimbabwe, near Fort Victoria in Southern Rhodesia, have been investigated by archaeologists. (See ZIMBABWE.) For the most part the stone walls seem to have been fortifications for mud dwellings, and it has been shown that the practice of building in stone dates from at least as early as the 10th century and continued, gradually deteriorating, until at least the 18th century. The builders of the *zimbabwe* are generally considered to have been ironworking and gold-mining Bantu, the ancestors of the modern tribes of the region, but there is some evidence (*e.g.*, at Mapungubwe in the northern Transvaal) to suggest that the Monomotapa-Zimbabwe culture may have been originated by earlier inhabitants! probably the ancestors of the modern Hottentots, who were subsequently overrun and absorbed by the Bantu.

The Monomotapa culture was probably already in decline when the Portuguese encountered it. Its deterioration seems to have been connected partly with a decline in the gold yield and partly with the disturbances caused by successive waves of Bantu invasion and conquest. The earliest Bantu elements of the Zimbabwe culture may have been akin to the modern Sotho of southern Africa, and it seems likely that they were invaded first by the ancestors of the modern Karanga and Shona peoples of Southern Rhodesia, and then (about 1700) by the Rozwi, who created the Mambo empire which survived until its destruction by the Ngoni and Ndebele in the 1830s.

Northwest from the Zambezi toward the lower Congo there was a group of comparable states which, though sometimes more extensive, seem generally to have been less stable. This was possibly because, without the stimulus of foreign trade (as in the Monomotapa region from about the 10th century and on the lower Congo from the 16th century), the tendency of the population to increase following the establishment of organized governments was apt to overstrain the resources of wealth available from cultivation of the dry savanna soils. Among these northern states of the central Bantu was the empire of the Luba in the southeastern Congo, at its peak in the 15th and 16th centuries. This seems to have influenced the subsequent rise of the Lunda empire farther to the southwest (which flourished in the 16th and 17th centuries), the kingdom of Cazembe in northeastern Northern Rhodesia (18th century) and the Lozi kingdom in the richer riverain lands of the upper Zambezi (Barotseland), which reached its apogee in the 19th century. Most of the central Bantu monarchies seem to have been influenced in their beliefs, ritual and methods of organization by the divine kingship of the states of the Lacustrine Bantu in east Africa. Lacustrine influences doubtless entered the Congo through the Luba, but their mode of transmission to the Monomotapa region is uncertain.

Portuguese Exploitation. — Both on the lower Congo and in the hinterland of Mozambique, the Portuguese attempted to control the native states and their trade by converting their rulers into Christian vassals of the Portuguese kings, but they achieved little permanent gain. In the west, political and religious intervention by the Portuguese and their attempt to monopolize foreign trade occasioned stresses which gravely weakened organized government in the Bantu kingdoms. In the east, Portuguese hopes

of engrossing the gold exports were frustrated by the difficulty of communication with inland Monomotapa and by the growing weakness of its governments. In the 17th and 18th centuries, therefore, the Portuguese fell back upon direct exploitation of the coastal regions of Angola and Mozambique, developing a meagre plantation economy in the latter and treating the former principally as a reservoir from which slave labour could be exported through their ports at Luanda and Benguela to their plantations in Brazil. Portuguese activities in the interior were increasingly left to half-caste *pombeiro* traders, though the Christian missionary work, which had begun so brilliantly in the 16th century, never entirely ceased.

European Exploration. — In the 19th century central Africa began to be influenced by the growth of European settlement farther south. First, the increasing shortage of land led some southern Bantu groups to raid and conquer to the north. The Rozwi state was destroyed by the Ngoni, who then pressed on to settle and raid in Nyasaland, leaving the Shona of Southern Rhodesia to be preyed on by another Zulu splinter-group, Mzilikazi's Ndebele, who established themselves around Bulawayo. The Lozi kingdom was conquered by the Kololo, an offshoot of the southern Sotho. Secondly, European hunters, traders, missionaries and concession-seekers began to penetrate northward despite the hostility of Mzilikazi and his successor Lobengula. Southern Rhodesia and its gold resources were revealed to the outside world from 1860 onward through the journeys of men like Karl Mauch, Thomas Baines and F. C. Selous.

The great explorations (1852–73) of David Livingstone (*q.v.*) had much wider consequences: during 1852–56, desiring to widen the field of missionary activity, he traveled to the upper Zambezi from Bechuanaland and having been favourably received by the Kololo rulers of Barotseland, went first westward to Luanda and then eastward to Quelimane, seeking an easier route of access to their country. In so doing he began to appreciate the extent to which central Africa was suffering from the slave trade that was being developed by the Zanzibar Arabs and countenanced by the Portuguese; he concluded that only through the example of pioneer settlements of European missionaries and farmers could central Africa be rescued from barbarism. Livingstone's accounts of his two subsequent journeys, which did much to awaken European hostility to the east coast slave trade, led to the first missionary settlements in Nyasaland and inspired H. M. Stanley's transcontinental expedition of 1874–77, with its revelation of the great Congo waterway to the heart of Africa. (See STANLEY, SIR HENRY MORTON.)

Colonization of Central Africa. — The exploitation of Stanley's work by Leopold II of Belgium, led to the establishment of the Congo Free State and to the Berlin conference on Africa (1884–85), and ushered in the colonial phase of central African history. During 1885–94 there was intense competition for the possession of central African territories. Portugal's ancient claim to suzerainty over all land between the coasts of Angola and Mozambique was ignored. Cecil Rhodes's British South Africa company sought, in competition with trekkers from the Transvaal, to expand the frontiers of European settlement from the south. The British Protestant missions in Nyasaland consolidated their position with the aid of Scottish merchants who waged war on the Arab slave traders. Agents of the Congo Free State, having limited French competitors to the regions north of the Congo (which became French Equatorial Africa), penetrated eastward to the great lakes and southward into Katanga. Despite opposition from Portugal and from the Transvaal, pioneers from Rhodes's company occupied Mashonaland in 1890, and in 1893–94 conquered Lobengula and the Ndebele. The Ndebele and Shona risings of 1896–97 ended with the disruption of Bantu society, and although the gold resources proved disappointing, the British South Africa company had by 1914 established Southern Rhodesia as a colony of European settlement in which a growing voice in the government was entrusted to the settlers' representatives. Lack of resources and poor communications made the comparable development of the larger territory of Northern Rhodesia much slower. Barotseland became a

protectorate, and after about 1909 the British South Africa company's administration was thinly extended over the rest of the colony. Nyasaland became a British protectorate in 1891. Its dense African population and lack of minerals did not encourage European settlement, and it remained essentially an African territory, though linked to the Rhodesias through its transport system and its export of labour.

The Portuguese took measures for the proper administration and economic development of the lands remaining to them in Angola and Mozambique. On the economic side this was facilitated by encouraging the investment of foreign capital. Politically the Portuguese endeavoured gradually to assimilate their African subjects to Portuguese civilization.

During 1885–1908 the Congo was under the personal rule of Leopold II. His administration eradicated the slave trade, but, lacking the financial resources available to the colonial administrations of European governments, it embarked on desperate measures to make its vast undeveloped territory economically profitable, leasing out large concessions to companies and, in common with them, employing forced labour and other unsavoury means to bring in revenue. International public opinion was eventually aroused, with the result that in 1908 control of the Congo passed to the Belgian government.

French Equatorial Africa was organized as a federation of four colonies—Gabon, French Congo, Ubangi-Shari and Chad. Attempting to speed up the economic development of the two southern colonies, the French were led to adopt a concessions policy similar to that of Leopold II, and with comparable unhappy results. However, steps were taken after 1906 to end the abuses of company exploitation and to bring the country under proper administrative control.

E. SOUTHERN AFRICA

By about the 15th century A.D., Bantu-speaking Negroes who, in the region from the Limpopo to the Zambezi valleys had already developed advanced states where agriculture was practised and iron and gold were mined and worked, were expanding southward across the Limpopo into country inhabited by more primitive peoples—groups of Stone Age Bushmen hunters and tribes of pastoral Hottentots. The main route of the migration, which was probably caused by pressure of population on land, was down the better-watered eastern side of the subcontinent, and by the latter part of the 18th century the Bantu had occupied all the fertile eastern coastlands as far as the Great Fish river, and were also more thinly spread over the dryer high veld south to the Orange river and west to the upper Limpopo. The surviving Bushmen had been pushed westward toward the Kalahari desert. Many of the Hottentots had been absorbed in the society of the newcomers, and those of their tribes that had survived were confined mainly to what is now the western part of the Cape Province.

The early history of the southern Bantu is not easily unraveled from the surviving traditions. The land they had entered was both extensive and relatively thinly populated, and they were apt to spread widely over it, with the result that tribal groupings were continually fragmenting. Later arrivals would often consolidate earlier settlements into new groupings which would in turn divide as elements moved farther afield. However, by the mid-18th century, the four major modern divisions of the southern Bantu were probably already discernible. In the northern Transvaal and southern Southern Rhodesia were the Lemba and Venda tribes, both probably southern survivors from the early Limpopo-Zambezi states. Farther east, in the lower Limpopo valley and southern Mozambique, were the agricultural Tonga, also relatively long-established. South of these, on the rich coastal plain east of the Drakensberg, were the numerous Nguni tribes. The presence of clicks in many of their languages, and perhaps also the importance attached by them to cattle keeping, suggest that the Nguni had absorbed a considerable Hottentot element.

Farther west, the Sotho tribes, probably the most recent arrivals, were dispersed over the high veld. The eastern Sotho had absorbed some Nguni elements while the western Sotho incorporated some Bushman stock.

European Settlement, 1650–1814.—Until the 17th century European expansion took little account of South Africa. Its coastal peoples could not offer much trade to offset the lack of safe anchorages, and on their way to the east the ships of the early explorers and traders (predominantly Portuguese) made no regular calls before Mozambique. In the first half of the 17th century, however, the Dutch East India company pioneered a quicker route to the East Indies, by-passing east Africa and sailing directly eastward in about latitude 40° S. after rounding the Cape of Good Hope. In 1652 the company sent out a small party of soldiers and officials under Jan van Riebeeck to establish a base on Table bay at the northern end of the Cape peninsula. The intention was to control this vital point which all ships sailing from the Atlantic into the Indian ocean had to pass, and to provide there a supply station for the company's ships. To this end van Riebeeck's men were to grow foodstuffs and secure cattle by barter with the local Hottentots, but they were to avoid involvement with the country and its peoples. However, settlement solely by employees of the company proved an expensive and inefficient expedient for a commercial enterprise anxious to limit costs. To provide an adequate military force to defend the fort (begun in 1666 to meet possible English and French threats) and also to insure an adequate and cheap supply of farm produce, the company encouraged independent farmers to settle at the Cape. The immigrants were mainly Dutchmen but also, after 1688, French Huguenots. Under the governorship of Simon van der Stel (1679–99) and of his son Willem (1699–1707), a successful agricultural community began to emerge. The land by the fort, however, was poor, and settlement quickly extended to the valleys fringing the interior plateau.

By the early 18th century the settlers had begun to feel discontent with the role assigned to them by the company, which controlled prices in the limited local market for their produce, forbade them to engage in more lucrative enterprises such as tobacco-growing and trading with the Hottentots, and allowed them no voice in the affairs of the colony. The company sought to lower the costs of farming by bringing in slaves from elsewhere in Africa and from the East Indies, but succeeded only in confirming a growing belief that the role of the white man was to direct coloured labour rather than to work with his own hands. Miscegenation between Europeans, Hottentots and slaves laid the foundations for a new intermediary class, the Cape coloured. The younger sons of the prolific settler families, unhappy at the lack of opportunity under the company's regime, began increasingly to turn their backs on the Cape and to make their way into the interior. They began by hunting and trading (illegally) with the natives, and gradually established a new society of their own, that of the *trekboeren* (seminomadic farmers). The main features of this society were extensive, pastorally based farming (indifferent water supplies made 6,000 ac. the average size for a farm) which was nearly self-sufficing, and a sturdy belief that the *trekboeren* could rely on no one but themselves and God. The government at Capetown was regarded as alien and hostile, neither able to afford them protection and civilized administration nor willing to allow them independence. In the circumstances, the Calvinist Boers began to see themselves as the children of God in the wilderness, a Christian elect to whom God had given the right freely to take the land and to whom he had also entrusted a natural and lasting dominion over its backward native inhabitants.

The general trend of Boer expansion was east and northeast toward the area of better rainfall, and at first there was no effective check to it. Proclamations from Capetown attempting to establish boundaries for the colony and so avoid conflict with the natives, were ignored, and the scattered Hottentot tribes were easily driven away or absorbed by the Boers. By the 1770s, the Boer vanguard had reached the Great Fish river and had made contact with the foremost Bantu, advancing in the opposite direc-

tion. Their tribes were appreciably better organized and stronger than those of the Hottentots, and like the Boers they were constantly seeking more land for their growing populations and herds of cattle. Conflict between the two expanding pastoral peoples was inevitable, and in 1779 the first of the Kaffir wars broke out along what had become the eastern frontier of the Cape colony.

The company was neither willing nor, by this time, able to afford to garrison and govern the frontier effectively. Its attempts at intervention eventually led the frontier Boers, already organizing commandos for their own defense and electing their own local military and civil officers, to proclaim the independent republics of Graaff Reinet and Swellendam (1795). In the same year, Great Britain, at war with a France whose army had occupied Holland, took possession of the Cape in the name of the prince of Orange in order to prevent its use by French warships preying on British communications with India. After the treaty of Amiens (1802), the Cape was returned to the government of the Batavian republic, but in 1806 the British re-occupied it. In 1814 the Cape was formally ceded to Great Britain.

Conflicts Between Bantu, Boers and British, 1814-1910.—

Like the Dutch, the British were mainly concerned with the strategic importance of the Cape. In 1820 they attempted to seal off the eastern frontier by planting along it 5,000 British settlers—former soldiers and their families. On both sides of the frontier, however, there was pressure on land, so that the wars with the Bantu continued, involving the British in expensive and unwanted military commitments. The European frontier had checked the advance of the southern Nguni, with the result that the northern Nguni could expand only at their expense. Under two great kings, Dingiswayo (c. 1790-1818) and Chaka (1818-28), the Zulu clan of the northern Nguni developed a formidable fighting machine, grouping the young men in disciplined regiments which, fighting in close order with the stabbing assegai, carried all before them. Some Zulu elements struck out on their own: Mzilikazi's Ndebele onto the high veld, the Shangaans to conquer the Tonga and Zwangendaba to lead his Ngoni to raid as far north as Lake Nyasa. Southern Natal became depopulated, the pressure on the eastern frontier increased and the Basutoland and Swaziland mountains became areas of refuge where eventually able leaders like Moshesh, Sobhuza and Mswazi arose to form new nations to match the Zulu power.

Meanwhile British rule at the Cape meant for the scattered Boer communities more effective administration and, with the increase of missionary activity among the natives, new ideas. From 1828 onward legislation was introduced which gave non-Europeans equality before the law and brought Boer dealings with natives and their transactions over land under administrative control. In 1834 Sir Benjamin D'Urban (*q.v.*) arrived as governor with instructions both to liberalize the government and to reduce its cost. Seeking to cut down military expenditure, he brought the frontier Bantu under British rule, a measure which also promised more land for European settlement. However, this annexation and racially discriminatory legislation introduced into the new legislative council by settler representatives were both disallowed by the colonial office at a time when there was dissatisfaction with the compensation provided after the freeing of slaves under the emancipation act of 1833. Consequently in 1836 a growing stream of Boers began to move out of the eastern Cape colony intending, under the inspiration of men like Piet Retief, to establish new independent communities in the relatively empty spaces of the high veld and southern Natal in which they might lead their traditional life free from interference. The Ndebele were driven northward across the Limpopo and, after some bloody fighting with the Zulu, the republic of Natal was proclaimed in 1839.

The British, however, not wishing Port Natal (Durban) to be controlled by an independent government, and concerned also at the effect the expansion of Boer settlement might have on the frontier tribes, annexed Natal in 1843. Many of the Boers, led by Andries Pretorius, trekked back to the high veld. In 1852 the British government agreed to recognize the independence of the settlers in the Transvaal (later the South African Republic) and

in 1854 of those in the Vaal-Orange area (later the Orange Free State). In 1852, on the understanding that it would henceforth pay for its own defense, Cape colony was granted representative government, with an electorate open to all men possessing certain property qualifications. Self-government followed in 1872 when first the export of wool and then the discovery of diamonds had laid the foundations for economic advancement. Natal (where the Europeans were very few in relation to the Bantu) became a separate crown colony in 1856.

The two Boer republics and the two British colonies expanded at the expense of the Bantu tribes. The Cape absorbed the old frontier districts, achieving a common boundary with Natal by 1894, and thus acquiring a considerable Bantu tribal population difficult to assimilate into its nonracial parliamentary democracy. Natal, granted responsible government in 1893, when sugar-planting with immigrant Indian labour had begun to afford some prosperity for its predominantly English settlers, finally absorbed Zululand in 1897. Continued trekking occasioned difficulties for the economically stagnant Boer republics. Incessant warfare between the Orange Free State and the Basuto ended only when Basutoland was annexed to Cape colony in 1871. The diamond-bearing region of Griqualand West, claimed by the Orange Free State, became a British possession in 1871 and was transferred to Cape colony in 1880. The bankrupt Transvaal was involved in border disputes with the Zulu and Swazi, which brought about the British annexation of the republic in 1877. This annexation was a stage in the plan of Lord Carnarvon (British colonial secretary, 1874-78) to federate the south African administrations so as to allow a unified approach to the many frontier and racial problems—an idea already put forward by Sir George Grey (governor at the Cape, 1854-59). However, when the Transvaal did not receive the self-government promised at the time of annexation, its burghers rose and in 1881, after defeating a British force at Majuba, regained their independence subject to British supervision of their frontiers, their foreign policy and their dealings with the natives. (Pretoria convention, 1881, subsequently relaxed by the London convention, 1884.) Meanwhile, encroachment by Transvaalers into Bechuanaland, across the route used by traders and missionaries from the Cape, together with the appearance of Germany in South-West Africa, induced the British to occupy Bechuanaland in 1884-85.

South African affairs were revolutionized by the rapid exploitation of the gold of the Witwatersrand, discovered in 1886, which made the Transvaal potentially the richest state in south Africa. Under the presidency of Paul Kruger, its burghers were able to consolidate their republic and to aspire to extend its principles throughout south Africa. Within the Transvaal opposition developed among the growing number of non-Boer settlers (*Uitlanders*), attracted by the development of the mining economy. Outside the Transvaal, Kruger was opposed by Cecil Rhodes who made a fortune through the amalgamation of the diamond mines, entered Cape politics and in 1890 became prime minister. Rhodes, generally supported in Great Britain by the Conservative party, aimed at unifying south Africa under the leadership of Cape colony in a self-governing British parliamentary democracy, which would serve as a base for the development of central and eastern Africa through European settlement. (See KRUGER, STEPHANUS JOHANNES PAULUS.)

The conflict between Rhodes and Kruger was first apparent in economic issues. Rhodes wanted the Boer republics to be linked with the Cape and Natal through common railways and customs tariffs, but the opening of its own railway to Delagoa bay in Portuguese East Africa in 1893 gave the Transvaal an independent outlet, and the occupation of the lands north of it by the pioneers of Rhodes's British South Africa company in 1890 served more to antagonize the Transvaal than to force it into closer relations with the south. The *Uitlanders*, restless under a government which taxed their wealth but which was increasingly reluctant to accord them citizenship lest they should subvert the Boer state, plotted rebellion, to aid which Rhodes countenanced the invasion of the Transvaal by an armed force under Sir Leander Starr Jameson (*q.v.*) in 1895. However, the *Uitlanders* failed to rise as had been

planned and Jameson's men were rounded up by Transvaal commandos. Rhodes subsequently resigned his premiership. The Transvaalers, convinced that the British wished to destroy their republic, prepared for war and the Orange Free State, hitherto not committed in the struggle, finally aligned itself with the Transvaal.

In the South African War (*q.v.*) the Boers gained initial successes (1899), but by 1900 a large British army had entered the capitals of the Boer republics. After two years of increasingly bitter guerrilla warfare, the Boers surrendered and agreed to the treaty of Vereeniging (1902). The republics became British colonies and their badly damaged economies were rapidly restored under Sir Alfred Milner (high commissioner, 1897–1905). However, little progress had been made with Milner's cautious policy of political rehabilitation when Britain's attitude toward South Africa was radically changed following the Liberal party's electoral victory in 1905–06. Full self-government was granted to the Transvaal in 1906 and to the Orange Free State in 1907. Under Lord Selborne (high commissioner, 1905–10), political leaders in the four colonies came together and worked out a scheme of union, implemented in the South Africa act (1910). The surviving Bantu territories—Basutoland, Bechuanaland and Swaziland—remained as separate British protectorates.

F. EAST AFRICA

The earliest written reference to the east coast of Africa is contained in the *Periplus of the Erythraean Sea*, a work of the 1st century A.D. This account suggests that there was regular trade from southern Arabia to the east African coast south of the Horn of Africa, but there is no indication as to how far south the traders sailed nor is it known with whom they carried on their trade. The geographer Ptolemy (2nd century A.D.) confirmed the account of the earlier writer but added no new information. Roman coins, however, have been found at Bircaio (Port Durnford) in Somalia and coins of the Egyptian dynasty of the Ptolemies as far south as Msasani near Dar es Salaam. Ruined buildings on some of the islands off the coast of Tanganyika may belong to the pre-Islamic period, but the next written records occur in the works of medieval Arab geographers who described Arab trading posts along the coast dating from the 10th century. None of these sites has been identified and the earliest archaeological evidence dated with certainty belongs to the 13th century, although the mihrab (prayer niche) in the mosque at Kizimkazi on Zanzibar Island bears the date 500 A.H. (A.D. 1107).

Supremacy of Kilwa.—For a long time it was believed that the town of Kilwa on the coast of Tanganyika was founded in the 10th century by migrants from Shiraz in Persia. This legend stemmed from the *Chronicle of Kilwa*, a record of the ruling family of the town, which, although probably accurate from the late 14th century, is less reliable as regards the earlier period. Archaeological evidence in fact suggests that Kilwa belonged in its earliest days to an Islamic culture of Arabian origin which flourished in a number of coastal towns from the 13th century and reached its peak in the 15th. The traveler Ibn Batuta, who visited the east African coast in 1332, spoke with admiration of the fine mud and wattle buildings of Kilwa and of its inhabitants' devotion to Islam. It is probable, too, that the rulers of Kilwa exercised some form of authority over some of the other towns for limited periods.

In spite of Ibn Batuta's reference to warfare against the pagans of the hinterland, the relations between the Arab settlers and their African neighbours appear to have been generally friendly. There was some intermarriage and a mixed Arab and African (Swahili) culture sprang from the association between the two peoples.

The pre-eminence of Kilwa rested largely upon its control of the gold supplies from what is now Southern Rhodesia. The gold was brought to Sofala (on the Mozambique coast), which for a considerable period was controlled by Kilwa. The trade of east Africa, however, consisted of a variety of items, among which ivory and slaves were always important, while numerous other

products such as tortoise shell and frankincense may well have been imported for re-export. The principal commercial contacts were with India and Arabia, and both these countries influenced the cultural development of the east coast. Chinese celadon of the Ming period was in regular use in a number of towns, but only two Chinese expeditions are known to have visited east Africa. The first, between 1417 and 1419, reached Malindi, while the second (1421–22) only traveled as far south as Brava and Mogadiscio on the Somali coast.

Portuguese Settlements.—The decline of Kilwa and of some of the other more southerly towns began with the arrival of the Portuguese at the end of the 15th century. During the course of his first voyage around the Cape of Good Hope in 1498 Vasco da Gama called at Mozambique, Mombasa and Malindi on his way to India, but was carried past Kilwa. At Malindi he met with a friendly reception which laid the foundations of an alliance between Malindi and Portugal. This alliance survived the conflicts between Portugal and the other coastal towns during the 16th century.

In 1502 Vasco da Gama forced the ruler of Kilwa to acknowledge the overlordship of the king of Portugal and to promise to pay an annual tribute. On the departure of the Portuguese fleet, however, the promise was forgotten until 1505 when another Portuguese force arrived under the leadership of Francisco de Almeida. Sofala had already fallen to these conquerors and Kilwa quickly followed. The ruler fled, a Portuguese nominee was appointed sultan and a fort erected. The Portuguese occupation, however, was short, the garrison being withdrawn in 1513 and the fort dismantled, as the capture of Sofala and the construction of a fort at Mozambique made Kilwa less important.

After his capture of Kilwa, Almeida sailed on to Mombasa, where the resistance of the defenders was overcome and the town looted. No fort was built, however, and the Portuguese force withdrew to continue its northward voyage of conquest as far as Socotra Island at the southern end of the Red sea. Left to its own devices, Mombasa became the centre of resistance to the Portuguese and succeeded to the pre-eminence of Kilwa among the coastal towns. So strong, however, were the jealousies existing among the ruling families along the coast that no united front was presented to the Portuguese, and when in 1528 a further attack was launched against Mombasa a number of towns supported the Portuguese in their operations.

The Portuguese made little attempt to exploit their conquest. Their objective was to capture the trade of the Indian ocean, and when it was seen that the limited produce of east Africa could be controlled from a handful of bases at Mozambique, Sofala, Zanzibar, Pemba and Malindi, no effort was wasted on administering the coast. Gradually, too, it was recognized that the best route to India lay directly across the Indian ocean, so that the towns on the east African coast north of Mozambique lost their earlier importance as stations along a vital line of communication. After the first years of conquest the east African settlements were administered from Goa, mainly with the assistance of friendly local rulers. Even the Portuguese flair for exploration found little outlet. Apart from a journey to Ethiopia in the 16th century the only exploration of the east African hinterland was undertaken by Gaspar Bocarro who, early in the 17th century, traveled up the Zambezi to take charge of some tin mines near Tete (Mozambique) and, after being attacked by the local population, made his way to the coast at Kilwa in 1616. His record of what he saw on the way is the only account of the interior before the coming of the Arabs in search of slaves. From Bocarro's writings it is clear that although neither Arabs nor Portuguese penetrated far into the continent, trade goods found their way a considerable distance into the hinterland. This was mainly the result of the movement of caravans between the interior (particularly Unyamwezi in western Tanganyika) and the coast, a practice which became increasingly common in the later 17th and 18th centuries.

In 1585 the east coast was subjected to the attention of raiders. Mirale Bey, a Turkish corsair, sailed down the coast and, though he achieved no important conquests, was encouraged by the friendship of Mombasa to visit the coast again in order to challenge

the power of the Portuguese. In 1589 he occupied Mombasa but was attacked by a Portuguese fleet from Goa. The Turkish squadron was defeated, Mirale Bey surrendered to the Portuguese and the town was destroyed by the warlike Zimba tribe.

The Zimba appeared on the scene with the destructive force of a swarm of locusts. Coming, in all probability, from the upper reaches of the Congo, they sacked Kilwa in 1587. Turning northward they arrived outside Mombasa just at the moment when the Portuguese were engaging Mirale Bey. After the destruction of the town the Zimba turned northward again and launched an assault on Malindi. The walls of the town were breached, but the attackers were almost completely wiped out by the defending force and by the Segeju, a local tribe which came to help the townsmen. The Zimba then disappeared from history, and the Segeju advanced against Mombasa, which they captured in 1592. They delivered the town to their ally, the sultan of Malindi, who transferred his headquarters there, and then in turn handed the town over to the Portuguese. In 1593 work began on the construction of Fort Jesus which became the most important Portuguese station north of the Kovuma river.

Predominance of Oman.—The resurgence of Portuguese interest in east Africa was brief. In 1631 the sultan of Mombasa, whose father had been killed at the instigation of the Portuguese, rebelled against his family's former allies and, though quickly driven from the town, maintained a sporadic resistance against the Portuguese for several years. The rising struck a serious blow at their precariously balanced authority and a number of other towns followed the example of Mombasa. These individual uprisings were dealt with one by one, but a more serious threat occurred in 1696 when forces from Oman on the Arabian peninsula laid siege to Mombasa. An epic resistance lasting 31 months ended when the handful of survivors of the garrison were forced to surrender. After this victory the ruler of Oman received the submission of the other coastal towns and either appointed governors or else left the existing rulers in direct charge under his suzerainty.

In 1728 the Portuguese made their last bid for power. Taking advantage of the preoccupation of the sultan of Oman in his own country they once again seized Mombasa, but were able to hold it only until the following year. From this time they continued to maintain forts at Mozambique and Sofala but their authority north of the Rovuma river was at an end. The rivalries between the coastal towns soon threatened the temporary unity imposed by the Omani victories. In 1741 the Busaidi family overthrew the Yorubi dynasty in Oman and this provided the opportunity for a number of the towns to renounce their allegiance. First among these was Mombasa, where the Mazrui family claimed authority over a considerable section of the coast north and south of the island and challenged the sultan of Oman to dispute their independence. Kilwa also rejected the Omani overlordship.

Slave Trade and Zanzibar.—The next outsiders to exert their influence on the coast were the French, who, in search of slaves for the *île de France* and Bourbon, entered into negotiations with the sultan of Kilwa in 1776. There began the revival of the slave trade which was to reach vast proportions in the 19th century, and the renewed importance of Kilwa induced the sultan of Oman to make an effort to reassert his authority in the early 1780s. Henceforward, the French traded with the sultan's representatives. Zanzibar, meanwhile, had remained loyal to Oman, but the sultan's authority in east Africa extended no farther.

The next important developments along the coast took place as a result of British interest in the antislavery campaign that began in the early 19th century. During the Napoleonic Wars the British hesitated to take any steps that might offend their ally Said ibn-Sultan, the ruler of Oman, but the flourishing trade from Kilwa and Zanzibar induced the British authorities in India to take action as soon as peace was restored. In 1822 a treaty was signed between Said and the British which restricted the east African slave trade to the sultan's possessions in east Africa and Arabia. Though the treaty's reference to his east African possessions gave an exaggerated impression of Omani authority along the coast, Said felt encouraged by British friendship and decided to attack the Mazrui of Mombasa. The town fell, as a result rather

of his guile than of his military prowess, and he then moved on to visit his loyal subjects in Zanzibar.

The attractive climate of Zanzibar Island and the obvious trading prospects appealed greatly to Said, who, though he had to return to Oman, probably decided during his visit to transfer his headquarters to Zanzibar. Mombasa, however, continued to be a problem and it was not until 1837 that the pretensions of the Mazrui were finally destroyed. Said spent increasingly lengthy periods in Zanzibar from this time and set himself the task of increasing the prosperity of the island by planting cloves and by financing trading caravans and encouraging them to venture into the interior of the continent. During the second quarter of the 19th century Arab and Swahili traders began for the first time to push beyond the immediate hinterland of the east African coast and to penetrate ever farther toward the great lakes of central Africa in search of slaves and ivory.

As the slave trade grew the British became more intent on restricting its effects. In 1841 a British consul was posted to Zanzibar in order to be in touch with the sultan, whom the British believed to be the one man with whom they could negotiate in the hope of controlling the trade still further. In 1845 Said reluctantly agreed to another treaty which restricted the slave trade to the east African coast alone. While he loyally did his utmost to fulfill his obligations he recognized that he did so against the wishes of almost all his Arab subjects, and the British naval patrol operating against the slave trade along the coast achieved only limited success in the face of almost universal opposition.

Whereas the only interest displayed by Great Britain in east Africa had been in the suppression of the slave trade, other countries now began to be attracted by the prospects of legitimate trade along the coast. Americans, Germans and Frenchmen all obtained trading rights from Said ibn-Sultan, although the trade was limited and could provide profit for only a few merchants. British influence, however, continued to be paramount in Zanzibar and increased after Said's death in 1856, when his son Majid was established as his successor with the support of the British consul and a body of British sailors who helped him to put down the revolt of his brother Barghash. In 1860 an appeal was made to Lord Canning, the governor general of India, who decided that the sultanates of Zanzibar and Oman should henceforward be separated, and in 1862 Great Britain and France agreed to recognize the independence of Majid as sultan of Zanzibar. This independence was of doubtful value. The French gave up their attempts to acquire slaves from the coast and ceased to interfere in the political affairs of Zanzibar, but the sultan's efforts to observe the terms of the antislavery treaties made him dependent upon British support against his own subjects. This dependence was still further increased in 1873 when Barghash, who had succeeded his brother in 1870, was forced by Great Britain to abolish the slave trade in Zanzibar and the coastal towns.

It was in the 1870s that the relationship between Zanzibar and the mainland was first questioned. The main interest of Said and of his two sons in both the coast and the hinterland had been in their commercial possibilities. They had maintained a few small garrisons in some of the coastal towns and had representatives at some of the main trading centres in the interior. They had never sought to administer the mainland, however, and in spite of their political claims the suzerainty that they exercised was of a purely commercial character.

In the 1850s through the 1870s, a number of European explorers using Zanzibar as their base had penetrated to the region of the great lakes and several missionary societies had established themselves in Zanzibar and on the mainland. Moreover, after Stanley's great journey across Africa from east to west there had been a growing interest on the part of certain European powers in tropical African trade and colonization. Fearing an attempt to encroach upon Zanzibar's trading activities on the mainland, the British consul general, Sir John Kirk (*q.v.*), urged Barghash to seek British aid in establishing his claim to sovereignty in east Africa. Having lost the profits from the slave trade as a result of the most recent treaty with Great Britain, Barghash had already in 1878 offered a concession of all his mainland territories "between the

coast and the great lakes" to Sir William Mackinnon, chairman of the British India Steamship company. Mackinnon, however, had been unable to obtain the British government's approval for his acceptance of the offer, and the British government was equally unwilling to become involved in Kirk's attempt to define the limits of the sultan's authority on the mainland. Barghash consequently was at the mercy of the rival contenders for supremacy in east Africa.

Chief among these contenders was Germany, which first took an interest in the mainland through the activities of Karl Peters who, late in 1884 and in spite of the sultan's protests, made a number of treaties in the Usambara area which were subsequently ratified by the German government. Some British businessmen had also shown interest in the Kilimanjaro area with the sultan's approval, but they got little support from their own government. To avoid disputes the British agreed in 1886 to a German proposal that the limits of the sultan's authority on the mainland should be defined and that the rest of the territory should be divided into British and German spheres of influence. A boundary commission was appointed and as a result of its efforts the sultan's territories on the mainland were recognized as comprising a strip, 10 mi. wide and stretching from the Rovuma river in the south to the Tana river in the north with, in addition, a few coastal towns extending as far northward as Mogadiscio.

Colonization of East Africa. — In 1888, Mackinnon's British East Africa association (incorporated by royal charter as the Imperial British East Africa company) was authorized to develop the British sphere of influence in east Africa on behalf of the British government. Next, by the Anglo-German agreement of 1890, the British and the German spheres of influence in east Africa were further defined, and Germany recognized a British protectorate over the dominions of the sultan of Zanzibar. Then, in 1891, the German government proclaimed a protectorate over its sphere of influence in east Africa. The British East Africa company in 1895 surrendered its charter to the British government, which then took direct responsibility for its territories as the British East African protectorate (later Kenya colony and protectorate).

During World War I, German East Africa was occupied by Allied troops. After the war the administration of the major part of it was assigned to Great Britain under a League of Nations mandate, its name being changed to Tanganyika. The Ruanda-Urundi area was assigned to Belgium. A British protectorate had been proclaimed over Buganda in 1894 and later extended to other parts of Cganda. To the south, moreover, the Anglo-Portuguese treaty of 1891 had confirmed the Portuguese in their possessions there.

G. PARTITION OF AFRICA

Before the last two decades of the 19th century Europe showed little interest in colonizing tropical Africa. Where climate permitted Europeans to settle permanently, the French had established themselves in Algeria and the British in the Cape colony and in Natal. Elsewhere, European colonies were confined to coastal enclaves, often legacies of slave-trading days. Portugal had claims to the interior of Angola and Mozambique, but maintained only a sketchy administration over the coasts. Lack of interest in Africa was partly due to the fact that all the major western European powers, except Great Britain, had internal problems so acute as to preclude a sustained policy of colonial expansion. The British were mainly concerned with attempting to expand trade in Africa and to put down the traffic in slaves, without undertaking the costly and troublesome task of establishing colonies.

Tunis and Egypt. — By the end of the 1870s most of the internal problems of the major European states were resolved. Germany had emerged as the strongest military power in Europe, having in 1870 inflicted a crushing defeat on France. The German chancellor, Otto von Bismarck, hoped to lessen the hostility of France, embittered by the loss of Alsace and Lorraine, by diverting its energies into colonial activity. During the congress of

Berlin (*q.v.*) in 1878 he urged France to take Tunis, which exposed the eastern frontiers of Algeria. The French feared Italian designs on Tunis, which had 20,000 Italian settlers, and in 1881 a French force occupied the country. The bey was made to sign a treaty accepting a French protectorate, Italy remaining powerless in the face of Bismarck's tacit support of the French.

Meanwhile in Egypt in April 1879, the khedive Ismail, nominally a vassal of Turkey, dismissed the British and French financial officials who had been imposed upon him in 1876. In reply Great Britain and France arranged for the sultan of Turkey to depose Ismail, and replace him with Ismail's son Tewfik Pasha. This action sparked off a nationalist revolt among army officers, led by Arabi Pasha, who gained control of Egypt. Great Britain and France, in May 1882, agreed on a joint intervention, but as a result of maladroit diplomacy and political changes in France it was eventually the British alone who bombarded Alexandria and landed the force which defeated Arabi. The British had no plan for establishing a colony or even a protectorate in Egypt. The prime minister, W. E. Gladstone, thought that Great Britain could "restore the khedive's authority" and withdraw, but the restoration of the khedive's authority (*i.e.*, Egypt's ability to pay its debts) proved to be the work of more than a generation of financial, political and social reform.

The British occupation of Egypt was deeply resented by the French, who had long believed that their financial investment in Egypt and the fact that the Suez canal had been a French project, entitled them to a predominant position there. It set the pattern for intense rivalry between Great Britain and France in Africa, which was to remain constant until 1898. French statesmen, such as Jules Ferry, convinced that France's trade and industry needed colonial markets that could be protected by tariffs, began to feel that the French must act quickly in other areas if they were not to be forestalled by the British.

Tropical West Africa and the Berlin Conference. — In 1884 the British position on the western side of tropical Africa suffered a severe setback. Through his supposedly philanthropic International Association for the Exploration and Civilization of Africa, King Leopold II of the Belgians had been laying plans for the creation of a personal domain in the Congo. The French countered by sending out the explorer Count Savorgnan de Brazza, who by 1882 had secured the north bank of the Congo mouth for France and laid the foundation for the colony of Gabon. At the same time the French government began actively to support its traders on the Niger, where British trade had been predominant. In the Anglo-Portuguese treaty of Feb. 1884, Great Britain, by recognizing Portuguese claims to the Congo mouth in return for the granting of easy access to this region to British missionaries and traders, tried to thwart both the French and King Leopold.

It was this situation which Bismarck decided to exploit in order to create a German empire in Africa. He himself did not favour the idea of founding colonies, but by launching Germany as a colonial power he was bidding for votes in the German elections and hoped to win over France and so to create some kind of Franco-German entente based on a common anti-British policy in Africa.

Throughout 1883 Germany had been sounding the British as to their claims around Angra Pequena in southwest Africa, where a German merchant, Franz Liideritz, was asking for his government's protection. Germany was met first with evasion, but in November was told that although Great Britain did not intend to establish any authority in the region, any German claim would infringe British "legitimate rights." This attitude infuriated Bismarck and in April 1884 he proclaimed a German protectorate over Angra Pequena. France and Germany then together denounced the new Anglo-Portuguese treaty and in June the British, seeing their isolation, recognized the German protectorate at Angra Pequena and abandoned the Portuguese treaty. In July the German consul in west Africa, G. Nachtigal, proceeded to annex Togoland and the Cameroons. In August, Bismarck extended the Angra Pequena protectorate to cover all the territory between Angola and Cape colony. Finally the fruits of Franco-German co-operation were revealed when the two powers invited Great Britain to a conference at Berlin to discuss ways of establishing

international control over the Congo and Niger rivers and of defining future acquisitions on the coasts of Africa.

The Berlin conference, which began its work in Nov. 1884, finally rejected any Portuguese claims to the Congo region, which became the Congo Free State under the personal sovereignty of King Leopold. On the Wiger the British managed to retrieve something of their predominant position, largely because George Goldie Taubman (later Sir George Dashnood Goldie [*q.v.*]) had succeeded in buying out the French traders on the eve of the conference, so that the British were alone on the lower Niger. Meanwhile the Franco-German entente was breaking down, as the French government feared that the electorate might turn violently against policies which appeared pro-German. As a result, Great Britain was made responsible for administering the Niger. Accordingly, in 1886 Goldie's company was granted a royal charter of administration and became the Royal Niger company. East of the Niger, where there were several British firms, the foreign office administered the Oil Rivers region.

British and German Rivalry in East Africa.—Throughout the 19th century British consuls, notably Kirk, had norked to make Zanzibar a progressive Arab state controlling the east African coastline. After the German annexations in west Africa some British cabinet ministers wanted to forestall any German moves in east Africa by establishing a British protectorate, but Gladstone vetoed the idea; in Nov.-Dec. 1884, Peters (working for the German Colonization society) succeeded in making treaties inland, in what is now Tanganyika. In 1885, Peters' society was granted German protection and the right to administer its claims.

The international situation did not allow Britain to resist Germany in east Africa. The Germans were allowed to expand inland to establish themselves farther up the coast at Witu and to force the sultan of Zanzibar, under threat of naval bombardment, to accept what had been done. A joint British-French-German commission "delimited" the sultan's possessions exactly as the German representative wished.

The British attempt to salvage some position in east Africa was made expressly with German approval. The initiative came once more from private interests, prompted by the consular officials at Zanzibar. It was proposed to revive a scheme broached in 1879 and to rule what is now Kenya by a chartered company headed by Mackinnon under concessions from the sultan of Zanzibar. Though Mackinnon's associates began to make treaties in 1886 they could not at once obtain open official support. In Oct. 1886, an Anglo-German agreement was reached to divide the mainland between the Rovuma and Tana rivers along a line from the Uмба river to Lake Victoria, retaining Witu as a German enclave inside the British sphere. Yet the German government still hesitated. The Conservative prime minister, Lord Salisbury, intended to restore control of Egypt to Turkey. Salisbury's negotiations failed, however, because of French and Russian opposition, and he then saw that if the British could not evacuate Egypt, Mackinnon's British East African association would have to protect the approaches to the sources of the Nile (on whose waters Egypt depended) and, if possible, occupy Uganda. In 1888 the association was incorporated by royal charter as the Imperial British East African company.

There followed a period of intense rivalry between the British and German companies for the control of the Nile sources. At first the rivalry concentrated on the Equatoria province of the Egyptian Sudan, where a German, Emin Pasha, still held out against the Mahdists. At the end of 1889 Emin was relieved by Stanley's expedition, and the Mahdists occupied Equatoria. Uganda then became the centre of competition. Both British and German companies sent expeditions to Buganda, but the Germans were first to make a treaty. By the Anglo-German agreement of 1890, however, Germany withdrew from Witu, recognized Uganda as within the British sphere and accepted that the island possessions of Zanzibar should become a British protectorate. In return Great Britain ceded to Germany the island of Heligoland in the North sea.

The sole remaining rival to Great Britain with regard to the eastern approaches of the Nile was Italy, already established in

Eritrea and Somaliland. France, Great Britain and Italy were all established in Somaliland soon after the British occupation of Egypt. In 1888 France, and in 1889 Italy, made agreements with Great Britain which divided Somaliland into separate spheres. Also in 1889, the Italians concluded a treaty with the emperor Menelik of Ethiopia, which, they claimed, gave Italy a protectorate over his country. If substantiated, such a claim would have given Italy control of the Blue Nile. In 1891 Great Britain agreed to recognize Italy's claims, but the boundaries were drawn to preclude Italian access to the Nile, and Italy agreed not to alter the flow of water by building dams on the Nile tributaries. In return, Great Britain in 1892 persuaded the sultan of Zanzibar to lease the Benedir coast to Italy. In 1905 the lease was ceded outright and the territory incorporated into Italian Somaliland.

Anglo-French Rivalry in Guinea and the Sudan.—The Anglo-German treaty had recognized a British protectorate over Zanzibar despite an Anglo-French agreement of 1862 to maintain the sultan's independence. The French used this to extract a British recognition of a French protectorate over Madagascar and to try to limit British expansion in west Africa. The Anglo-German treaty had also settled the boundaries between British possessions and the German colonies of Togoland and the Cameroons, hinting moreover at a partition of the Lake Chad region. The French feared that the Royal Niger company might advance right across to the Nile and prevent France joining Algeria and Senegal with Gabon in one block. Thus they readily agreed (in the Anglo-French declaration of Aug. 1890) that the frontier between French and British spheres should be a line from Say on the Niger to Barruwa on Lake Chad, leaving the Sokoto empire in the Niger company's sphere. The company's eastern and western boundaries, however, remained exposed to future rivalry. Goldie in 1893 obtained an Anglo-German agreement extending German Cameroons so far northward that the company's eastern frontier was protected by German territory, but the western frontier of Nigeria remained open. The French, after conquering Dahomey, began pushing troops into areas claimed by the company, and by 1898 there was danger of war. The "Niger crisis," however, was settled by a frontier agreement in June 1898, which established the basis of Nigeria's frontiers and also settled the limits to the hinterlands of the other French and British west African colonies.

The Niger crisis was almost immediately followed by the Fashoda incident. Whereas in 1893 the British had hoped that German expansion from the Cameroons might prevent the French approaching the Nile from Gabon, a Franco-German agreement of March 1894 drew a frontier to the Cameroons that left the Nile approaches open. The British thereupon agreed with King Leopold (May 1894), to seal off the Nile by leasing the Bahr al-Ghazal to Leopold who leased to the British a strip of territory linking Uganda with Rhodesia. France and Germany protested and in August the French persuaded Leopold to drop the agreement. The French then began to organize the expedition to cross Africa from Gabon to the upper Nile. Furthermore, when the Italians tried to control Ethiopia (they mere to be disastrously defeated by the Ethiopians at Aduwa in March 1896), the French supported the Ethiopians and Great Britain feared that the Nile now lay open on both sides. Two weeks after the Italian defeat, the British decided to reconquer the Sudan. Sir Herbert (later Earl) Kitchener's army from the north and J. B. Marchand's French expedition from the west met shortly after Kitchener's defeat of the Mahdists at Omdurman in Sept. 1898. After a period of acute tension the French, failing to obtain diplomatic support, withdrew and, in March 1899, accepted exclusion from the Nile valley in an agreement with the British. The Anglo-French colonial conflict was virtually over and the basis laid for the realignment of European powers in the entente cordiale of 1904.

Southern Africa.—The partition of southern Africa was influenced much more by local factors, particularly the rivalries of British and Boer settlers. Great Britain had consistently refused to permit the Boer republics of the Orange Free State and the Transvaal to obtain access to the sea, so that no help could come to them from other European powers. When the Germans established themselves in east Africa and southwest Africa during 1884—

85, there seemed a danger that the two German colonies might expand to join together, preventing British expansion northward and giving Germany a contiguous frontier with the Transvaal. German intervention also stimulated Portuguese efforts to realize claims to territories joining Angola and Mozambique. It therefore seemed essential that "the road to the north" should be secured and once more Great Britain was able to use private interests. Cecil Rhodes (*q.v.*) in 1889 obtained the incorporation by royal charter of the British South Africa company, and soon began the settlement of Mashonaland. The company also undertook to subsidize the administration of the Nyasaland protectorate. There was bitter rivalry with the Portuguese until the boundaries of Mozambique were settled in the Anglo-Portuguese convention of 1890–91. Rhodes then turned to the problem of unifying southern Africa. The Jameson raid of Dec. 1895, originally planned to assist a revolution in the Transvaal, ended disastrously.

Germany attempted to use the raid to build a league against Great Britain, but France and Russia remained aloof. The German navy was not strong enough to permit German assistance to the Boers, who in the succeeding years were isolated by British diplomacy. By an Anglo-German agreement of Aug. 1898, the Germans renounced all interest in Delagoa bay, the Mozambique port which was the Transvaal's outlet to the sea. The South African War of 1899–1902 was the final act in the partition of southern Africa, ending in complete British control of the Transvaal and the Orange Free State. (See fig. 6.)

Final Acquisitions.—Morocco and Tripoli remained the only considerable states in Africa still ruled independently, except Ethiopia and Liberia. France did not want a foreign protectorate in Morocco, lying next to Algeria, while Great Britain feared that any French control of northern Morocco would nullify the strategic importance of Gibraltar. After the settlement of the Fashoda incident, however, France and Great Britain drew together, and in 1904 France obtained British and Italian recognition of French preponderance in Morocco, recognizing in return British control of Egypt and giving Italy a free hand in Tripoli. In the same year a secret Franco-Spanish agreement delimited two zones in Morocco, the northern to be Spanish. Although Germany was not much interested in Morocco, the German foreign office used the Moroccan question to promote a series of incidents designed to test the strength of the Anglo-French entente. The effect was merely to cement Anglo-French co-operation. In Nov. 1911 Germany, in return for French territory transferred to the German Cameroons, accepted the French position in Morocco. In March 1912 the sultan of Morocco agreed to a treaty making Morocco a French protectorate, and later in the year the Spanish zone was finally delimited.

The Italians did not take up their option in Tripoli until 1911, when they invaded the country (see ITALO-TURKISH WAR). World War I, in which the Turks assisted local resistance, delayed effective Italian occupation. After the war the Italians pursued the conquest ruthlessly, but the last resistance was not crushed until 1932.

The Versailles peace treaty of 1919 substantially altered the map of Africa by allocating the German colonies under mandates to the victorious allies. The French and British partitioned Togoland and the Cameroons; the British obtained most of German East Africa (renamed Tanganyika), the remainder going to Belgium; South Africa was given German South-West Africa.

Ethiopia, which alone of all the African countries, except Liberia, was still independent after World War I, was invaded by the Italians in the autumn of 1935. In the Hoare-Laval pact of Dec. 1935 Great Britain and France attempted a solution in the old style, which would have granted what Italy demanded, preserved British and French interests and left a truncated Ethiopian state, but the pact had to be dropped because of opposition in Great Britain. The League of Nations tried unsuccessfully to check Italy with economic sanctions. In 1936 the Italian conquest of Ethiopia was completed.

(J. E. FL.)

H. AFRICA AFTER WORLD WAR I

The most distinctive feature of African history during the four

decades following World War I was the creation of African nations within the territorial limits laid down by the colonial powers. Territorial boundaries changed very little after 1918–19. The four German colonies were transferred to Allied powers under a mandate from the League of Nations. German South-West Africa was entrusted to South Africa, and German East Africa was divided between Great Britain and Belgium, creating Tanganyika and Ruanda-Urundi. Both Cameroons and Togoland were divided between France and Great Britain, with France receiving the larger share in each case.

Most of the European conquest of Africa had been accomplished before World War I, and postwar military operations were mainly concerned with the suppression of African resistance on the fringes of the Sahara and in a few remote areas in other parts of the continent. In 1935, however, Italy began the invasion of the independent kingdom of Ethiopia, with the aim of creating a permanent Italian empire. The Italian occupation of Ethiopia was cut short in 1941 during World War II, by the intervention of British forces, and Ethiopia's independence was re-established.

Administration and Development in Colonial Territories.—The principal concern of the European powers in the interwar period was the extension of their administration and the economic development of their spheres of control. All the colonial powers (and the self-governing European minorities in South Africa and Southern Rhodesia) organized their respective territories on the initial assumption that their rule would last for a long and indefinite period. Ultimate responsibility for government was retained in the hands of the Europeans, but a full administrative bureaucracy on the European model staffed by Europeans would have been prohibitively expensive. The colonial powers, therefore, tended to use the traditional African political authorities where possible as the basis of local government, while European officials occupied the higher posts in the administration. In British territories this system of mixed administration was called "indirect rule" and it was most fully developed in northern Nigeria. Other powers, however, did much the same thing under different names, and even where "direct administration" was established in theory the need for cheap government forced a great deal of *de facto* delegation of power to African chiefs and village heads. African political traditions thus retained some of their vitality throughout the colonial period.

The new African nations which emerged at mid-20th century were not, however, to be based on the traditional political units of the pre-colonial era. They developed instead within the colonial framework, in which national life was gradually superimposed on the existing diversity of traditional cultures by unified economic development and a unified educational system.

Planning for economic development was of vital importance to the colonial territories from the beginning of European rule. There was a European demand for tropical products, and it was essential to have a taxable economic base in order to pay for the colonial administration. Economic development meant first of all the development of transport, and new transport networks, whether by river, rail or road, were constructed to serve each colony. The flow of trade and the movement of people followed the pattern of the transport routes which led to the sea and contact with Europe rather than across colonial boundaries. Mining centres and the new distribution centres (such as Port Harcourt in Nigeria, Stanleyville in the former Belgian Congo and Bangui in former French Equatorial Africa) attracted people of many different cultures, speaking a variety of languages, and subjected them to the influences of urban life. The circle of vision of urban Africans gradually extended from the village and the traditional society that they had left behind to the new colonial territory. Social and political organizations, even in the urban areas, were at first tribal and local, but as time passed more and more of them became general and national in scope.

The process of nation building was accelerated between the wars by the development of education. Even primary education brought young people into contact with a wider world, and the secondary schools were the principal training ground for the new African leadership. Teaching in secondary schools—which were

often boarding schools serving a wide area — was always conducted in the language of the colonial power. Achimota college in the Gold Coast and Fourah Bay college in Sierra Leone drew students from all parts of British West Africa, while the *lycées* at St. Louis and at Dakar served not only Senegal but the whole of former French West Africa. Students established broad contacts and came to see themselves as members of a nation conterminous with the colonial boundaries rather than subjects of the traditional African states. Ultimately they, and not the traditional rulers, formed the principal cadres for the nationalist movements.

Rise of Nationalism. — The processes of education, economic growth and nation building were not uniform throughout the continent. Nationalist movements on the European pattern had developed on a small scale before World War I in some parts of Africa — notably in Egypt, in the French North African territories, in Senegal and in British West Africa. Elsewhere there were movements of protest against colonial rule, but they were often traditional in organization and aimed at creating something less than a modern national state. Some were started to counteract the European cultural impact by giving Christianity an African flavour, as in the case of Kibangism in the lower Congo during the 1920s. Others were local protests against specific grievances, such as the "women's riots" in Aba (Nigeria) in 1929.

Still others combined both of these elements with tribal particularism, as in the Mau Mau revolt in Kenya during the early 1950s, and there were many other variants. Some of these pre-nationalist protest movements were important in preparing the way for later national independence, but most were unsuccessful in achieving their own aims. In the long run, the only successful movements opposing European rule were those led by men with enough western education to take over and operate the administrative organization created by the colonial powers. This stage in the maturity and growth of nationalist movements was reached only after the end of World War II.

Although military operations in Africa during World War II were limited to the north and to Italian East Africa, the impact of the war on Africa was far-reaching: Africans participated in the war effort, and urbanization and economic development were accelerated. Before the end of the war, it was clear to Great Britain and to France alike that Africans would demand a greater share in the colonial governments, and both countries made plans for a new departure in their colonial administrations by introducing an element of African representation in government. Portugal and Belgium, however, retained their nonrepresentative colonial administrations, and in the later 1940s and in the 1950s the government of South Africa assumed even stricter control of the country's African majority.

Toward Independence. — The movement for national independence followed a different course in the various major divisions

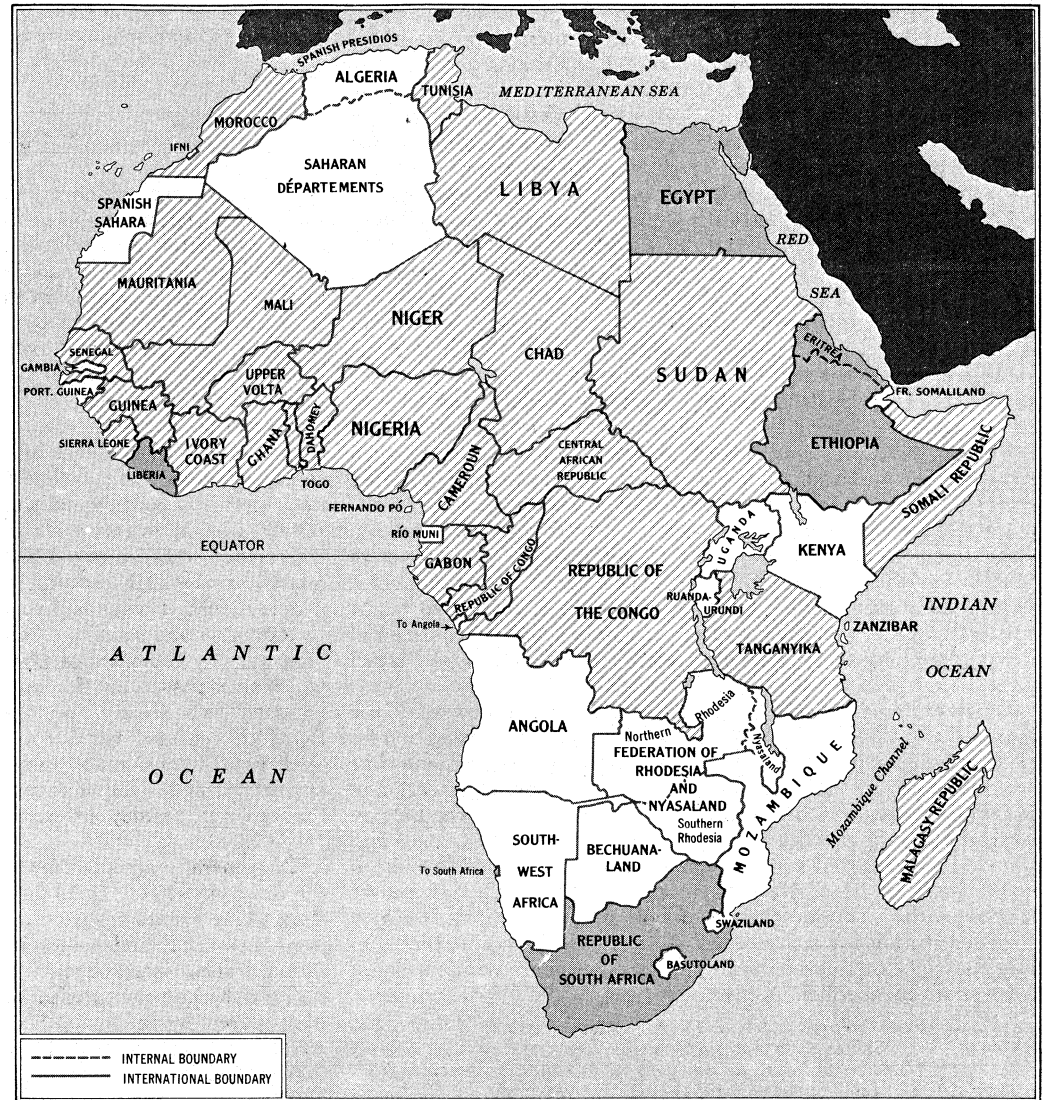

FIG. 10. — POLITICAL DEVELOPMENTS IN AFRICA. SHADED AREAS INDICATE THOSE COUNTRIES WHICH WERE INDEPENDENT IN 1950; CROSSHATCHED AREAS, THOSE WHICH ACHIEVED INDEPENDENCE AFTER 1950

of the continent. (See fig. 10.) In north Africa, where there was a long history of contact with Europe, Great Britain ended its military occupation of Egypt in 1947, withdrawing its troops to the Suez Canal Zone. Libya became independent in 1951 and the Anglo-Egyptian Sudan became a republic in 1955. In the Maghreb, where there were large minorities of European settlers, the independence movement was slower, but the two French protectorates, Tunisia and Morocco, became independent by agreement with France in 1956, and Spanish Morocco was reunited with the rest of Morocco in the same year. After an unsuccessful rising in 1945, the Algerian nationalists organized a full-scale rebellion in 1954, which continued into the 1960s without a decisive victory for either the French or the Algerians.

South of the Sahara two quite different situations confronted the European powers. In those regions north and west of the Congo and the Ubangi rivers, there were only negligible numbers of European settlers. South and east of the Congo-Ubangi line, however, there were substantial minorities of Europeans and Asians, and the European powers took the view that the rights of the settlers should be safeguarded. They were therefore reluctant to allow democratic self-government, since this would mean government controlled by the African majority.

In the region where settlers were few, both France and Great Britain introduced a measure of local representation in the colonial governments in the years immediately following World War II, but at that time the west African nationalist movements were

still small organizations of the educated elite, and the balance of political power rested firmly with the ruling countries. The movement toward independence depended on two developments still to come. One of these was the broadening of the nationalist movements into well-organized political parties with mass support throughout the various countries, a change that was accomplished in most of the west African territories before the end of the 1940s and spread gradually east and south during the course of the 1950s. The second necessary development was the recognition in Europe that token representation would have to give way to genuine self-government. This particular change was achieved in British policy toward west Africa in 1949, and it led directly to the independence of Ghana in 1957, Nigeria in 1960 and Sierra Leone in 1961.

The equivalent change in French policy came in 1956, with the passage of a new constitutional act (*loi cadre*), which granted substantial rights of internal self-government to elected assemblies in all French territories south of the Sahara. This was followed in 1958 by the formation of the French Community (*q.v.*), whose member countries possessed even greater powers of local self-government and the option of independence through referendum. Only Guinea seized the opportunity for immediate independence in 1958, but in 1960 a new status of independence within the community was recognized and available to those territories that might choose it. Consequently, by 1961 the only areas of continental Africa remaining under French control were Algeria and French Somaliland.

In the early 1960s all African countries north and west of the Ubangi-Congo line were thus independent with the exception of Spanish and Portuguese possessions and Algeria. At the same time the movement for national independence was spreading east and south into the regions of European settlement. In 1959 the Belgian government announced a new policy for the Belgian Congo, and independence granted in 1960 was followed by turmoil leading to the dispatch of United Nations troops. Within the British sphere there was also a major change of policy in the negotiation of a new constitution for Kenya early in 1960, which accepted in principle the right of the African majority to ultimate political dominance in an independent Kenya. VI. POPULATION

The racial composition, tribal groupings and characteristics, and social organization of the peoples of Africa have been described above (see *Ethnography*). This section is concerned with numbers and the distribution and density of population, and with some of the problems arising from these facts. (See fig. 11.)

Knowledge of even the approximate size of the population of Africa in past centuries is very slight. As previously seen, the repellent nature of much of the physical environment, and of the coastlands in particular, checked direct contact between Europeans and the native peoples, a situation greatly reinforced on the west coast by the existence of the slave trade. Information given to the explorers and travelers of the 18th and 19th centuries was not necessarily correct, and some of their observations are clearly far from being objective. Moreover, in an area like east Africa, where the Arab-controlled slave trade continued until the last quarter of the 19th century, there were very good reasons why people should, if possible, live well away from the routes followed by explorers and slavers. This did not, however, deter travelers from making estimates of population not only for areas through which they passed but for much larger regions and even for the continent as a whole. Thus there is a range of estimates early in the 19th century, varying between 28,000,000 and 41,000,000—all figures considerably below that of 150,000,000 which was current during the previous century. Later, under the influence of the explorer Stanley in particular, the estimate moved up to 180,000,000.

The generally accepted figure early in the 20th century was of the order of 120,000,000 to 130,000,000. Following the end of World War I statistics were collected through the League of Nations secretariat and, subsequently, the United Nations organization. These figures are as good as any others available, especially with the proviso with which they are published that they may be out by up to $\pm 10,000,000$. They provide the figures: 1920, 140,000,000; 1930, 155,000,000; 1940, 112,000,000; 1950, 200,000,000; the 1960 figure is estimated at rather more than 230,000,000. (See Table II.)

*Areas correspond to population figures as listed. †Northern Cameroons joined Nigeria on June 1, 1961; Southern Cameroons joined Republic of Cameroun in Nov. 1961. ‡1950, §Became independent Dec. 1961.

The problem of the over-all continental figure arises not particularly from the size of the area or of the population but from the multiplicity of political authorities and from the poverty and inaccuracy of the census data available. No territory has had accurate counting for long, except Algeria after the French occupation of 1830 (and the early non-European figures are suspect). Few detailed counts were taken before 1900, and these were for very restricted areas or groups of people; more elaborate, and thus more valuable, censuses are nearly everywhere features only of counts after World War II. Even in the early 1960s there were political areas where no census was taken or where it was admitted that the figures produced were valueless. Population study in Africa is full of pitfalls and inexplicable anomalies are common. An oft-quoted example is that of the former Belgian Congo, which at one time was stated to have 40,000,000 inhabitants but whose

official population in 1910 was given as 15,500,000 and in 1933 as only 9,250,000. It seems unlikely that population would have declined so strikingly simply as a result of mismanagement of the Free State before it came under direct Belgian control, and this could hardly explain the further marked decline between 1910 and 1930. The 1911-36 figures for former French Equatorial Africa are even more puzzling: the figure for 1911 was given as 20,000,000, but only 7,500,000 for 1921 and only one-third of this figure, a mere 2,500,000 for 1931. This was followed five years later by a French official figure of 3,400,000.

Census-taking operations in most parts of Africa are fraught with difficulties: a predominantly illiterate population, a suspicion of the intentions of authority, a lack of precise information about age and a shortage of skilled personnel for use as enumerators. Undue reliance must not, therefore, be placed upon such figures as are available, and it must be recognized that there is rarely enough information on which to base any reliable forecast of trends. In 1936 an authority cautiously suggested that Africa's population was "probably not decreasing: it may very likely be about stationary: it is not impossible that it may be increasing, but if so the rate of increase is certainly slow." Since then it has been claimed that the rate of increase is of the order of 1.5% to 2% per annum in many areas—a rate of growth that could lead to the doubling of population within a period of 35-40 years. Even if these figures are on the high side, as is claimed by some demographers after close study of selected areas, it seems well established that population is increasing quite rapidly over wide areas of the continent, largely through improved conditions of health and hygiene. Such growth of numbers is bound to create pressure on the food and other resources of the land, especially in those areas that already support fairly large populations. On the other hand many districts would seem capable of supporting rather larger numbers and are at present underdeveloped as much because of lack of people as because of the difficulties of communication and other factors.

Table II indicates the political status, area and population of the major political units of Africa and fig. 8 shows the distribution and density of population over the whole continent. Africa has 23% of the land surface of the globe but only 8% of the world's population. With an average of less than 20 persons to the square mile, it is, after Australasia, the least populated of the continents. The maps indicate the great contrasts between, say, the extensive desert lands with virtually no inhabitants and the smaller, but very marked, areas of concentrated population in the Kile valley, in Ruanda-Urundi or in the Witwatersrand districts of South Africa. Figures of density of population per square mile do not, however, tell the complete story and can in fact be misleading. Population needs to be seen in relation to the cultivable and other resources of the area in which it lives, especially in countries with large uninhabitable tracts. Thus Bechuanaland with only 1.2 persons to the square mile or Somali Republic, with 8.5, would be hard-pressed to support many more people in their semi-arid environment. Ghana and Nigeria, on the other hand, with about 72 and 100 per square mile respectively, have shown an ability to maintain a greater population. Other territories—

Southern Rhodesia, for example—might be able to make better use of their resources if they had greater populations so that they were less dependent upon migrant labour.

There are, however, some countries or at least areas within certain countries where the density of population is high by African standards and where there is a state of overcrowding if not of overpopulation under present economic conditions and with existing agricultural methods. For example, many of the interior districts of the former French West Africa, some of the African tribal areas in Kenya, and parts of southern Nyasaland and of Ruanda-Urundi have to support more people, often at a very low standard of living, than their resources justify; and from them all there is considerable movement of people to areas such as Ghana, the Kenya highlands, Southern Rhodesia and Uganda where there are much greater economic opportunities and a constant demand for labour. In these more densely peopled areas the signs of overpopulation include declining crop yields, soil exhaustion, the

cultivation of excessively steep slopes, soil erosion, overstocking and the overuse of grazing grounds and falling water tables. Fortunately at this stage the problem is essentially not one of chronic overpopulation but rather occasional and local overcrowding; it can generally be met by redistribution of population, the opening of new areas to settlement, the improvement of farming methods and the development of other resources. Many governments are conscious of the need for a careful watching of the situation in the light of population trends. If more serious problems are to be avoided in future years. In Africa as a whole the more significant problem in the 1960s was one of lack of population rather than one of excessive numbers, and the emphasis had been on the desirability of increased numbers in many areas for the sake of more complete and balanced economic development.

Migration.—Reference has, already been made to movements of people from one area to another. Migration has always been a characteristic of the population of Africa, as suggested by the spread of Arabs (together with Islam) throughout north Africa and the gradual extension of Bantu-speaking tribes from Ethiopia across the equator and almost to the extreme south of the continent. In modern times these migrations have become permanent features between some of the poorer (but sometimes quite densely peopled) areas that have remained isolated from commercial development and those districts whose economic progress has demanded greater supplies of labour. In north Africa movements have been well established throughout the period of French occupation, and there are also regular seasonal migrations of tribes between the mountains and the lowlands and on the northern fringes of the Sahara. Mining areas have frequently become particular focal points of labour, often from remote places. In the gold mining and industrial districts of the Witwatersrand of South Africa, for example, there is a tremendous concentration of tribesmen from the Bantu areas of the republic itself, as well as from Basutoland, Mozambique and even Nyasaland. The European farmers, as well as the mines and industries of Southern Rhodesia, are especially dependent upon Nyasaland labour. There is a steady flow of labour to the copper belt of Northern Rhodesia and to the mining centres in Katanga. European estates are major users of African labour in east Africa, though the bulk of the large-scale labour migration from Ruanda-Urundi (with 222.8 persons per square mile the most densely peopled agricultural area in Africa) is directed toward the African cotton-farming district of Buganda in Uganda. Similarly in west Africa there is (alongside the movement of labour to mining areas in Nigeria and Ghana and to the towns and ports of the Guinea coast) appreciable employment of Africans by Africans, particularly on the cocoa farms of southern Ghana and the Western Region of Nigeria. Such economic development not only creates labour demands but also makes possible the support of larger populations and, ultimately, an improvement in the standard of living.

Migration may be regular, as with the seasonal movements of pastoral tribes, or spasmodic, as with mining labour. In South Africa a deliberate attempt has been made to prevent the permanent settlement of Africans in mining and industrial centres, and the policy of apartheid seeks ultimately to restore all those at present living in towns to permanent homes in the Bantu areas. Elsewhere many workers prefer to remain only temporary residents in the towns. By maintaining their mobility they are free to return to the rural districts whence they came after the accumulation of sufficient earnings or in the event of sickness or prolonged unemployment or when they are too old to work regularly. But in some countries governments and employers have come to recognize the desirability of a stable population and a regular labour force that can be well trained and acquire considerable skill. Stabilization of labour, as it is called, is increasingly common in the Rhodesias and Katanga, and ever-growing numbers of Africans are settling, of their own volition, in towns in northwest and east Africa.

Urbanization.—This tendency may be noted in all those parts of Africa where there is considerable economic development. Conditions along the north African seaboard are rather different from those elsewhere, the coastal town always having been char-

acteristic of the pattern of population in the Mediterranean area. Cities like Marrakesh, Fez, Algiers, Tunis, Alexandria and Cairo are old-established places with large populations. South of the Sahara the towns are usually predominantly non-African creations, though with notable exceptions such as the Hausa town of Kano and the Yoruba towns in Nigeria, particularly Ibadan (with [1960 est.] 600,000 inhabitants, the largest African town in Africa). They are, therefore, of recent growth and the increase of population, especially after World War II, has sometimes been spectacular. Probably between 8% and 9% of all the people in intertropical Africa now live in towns with 5,000 or more inhabitants. The towns are increasingly becoming centres of social and intellectual life as well as focal points of economic activity and political influence. They are not, however, without their problems. Apart from those of housing, food and water supply, and communications there are the social problems that arise from the admixture of different tribes and from the tendencies toward detribalization resulting from the relaxation of the accepted conventions and restraints of the tribal society to which most of the peoples were previously accustomed.

Non-African Population.—So far reference to the non-African population of Africa has been incidental. Though numerically insignificant (less than 2% of the total population), some elements, particularly the European, have played an overwhelmingly important part in the economic development and political life of many countries, particularly in Algeria, South Africa, Southern Rhodesia and Kenya. These are the countries where large settled European populations have been established and they contrast markedly with the west African territories where the European works for relatively short periods, as government official, educationalist, trader, engineer or missionary. But even in these areas an important contribution was made by the European to the organization of countries like Ghana, Guinea and Nigeria during the period leading to political independence.

Other nonindigenous communities include the Syrian or Lebanese traders of west Africa and the considerable Asian (predominantly Indian) populations of South Africa, Tanganyika, Kenya and Uganda. In south Africa, Indians first came as indentured labourers for work on the sugar plantations of Natal in the 1860s but they have remained in various occupations and now number nearly 500,000. The Asians of east Africa have for many years played a large part in the organization of trade, particularly retail trade and the cotton export trade of Uganda.

The non-African peoples are widely scattered throughout the continent, so that there are innumerable contacts with the indigenous populations nearly everywhere. Interracial co-operation is essential for the good of the community, though in South Africa a different solution is being sought by the government through the systematic application of the policy of racial segregation known as apartheid (*q.v.*).

For further information see articles on the individual countries and regions. See also Index references under "Africa" in the Index volume.

(R. W. St.)

AFRICA, ROMAN PROVINCE OF. The Roman prov-

ince of Africa consisted of a territory with varying boundaries which at times roughly corresponded with those of modern Tunisia. The name Africa was also used by the Romans to denote (1) the whole continent, and (2) Africa north of the Sahara, but was given specifically to the province proper, this being the first piece of African territory acquired by the Romans, into whose hands it came in 146 B.C. when Carthage (*q.v.*) was destroyed. It first comprised the territory which had been subject to Carthage in 149 B.C., when the 3rd Punic War broke out, and was divided from the kingdom of Numidia (*q.v.*) by a ditch and embankment running roughly southeastward from Thabraca (Tabarka) to Thaeanae (southwest of Sfax), leaving Vaga (Béja) to the west. Its area amounted only to about 5,000 sq.mi., much of it belonging to seven former Carthaginian cities which were given local independence for having sided with Rome. The indigenous Libyans were mostly still backward in culture and living in small villages. The province was governed by a praetor stationed at Utica (near the mouth of the Medjerda river).

Roman interest in the territory was negligible till Gaius Sempronius Gracchus passed a law (123 or 122 B.C.) establishing a colony to be called Junonia on the site of Carthage. Although the project collapsed after the assassination of Gracchus, many of the proposed 6,000 colonists had already taken possession of their allotments and were left undisturbed. Interest among Roman farmers and investors was now stimulated: and in 111 B.C. a law was passed to regulate the different forms of tenure and exploitation in the province. Next, veterans of the army of Gaius Marius were given land in the Bagraas (Medjerda) valley shortly before 100 B.C., and the boundary of the province was extended westward almost as far as the present Algerian-Tunisian border. During the next 50 years there was some further immigration, but political uncertainties caused land to fall mainly into the hands of large landowners, often absentee.

The turning point in the province's history came in the 1st century B.C. when Julius Caesar and later the emperor Augustus founded between them some 19 colonies of Roman citizens both from army veterans and from civilian immigrants. The most notable foundation was Carthage itself which rapidly became the second city in the western part of the Roman empire. A number of native communities which were relatively advanced thanks to earlier contacts with Carthaginian civilization were given local independence. Augustus extended the province southward as far as the Sahara and, by controlling destructive nomadic movements, created conditions for four centuries of prosperity. To the east, the coastal area as far as Arae Philaenorum (at the southernmost point of the Gulf of Sidra), which marked the western boundary of Cyrenaica, was added to the province.

In the west, after the battle of Thapsus (46 B.C.), Caesar had formed a new province called Africa Nova out of the old Numidian kingdom of Juba I, and after the death of Bocchus (*q.v.*) in 33 B.C. the Romans took over his kingdom of Mauretania. Augustus, after restoring Juba II to the throne of Rlauretania and part of Numidia (25 B.C.), eventually amalgamated the old province of Africa Vetus with Africa Nova. The western boundary now lay on the Ampsaga (Rummel) river in what is now northeastern Algeria and ran southwest toward the Chott el-Hodna lake. In the division of responsibility for imperial provincial government made by Augustus Africa was controlled by the senate; its governor was of proconsular rank, and it was unique among senatorial provinces in that it had a legion (*legio III Augusta*) stationed in it. The position was altered by Caligula, who placed the *legatus* (commander) of the legion directly under the emperor's orders and gave him jurisdiction over the area in which the army was most active. This military zone comprised most of the old Numidian kingdom with the exception of the area east of a line from Rusicade to Theveste (Philippeville and Tebessa in northeastern Algeria), together with that part of the hinterland of Tripolitania which is not desert. In effect a new province of Numidia was created, though it was not formally constituted till the reign of Septimius Severus (A.D. 193-211).

The first century A.D. was a time of rapid growth in African prosperity. Private estates of considerable size grew up which at-

ROMAN RUINS OF ANCIENT LAMBAESIS (LAMBESSA. ALGERIA)

tracted the greed of the emperor Nero, who executed a number of wealthy landowners and took their lands. This was the foundation of a vast imperial domain in North Africa. Cereals remained the chief crop, but late in the century olives became profitable, especially around Taparura (Siax). Vast quantities of these and other products such as fruit and hides were exported. The period from the reign of Nerva (A.D. 96-98) to that of Alexander Severus (A.D. 222-235) was probably the most prosperous and peaceful that the area ever enjoyed. The amenities of urban life became available in many cities and over much of the country opulent villas were built. Many public buildings were erected, important remains of which may still be seen in Tunisia, at Carthage, Thysdrus (El Djem) and Utica (*qq.v.*) and at Thurburo Maius (Henchir Kasbat), Thugga (Dougga), Mactaris (Mactar) and Sufetula (Sbeitla, *q.v.*). Substantial elements of the Libyan population were romanized and many communities received Roman citizenship, with the title of *municipium* or *colonia*, long before it was extended to the whole empire in A.D. 212. More and more men from Africa began to enter the imperial administration, and at the end of the 2nd century, an African, Septimius Severus, became emperor. In the rural areas, however, many of the Libyans were little affected by Roman civilization.

In the later 3rd century Africa, in common with the rest of the empire, suffered a decline in prosperity, though relatively free from invasion and war. When the empire was reorganized by Diocletian, two provinces, Byzacena and Tripolitania, were formed from the southern and eastern parts of the old province. The most important events in the 4th century were connected with the Christian Church. Christianity, established in Africa in the 1st century, had rapidly spread. There were more than 100 African bishops by A.D. 256, and Africa had produced such distinguished figures as Tertullian and Cyprian (*qq.v.*). The African Church had its share of martyrs up to the time of the final persecutions of A.D. 303-305 under Diocletian; its strength was subsequently reduced by the Donatist schism (see DONATISTS) from 312. In this; however, the majority of the African clergy and laity supported the Catholic cause, whose principal champion was Augustine, bishop of Hippo Regius. Imperial intervention in the dispute culminated in a council held at Carthage in 411 at which Donatism was condemned, and persecution of its adherents followed.

Africa fared better than most parts of the empire in the 4th century and even enjoyed a modest amount of prosperity, but there were symptoms of decline. City life decayed particularly toward the end of the century, and while wealth was concentrated in the hands of a few, the peasants tended to become poorer and more oppressed. In addition, the inhabitants had lost any military tradition that they may have had and were an easy prey to invaders. In A.D. 429 the Germanic tribe of the Vandals under Gaiseric (*q.v.*) crossed from Spain to Morocco, and in 430 they arrived in the province of Africa. After a short period of truce (A.D. 435-439) Carthage fell and became the capital of the Vandal kingdom. Ro-

man civilization decayed more rapidly in spite of the numerical inferiority of the Vandals, and though the latter were destroyed by Belisarius, general of the Eastern emperor Justinian I, in 533 and imperial control was restored, the decline was irreversible. Africa offered little resistance to the Arab invaders who took Carthage in 697.

AFRICAN LANGUAGES. The number of separate languages spoken by the inhabitants of the African continent is variously estimated as from 600 to 800. Until more data are available from some areas and until a more rigorously defined criterion as to what constitutes a separate language is agreed upon! no exact number can be given. The figures quoted are sufficient, however, to show the great linguistic diversity that is characteristic of Africa, particularly that portion which lies south of the Sahara. In certain parts of Africa, such as the Bauchi plateau of Nigeria and the Nuba hills of Kordofan, scores of distinct languages are spoken in a relatively small area. There are also languages with millions of speakers, answering to the needs of wider communication both before and after European contact. Examples of such languages are Swahili in east Africa, Lingala in the Congo basin, Sango in equatorial Africa, Hausa in west Africa and Arabic in north Africa and large areas of the Sudan. In spite of the fact that the languages of Africa cannot be shown to have a common origin, the cultural unity of Africa south of the Sahara is reflected in certain widespread common features which distinguish this region linguistically from the neighbouring area of the near east.

The prevailing classification of African languages which became established in the period 1910–20, chiefly as a result of the work of Carl Meinhof and the earlier work of Diedrich Westermann, divided African languages into five families. Semitic, Hamitic, Sudanic, Bantu and Bushman, forming, in general, successive east-west layers from Semitic and Hamitic in the north to Bushman in the extreme south. This scheme underwent considerable modification through the efforts of Marcel Cohen, Johannes Lukas, Joseph Greenberg and the later works of Diedrich Westermann. The chief points of criticism of this earlier classification on the basis of which the present version is presented, are as follows:

1. It is evident that Semitic is not an independent family but is related to Hamitic.

2. Hamitic, as pointed out by Cohen, is not itself a unity as against Semitic. The situation is rather that Semitic is but one of a number of branches in a larger Hamito-Semitic family to which Greenberg has applied the name Afro-Asiatic.

3. Most of the various extensions of Hamitic proposed by Meinhof in *Die Sprachen der Hamiten* are invalid. There is general agreement that Hottentot, Fulani (Ful, Fulfulde) of west Africa and the so-called Nilo-Hamitic languages of east Africa (Masai, Nandi, Turkana, etc.) are not Hamitic.

4. The earlier all-embracing Sudanic unit, to which were assigned all the languages spoken by Negroes except the Bantu languages of the southern part of the continent, has been successively broken into smaller independent units in the later work of Westermann, who first proposed it. The same author showed the relation of the Bantu family, hitherto considered independent, to the western section of the former Sudanic family (*i.e.*, West Sudanic). Greenberg pointed out the special position of Bantu as a member of one of the subdivisions of the West Sudanic group spoken in Nigeria and the Cameroons, languages often called semi-Bantu because of their resemblances to the Bantu languages (*q.v.*).

j. Lukas has distinguished a separate Saharan family, formerly assigned to Sudanic and containing, as principal languages, Kanuri, Teda and Zaghawa.

The Hamito-Semitic (Afro-Asiatic) Languages. — This family of languages covers all of northern Africa while its Semitic branch extends into the adjoining areas of Asia. It consists of five branches: (1) Berber, formerly spoken in all of north Africa except Egypt, by the Tuareg of the Sahara and in the Canary

Islands. It is now largely confined to Morocco, Algeria and parts of the Sahara. Ancient Berber inscriptions, known as Libyan, are found written in an alphabet probably derived from that of the Phoenicians of Carthage. This alphabet is still in use. (2) Ancient Egyptian, known from hieroglyphic inscriptions and in its later form, called Coptic, written in an alphabet derived from Greek. It is now extinct. (3) Semitic, including Arabic, which is dominant in north Africa, the Ethiopian Semitic languages, as well as languages in western Asia. Ethiopian Semitic is usually divided into a northern subdivision with Tigre and Tigrinya and a southern subdivision consisting of Amharic, the Gurage dialects. Gafat and Harari, the language of the Moslem centre of Harar in southern Ethiopia. (4) The Cushitic languages spoken in Ethiopia and neighbouring areas. Cushitic consists of five groups of languages: (a) Beja; (b) Agau group; (c) Eastern Cushitic (Galla, Somali, Afar, eastern Sidamo, Konso, Arbore, Geleba); (d) Western Cushitic (Kaffa group); and (e) Southern Cushitic (Mbugu and Mbulunge in Tanganyika). (5) The Chad languages of northern Nigeria and surrounding area. The most important of these languages is Hausa, a large group which can only tentatively be grouped. Among the better-known languages are Angas, the Kotoko group of dialects including Buduma and Logone, the Bata dialects, Mandara, Musgu, Somrai, Sokoro, Tuburi and Mubi.

The characteristics of Hamito-Semitic speech include: (1) absence of tone; some or all of the Chad languages, however, have acquired tonal systems under the influence of neighbouring languages; (2) grammatical gender—Shilh (Berber): masc. *idilli*, fem. *t-idilli-t* "black"; Hausa (Chad): *yazo* "he came," *tazo* "she came"; (3) a variety of plural formation in the noun including the use of suffixes, internal change, particularly to *a*, and partial reduplication, as Shilh (Berber): *ilivi*, pl. *ilawan* "thorn"; Logone (Chad): *ngun*, pl. *ngwaren* "belly." Hebrew (Semitic): 'ir, pl. 'arim "city"; (4) presence of internal change combined with both prefixes and suffixes to form verb conjugational systems; and (5) a complex system of forming derivative verbs, causative, reflexive, passive, etc., usually by prefixes. Bedauye (Cushitic): *kehan* "to love," *atkehan* "to be loved." *gumad* "to be long," *sugumad* "to lengthen." *dir* "to kill," *mdedar* "to kill each other."

The Niger-Congo Family. — This family has a vast and nearly continuous distribution, covering almost all of west Africa south of the Sahara, and most of the Congo basin and south Africa. The problem of subdivisions within this family had yet, at mid-20th century, to be solved in a definitive matter. Certain groupings, however, can be tentatively described.

1. In the far west are the West Atlantic languages subdivided into an eastern group comprising Temne, Bulom, Kissi, Limba and Gola and a western group containing Dyola, the Bissao-Bolama cluster (Bola, Sarar, Pepel, Kanyop), Bijogo, Bulanda, Cobiana-Cassanga, Banyun. Nalu. Serer-Sin. Serer-Nono. Konyagi, Wolof and Fulani. The position of Fulani, spoken by several million people scattered from Senegal to Wadai, east of Lake Chad, was long disputed, but it clearly belongs in the West Atlantic subgroup of this family. Within this subgroup, it is most closely related to Serer-Sin, and somewhat more remotely to Wolof, Serer-Nono and Konyagi.

2. A second subdivision is that of the important Mandingo languages, spoken in the central and lower Niger valley in former French West Africa, and in much of Liberia and Sierra Leone. The traditional division into Mande tan and Mande fu based on the numeral for ten is misleading. Mande tan is but one subgroup among several. Mandingo languages include Malinké, Bambara, Soninke. the Kpelle-Mende group in Sierra Leone and Liberia and a number of small languages as far east as Boko-Busa in the north-west corner of Nigeria.

3. The Gur subdivisions, including the following groups: (a) Mossi (Mossi, Dagomba, etc.); (b) Grussi; (c) Tem; (d) Bargu; (e) Gurma; (f) Kilina; and (g) Senufo. This latter group is somewhat remote from the remainder of the Gur languages but should probably be classed with them.

4. The Kwa subdivision contains the middle Togo group, hitherto classified separately, the Ewe-Akan languages (Ghana,

Dahomey) and Yoruba. Nupe, Ibo, Edo and probably the Yala (Idoma) group, all in Nigeria. The Ewe-Akan languages, including Ewe, the Fõ of Dahomey. Twi, Ashanti, Fanti, Agni, Guang and Gã belong in the same subdivision with the Togo languages (Avatime, Adele and others) and the various languages of the Ivory Coast lagoon. The Kru languages of Liberia probably belong in the Kwa subdivision also.

j. The central group contains as a subdivision Bantu which covers the vast areas of the Congo basin, Angola, Mozambique and much of South Xirica; the rest of the languages are in Nigeria and the western Cameroons. They include Bassa, Kamuku, Katab, Munshi (Tiv), Jukun, Ekoï and Eñik. The Eute language of the Cameroons may belong to this group.

6. The Ijo (Ijaw) language of the Niger delta seems to form a separate group.

7. A large group of little-known languages mostly in the Cameroons constitute the Adamawa group. Examples of Adamawa languages are Chamba, Daka, Vere, Longuda, Tungur, Jen, Kam, the Mbum group, Masa and Bua-Nielim-Koke.

8. An eastern group extends as far as the Sudan and includes Banda, Zande, Sango, Bwaka, Mondunga, Sere-Ndogo, Barambo and possibly Gbaya. Gbaya shows some evidence of affiliation with the Adamawa group, and the Adamawa and eastern groups may turn out to form a single group.

The Niger-Congo languages are tonal with few exceptions. Nouns are generally divided into classes each marked by a pair of affixes, one for the singular and one for the plural. These changes are marked by either prefixes, suffixes or both in combination. Examples are: (1) prefixes, Yagua (central group): *u-tu*, pl. *a-tu* "ear"; (2) suffixes, Guresha (Gur group): *tu-i*, pl. *tu-e* "ear"; (3) both in combination, Gurma (Gur group): *o-yontb-o*, pl. *i-yomb-i* "slave." Human beings, without regard to sex, usually belong to a single class. liquids to another. All names of trees are usually found in another class but along with nouns having other meanings. For other classes, no general principle of classification is discoverable. A minority of languages such as Ewe (Kwa group), Malinke and many other Mandingo languages, Jukun (central group), Kam (Adamawa group) and Bwaka (eastern group) have lost most or all of this system of classification. These languages generally resort to the addition of the pronoun "they" to form a plural and rely on word order in place of the agreement between noun and adjectives or noun and verbs characteristic of the class languages of the family, such as Bantu. This process of agreement may be illustrated from Swahili, a Bantu language. In the sentence *ki-su ki-kali ki-moja ki-me-potea* "knife sharp one has-been-lost," i.e., "one sharp knife has been lost." -*su* "knife" has *ki-* as its class prefix, and this is repeated before every word agreeing with *-su*. The plural prefix corresponding to *ki-* is *vi-*; thus the plural of the preceding is: *vi-sir vi-kali vi-nane vi-me-potea*, "eight sharp knives have been lost."

The affixes, whether prefixed, suffixed or both, are in general agreement throughout the Niger-Congo family and must therefore belong to the original language from which the modern languages have evolved.

The Niger-Congo verb is usually unchanged except for tonal modifications. Tenses and moods are indicated by such changes and, by the use of auxiliary verbs, for example, the verb "to come" to indicate the future. Some languages particularly in the West Atlantic. Gur and central groups including Bantu, have elaborate systems of verb derivation. To cite Swahili again, from *patā* "to obtain" the following derivatives may be formed: *patana* "make an agreement," *patanisha* "to unite," *patia* "to obtain for somebody," *patika* "to be vexed," *patiliza* "to vex someone," *patilizana* "to vex each other" and others.

The Macro-Sudanic Family.— This group of languages is widespread in east Africa and the upper Nile valley. It extends westward in the Congo-Nile divide area as far as the Sara languages near Lake Chad. The subdivisions of this family are (1) East Sudanic, containing: (a) the Nubian dialects of the Nile valley and of Kordofan and Darfur to the west; (b) Tabi; (c) Didinga-Murle; (d) Merarit; and (e) Dagū. The most important branch is a southern group (fj, of which there are two subgroups, Nilotic

(Shilluk, Dinka, Nuer, Acholi, Anuak, Lango, Jur, etc.) and Great Lakes (so-called Nilo-Hamitic; Masai, Bari, Teso, Karamojo, Turkana, Lotuko, Nandi, Suk). (2) Central Sudanic with the following branches: (aj) Bongo-Baka-Bagirmi-Sara; (b) Kredj (Kreish); (c) Moru-Madi; (d) Mangbetu; (e) Mamvu-Balese (including the language of the Efe pygmies of the Congo); and (f) Lendu. (3) Kunama, spoken in northwestern Ethiopia. (4) Berta, spoken in the Ethiopia-Sudan border area. Berta is particularly close to Eastern Sudanic and probably forms a group with it.

Thebe languages are likewise tonal as far as is known. Nouns have complex plurals but no division into noun classes. The Great Lakes division of the Eastern Sudanic family has grammatical gender and some other languages of the Eastern Sudanic family exhibit traces of it. Eastern Sudanic languages often have a complex system of verb derivatives: e.g., Nubian and Masai.

The Click Family.— This family contains three branches: (1) the Khoisan languages of the Bushman (*q.v.*) and Hottentot (*q.v.*) of south Africa; (2) Sandawe of east Africa; and (3) Hadzapi of East Africa. The Khoisan languages in turn fall into a northern, central and southern branch. The Hottentots form a subdivision of the central branch along with the closely related Naron and Xuen Bushman languages.

As indicated by their name, these languages are characterized by the presence of click sounds, sounds not found anywhere in the world outside Africa. A few of the neighbouring Bantu languages have borrowed click sounds from their Khoisan neighbours. The click languages are probably all tonal. Hottentot, Naron, Xuen and Sandawe have grammatical gender; e.g., Nama Hottentot *khoi-b* "man," *khoi-s* "woman." There are traces of a verbal derivative system particularly in Hottentot. Plural formation is usually simple, outside of some southern Bushman languages.

The Central Saharan Family.— This comprises: (1) Kanuri, the chief language of the aboriginal Bornu kingdom on the borders of Lake Chad in northern Nigeria; (2) Tebu of Tibesti, the large mountainous region of the central Sahara; and (3) Zaghawa and Berti, spoken farther to the east. These languages are probably all tonal, though there is no information in this regard except for Kanuri. They differ somewhat in type from the languages already described. They have neither noun classes nor gender divisions. On the other hand the noun has a case system, a feature also found in Nubian and Nuer in the Eastern Sudanic subdivisions of Macro-Sudanic. The verb has an elaborate conjugational set of inflections for person and number in various moods and tenses and a set of subordinating forms by means of which complicated sentences can be constructed. There is also a fairly simple system of verb derivatives.

Minor Families.— In addition to these major families, there are a number of other families of minor size which on present evidence must be considered independent. However, some of the languages were not at all well known in the 1950s and might prove their membership in one of the larger families. The Kordofanian family consists of a large number of languages spoken in the Nuba hills of Kordofan in the Sudan. These languages have class prefixes whose function is very similar to that of affixes of the Niger-Congo family, although they show little evidence of etymological connection. These languages are insufficiently known but are probably tonal. There is some evidence for a verb derivational system. The Coman family consists of the various Coma dialects. Gule (Hameg) and Gumus all found in a relatively restricted area of the Ethiopian-Sudan border area. They are little known. Gule, at least, appears to have grammatical gender. In the western part of the Sudan is found Fur, the chief language of Darfur and still further west in Wadai a group consisting of Maba, Mimi and other related languages of the Maban stock. Both Maba and Fur are of the same general type as the Central Saharan languages. Maba is definitely known to be tonal. An important isolated language is Songhai, the speech of Tombouctou, of the city of Agades in the air oasis of the Sahara, and of the Niger valley farther south in the region of Djarma. This language has neither noun classes nor gender; in its general grammatical simplicity, it reminds one of English. The verb has a causative suffix. Minor, almost unknown languages, which must be considered independent are Ny-

angiya, surrounded by Lotuko (Eastern Sudanic) dialects in east Africa and two related languages of the Nuba hills, Temainian and Teis-um-Danah, both only known from a 20-word vocabulary. The languages of the island of Madagascar are Malayo-Polynesian being most closely related to those of Indonesia. Meroitic was spoken in the area of the junction of the Blue Nile and White Nile and written in a hieroglyphic alphabet for several centuries before and after the birth of Christ. In the absence of bilingual inscriptions it is only imperfectly known and thus cannot be related to any other language.

The outstanding problems of classification which remain are the precise subdivisions of the Niger-Congo family and of the Bantu subgroup within it and the status of the smaller families.

Common Features of African Languages.—From this review it can be seen that there are certain features common in African languages. Among those which have been mentioned are tone, the presence of noun-classes and of verb derivational systems. Other general characteristics of African languages are the following. Vowel systems most commonly contain five vowels as in classical Latin (*a, e, i, o, u*), or seven as in Italian (*a, e, i, o, u, ø, ü*). Unvowelled vowels like those of German are quite rare. In addition to the clicks already mentioned there are labiovelar consonants (*kp, gb*) over a widespread and continuous area mostly occupied by Niger-Congo and Macro-Sudanic languages and there are implosive consonants. While neither labiovelars nor implosives are confined to Africa, they are rare elsewhere in the world. Outside of Hamito-Semitic, consonant systems tend to be simple. Tones are based on pitch levels usually two or three in number. They are thus unlike the contours of rises and falls characteristic of Chinese and other tonal languages of southeastern Asia.

There are many features of semantics and idiom which are widely distributed in Africa. For example, a verb meaning "to surpass" is used to express the comparative. Hausa *yā finī girmā*, "he surpassed-me size"; *i.e.*, "he is larger than I am." Parts of the body are often used as prepositions; "upon" is, literally, "head of," "in front" is "chest of," etc. Other examples of such semantic resemblance is the use of a single term meaning both "animal" and "meat" and the extended metaphorical use of the verb "eat" in the sense of "conquer, win, gain! etc."

Language and History.—The linguistic groupings enumerated above are, as might be expected, only in imperfect agreement with the distribution of physical types in Africa. The clearest correlation is that between the Hottentot-Bushman racial type and the click language. On the other hand, the Pygmies have not yet been demonstrated to have a language of their own, though such may exist. The Hamito-Semitic family is spoken both by Caucasian and Negro peoples. The speakers of Semitic, Berber, and the extinct Egyptian languages are white while those of the Cushite and Chad branches are predominantly Negro. The origin of this situation is unknown. It has been noted that the term Hamitic does not designate any linguistic entity. Whatever its racial value may be, it therefore has no linguistic support.

Distributions of language are valuable indicators of movements of people in the absence of direct historical records. The most important conclusions regarding the pre-history of Africa to be drawn from linguistic evidence are (1) the origin of the Bantu in the Nigeria-Cameroon area followed by a general southeastward movement beginning perhaps 2,000 years ago, and (2) the African, probably upper Nilotic or Abyssinian, origin of the Hamito-Semitic peoples, the Semitic branch resulting, no doubt, from a migration into Asia, probably Arabia. Many other details of movements can be reconstructed from linguistic evidence used in conjunction with written documents, recorded traditions and archaeology. Much work which will be of value for African history remains to be done with loan words which reflect cultural contacts. Words from Greek, Latin and Punic have penetrated into the Sudan, usually via Berber. Moslem influences are discernible in the spread of words from Arabic and more recent European influence, particularly Portuguese, is found in words for domestic plants and animals and technological terms.

AFRICAN LILY (*Agapanthus africanus*), a member of the family Liliaceae, a native of the Cape of Good Hope, from whence it was introduced at the close of the 17th century. It is a handsome greenhouse plant, which is hardy in the south of England and the warmer parts of the United States. The basal, tufted leaves are long, narrow, arching, six inches to two feet long. A central flower stalk, two to three feet high, ends in an umbel of bright blue, funnel-shaped flowers. The plants are easy to cultivate and are generally grown in large pots or tubs which must be protected from frost in winter. During the summer they require plenty of water and are effective on the margins of lakes or running streams, where they thrive admirably. It may be propagated by dividing the rootstock in early spring or autumn. Dwarf and white-flowered forms are known in cultivation.

AFRICAN MUSIC. Africa falls, musically, into two main areas separated by an east-west line running south of the Sahara and Ethiopia. North of this line the music is predominantly Arabic; south of it is found what is called African music—the music of the Negroid peoples. In spite of the different language families represented by the large number of tribes (more than 2,000), the music of this huge area is fundamentally homogeneous and its chief characteristics are: (1) Spontaneous creation; while the tune and words of a song or the drumming for a dance will keep within the traditional pattern of melody or rhythm, they are not crystallized in a standard form, but are modified at each rendering by the creative genius of the performers. This modification is not an embellishment but a fundamental principle of the system, which may be defined as "free creation around a traditional framework." (2) A melody tied to the rise and fall of speech in the "tonal" languages, where the meaning of words depends on the pitch at which each syllable is spoken—in such cases, the course of a melody cannot be dictated solely by musical principles, but must (to preserve the word sense) move generally up and down in conformity with the spoken word, a powerful inhibiting factor to the development of musical form. (3) A limited harmonic development. (4) An exceedingly complex rhythmic structure.

Rhythmic System.—The essence of the African rhythmic system is tension. Thus, while in western music the accents of a melody usually coincide with time beats (indicated by a baton or a handclap), in African music they normally must not do so. The

melodic accents are in free rhythm (yet, in repetitions, always falling in the same places), and although the melody itself is tied to the claps, which may be either a regular beat or an irregular short pattern constantly repeated, the claps do not determine the rhythm.

The principle of rhythm in drumming is different. Here tension is attained by a deliberate staggering of the main accented beats of the several drums. To state the matter at its simplest, if two drums were to beat in triple time; the main beats of the second drum would fall on the second or third beat of the first drum's bar, never on its first beat. In addition, the various drums may be playing in different metres, thus further staggering the main beats (e.g., 3 against 2: 4 against 3); but this is not necessarily the case. In practice, where three drums are used, the small drum beats a simple duple or triple pattern while the master drummer, playing the big drum, has in each different kind of dance five or six fairly long standard patterns in free rhythm, the accents of which lie athwart those of the small drum. Using one of his patterns as a basis, the master drummer plays spontaneous variations on it with great virtuosity, modifying them to suit the style of individual dancers. Meanwhile, the middle drum gives standard "replies" to the master drum, the accents of which also cross those of the small drum. Thus a full dance, which is both the norm and the flower of African music, is a complex interweaving of melodic and rhythmic patterns the inherent accents of which are in a constant state of tension.

Use of Harmony. — Both vocal and instrumental forms of simple harmony or heterophony are found, though some tribes restrict themselves to unison. This heterophony is usually in the form of organum and is either in parallel thirds or in fourths or fifths. The groups favouring the one or the other are mutually exclusive, though there are a few borderline tribes which use both. There is reason to think that the thirds tradition is of Indonesian origin: it is met with in pockets in the Malay archipelago and notably on the Island of Madagascar, while in Africa it seems to have started on both the east coast and the west (Gulf of Guinea) and to have spread inland.

Instruments. — African musical instruments (a great variety of drums, xylophones, strings, horns, flutes and idiophones) even if of primitive appearance, often exhibit a considerable musical precision, although it is necessary to distinguish between an instrument as it leaves the craftsman and as it is later modified by indifferent performers. Functionally, instruments may be classified according to whether they are used for community occasions, for solo playing or solo accompaniment or for the performer's own pleasure. In areas where Islamic influence is felt, such as the lake regions of Uganda, in the northeast part of the Republic of the Congo and in Nigeria, stringed instruments are prominent.

Among the Chopi in Mozambique, where the xylophone is paramount, drums play a minor role. The Venda of South Africa use a flute ensemble for some dances. All these instruments are used for communal dances but usually the drums, with rattles and often iron clapperless bells, are the main communal instruments.

Of special interest are the *sansa* (known also as the *mbila* and as the Kaffir piano) and the xylophone. The former consists of a calabash resonator with a small soundboard on which is mounted a tuned series of metal or bamboo prongs which are played by the thumbs, the instrument itself being supported by the fingers of both hands. The *sansa* has not been found in any other part of the world, yet its distribution in Africa is similar to that of the xylophone, with which it sometimes shares the name *mbila* and to which it is similar in tuning. The African xylophone has two characteristic tunings: equitonal heptatonic and equitonal pentatonic.

Close parallels with the African xylophone in tuning and pitch are found in the xylophones of Thailand and Cambodia (for heptatonic) and in those of Java (for a modified heptatonic scale known as *Pelog*, and also for the pentatonic *Slendro* system). Recent research suggests that Africa may owe a large musical debt to Indonesian colonization. (See also MUSICAL INSTRUMENTS:

Chronological Evolution of Instruments; PERCUSSION INSTRUMENTS.)

Relation to Tribal Life. — Music is of the very fibre of African tribal life. It is an essential part (and not an adornment) of religious ceremonies. It is integrally associated with the events of the life cycle—birth, marriage and death—with initiation (for which special music is learned) and with serious sickness (when the patient must be induced to dance to the music). It is closely associated with royalty, the chiefs owning court orchestras and their movements being accompanied by music. It is the universal spur to protracted work, and here the rhythms of work are deftly exploited: pounding grain, paddling canoes, hoeing the fields, rock drilling in the copper mine, are all accompanied by singing, while even the operation of a European sewing machine is turned into a rhythmic pattern. Communal recreation must have music: folk-tales are interspersed with songs in which the chorus is sung by the audience; a "beer-drink" has singing and dancing; and the most common recreation for the whole village is to gather for drumming, singing and dancing. But besides this communal aspect, music (instrumental or vocal) is a form of individual delectation. One sings or plays to oneself just for pleasure. Music thus plays a part in African life which is vital both to society and to the individual. African music proliferates without any conscious theoretical system, depending entirely on creative musicianship within traditional practice.

Modern Developments. — After about 1920, there developed all over this area a new type of music, part western, part African, deriving from the spread of popular American dance music, heard on phonograph records, and from four-part western harmony learned in schools and churches. Basically this music is western in rhythm (usually in common time) and in harmony (the most usual chordal sequence being the triads on tonic-subdominant-dominant and tonic, constantly repeated) but the melody tends, as time passes, to become more and more African. It is played on western dance band instruments, particularly the guitar and the accordion, though occasionally (e.g., in Ghana) indigenous instruments or their substitutes are used (for instance, a wine bottle struck with a spoon in place of an African iron bell and wooden striker). This hybrid music, which has tended to replace the traditional forms at least in urban areas, has a great urge; new musical forms in this idiom and new modifications of it appear every few years.

J.)

AFRICANUS, SEXTUS JULIUS, a Christian traveler and historian of the 3rd century, wrote a history of the world in five books, from the creation to A.D. 221, which introduced a system of chronology widely adopted in the eastern churches. He was probably born at Aelia Capitolina (Jerusalem) and lived at Emmaus, and may have served under Septimius Severus against the Osroenians in A.D. 195. In his history he calculates the period between the creation and the birth of Christ as 5,499 years, antedating the latter event by three years. This method of reckoning was known as the Alexandrian era. The history, which had an apologetic aim, is no longer extant, but copious extracts from it are to be found in the *Chronica* of Eusebius of Caesarea. There are also fragments in Syncellus, Cedrinus and the *Paschale Chronicon*.

Eusebius also gives a letter to Aristides, and one to Origen, impugning the authority of the book of Susanna. The ascription to Africanus of the *Kestoi*, a work on agriculture, natural history, military science, etc., has been disputed. Neander suggests that it was written by Africanus before he had devoted himself to religious subjects.

AFRICAN VIOLET, also known as Usambara violet, belongs to the genus *Saintpaulia* of the botanical family Gesneriaceae. Four species are known in tropical Africa, but only two of these, *S. ionantha*, the common African violet, and *S. kewensis*, the Kew African violet, appear to be in cultivation. The plants are small and often stemless, hairy, perennial herbs, with basal long-stalked leaves and two-lipped, almost white to violet or red flowers in few flowered cymes. Through breeding and careful selection after about 1925 a large number (perhaps as many as zoo) of horticultural varieties were developed and named, although the plant had been discovered only late in the 19th century. It became a popular greenhouse plant and one of the favourite potted window plants for home growing.

Propagation is by seed and by leaf cuttings inserted in sand. The ripened leaves should be cut off with about an inch of the petiole attached, and inserted in sand with only a little of the leaf blade covered. The sand should be kept moist but not too wet while rooting is occurring to avoid rot.

The method of watering and the temperature of the water have a marked influence on vigour and flowering, although plants watered in different ways may do equally well.

One common method is to permit the plants to become fairly dry, then soak thoroughly by placing the pot in a shallow pan of water overnight; allow to again dry fairly well before watering again, but take care to prevent water reaching the leaves or washing over the rim of the pot. Although the size and type of pot, the season of the year, the weather and temperature and the light condition are all important factors affecting the water requirement, no fast rule can be prescribed. Cleansing the foliage of dust at intervals by means of a syringe or a rubber sprayer is beneficial and recommended. The temperature of the water preferably should be warmer than that of the room in which the plants have been growing. Allow drying to occur away from direct sunlight and in warm circulating air. With experience and care African violets may be grown easily and successfully. It is easily possible to keep them flowering through the entire year, or the plants may be given periods of rest by reducing the supply of water.

AFRIDI, a powerful Pathan (*q.v.*) tribe, with a fighting strength estimated at about 50,000 men in the 1960s, inhabiting the hill country from the eastern spurs of the Safed Koh to the borders of the Peshawar district in West Pakistan. Important because they straddle the Khyber pass, they have a fertile but inaccessible base in the Tirah (*q.v.*) uplands (6,000–7,000 ft.).

Zahir-ud-din Babur, the Mogul invader of India, found them in the Khyber area in 1504, outside the control of any organized government. They remained so despite repeated Mogul efforts to control the road to Kabul. The emperor Akbar (*q.v.*) drove a cart road through the Khyber in 1581, but Afridi resistance, inspired by Jalal-ud-din, leader of the heretical Roshania movement, closed the pass to the emperor's first governor of Kabul, Man Singh, in 1585. Heavy fighting and the grant of allowances were needed to reopen it.

In 1622 a Mogul attack on Afridi and Orakzai Roshanias in Tirah ended in disaster on the Sampagga pass. Then, in 1630, after another Kabul governor, Muzaffar Khan, had suffered ignominious loss in the Khyber, a general tribal rising occurred, and Peshawar city was taken. The tribesmen were caught in the city and thoroughly beaten, and the Roshania leaders were exiled to India, but in 1672 another Mogul commander lost his entire army to the attacks of Afridis, who went on to capture Nowshera fort. The em-

peror Aurangzeb himself had to come north in 1674 to restore order by multiple campaigns and bribes.

The Afghan amir Ahmad Shah Durrani (*q.v.*) in the 18th century also paid allowances to the Afridis and employed them in his armies, and his grandson Shah Shuja received considerable support from the Afridis and asylum in defeat. They joined Dost Mohammed in attacking the Sikh, Hari Singh, at Jamrud in 1837.

British encounters with the Afridis began during the first Afghan War (1839–42), notably when Gen. George Pollock, marching his avenging column to Kabul, first used the flank picket technique against them with success. After the British annexation of the Punjab in 1849 all the old expedients were tried to keep the Khyber open: allowances, punitive expeditions such as those of 1878 and 1879 against the Kohat and Khyber Afridis, and the use of tribal militia (the Khyber Rifles, raised by Sir Robert Warburton). More novel and lastingly effective were the building of the Khyber railway and the foundation, by Sir George Roos-Keppel, chief commissioner of the North-West Frontier province, of Islamia college, now the University of Peshawar.

Throughout the 1930s the British position was complicated by the Indian Congress party's success in enlisting tribal support for the Red Shirt political movement under Khan Sahib and his brother Abdul Ghaffar Khan. After 1947, moreover, Pakistan had to face an Afghan-supported movement for an independent Pakhtunistan or Pathan state and to protest against Afghan support for Afridi attacks.

The Afridis, wiry, shaven-headed, full-bearded, Pakhtu-speaking hillmen, are of uncertain origin. Their genealogies loosely connect them by the adoption of a founding child with the other Pathan tribes, but they also link them with Urmaris, who speak an East Iranian language, so that it seems probable that the Afridis are older settlers; who have adopted the Pathans' language and customs. Indeed, the Afridis have been identified with the Aparytae mentioned by Herodotus as living in the Peshawar area. While Henry Bellew, Sir George Grierson and Sir Aurel Stein supported this identification, G. Morgenstierne and H. W. Bailey rejected it, but a persuasive restatement of it was made by Sir Olaf Caroe (see *Bibliography*, below).

AFTERBIRTH includes the placenta, amniotic fluid, fetal membranes and umbilical cord. They are usually expelled from the uterus in a single mass 15 to 30 minutes after the birth of the child. The placenta is a soft, beefy red disk, about 8 to 10 in. in diameter and 1 to 1½ in. in thickness. It is the organ by which the mother nourishes the child and is composed largely of capillary loops from mother and child, in close contact. While the mother's blood does not pass into the blood vessels of the child, the constituents necessary for growth pass through the capillary walls into the child's circulation by a process called osmosis, and the waste products in the fetal blood pass in the other direction and are eliminated by the mother. One surface of the placenta is attached to the inside of the uterus, whence it draws its maternal blood. The other surface presents the branching blood vessels of the fetus, which unite into one artery and two veins. These vessels form the umbilical cord, which usually starts from the middle of the placenta and enters the body of the fetus at the navel. It is about 22 in. long. Around the edge of the placenta is the thin torn membrane which envelops the fetus in the womb. It forms the water bag in which the fetus lies and usually breaks shortly before the birth of the child. If, however, the child is born with the membranes intact, he is said to be born in a caul. AFYONKARAHISAR, the popular name of Kara-hisar Sahip, the chief town of an *il* (province) of the same name in west-

JOHN H. GERARD
AFRICAN VIOLET (SAINTPAULIA
IONANTHA)

ern Asiatic Turkey, nearly 200 mi. E. of Izmir and 50 mi. S.S.E. of Kutahya. Pop. (1960) 38,392. Called Nicopolis by Leo III after his victory over the Arabs in 740, the town's name was changed by the Seljuk Turks to Kara-hisar. It stands partly on level ground and partly on a declivity, and above it rises a precipitous trachytic rock (400 ft.) on the summit of which are the ruins of a Byzantine castle. It contains several mosques, one of them a very handsome building. It is an important railway junction, connected with Izmir, Konya, Ankara and Istanbul, and is on the Konya-Istanbul road. The town is a centre of trade, notably for opium, which is produced in large quantities in the vicinity. Wheat and barley are the other chief products of the district, and stock raising is an important occupation. Black felts and carpets are manufactured.

(N. Tu.; S. ER.; E. Tr.)

AFZELIUS, ADAM (1750–1837), Swedish botanist who founded the Linnaean institute at Uppsala, in 1802, was born at Larf, Vastergotland on Oct. 8, 1750. From 1792 he spent several years on the west coast of Africa, and in 1797–98 he acted as secretary of the Swedish embassy in London. In 1812 he became professor of materia medica at the University of Uppsala. In addition to his various botanical writings he published the autobiography of Linnaeus in 1823. Afzelius died at Uppsala in 1837.

His brother **JOHAN AFZELIUS** (1753–1837), known as Arvidson, was professor of chemistry at Uppsala; another brother **PER AF** (1760–1843), who became professor of medicine at Uppsala in 1801, was distinguished as a medical teacher and practitioner.

AGA (AGHA), a Turkish word indicating, under the Ottoman empire, a person of high rank or social position. Combined with the names of military units or administrative departments it formed the official titles borne by the chief officers of the janizaries and of the cavalry, by the principal members of the imperial household and by the eunuchs controlling the sultan's harem. Later it was applied to officers of lower rank and, socially, as a term of respect to heads of families and villages and to landowners. In republican Turkey the official title disappeared, the social use of the word surviving only among the lower classes. (A. D. A.)

AGADE, a city founded as his capital in Babylonia by the Semitic conqueror Sargon I about 2300 B.C.; from it the northern part of the country was called Akkad (*q.v.*). The proposed location of it at Tall ad-Der, near Sippar, is questionable; as a chronicle records that Sargon took earth from Babylon to build his new city, it cannot have been far from the later capital. After its foundation Agade was the seat of a dynasty of 11 kings, but only the first four or five of these ruled over neighbouring lands. The city, as a principal sanctuary of the goddess Ishtar, remained of some religious importance until Babylonian rule ended in the 6th century B.C.

See S. Langdon, *Excavations at Kish*, 1,7 (1924). (C. J. G.)

AGADIR, a town on the Atlantic coast of southern Morocco, Africa, about 6 mi. N. of the Wadi Sous, and capital of the province of the same name, was entirely destroyed by a severe earthquake on Feb. 29, 1960. The site was flattened and plans were made for a new town about 3 mi. S., with buildings incorporating antiseismic features. The port, constructed in 1914, enlarged in 1930 and again greatly enlarged and refitted in 1953 was not entirely destroyed and was brought into use again. The population in 1960 was 16,695, of whom 15,828 were Moroccans. Its growth from 1,000 in 1913 was due to the development of agriculture in the Sous plain, to the exploitation of mineral resources in the interior and to the large fish-canning industry (mainly sardines).

Agadir was occupied by the Portuguese in 1505 and known as Santa Cruz del Cabo de Aguer. The Berber tribes of Sous carried on an intermittent holy war against the fortress and it was captured in 1541 by the Saadian king of Sous. The town came into prominence during the Moroccan crisis of 1911 when a German gunboat appeared off the town "to protect German interests" in spite of the international agreement of Algenciras in 1906 to which Germany was a party. This crisis was settled between France and Germany on Nov. 4, 1911, and Agadir was occupied by French troops in 1913.

The province of Agadir extends over the plain of Sous and over part of the western High Atlas mountains and of the Anti-Atlas, and has a population of (1960) 843,758. (A. Aar.)

AGA KHAN, title of the imam or spiritual leader of the Ismaili sect of the Shi'ite Muslims.

AGA KHAN I (Hasan Ali Shah) (1800–1881), the first holder of the title, claimed to be directly descended from Ali, the son-in-law of the prophet Mohammed, and his wife Fatima, Mohammed's daughter, and also from the Fatimid caliphs of Egypt. He was the governor of the Persian province of Kerman and was high in the favour of the shah, Fath Ali. It was from the Persian court that he acquired the title of Aga Khan. Under Mohammed Shah, however, he felt his family honour slighted and rose in revolt in 1838, but was defeated and fled to India. He helped the British in the first Afghan War (1839–42) and in the conquest of Sind (1842–43) and was granted a pension and also the style of "His Highness." After he had settled in Bombay, he encountered some opposition from a minority of his followers, who contested the extent of his spiritual authority and in a lawsuit challenged his control over the community's funds, but he won his case (1866). He died in April 1881.

AGA KHAN II (Ali Shah) (d. 1885), the eldest son of the Aga Khan I, succeeded his father in 1881 and, in his short imamate, sought to improve the conditions of his community. He died at Poona in Aug. 1885.

AGA KHAN III (Sultan Sir Mohammed Shah) (1877–1957), only son of the Aga Khan II, succeeded his father in 1885. He was born at Karachi on Nov. 2, 1877. Under the care of his mother, a daughter of the ruling house of Persia, he was given not only a religious and oriental education but also a western one. Besides attending diligently to the affairs of his own community, he rapidly acquired a leading position among India's Muslims as a whole. In 1906, he headed the Muslim deputation to the viceroy, Lord Minto, which claimed that in any extension of representative institutions in India the Muslim minority should be granted a position that accorded not merely with their numerical strength but with their loyalty and political importance. The Morley-Minto reforms of 1909 consequently provided for separate Muslim electorates. He served as president of the All-India Muslim league during its early years and initiated the fund for raising the Muslim college at Aligarh to university status, which was effected in 1920.

When World War I broke out the Aga Khan cabled to the *jamats* or councils of the millions of Ismailis within British territories and on their borders, directing his followers to place themselves unreservedly at the disposal of the British authorities. When Turkey was drawn into the war, he issued a manifesto calling upon the Muslims of the British empire to remain loyal. However, at the peace conference and subsequently he urged that Turkey should be leniently treated. For his services during the war he was granted a salute of 11 guns. He played an important part in the Round Table conferences on Indian constitutional reform in London (1930–32): besides leading the Muslim delegation, he was made chairman of the entire British-Indian delegation. He also represented India at the World Disarmament conference in Geneva, Switz., in 1932, and at the League of Nations assembly in 1932 and from 1934 to 1937. He was appointed president of the league in 1937. During World War II he lived in Switzerland and withdrew from political activity.

In his leadership of the Ismailis the Aga Khan concerned himself with their temporal as well as spiritual welfare. Though they are distributed over a large area (including Syria, Iran, central Asia, India, Burma, Malaya and east Africa), he was able to make his views known to them as a result of their organization into local and regional councils. In general, he advised them to conform to the customs of whatever country they happened to be living in. He took particular care to encourage them to form co-operative enterprises such as banks, insurance companies, building societies and organizations for social welfare.

The Aga Khan was well known as a successful owner and breeder of thoroughbred horses and won the English Derby five times. He died at Versoix, Switz., on July 11, 1957.

AGA KHAN IV (Prince Karim) (1936–), nominated to the imamate by his grandfather, the Aga Khan III, was born at Geneva, Switz., on Dec. 13, 1936, the elder son of Prince Aly Khan by his first wife, the daughter of the 3rd Baron Churston. The new Aga

Khan, having completed his studies at Harvard university in June 1959, continued the visits to his Ismaili peoples which he had started in the first year of his reign.

BIBLIOGRAPHY.—Sultan Sir Mohammed Shah, *The Memoirs of Aga Khan* (1954); N. M. Dumasia, *The Aga Khan and His Ancestors* (1939); J. N. Hollister, *The Shi'a of India* (1953). (KE. A. B.)

AGALMATOLITE, a compact variety of the soft mineral pyrophyllite (*q.v.*), hydrous aluminum silicate, also called pagodite, used by the Chinese for carving, especially into grotesque figures (hence called figure stone).

AGAMEDES, in Greek legend, king of Orchomenus in Boeotia. He and his stepbrother Trophonius were skilled architects and constructors of underground shrines and treasure houses. When building a treasure house for the Boeotian king, Hyrieus, the brothers fixed one of the stones in the wall in such a manner that they could remove it whenever they pleased and help themselves to the treasure. Hyrieus set a trap in which Agamedes was caught; Trophonius to prevent discovery cut off his brother's head and fled with it. He was pursued by Hyrieus, and swallowed up by the earth in the grove of Lebadeia. On this spot was the oracle of Trophonius in an underground cave; those who wished to consult it, first offered a ram and called upon the name of Agamedes. A similar story is told of the treasure of Rhampsinitus by Herodotus. The brothers built the temple of Apollo at Delphi. When they asked for a reward, the god promised them one in seven days; on the seventh day they died.

AGAMEMNON, a Homeric hero, king of Mycenae (according to Homer) or Argos (according to Aeschylus), son of Atreus and Aerope, grandson of Pelops, great-grandson of Tantalus and brother of Menelaus. After the death of Atreus (*q.v.*), Agamemnon and Menelaus took refuge with Tyndareus, king of Sparta, and his wife Leda, whose daughters, Clytemnestra and Helen, they respectively married. By Clytemnestra, Agamemnon had three daughters, Iphigenia (Iphianassa), Electra (Laodice) and Chrysothemis, and a son, Orestes. Menelaus succeeded Tyndareus, while Agamemnon, with his brother's assistance, drove out Aegisthus and Thyestes and recovered his father's kingdom. He extended his dominion by conquest and became the most powerful prince in Greece. In some ancient sources he is represented as ruler of a large part of Achaea.

When Paris (Alexandrus), son of Priam, had carried off Helen, Menelaus' wife, Agamemnon went to the princes of the country and called upon them to unite in a war of revenge against the Trojans. He himself furnished 100 ships, the largest contingent of the expedition, and was chosen commander in chief of the combined forces. The fleet, numbering 1,200 ships, assembled at the port of Aulis in Boeotia, but was prevented from sailing by calms or contrary winds. Agamemnon had in some way offended Artemis (perhaps by shooting a sacred stag, as related in Sophocles' *Electra*), who in revenge refused to permit the fleet to proceed. Calchas announced that the wrath of Artemis could be appeased only by the sacrifice of Agamemnon's own daughter, Iphigenia (*q.v.*), to which he consented. The fleet then set sail.

Little is heard of Agamemnon until his quarrel with Achilles (see HOMERIC POEMS). After the capture of Troy, Cassandra, the daughter of Priam, fell to Agamemnon's lot in the distribution of the prizes of war. On his return, after a stormy voyage, he landed in Argolis. Aegisthus, who in the interval had seduced Agamemnon's wife, treacherously plotted the murder of Agamemnon. According to Homer, Aegisthus arranged a feast to welcome the returning king and slew him, his comrades and Cassandra as they dined. The version of Aeschylus' Agamemnon attributes the murder to Clytemnestra alone (out of mixed motives: in retribution for the sacrifice of Iphigenia, out of jealousy of Cassandra and in order to continue her life with Aegisthus). Helping her husband in the bath, she enveloped him in a great robe and stabbed him to death. The murder was avenged by Orestes, who returned to slay both his mother and her paramour (Aeschylus, *Choephoroi*; Sophocles, *Electra*; Euripides, *Electra*).

Agamemnon is quite possibly a more or less historical character, overlord of the Mycenaean or Achaean states of the Greek mainland. In Hellenistic times, at Sparta, he was worshiped under the

title of Zeus Agamemnon.

AGANA, the capital of Guam, an unincorporated Pacific island territory of the United States. It is situated at the centre of the west coast of the island on a sandy beach surrounding Agana bay and at the mouth of the small Agana river. A city of 10,000 inhabitants in 1940, it was destroyed by bombardment in World War II. Its population increased only slowly after the war, reaching 1,643 in 1960.

Reconstruction was retarded by the fact that it was very difficult to determine the ownership of many small, scattered pieces of land used for new, wide streets constructed by the U.S. navy after reoccupation of the island in 1944. As a result of the difficulty of obtaining clear title to real estate, few new buildings have been erected. The town of Tamuning, just north of Agana, and Piti to the south have grown to be important business centres at the expense of the capital. The mean annual temperature, about 81° F., is nearly constant throughout the 12 months. Tropical hurricanes which hit the town almost every year occasionally do considerable damage. Agana is the seat of the unicameral legislature of the territory. The non-American population is made up of Chamorros and Filipinos. Agana has been the seat of government for Guam under three nations—Spain, which ruled the island for 300 years; the United States, which acquired it on Feb. 1, 1899; and Japan, which occupied it from 1942 to 1944.

(J. W. CR.)

AGAPE, the Greek word for "love," used (1) to describe the love of God or Christ or the love of Christians for one another and (2) the early Christian love feast.

In the first meaning the word is used most often in I Cor. xiii. but it is also found in the synoptic gospels (Matt. xxiv, 12 and Luke xi, 42) and elsewhere. It was coined perhaps from the verb *agapao* in order to avoid use of *eros*, which sometimes had sensual connotations. It is translated in Latin as *caritas*, English "charity."

The history of the agape as a common religious meal coincides, until the end of the 2nd century, with that of the Eucharist (*q.v.*), agape being the meal shared by the communicants immediately before celebration of the Eucharist. The classic New Testament allusion is I Cor. xi, 17–34, and among the early writers who refer to it are St. Ignatius (letter to the Smyrnaeans), Pliny (letter to Trajan), Tertullian (Apology), Clement of Alexandria (*Pædagogus*) and the historian Socrates (*Church History*). By the time of St. Cyprian (3rd century) the two were separated, the Eucharist being celebrated in the morning (fasting) and the agape in the evening, but Socrates (c. 380–450) records the survival (which he characterizes as singular), around Alexandria and in the Thebaid, of love feasts combined with the Eucharist, and St. Basil the Great (c. 350), states that in Egypt the laity, as a rule, celebrated the communion in their own houses, and partook of the sacrament by themselves whenever they chose. In the old Egyptian church order, known as the Canons of *Hippolytus*, there are numerous directions for the service of the agape, held on Sundays, saints' days or at commemorations of the dead. The holding of agapes in church was forbidden by the councils of Laodicea (363) and Carthage (418), and later by the council in Trullo (692).

In the Syrian, Armenian and Georgian churches the agape came to be combined with animal sacrifices of a pre-Christian age. Paulinus of Nola (c. 400) describes such sacrifices in Italy and Gaul on saints' days, and early in the 7th century Gregory the Great sent to beblittus, bishop of London, a written rite of sacrificing bulls for use in the English Church. The association in the synoptics of the earliest Eucharist with the paschal sacrifice may have provided a model, and long after the Eucharist was separated from the agape on other days of the year, the sacrifice of the paschal lamb, immediately followed by a Eucharist, was celebrated on the evening of Maundy Thursday. The council of Carthage enacted that the Eucharist should be received fasting, except on the anniversary of the Lord's supper.

Oesterley, *The Jewish Background of the Christian Liturgy* (1925); H. Lietzmann, *Messe und Herrenmahl* (1926); G. Dix, *The Shape of the Liturgy* (1913).

AGAPETUS (AGAPITUS), the name of two popes.

SAINT AGAPETUS I (d. 536), pope from 535 to 536, was a nobleman born at Rome, the son of Gordian, a priest. He was elected bishop of Rome on May 13, 535. At the time of his elevation he was an archdeacon. At the urging of the Ostrogoth king Theodahad, he headed an unsuccessful mission to Constantinople to deter the emperor Justinian I from his plans to reconquer Italy. While there he did succeed in choosing and consecrating Menas as successor to the patriarch Anthimus, whom he deposed as a Monophysite. Agapetus died in Constantinople April 22, 536, but his remains were buried in Rome. His feast is commemorated on April 22 and Sept. 20. (JN. F. B.)

AGAPETUS II (d. 955), pope from 946 to 955. He was elected on May 10, 946. A wise and pious administrator, he endeavored to restore ecclesiastical discipline. The chief events of his pontificate are the spread of Christianity in Denmark, the settlement of the dispute over the see of Reims and the attempt of the German king Otto I to become emperor in 951, which failed because the real ruler of Rome, Alberic, son of Marozia, was too powerful. Agapetus died in Dec. 955. (C. P. L.)

AGAR, or **AGAR-AGAR**, is a gelatinlike product of red seaweeds, made from *Gelidium* and other agarophytes (agar-bearing plants) such as *Gracilaria*, *Ahnfeltia* and *Pterocladia*. It is best known as a bacteriological culture medium and is extensively used for food, as roughage, and in making jelly desserts, confectionery, icings, salad dressings and dairy products. It is employed in canning meat and poultry, in laxative preparations, as a constituent of medicinal pills and capsules, in numerous pharmaceutical and cosmetic creams and jellies, as a dental impression mold base and in wire-drawing lubricants. Agar is prepared by boiling the agarophytes in water and subsequently purifying and drying the product. It is produced chiefly in Japan and also in China, the U.S.S.R., the United States, Mexico, South Africa, New Zealand and Australia. It is amorphous and translucent and may be found on the market in the form of powder, flakes, shreds or bricks.

Agar is insoluble in cold water, but swells considerably, absorbing as much as 20 times its own weight of water. It readily dissolves in boiling water and is able to set to a firm gel at concentrations as low as 0.5%. Although a 1% agar sol solidifies at about 104° F., its gel does not melt until about 203° F., showing a striking case of hysteresis. Agar gels carry small negative electric charges. Like other gels, they exhibit syneresis. Chemically, agar is the sulfuric ester of a linear galactan, consisting of a long chain of d-galactose residues attached to each other by a 1, 3-glycosidic linkage. This chain is terminated by one 1-galactose residue which is attached to the rest of the chain through carbon atom 4, and is esterified at carbon atom 6 with sulfuric acid. There are probably as many as 53 galactose units to each SO₄H group. In the natural state, agar occurs as a cell wall constituent of the agarophytes, probably existing in the form of its calcium salt or a mixture of calcium and magnesium salts.

Tseng, "Agar: A Valuable Seaweed Product," *Scientific Monthly*, 58: 24-32 (1944); C. K. Tseng, "Phycocolloids: Useful Seaweed Polysaccharides," in Jerome Alexander, *Colloid Chemistry*, vol. vi, *Technology and Applications of Colloids*. (C. K. T.)

AGARDE, ARTHUR (1540-1615), English antiquary, a friend of Sir Robert Cotton and William Camden, and one of the group of early antiquaries and bibliophiles on whose industry later scholars depend for their materials. He was born at Foston, Derbyshire, in 1540. He was trained as a lawyer, although eventually he entered the exchequer as a clerk. Anthony à Wood stated in his *Athenae Oxonienses* that Agarde was appointed deputy chamberlain in 1570 by Sir Nicholas Throckmorton and that he held this post for 45 years, but his patent of appointment proves that he succeeded one Thomas Reve in the post on July 11, 1603.

Agarde was an early and keen member of the Society of Antiquaries founded by Archbishop Matthew Parker in 1572, and later joined by Camden, Cotton and Selden. He devoted much time to cataloguing the exchequer rolls and state papers, and made special studies of the Domesday Book, the origin and privileges of the inns of court, the antiquity of shires and the ancient character of parliament, earning John Selden's description of him as "a man known to be most painful, industrious, and sufficient." Six of his essays were published in the enlarged edition of Thomas Hearne's Collection of *Curious Discourses Written by Eminent Antiquaries* (1771)

Agarde died on Aug. 22, 1615. The manuscripts relating to the exchequer he bequeathed to it, the remainder to Cotton; these were later acquired by the British museum.

AGARIC, any fungus having the spores borne on gills (mushrooms), from the generic name *Agaricus*. Also, an obsolete medicinal preparation derived from the fungus *Fomes officinalis* (*Fomes laricis*) a polypore growing principally on larch and pine. (V. E.)

AGASIAS, the name of two Greek sculptors. Agasias, son of Dositheus, signed the "Borghese Warrior" in the Louvre. Agasias, son of Menophilus, was the sculptor of a number of portrait statues found at Delos. Both were Ephesians, and perhaps of the same family. They probably flourished in the late 2nd or early 1st century B. C. (C. M. RN.)

AGASSIZ, ALEXANDER (1835-1910), U.S. marine zoologist, also did valuable work on mine surveying. The son of J. L. R. Agassiz (*q.v.*), he was born in Neuchâtel, Switz., on Dec. 17, 1835. He went to the United States with his father in 1849; graduated from Harvard in 1855, subsequently studying engineering and chemistry, and taking the degree of bachelor of science at the Lawrence scientific school of the same institution in 1857; and in 1859 became an assistant in the U.S. coast and geodetic survey.

Although a specialist in marine ichthyology, Agassiz devoted much time to the investigation and superintendence of mines, being superintendent of the Calumet and Hecla copper mines, Lake Superior, from 1865 to 1869, and afterward, as a stockholder, he acquired a fortune, out of which he gave to Harvard, for the Museum of Comparative Zoology and for furthering the study of biology at Harvard and elsewhere, more than \$1,000,000. In 1875 he surveyed Lake Titicaca, Peru, examined the copper mines of Peru and Chile, and made a collection of Peruvian antiquities for that museum, of which he was curator from 1874 to 1885. He assisted Sir Wyville Thomson in the examination and classification of the collections of the "Challenger" exploring expedition, and wrote the Revision of the Echini (1872-74) in the reports. Between 1877 and 1880 he took part in the three dredging expeditions of the steamer "Blake," of the U.S. coast and geodetic survey, and presented a full account of them in 1888.

Of his other writings on marine zoology, most are contained in the bulletins and memoirs of the Museum of Comparative Zoology; but he published in 1865 (with Elizabeth Cary Agassiz, his stepmother) *Seaside Studies in Natural History*, an exact and stimulating work, and in 1871 *Marine Animals of Massachusetts Bay*.

He died at sea on the "Adriatic" bound for the United States on March 27, 1910.

See G. R. Agassiz (ed), *Letters and Recollections of Alexander Agassiz: With a Sketch of His Life and Work* (1913).

AGASSIZ, (JEAN) LOUIS (RODOLPHE) (1807-1873), Swiss-U.S. naturalist, geologist and teacher whose studies ranged from fish forms to glaciers, was born on May 28, 1807, the son of the Protestant pastor of Motier, on the shore of Lake Morat, Switzerland. His father was the last of a long line of clergymen, the first of the series having been driven from France by the revocation of the Edict of Nantes. His mother, Rose Mayor, was a gifted woman from whom especially he inherited his love of animals and plants. In boyhood he spent four years at the gymnasium in Bienne and later attended the academy at Lausanne. He then entered, successively, the universities of Zurich, Heidelberg and Munich. On completion of his academic courses, Agassiz took at Erlangen the degree of doctor of philos-

ophy and at Munich that of doctor of medicine.

Although as a youth he gave some interested attention to the ways of the brook fish of western Switzerland, his permanent and lifelong interest in ichthyology arose from his being chosen to study the fishes of Brazil. In 1819 and 1820 two eminent naturalists of Munich, J. B. Spix and C. P. J. von Martius, had made an extensive tour in Brazil, bringing back a large collection of fishes, mostly from the Amazon river. The classification of these species was begun by Spix; he died in 1826, however, and the whole collection was then turned over by Martius to Agassiz. The work was completed and published in 1829, as *Selecta Genera et Species Piscium*. This was a splendid accomplishment, the author being at that time only 22 years old. The study of fish forms became henceforth the prominent feature of Agassiz's scientific research. In 1830 he issued a prospectus of a *History of the Fresh Water Fishes of Central Europe*, a valuable contribution printed in parts from 1839 to 1842.

The year 1832 proved the most significant in Agassiz's early career, because it took him first to Paris, then the centre of general scientific as well as medical research, and afterward to Neuchâtel where he spent many years of amazingly fruitful effort. While in Paris he lived the life of an impecunious student of the *quartier latin*, supporting himself, helped at times by the kindly interest of friends, such as Baron von Humboldt, who soon secured for him a professorship at Neuchâtel, and Baron Cuvier, the most eminent ichthyologist of his time. At Paris his scientific activities largely centred in the Natural History museum of the great park now known as the Jardin des Plantes.

Already Agassiz had become interested in the rich stores of the extinct fishes of Europe, especially those of Glarus in Switzerland and of Monte Bolca near Verona, of which only a few at that time had been critically studied. As early as 1829, Agassiz planned a comprehensive and critical study of these remains. To this end he gathered material wherever possible. His epoch-making work, *Recherches sur les Poissons Fossiles*, appeared in parts from 1833 to 1844. In it the number of named fossil fishes was raised to nearly 1,000, and the ancient seas were made to live again through disclosure of their inhabitants. The great importance of this foundation work rests on the impulse given to the study of extinct life itself. Turning his attention to other extinct animals found with the fishes, Agassiz published in 1839-40 two volumes on the fossil echinoderms of Switzerland, and later (1840-41) his *Etudes Critiques sur les Mollusques Fossiles*.

From 1832 to 1846 he served as professor of natural history in the University of Neuchâtel. In Neuchâtel he acted for a time as his own publisher, his private residence even becoming a hive of activities. Numerous young men were co-workers with him, dividing between themselves the scanty returns from his lectures and publications. He now began his *Nomenclator Zoologicus*, a catalogue, with references, of all the names applied to genera of animals from the beginning of scientific nomenclature, a date since fixed at Jan. 1, 1758.

In 1836 Agassiz began a new line of studies, that of the movements and effects of the glaciers of Switzerland. Several writers had expressed the opinion that these rivers of ice had once been much more extensive, and that the erratic boulders scattered over the region and up to the summit of the Jura mountains were carried by moving glaciers. On the ice of the Aar glacier he built a hut, the "Hôtel des Neuchâtelois," from which he and his associates traced the structure and movements of the ice. In 1840 he published his *Études sur les glaciers*, in some regards the most important of all his works. In it he was able to show that at a period geologically recent Switzerland was covered by one vast ice sheet. His final conclusion was that "great sheets of ice, resembling those now existing in Greenland, once covered all the countries in which unstratified gravel (boulder drift) is found."

In 1846 Agassiz was led to visit the United States for the general purpose of studies in natural history and geology, but immediately to give a course of lectures in the Louell institute in Boston. These were followed by another series in Charleston, and afterward by lectures both popular and technical in various cities. In 1848 he accepted a professorship of zoology at Harvard

university.

In America his chief volumes of scientific research were the following: *Lake Superior* (1850); *Contributions to the Natural History of the United States* (1857-1863, in several quarto volumes, the most notable being on the embryology of turtles); and the *Essay on Classification*, a brilliant production, which, however, failed to grasp the trend of modern zoology. Besides these extensive contributions appeared a multitude of short papers on natural history and especially on the fishes of America. His two excursions of highest importance were, first, to Brazil in 1865, and second, to California in 1871, the latter trip involving both shores of South America. *A Journey in Brazil* (1868) by Mrs. Agassiz and himself, gives a very interesting account of their experiences on the earlier voyage. His most important paper on American fishes dealt with the remarkable group of viviparous surf fishes of California.

Agassiz was deeply absorbed in his cherished plan of developing at Harvard university a comprehensive museum of research in zoology. This institution, which was established in 1859 and ultimately grew into the present splendid museum of comparative zoology, enjoyed his fostering care during the rest of his lifetime. In America Agassiz's industry and devotion to scientific pursuits were as strongly marked as in Europe, but two other traits here assumed a much greater importance. As a teacher of science he was extraordinarily skillful, certainly the ablest America has ever known. In addition he was personally devoted to his students, who were in the highest sense co-workers with him—"the best friend that student ever had."

Agassiz's method as teacher was to give contact rather than information. He discouraged the use of books except in detailed research. Among his favourite expressions were: "If you study nature in books, when you go out-of-doors you cannot find her!" "It's not text-books we want, but students. The book of nature is always open." "Strive to interpret what really exists." The result of his instruction at Harvard was a complete revolution in natural history study in America. The purpose came to be not a category of facts taken from others, but the ability, through contact, to gather the needed facts. As a result of his activities every notable teacher of natural history in the United States for the second half of the 19th century was at some time a pupil of Agassiz or of one of his students.

In the interests of better teaching and of scientific enthusiasm, he organized in the summer of 1873 the Anderson school at Penikese, an island in Buzzard's bay. "The school of all schools which has had the greatest influence on science teaching in America was held in an old barn on an uninhabited island, 18 miles from the shore; it lasted but three months; it had virtually but one teacher. It existed in the personal presence of Agassiz. When he died, it vanished." (David Starr Jordan, *Agassiz at Penikese*.)

As Agassiz was beyond question one of the ablest, wisest and best informed of the biologists of his day, it is often asked why his attitude towards Darwinism was, throughout all his lifetime, cold and unsympathetic. It seems possible that his position was determined in part by a misunderstanding. He seemed to regard Darwinism as a theory of continued progress instead of one of divergence, tempered by the weeding out of unadapted individuals. He failed to recognize the importance of separation and segregation in the development of new specific forms. He once said that in his studies of fossils he "was on the verge of anticipating Darwinism," but was withheld by the discovery that "we had the higher fishes first." In a sense this was true, for the brain development of the sharks is higher, as a whole, than that of the bony fishes. But the latter are far more specialized in fitness for aquatic life. In his philosophy each species of animal or plant was in itself "a thought of God." Their homologies or fundamental unities were "associations of ideas in the Divine Mind."

He married twice. His first wife, Cecile Braun, was the sister of an eminent botanist. In 1850, after his first wife's death, Agassiz married Elizabeth Cabot Cary, of Boston, well known as a writer and as a promoter of the education of women.

Agassiz died on Dec. 12, 1873. He was buried in Mt. Auburn at Cambridge, and by his grave stands a boulder from the moraine

of the Lauteraar.

AGATE, a variety of silica composed of alternating layers of variously coloured chert or granular cryptocrystalline (very fine grained) quartz. (See **CHERT AND FLINT**.) According to the Greek philosopher Theophrastus the agate was named from the Achates river (modern Acate), where the stone was originally found.

Agate is a widely scattered material and is found in many countries throughout the world. In the United States it is produced in several western states, with Oregon, Washington, Idaho and Montana the chief sources of gem stones. The most agates occur in eruptive rocks or ancient lavas, where they fill the cavities which were produced by the liberation of gas during the solidification of the molten rock. These agates have a banded structure, successive layers being approximately parallel to the sides of the cavity.

A number of varieties of agate are characterized by peculiarities in the shape and colour of the bands, which are seen in sections cut at right angles to the layers. In riband agate the bands are plane or nearly plane surfaces which in cross section appear as straight lines. Such agate with cloudy bands alternating with bands of another colour is known by the general term onyx. Many cross sections of agate give patterns that mimic familiar objects and are named accordingly. A ring or eye agate is one which, when sectioned, has the differently coloured bands disposed in concentric circles. A Mexican agate, showing only a single eye, has received the name of cyclops. When the banding forms a zig-zag pattern, suggesting the plan of a fortress, it is called fortification agate.

Certain agates occur, to a limited extent, in veins, of which a notable example is the beautiful brecciated agate of Saxony—a stone mostly composed of angular fragments of agate cemented with amethystine quartz. A variety having included matter of a green colour, embedded in the agate and disposed in filaments and other forms suggestive of vegetable growth, is known as moss agate. Dendritic, or branchlike, markings of black or brown colour, due to infiltration of oxides of manganese and iron, produce the variety known as Mocha stone.

It is probable that agates occurring in cavities in lava flows have been formed in a number of ways, and various theories of their origin have been proposed. The theory which is now generally accepted is as follows. During cooling of the lava, but before solidification, gas and steam accumulate to form bubbles. These bubbles slowly rise; some escape at the top but others, overtaken by solidification, are frozen in, forming cavities. Long after, when the rock has solidified, water carrying silica in solution, probably as alkali silicate, penetrates into the region where the bubble is located. It then diffuses into the cavity and subsequently the solution coagulates to a silica gel. The alkali present with the silica attacks the iron-bearing rock surrounding the cavity, giving rise to iron salts. These diffuse into the silica gel and produce the regular layers of iron hydroxide after the manner of Liesegang rings (see **COLLOID**). Finally the whole mass gradually hardens with loss of water and crystallization of much of the silica as quartz or chert. During the process of crystallization the coloured bands are not disturbed and hence we have the final agate as it is now found.

Agate is essentially quartz and thus its physical properties are in general those of that mineral. It has a hardness of 7 on Mohs' scale (*q.v.*). Its specific gravity is 2.65, and it breaks with

B M SHAUB
BANDED AGATE

a conchoidal fracture.

The agate working industry grew up in the Idar-Oberstein district, Ger., many centuries ago by reason of an abundance of agates in the region. After 1900 the stones used were mostly imported from Brazil and Uruguay.

Most commercial agate is artificially stained so that stones naturally unattractive because of their dull gray tints come to be valuable for ornamental purposes. The colouring matter is absorbed by the porosity of the stone, but different stones and different layers of the same stone exhibit great variation in absorptive power. To produce a dark brown or black colour, the agate is soaked in a sugar or honey solution for several weeks, after which it is treated with sulfuric acid. The acid carbonizes the sugar, thus colouring the more porous layers brown or black but leaving the more impermeable layers white to obtain an alternation of light and dark bands. Agates are stained red by ferric oxide; green by chromium and nickel solutions; and yellow by hydrochloric acid.

Among the uses to which agate is applied may be mentioned the formation of knife-edges of delicate balances, small mortars and pestles for chemical work, burnishers and writing styles, umbrella handles, paper knives, seals, brooches and other ornaments. Real cameos are cut from banded onyx (*q.v.*), one layer forming the medallion, the other the design in relief.

(W. A. W.; C. S. H.)

AGATHA, SAINT, a Sicilian martyr put to death at Palermo or, more probably, Catania, perhaps in the 3rd century. The traditional particulars of her martyrdom are of no historical value; according to them she resisted the advances of a Roman official who thereupon ordered her to be tortured, and she died in consequence. In the torture her breasts were cut off, a circumstance reflected in her iconography. She is named in the canon of the Roman mass, and her feast is kept on Feb. 5, on which day she figures in the calendar of the Book of Common Prayer.

See H. Thurston and D. Attwater (eds.), *Butler's Lives of the Saints*, vol. i, pp. 255–256 (1956).
(D. AR.)

AGATHIAS (c. 536—before 582), Byzantine poet and author of a history covering part of Justinian I's reign, was born at Myrina in Aeolis in Asia Minor. After studying law at Alexandria, he completed his training at Constantinople and practised in the courts as an advocate (*scholasticus*). He wrote a number of short love poems in epic metre, called *Daphniaca*. He compiled an anthology of epigrams by earlier and contemporary poets, including his own. About 100 epigrams by Agathias have been preserved in the *Greek Anthology*. After the death of Justinian I (565), some of Agathias' friends persuaded him to write the history of his own times. This unfinished work in five books, which begins where Procopius ends, is the chief authority for the period 552–558.

Migne, *Patrologia Graeca*, vol. 88, col. 1249–1608 (1860). Poems also ed. with Eng. trans. by W. R. Paton, *Greek Anthology*, in the "Loeb Series," 5 vol. (1916–18). See also G. Moravcsik, *Byzantinoturcica*, vol. i, pp. 214–217, 2nd ed. (1958); P. N. Ure, *Justinian and His Age*, pp. 184–187, 190–193 (1951); F. A. Wright, *History of Later Greek Literature*, pp. 388–397 (1932).
(J. M. HY.)

AGATHO, SAINT (c. 577–681), pope from 678 to 681 was of Sicilian origin but became a cleric at Rome. He was elected in June 678. He judged that Wilfrid, bishop of York, had been unjustly deprived and ordered his restoration; and he received the submission of Theodore of Ravenna, whose predecessors had aspired to autonomy. Through legates, he participated in the sixth ecumenical council (680–681), which accepted his definition of two wills in Christ. He prevailed upon the emperor Constantine IV to abolish the tax formerly exacted at the consecration of a newly elected pope. Agatho died in Jan. 681. His feast is celebrated on Jan. 10.
(A. G. BI.)

AGATHOCLES (361–289 B.C.), tyrant of Syracuse from 317 to 304 and self-styled king of Sicily from c. 304 to 289, was born at Thermae Himerenses (mod. Termini Imerese) in Sicily. He moved to Syracuse (*q.v.*) in 343 and served with distinction in

its army. In 333 he married the widow of his wealthy and influential patron Damas. He was twice banished from Syracuse for attempting to overthrow the oligarchical party there, but in 317 he returned with an army gathered from Sicel towns discontented at the growth of Syracusan influence. He then banished or murdered about 10,000 citizens (including the oligarchs) and, proclaiming himself champion of the people and exacting the support of the popular assembly, seized the tyranny.

Agathocles now embarked on a long series of wars. His first campaigns, against the other Sicilian Greeks (316–310), won him control of many of their cities, including Messina, but this made the Carthaginians fear for their own possessions in Sicily. They therefore sent a large force to the island, and the struggle that had gone on intermittently since the 6th century between the Sicilian Greeks and Carthage was renewed. In 310 Agathocles, defeated and besieged in Syracuse, resolved to break through the blockade and attack the enemy in Africa. He carried on the war in Africa with considerable success till 308. Then reverses in Sicily caused him to leave Africa when he was blockading Carthage, and on returning to Africa in 307 he was defeated. Nevertheless, the peace concluded in 306 with the Carthaginians restricted their power in Sicily to the area west of the Halycus (Platani) river, the frontier being the same as that previously agreed to between Carthage and the tyrant Dionysius (*q.v.*). Agathocles continued, moreover, to strengthen his rule over the Greek cities of Sicily and by c. 304 B.C. felt secure enough to assume the title of king of Sicily. He also extended his influence into southern Italy and the Adriatic.

The reign of Agathocles as king was orderly and peaceful, and he enriched Syracuse with many public buildings. Dissension among his family about the succession caused him in his will to restore liberty to the Syracusans. His death was followed by a recrudescence of Carthaginian power in Sicily.

AGATHON (b. c. 445 B.C.), Athenian tragic poet, whose innovations as a dramatist are mentioned by Aristotle, and whose first victory (416 B.C.) in the contest for tragic poets held at the Dionysiac festival became the imagined occasion of Plato's *Symposium*.

Like Euripides, he accepted the invitation of King Archelaus to the court of Macedon about 407. The length of his stay and the date of his death are uncertain. The 40 surviving lines of his plays make little impression save of a turn for paradox and antithesis, borne out by an anecdote in Aelian's *Varia Historia* and by Plato's characterization of his prose rhetoric in the speech given to him in the *Symposium*. In Plato's *Protagoras* he makes his appearance as a beautiful boy already at home in aristocratic and sophistic circles, and it is clear from his style that he learned much from the sophists, Gorgias especially; but he seems to have been a dramatist of some importance and originality.

In the prologue of the *Thesmophoriazusae* Aristophanes not only makes rude fun of him as an effeminate aesthete but parodies the style of his lyrics at some length, and in the *Frogs*, though Dionysus' approval should not be taken too seriously, he is not dismissed with contempt like most of the minor tragedians. From references in Aristotle's *Poetics* it seems that he was not afraid to go the whole way in "modernist" tendencies in drama: he sometimes overcrowded his plots; he was the first to write a play (Antheus) about imaginary characters instead of taking them from heroic mythology, and the first to compose lyrics as pure choral interludes instead of as a comment on the dramatic situation and an integral part of the play.

For the fragments of Agathon's plays, see A. Nauck (ed.), *Tragicorum Graecorum Fragmenta*, "Teubner Series" (1926). (A. M. DE.)

AGATHOS DAIMON, in ancient Greek religion, the "good spirit" protective of individuals and families. He received a libation of pure wine at the end of each meal. In Hellenistic and later times he was associated with Tyche, the goddess of luck, as a somewhat impersonal providence. He is portrayed as a serpent or as a young man with a horn of plenty and a bowl in one hand and a poppy and ears of corn in the other.

See M. Nilsson, *Geschichte der griechischen Religion*, vol. ii, pp. 202 ff. (1950). (H. W. PA.)

AGAVE, a genus of about 300 species of plants of the amaryllid-

aceae family (Amaryllidaceae). Some agave species may require many years to bloom, especially in cultivation. Hence the name century plant is applied to members of the genus, particularly the larger species such as *Agave americana*. Agaves may also be called American aloes because they resemble plants of the old world genus *Aloe*.

The genus was originally confined to the Americas but many species have been planted in warmer parts of the old world, where in certain areas (as in India) some are naturalized and appear native. The plants grow mainly in dry habitats and are typically stemless or shortstemmed, producing a rosette of large, elongate, fleshy and often spiny-margined and spine-tipped leaves that persist from year to year.

WILLIS PETERSON

CENTURY PLANT (AGAVE AMERICANA), WHOSE FLOWER STALK MAY REACH 40 FT.

A frequently massive and tall flower stalk bearing many greenish or yellowish flowers arises from the centre of the rosette. Some agaves flower annually, others occasionally, but many flower once and then die, often leaving basal suckers that develop into new plants.

Most agaves (99%) are North American, the greatest concentration of species being found in the highlands of central Mexico. About 150 native species occur in Mexico, 50 in the West Indies, and 20 in the United States, mainly in the southwest, 10 in Arizona alone. In South America, one species occurs in Venezuela, and two are reported from Colombia. Many species are known only in cultivation. Agaves range in size from dwarfs such as *A. parviflora*, with leaves 4 in. long and a thin flower stalk 5 ft. high, to enormous plants such as *A. atrovirens*, which may have leaves 8 ft. long and a flower stalk as thick as a man's body and 30 ft. high. The flower stalk of *A. neglecta* may reach 42 ft.

Several agaves are among the world's major cordage fibre plants, including henequen (*A. fourcroydes* and *A. zapufo*) cultivated extensively in Cuba and Yucatan, and sisal (*A. sisalana*), in East Africa and Indonesia. Other species are locally much used for fibre in Latin America. Agave fibres are obtained from the leaves. Pulque (*q.v.*), a Mexican beverage important both as food and drink, is fermented sap of several large species, especially *A. atrovirens*, great plantations of which are maintained for pulque production. Mescal is a liquor distilled from fermented mash made from stems and leaf bases of various Agave species. Tequila, made chiefly in Jalisco (Mex.), is one of many varieties of mescal. Some agaves contain in their leaves significant quantities of a compound (hecogenin) that is convertible into cortisone. Many species are cultivated as ornamentals outdoors in frost-free regions or as conservatory and house plants. Agaves are much used for hedges and for erosion control.

The genus is divided into 3 subgenera: (1) *Euagave*, plants with a flower cluster (panicle) having candelabralike branches; (2) *Littaea*, plants with a long cylindrical cluster of flowers that are in groups of from two to several; and (3) *Manfreda* (often given generic rank), plants that die down annually and have a slender spike of flowers that are borne singly. Flowers of Agave are more or less fleshy and cylindrical or funnel-shaped. The three sepals and three petals are similar and are usually exceeded in length by the six stamens, which bear large elongate anthers. The ovary is inferior, three-celled with axile placentae, and the style is long and

slender with a usually capitate three-lobed stigma. Numerous flat, thin, black seeds are borne in two rows in each cell of the leathery or woody capsule.

AGAZZARI, AGOSTINO (1578–1640), Italian musician less distinguished for his compositions than for his short treatise *Del sonare sopra il basso* (1607; facsimile ed. 1933), one of the earliest instruction books for performing from the figured bass (*q.v.*). The treatise is particularly important because in it he distinguishes between "melody" and "fundamental" instruments and thus recognizes that, whereas usually in Renaissance music all voices of a composition had been equally important, in baroque music a new and significant concept was being developed—the polarity of the upper and lower parts, with neutral improvised inner parts. Agazzari was born in Siena, Dec. 2, 1578, and died there, April 10, 1640. He held various church appointments, and wrote music in both the old and the new styles.

See O. Strunk, ed., *Source Readings in Music History* (1952) for a complete Eng. trans. of *Del sonare sopra il basso*. (N. Fo.)

AGELADAS or (as the name is spelled in an inscription) HAGELAIIDAS, a great Greek sculptor of Argos who flourished in the latter part of the 6th and the early part of the 5th century B.C. Ageladas was said to have been the teacher of Myron, Pheidias and Polycleitus; this tradition is a testimony of his wide fame, though historically doubtful.

AGEN, a town in southwest France, capital of Lot-et-Garonne *département*, 88 mi. S.E. of Bordeaux by road. Pop. (1954) 28,591. It lies at the foot of Ermitage hill, and is skirted on the west by the Garonne river, which is spanned by road and canal bridges. Two boulevards cross the town at right angles and others run round the edges, while in the centre are many narrow streets dating from the middle ages. The Promenade du Gravier, an open space alongside the Garonne is a well-known local beauty spot. The cathedral, dedicated to St. Caprais, was built between the 12th and 14th centuries; the church of the Jacobins has two naves, a relic of the days when it was used by the Dominicans. The museum, in two 16th-century mansions, contains valuable collections of ceramics, paintings and archaeological remains.

Agen is on the railway from Bordeaux to Sète, and another runs to Paris. There is a bus service to Toulouse. Its canals make it the outlet for the rich agricultural produce of the district, the chief being plums, which are dried and filled with almond or plum paste. It is a market for early vegetables, fruit, eggs, poultry, cattle and *foies gras* (fatted goose liver). Cold storage enables fruit and meat to be kept for long periods.

As the capital of the Nitiobriges, Agen (Aginnum) is mentioned by Caesar. The district was converted to Christianity by St. Foy about the 4th century. Later, Agen was the headquarters of the earldom of Agenais (*q.v.*), and played a part in the Albigensian War, the Hundred Years' War and, subsequently, the Wars of Religion. It is the seat of a bishop, a court of appeal and assizes, a chamber of commerce and the prefecture of Lot-et-Garonne.

(A.-M. L.)

AGENAIS or AGENOIS, a former province of France, of which Agen was the centre and to which the modern *département* of Lot-et-Garonne (*q.v.*) nearly corresponds. In ancient Gaul it was the country of the Nitiobriges, then a Gallo-Roman *civitas* (the 4th-century *Civitas Agennensium*), whose limits became those of the diocese of Agen. Having in general shared the fortunes of Aquitaine during the Merovingian and Carolingian periods, Agenais eventually became an hereditary countship. From the middle of the 10th century it was part of the demesne of the counts of Bordeaux, dukes of Gascony, from whom it passed in 1036 to Eudes of Poitiers, later duke of Aquitaine. The marriage of Eleanor of Aquitaine with Henry Plantagenet in 1152 brought it under England; but when Richard I married his sister Joan to Raymond VI of Toulouse in 1196 Agenais formed part of her dowry, although remaining in the vassalage of Gascony. In 1249, with the other estates of Raymond VII, it lapsed to Alphonse of Poitiers, his son-in-law and the brother of Louis IX of France; but in 1259, by the treaty of Paris, Louis IX promised that if Alphonse and his wife Jeanne died childless their demesnes in Agenais would return

to the king of England. When Jeanne did die childless in 1271, Philip III of France had the country occupied; but Edward I recovered it for England by the treaty of Amiens in 1279. Yet the king of France claimed direct overlordship on a number of places, and the dispute over one of them, Saint-Sardos, brought a renewal of the war between England and France under Charles IV. During the Hundred Years' War Agenais was several times taken and retaken until the final retreat of the English.

In 1578 the countship was given to Margaret of France (Marguerite de Valois) in part settlement of the dowry due on her marriage to Henry of Navarre. On her death (1615), it was finally reunited to the French crown. In the last years of the *ancien régime* Agenais was a *sénéchaussée* within the *gouvernement* of Guienne and the *intendance* of Bordeaux. Since the late middle ages the country has been agriculturally rich, subject, however, to alternating phases of depopulation and immigration.

Deffontaines, *Les Hommes et leurs travaux dans les pays de la Moyenne Garonne* (1932); *Histoire de l'Agenais*, issued by the Société des Sciences, Lettres et Arts d'Agen (1943). (F. Cr.)

AGENCY, broadly speaking, refers to the relationship that exists whenever one person engages another to act for him, *e.g.*, to do his work, to sell his goods, to manage his business.

The essential quality of agency is that the agent, whether he be printer's devil or editor, office boy or chairman of the board, acts for another. He is to follow instructions, and may be discharged for cause if he fails to do so or if he is insubordinate. His is a personal-service relationship, terminable upon the death of either party. Equally significant, the gains or benefits of the agent's activities are to go to the proprietor; the agent is paid a wage or commission for his services. The agent, moreover, is placed by the courts under strict fiduciary duties to his principal; a legal sanction is thus added to the moral one, to make sure that gains reach the proprietor's pockets, not those of his agents.

In commercial matters it has long been the rule that the principal must indemnify his agent for pecuniary losses growing out of the work. This principle was even applied in so unusual a case as *D'Arcy v. Lyle* (1813) to give recovery for money the agent had been compelled to pay out (under threat of having to stand trial by battle before King Henry Christophe in Haiti) after his agency had ended. Some courts refuse to give indemnity to corporate officers or directors for their expenses incurred in successfully defending a shareholder's action for mismanagement. Many corporations, however, now expressly agree to indemnify officers and others for such losses.

No similar remedy was developed in the courts to put personal injury losses on the employer. These, it was assumed, were to be borne by agent or workman, much as any other member of society would bear his losses. In the famous case of *Priestly v. Fowler* (1837), the court refused to hold the employer liable for injuries caused by the negligence of a fellow servant. Thus was born the "fellow servant" rule (or, in England, the "common employment" rule) which was not to be set aside for the better part of a century. In fact, in the U.S. it remained for the legislature to abolish the rule, first by enacting the Federal Employers' Liability act (1908) in the case of carriers, and then by adoption of the various Workmen's Compensation statutes for other occupations.

Respondent Superior.—Much of the early law of agency came to be classified under the heading master and servant. This topic covered not only the relationship between master and servant but also the very large area of litigation concerned with injuries to third persons, brought about by the servant's departure from instructions or by his negligence in carrying them out. The master, of course, could be held liable on ordinary tort principles when he was negligent or had directed the particular wrongful act. But by the end of the 17th century in England, the courts had announced the doctrine of *respondent superior*, by which the injured person is given a direct recovery against the master, even though the injury was due to the fault of the servant.

Though *respondent superior* is firmly established in the U.S., as in other common-law countries, there has been no agreement on the basis for the doctrine. The early rationalization that master

and servant are one, and hence that the master should be liable for whatever his servant does: is both artificial and inaccurate; that the master selected the servant and could direct his actions, while true: would find fault in the employer, for which he might well be liable, but on quite different grounds. Actually, the doctrine may have been a pragmatic outgrowth from early custom; the feudal landholder enjoyed the fruits of his serfs' labour and, as matter of course, seems to have been responsible to third persons for their actions.

It is hard to gainsay that the doctrine has survived as a tacit recognition of the economic stratification existing between proprietor and employee. The injured third person must, as a matter of social policy, be given recourse to the "deep pocket"; it would be quite unrealistic to put him off with a judgment against the servant, while allowing the employer to take the gains from the business, which in ordinary course should be used to meet such losses. Or, as Lemuel Shaw put it in 1842, it is for the employer to so conduct his affairs, "whether by himself or by his agents or servants," as not to injure others.

Whether *respondeat superior* permits a master (who has had to pay a third person for injuries) to shift his losses to the negligent workman, was not litigated when the doctrine was announced. That may have been because the workman of that day did not have money, but in the U.S. the courts have come to give the master a recovery by holding, somewhat mechanically, that he is subrogated to the rights of the injured third person. In Britain, the same result was reached in the *Lister* case (1957), but there the house of lords improvised a contract on the part of the servant, by which he was said to have agreed to indemnify his employer against any losses caused by his negligence. In both countries, there is opinion that unintended risks of this sort should be borne by industry.

Principal and Agent.—The great increase in shipping, banking, insurance and mercantile transactions generally, which occurred in the late 18th and early 19th centuries, brought another kind of agent to the fore. The ship's captains, insurance brokers, bank managers, factors and salesmen of the time were concerned with commercial transactions. Moreover, they could not aptly be called "servants"; indeed, it is not appropriate, as a matter of common parlance, to speak of the modern industrial workman as a servant, even though he is still classified that way by the courts. At all events, the branch of agency dealing with salesmen and others having power to make contracts for their employers came to be separately treated under the topic principal and agent.

There have been many fruitless attempts to define "servant" and "agent" as mutually exclusive terms. Plainly, a useful distinction may not be drawn with respect to the employment relationship, for both "agent" and "servant" must follow orders and both are under strict fiduciary duties. Nor will it do to say that an employer is liable only for the torts of his "servant," not the servant's contracts; for it is only too plain that a chauffeur, for example, who as a "servant" may make his employer liable for injuries to others, may have some power to contract, as for fuel or repairs. And the bank manager, whose work as "agent" may be that of making contracts, also may subject his employer to liability for fraud or misrepresentation. Thus, if there are two concepts, the same man may wear both hats, that of "agent" and of "servant."

This concern with definition has not been just a battle of words. It marks a line behind which the employer has sought to limit his liability for injuries to third persons. For illustration, it is one thing for an employer to be liable when his messenger boy carelessly bumps into a woman on the street, injuring her; and perhaps an entirely different thing for an employer to be liable if a salesman, the manager of the business or its president, were to behave similarly while in course of his work. The difference lies in two things: the employer's assumed right to control physical conduct becomes increasingly tenuous in the latter cases; and, equally important, the ascending pay scale gives increasing assurance that the agent may be able to pay for his carelessness out of his own pocket. Hence, it is possible for the courts to say, consistently with *respondeat superior*, that at some point the employer is not to

be held liable.

The courts speak of a salesman, for example, as an "independent contractor" when he is held solely responsible for physical injuries to others, or, speaking more strictly, he is a contractor as to so much of his work, for he may be both agent—in the commercial sense—and independent contractor at the same time. Thus, a bank in handling a customer's paper for collection, or a factor in selling a consignor's goods, acts both as agent and as independent contractor. The contractor, as an essential part of the bargain recognized by the courts, undertakes for a consideration to do the work in his own way without exposing the employer to liability for collateral negligence.

Agency in Commercial Matters.—In *Combes* case (1613), it was recognized that a principal may conduct most transactions by means of an agent quite as effectively as if he were present and acting for himself. There were relatively few cases concerning agents however, until late in the 18th century; by the end of the 19th century, the outlines of the subject were well defined.

An agent may ordinarily be appointed very informally—by word of mouth, by letter or by power of attorney. At common law, in the case of instruments under seal, however, it was required that the agent's authority must be executed with equal dignity. And while, in the U.S., many states have passed statutes abolishing the significance of seals, it is still not unusual to require that an agent's authority to make a conveyance of land must be under seal. Moreover, in those cases where the statute of frauds requires written record, the substance of the equal-dignity rule is usually retained by requiring that the agent's authority also must be in writing.

It was held quite early that a principal may ratify contracts made in his name by an unauthorized agent. The effect of this is to give the principal the same rights (and subject him to the same liabilities) as if he had originally authorized the transaction, for, as the courts put it, ratification relates back. But the doctrine requires that the entire contract be ratified; a principal may not take the good and reject the bad. In the case of promoter's contracts, it is said not to apply at all, for, literally speaking, the promoter cannot be an agent for a not-yet-in-existence principal. But, in the U.S., much the same result is obtained by permitting the newly-born corporation to "adopt" its promoter's contracts. Upon adoption, as in the case of ratification, the corporation is bound and the agent released.

The undisclosed-principal doctrine, also, has raised some theoretical problems. In *Watteau v. Fenwick* (1893) an undisclosed owner of a beerhouse was held liable for the price of supplies purchased by his agent (who appeared to be owner), even though the purchases were not authorized. Some writers have insisted that there could not be a contract in such case. But the doctrine is well established, for here, as in *respondeat superior*, a principal may not take the benefits of a venture and limit the third person to an action against the agent. The split today arises when, on discovering the principal, the third person seeks to hold both agent and principal until he gets satisfaction, as if he had bargained for two contracts. Most jurisdictions give him a choice of one or the other, but not both. Were it not for the undisclosed-principal doctrine, many realty transactions could not be conducted without greatly inflating prices.

Much litigation centres on questions concerning the agent's apparent authority. As early as 1812, it was recognized in England that a principal may be held liable despite the fact that the agent exceeded his express authority; in this instance the agent's sale of a quantity of hemp belonging to the principal was sustained, upon the theory that the principal, by permitting the hemp to be put in the agent's name on the wharfinger's books, had held him out as having an authority to sell. In a sense this is an estoppel, but in the U.S. the view prevails that a contract is made at the time of the negotiation, regardless of any change of position by the third person.

In broader context, it is evident that by use of apparent authority, the courts may increasingly give effect to business expectations. While in the older, landed society, they stressed the security of property, now, in a commercial world, they emphasize the security of transactions. In a way this compares with the

development under *respondeat superior* through which the courts make use of another variable, scope of employment, to give sanction to social change; that is, many acts of a servant which, in an earlier and simpler economy, might well have been found to fall outside the scope of his employment, may now be held to come within the test, and thus subject the employer to liability. The employer, more often than not, is amply insured.

The Agent's Role.—The agent or broker, who may have exceeded his authority in dealings with third persons, was originally held liable in deceit. Some courts made him a party to the contract, although neither he nor the third person intended that. But in *Collen v. Wright* (1857) an English court gave recovery upon the theory that an agent impliedly warrants his authority to third persons. Thus, it became much simpler to achieve recovery, for the older action of deceit required a showing of intent to injure, which often was difficult to prove. While most courts in the U.S. recognize the warranty doctrine, many still award damages measured by the tort test; that is, they give judgment for those losses which naturally flow from the wrong, and deny a benefit-of-the-bargain recovery.

When an agent acts within his authority, however, as in selling goods for his principal, he is without liability to the third person. There are exceptions, of course, for the agent may so sign the contract as to bind himself, or he may have failed to disclose his principal and thus have made himself liable at the election of the other party. Similarly, the agent is not ordinarily liable to his principal, should the third person default. But there has long been a custom in some fields for the agent to act on a *del credere* basis; that is, for an additional commission the agent undertakes that should the buyer default, he will pay the amount due. For a form of agency known as factoring, see FACTOR.

During the 19th century, manufactured goods were generally marketed through a system of jobbers and dealers. Each transaction took the form of a sale and, in legal theory, the buyers were free to dispose of the goods as their own. Thus, they were not agents, and the customer had no direct recourse to the manufacturer. However, in the 20th century the independent jobber's lot has become a difficult one. Many manufacturers, because of a desire to control resale prices, to save costs of distribution, and so on, have set up their own sales organizations. While this has brought them nearer to the consumer, the courts have been reaching in that direction anyway. This they have done by stressing that even a jobber or dealer is in some sense an agent, as in advertising or warranting the product. In other instances, by treating the product as "inherently dangerous," they have disregarded the jobber or dealer and held the manufacturer directly liable for negligence. See also MASTER AND SERVANT. (R. T. S.)

AGENOR, the name of three figures in Greek legend and mythology.

1. Agenor, the son of Poseidon, grandson of Epaphos and great-grandson of Io, is usually agreed, although the genealogy is greatly confused, to have been father to Europa, Phoenix, Cadmus and Cilix. When Europa was stolen by Zeus, the brothers were ordered by their father to search for her and not to return without her. Consequently Cilix settled and gave his name to Cilicia, as Phoenix did to Phoenicia; Cadmus (*q.v.*) eventually reached Boeotia.

2. Agenor, one of the sons of the Arcadian king Phegeus, was the slayer of Alcmaeon (*q.v.*).

3. Agenor in the *Iliad* was a Trojan warrior who fought Achilles singlehanded. His form was taken by Apollo to confuse Achilles and to permit the Trojans to withdraw. (T. V. B.)

AGENT: see AGENCY.

AGESANDER, a Rhodian sculptor who is mentioned by Pliny in his *Natural History* as author (with Polydorus and Athenodorus) of the group of the Laocoon. Inscriptions found at Lindus in Rhodes date Agesander and Athenodorus to the period 42–21 B.C.

AGESET is the name given to a system of compulsory grouping by age found among certain peoples of east and northeast Africa. In these societies every male of the tribe belongs either from birth or from a determined age to a named set which is connected with circumcision or initiation and which plays an important part in

social and political organization. Women do not have age sets. The sets are not age grades (although they used so to be called in the older anthropological literature); for, once a man has entered a set, he remains a member of it for the rest of his life. Age grades, on the other hand, may be complementary to and coexistent with age sets, and men pass through them in succession, remaining in each grade for a fixed period; but they always belong to the same age set. The basic features of the age-set system are: (1) the number of sets is limited, and their names recur in a cycle, apparent exceptions being due to modification or breakdown; (2) at any given time one set is always that of the warriors or power group; (3) every male must belong to a set; (4) each set has a corporate unity. This pattern of age sets differs in a number of respects from age groups found else here in Africa, and the east African age set, although it has military and governmental functions, is not primarily a regimental system like the age groupings of, e.g., the Swazi of south Africa.

The age-set systems found in east and northeast Africa may be divided into categories according to the extent of their divergence from an assumed prototype. This prototype is believed to be the Galla system, and although this assumption is not accepted by all ethnographers it was not yet disproved in the early 1960s. The categories are: (A) Galla, with age sets working through a series of grades; (A1) Darasa; Konso (both southwest Ethiopia); (B) Nandi and other tribes of the Nandi (Kalenjin) group in Kenya; Masai (Kenya and Tanganyika); Dorobo (Kenya); (C) Central Nilo-Hamitic: Suk, Turkana, in Kenya; Teso (obsolete). Jie, Toposa, in Uganda; Donyiro (Sudan)—all accompanied by systems of age grades, some strongly, others weakly developed; (D) Northern Nilo-Hamitic: Bari, Lotuko, Lokoia, Lango, all in the Sudan; (E) Nilotic: Nuer, Shilluk, Dinka, in the Sudan; Lango of Uganda (obsolete); (F) of uncertain pattern: Didiya, Gelaba, Murle, all on the Sudan-Uganda-Ethiopia border. The age-set system has been borrowed by various Bantu peoples those possessing age sets or comparable institutions being the Luhya (Kavirondo) of western Kenya, who have borrowed them from the Kandi, some with Kandi names, others with topical names; the Chagga of northern Tanganyika and the Taveta of southern Kenya, both of which have borrowed from the Masai, those of the Taveta being a very close and old copy; the Ngurimi and Nata (Ikoma) with grades of Galla type and the Kurya (Tende) with linear sets, all in northern Tanganyika; the Giryama of the Nyika group and the Pokomo of the Tana valley, the latter having the Galla grade system without age sets; the Kikuyu of Kenya with topical names and institutionalized grades of elders.

Categories A, B and C, to which should be added the Nuer, are integral parts of the social system and their removal would have meant the collapse of the social and political order. Among many of the Bantu peoples, on the other hand, the age set is a borrowed feature fitted into tribal culture without real integration.

The principle of the Galla system was that all the males in a tribe were included in ten groups called *gada*, which were divided into two half-cycles of five, the sons of members of the first half-cycle being automatically members of the second half-cycle. A man belonged to the same *gada* all his life. Until its members reached the age of 40 each *gada* in turn passed through a series of five eight-year grades which were also called *gada*, although members belonged to each of these for eight years only, and on completion of the 40-year period ceased to belong to any grade, but were still members of their set. As an example, the ten age sets recorded by Antoine d'Abbadie were these:

First half-cycle. Birmaji Malba Mudana Robale Dulo; their sons belonged to:
 ↓ ↓ ↓ ↓ ↓
 Second half-cycle: Aldada Horata Bifole Sabaqa Kirole

Each of these sets passed in succession through these grades:

Age 1 to 8 years: Daballe	} Luba	status: boys, of little account
8 to 16 years: Folle		status: boys, of little account
16 to 24 years: Qondala		status: "learners," more important
24 to 28 years: Dori		status: first half of governing period
28 to 32 years: Luba		status: second half of governing period
32 to 40 years: Yuba		status: advisory only

Circumcision took place in the Luba half-period. By the time that Birmaji, for example, had reached the end of the Yuba grade, their sons, Aldada, entered the Daballe grade, and so on. The names of the *gada* sets recurred after the completion of the 80-year cycle, and this type of age set may thus be called cyclic to distinguish it from the kind in which a new name is chosen for each set as it is formed, this latter type being called linear.

The Nandi system had no progressive grades, but every male in the tribe belonged from birth to a set which was normally that next below his father's. There were seven sets, *ipinda*, with recurring names, on the principle that at any given time there is one set of warriors, two of boys and four of elders. The names of the sets and their order at three different periods were as follows:

1908	1923	1938
Maina: boys	Juma: boys	Sawe: boys
Nyonggi: {circumcision 1911-15	Maina: {circumcision 1926-30	Juma: {circumcision 1940-44
Kimnyike: warriors	Nyongi: warriors	Maina: warriors
Kaplelach } elders	Kimnyike } elders	Nyongi } elders
Kipkoimet }	Kaplelach }	Kimnyike }
Sawe }	Kipkoimet }	Kaplelach }
Juma }	Sawe }	Kipkoimet }

Sons of Nyongi are normally Juma, sons of Kimnyike are Maina, etc. Every 15 years the warrior set handed over its functions to the set which had been circumcised during the previous 15 years and became the junior set of elders; *i.e.*, in 1923 Kimnyike gave place to Nyongi, the senior set of elders (all its members being dead by then) disappeared as such, and its name became that of the small boys' set. Since 15 years is too long a period for a man to be an active warrior, there was an institutionalized overlap by means of which men after they had been circumcised became junior warriors, relieving senior warriors of their active duties although their set did not become officially the warrior set till the full 15-year period was completed.

The Masai did this somewhat differently. They had a system which is now apparently linear but seems formerly to have been cyclic. The men of each tribe are divided into "generations," *ol-aji*, each of which is subdivided into two age sets, *ol-poror*, the senior being called *e-murata e-tatene*, "the right-hand circumcision," and the junior *e-murata e-kedyanye*, "the left-hand circumcision." Those of the right hand are circumcised first, during a period of four years; when this is finished, the new warriors are formed into companies, *i-sirit*. About seven or eight years from the beginning of the right-hand set, the members of the left-hand set are circumcised, becoming warriors three to four years later. Thus there are two warrior sets and the overlap practised by the Nandi is not necessary. The left-hand set, however, has a shorter warrior life than the right-hand set, because both right and left become elders simultaneously. The left hand is thus considered slightly inferior to the right hand.

An example of a Bantu age-set system is that of the Isukha (Kakumega) of North Nyanza (Luhya group, Kenya). They had a linear system in which age sets, *elikhula*, were formed as required when the circumcision periods were finished, at irregular intervals ranging from two to five years, each set taking its name from some current event, such as *Intsike*, "locusts," given to a set formed in 1928 when there was an infestation of locusts.

It may be said of age sets in general that, besides being corporate, they provide a means of tribal education and training in discipline when the boys are collected in groups for initiation; that hospitality and mutual assistance are practised within the group; and that they tend to affect rules of kinship and behaviour, since there is often a great gulf between senior and junior sets. However slight may be the degree of integration of age sets into the structure of a tribal society, membership produces a bond of comradeship between age mates; and in societies where the sets are deeply integrated they influence not only social behaviour but also the political system. Among the Galla, for example, within the framework of the *gada* sets the members of the fourth grade formed the tribal government, one of them being the tribal ruler, the *Abba Roku*, "father of the staff." In the Nandi and Masai systems three age groupings, of boys, warriors and elders, were clearly distinguished and separated; and this separation ensured

readily available manpower for fighting at all times. Where integration was less, the effect was mainly on the social side, and age sets played little or no part as military or governmental factors.

AGESILAUS II (c. 444–360 B.C.), king of Sparta from 400 or 398 to 360 B.C., of the Eurypontid house, was a son of Archidamus II and succeeded his half brother Agis II after he and Lysander (*q.v.*) had persuaded the city to set Agis' son Leotychidas aside as illegitimate. Sparta was at war with Persia in Asia Minor, an aftermath of the expedition of the younger Cyrus (*q.v.*), and news of naval preparations in Phoenicia caused the dispatch of Agesilaus to Asia in 396 with Lysander, who hoped to re-establish his influence there. Imitating the legendary Agamemnon, Agesilaus sailed from Aulis in Boeotia, but the Thebans, already on bad terms with Sparta, prevented him from sacrificing there. On arrival at Ephesus he made a three months' truce with the Persian satrap Tissaphernes, during which he succeeded in shaking off Lysander's control.

Agesilaus raided Phrygia later in 396, organized a cavalry force, made a successful incursion into Lydia in spring 395 and then ravaged Phrygia again. He was unable, however, to prevent the building up of a powerful Persian fleet under the Athenian Conon, or to co-operate effectively with the Spartan navy in the south. His plan for 394 was said to be a march deep into the interior of Asia Minor. and Xenophon and others believed that he was on the brink of important conquests when he was recalled by war in Greece, though it is hard to see what he could have achieved. The Spartan navy was completely defeated by Conon at Cnidus soon after his departure.

Sparta had already in 394 defeated the coalition of Thebes, Athens, Argos and Corinth, near Corinth, before Agesilaus' rapid march home, and Agesilaus defeated them again in the same year in the battle of Coronea (*q.v.*) but not decisively, and Sparta's hold in central Greece was for the time lost. He fought round Corinth in 391 and 390 and conducted a subsidiary campaign in Acarnania in 389.

In spring 386 the war of the coalition was ended by the peace of Antalcidas (*q.v.*). Agesilaus exploited this peace to the full, using the clause that guaranteed the independence of all Greek cities to enforce the dissolution of the Boeotian league and of the union between Argos and Corinth. When the Spartan Phoebidas seized the citadel of Thebes in 382, Agesilaus supported his action, and after the liberation of Thebes in the winter of 379–378 he brought the city near starvation in two campaigns in 378 and 377. At the conference in Sparta in 371 he refused to allow the Thebans to sign the peace on behalf of all Boeotia, and this precipitated the campaign against Thebes in which the other Spartan king, Cleombrotus, was heavily defeated in the battle of Leuctra (*q.v.*). This battle altered the whole balance of power and put Sparta on the defensive. In 370 Agesilaus invaded Mantinea territory in an attempt to restore Spartan prestige, but later in the year had to defend Sparta itself against Epaminondas. Some time afterward he went abroad to gain money for the war by assisting the rebellious Persian satrap Ariobarzanes. In 362 he again rescued Sparta from Epaminondas, but he took no part in the subsequent battle of Mantinea. In 361 he was abroad again, serving Zedhor (Tachos), king of Egypt, in his invasion of Phoenicia and Syria. During the campaign a revolt broke out in Egypt, and Agesilaus, who had already quarreled with Zedhor, eventually went over to his rival Nekhtarheb (Nectanebo II) whom he helped to defeat a further rival. On his way home from Egypt he died, at Cyrene, at the age of 84.

Agesilaus was an adroit politician and a brave commander with great tactical skill. He embodied the opportunist spirit shown by Sparta in the 4th century. The panegyric of him by Xenophon (*q.v.*) set the tone for later writers but other contemporaries were sometimes critical, arguing that it was his hatred of Thebes that led, through the battle of Leuctra, to the loss of Spartan supremacy

in Greece.

See Xenophon, *Agesilaus*; Plutarch, *Life of Agesilaus*. (A. As.)

AGGEUS, PROPHECY OF: see HAGGAI.

AGGLOMERATE is a term generally applied to coarse fragmental rock produced by explosive volcanic action. Although similar in appearance to conglomerates, which are produced by sedimentary processes (see CONGLOMERATE), the agglomerates consist almost wholly of angular to subrounded fragments of lava in a poorly sorted tuffaceous matrix or rock composed of volcanic dust or ash. Agglomerates are closely associated with lava flows.

The term is restricted by some to rocks composed of volcanic bombs—gobs of lava at least partly plastic when erupted—and the term volcanic breccia is reserved for those fragmental accumulations which were erupted in a solid condition.

See also BRECCIA: VOLCANO. (F. J. P.)

AGGLUTINATION, in philology, is the method by which two significant words or roots are joined together in a single word to express a combination of the two meanings each of which retains its force (Lat. *ad* and *glutinare*, lit. to fasten together with glue). This juxtaposition or conjoining of roots is characteristic of languages such as the Turkish and Japanese, which are therefore known as agglutinative, as opposed to others, known generically as inflectional, or fusional, in which differences of termination or combinations in which all separate identity disappears are predominant. See LANGUAGE: *Language Typology*.

AGGLUTININ is a typical antibody that occurs in the serums of immunized and normal human beings and animals. When added to uniform suspensions of particles containing specific antigens on the surface, with which agglutinins react, such as bacteria, protozoa and red cells, the suspended objects adhere to each other, form clumps, fall to the bottom and leave the suspending diluent clear. This phenomenon of agglutination is a typical antigen-antibody reaction, is highly specific, is reversible and involves small reacting groups on the surface of each. An agglutinin may act as a precipitin or as other antibodies under appropriate conditions.

4 particular antibody is usually in greatest amount (titer) in individuals who have been immunized with the specific antigen by infection or by other active immunizing procedures. For this reason, agglutination is used as a test for the presence of agglutinins in the serum and indirectly for past or present infection or immunization with the specific antigen. Conversely, serums containing agglutinins to known antigens can be used to identify various bacteria, red cells and other particulate materials containing the specific antigen.

Isohemagglutinins that clump red cells are found in man. The four main blood groups are separated with respect to two antigens, A and B, in the red blood cells and two isohemagglutinins, anti-A and anti-B, in the serum. Thus, in man, type O has neither antigen but both agglutinins, type A has A antigen and anti-B agglutinin, type B has B antigen and anti-A agglutinin and type AB has both antigens but neither agglutinin. These substances are unique markers because they are present at birth. There are also many additional red cell antigens in man, such as the MN and Rh₀ or D ones. In fact, it has been estimated that several million different blood groups could arise from various combinations of the known antigens.

The blood groups are of great importance, especially from the standpoint of human genetics and medicolegal applications, blood transfusions, and hemolytic diseases of the newborn. Blood group factors are used medicolegally in such problems as questioned parenthood and the matching of blood stains with their suspected source. The determination of the blood group of a prospective donor and his recipient is a usual preliminary before transfusion because incompatible blood cells may result in intravascular agglutination. The anemia of the newborn, erythroblastosis fetalis, is most frequently associated with an antigen designated Rh₀ or D. It is an extremely serious but, fortunately, rare disease caused by antibodies produced in the mother which react with antigens in the fetus that were derived from the father.

AGGREGATE, a term used in building and construction to designate the material with which cement, bitumen, lime, gypsum or other adhesive material is mixed to form a concrete (*q.v.*) or mortar. The most common aggregates are sand, crushed or broken stone, gravel or pebbles, broken blast-furnace slag, boiler ashes or clinkers, burned shale and burned clay. The purpose of the aggregate is to provide the finished product with volume, freedom from change in volume, resistance to wear or erosion and other desired physical properties.

Aggregates are divided into two general classes, fine aggregate and coarse aggregate. The fine aggregate is generally sand, crushed stone or crushed slag screenings; the coarse aggregate is gravel (pebbles), fragments of broken stone, slag and the other substances mentioned above. The dividing line between fine and coarse aggregate is usually a $\frac{1}{2}$ -in. screen opening, sometimes a $\frac{3}{8}$ -in. opening. Aggregates are mixed with the cement or binding material in proportions varying from one part of cementing material to one part of fine aggregate for a "rich grout" to one part of cement to nine or ten parts of mixed fine and coarse aggregates for a "lean" concrete. The theory upon which such mixtures are proportioned is that there shall be sufficient cementing material to coat all of the particles in the fine aggregate, and that sufficient mortar will be produced to fill all the voids in the coarse aggregate. The ideal concrete would consist of closely packed fragments of crushed stone, slag or pebbles in which all the fragments are coated with mortar, and all the voids between the coarser fragments filled with mortar. Under actual conditions in construction work there is practically always an excess of mortar.

Preparation of aggregate depends upon the requirements of the job. Specifications usually include cleanliness (with a maximum set on extraneous impurities), allowable percentages of the various sizes of aggregate components, and soundness (*e.g.*, tests for freezing, thawing and mineralogical composition). After the raw materials are mined, they are processed into aggregate by mashing, screening, crushing, grading and mixing. Fine aggregate often is graded and mixed hydraulically. For the strongest mortar or concrete, fine aggregate requires a gradual variation in material size from about 50 mesh (50 openings per linear inch) to $\frac{1}{4}$ -in. mesh. For coarse aggregate, any hard, tough, durable material ranging in size from $\frac{1}{4}$ in. to $3\frac{1}{2}$ in. or more may be used.

It was long the custom to refer to mineral aggregates as "inert." It is now recognized that certain silica or silicate aggregates react chemically with the alkalis in portland cement and cause ultimate disintegration of concrete. Hence, chemical as well as physical tests are now considered essential for most aggregates that have not proved their stability by experience.

See American Society for Testing Materials, *Standards on Mineral Aggregates and Concrete* (1958). (N. C. R.; X.)

AGGREGATES, THEORY OF: see SET THEORY (THEORY OF AGGREGATES).

AGGREGATION, in physics, a collective term for the forms or states in which matter exists. Three primary states of aggregation are recognized—gaseous, liquid and solid. Generally, if a solid is heated to a certain temperature, it melts or fuses, assuming the liquid condition (see HEAT: *Change of State*); if the heating is continued the liquid boils and becomes a vapour (see VAPORIZATION: *One-Component Systems*). On the other hand, if a gas is sufficiently cooled and compressed, it liquefies; this transition is treated theoretically in the article LOW-TEMPERATURE PHYSICS.

In a more technical sense the term molecular aggregation, a clustering together of molecules into groups, is used antithetically to the term molecular dissociation, the breaking up of molecular groups. (H. B. LM.)

AGGRESSION refers in a psychological sense to any manifestation of a self-assertive disposition, in a political sense to any manifestation of an expansive policy, in a military sense to an unprovoked military attack and in a legal sense to the use of

armed force by a government in violation of an obligation under international law or treaty. In the last sense, the term has appeared in numerous treaties and official declarations since World War I, including the League of Nations covenant (art. 10) and the United Nations charter (art. 39). The acceptance by most states of obligations not to "resort to war" (covenant. art. 12), not to use nonpacific means for the settlement of disputes (Kellogg-Briand pact, art. 2), and to "refrain in their international relations from the threat or use of force" (UN charter, art. 2, par. 4) has often made it necessary for international organs to consider the problem of aggression in the hostilities which have occurred after World War I. In such cases the League of Nations and the United Nations have usually followed the procedure of ordering a "cease fire" ("provisional measures") and have considered a government an aggressor only if it failed to observe that order.

Such cease-fire orders ended the hostilities between Turkey and Iraq in 1925, Greece and Bulgaria in 1925, Peru and Colombia in 1933 (Leticia Trapezium). Greece and its neighbours in 1947, the Netherlands and Indonesia in 1947, India and Pakistan in 1948 (Kashmir), Israel and its neighbours in 1949 and Israel, Great Britain and France against Egypt in 1956. None of these states was at the time declared an aggressor. On the other hand, Japan was found to be an aggressor in Manchuria in 1933, Paraguay in the Chaco area in 1935, North Korea and the People's Republic of China in Korea in 1950 and 1951, and the Soviet Union in Hungary in 1956 because they refused to observe cease-fire orders. The aggressions of Italy in Ethiopia in 1935 and of the Soviet Union in Finland in 1939 were so flagrant that aggression was found without cease-fire orders. In Italy's attack on Corfu (1923), the Italian and German interventions in the Spanish civil war (1936) and axis attacks after 1938, cease-fire orders were not given for political reasons, but a commission of jurists implied that Italy was an aggressor in Corfu and the axis aggressions were established by general recognition and the post-World War II war crimes trials.

International organs have usually been able to stop hostilities or to determine the aggressor but they have often failed to frustrate the success of the aggressor, at least for a considerable period. Economic sanctions have proved inadequate and military sanctions have not been undertaken for they might widen local hostilities into general war unless it appeared that overwhelming force could be collected as in the case of Korea. Eventually, Japanese aggressions in Manchuria, Italian in Corfu and Ethiopia, Russian in Finland, and axis aggressions in World War II failed.

For the purpose of reparation or punishment after hostilities, aggression has been defined as any use of armed force in international relations not justified by defensive necessity, international authority or consent of the state in whose territory force has been used. This conception was applied by the Nuremberg and other war crimes tribunals in dealing with the indictment of certain axis leaders for initiating aggressive war and was accepted by the United Nations International Law commission in its draft code of "Offenses against the peace and security of mankind." This code included among acts of aggression "the employment by the authorities of a state of armed forces against another state for any purpose other than national or collective self-defense or in pursuance of a decision or a recommendation of a competent organ of the United Nations."

The United Nations general assembly has recognized the need for a definition of aggression which would command universal acceptance, but continuous efforts have failed to produce such a definition largely because of the desire of some states to include "indirect aggression" such as subversion, infiltration, hostile propaganda and other acts of psychological or political aggression. The purpose of a definition of aggression is, however, to designate the circumstances which justify military action in self-defense or as an international sanction. That such action is permissible only in response to an illegal use of armed force has been affirmed by practice and by art. 42 and 51 of the charter. See also BELIGERENCY; CONQUEST; INSURGENCY; LEAGUE OF NATIONS; PEACE, INTERNATIONAL; UNITED NATIONS; WAR; WAR CRIMES.

AGHLABIDS (BANU 'L-AGHLAB), an Arab dynasty which ruled Ifriqiya (Tunisia and eastern Algeria) from A.D. 800 to 909, nominally subject to the Abbasid caliphs of Baghdad but in fact independent. Their capital city was Kairouan. The most interesting of the 11 Aghlabid amirs were the energetic and cultured Ibrahim ibn al-Aghlab (ruled 800–812), founder of al-Abbasiyya (2 mi. S. of Kairouan), who received an embassy from Charlemagne; Ziyadatallah I (817–838), who broke the rebellion of the Arab soldiery and sent it to conquer Sicily; Abu Ibrahim Ahmad (856–863), who commissioned many public works; the neurotic Ibrahim II (875–902), founder of Raqqada; and the depraved Ziyadatallah III (903–909), whose inability to defend his territory against the Kutama Berber tribe of Kabylia led to the accession of the Fatimids (see FATIMITES).

During the 9th century the brilliant Kairouan civilization was evolved. Thanks to Sahnun and his disciples Malikism became the religion of the people, while Mu'tazilism and Hanafism were predominant at court and Kharijism in the south; philosophy and the exact sciences were studied in a sort of university, the Bayt al-Hikma ("House of Wisdom"). The Aghlabid amirs maintained a splendid court and are frequently reproached by historians for their oppressive taxes. Their magnificent buildings, however, in addition to al-Abbasiyya and Raqqada, include the great mosques of Kairouan, Tunis and Sfax and the *ribats* (hermitages) of Sousse and Monastir; their public works for the conservation and distribution of water contributed to the prosperity of a country which was on the whole peaceful. Their fleet was supreme in the central Mediterranean.

See M. Vonderheyden, *La Berberie orientale* . . . (1927); G. Marçais, "Aghlabids," *Encyclopaedia of Islam*, vol. i, 2nd ed. (1954–60).

(H. R. I.)

AGIN-BURYAT NATIONAL OKRUG lies in Chita *oblast* of the Russian Soviet Federated Socialist Republic. U.S.S.R., on the left bank of the lower Onon, a headwater of the Amur, with the tributary valley of the Aga as its main axis. The western part of the okrug (district) consists of hilly country of the Onon and Daurian ranges. The area has a relatively mild climate for central Siberia, with a low rainfall (Chita has 12.3 in. a year). As a result the vegetation is mostly of a steppe type in the lower east, with forests on the higher hill slopes of the west. The population of 49,000 (1959) consists largely of Buryats, who form an exclave of the larger Buryat group living east and south of Lake Baikal. There are no towns in the district, the administrative centre being the village of Aginskoye. The economy is essentially pastoral and large herds of cattle and sheep are kept. The okrug and neighbouring parts of Chita *oblast* form the major stock-rearing region of the eastern U.S.S.R. The thin snow cover on the steppe pastures allows grazing all year. Spring wheat and oats are the main crops. Tin and gold are found in the area but the chief mining centres lie just outside the okrug borders. The former Chinese Eastern railway from Chita to Harbin crosses the eastern part of the district, while the west is traversed by the highway from Chita to Choybalsan in Mongolia. (R. A. F.)

AGINCOURT, BATTLE OF (Oct. 25, 1415), the victory of a small English army led by King Henry V over a French force commanded by Charles d'Albret, constable of France, during the Hundred Years' War. It was fought near the village of Agincourt (Azincourt in the modern French *département* of Pas-de-Calais). After capturing Harfleur in Normandy (Sept. 1415), Henry had decided to return to England via Calais but on Oct. 24 he found the French blocking his line of advance. Although his men had marched for 18 days and were tired and hungry, Henry saw that he had to fight. At dawn on St. Crispin's day (Friday, Oct. 25) the armies prepared for battle. The French had unwisely chosen a site with a narrow frontage: being enclosed on two sides by the woods of Agincourt and Tramecourt and only about 1,000 yd. wide. Thus it became impossible to make effective use of an

army which outnumbered the English by at least three to one. Three French divisions, the first two dismounted, were drawn up one behind another. Henry had only 800–900 men-at-arms and 3,000–5,000 archers whom he arrayed in dismounted line between the southern ends of the woods. On each flank was a mass of archers set forward in wings and projecting wedges of archers also linked three groups of men-at-arms. After waiting for a French attack, Henry led his men forward and archery shots from long range at last provoked the French to action. Small cavalry charges upon the English wings ended in confusion and the retreating horsemen broke through the French van as it moved forward. Sodden plowed land and heavy armour also hampered the French, who were bunched so tightly that some could barely raise their lances. Despite heavy archery shooting the French advanced bravely and at the first clash the English line yielded, only to recover quickly. Then Henry signaled his archers to attack with ax and sword. This was the decisive moment of the battle, for the lightly armed bowmen wrought havoc upon the French. Within three hours the van and second line had been routed, and most of the rear had fled. The dead lay in heaps and there were many prisoners, some of whom were later killed when a fresh attack appeared imminent. The French losses were commonly believed to amount to about 10,000 dead. Contemporary estimates of English losses range from 14 to 1,600, but clearly they were relatively light. At Agincourt the English, brilliantly led by their king, snatched victory from what had appeared a desperate situation, but the incoherent tactics of the French greatly influenced the result. Although the battle brought Henry no immediate territorial gains, this display of his military ability and the resultant demoralization of the French, who were already politically divided, contributed to his later successes.

See Sir Nicholas Harris Nicolas, *Battle of Agincourt*, 2nd ed. (1832); J. H. Wylie, *The Reign of Henry the Fifth*, vol. ii (1919).

(J. W. SE.)

AGING, a part of living, involves growth and development as well as senescence or deterioration. As a complex biological process, which begins with conception, accompanies growth and often accelerates as growth ceases, its most obvious signs are a continuing reduction of the capacity of self-maintenance and repair of cells to the point at which death occurs. See GERONTOLOGY AND GERIATRICS; GROWTH; DEATH (BIOLOGICAL).

AGIO, a term used in commerce in three connections.

1. The variations from fixed pars or rates of exchange in the currencies of different countries. For example, in most gold-standard countries, the standard coin is kept up to a uniform point of fineness and so bears a constant relation to coins of other countries in a similar condition. This is what is known as the mint par of exchange. The balance of trade between the various countries is the factor determining the rate of exchange. Should the balance of trade be against one country, that country must remit money as payment for the indebtedness. Because of the expense of shipping gold there will be a demand for paper money for which it will be necessary to pay a premium, called the agio.

2. The term is also used to denote the difference in exchange between two currencies in the same country. Where silver coinage is the legal tender, agio is sometimes allowed for payment in the more convenient form of gold. Where the paper currency of a country is reduced below the bullion which it professes to represent, an agio is payable on the appreciated currency.

3. Lastly, in some states the coinage is so debased because of the wear of circulation that the real value is greatly reduced below the nominal value. Suppose this reduction amounts to 5%. If 100 units of money are offered as payment of a debt in the country where the units are current at their nominal value, they will be received as just payment. If they are offered as payment of the same amount of debt in a foreign country, they will be received only at their intrinsic value of 95 units, the additional 5 units constituting the agio. When a country keeps its coinage up to a standard value no agio is required.

(F. GR.)

AGIS, the name of four Spartan kings, the first of the Xgiad family, the rest of the Eurypontid house.

AGIS I was traditionally the son of Eurysthenes (one of the

legendary twin founders of Sparta). The Agiad line of kings was named after him, which may indicate that unlike Eurysthenes, he was an historical figure. Ephorus, writing in the 4th century B.C. attributes to him the capture of the city of Helos in Laconia and the reduction of the inhabitants to helots (*q.v.*).

AGIS II (d. 400 or 398 B.C.), son of Archidamus II, succeeded his father probably in 427 B.C. From 426 to his death he commanded all operations of the regular army. In 418, when the peace of Nicias (see PELOPONNESIAN WAR) had produced much disaffection in the Peloponnese, he invaded the Argolid and cut the Argive army off from their city while his allies threatened their rear, but then made a truce and withdrew. His reason is not clear—the timing of the operation perhaps went wrong—but each side believed that it had the other at its mercy and was indignant with its leaders, and Agis only escaped heavy penalties by promising better performance. A few weeks later he defeated the Argive alliance at Mantinea and restored Spartan prestige.

In 413, when war with Athens was formally resumed, Agis led the force which thereafter occupied Declea in Attica, and Thucydides stresses the influence that he exerted from there. Though the occupation caused great hardship to Athens, it was Lysander's naval victory that ended the war in 404. Agis took no part in the subsequent settlement at Athens. In 402 (or 400) war broke out with Elis, and by ravaging the countryside Agis brought Elis to surrender in spring 400 (or 398). He fell ill on the way home from dedicating spoils at Delphi and died soon after.

AGIS III (d. 331 B.C.), succeeded his father Archidamus III in 338. After Alexander the Great (*q.v.*) had embarked on his campaigns in Asia Minor, Agis prepared to profit by his absence from Greece by raising the Greek cities against the Macedonians. With Persian money and 8,000 Greek mercenaries who had escaped from the battle of Issus (333) he tried to hold Crete against Alexander. In 331 he raised a coalition in the Peloponnese and laid siege to Megalopolis. Alexander's regent Antipater patched up peace with the Thracians with whom he was engaged, marched south and won a hard-fought battle near Megalopolis (331). Agis was killed and Spartan resistance was broken.

AGIS IV (d. 241 B.C.), succeeded his father Eudamidas II in 244 when he was 19 years old. Land and wealth were then very unequally distributed in Sparta, many estates were mortgaged and the poor heavily burdened with debt. The system of common meals and military training had lapsed, and there were only 700 full citizens. Tradition about the Lycurgan system (see LYCURGUS) helped to shape Agis' scheme of reform, which included cancellation of debts; the division of the Spartan homeland into 4,500 lots for citizens, their number to be made up with perioeci (*q.v.*) and foreigners; the distribution of 15,000 lots to the remaining perioeci; and the restoration of the Lycurgan discipline.

Agis was supported by his wealthy mother and grandmother, who surrendered their property; by his uncle Agesilaus, whose estates were much encumbered; and by Lysander, ephor in 243, who put his proposals before the council. The wealthy, led by the other king, Leonidas II, defeated them by a bare majority, whereupon Leonidas was deposed in favour of his son-in-law Cleombrotus. When the ephors of 242 tried to reverse this, they were replaced by a board headed by Agesilaus.

Agesilaus now persuaded Agis to carry out the cancellation of debts first and then delayed the redistribution of land. Aratus (*q.v.*) of Sicyon, temporarily Sparta's ally, asked (241) for help against the Aetolians, and Agis went to the Isthmus of Corinth with an army, but Aratus declined battle. Agis returned to find that his supporters were disillusioned by the delay of his reforms and discontented under Agesilaus' rule, and that Leonidas had returned to power, supported by mercenaries. Agis took sanctuary rather than engage in war with Leonidas, but was enticed out, given a form of trial and executed with his mother and grandmother.

Such radical reform was almost equally unwelcome to the Macedonians and to the Achaean league, the two major powers struggling for domination in Greece; it was therefore unlikely to succeed by peaceful means. Agis' opponents were less scrupulous than he (who twice spared Leonidas' life), and even his supporter

Agesilaus was merely exploiting him.

(A. As.)

AGLAUROS (AGRAULOS), in Greek mythology a daughter of Cecrops, was killed with her sisters by the infant Erichthonius (see ERECHTHEUS). But Ovid relates that Aglauros was turned to stone by Mercury in retribution for her attempt to frustrate his abduction of Herse.

Aglauros and her sisters were originally, apparently, fertility deities. She had a sanctuary on the Acropolis in which young men of military age swore an oath to her as well as to Zeus, Ares and minor deities. The honour may stem from yet another legend, that Aglauros had sacrificed herself for the city during a protracted war.

(T. V. B.)

AGNANO (LAGO DI AGNANO), a lake that formerly occupied an extinct volcanic crater and was drained in 1870. The lake bed, in the volcanic region 6 mi. W. of Naples, Italy, was known to the Greeks and Romans for its thermal baths, but its present name is assumed to be of Norman origin. There are 75 springs and an active *solfatara*. The large thermal establishment utilizes mineral waters, gushing forth at various temperatures.

(G. KH.)

AGNELLI, GIOVANNI (1866–1945), founder with others, in 1899, of the Fiat (Fabbrica Italiana Automobili Torino) company of Italy and the chairman and managing director almost from its inception, was born in Villar Perosa, Piedmont, on Aug. 13, 1866. He entered the military academy in 1884 and became a cavalry officer in 1886. Agnelli was largely responsible for establishing the ball- and roller-bearing industry in Italy. In 1906 he founded the Officine di Villar Perosa company (RIV bearings) and in 1907 he was made a Knight of Labour. He was a senator from 1923. In 1937, the Turin polytechnic conferred on him an honorary degree in industrial engineering. Before and during World War II, Agnelli was one of the chief mobilizers of Italian industry for war. He personally survived the fall of the Mussolini government although he lost his factories. He was responsible for many philanthropic works. Agnelli died at Turin on Dec. 16, 1945.

(St. J. C. N.)

AGNES, SAINT, one of the most celebrated Roman martyrs, who suffered possibly at the beginning of the 4th century; her epitaph, written by Pope Damasus I (d. 384), is extant. According to the tradition, of uncertain value, Agnes was a girl of about 13 years old who refused a good marriage for the sake of religious virginity and in punishment was exposed in a brothel. There she suffered no harm and so was put to death by being either beheaded or stabbed in the throat. She is mentioned in the canon of the Roman mass and her name figures in the calendar of the Book of Common Prayer. Her feast is kept on Jan. 21; on that day two lambs (Lat. *agnus*) are blessed in the church of Sta. Agnese in Rome and from their wool are made the pallia sent by the pope to archbishops as tokens of jurisdiction. Agnes is a patron saint of girls and Keats's poem, "Eve of St. Xgnes," refers to a superstition connected with this aspect of her cult.

See H. Thurston and D. Attwater (eds.), *Butler's Lives of the Saints*, vol. i, pp. 133–137 (1956).

(D. Ar.)

AGNES OF MERAN (d. 1201), queen of France, was the daughter of Bertold IV, duke of Meran in Tirol. In June 1156, despite Pope Celestine III's protest, she was married to Philip II, king of France, who had repudiated Ingeborg of Denmark in 1193. Pope Innocent III, however, protested more forcefully in 1198 and in 1200 put France under an interdict, whereupon Philip pretended to agree to a separation from Agnes. In fact he did not turn her away and Ingeborg was imprisoned. Xgnes died at Poissy in Aug. 1201. Innocent legitimized her children by Philip; viz., Marie (c. 1198–1238), later countess of Namur; and Philippe Hurepel (1200–34).

See Duc de Lévis-Mirepoix, *Les Trois Femmes de Philippe-Auguste* (1947); E. Rossier, *Sur les degrés du trône* (1940).

AGNESI, MARIA GAETANA (1718–1799), Italian mathematician and philosopher, was born on May 16, 1718, in Milan, where her father was professor of mathematics. She was an extremely precocious child. At an early age she mastered Latin, Greek, Hebrew and several modern languages: when she was only nine years old her Latin discourse in defense of higher education for women was printed. In 1738 appeared her *Propositiones philosophicae*, a series of essays on philosophy and natural science,

based upon discussions before a scientific group meeting in her father's house. Her best-known work, *Istituzioni analitiche ad uso della gioventù italiana*, dedicated to the empress Maria Theresa, was published in 1748. It enjoyed great popularity and was translated into several languages (Eng. trans. by John Colson, 1801). In this text is found a discussion of the Agnesi curve, a cubic, the *versiera* or versed sine curve, which, through a misunderstanding, became known as the Witch of Agnesi in English (see CURVES, SPECIAL).

In 1749 Xgnesi was appointed honorary lecturer at the University of Bologna by Pope Benedict XIV. She was always deeply religious, and after the death of her father in 1752 devoted herself almost exclusively to charitable work and religious studies. In 1771 she was appointed director of the Pio Albergo Trivulzio, a charitable institution; there she died on Jan. 9, 1799.

Her sister, MARTIA TERESA AGNESI (1724–1780), was an accomplished musician and composer.

See A. F. Frisi, *Elogio storico di Domina Maria Gaetana Agnesi milanese* (1799); L. Anzoletti, *Maria Gaetana Agnesi* (1900). (O. Oe.)

AGNI, the fire god of the Hindus, second only to Indra in the Vedic mythology of India. He is invoked as "priest of sacrifice" in the first verse of the Rigveda and, since he acts as messenger between gods and men, sacrifices to him are upborne to the deities. On earth his parents are the two sticks of the fire drill and every day he is reborn an immortal, living among men and supreme director of religious rites and duties. His form is, however, threefold—fire on earth, lightning and the sun—and in art he is depicted as ruddy, with two faces, one beneficent and one malignant, and three-legged (as in the swastika, with seven arms). Later he was identified with Rudra (*q.v.*). In modern India he has no professed sect but is invoked in many ceremonies, especially by Agnihotri Brahmans. See also HINDUISM.

AGNI. The Agni (Anyi) belong linguistically and culturally to the Akan (*q.v.*) peoples of the Kwa subfamily of the Nigritic (Western Sudan) stock. They live in southwestern Ghana and the Ivory Coast, between the Ashanti and the Baule. The Agni embrace the Arichin, Asaye, Bettie, Bini, Bonai, Brisa, Dadia, Kumwe, Moro, Ndeye, Safudi, Sanwi and Sika tribes. They number about 100,000. They live largely in dispersed homesteads, practising shifting hoe cultivation and fallowing. Yams, bananas and taro are among the staple crops. Inheritance, succession and political allegiance are determined by matrilineal descent though, like other Xkan peoples, they recognize partially exogamous patrilineages.

(K. A. BU.)

AGNOETAE (THEMISTIANS) (Gr. *agnoeō*, "be ignorant of"), a small monophysite group of eastern Christians of the 6th century who, contrary to the prevailing view, maintained that Christ as man was ignorant of many things (Mark xiii, 32; Luke ii, 52); founded by Themistius, a deacon of Alexandria. The doctrine was condemned by Pope Gregory the Great. See MONOPHYTES.

(V. C. S.)

AGNOLO, BACCIO D' (BARTOLOMEO D'AGNOLO BAGLIONI) (1462–1543), Florentine wood carver, sculptor and architect, exerted an important influence on the Renaissance architecture of Florence. Born on May 14, 1462, he started as a wood carver, and between 1491 and 1502 did much of the decorative carving in the church of Sta. Maria Novella and the Palazzo Vecchio in Florence. At the beginning of the 16th century he was engaged with Il Cronaca in restoring the Palazzo Vecchio, and in 1506 he was commissioned to complete the drum of the cupola of the metropolitan church of Sta. Maria del Fiore. The latter work, however, was interrupted on account of adverse criticisms from Michelangelo, and it remained unexecuted. Baccio d'Agnolo also planned the Villa Borghese and the Bartolini palace, with other fine palaces and villas. The Bartolini palace was among the first houses to be given frontispieces of columns to the door and windows, previously confined to churches, and he was ridiculed by the Florentines for this novelty. He designed the campanile of the church of S. Spirito. His studio was the resort of the most celebrated artists of the day, Michelangelo, Sansovino, the brothers Sangallo and

the young Raphael. He died March 6, 1543, in Florence, leaving three sons, all architects, the best known being Giuliano.

AGNON, SAMUEL JOSEPH (formerly CZACZKES) (1888–), the foremost 20th-century Hebrew novelist and short-story writer, was born July 17, 1888, at Buczacz, eastern Galicia, the area in which most of his stories are set. They form a saga of the decline of Galician Jewry from the golden age of Hasidism (1750–1850)—theme of the picaresque *Hakhnasat kallah* (1922; Eng. tr. *The Bridal Canopy*, 1937)—to the apocalyptic ruin after World War I pictured in *Oreah natah lalun* ("A Wayfarer Tarrieth the Night," 1945). Almost all of Agnon's other stories are set in Palestine, where he lived from 1908 to 1913 and after 1924, and deal with the replacement of the religious world of the "Old Settlement" by the secular and scientific society of European Zionist settlers, which he faced with deep misgivings, expressed in situations of Kafkaesque failure. The treatment varies from the straight narrative of his greatest novel, *Temol shilshom* ("Only Yesterday," 2nd ed., 1947), the epic of early pioneer immigrants, to the nightmares of *Sefer ha-maasim* ("The Book of Deeds") and the biting satire of *Sefer ha-medinah* ("The Book of the State"). An important anthologist of Hasidic and other religious thought, he nearly always employs the simple yet allusive 18th-century Hasidic style. His work has not yet been translated successfully, though attempts have been published in 15 languages. Agnon's style, different from contemporary Hebrew, was adopted by several younger Israeli-born novelists after the mid-20th century.

See *Kol Sipurim* (Agnon's collected stories), 3 vol. (1931) and later editions; E. M. Lipschitz, S. J. Agnon (1926); D. Sadan, *Al S. J. Agnon* (1959). (C. Rn.)

AGNOSTICISM is, strictly speaking, the doctrine that man cannot know the existence of anything beyond the phenomena of his experience. The doctrine has been applied especially to the three unresolved antinomies defined by Kant's *Critique of Pure Reason*—God, freedom and immortality (see KANT, IMMANUEL). From this application the term has come to be equated in popular parlance with skepticism (*q.v.*) about religious questions in general, and in particular with the rejection of traditional Christian beliefs under the impact of modern scientific thought. Disregarding the nice distinctions developed by philosophers and theologians, many persons use such terms as agnostic, atheist, infidel, deist and skeptic quite indiscriminately.

Agnosticism both as a term and as a philosophical position gained currency through its espousal by Thomas Huxley, who seems to have coined the word agnostic in 1869 to designate one who repudiated traditional Judaeo-Christian theism and yet disclaimed doctrinaire atheism, transcending both in order to leave such questions as the existence of God in abeyance. Huxley himself defined agnosticism as the principle

... that it is wrong for a man to say that he is certain of the objective truth of any proposition unless he can produce evidence which logically justifies that certainty. This is what Agnosticism asserts; and, in my opinion, it is all that is essential to Agnosticism. That which Agnostics deny and repudiate, as immoral, is the contrary doctrine, that there are propositions which men ought to believe, without logically satisfactory evidence; and that reprobation ought to attach to the profession of disbelief in such inadequately supported propositions (*Science and Christian Tradition*, p. 310, 1900).

From this definition and from the way the word has been used in ordinary speech it is evident that there are two related but nevertheless distinct viewpoints suggested by the term agnosticism. It may mean no more than the suspension of judgment on ultimate questions because not all the evidence has come in or because not all the evidence can ever come in. In this sense even the New Testament's definition of faith as "the assurance of things hoped for, the conviction of things not seen" might conceivably be called agnostic in its tenor, for it asserts that the final grounds of man's belief lie beyond the realm of evidence and experience. As doubt has been a path to faith in the thought of men such as St. Augustine, Pascal and Kierkegaard, so agnosticism in this sense belongs to the biblical interpretation of man's relation to God.

But the setting of Huxley's words quoted above makes clear that this very biblical interpretation of man's relation to God was the intended polemic target of agnosticism. The suspension of judg-

ment on ultimate questions for which it called was thought to invalidate Christian beliefs about "things hoped for" and "things not seen." Indeed, Huxley's essay on "Agnosticism and Christianity" was actually a discussion of such questions as the Mosaic authorship of the Pentateuch, the credibility of biblical miracle stories and the superiority of the ethic of Jesus. The inventor of the word agnosticism was himself responsible for its nontechnical use as a designation for one of the combatants in the 19th-century "warfare of science with theology."

Huxley's role in the struggle over the teachings of Charles Darwin helped to establish this connotation as the primary one in the definition of agnosticism. When such prominent defenders of the Darwinian hypothesis as Clarence Darrow likewise labeled themselves as agnostics, the writers of popular apologetic pamphlets found it easy to equate agnosticism with hostility to conventional Christian tenets. Because of the opprobrium attaching to it, the term agnosticism had lost favour by the second half of the 20th century. Its place was taken by the older term skepticism, but the field of the battle had likewise been shifted. Not the question of Christian evidences but the problem of evidence and verification as such had become the central issue among philosophers. Thus logical positivism (*q.v.*), which bore certain resemblances to agnosticism in its refusal to speculate about ultimate and unknowable questions, also went beyond the agnosticism of Huxley.

See T. H. Huxley, *Science and Christian Tradition* (1900); J. Ward, *Naturalism and Agnosticism*, Gifford Lectures for 1896–98 (1899).

(J. J. Pn.)

AGNUS DEI, "Lamb of God," a designation of Jesus Christ in Christian liturgical usage. It is based upon the saying of John the Baptist quoted in John i, 29: "Behold, the Lamb of God, who takes away the sin of the world!" In the Roman Catholic liturgy of the Mass (*q.v.*) the *Agnus Dei* is employed in the following text: "Lamb of God, who takest away the sin of the world, have mercy upon us! Lamb of God, who takest away the sin of the world, have mercy upon us! Lamb of God, who takest away the sin of the world, grant us peace!" Coming as it does between the Lord's Prayer and the communion, the *Agnus Dei* sounds the themes of sacrifice and of adoration. Thus it unites the sacrifice of the Mass to the sacrifice of Christ on the cross as the Lamb of God, and calls to mind the sacrifice of the lamb in the cultus of the Old Testament. Both Anglican and Lutheran liturgies have retained the *Agnus Dei* in their eucharistic rites. It appears also as a part of many of the litanies. The name *Agnus Dei* is applied as well to figures of Christ as the Lamb of God, especially to waxen disks impressed with this figure and blessed by the pope. (J. J. Pn.)

AGOBARD, SAINT (c. 769–840), Frankish prelate active in ecclesiastical and political affairs under the emperor Louis I the Pious, became archbishop of Lyons in 816, in succession to Leidrad, having been a suffragan bishop in the archdiocese since 804. While he wrote against the adoptionist heresy of Felix of Urgel (who was confined at Lyons from 800 to 818), Agobard's zeal for reform led him to attack trial by ordeal and image worship, and his critical spirit went so far as to deny the verbal inspiration of the Bible and to object to the invocation of the saints.

Agobard was in frequent conflict with the secular power from 821, when he and Nibradius, bishop of Narbonne, ignoring the lay overlord, supervised the election of an abbot of Aniane in Languedoc. His struggle to reclaim ecclesiastical lands in accordance with the diet of Attigny (822) was ineffective, as were his protests against imperial protection of the Jewish communities (827). Having written a public justification of the deposition of Louis the Pious in 833, Agobard lost his see when Louis was restored (835). He retired to Italy until 838, when he was reinstated. He died in Saintonge on June 6, 840. Agobard is revered as a saint in Lyons, although his canonization is not recorded. His works are printed by J. P. Migne in *Patrologia latina*, vol. 104 (1851).

See A. Bressolles, *Saint Agobard évêque de Lyon* (1939); Allen Cabaniss, *Agobard of Lyons, Churchman and Critic* (1953).

AGONOTHETES, in ancient Greece, the president or superintendent of the sacred games. At first the person who instituted the games and defrayed the expenses was the Agonothetes. In the public games, however, such as the Olympic and Pythian, these super-

intendents represented different states, or were chosen from the people in whose country the games were celebrated; thus at the Panathenaea at Athens ten *athlothetai* were elected for four years to superintend the various contests. They were variously called "regulators," "arbitrators," "judges of contests," "stewards of the games" (at Athens), "rod-bearers" (from the rod or sceptre emblematic of their authority), but their functions were generally the same.

AGORA, a word found in Homer's works meaning both assembly of the people and meeting place and in later writings meaning also market place, was the name given by the classical Greeks to what they themselves regarded as a typical feature of Greek life: the daily scene of their religious, political, judicial, social and commercial activity. The agora was an open space, either in the middle of the city or near the harbour, which was surrounded by public buildings (such as the council house or *bouleuterion*) and by temples. Colonnades, or stoas, often served to enclose the space, and statues, altars, trees and fountains adorned it. There might be shops inside the colonnades. Earlier stages in the evolution of the agora have been sought in the east and, with better results, in Minoan Crete (for instance at Ayia Triada) and in Mycenaean Greece (for instance at Tiryns).

In the 5th and 4th centuries B.C. two types of agora competed with each other. Pausanias, writing in the 2nd century A.D., calls one archaic and the other Ionic. He mentions the agora of Elis (built after 470 B.C.) as an example of the archaic type in which colonnades and other buildings were not co-ordinated. The general impression was one of disorder. The agora of Athens (*q.v.*) was one of this type even when it was rebuilt after the Persian wars. The Ionic type was more symmetrical, often combining colonnades to form either three sides of a rectangle or a regular square; Miletus, Priene and Magnesia ad Maeandrum, cities in Asia Minor, provide early examples. This type prevailed and was further developed in Hellenistic and Roman times. The general trend was to isolate the agora from the rest of the town. In this later period the agora influenced the development of the Roman forum and was in turn influenced by it.

Even in classical times the agora did not always remain the place for popular assemblies. In Athens the ecclesia, or assembly, was moved to the Pnyx (a hill to the west of the acropolis) though the meetings devoted to ostracism were still held in the agora; the main tribunal remained in the agora. A distinction was maintained between commercial and ceremonial agoras in Thessaly and elsewhere (Aristotle, *Politics*, vii, II, 2). In the highly developed agora like that of Athens each trade or profession had its own quarter. Many cities had officials called *agoranomoi* to control the place.

The agora also served for theatrical and gymnastic performances until special buildings and spaces were reserved for these purposes. In Athens respectable women were seldom seen in the agora, and men accused of murder and other crimes were forbidden to enter it before their trials. But free men went there not only to transact business and to act as jurors, but to talk and idle—a habit often mentioned by comic poets. A tomb in the agora was granted in exceptional circumstances as the highest honour for a citizen.

(A. D. Mø.)

AGORACRITUS, a Parian and Athenian sculptor, said to have been the favourite pupil of Pheidias. His most noted work was the statue at Rhamnus of Nemesis, by some ancient authorities attributed to Pheidias himself. Part of the head is in the British museum; fragments of the pedestal reliefs are in Athens.

See Gisela M. A. Richter, *Sculpture and Sculptors of the Greeks*, rev. ed., pp. 240–242 (1950).

AGOSTINO DI DUCCIO (1418–1481?), one of the celebrated Florentine marble sculptors of the 15th century. His style, with its linear emphasis, cursive drapery and flat, schematic forms, lacks the fundamentally naturalistic intention of most Florentine sculpture of his time, and owes its mannerisms largely to the humanist environment of Rimini, where his best work was pro-

duced. In 1433 he left his native Florence, and in 1442 carved an altar at Modena (later on an outer wall of the cathedral). Subsequently he returned to Florence; from there he fled in 1446 (apparently accused of larceny) to Venice. In 1454 he was employed at Rimini, and between 1457 and 1462 was at work on the façade of S. Bernardino at Perugia. In 1463–73 he was active in Florence and in the latter year returned to Perugia, where he undertook an altar in S. Domenico, the altar of the Sacrament in the cathedral, the so-called "Maestà delle Volta" (figures from which survive in the Pinacoteca Nazionale) and the Porta di S. Pietro. Agostino's name is associated mainly with the wealth of sculptured decoration in the Tempio Malatestiano at Rimini. The only work in the Tempio with which he can certainly be associated is the Arca degli Antenati, and it is likely that his share in the sculptures was limited to those in the chapels of S. Sigismund, the "Sibyls" and the "Infant Games," and to some decorative carvings. Whether or not he also carved the much superior reliefs in the Chapels of the "Planets" and the "Liberal Arts," he was profoundly influenced by the Neo-Attic reliefs on which these were based. Of his smaller sculptures the most notable are reliefs of the Virgin and Child in the Victoria and Albert museum, London, the National Gallery of Art, Washington, D.C., the Museo Nazionale, Florence, and the Louvre, Paris.

See A. Pointner, *Die Werke des florentinischen Bildhauers Agostino d'Antonio di Duccio* (1909); C. Ricci, *Il Tempio Malatestiano* (1925).
(J. W. P.-H.)

AGOSTINO DI GIOVANNI, Italian sculptor, is first heard of in Siena in 1310 and was again resident in Siena in 1340–43. After 1320 he seems to have been active, with Agnolo di Ventura (documented 1312–49), at Volterra, where the two sculptors executed a number of scenes from the lives of SS. Regulus and Octavian. Between 1329 and 1332 they were jointly employed at Arezzo on the monument of Guido Tarlati in the cathedral.

In 1337 Agostino di Giovanni was at Orvieto, and later he seems to have been responsible for the monument of Cino da Pistoia (d. 1336) in the cathedral at Pistoia. The work of the two sculptors cannot be clearly differentiated and stems mainly from that of Tino di Camaino.

Agostino di Giovanni and Agnolo di Ventura were also active as architects, and a number of buildings in Siena, among them the Porta Romana and the church of S. Francesco, are conjecturally ascribed to them.
(J. W. P.-H.)

AGOULT, MARIE CATHERINE SOPHIE DE FLAVIGNY, COMTESSE D' (pseudonym, DANIEL STERN) (1805–1876), French writer, famous for her position in Parisian society in the 1840s and for her liaison with the composer Franz Liszt, was born Dec. 31, 1805, at Frankfurt am Main, Ger., the daughter of the *émigré* comte de Flavigny. In 1827 she married Col. Charles d'Agoult, 20 years her senior. She had early shown strength of will and enthusiasm for justice and freedom, and her marriage disappointed her expectations. Meeting Franz Liszt, she decided in 1834 to run away with him. Their relationship lasted till 1839 when Liszt, who had no private income and a strength of will to equal hers, felt that his musical career prevented a settled life. Their separation became permanent in 1844. Of their three children, Blandine married Émile Ollivier, Napoleon III's future minister, and Cosima married the pianist and conductor Hans von Bülow but divorced him to become Wagner's second wife.

Returning to Paris in 1839, Mme Agoult began her career as a writer and in 1846 published a largely autobiographical novel, *Nélida*. A close friend of George Sand, whose views on morals, politics and society she shared, and in whose house she had lived for a time with Liszt, she also became the leader of a *salon* where the ideas which culminated in the revolution of 1848 were discussed by the outstanding writers, thinkers and musicians of the day. Her own writings included *Lettres républicaines* (1848), *Histoire de la révolution de 1848* (1851–53), a play, *Jeanne d'Arc* (1857), a dialogue, *Dante et Goethe* (1866) and *Mes Souvenirs 1806–1833* (1877), supplemented by *Mémoires, 1833–1854* (1927), as well as articles for liberal and republican journals. She died in

Paris, March 5, 1876.

BIBLIOGRAPHY.—The *Correspondance entre Liszt et la comtesse d'Agout* was published by their grandson, Daniel Ollivier (1933). See also M. O. Monod, *Daniel Stern, comtesse d'Agout* (1937); C. Aragonnes, *Marie d'Agout* (1938); S. Gugenheim, *Madame d'Agout et la pensée européenne de son époque* (1937); Jacques Vier, *Marie d'Agout, son mari, ses amis* (1949). (R. DL.)

AGOUTI (AGOUTY), any rodent of the genus *Dasyprocta* of tropical America. They range from northern South America to southern Mexico, including the Lesser Antilles. Agoutis attain the size of a large rabbit; they have an elongate body, small ears, a vestigial tail and slender feet terminating in long, hooflike claws. The fur is reddish-brown and wiry, the individual hairs being multibanded (agouti pattern). Agoutis are terrestrial herbivores mostly active during the night; they eat roots, leaves and fruit. Two to four young are produced in burrows, situated among boulders or roots on the forest floor. Their flesh is a prized food of the Indians. (E. T. Ho.)

ARTHUR W. AMBLER FROM NATIONAL AUDUBON SOCIETY

CENTRAL AMERICAN AGOUTI (*DASYPROCTA PUNCTATA*)

by the Moguls. They made it their capital for more than 100 years in the 16th and 17th centuries, until Aurangzeb removed the seat of the monarchy to Delhi in 1658. It was in Agra that Akbar received a letter from Queen Elizabeth I of England and Jahangir issued a *firman* (charter) to Thomas Aldworthe, a merchant of the British East India company, granting freedom to trade in India (1612). In Agra too was founded and flourished the Mogul school of painting. In the latter half of the 18th century it was taken successively by Jat, Maratha and Mogul forces, by Scindhia of Gwalior and by the English. Under the East India company the city was the capital of Agra (later Northwest) province from 1833 to 1858. In 1863 it was made a municipality and from 1959 was administered by a city corporation.

AGRA DISTRICT is mainly level plain (650–700 ft. above sea level) intersected by several rivers, the principal being the Jumna (*q.v.*). Pop. (1951) 1,501,391. Area 1,861 sq.mi. To the southwest is a succession of parallel sandstone ridges, with watercourses running in ravines. On the western border is the Thar desert (see INDIAN DESERT) of Rajasthan. The district's main crops are millets, pulses, barley, wheat and cotton. Twenty-three miles by rail W.S.W. of Agra is the deserted, hut intact, Mogul city of Fatehpur-Sikri (*q.v.*).

AGRA DIVISION comprises the districts of Aligarh, Etah, Mainpuri (*qq.v.*) Mathura (Muttra, *q.v.*) and Agra. Pop. (1951) 6,075,462. Area 8,662 sq.mi.

See K. C. Majumdar, *Imperial Agra of the Moghuls* (1934). (B. St.)

AGRA CANAL: see JUMNA.

AGRANULOCYTOSIS, is an acute disorder usually characterized by fever, prostration and overwhelming infection especially involving the mouth and throat. There is a striking diminution or complete absence from the blood of a particular type of white blood cell known as the granulocyte (polymorphonuclear leukocyte), the cell that normally functions in combating invading bacteria. The severe sepsis that develops in agranulocytosis is therefore attributed to absence of cellular defense mechanisms with subsequent bacterial invasion.

Agranulocytosis is a disorder of multiple causation. Many medicinal agents have been implicated, among them sulfonamides, certain analgesics and drugs used in treating rheumatism, hyperthyroidism, epilepsy, leukemia and malignancies. In persons with unusual sensitivity, agranulocytosis may result from a single dose of a drug. Decrease in granulocytes also may develop following exposure to excessive X-irradiation. Since granulocytes are formed in the bone marrow, direct damage to the marrow may result in complete absence of these cells or granulocytes may be released in the earliest stages of their development (maturation arrest). Other possible mechanisms include toxic effects on circulating granulocytes or formation of leukocyte antibodies.

Treatment consists of prompt removal of the offending agent and use of antibiotics to combat infection until recovery occurs and normal defense mechanisms are restored. (A. S. WE.)

AGRAPHIA ("unwritten [sayings]"), the name given to certain utterances ascribed, with some degree of certainty, to Jesus and preserved in documents other than the Gospels: *e.g.*, Acts xx, 35, and the Logia (*q.v.*) discovered in 1897 and 1903 at Oxyrhynchus. See also APOCRYPHA, NEW TESTAMENT.

AGREDA, MARIA DE (1602–1665). Spanish mystical writer, was born in Agreda, Spain. Her real name was Maria Fernández Coronel, her name in religion Sor Maria de Jesús. In 1620 she made profession of a Franciscan rule for nuns and in 1627 became abbess of a Franciscan monastery in Agreda, retaining this office, except for a brief period, until her death in 1665. Her virtues and holy life were universally acknowledged, but controversy arose over her mystical writings, her political influence and her missionary activities. Her best-known work is *The Mystical City of God* (1670; English trans., 4 vol., 1916), a life of the Blessed Virgin based on revelations granted to Maria. The Roman Index condemned it in 1681, but the ban was lifted in 1747. Spanish theologians having maintained from the start that most of the opposition arose from a misunderstanding of the Spanish text. Though the book contains evident historical, geo-

AGRA, a city in Uttar Pradesh, India, headquarters of Agra district and division, lies on the Jumna river, 117 mi. S.S.E. of Delhi. Pop. of city (1951) 375,665. Area 24 sq.mi.

Monuments.—Agra is essentially the city of the Taj Mahal (*q.v.*), held by generations of travelers and art critics to be the world's most sublime building. The earliest surviving monument, however, is the fort, built in 1564–75 by the emperor Akbar. Its 70-ft. high red sandstone walls are 1½ mi. in circumference. Within are the famous Pearl mosque (Moti Masjid), built by Shah Jahan in 1648–55, and the Jahangiri Mahal or palace (*c.* 1570). The former, of simple white marble, is noted for the beauty of its proportions and design; the latter is a fine Mogul adaptation of the stately solidity and commanding symmetry of the Hindu style. Next to the fort is the Jami Masjid (great mosque) built in 1644–49 by Shah Jahan's daughter Jahan Ara. On the east bank of the Jumna is the elegant tomb (built *c.* 1628–30) of Itimad ud-Daula, father of Jahangir's empress. Architecturally, it is important as marking a transition from the opus *sectile* (pierced stonework) to the *pietra dura* (solid stonework) style; it represents the first triumph in Mogul India of marble inlaid work in imitation of Persian ceramic decoration.

Five miles northwest of Agra is Sikandra, Akbar's burial place (though the emperor's remains were later looted and scattered by Jat raiders). His tomb (completed 1613) is a noble building in a fine setting, with an imposing gateway surmounted by four minarets.

The Modern City is crowded and busy near the fort but extends out to spacious suburbs. It is a military and air force centre with a fine cantonment. In the suburbs are Dayalbagh, a colony of the Radhasnamy sect formed there in 1861, and the state mental hospital. Agra university (1927) conducts most of its teaching through more than 100 affiliated colleges and institutes in Uttar Pradesh. In the city itself are seven of its degree colleges, including a medical school, an engineering college, an educational institute and a women's college.

Agra is a communications centre, being on the air route linking Delhi and Bombay; on the Grand Trunk road from Delhi to Calcutta; and at the junction of the Central railway (Delhi-Bombay via central India), the Western railway (Agra-Bombay via Baroda and the west coast) and the Northern railway, a spur of which connects the city with the main Northern system, Delhi-Kanpur, etc. A metre-gauge line of the Western railway runs westward from Agra into Rajasthan.

The city is also a big commercial centre with several markets. Its main industries are cotton ginning and pressing, carpet weaving, tanning and shoemaking; shoes are exported.

History.—The city is relatively modern, having been founded

graphic and chronological errors, it is valuable as an ascetical and mystical treatise.

In 1643 Philip IV paid Maria a visit, originating an interchange which was maintained either through personal visits or letters until her death. The letters form an invaluable source for the later period of Philip's reign. Maria gave a marked impetus to mission activity, especially among the Franciscans. She frequently repeated that God had revealed to her his desire to convert the Indians and assured the missionaries the reward of an apostle, and though some thought her words fanciful, many others, fortified with this assurance of success, took up mission work, among them Junipero Serra and Antonio Margil. Maria de Agreda died on May 24, 1665.

AGRICOLA, ALEXANDER (1446?-1506), one of the leading composers of the late Burgundian polyphonic school. Born in the Netherlands, probably in 1446, he was educated there and later went to the court of Milan. In 1474 he was at the court of Lorenzo de' Medici and in the same year returned with his family to the Netherlands. In 1500 he was appointed chaplain and chanter to Philip the Fair, whom he accompanied to Spain. He died at Valladolid in 1506. Of his masses and motets the *Missa in die pasce* and the motet *Regina coeli* are highly esteemed for their musical quality.

AGRICOLA, GEORGIUS (GEORG BAUER) (1494-1555), German scholar and man of science, known as "the father of mineralogy," was born at Glauchau in Saxony on March 24, 1494. After studying philology at the universities of Leipzig, Bologna and Padua, he earned a degree in medicine at the University of Ferrara. From 1527 to 1533 he was city physician in the flourishing mining town of Joachimsthal in Bohemia and from 1534 to the end of his life practised medicine in Chemnitz. He adopted the latinized form of his name and wrote in Latin.

Although he made contributions to medicine, chemistry, mathematics, theology and history, his most important writings were on mineralogy and mining. Living in what was then the greatest mining region in Europe, and in close touch with all phases of the industry, his intimate and practical knowledge enabled him to become the first ariter on these subjects to rely on direct observation rather than on speculation. He exerted a direct influence on his contemporaries and successors and through them on the development of geological science. Best known of his six books on geological subjects is *De re metallica*, published posthumously in 1556, dealing chiefly with the arts of mining and smelting and containing many informative and attractive woodcuts. It was translated into English by Herbert Clark Hoover and Lou Henry Hoover, appearing in a limited edition in 1912 and in a trade edition in 1950.

In Agricola's *De natura fossilium* (1546), translated into German by Ernst Lehmann (1809-10) and into English by Mark C. Bandy and Jean A. Bandy (1955), and considered the first mineralogy textbook, he presented a new classification of minerals based on their physical properties; he described many new minerals, chiefly metallic ores, their occurrence and mutual relationships. His first mineralogical work, *Bermannus, sive de re metallica dialogus* (1530), was a treatise on the Erzgebirge mining district. In *De ortu et causis subterraneorum* (1546) he recognized clastic rocks and mineral-bearing solutions. His other geological works are *De natura eorum quae effluent ex terra* (1546) and *De veteribus et novis metallis* (1546).

Agricola died Nov. 21, 1555.

(L. W. P.)

AGRICOLA, GNAEUS JULIUS (A.D. 40-93), Roman general celebrated for his conquests in Britain and as the subject of a biography by his son-in-law the historian Tacitus, was born on June 13, A.D. 40, at Forum Julii (modern Fréjus) in Gallia Narbonensis. His grandfathers were of equestrian rank; his father became a senator but was executed by Caligula, and Agricola was brought up by his mother at Massilia (Marseilles). He served as military tribune (59) on the staff of Suetonius Paulinus in Britain, returning to Rome in 61 and marrying Domitia Decidiana, of a dis-

tinguished Narbonese family. In 64 he was quaestor in Asia, in 66 people's tribune, in 68 praetor, and in the civil war took the side of Vespasian, who appointed him in 70 to command the 20th legion in Britain. On return to Rome in 73 he was created a patrician and appointed governor of Aquitania, where he spent three years (74-77). Appointed consul in 77, he was admitted to a priesthood and made governor of Britain. In the same year he betrothed his daughter to Tacitus.

Agricola spent seven years in Britain, from 77 (if we reckon his term of office as beginning in the late summer of that year and not in 78) to 84. After conquering in north Wales, the Ordo- vices and the island of Mona (Anglesey), he forwarded the construction of a new legionary fortress for the 2nd legion (*Legio II Adiutrix*) at Deva (Chester). During the next two years he completed the conquest of what is now northern England and advanced to the river Tay. Between campaigns he encouraged the romanization of the province. In his fourth year he established a line of posts between the firths of the Clota and Bodotria (Clyde and Forth) rivers as a temporary frontier behind which he was to achieve in the fifth year the occupation of Galloway and the Ayrshire coast. After Agricola's army had spent the two following years in reconnaissance by land and sea, the Caledonians north of the Forth, commanded by Galgacus, were provoked in Agricola's seventh year by naval forays and an advance through the territory of the Venicones and Taexali (Angus, Kincardineshire and Aberdeenshire) to a decisive battle at an unidentified site called Mons Graupius, which ended in their complete defeat. Agricola's permanent occupation of Scotland reached the fringe of the highlands (*see* BRITAIN); he blocked the main passes with forts and placed a legionary fortress at Inchtuthil (near Dunkeld in Perthshire). He was recalled to Rome after his victory, where he lived in retirement, refusing the proconsulship of Asia.

See I. A. Richmond, "Gnaeus Julius Agricola," *Journal of Roman Studies*, vol. xxxiv, pp. 34-45 (1944); R. Syme, *Tacitus* (1958).

(I. A. Rb.)

AGRICOLA, JOHANN (JOHANNES; originally SCHNEIDER, then SCHNITTER) (1494?-1566), German Lutheran reformer and advocate of antinomianism (*q.v.*), was probably born on April 20, 1494, in Eisleben. A student at Wittenberg in 1515, he was recording secretary at the Leipzig debate between Martin Luther (*q.v.*) and Johann Eck in 1519. He became an influential member of the theological circle around Luther and helped to introduce Lutheranism in Frankfurt in 1525. Having taken the position of preacher and schoolmaster in Eisleben, he began to teach that repentance comes only from the message of love in the Gospel, not from the Law, which he regarded as a Jewish code: "The Decalog belongs in the courthouse, not in the pulpit. . . . To the gallows with Moses!" Returning to Wittenberg in 1536, Agricola energetically espoused this antinomianism. Luther replied with five disputations and the treatise "Against the Antinomians." Agricola retracted and in 1540 was appointed court preacher in Berlin by Joachim II of Brandenburg, and later general superintendent. Welcoming Charles V's victory over the Protestants, he helped write and promote the provisional religious settlement, the Augsburg Interim (1548), which earned him the hatred of staunch Protestants.

Meanwhile, he defended strict Lutheranism in other theological controversies. He died Sept. 22, 1566. A gifted preacher, theologian and administrator, Agricola's character was marred by vanity: contentiousness and moral weakness. Lasting achievements were his collections of German proverbs published in 1528, 1529 and 1548.

BIBLIOGRAPHY.—B. Kordes, *Joh. Agricolae Schriften möglichst vollständig verzeichnet* (1817); G. Kawerau, *Johann Agricola von Eisleben* (1881), and notice in *The New Schaff-Herzog Encyclopedia of Religious Knowledge*. (Ro. H. F.)

AGRICOLA, MARTIN (1486?-1556), German composer, teacher and writer on music, was one of the first musicians to concern himself with the needs of the Reformed churches and to publish musical treatises in the vernacular. Much of the German musical vocabulary which he invented is still in use and his hooks give a valuable picture of the musical life of his time, particularly

in his descriptions of early 16th-century instruments. Born, according to his own doubtful testimony, on Jan. 6, 1486, at Schwiebus, he was self-taught, called to music "from the plough" as his chosen surname suggests (his real name was Sore or Sohr). He worked in Magdeburg from about 1520 and died there on June 10, 1556. Most of his unpublished compositions are lost but his printed volumes include a good deal of functional sacred music and many instrumental pieces which are transcriptions of vocal part-songs.

BIBLIOGRAPHY.—Agricola's German publications include *Ein kurtz deudsche Musica* (1528); *Musica instrumentalis deusch* (1529, completely revised 1545; modern ed. of both versions by R. Eitner, in *Publikationen alterer praktischer und theoretischer Musikwerke*, vol. 20, 1896); "Instrumentische gesenge odder exercitia" (in *Duo libri musices*, 1561; mod. ed. by H. Funck, 1933); *Ein Sangbuchlein aller Sontags-Evangeliën* (1541). See also H. Funck, *Martin Agricola, Ein friihprotestantischer Schulmusiker* (1933). (B. L. TR.)

AGRICOLA, RODOLPHUS (properly ROELOF HUYSMAN) (1443 or 1444–1485), Dutch humanist, important as an exponent of Renaissance ideas in northern Europe, was born at Baflo, north of Groningen, and educated at Groningen, Erfurt, Cologne and Louvain, where he graduated in 1465. After some months in Italy in 1469, he returned to the Netherlands for about three years and then returned to Italy. He seems to have been in Pavia from 1473 to 1475 and in Ferrara, studying Greek under the protection of the reigning duke, from 1475 to the end of 1478. For the next five years he traveled between centres of learning in northwestern Germany and the Netherlands; in 1481 he went as envoy from Groningen to the court of the emperor Maximilian I in Brussels. In 1484 he went to Heidelberg to lecture on classical literature at the invitation of the bishop of Worms, Johann von Dalberg, whom next year he accompanied to Rome. Agricola died, on his return to Heidelberg, on Oct. 27, 1485.

Agricola's writings include an oration in praise of philosophy (1476), a life of Petrarch (1477), *De inventione dialectica* (1479; a criticism of scholastic philosophy) and *De formando studio* (1484; on education). His emphasis on individual freedom and on the cultivation of a complete personality, with attention both to intellectual attainments and to physical development, had an important influence on Erasmus and other 16th-century thinkers.

His works were edited, in two volumes, by Alard of Amsterdam (1539).

See P. S. Allen, "The Letters of Rudolph Agricola," *Eng. Hist. Review*, vol. xxi (1906); H. E. J. van der Velden, *Rudolphus Agricola* (1911).

AGRICULTURAL ECONOMICS, primarily applies the principles of economics and other sciences to organizing resources in agriculture for their most economical or efficient use. Agricultural economics has been described as "the business side of farming," using the term business in the broadest sense and projecting the concept of farming to include production, marketing and questions of farm policy.

Agricultural economics is an applied field. It is related to sociology and political science on the one hand and to the various production sciences of agriculture on the other. These include fields in animal industry, agronomy, soils, etc.

Agriculture is the major source of food, fibre and raw materials essential to human life. Consequently agriculture has been one of the basic occupations of man throughout the world. Interest in the economic aspects of production, distribution and economic policy relating to agriculture and to the use of farm products is, therefore, world-wide.

This article is divided into ten main sections covering the principal aspects of agricultural economics. In addition to the cross references to related articles given under the various headings of this article, see the summary AGRICULTURE (ARTICLES ON). For general discussion see also AGRICULTURE; FARM MANAGEMENT.

Following are the main divisions of this article:

- I. History
- II. Agricultural Prices and Income
- III. Farm Appraisal
- IV. Agricultural Credit Systems

- V. Agricultural Insurance
- VI. Farm Taxation
- VII. Marketing Agricultural Products
- VIII. Agricultural Co-operation
- IX. Agricultural Labour
- X. Law in Agriculture

I. HISTORY

1. Early Developments.—Agricultural economics is relatively new in comparison with most disciplines and is still in a stage of rapid development. Economic problems of agriculture received the attention of many of the 18th- and early 19th-century economists such as Adam Smith and David Ricardo in England, and the German, Austrian and French economists in Europe. Evidences of this development appeared in the course offerings of leading German universities, often under the title of *Agrarpolitik* (agriculture in relation to the state and society). As early as 1851 the Institute of Agronomy at Versailles, France, offered a course named *économie rurale*. In 1875 a book by Alexei P. Ludogovsky was published in Russia on *Fundamental Outlines of Agricultural Economics and Farm Accounting*. In the United States, a few courses were offered in universities after the Civil War but major development of the field did not occur until the turn of the 20th century.

2. Growth in the United States.—In the United States the first public appropriation for work in fields relating to agricultural economics was a modest grant to the patent office in 1839. In this grant, congress provided for "the collection of agricultural statistics, investigations for promoting agriculture and rural economy and the procurement of cuttings and seeds for gratuitous distribution among farmers." This work laid the foundation for the United States department of agriculture. Work in the United States was largely statistical until about the 1890s when, as a result of an agricultural depression, agitation was carried on by farmers' organizations and other rural groups to try to improve the economic position of agriculture, and from then on development of the field was more rapid. During the "golden era of American agriculture," from 1895 to 1914 when farm prices reached their most favourable balance with other prices, attention rested primarily on questions of credit and agricultural co-operation. During the decade from 1910 to 1920, a small number of persons in U.S. universities became concerned primarily with problems of farm efficiency, farm ownership, credit and tenure. Toward the end of the 1920s, attention was on the immediate problems brought on by World War I and agricultural economists were strongly influenced by the depressed condition of agriculture as related to other parts of the economy. This gave considerable force to the discussion of agricultural prices, marketing, co-operatives and tariff policy.

In the 1930s farm economists gave greater emphasis to methods for lifting agriculture out of its depressed condition. Major interest centred on agricultural adjustment to reduce surpluses and raise farm income. This included national legislation to control agricultural output, programs of land-use planning and farm planning which involved adjustments in individual farm organization. During the 1940s agricultural economics was greatly influenced by World War II. Ways of increasing agricultural output received major attention. Finally more effort was put into the study of national policy. Adjustments in size and type of farm, and studies in marketing and land use also received considerable attention.

3. European Development.—In many European countries, agricultural economics centred largely on problems associated with management of the individual farm business. Particular attention has been given to farm accounts and farm costings (production costs). This has been particularly true in most of the countries of northern Europe. In Germany, two main lines have been followed: one, *Agrarpolitik*, centred on questions of policy at the national and international levels. The other concerned problems of the individual farm, including production costs and credit. Germany, in fact, pioneered in a system of co-operative agricultural credit and this system has been used as a model in other countries. Agricultural co-operation has played a leading

role in marketing of farm products throughout the Scandinavian countries. Sweden has developed a unique system for pricing farm commodities which involves government pricing and the marketing of a large part of its agricultural produce through co-operatives. Problems of land use and land evaluation received considerable attention in Italy especially after World War II (*see ITALY: Economy*).

In Great Britain work in agricultural economics developed in several universities and in the British government. Considerable attention has been given to farm accounts and production costs.

During World War II considerable attention was given to national policy and to methods for increasing agricultural output. Britain pioneered in using local boards to set production goals and establish practices for increasing agricultural output.

4. Development in Other Countries. — In most other countries of the world agricultural economics developed more slowly. After World War II, as countries moved from a relatively underdeveloped situation to a more developed status, one of the major problems was the reorganization of agriculture to save labour and to make use of more modern equipment. Consequently, agricultural economics received increased emphasis in various countries.

5. Professional Development. — The most extensive work in agricultural economics developed in the United States, although agricultural economics gained prominence in Europe, Canada, Australia and New Zealand, and increasing interest was shown in Latin America and many of the countries in Asia. Students from India, China, Japan, the middle east and other areas came to universities in the United States and Europe in increasing numbers to secure training in agricultural economics. At mid-20th century several of the larger universities in the United States had large numbers of graduate students from other countries. Part of this development was the result of the awakening world-wide interest in improving diets and levels of living and in promoting economic development.

All of the land-grant colleges in the United States and many universities throughout the world provide courses in agricultural economics. These involve courses in farm management, agricultural marketing, agricultural policy, land economics, agricultural credit, production economics, agricultural prices, statistical methods and techniques.

In all of the large countries agricultural economic associations provide a basis for professional interchange of ideas and for growth and development. Most of these associations publish individual journals. The Agricultural Economics society (Great Britain) publishes the *Journal of Agricultural Economics*; the Indian Society of Agricultural Economics, one of the newer organizations, publishes the *Indian Journal of Agricultural Economics*; the Canadian Agricultural Economics society publishes the *Canadian Journal of Agricultural Economics*; the American Farm Economic association in the United States publishes the *Journal of Farm Economics*. Journals such as these carry reports of research and discussions about major problems of the day and suggested improvements and research methods. The journals also carry discussions pertaining to agricultural policy, agricultural marketing, land economics, etc. The International Conference of Agricultural Economists, which meets every three years in various countries, provides a basis for exchange of professional ideas on a world-wide scale. Agricultural economists meeting in their national and international associations discuss how technical changes can be brought about and how advancement can be made in development of the agricultural economy.

In summary, agricultural economics started in the early 19th century. It developed in the latter half of the century as the result of increasing interest in economic problems associated with agriculture. In the 20th century agricultural economics expanded and the work developed to embrace all the major countries. The work centred on analysis of the economic problems involved in obtaining more efficient use of agricultural resources both in production and marketing. Questions of national policy were involved in many countries. Much interest centred on the question of how low income in agriculture could be alleviated. The three central objectives, therefore, involved (1) more efficient use of

resources; (2) elimination of poverty; and (3) the promotion of economic development.

II. AGRICULTURAL PRICES AND INCOMES

1. Past Instabilities. — The prices of agricultural products vary relatively to prices of nonagricultural products and to each other. The incomes received by agricultural producers have been generally lower and more variable over periods of time than those of other entrepreneurs.

The economic forces determining price changes are numerous. The general level of prices, both for farm products and for other products and services, varies (1) with the general level of demand for goods and services; (2) inversely with the general level of their supply; (3) with the supply of money; and (4) inversely with demand for money. These forces tend to operate on a world-wide basis, but as a result of different monetary and fiscal policies, individual countries experience different general price movements. Inflation of prices can result from demand for goods increasing more rapidly than supply, or from demand for money falling relative to supply of money, as typically in times of war. Inflation can also come about through an increase in the supply of gold or other base of a currency, or from devaluation of a currency.

Michael Rostovtzeff (*Social and Economic History of the Roman Empire*, 1926) produced evidence that price increases in the 3rd and 4th centuries A.D. were related to the successive debasement of the currency—silver in the 3rd century and silver-washed bronze in the 3rd and 4th centuries. George F. Warren and Frank A. Pearson showed that in the 16th century prices in Spain rose with increasing supplies of gold and silver and that in the 18th and 19th centuries there was a close correlation between the general movement of agricultural prices and the ratio of the supply of gold to the demand for it in Europe and North America. But long-run changes in the supply of agricultural products and in population can themselves cause price changes. Michael Postan (in *The Cambridge Economic History of Europe*, vol. ii, 1952) showed that the threefold rise in agricultural prices in England between 1150 and 1225 and the 50% increase in southwestern Germany between 1250 and 1350 were not general in Europe, but related to the pressure of population on the land more than to the influx of silver.

In periods of comparatively rapid changes in the general price level, prices paid to farmers tend to be more flexible than prices paid by them for many of the goods and services used in production or consumed on farms. Agricultural production is slow to respond to a fall in demand, for example, and agricultural prices fall further, than industrial prices. The terms of trade of agriculture with other industries, and of agricultural countries with nonagricultural, have therefore been unfavourable in depression periods; and these unfavourable terms have tended further to reduce agriculture's effective demands on other industries. John R. Bellerby concluded that before 1939 the general average reward for human effort in agriculture was only 55% of that outside. Of the countries studied, only in Australia, New Zealand, France and possibly China was the return to farmers approximately equal to that in the average of nonfarm occupations over any considerable period of time.

This relatively low level of incomes is related to the lower productivity of labour in agriculture. But where in industrial countries, as in North America, a big increase in national income is brought about, the low income elasticity of demand for foodstuffs still keeps agricultural incomes relatively low, even though agri-

cultural productivity is increasing; as incomes rise the demand for foodstuffs rises but little, whereas that for manufactures and urban services expands greatly.

In the richer countries, likewise, price elasticities of demand for foodstuffs are comparatively low, so that large harvests may cause price reductions sufficient to depress incomes. However, prices fall less than outputs rise where domestic disposals, exports or stocks expand sufficiently. And in the poorer countries such as India consumption may increase markedly in response to a fall in price or an increase in real income. The more serious year-to-year fluctuations in incomes are attributed to highly variable harvests of particular products in individual countries. Because these countries export or import only small parts of the world's total supplies of these products, world prices are not substantially affected. Thus northern Nigeria may have a poor peanut harvest but world prices of oilseeds and edible oils are not raised much in consequence.

2. Past Attempts to Control Price Fluctuations.—

Throughout history, up until the 1930s, governments were concerned more with maintaining supplies and stable prices of foodstuffs for their urban populations than with safeguarding the incomes of agricultural producers.

In the imperial age of Egypt supplies were stored against famine years and stability of prices was partially maintained through imposition of taxes on land which were collected in kind and stored in treasury granaries. Under the Roman empire, taxation in kind removed during several centuries large quantities of agricultural products from the market and reduced the scope of the money economy. The direction of imports and exports of food products was controlled. The large imports of grain from Egypt, Sicily and north Africa were imported and stored under government control. The emperor Diocletian went farther in the direction of a controlled economy and by the edict of A.D. 301 fixed maximum prices for many commodities, including foodstuffs, throughout the empire. The edict was a failure for, according to Lactantius Firmianus, black market operations ensued.

In England, also, the earliest government intervention was designed to protect the urban populace rather than to help the agricultural producer. In the 14th century the long series of statutory corn laws was begun that only ended in 1846. The policy followed by Edward III was to keep internal prices down by forbidding almost all exports of corn. His successor, Richard II, encouraged corn growing by permitting corn exports on payment of duties and subject to orders in council. No import restrictions were imposed until 1463, when imports of corn were forbidden so long as the home price was under 6s. 8d. a quarter. The landed interests became aware of the benefits to themselves of keeping up farmers' prices, and variations in the corn laws were employed to this end for nearly 400 years. (See CORN LAWS.)

In the 20th century many governments intervened in the marketing of agricultural products and attempted to control price movements directly or indirectly. The period between World Wars I and II was marked by attempts to raise the prices of agricultural products by restricting supplies. It has been estimated that the operation of the Agricultural Adjustment act of 1933 reduced the U.S. cotton crop of 1933 to 25% and the tobacco crops of 1933 and 1934 to 33% below the 1932 output. In Great Britain the hops and potato marketing boards, set up in 1932 and 1934 respectively, restricted production of those crops by a strict acreage quota system. Other countries tried to keep up world prices by restricting supplies to export markets. The Stevenson scheme of 1922 aimed to restrict production of rubber in British territories by production and export quotas. In 1931 the Chadbourne plan for sugar allotted an annual export quota to each participating country. In 1931-37 the government of Brazil took strong measures to reduce supplies of coffee on the export market by a ban on planting and by destroying a substantial part of the harvested crop. The chief result of these schemes was a fall in the share of the world output of these commodities produced by the participating countries. After 1945 international commodity schemes attempted to secure wider support among producing countries and a measure of agreement between the major exporting

and importing countries.

3. Modern Systems of Agricultural Income and Price Supports.— There are significant differences between the objectives pursued by different countries through their agricultural protection policies. Certain governments undertake to maintain the general level of farm incomes; some maintain price support or controls only for particular commodities; others only give encouragement to increasing production and efficiency.

At the beginning of the 1960s the position in individual countries was as follows. In the United Kingdom and Sweden there were statutory obligations to ensure an appropriate level of income for the greater part of the agricultural industry, but the incomes of individual farmers were not guaranteed. In the United States the policy was to support the prices of individual commodities. Since a large proportion of the output of smaller farms was in products whose prices were not supported, the effect on their incomes was mostly indirect through increases in the general agricultural price level. In Austria, Belgium, France and the Netherlands there were no provisions for total income maintenance but, in the formulation of general agricultural policy, attempts were made to secure a considerable degree of income control. In Germany, Iceland and Switzerland there were statutory provisions to improve agricultural incomes, and to secure equality with the wages of certain groups of industrial workers. In other European countries such as Spain, Greece, Portugal, Turkey and Yugoslavia the emphasis of policy was on increasing production and reducing price fluctuations. In Canada, too, the state had no clear income obligations but aimed to secure increased efficiency in production. In the countries of eastern Europe the official policy after 1956 was to increase the material incentives to agricultural producers by raising product prices, reducing prices of factors and services involved in agricultural production and relaxing the system of compulsory deliveries of produce.

Modern systems of price support in selected countries are reviewed below in more detail.

 U.S. DEPARTMENT OF AGRICULTURE

United States.— The Agricultural Adjustment act of 1933 had as its goal the restoration of prices received by the farmers for their products to a level that would be equivalent in purchasing power to that of 1910-14, a period of comparative stability. The ratio between an index of prices received for the farmer's products and an index of prices paid by him for supplies during that period was taken as parity, or 100, as indicated in the accompanying chart, and this was made the chief basis for setting price-support levels. The index of prices received by the farmer for his products is indicated by the solid line in the upper part of the chart; the index of prices 'paid, by the broken line. The ratio between the two indexes, shown in the lower part of the chart, represents the purchasing power of farm products per unit (per bushel, bale, etc.): when the two indexes are equal, the ratio between them is 1, and the purchasing power of farm products per unit is equal to their purchasing power during the base period, or is at parity. Subsequent legislation, while retaining 1910-14 as the base pe-

rod for the ratio between the general level of prices received and prices paid, modified this strict concept of parity; and a more flexible system, basing parity for individual commodities on average prices over the most recent ten-year period to reflect the changing relationships among commodities, provided support for basic commodities—wheat, corn (maize), cotton, rice, tobacco and peanuts—within a range of 60%–90% of their purchasing power parities. The support prices were linked by a sliding scale to the relationship between their estimated and normal supplies. Certain nonbasic commodities were also included in the support formula but their relation to parity was determined by different

criteria. Farmers' prices for meat, poultry, eggs, potatoes and fruit were not supported.

The method of price support most widely used was the nonrecourse loan made by the Commodity Credit corporation to the farmer; he might repay the loan by delivering his produce at support prices or might redeem it by cash if market prices were higher. In 1956, 46% of the cash receipts of farmers were from marketings of price-supported commodities. After 1952, one-third

TABLE III.—Index Numbers of Farm Income*

(1952 = 100)

Year	United States	United Kingdom	Canada	Netherlands	France
1936–38	58	49	33	51	n.a.
1948	122	89	101	83	118
1950	101	88	85	95	103
1952	100	100	100	100	100
1954	88	90	63	101	103
1956	77	92	90	105	107

of the cash receipts from corn came from such nonrecourse loans. For wheat the proportion varied from 20%–50%; for cotton from 10%–20%.

Though equality of farmers' incomes with incomes in nonagricultural occupations was envisaged in the Soil Conservation and Domestic Allotment act of 1936, and in the Agricultural Adjustment act of 1938, the support system did in fact aim to stabilize the level of the real prices of farm products.

In spite of the support program (or because of the lower support ratios) total U.S. farm income declined between 1951 and 1955. A fall of nearly 10% in the farm population kept the income per head higher than it would otherwise have been, but, as shown in Table I, it declined relatively to the income per head earned outside agriculture until 1956.

United Kingdom.—The Agriculture act of 1947 aimed to secure continuously "a stable and efficient agricultural industry capable of producing such part of the nation's food and other agricultural produce as in the national interest it is desirable to produce in the United Kingdom, and of producing it at minimum prices consistent with proper remuneration and living conditions for farmers and workers in agriculture and an adequate return on capital invested in this industry." An elaborate system was therefore built up of guaranteed prices and assured markets for the main products, accounting for 80% of the total United Kingdom's agricultural output.

The guaranteed prices reviewed each year took into account the general level of costs and the income of the agricultural industry as a whole. Under the Long Term Assurance for Agriculture (Cmd. 23, published Nov. 1956), the government undertook not to reduce the total net income guaranteed (assuming normal weather conditions) by more than 2½% in any one year, nor the prices guaranteed for individual products by more than 4% in any one year, nor those for livestock products by more than 9% over any period of three years. The Agriculture act of 1957, among other provisions, gave statutory form to these assurances.

The methods used to support prices and incomes after 1947 were various. Until 1953 many of the major products were purchased by government agencies at the guaranteed prices. After 1954 a system of "deficiency payments" was introduced for grains and fatstock, the state making good the difference between the open market price and a guaranteed minimum. This system left market prices free to fluctuate, but, without recourse to import controls, provided support levels for farmers' returns. Under the Agriculture act of 1957 the government had the right to limit the guarantee to specified quantities of any product and, in fact, after 1954 the guaranteed price for milk applied only to a certain "standard quantity."

In addition to these commodity subsidies, 60% of which, it has been estimated, went to one-third of the farmers, the government subsidized fertilizers and some other factors and farming operations and made various grants for improvements to the smaller and poorer farms.

France.—The price control policy pursued in France aimed to improve agricultural incomes, especially those of small family farms, and to adjust production to market demand. For the main products "target" prices were fixed either for unlimited quantities or for specified amounts, or alternatively (e.g., for meat) as the base prices for fixing minimum and maximum limits. Target prices were recalculated each year and linked with indexes of prices of industrial goods, retail prices and agricultural wages in order to protect agricultural incomes against declines in the purchasing power of money.

German Federal Republic.—The Agriculture act of 1955 aimed to secure that efficient farmers obtained incomes equivalent to the earnings of workers in comparable industries. For major commodities, except meat, prices were fixed at the producer or consumer stage, and imports were adjusted to enable supplies to balance demand at that level.

U.S.S.R.—The freedom of peasant holdings, sanctioned by early Soviet agrarian legislation (1917–18), was limited during the period of War Communism (1918–21); crops were requisitioned and free markets in farm products were abolished. The

New Economic Policy of 1921 restored free markets and substituted taxes for the requisitioning of crops, but under the first five-year plan of 1928-33 the agricultural industry was consolidated into two forms of organization, state farms and collective farms, and a regular form of crop requisitioning at fixed prices was established. Collective farms had to deliver fixed quotas of their produce to the state at prices considerably lower than free prices would have been and also make payments in kind to the machine-tractor stations in return for work done. Any surpluses could either be sold to the state for somewhat higher prices and some priority in the distribution of scarce manufactured goods, or could be sold in local free markets which were restored in 1933. This system favoured the geographically and climatically more fortunate areas and kept agricultural prices lower than they would have been in relation to those of manufactured goods.

From 1953 the Soviet government undertook to increase agricultural production and bring about a big investment in agriculture. Procurement obligations were lowered, higher purchase prices were established and incentives were offered to peasants to sell more from their individual holdings. But the price structure remained unbalanced; for instance, prices for cotton and cottonseed, flax and hemp were high relative to prices for grain and meat.

In 1958 a complete reappraisal of the pricing policy aimed to secure a more equitable distribution of income between collective farms and to increase their production of meat and dairy products. The obligatory deliveries to the state by collective farms and the payments in kind to the machine-tractor stations were formally abolished. The stations were disbanded and the machines distributed to the collectives. Farms were still under an obligation to sell substantial portions of their production to the state for cash but quotas were varied according to soil fertility. Multiple pricing was abolished. Regional prices were set to cover average production costs and a residual income to collective farmers in the area. They were, however, to be related to average costs for the whole of the U.S.S.R., although they might be altered in the republics from year to year according to yield fluctuations and production trends.

Eastern Europe.—In Poland agricultural incomes rose after 1956 following the increase in the fixed price level of state purchases, while costs were kept proportionately lower by reductions in land taxes and by state investment in agriculture.

In Rumania, Hungary and Bulgaria, compulsory deliveries to the state at fixed low prices were replaced by contractual delivery systems. The governments undertook to maintain the relation between prices paid to and by farmers. Compulsory deliveries of farm produce were also abolished in Yugoslavia in 1957 and were replaced by a system of guaranteed minimum prices for most cereals and meats. These were implemented by state-purchasing organizations which contracted with farms (collective, state and private) in advance.

4. Farm Price Levels and Income Trends.—World economic conditions during World War II and immediately afterward altered the relationship between the prices of agricultural and industrial products and raised agricultural incomes above the relatively low level of the 1930s.

After 1945 short-term fluctuations were reduced and prices received by farmers were kept more stable than in the years following World War I. Prices after 1946 rose more gradually than in 1919-20 and there was no sudden fall such as occurred in 1920-21. But price control did not eliminate longer-term price fluctuations resulting from the major economic forces. The experience of the 1950s showed that it was not possible for countries with considerable trade to keep national prices above the international market level for an indefinite period. The support system practised in North America, involving government purchases and storing, led to serious surpluses of wheat and other products. The experience of marketing boards in west Africa also illustrated the difficulty of attempting long-term stabilization of prices of export products.

Table II shows that between 1947 and 1957 prices received by farmers fluctuated least in countries such as Canada and the Netherlands which were most dependent on export market prices

and did not try to maintain a high internal price structure. The table also indicates that from 1951 to 1957 in most countries for which statistics were available the indexes of real prices received by farmers fell. This was because prices paid by farmers continued to rise, or did not fall as much as agricultural prices.

In spite of the extensive price-support measures after World War II, farm incomes showed, especially in exporting countries, considerable fluctuations from year to year. Canadian farm incomes fell by some 30% from 1953 to 1954. Australian incomes, influenced by fluctuating wool prices, rose by 16% from 1955 to 1956 but fell 25% from 1956 to 1957. Table III indicates the change in agricultural income in selected countries after World War II. It shows that, in spite of a downward trend in some major countries after 1951, total farm incomes were still appreciably higher than before the war. When allowance is made for the decline in the number of people engaged in agriculture in Europe and North America, the increase in incomes is even more significant.

III. FARM APPRAISAL

A farm appraisal is a valuation of farm real estate made by one skilled in this task. Farm appraisals are made for four major purposes: (1) for use in making farm mortgage loans; (2) for the use of buyers and sellers of farms; (3) for assessments used in levying property taxes; and (4) for condemnation where governments and other agencies with the power of eminent domain use appraisals in acquiring farm land.

Down through history there have been varying amounts of emphasis placed on farm appraisal. In China as early as the 23rd century B.C., the government had a system of rents based on soil properties. The Greeks and Romans of ancient times levied taxes in relation to estimated crop yields. During the middle ages in Europe, much attention was given to land surveying which included not only measurement of land but ratings of land productivity.

1. Modern Practice.—In modern times farm appraisal has taken on a stronger economic base, with specialists in Italy, Germany and Switzerland pioneering in the development. Italy, through a long tradition of appraisal writings by economists, has a highly developed farm appraisal profession which uses a combination of sales comparisons and income estimates. Germany, through the writings of Friedrich Aereboe, pioneered in the use of sale value comparisons and later, under Walter Rothkegel, developed a unique bench mark system of land assessment. Under this system a farm in Magdeburg was given a rating of 100 and other farms in Germany were rated up or down from this standard of 100. In Switzerland Ernst Laur used farm account records as the base for valuations. In Great Britain chartered surveyors, who represent the farm appraisal profession, not only value farm real estate but also handle many valuation questions connected with farm leasing. The Royal Institution of Chartered Surveyors had its beginning in Great Britain in 1868. In France the *Ordre des Géomètres-Experts Français* existed continuously under various names from 1838 and its journal, the *Revue des géomètres-experts et topographes français* (Paris), became the official organ for the International Federation of Surveyors or *Fédération Internationale des Géomètres* (F.I.G.).

In the United States extensive development of the farm appraisal and emergence of a farm appraisal profession was the result of faulty farm valuations made for the most part following World War I. Farm mortgage foreclosures in the 1930s indicated that appraisals had been too high on the poor land, too low on the best land. Reform by farm lenders was the logical result and formation of the American Society of Farm Managers and Rural Appraisers in 1929, with its provisions for certification of ap-

praisers. gave the movement professional support.

2. Physical Inventory and Monetary Valuation.—The modern farm appraisal fundamentally is made up of two parts—the physical inventory and the monetary valuation. A brief description of a typical appraisal follows:

The physical inventory generally contains the location and legal description of the farm, an aerial map where one is available, and an appraisal map showing areas of uniform producing soil, slope, erosion, areas of nontillable land, drainage, orchards, timber, farmstead and other features. The map is made as the appraiser walks over and inspects the farm, using a soil auger or spade to evaluate the soil. Additional material is gathered on buildings and improvements, including measurements, descriptions and sometimes photographs. Information is also noted on climatic data, and typical crops grown and their yields. With this information the appraiser estimates the over-all productivity of the farm in the hands of a typical or average operator.

The second major aspect of appraisal—conversion of this physical classification into a monetary value—can be accomplished by estimating net income, by comparing sales of similar properties or by a combination of both procedures. The combination method has received wide acceptance.

Net income is estimated by putting an estimated price on the production of the farm, and subtracting expenses to get the net income likely in the years that lie ahead. Either net landlord income or net owner-operator income can be used as a base. Net income can be converted into value by the process of capitalization; that is, by dividing net income by a rate of capitalization (value = income/rate). This rate can be based on the farm mortgage interest rate since investment in a farm is an alternative to investment in a mortgage. For example, a farm yielding a net income of \$1,000 annually with a 5% rate of capitalization would have an income value of \$20,000.

Sale value comparisons require a search for farm sales within the neighbourhood or district of the farm being appraised. Each of the farms sold has to be compared in terms of productivity with the farm being appraised. Further, if there has been a change in the general market value of farms since one of the farms was sold, this has to be taken into consideration by an adjustment in the sale price. The sale value, determined by comparison, will in all probability be higher than the income value arrived at by capitalizing net income because the sale value includes nonincome features. For example, a sale value estimate of \$25,000 might be indicated for the farm that had a capitalized net income value of \$20,000.

Since both net income estimates and sale value comparisons involve estimating and judgment, farm appraisers generally have found it desirable to have as many checks on their work as possible. In consequence, the professional farm appraiser commonly uses both net income and sale value approaches in arriving at the final amount which in his best judgment represents the value of the farm.

IV. AGRICULTURAL CREDIT SYSTEMS

1. Nature and Role of Agricultural Credit.—In agriculture, as in commerce or industry, credit is needed to overcome a shortage of capital. Lack of capital and too little capital are major problems facing many farmers in various countries. These problems are more acute in underdeveloped countries where incomes are generally low and contribute relatively little to the building up of capital through savings.

Credit, in effect, is a tool to increase production, raise the quality of what is produced, or otherwise improve operations to make them more profitable. Its use must at least result in producing enough additional income to pay for the cost of the money borrowed and also assure repayment of these funds within the specified period of the loan.

A system of credit geared to the requirements of commerce and industry is not, without modifications, suited to the needs of financ-

ing in agriculture. The farm business and the home are closely associated. Many farm units are small and are operated by the persons who own them and production is normally on a seasonal basis. The primary fact that farming is based on plant and animal life results in a slow rate of turnover of invested capital and an uneven flow of income. The nature of farming is such that risks in agricultural lending are usually greater than is generally true in the case of commercial or industrial borrowing, and cash incomes in relation to capital invested and to production are low compared with commerce and industry.

2. Kinds and Sources of Credit.—Agricultural credit must of necessity be adapted to the peculiarities of farming. Loans are made for longer periods than in commerce or industry. The term of agricultural loans must be flexible and all such loans should have a repayment plan consistent with income.

Credit in agriculture can be placed in three groups according to the terms of the loans: (1) short-term; (2) intermediate; and (3) long-term. Short-term loans are used for annually recurring production and other cash expenses. Intermediate-term loans are used to finance such items as machinery, equipment, tools, breeding animals, work stock, drainage and soil terracing. Long-term loans are used to purchase land, construct buildings and to make other lasting improvements so that the farm will become more productive.

There are various sources of agricultural credit, including merchants, moneylenders, banks, co-operative organizations and governmental agencies. In many countries co-operatives and governmental agencies have developed into major sources of agricultural financing. Credit from merchants and moneylenders is usually costly in one way or another, and the financing from these sources is mostly short-term. Banks in some countries are cautious in making agricultural loans because of the risks involved. The borrower has to compete with local businesses for the funds available for loans.

Co-operatives or credit unions (*q.v.*) or societies have been formed by farmers in many countries for the purpose of financing farmers. By pooling their resources and credit needs through such organizations, farmers are able to improve their bargaining power and fill their requirements at lower cost and at terms adapted to their needs.

Governmental agencies are providing agricultural credit in an increasing number of countries. The state may have many purposes for entering this field, but usually one is to provide more adequate credit to farmers at low cost in order to encourage increased production and offer an incentive to greater development.

3. Co-operative Credit Systems.—Although credit co-operatives are often supported one way or another by the government, they function in many countries with only limited state intervention and provide for their farmer-members a good measure of self-help in meeting credit needs.

In Europe, for example, the local co-operative society constitutes the base of these credit structures. These bodies are associated in regional or state institutions which, in turn, are usually joined together in a single national government organization. The credit and other financial activities of these societies are generally subject to government regulation, but responsibility for management and control rests in the hands of their members and administrative staffs.

Many of the local credit societies, as in Austria, west Germany and the Netherlands, have unlimited liability on the part of their members. Others, especially in Belgium, have restricted this feature. Usually the local societies are relatively small in size and serve a village or other limited area. Their credit operations are sometimes combined with other co-operative activities such as purchasing, marketing or providing other services. (See CO-OPERATIVES.)

There usually are other sources of agricultural credit in addition to co-operative lending organizations. Countries such as Austria, Belgium, Sweden, Denmark, west Germany, Italy, the Netherlands and Switzerland also have systems of savings banks. In some countries such as west Germany, Austria and to some extent Switzerland, these savings banks are chartered and their

obligations are guaranteed by towns or other governmental units.

4. Credit Systems Associated With State Management.— In some countries the government has taken a direct hand in sponsoring, financing and even participating in the management of co-operative credit organizations. Under certain conditions, the co-operative status is maintained, but the organization has to depend more or less on the state for financing. In other cases, the co-operative is subject to some degree of administrative control by the government.

In France, farmers obtain about three-fifths of the money they borrow from a state-supported farm credit system. This credit system is administered by the *Caisses de Crédit Agricole Mutuel* which are co-operative societies. At the lowest level, there are the *Caisses Locales* which are private institutions covering a canton or commune. Next are the *Caisses Regionales* which are also private institutions organized in the same way as the *Caisses Locales* but covering the area of a *département*. The various *Caisses Locales* in their area are subordinate to them. The head organization is the *Caisse National*, a government body enjoying financial autonomy and administered by a plenary commission and a board on which the *Caisses Regionales* are abundantly represented. The supervisory powers of the *Caisse National* are such that it has an important say in the business and administrative activities of the *Caisses Regionales*.

Italy also has an agricultural credit system partly administered and financed by the government. Agricultural credit is supplied by several institutions which by law are required to hold authorization from the government. The *Consorzio Nazionale per il Credito Agraria*, which operates throughout Italy, and a number of other national and regional banks are authorized to make farm-improvement loans, the cost of which to the borrower is subsidized in part by the ministry of agriculture and forestry. Farm-operating loans are made by special farm credit banks and other authorized banks, including many which make farm-improvement loans. The small loans are usually made by rural co-operative banks (*casse rurali*).

In addition to its co-operative credit structure, Japan has the agricultural, forestry, and fisheries finance corporation, an independent government institution entirely capitalized by the government. Its purpose is to give long-term credit at low interest rates to farmers, forestry men, fishermen and their organizations where such credit is difficult to obtain from private institutions such as the Central Cooperative Bank for Agriculture and Forestry and other commercial banks. The corporation has no local branches of its own but, instead, its local business is entrusted to the Central Cooperative bank, the prefectural credit federations and local commercial banks.

In Turkey, the financing of about three-fourths of the loans to farmers is done by the Agricultural bank, a government-owned institution. This bank has branches and agencies serving nearly all of the rural areas. The second most important source of agricultural credit in Turkey is the more than 1,400 co-operatives. They serve about 10,000 villages. The remaining 25,000 villages depend on the Agricultural bank to provide credit to farmers directly. The co-operatives borrow from the bank to finance their lending operations.

5. Centralized Government-Controlled Credit Systems.— In countries where capital is scarce and farmers cannot readily organize credit co-operatives to meet their needs for financing, the government may be called upon to establish lending facilities and provide funds. In other countries, particularly as new lands are opened or where private capital shuns investment in agriculture, the government may organize a credit structure to finance agriculture directly. In still other countries, where government desires to exert direct control over the development of agricultural resources by allocating the flow of investment capital into particular areas and specific farming activities, the state may establish and operate a strongly centralized farm credit system. Although in all such situations some credit may be available from various private sources, the biggest part of the lending to farmers is done by the government-controlled institutions.

The primary source of agricultural credit in Argentina, the

Banco de la Nación, operates through its 278 main branches and 21 regional offices of loans and savings, and is a direct dependency of the ministry of finance.

In Chile, there are several government agencies supplying agricultural financing, but the most important credit source is the *Banco del Estado de Chile*. Various other government agencies such as the Colonization bank and the ministry of agriculture are active in providing agricultural credit, but the loans are mainly for special purposes.

In Colombia the *Caja de Crédito Agrario, Industrial y Minero*, a government credit institution for agricultural production and development, is practically the only source of credit for the small and middle-sized farmer, the share cropper and squatter.

In Guatemala autonomous government credit institutions furnish from one-half to two-thirds of all active bank credits for agriculture. The biggest agricultural lender is the *Crédito Hipotecario Nacional de Guatemala*. The most important source of financing for small farmers is the *Banco Nacional Agrario* which makes supervised loans primarily in connection with the establishment of family-type farms under the country's rural development program.

The Canadian farm loan board, established in 1929, is Canada's central agricultural credit institution. In addition; some of the provinces such as Quebec and Ontario have their own farm credit programs.

Two government-controlled credit institutions which make agricultural loans were established in Egypt. One is the Agricultural and Cooperative Bank of Egypt, established primarily to make short-term loans. The Egyptian government owns only one-half of the capital stock, but controls the policies and credit operations of the bank including types of loans and repayments. The other is the Agricultural Mortgage Bank of Egypt which is entirely owned by the government and was established to handle long-term real estate loans.

6. Agricultural Credit Systems in the United States.— Practically every system of agricultural credit is available in the United States. Government-sponsored credit systems frequently have paved the way for improved or increased agricultural lending activity by privately controlled institutions.

Commercial banks have long been an important source of credit for agriculture. Of some \$4,500,000,000 in farm loans held by banks in the second half of the 20th century, non-real estate loans accounted for more than twice as much as real estate-secured loans.

Insurance companies, with outstanding agricultural loans approximating \$2,500,000,000, also are important lending agencies in the farm mortgage field. Many banks enter into contracts with life insurance companies for sharing the farm mortgage business originated by the banks. Such arrangements often enable a bank to provide farm mortgage credit locally in greater volume and on longer terms than would otherwise be possible.

The Co-operative Farm Credit System.—U.S. farmers, soon after the turn of the 20th century, began to recognize that they should have mortgage credit better suited to their needs. Congress passed the Federal Farm Loan act in 1916. That act set up the co-operative land bank system.

Soon it became evident farmers also needed better short-term credit facilities. Congress created the federal intermediate credit banks in 1923 as wholesalers of such credit. These banks discount or purchase farmers' notes secured by chattel mortgages originally taken by local lending organizations and use these notes as collateral for short-term securities known as debentures. The credit banks also make loans to farmers' marketing co-operatives on the security of commodities in storage.

In 1933 congress provided for the establishment of a nationwide system of production credit associations as retailers of funds from the federal intermediate credit banks. In the same year congress also recognized that farmers needed permanent credit facilities to finance their marketing and purchasing activities. This need was met by the creation of 13 banks for co-operatives.

The co-operative farm credit system had grown until by the second half of the 20th century it consisted of over 1,000 local

national farm loan associations, almost 500 local production credit associations, 12 federal land banks, 12 federal intermediate credit banks and 13 banks for co-operatives.

While the banks and the associations making up the system are chartered by the federal government, operate under laws passed by the U.S. congress, and are supervised by the Farm Credit administration, a government organization, they are so set up as to provide for complete ownership by farmers. Farmers elect the members of the board of directors of their local credit co-operatives and have a part in electing five of the seven members of the farm credit district board of directors. Farmers also have a voice in the selection of the 13-member part-time, policymaking federal farm credit board which was established to direct, supervise and control the Farm Credit administration.

Early in the second half of the 20th century, farmers and their co-operatives had about \$3,316,000,000 outstanding in loans from the co-operative farm credit system. This consisted of some 367,000 long-term land bank loans for about \$1,900,000,000; some 260,000 loans for about \$961,000,000 from production credit associations; some 2,300 loans amounting to about \$384,000,000 from the banks for co-operatives; and about \$71,000,000 of financing by the federal intermediate credit banks through other financing organizations.

U.S. farmers finance about 18% of their outstanding farm mortgage loans through national farm loan associations. About 8% of the non-real estate credit they use is production credit association loans. About one-half of farmers' co-operative credit is from the banks for co-operatives.

Farmers Home Administration.—The Farmers Home administration, an agency in the United States department of agriculture, was established in 1946 to meet certain credit needs of farmers not being met by other lenders. Credit extended by the Farmers Home administration supplements but does not compete with loans made by private and co-operative lenders. Most loans are made for the operation, purchase and improvement of family-type farms. All loans are made through the agency's 1,500 local offices serving all agricultural counties. Loans are subject to approval of applicants' eligibility by the Farmers Home administration committee for the particular county. Each county committee is made up of three local persons, at least two of whom are farmers.

The Farmers Home administration supervisors in charge of the local offices, many serving more than one county, receive applications, make loans, assist borrowers with planning and carrying out farm and home plans, receive payments and handle other phases of program administration.

Rural Electrification Administration.—The Rural Electrification administration (REA), a lending agency in the United States department of agriculture, was established in 1935 by presidential executive order and given permanent status in 1936 under the Rural Electrification act. Until 1949 loans were made only for rural electrification; in that year congress granted authority also to finance rural telephone service.

In its first 25 years of operation, REA made, to more than 1,000 local co-operative organizations electrification loans amounting to \$3,500,000,000 of which \$2,900,000,000 had been invested by the borrowers in electrical facilities, including 1,390,000 mi. of line, to serve 4,350,000 farmers and other rural consumers. Loans for rural telephone service were made to commercial and nonprofit type telephone corporations. In the first 10 years of this program, REA had approved loans totaling more than \$391,000,000 to about 350 commercial companies and 200 nonprofit borrowers to serve 863,000 rural families over 105,000 mi. of line.

Commodity Credit Corporation.—The Commodity Credit corporation (CCC), established in 1933, functions primarily in connection with commodity price support programs of the U.S. department of agriculture. The CCC is managed by a board of directors appointed by the president, subject to general supervision and direction of the secretary of agriculture, who is an ex officio director and chairman of the board. It also has a five-member advisory board.

One of the major activities of CCC is the making of nonrecourse price-support loans on agricultural commodities. Legisla-

tion in effect early in the second half of the 20th century provided mandatory price support for corn, wheat, rice, tobacco, cotton, peanuts, wool, mohair, tung nuts, honey and milk and butterfat. It provided permissive price support for other commodities.

Under the nonrecourse loan feature, the farmer has the right to redeem the price-support loan by paying off the principal plus interest, or to deliver the commodity given as security in full settlement of the loan. Commodities acquired by CCC are dispersed of through domestic and export sales, transfers to other governmental agencies and donations for welfare use.

The CCC also administers a storage facilities program under which it makes loans for the construction or expansion of farm storage facilities, and undertakes other operations necessary to provide storage adequate to meet its program needs.

V. AGRICULTURAL INSURANCE

Various risk-meeting devices used by farmers, as well as by early shepherds and herdsmen, are as old as the arts of agriculture. These devices were the forerunners of insurance. The earliest forms of risk meeting involved mutual aid in the preservation of life and property, including the safeguarding of food supplies. Protection of this kind became a discipline of the family, the clan or the local group. If unfortunate events occurred to either property or person, the loss was alleviated by services or other aid that members of the group could contribute.

The developments of trade and a money economy brought new methods of risk bearing. Over a long period in history, the emphasis on risk sharing gradually shifted from "the recourse of neighbors" to greater dependence on money. During the change, there was a period in which reliance was placed on voluntary contributions to alleviate any loss sustained by a member of the group, but the dependability of this device for adequate relief broke down. From this experience, the idea of organized risk sharing against common perils, based on a businesslike method of collecting contributions, gradually evolved into the modern institutions of insurance.

1. Early Plans.—The earliest insurance plans were in effect before the Christian era, with the insurance of hazards peculiar to commerce and sailing. At first, thought was given only to protection against hazards to property. Life insurance, as well as social security programs, were later developments.

By comparison with commerce and industry, insurance programs for agriculture developed more slowly. In general, they followed the mutual principle of sharing unpreventable losses. The main reasons for this lag in the application of insurance to agriculture were that farmers, who were largely self-sufficient, were willing to accept the risks connected with small property valuations that were relatively easy to replace. They also felt that insurance was too expensive. As specialization developed under technological advances, the need for financing greater investments in properties grew and along with it the need for insurance. But into the second half of the 20th century, legislation authorizing farmers' mutual insurance companies remained limited. Also, a lack of knowledge of the effect of the various risks slowed down efforts to include many of them.

The more important hazards to agricultural production are fire and weather risks, such as cold, heat, hail, lightning, windstorm, drought or too much rainfall; diseases among both plants and animals; insect infestation, as well as animal damage to crops; risks of inefficient management; risks of sickness, injury or death to the breadwinner; and risks that arise from price fluctuations.

There is some evidence that the idea of nonprofit mutual insurance for farmers developed rather extensively first in Germany in about the 11th or 16th century. In Iceland, mutual insurance of livestock has been traced back to A.D. 1100. At first, small assessment companies or local co-operative societies were established by farmers themselves. They were designed to operate at low overhead costs. At the start, assessments were levied after each

loss by a member. Later, as the societies began to gain experience, they tended to change over to a system of collecting in advance an amount based on average underwriting experience. Rate refinements by classes of property developed as loss experience was gained. As the business grew, the idea developed for the organization of reinsurance pools based on regional, as well as national, federations.

Because of the difficulty of insuring the varied risks of production, government aid has been enlisted in insuring against some types of risks. This has been particularly true with respect to crop and livestock insurance. In some countries, governments have promoted the organization of farm mutual insurance companies by direct grants and with liberal laws, sometimes exempting them from taxation. In other instances, subsidies have been granted, even subsidies for paying part of the premium tax when the risk was great. In some instances also, governments have entered directly into the agricultural insurance field, thus making it possible for farmers to obtain insurance that otherwise would not be available to them.

2. Property Insurance.— Starting with buildings and cattle, insurance programs gradually added other properties, including general lines of livestock, stored produce, farm implements and machinery, automobiles and motor trucks and growing crops.

3. Fire and Lightning Hazards.— From earliest times, insurance against damage caused by fire was provided widely. The earliest contracts did not cover damage from lightning in all instances. Later, lightning was covered if fire ensued, and the basic fire contract has been expanded to include windstorm and several minor risks, such as damage caused by falling aircraft and by motor vehicles, explosion, riot and smoke. Other coverages added include damage to an upset tractor, theft of property and loss of livestock if killed on the highway by passing traffic. A plan of forest fire insurance was developed early in the Scandinavian countries; it spread to countries with large timber reserves. Fire insurance on growing crops has been made available in countries where dry weather may increase the fire hazard at harvesttime.

4. Windstorm and Hail Hazards to Buildings.— Early windstorm insurance programs for agriculture were developed in Switzerland, Argentina, Denmark and the United States. Because of the catastrophic effects of windstorm and hail damage, these perils are more hazardous to insure than fire.

5. Livestock Insurance.— Crude forms of risk sharing against loss of livestock, particularly work cattle, are known to have antedated the modern forms of insurance. Some form of group risk sharing against loss of work stock was in operation in China many centuries ago. Although insurance against death from accident and disease has been made available in a number of countries, probably most livestock have been covered only against damage caused by fire, lightning and windstorm. All-risk coverage has been offered only on highly valued animals. The need for all-risk protection has been more acute for a farmer with only one or two head of livestock.

6. Multiple-Line Insurance.— For a long time, insurance companies were organized to undertake only one main line of underwriting, such as fire, windstorm or casualty insurance. The tendency, however, has been to combine these three lines into one basic contract.

7. Crop Insurance.— Earliest efforts toward insuring crops undertook to insure only against the single peril, hail, a practice that is still in force in many countries, particularly in Europe and North America. But the tendency has been to expand the list of perils until all-risk crop insurance has been offered in a number of countries, often with government aid. The catastrophic character of crop risks has brought support for subsidies, or government insurance as a monopoly or to compete with private companies.

In the U.S.S.R. crop insurance has been offered as a state monopoly. For the main crops and for certain minimum insurance requirements, the program has been on a compulsory basis. Supplementary insurance has been on a voluntary basis. In general, the hazards covered have been fire, wind, hail, frost and flood. However, industrial crops such as cotton, castor beans and tobacco, also have been covered against drought. Damage from hail causing

deterioration in the quality of tobacco also has been covered.

A program for covering bananas against hurricane damage operates in Jamaica through a quasi-governmental agency. In Puerto Rico, a government agency has been established to insure coffee beans and coffee shade trees against windstorm damage. In Mauritius, a British colony in the Indian ocean, windstorm and drought insurance have been made available to cover damage to sugar cane plantations.

8. All-Risk Crop Insurance.— In a number of countries, all-risk crop insurance systems, either supported partly by governments or actually operated by them, or with private insurers subsidized, have been made available for some crops. In Brazil, a quasi-government corporation, the National Agricultural Insurance company, has a part of its capital stock subscribed by the government and the rest by private insurers and investors. It was established to insure crops and livestock.

Compulsory crop insurance covering damage to paddy and upland rice, grain and silkworms has been developed in Japan. This is a heavily subsidized semigovernment program and has had underwriting deficits. The farmer pays a part of the premium and the government the rest. Insurance covers if the yield of rice is below 70%, but is limited to 50% of normal yields. In 1954, the Mexican government sponsored a two-part subsidy program for all-risk crop insurance covering only investment and labour costs. The program utilizes the services of both stock and mutual companies. Insurance is voluntary, although the two national farm credit banks grant loans only to those who carry insurance.

In the United States, an all-risk form of crop insurance operated by the federal government was begun in certain counties in 1938 with the insurance of wheat. In 1942 cotton was added. Because of adverse experience, the program was abandoned in 1944 but was revived in 1945. Beginning in 1948, the program was placed on an experimental basis to obtain experience on additional crops as well as tree crops.

Under the program as it started, farmers were offered all-risk insurance, which essentially covered production costs. The administrative expense was borne by the government. But beginning in 1955 some provisions were made to charge part of the operating costs against the premium income. By 1956 the accumulative experience showed that outgo exceeded income in the programs with cotton, beans, grain, multiple crops and corn, in that order. Over the total experience, premiums were adequate to cover losses to flax and tobacco.

9. Flood Insurance.— As early as 1846 flood insurance was undertaken in Austria. In 1865 it was undertaken in France but did not succeed. In the United States flood loss was included in the all-risk insurance program. In 1956 congress adopted a federal flood indemnity program which was abolished in 1957 because of lack of appropriations.

10. Liability Insurance.— With the development of financial responsibility laws, farmers were faced with increasing need for insurance to cover their liability for injury to others through use of their machinery and motor vehicles. Farmers also needed liability insurance to protect them against lawsuits if through their negligence a visitor should be injured on the farm premises, or if someone should be injured as a result of any activity in connection with their operations wherever the operations may occur.

11. Workmen's Compensation Insurance.— If power machinery is used or if a specified minimum number of employees are hired regularly, farmers are specifically required to comply with workmen's compensation laws, which provide relief for injured employees in at least 30 countries. Workmen's compensation laws also are of general application to all employers, including farmers, in 12 additional countries. In most states of the United States, farmers generally may elect to obtain this protection even if they are not required to do so.

12. Life Insurance.— For the most part, farmers obtain life insurance from private stock or general writing mutual companies. More and more, life insurance is used to strengthen the family financial position.

13. Social Security Insurance.— Laws in at least 16 countries specifically include small farmers or agricultural employees

under old-age, disability and survivors insurance in which benefits are provided without an income test. In addition, laws of this kind are in effect and applicable to all citizens without regard to occupation in 10 countries.

VI. FARM TAXATION

Agriculture, perhaps more than any other industry, has given shape to systems of taxation. At an early date, the organization of society under clans or tribes gave rise to crude forms of taxation as a recognized right of the leader or chief. In this primitive stage, cultivation of the soil remained the principal form of production, and land and livestock, the principal form of wealth, so that virtually all tax revenue came of necessity from agriculture. A certain proportion of the produce was commonly pre-empted for the chief or, later, the sovereign, and payment was often made in kind. This simple form of taxation endured in some parts of the world into the second half of the 20th century. Economic change has contributed to its rapid disappearance.

At a later stage in economic development, the rise of nonagricultural employments created new forms of wealth and new sources of income for the payment of taxes. In time, the revenue system of earlier periods was found to be ill suited to taxation of the developing manufacturing and commercial industries, and other taxes were devised for this purpose. These newer methods, which relied heavily on money payments, in turn were imperfectly adapted to obtaining revenue from agriculture. Thus it frequently came about that two separate tax systems existed side by side, one applicable to farming, the other to nonagricultural pursuits.

As subsistence farming has gradually given way to commercial agriculture, the distinctions between farming and other trades or businesses have diminished and the necessity for special tax treatment has become less urgent. This synthesis requires that agriculture be fairly well integrated into the money economy. Important also is the achievement of effective techniques of tax administration, especially in connection with taxation of agricultural income. In most of the English-speaking nations, agriculture has come to be taxed under the same laws and rate schedules that apply to other industries.

For additional information on the history and development of taxes in various countries see **TAXATION, LOCAL**; **LAND TAXES**; **TAXATION**.

1. Property Taxation.—Property taxation in one form or another is almost universal. Some countries tax only land. In others, structures are also included and in still others, the tax base includes many types of personal property. The tax may apply to the estimated value of the land, the annual rental or the yield or income (see *Farm Appraisal*, above). In the United States, taxes on the assessed value of real and personal property are the chief source of revenue for local governments. State governments collect but little revenue from property taxation, and the federal government none at all. In Great Britain, taxes on the rental value of real estate are important to local governments, but farm property has been exempt since 1929.

The farm business, with its heavy investment in land and buildings, is peculiarly vulnerable to property taxation. In the second half of the 20th century, taxes levied on U.S. farm real estate amounted to about 3% of gross farm income. These taxes averaged \$0.91 per acre of farm land, and mere equal to about nineteenth of 1% of the estimated market value of farm real estate. Levies on farm personal property, such as livestock, farm machinery, motor trucks and automobiles, involved substantial but smaller amounts.

The combined burden of real and personal property taxes on

U.S. agriculture has occasionally given rise to serious economic problems. Property taxes are a relatively fixed charge on the farmer. The amount of the tax is affected very little by the value of current farm output, so that adjustment of the property tax load to changing economic circumstances is slow. During the depression of the 1930s, the burden of property taxes in relation to shrunken incomes and property values increased to a point at which many farmers were unable to carry it. Rural tax delinquency reached serious proportions in a number of farm states and remained troublesome for several years. Improved farm incomes and property values, as well as more favourable financial conditions for most farmers, caused the problem to diminish after a few years.

In its place came a new cause for concern. After World War II, property taxes turned sharply upward. By accentuating inequalities in valuations placed on property for tax purposes, higher tax rates focused attention on the need for improved methods of assessment. Various studies showed that farm land and buildings as a class were generally carried on the tax rolls at a higher fraction of true market value than were most other categories of property. Moreover, serious inequalities were found in the assessment of individual properties. Increasing awareness of these inequalities, coupled with a steady uptrend in revenue requirements of state and local governments, stimulated considerable interest in thoroughgoing reassessment programs. By the 1960s, several states had carried through complete revaluations of taxable property and others had plans to do so.

Efforts at property tax reform in the years following the close of World War II were not confined to the United States. Certain countries of Asia, Africa, the middle east and Latin America undertook basic revisions in their systems of land taxation as part of broad efforts to improve the productivity of agriculture. In many parts of the world, land tenure and taxation systems handed down from antiquity tended to keep much of the arable land out of cultivation and in the hands of large-scale landowners. Land tax reforms usually attempted to substitute an assessment based on potential yield for one based on actual yield or output, in order to encourage owners to place additional land under cultivation. For fuller discussion of the historic development of land taxes and tenure and their relation to modern programs and problems, especially in India, China and other countries of the far east, Italy and other countries of the Mediterranean, Mexico and Hispanic America, and of the trend toward compulsory collectivization in the countries of eastern Europe, see **LAND REFORMS**.

2. Income Taxation.—Farm incomes have been taxable under the British income tax since its original enactment in 1799. For 150 years, however, they were subject to a special lower rate schedule and were eligible for optional treatment under a provision that allowed farm taxes to be based on a certain proportion of the annual rental value of the land rather than on actual income. The aim of these special provisions was twofold—to facilitate compliance for the many farmers who maintained no adequate records, and to soften the impact of the tax on agriculture. In 1948, both the special rate schedule and the presumptive basis for taxing farming profits were abandoned. Since then, agriculture has been taxed like any other trade or business.

Farmers in the United States were never singled out for special treatment under the federal income tax, as to either rates or method of reporting. Until the outbreak of World War II, however, a combination of low farm income and high personal exemptions kept all except a few farmers off the income tax rolls. After 1940, lower personal exemptions and improved farm incomes brought many more farmers under the tax. In the immediate post-war period, when agriculture was especially prosperous, income tax payments of farmers rose to an estimated \$1,365,000,000, or more than double the tax bill on farm real estate at that time. In the decade following the close of the war, total income tax payments of farmers varied from 4% to 7% of their net income from all sources.

By the second half of the 20th century, however, federal income taxes were taking such a large share of income that few farmers could afford any longer to ignore the tax consequences of various

management decisions. Strong interest developed in ways of minimizing taxes on farm income, for example, by timing of sales of crops or livestock to avoid undue concentration of income in any one tax year, and through devices whereby income could be realized in the form of capital gains, which are subject to preferential rates, rather than in the form of ordinary income. Several new provisions enacted in the early 1950s also had the effect of reducing farmers' taxes. Thus, income realized on sales of draft, breeding or dairy livestock held six months or more was made eligible for low-rate taxation as a capital gain. And outlays for soil and water conservation were declared to be deductible expenses, even though they ordinarily added value to the land.

In the 1960s, apart from the federal government, about 30 of the states were collecting some form of personal income tax. In general, the provisions of these laws, like the federal income tax laws, applied to income regardless of industrial origin. The rates, however, were much lower than those of the federal levy, so that farmers' payments in state income taxes totaled only a small fraction of that paid to the federal government.

3. Other Forms of Agricultural Taxation.— Taxes paid primarily by the consumer in the form of higher prices, including sales taxes of various kinds, are important components of the revenue systems of many countries. The Canadian excise tax on manufactured goods and the British system of consumption taxes doubtless account for a significant share of the tax load of agriculture in those countries, although the precise amount would be difficult to determine. Still other countries, especially those with low per capita incomes, depend greatly on consumption taxes that bear heavily on the poor, including those in rural areas. Communist countries in which the state has resold agricultural products commonly have added a so-called turnover tax which in the U.S.S.R. in the mid-1950s accounted for about one-half of the budget revenue (see *RUSSIA: Finance*). (See also *EXCISE TAX*.)

In the United States, two-thirds of the states collected taxes on retail sales in the 1960s. The rates were typically 2% or 3%. These taxes were not levied on farming as such, but they applied to a wide range of consumption items purchased by farmers, as well as to many types of material and equipment bought for use in the farm business. It was estimated that U.S. farmers paid about \$300,000,000 annually in state sales taxes.

Federal and state taxes on motor fuel, together with charges for automotive licences and permits, cost farmers about \$400,000,000 (net of refunds) a year. The state levies were viewed as highway use taxes, and taxes paid on fuel used off the highways were either wholly or partially refunded. Starting in 1956, the federal tax on motor fuel was also restricted to fuel consumed on the highways. In consequence, farmers were almost completely freed of taxes on fuel used in tractors or in other farm machinery. They continued, however, to pay taxes on motor fuel used on the public roads.

Finally, some countries tax agriculture indirectly through such devices as multiple exchange rates, export taxes, fiscal monopolies or government marketing boards. These methods are most effective and commonest where agriculture is dominated by one crop. Multiple exchange rates, as found in the exchange control policies of several Latin-American countries, may involve a relatively unfavourable exchange ratio for export crops. The usual result—a lower net return to the primary producer—is the same under an export tax.

Fiscal monopolies and government marketing boards are methods by which the government can exact a monopoly price for products obtained from the farmer at a lower, competitive price. The difference between buying and selling prices is a form of tax on agricultural production.

See Harvard University, International Program in Taxation, papers and proceedings of the conference on agricultural taxation and economic development, 1954 (1954); "Farm Credit, Farm Insurance, Farm Taxation," *Agric. Fin. Rev.*, vol. 21, (July 1959).

VII. MARKETING AGRICULTURAL PRODUCTS

Marketing centres upon the exchange of goods and services, whether by barter or by purchase and sale for money, but agricultural marketing is usually defined to include much more than the

act of exchange. It includes a great variety of acts to facilitate exchange—for example, processing, storing, transporting, grading, inspecting, pricing, advertising, wholesaling and retailing. In short, agricultural marketing refers to everything that is done to a commodity from the time it leaves the farm until it reaches the final consumer. Thus, hog marketing includes the processing of the hog and the distribution and selling of fresh and cured pork, sausage and numerous by-products.

1. Primitive Forms of Marketing.— In the simplest societies there is little marketing of any kind. Each family or local tribe is practically self-supporting, gathering or producing most of the foodstuffs it consumes. Even so, some form of trade is found in the most primitive societies and early in history men began to exchange foods (see *TRADE, PRIMITIVE*). Two reasons impelled them to do so: first, to obtain more varied diets; second, to receive the advantages of specialization.

To obtain varied diets, fruit or grain was exchanged with neighbouring hunters or nomadic herders for meat; expeditions were sent from interior points to the seacoast for salt and fish; islanders traded with mainlanders. As towns and cities grew, an increasing number of professional men, traders and soldiers produced no food at all. They could buy it to better advantage from farmers, and even farmers began to specialize; each producing only a few items which were suited to his land and his skills. Many of the most successful farmers have no garden, no poultry, no hogs. They, like the factory worker and the doctor, buy most of their own food. Marketing has made such specialization possible.

In the earliest forms of marketing, the farmer doubtless sold directly to the final consumer. There was no middleman between farmer and consumer. To make direct marketing more convenient to buyer and to seller alike, specific market places and definite times of business were designated. The farmers' market is an ancient institution throughout the world. The city authorities usually set aside a suitable space, provided simple facilities, established and enforced rules of trading and collected rents from the farmers who used the market (see *MARKET*).

Usually only farmers were allowed to sell in a farmers' market. If dealers were allowed, they might be required to use a special part of the market and often they were charged a higher rate than farmers. Moreover, some markets gave preferential treatment to local farmers, and even excluded distant producers.

Farmers' markets still exist in most countries. Also, other forms of direct marketing are fairly common. Farmers may peddle their eggs or milk from door to door; they may sell apples by parcel post; or they may sell fruit or vegetables at a roadside stand.

2. The Rise of the Middleman.— Although many kinds of direct marketing continue, the great bulk of agricultural products is marketed through a chain of processors, transporters, wholesalers, retailers,—in short, middlemen. This is especially true in the most highly industrialized countries. Direct marketing of foods is an exception to the general rule in western Europe and in the United States, for example, and few farmers in these countries sell their products to the final consumer.

Traditionally, both the farmer and the consumer have been suspicious of the middleman. They have looked upon him as unproductive, parasitical and often dishonest. Several centuries ago, laws were passed in England and in other countries to forbid forestalling,—that is, buying from a farmer before he reached the market in order to resell to the public. Similar laws tried to suppress engrossing,—that is, selling goods at a higher price than was paid to the farmer.

Yet, middlemen, like moneylenders, continued to do business because they performed useful services. Some philosophers, Plato and Thomas Aquinas, for example, and such early economists as Adam Smith, understood that the middleman was necessary in order to obtain the benefits of specialization. But only from about 1900 have students generally recognized that the services provided by middlemen in agricultural marketing are often truly productive. By transporting farm products, they produce space utility; by storing them, they produce time utility; by processing them, they produce form utility; and by buying and selling, they produce possession utility.

3. Transportation and Geography. — Marketing would be impossible without transportation. In early history, the lack of dependable and efficient transportation greatly limited the areas in which goods could be distributed. Even in the second half of the 20th century, producers and consumers in many parts of the world were unable to trade freely because of poor transportation.

From the time of the Phoenicians, the development of ocean and river transportation opened up large areas of the world to agricultural marketing. Later, highways, canals and railroads brought better transportation into the interior parts of most countries. The airplane and the development of air freight transport brought some transportation even to tropic jungles and to arctic outposts. (See TRANSPORTATION.)

Johann Heinrich von Thiinen (1783-1850) was the first major economist to analyze how transportation costs affect the geography of agricultural production. He pointed out that some foods, such as butter, can be shipped for long distances because their value is high in relation to their weight. At the other extreme are bulky foods, such as fluid milk, the value of which is low in relation to their weight. If such foods were shipped long distances, the freight bill would be more than they were worth. Partly for this reason (and also because of many local regulations) market areas for fluid milk (often called milksheds) usually are limited in size. Market areas for cream, condensed milk and butter are much larger, because of their higher value in relation to weight.

In a perfectly competitive situation, each producer would ship to whatever market offered the highest net price (*i.e.*, market price less freight). This would lead to definite, predictable, geographic patterns of prices, shipments and consumption. On the one hand, the wholesale price of U.S. number 1 Maine potatoes in any consuming market would be the f.o.b. Maine price plus freight, so market-price differentials would equal freight differentials throughout the area in which Maine potatoes were sold. On the other hand, if Maine and Idaho both ship potatoes to Chicago, Ill., the relation between the f.o.b. prices in Maine and in Idaho depends upon two factors: (1) differences in the quality of the potatoes, leading to premiums or discounts in the consuming market; and, (2) differences in freight rates.

Market news has been developed both by private industry and by governments in order to help shippers find their most profitable markets, and is a powerful aid to competition.

Although economists sometimes have assumed that the ideal market is purely competitive, it is clear that in many cases the purely competitive market is not the most profitable to the producer or the shipper. He can often gain from "dumping" part of his supplies in one area in order to maintain a higher price in other areas. Export dumping is a case in point. Here domestic producers export their surpluses at a low net price in order to maintain a higher price in the domestic market.

4. Storage and Timing. — In the case of extreme perishables, such as fresh fish and fresh strawberries, man in the past has had little choice as to the timing of marketing. Until he had some way to keep these foods without spoiling, he had to sell them when they were ready, or not at all. But many agricultural products could be readily stored for considerable periods of time, without serious deterioration of quality. Aging actually improves the quality of some meats, cheeses, tobacco, wine and other farm commodities.

Great advances have been made in methods of preserving and storing foods. Improvements in canning, dehydration and freezing have brought year-round markets for such perishables as peas and orange juice as well as fish and strawberries. Experiments with radiation offered promises of extending still further the markets for many perishable foods. Farmers and food processors can choose when, within a considerable period of time, they will sell their goods. If they expect higher prices next week, next month or next year, (or if it will improve their tax situation) they may decide to hold their goods off the market for a time. On the other hand, before the seller even owns any wheat or cotton, he may sell a futures contract, *i.e.*, a contract to sell a specified amount and grade at a specified time in the future.

In a purely competitive market, price differentials might be ex-

pected, over a period of time, to equal the costs of storage. For example, the November price of storage eggs might be expected to equal the April price, plus the cost of storing eggs from April to November. Actually, the price differentials through time often differ widely from this theoretical model. The departures are attributed in part to imperfect knowledge of future demand and supply conditions. And in part they are the result of institutional factors that cause such phenomena as "inverted markets," in which the futures price may be typically less than the current price (commonly called the spot price).

Many governments store agricultural products, or assist farmers to store them in order to help to stabilize prices. In the United States, for example, the Commodity Credit Corporation (CCC) offers loans for cotton, wheat and several other farm products. The farmer can repay his loans and take back his commodity within a certain period of time, but he has the option of leaving it with the CCC to sell (see Agricultural Credit Systems, above). In periods of surplus production and low prices, the CCC obtains large stocks of farm products. In periods of high demand, such as occurred during World War II and again in 1950-51, the stocks are sold. Such a program to stabilize market supplies and prices has been called an ever-normal granary. Most storage programs operated by modern governments are intended not only to stabilize prices, but to raise them. To succeed, this usually requires measures to reduce production, to increase consumption or to divert the surpluses into noncompetitive markets where they may be sold at lower prices.

5. Different Forms of the Commodity. — Most agricultural commodities can be sold in several different forms. Milk may be sold as fresh whole milk, skim milk, cream, butter, cheese and other products. Tomatoes may be sold fresh, canned or made into juice, soup or catchup.

The economic principles here are the same as those applying to the geographical and time dimensions discussed above. Thus, assuming perfect competition each unit of the commodity would be sold in whatever form would return to the producer the largest net price.

The differentials between prices of the different forms of a commodity would tend to be equal to the differentials in cost. For example, the price of canned tomatoes would tend to equal the price of the tomatoes plus the costs of canning.

In actual practice, the differentials between market prices of different forms of a commodity may be substantially different from those that could be explained by differences in cost alone. In some cases, this difference is accidental, because of imperfect information. In other cases, it reflects business decisions. For example, surplus walnuts may be shelled, canned and sold at prices lower than those charged for walnuts in the shell. Again, surplus lemons may be converted into citric acid, even though the net price is far below that for fresh lemons.

E. H. Chamberlin made "product differentiation" a main factor in the theory of imperfect competition. There is very little product differentiation in the case of unprocessed agricultural products, although some of it is done through packaging and through brand names. But there is a growing proliferation of brands and packages of most processed foods.

Also, in times of agricultural surplus, there is great interest in the possible development of industrial uses of farm products, even though such uses might have to be subsidized. A case in point was the development from surplus corn of dialdehyde starch, a potentially cheap agent for tanning leather.

6. The Perfect Market Reconsidered. — Some economists have thought that perfect and pure competition would be the ideal, or the perfect market. In actual markets for farm products, the student can observe many departures from this norm. These departures are indicated by price differences in space, in time, by form of the commodity, or by groups of consumers. Such departures are profitable to farmers in some cases. Also, they may benefit certain groups of consumers. The pre-World War II food stamp plan in the United States was profitable to farmers and also helped low-income families. In some situations, at least, price differentiation — involving purposeful departures from the competi-

tive norm—may benefit the general public.

7. Government Agricultural Marketing Services.—All governments assist marketing to some degree. Some governments go to the extremes of setting prices, rationing food or even establishing a governmental monopoly to distribute farm products. Except in time of war, the democracies generally avoid programs of these types. Instead, they generally rely mainly upon free, private enterprise and competition. This is not, however, a program of laissez-faire, it involves many governmental services and regulations. Among the oldest government services that assist marketing are police protection, the protection of public health and the enforcement of standard weights and measures. All governments have programs in these fields and most governments provide some agricultural statistics and some current market news. In the United States, the federal and state governments co-operate to supply detailed statistics on planted acreages, the condition of growing crops, production, storage stocks and similar factors of importance to marketers. They also supply day-to-day information on shipments, market receipts and market prices. In addition, they supply current outlook and situation reports, discussing current and foreseeable trends for the principal farm products.

Many governments have established official grades for farm products, and have set up inspection services to determine the actual grade of any specific lot of a commodity. Official grades have greatly facilitated marketing over long distances. For example, a carload of California lettuce may be sold in New York by wire on the basis of an inspection certificate. Or a shipload of North Dakota wheat may be sold in Liverpool. In general, grades are not based upon nutritive values, but upon market preferences. Foods that qualify for any of the official grades of the United States are good nutritionally.

In addition to such services as market news, grades and inspection, healthy competitive marketing requires some supervision of trade practices, especially some deterrents to antisocial forms of monopoly. The growth of large corporations in meat packing, cigarette manufacturing, milk distribution and food retailing has been in part a result of economies of scale. But they have also concentrated great power in the hands of a few large concerns. The aim of governmental programs in this field is to give the public the benefits of greater efficiency because of bigness, and also to protect the interests of both farmer and consumer.

While most democratic countries attempt to suppress monopoly, many of them also have programs to enable groups of farmers to work together in setting prices, or in regulating the flow of their products to market. Examples are the marketing schemes of several countries in the British empire, and the marketing agreements and orders in the United States. Such programs are generally effective only when adopted by growers in a referendum and when approved by some responsible agency of the government. (See also **MARKETING.**)

VIII. AGRICULTURAL CO-OPERATION

Farmers in most countries have developed business enterprises known as co-operative associations. These organizations differ from other forms of business in that the patrons or customers (those who use the services of the associations) own and operate them. For discussion of the history of co-operatives and their development and operation in various countries see **CO-OPERATIVES.**

1. Organization.—The members of co-operatives provide the capital required, elect directors to determine policies and programs to be followed, and delegate to them authority to employ an operating manager. Farmers use co-operative associations to market their products, to procure farm supplies and to obtain such services as insurance, irrigation, credit and electric power.

Co-operatives are usually incorporated. The incorporators may organize an association with capital stock, or a nonstock membership organization. In a capital stock co-operative, each member is required to purchase one or more shares of common stock. This stock carries voting rights and may be held only by members. In a nonstock co-operative, a membership fee is assessed. Additional financing may be derived from the sale of nonvoting, preferred stock, or from the purchase of certificates of interest by members of the association. The revolving capital plan is a method frequently adopted to maintain ownership of an association in the hands of active members. Under this plan members contribute capital in proportion to their individual use of the services of the association. The oldest outstanding contributions are repaid to members usually at the discretion of the board of directors.

Whatever form incorporation may take, the co-operative nature of the enterprise is safeguarded by the following provisions of its articles of incorporation or bylaws: (1) savings above operating costs are paid, or allocated, to each member in direct proportion to his patronage; (2) interest or dividends on invested capital, if paid, are limited to nominal rates of return; (3) voting by members usually is on a one-man, one-vote basis; occasionally it is based on patronage with a low limit on the number of votes one

TABLE IV.—Agricultural Employment in Selected Countries

Country	Year	Total population (in 000s)	Total economically active population (in 000s)	% of (1)	Active population in agriculture (in 000s)	% of (2)

member may cast. In a capital stock association, the number of voting shares a member may own is limited, usually one qualifying share.

2. Development.—Farmer co-operatives developed over a wide front in Europe and North America in the last half of the 19th century. Their activities varied widely in different areas, but the common objectives were to provide at cost needed services that were not performed satisfactorily by existing agencies. Credit, insurance, marketing and the purchase of farm supplies were among the earliest services provided.

The first associations were small community organizations. As the needs of farmers became more complex, with the general economic expansion in many countries, co-operative progress and growth continued. Many local associations formed federations to extend their services and increase their bargaining power. During the first half of the 20th century, co-operatives developed broad marketing and purchasing programs and established substantial facilities to package and process farm products and manufacture farm supplies. They kept pace generally with the great technical and industrial expansion following World War II.

Throughout most of the world, agricultural co-operatives fall into three broad classes: (1) those selling members' products; (2) those furnishing farm supplies, such as fertilizer, feed and petroleum products; and (3) those providing essential business services. Many co-operatives fall in all classes.

3. Services.—A marketing co-operative may handle a farmer's product at one or more stages as it moves from the farm to the consumer. Some act only as bargaining associations to represent farmers in transactions with dealers and processors. Some associations process commodities, producing, for example, cottonseed oil, butter, canned fruits or dressed poultry. Others advertise and merchandise the members' products under the co-operative's own trade-mark, selling direct or through brokers to wholesalers and large retailers.

In the second half of the 20th century, supply associations increased rapidly in the more mechanized agricultural areas where farming required increased investments in feed, petroleum products, fertilizer and other supplies. More and more local supply associations affiliated with the larger regional co-operatives that owned and operated manufacturing facilities. The local association usually was a member of the regional association and as such was entitled to patronage refunds which then were allocated or paid to its farmer members. Some regional co-operatives, either individually or in co-operation with other regionals, acquired oil wells and refineries, and were engaged in mining chemicals required in the manufacture of fertilizer and insecticides.

Co-operative business services offered farmers in many countries included insurance, rural electric service, transportation, irrigation, cotton ginning and rural health and hospital care. Some predominantly rural countries established handicraft and similar co-operatives in agricultural communities.

Although the principles of co-operation remain reasonably constant throughout the world, the operations and the progress of

farmer associations were affected by the economic development of agriculture in each country. In the more highly industrialized nations, such as Canada, Denmark, Sweden and the United States, local associations originally offered one type of service. They were formed to market one farm product, to buy a limited number of supplies or to perform one general service. Over the years, however, many of these single-purpose associations broadened the scope of their operations. In the second half of the 20th century, for example, 63% of the marketing co-operatives in the United States handled some supplies, while 27% of the farm supply associations also marketed certain farm products. Credit, insurance and electric power co-operatives, however, rarely engage in multiple activities. In other countries, less highly industrialized, a single community co-operative may provide insurance, credit and marketing services for farm products and purchase supplies, as well as perform other services. In parts of India and in Burma, for example, the policy has been to organize one multipurpose co-operative in each village.

The attitude of most governments toward farmer co-operatives ranges from neutrality to strong support. Generally, the nature of the support varies with the development and progress of the agriculture of the country. The governments of some highly agricultural countries often exercise extensive supervision over farmer associations, including audits of financial and operating records and reviews of performance programs. In other countries where agriculture is further developed, governments rarely exercise controls which are not applicable to all business. Technical help in organization and operation is extended to co-operatives by many governments whose policy is to render assistance to farmers in connection with their economic problems.

The need for farmers to be represented by organizations operating in their interests has sparked the development of agricultural co-operatives in all countries. The average farmer is a comparatively small producer. Membership in a co-operative increases his bargaining power when he sells his crops, when he purchases farm supplies or when he requires credit, insurance or other services that he can obtain by joint efforts through co-operatives.

Furthermore, supply co-operatives have pioneered in improving the quality of feed, fertilizer, seeds and other items farmers buy. Marketing co-operatives have been leaders in developing methods of operation that recognize superior product quality and tend to minimize speculative risks. One method employed to reduce speculative risks is the co-operative practice known as pooling. Returns from sales of members' products of like quality are pooled by many associations. This practice involves recording, according to quality and quantity, all products delivered by each member during the pooling period and making payment of sales returns to members based on the average price received per unit for all products of the same quality. In individual associations, the pooling period may extend from a few days to an entire marketing season.

Co-operatives, in addition, promote operating economy. If their capital permits, they invest in more efficient plants and labour-saving machinery and equipment whenever the directors are convinced that the investment will reduce handling margins or provide needed services. Such action by a co-operative is an application of the practice of improving service for members. As other efficient firms usually follow the lead of co-operatives in reducing handling margins, all farmers in the area benefit, whether they are members or not.

IX. AGRICULTURAL LABOUR

Agricultural labour or work on farms in many respects is unique among the major occupations. In no other major industry does so large a proportion of the work force consist of self-employed operators, or so small a proportion of wage or salary workers. Because farms produce living things, the activities on them are affected by natural factors such as climate, weather, life cycles of animals and other physical and biological factors. This results in a larger month-to-month variation in the need for workers than in most other industries. During periods of crop harvesting, for example, many more workers usually are required than during other seasons. Mechanized farming, however, tends to reduce the seasonal variations. Also, chiefly because of the natural factors, agricultural work consists of many separate tasks. And as most farm workers are not specialists, the work they do varies more from time to time than that of most nonfarm workers.

There are many kinds of agricultural workers. There is first the operator of the farm—whether owner or tenant, such as the European peasant or the United States family-type farmer—who himself works in the fields and cares for the farm animals. Next, there are the sharecroppers and similar types of labourer-tenants, who in many parts of the world work the land and share the proceeds with the owner. In some countries they are classified as farm operators, but in many instances they have more of the characteristics of workers than of operators. While they usually furnish the bulk of the labour, they own few tools and other farm resources and seldom make major management decisions. (See FARM TENANCY.)

Another group consists of members of the operators' family—chiefly wives and children—who work on the farm as unpaid workers. During slack seasons or school periods, they may help with only the usual farm chores or light routine work, but in the busy periods, they may work on a more nearly full-time basis. In some countries, school periods, at least for the older children, are adjusted to avoid conflict with peak periods of farm work. In many countries, however, there are regulations that govern the use of child labour and minimum school attendance.

Finally, there are the hired workers who may work on farms the year-round or only seasonally. The year-round or permanent workers derive their entire income from farm work. In many instances, they are farm boys who intend to make farming their life-long occupation and are working as farm labourers to accumulate sufficient capital to begin farming for themselves. In many parts of the world—in Turkey, for instance, and several Asian countries—seasonal workers are generally operators of small holdings who supplement their income by working on other farms as wage labourers. Other hired workers have regular urban or rural employment, but work on farms during the busy seasons. Still others have no other employment, but come to the farms for harvest work. An important group of seasonal workers are those who migrate from area to area with the crop, as in the United States, and who rely on farm work for the major source of their income.

For many reasons, valid statistics that are comparable from country to country are difficult to obtain. Table IV presents data for selected countries, for which statistics are available over a period of years. While total population has increased, as has the number of the economically active population in most countries, there has been a marked decline in the economically active population engaged in agriculture. The decline is less marked in the so-called underdeveloped countries. In many of the industrially advanced countries less than 20% of the active population is engaged in agriculture. The proportion is much higher in most of the less-developed countries.

Hired workers comprise a relatively small part of the farm work force in typical European peasant countries and in countries such

as the United States and Canada, where family-type farming is the rule. Hired workers are even less important in Japan, with its large number of small farms. In countries such as Argentina and Chile, where large-scale farming is important and where mechanization has not advanced, the proportion of hired workers is high. It is highest of all in Great Britain chiefly because of high labour needs for intensive crops such as vegetables. The number of hired workers has declined in some countries more rapidly, and in others less rapidly than the total farm labour force.

Historically, the level of farm wage rates has fluctuated in response to prevailing conditions of farm labour supply and demand including the lack or abundance of nonfarm employment opportunities, and to the general economic conditions as these affect the prices and income received by farmers. The data in Table V show, essentially, that, during the period 1930-50, wages in agriculture were substantially lower than wages in industry, but that in most countries wages in agriculture rose more rapidly. In many countries, farm workers usually receive farm produce, the use of land, a house, board and lodging or some of these allowances in addition to the cash wage. Especially in the less-developed countries, these perquisites make up a larger share of the total earnings. They are difficult to express in monetary terms.

The economic and social well being of farm labourers varies greatly among and within countries. An increasing number of countries have taken action to improve employment conditions in agriculture, giving attention to such problems as wages, hours, regularity of employment, housing and medical care. In some, such as several Latin-American countries, provisions of the general labour code apply to agricultural workers. In other countries, the regulation is entrusted to joint boards on which workers and employers are represented. Although trade unionism has lagged in agriculture, it is well established in a number of European countries, and regulation is effected by collective bargaining between workers' and employers' organizations. Various provisions of social security programs have applied to farm workers in an increasing number of countries. International labour conferences have adopted standards for improvement of living and working conditions in agriculture. The aim of these standards is to place farm labourers on an equal footing with industrial workers.

X. LAW IN AGRICULTURE

Much of the law which affects the farmer is not agricultural in the sense that it is designed especially for agriculture. Laws on property, contracts, taxation, agency and the administration of estates, for example, affect the farmer vitally, but for the most part are of general application. Only occasionally are laws molded especially to fit agriculture. For general discussion of laws as they affect the farmer in various countries see LANDLORD AND TENANT and LAND TENURE: ECONOMIC AND AGRARIAN ASPECTS. See also LAW for references to articles in that field. See also articles on separate countries.

A vast body of law, however, mainly administrative and regulatory in character, has been promulgated for the benefit of agriculture. Hence, the farmer has become familiar with regulations and administrators, but he has not developed an easy familiarity with the principles of statutory and common law which are important to him. Nor have lawyers developed an easy familiarity with a myriad of principles regarding land tenure, the farm landlord-tenant relationship or the agricultural credit structure—to mention only a few areas of common interest.

Broadly viewed, farm law includes the legislation from which

economic and social programs for agriculture have been constructed. It might even comprehend all policy-determining legislation having a direct bearing on agriculture. But for certain purposes there is something to be gained by excluding such legislation and considering farm law as those statutory and common-law principles which affect the personal and property rights of the farmer. In this light, farm law may be divided into several major areas—the legal incidents of property ownership and transfer; the use of farm property as security for credit; the landlord-tenant relationship; the employment of labour on the farm; drainage, irrigation and water rights; farm taxes; farm animals; fences; trespass; custom operators and other agents; liability and regulatory laws.

1. Farm Land Ownership.—Members of landowning farm families are vitally affected by law on property. Often the ability of a family to remain intact and continue a wise use and management of land after the termination of a present ownership depends upon the kind and quality of interest possessed by the member or members of the family holding the title. Present land use, future farm business plans and the ability to sell or mortgage depend to a large extent upon the kind of interest possessed by the present owner and upon the disposition which will be made of the property when that interest ends.

Members of landowning farm families are entitled to know the answers to such questions as these: Who holds the title to the farm? Is the owner a fee simple owner, life tenant, remainderman, corporation or individual? Is the title vested in more than one person? If so, are they joint tenants, tenants in common, or do they each own separate parts of the farm? What would happen to the farm if the owner were to die suddenly? Who would own it? Who would have the right to operate it? Would it have to be sold to pay debts? If it passed by descent, could those inheriting it co-operate in giving it proper management? Would they be apt to make a fair settlement within a reasonable period?

2. Farm Property as Security.—The use of land and personal property as security for an increased amount of rural credit focuses attention on laws relative to mortgages, trust deeds, chattel mortgages, land title transfer, interest rates, foreclosure and priority of creditors. To some extent laws on real estate and chattel mortgages have been modified to fit the farm enterprise. Likewise, bankruptcy laws have sometimes been altered to give preferred treatment to farm debtors.

3. Landlord-Tenant Relationship.—Most farm tenants and a great many farm landlords know little about the legal aspects of the landlord-tenant relationship. Yet where misunderstandings arise, as they often do, the parties must finally depend upon the various principles of tenancy recognized in law for a settlement of their differences. A better knowledge of the nature and effectiveness, under the law, of agreements made by landlord and tenant, and of the rights and duties of the two parties, would prevent many misunderstandings.

But much more than the avoiding of misunderstandings between landlord and tenant is involved in the matter of a legal basis for tenancy. Proper use of land and satisfactory economic, social and cultural levels of farm life are all bound up in the question of adequate functioning of the landlord-tenant relationship. If improvement is to be made in tenant farming, general knowledge of legal provisions is necessary on the part of both tenants and landlords. Dependence on oral leases and local custom tends to discourage change and to preserve the existing practices and systems of farming, whether good or bad.

4. Employment of Labour on the Farm.—The thoroughness with which farm employers and farm labourers discuss the terms of employment varies considerably. Many times such agreements are oral, and important items, such as the term of employment, Sunday work and perquisites of the labourer, are not discussed. Farm owners and operators, moreover, are faced with many problems about their liability for injuries to farm labourers or other labourers they employ, particularly as to liability under the provisions of workmen's compensation or employers' liability laws.

5. Drainage, Irrigation and Water Rights.—Common-law rules, statutory controls and laws enabling the organization of

drainage, irrigation, water conservancy and other types of districts or public corporations all attest to the importance of law in the area of water rights (*q.v.*).

6. Farm Taxes.—Tax laws generally give some special treatment to farmers. These are changed and modified frequently, yet up-to-date information on the various kinds of taxes that affect the farm business—property, income, gift, estate and other—is essential to the farm operator and owner. (See *Farm Taxation*, above.)

7. Farm Animals.—Many laws apply to the ownership of farm animals—relating to disease, animal trespass, cruelty to animals, liens for sire owners, injury by railroads, indemnity for loss from dogs, to mention only a few.

8. Fences.—Division fence laws requiring adjoining farm landowners to share in the construction and maintenance of such fences, laws defining a "legal" fence and laps requiring the trimming of hedge fences are common. However, the specific requirements of such laws vary a great deal.

9. Trespass.—One of the oldest and most venerated principles of property law is that which holds that an owner of land has the exclusive right of possession. This right is particularly important to farmers, whose crops, fences and livestock may be damaged by the entry of unauthorized persons. In many common-law jurisdictions the right as it pertains to farmers has been strengthened by statute.

10. Custom Operators and Other Agents.—Laws covering the independent contractor and agency generally are important because of the large amount of baling, threshing, grinding, construction, painting and other farm work done by contracting parties as distinguished from employees; and because of the use of farm managers to look after the owners' interests in rented land.

11. Liability.—Farmers annually pay out large sums to satisfy claims for damage. These payments are made to hired men, visitors, neighbouring farmers and many other classes of persons injured by the activities of the farm operator. To protect farmers against some of these risks, various types of liability insurance have been developed. The purpose of such insurance is to pay to injured persons the amount of damage the insured farmer would otherwise have to pay. Obviously the probability of some events happening is remote and need not be insured against—and insurance for certain other things would cost too much. Sound information on the principles of liability insurance, therefore, is important to farmers. (See *Agricultural Insurance*, above.)

12. Regulatory.—Seed, feed, fertilizers, stock remedies, community or auction sales, commission merchants and plant nurseries are a few of the many items or enterprises that are regulated and sometimes licensed by law. A knowledge of those regulations applying to a particular farm business is essential to the farmer. See REAL PROPERTY AND CONVEYANCING, LAWS OF; see also Index references under "Agricultural Economics" in the Index volume.

Dawood, "Agrarian Reform in Egypt: A Case Study," *Current History*, vol. xxx, no. 178 (June 1956). (H. W. H.H.; N. G. P. K.)

AGRICULTURAL EDUCATION AND RESEARCH.

Almost every country has its agricultural research stations and teaching organizations. The research stations are of two types: those concerned with the development of a subject; e.g. soil science, plant nutrition or plant pathology; and those using the knowledge thus gained for obtaining higher yields and better quality of crops and animal products. The education offered is of three categories: university departments for training experts and teachers; farm schools for prospective farmers; and itinerant instructors and advisers who help those actually farming.

This article is divided into the following main sections: United States; Commonwealth of Nations; Western Europe; Scandinavia; Central Europe; Southern Europe; Eastern Europe; the Soviet Union; the Far East; the Middle East; North Africa; Central Africa; South Africa; Latin America; and Inter-American and UN Institutions.

UNITED STATES EDUCATION

The impetus for agricultural education in the United States has been associated with demands for farm products by the increasing proportion of the total population engaged in nonfarming occupations. In 1820 only 13% of the population was engaged in non-agricultural occupations. A century later the proportion of rural farm population to the total population had decreased to 30%, and by the second half of the 20th century only 15% of the population lived on farms.

Until about 1900 new land was available as an additional source of food for the growing population. The U.S. farmer thereafter was confronted with the dual challenge of producing more total products and of obtaining increased yields per acre on the available land. The necessity of producing more products for each farm worker required increased mechanization and production efficiencies. Also the standard of living in the United States has improved from generation to generation, and no doubt agricultural education has had a significant role in this evolutionary process.

Early Agricultural Institutions.—Various agricultural institutions existed in the United States prior to the founding of the agricultural colleges and the development of public secondary schools in which formal education in agriculture is presented.

In 1743 Benjamin Franklin led in the organization of the American Philosophical society, which gave much attention to agriculture. The members' interest in agriculture led to the organization in 1785 of the Philadelphia Society for the Promotion of Agriculture, of which George Washington was an honorary member. Other agricultural societies were organized in several states about the same time. In 1852 it was estimated that there were about 300 active organizations in the 31 states and 5 territories, and in 1860 there were 941 agricultural organizations recorded in the books of the United States Agricultural society.

A second type of institution which preceded formal education in agriculture was the agricultural fair. What appears to have been the first fair of a modern kind was staged in 1810 in the District of Columbia with many notables in attendance, including Pres. James Madison and his wife. Elkanah Watson is credited with organizing the Berkshire Agricultural society at Pittsfield, Mass., which presented its first fair in 1811. Thereafter agricultural fairs increased rapidly in New England, the middle Atlantic states and the new regions of the west.

The farm press was another forerunner of the agricultural colleges and of agricultural education. The *Agricultural Museum* (Georgetown, D.C.) was founded in 1810 as a full-fledged agricultural journal. The *American Farmer* (Baltimore, Md.) and the *Plough Boy* (Albany, N.Y.) appeared in 1819. The *Prairie Farmer* (Chicago, Ill.) began its long career in 1841. By 1850, 40 or more agricultural journals had been established. Some did not last long, many being absorbed by other journals; e.g., the *American Agriculturist* (1842) took over the *Genesee Farmer*, *American Farmer*, *Plow*, *Loom and Anvil* and more than two dozen others. Those journals that survived exerted great influence.

Agricultural Colleges.—Agricultural colleges came into existence about the middle of the 19th century. A state agricultural college was established in New York in 1853. The oldest surviving state agricultural college in the second half of the 20th century is that of Michigan (now Michigan State university), which began classes in 1857. Similar colleges were established in Pennsylvania and Maryland (1859), and the incorporation of agricultural colleges was authorized in Iowa and Minnesota (1858).

Major developments in U.S. agriculture have been associated with national emergencies. In the midst of the Civil War, Pres. Abraham Lincoln signed the Morrill act of 1862, under which congress granted to each state 30,000 ac. of land for each repre-

sentative and senator for "the endowment, support and maintenance of at least one college where the leading object shall be—without excluding other scientific and classical studies and including military tactics—to teach branches of learning as are related to agriculture and mechanic arts." Sixty-nine state colleges were organized under provisions of the Morrill act. The land-grant colleges and universities (*q.v.*) are intimately associated with the U.S. department of agriculture.

In 1887 congress passed the Hatch act, which made provisions for agricultural research to be conducted by the state colleges of agriculture in co-operation with the U.S. department of agriculture. State agricultural experiment stations had been established previously in Connecticut (1875), California and North Carolina (1877), New York (1879 and 1882), New Jersey (1880), Ohio, Tennessee and Massachusetts (1882), Alabama and Wisconsin (1883), Nebraska (1884) and Michigan, Indiana, Kentucky, Maine and Minnesota (1885).

In 1914 congress passed the Smith-Lever act providing for agricultural extension teaching and the demonstration of improved agricultural and home economics practices. The creation of the extension service was related to World War I, as the land grants of the Morrill act had been to the Civil War. The extension service is recognized as an outstanding example of adult education in the United States.

Agricultural Schools.—The demand for instruction in agriculture at the secondary level gained momentum with the growing popularity of high schools about the beginning of the 20th century. Previously some agricultural schools were founded through private initiative in certain states, including New York and Connecticut. A noncollegiate school of agriculture based on the folk school concept was started at the University of Minnesota in 1888.

In 1908 Rufus Stimson was appointed director of the Smith's Agricultural school at Northampton, Mass., where he is credited with having developed the "home project" plan of teaching agriculture. In 1911 a report on the program was presented to the Massachusetts legislature with a request for state aid to subsidize the teaching of agriculture. In 1908 after Walter H. French became professor of agricultural education at Michigan State college, a new position created in the agricultural college, 67 agriculture departments in Michigan high schools were organized before federal aid was available for teaching vocational agriculture. The general assembly of Indiana enacted a vocational education law on Feb. 22, 1913.

Among other states in which systems of vocational education in agriculture were established prior to World War I were New York, Pennsylvania, New Jersey, Minnesota and Wisconsin. In 1916 the U.S. bureau of education reported that agriculture was being taught under state supervision in 421 high schools and without state aid in 2,760 public high schools.

Federally aided programs of vocational education in agriculture originated with the passage of the Smith-Hughes Vocational Education act in 1917, providing assistance to states. The act specified that the instruction must be designed to meet the needs of persons over 14 years of age who were preparing for farmwork or were engaged in farming. After 1917 additional acts, including the George-Barden act of 1946, were passed providing funds to supplement the Smith-Hughes act. Instruction in vocational agriculture involves three major groups—high school students who are preparing for farming, out-of-school young men who are enrolled in young-farmer classes and adults who are enrolled in adult-farmer classes. In the second half of the 20th century an average of about 750,000 students were enrolled annually in such classes in approximately 10,000 departments of vocational agriculture in the United States. (See also AGRICULTURAL ORGANIZATIONS; FOUR-H CLUBS; FUTURE FARMERS OF AMERICA.)

AGRICULTURAL RESEARCH

Agricultural research has helped to provide the people of the United States with ample food supplies, better nutrition and a host of valuable new products, from life-giving drugs to frozen concentrated orange juice. It has meant greater efficiency in crop and livestock production, higher yields per acre, more eggs, milk and meat from less feed, more effective control of diseases and pests, better use of land and water and improved methods of harvesting, storing, processing and marketing farm products.

Measured by the developments in the United States, agriculture had made more progress in the 75 years preceding the middle of the 20th century than in the previous 75 centuries. Agricultural research in America, of course, started very early. Christopher Columbus, on his second voyage in 1493, brought livestock, alfalfa and other farm products to America to see if they would thrive. Later explorers and settlers also brought seeds and cuttings to plant in the new world. The culture of figs, olives, grapes and many other crops dates to the early Spanish missions. Experimentation with such crops as rice and tobacco led to the successful colonization of the Carolinas.

For 300 years after the arrival of Columbus, agricultural research in North America was confined to the testing of crops and livestock introduced from Europe, Africa and Asia. The selection of those plants and animals that produced most abundantly led to the development of new varieties and breeds better adapted to North American soils and climate.

Introduction and development of improved plants and animals were conducted in the early years entirely by private individuals and companies. Washington, Jefferson and Franklin were among those who aided or encouraged the development of new plant varieties and new mechanical methods to handle crops. The growth of agricultural societies, beginning in colonial days, furthered agricultural research by co-ordinating the work of many agriculturists.

As the country expanded, the need for agricultural research increased. Soon private individuals could no longer afford to carry the full load. Although the idea of a department of agriculture in the federal government was voiced by Washington soon after he became president, it was not until 1862, during Lincoln's administration, that a federal agency devoted to the welfare of agriculture was created. The U.S. department of agriculture achieved cabinet rank in 1889. Federal-grant funds were made available to the states by the Hatch act of 1887, the Adams act of 1906, the Smith-Lever act of 1914, the Purnell act of 1925, the Bankhead-Jones act of 1935, the Agricultural Adjustment act of 1938 and the Research and Marketing act of 1946. These federal laws established the co-operative extension service, set up regional laboratories to discover basic scientific laws and principles relating to agriculture, and later to find new uses for farm products, and authorized the USDA to contract with other public and private agencies for the conduct of certain types of research, especially that aimed at improved utilization and marketing of agricultural commodities.

Federal and state governments together contributed about equally with industry in the second half of the 20th century in the financial support of agricultural research. The total investment in this research effort amounted to about \$470,000,000 annually. Funds spent by the public agencies, divided roughly half and half between USDA and the states, supported the work of some 13,000 scientists. About \$32,000,000 of federally appropriated funds went to state agricultural experiment stations as federal grants and became part of the state research budgets. Contributions by private industry to agricultural research included work aimed at improvement of farm and forest production and farm machinery, research on farm chemicals and development of new and improved agricultural products and methods of handling and marketing them. Industry also made sizable grants to public research agencies, plus land, facilities, materials and services.

Although federal research in agriculture began modestly, with simple objectives, many early advances were impressive, such as the development by Marion Dorset of a serum to combat hog cholera (swine fever); the fundamental discovery by Theobald Smith that insects transmit tick fever of cattle—a discovery that

paved the way for control of malaria, yellow fever and other insect-borne diseases; valuable basic discoveries in human nutrition; and the breeding of many new varieties of plants with superior food qualities and resistance to disease and insects.

As more funds became available from both federal and state budgets, government research activities expanded until by the second half of the 20th century work was carried out at more than 500 stations located in every section of the country.

Broadly speaking, agricultural research in the various states is aimed at the solution of problems affecting farm production, marketing and distribution, and the welfare of the people within the states. Research agencies of the federal department of agriculture, on the other hand, concern themselves mainly with problems that are national or regional in scope. Many regional research projects are studied co-operatively by two or more states, USDA agencies and privately supported organizations.

The state experiment stations provided a practical basis for co-operation with farmers and farm organizations, foundations interested in agricultural research and private organizations. Although federal grant funds have constituted a nucleus of financial support, more than three-fourths of the funds spent for state experiment station research have come from state legislative action, plus gifts or grants from co-operative farm groups, industry and other sources.

Crop Production Research.—Improved crop varieties that resist insects and diseases, better management of soils, more efficient methods of crop cultivation and harvesting, and better means of handling, packaging and marketing farm products have all contributed to increased farming efficiency. Hybrid corn was undoubtedly the most significant single development in crop production in the first half of the 20th century. High-producing hybrids, developed through research, enabled farmers to harvest about a third more corn per acre than they could with open-pollinated varieties. (See also CORN; PLANT BREEDING.)

The scientists who opened the way were engaged in basic research. Their concern was to advance knowledge of plant genetics, with little thought of immediate application. But they soon saw the practical value of their work for corn farmers and turned their new basic knowledge over to other scientists for economic development.

Basic research does not always result in startling new discoveries of immediate practical value, but most of the really big developments can be traced back to this type of scientific study. With this fact in mind, the USDA established in 1957 a number of Pioneering Research laboratories, organized around outstanding scientists, to give added emphasis to work in basic research.

Hybrid corn is only one example of the revolutionary changes in farming made possible by research. In little more than 20 years, improved varieties of soybeans put this crop near the top of the list of major crops in the U.S. Yields per acre, oil content and the area where this crop could be grown were all increased by soybean breeders.

Potato farmers before World War II often complained that their seed stock had "run out." They meant that yields were getting smaller each year. Tomato growers lost entire crops from wilt, and cabbage farmers were in trouble with a disease known as yellows. Nationwide breeding programs were organized with state and federal agencies co-operating. Most of the commercial varieties of these and other vegetables used since that time are an outgrowth of this teamwork.

In the second half of the 20th century, research aided the sugar beet and sugar cane growers economically, giving them varieties that resisted mosaic and curly-top disease, which once threatened to wipe out the U.S. sugar industry.

Other research developments were undertaken because of demands by housewives, who wanted better fruits, vegetables and other products. As a result many new varieties were developed, ways were found to insure that fresh and processed foods would arrive at retail stores in prime condition, and retailers were taught to care for these foods so that the consumers would receive them in their most attractive, nutritious and appetizing condition.

Stem rust and other diseases took an enormous toll of wheat and

other cereals until resistant varieties were developed and came into general use. After a few years, however, some of these new varieties also succumbed to disease. E. C. Stakman, a research scientist in Minnesota, demonstrated that there were many races or forms of stem rust and that varieties of wheat and other grains could be resistant to one form but not to another. Later it was learned that the rust spores could hybridize in nature just as research men hybridize plants. This discovery indicated that the struggle by scientists to save cereal crops from the ravages of plant-disease organisms was likely to continue for many years to come.

Insect Control.—Reducing agricultural losses from insects is a major function of research. Control of the housefly, mosquito, grasshopper and many other disease-carrying and harmful insects has been instrumental in reducing damage to crops and livestock and various threats to human life. Many plant-breeding and management practices developed by research were primarily instituted to outwit insects. The use of one insect to control another and the discovery of many new insecticides helped to reduce the dangers from insect pests.

The control of malaria and other diseases carried by mosquitoes and the control of hookworm giving protection from trichinosis were brought about by the endeavours of agricultural scientists. DDT was discovered in Europe during the 1870s, but its widespread use as an insecticide was the result of the work of USDA entomologists more than 50 years later. It has been applied in more ways to protect more crops and livestock from insects than any insecticide ever discovered. Use of DDT to protect troops during World War II from flies, mosquitoes and lice, and the diseases they transmit, introduced it as a further boon to mankind.

Mechanization.—Grain combines, hay balers, corn and cotton pickers and many other machines have been perfected by the farm-equipment industry, aided by research done by agricultural engineers in the public service. Mechanical devices for planting, weeding, thinning, fertilizing, spraying and cultivating have helped ensure better farm products. Aircraft has been adapted to disperse agricultural chemicals and to do many other jobs for farmers and stockmen. Labour-saving equipment, improved buildings and work procedures have been developed.

Sometimes it was easier to fit a crop to an existing machine than it was to build a new machine. Sorghum was made a dwarf by plant breeders so that it could be harvested with a combine. Soybeans were made to bear their seed pods higher on the stalk so they could be gathered more easily by a harvester. (See also FARM BUILDINGS; FARM MACHINERY.)

Soil and Water Research.—In spite of the many improvements in methods of crop production, average yields per acre increased very little until about 1935. Before that time, soil deterioration was progressing in the United States at a rate sufficient to offset much of the effect of better farming methods. At least part of the general increase in crop yields after the mid-1930s resulted from the slowing down of soil deterioration or, in many cases, to the actual improvement of the soil.

Research has made possible the use of all classes of land in more effective ways. The control of erosion and soil deterioration made other advances even more striking. The amount of water available for crop growth is one of the major limiting factors in crop production. Improved tillage and terracing practices were devised to conserve soil moisture; soil-management and land-use practices were developed to increase infiltration of snow, rain and irrigation water, thereby reducing losses due to runoff (see also DRY FARMING; IRRIGATION; SOIL EROSION AND CONSERVATION).

Research in the use of fertilizers and in methods of soil management has revealed many facts useful to farmers in aiding nature to make specific soils more productive. Much has been learned about crop rotations, legumes and green manure for replenishing soil humus and nitrogen; methods for determining and supplying the nutrient needs of crops; and soil management under irrigation, including salt control. Techniques based on these findings were put to use on farms to increase crop yields and improve soil fertility.

Fertilizers have been improved through both public and private

research. The importance of the minor plant nutrients has become more generally understood. Between 1945 and 1955, farmers in the United States more than doubled their use of chemical fertilizers, applying them in granular, liquid and gaseous forms (see FERTILIZERS AND MANURES; SPRAYS AND DUSTS IN AGRICULTURE).

Scientists discovered how to use radioactive isotopes to unlock a vast storehouse of knowledge regarding plants. Chemicals "tagged" with these isotopes were employed, for example, to follow the processes by which plants take up soil nutrients to yield fruits, grains and fibres.

Radioactive materials were used also to fight animal pests. One result was the complete eradication of screwworms from the island of Curacao in the Netherlands Antilles in 1955. Entomologists saturated the wild population of screwworms with thousands of laboratory-reared male flies made sterile by exposure to gamma rays from radioactive cobalt. The sterile males mated with the wild females so that finally all eggs laid failed to hatch. Similar techniques were used against the screwworm in Florida and other southeastern states in a larger eradication effort that began in 1958.

Forest and Range Research.—Next to soil, the greatest natural resource in the United States is its forests. During most of the nation's history, these forests were destructively exploited, until the danger of their extinction became evident. Early research in forestry was concerned with measuring forest products and estimating volumes of standing timber on a given tract of land. Later research turned to finding the minimum requirements for keeping forest land productive. The practice of leaving seed trees to ensure reseedling of desired species became common. Experiments in many parts of the country proved that forests could be managed to produce annual crops through selective cutting. Many farmers gained worthwhile supplemental income from such practices.

In many places where millions of acres of forest land had become barren, research found ways of growing trees in nurseries, transplanting them and making them live. Planting machines were developed to save as much as half the planting costs. Hybrid trees capable of growing larger and faster than native varieties were developed.

Much of the forest land is also range land. Almost half of the continental United States is in range, much of which has suffered from overuse. Research demonstrated that both forest and open ranges responded to good management, and helped cattlemen to produce twice the amount of beef they formerly could raise without the improved practices. Reseeding of western ranges increased the supply of forage in some localities by five to twenty times. This reseedling, along with better management practices, also contributed to soil and water conservation. (See also FORESTS AND FORESTRY; RANGE [IN AGRICULTURE].)

Livestock Research.—Successful efforts to safeguard and improve domestic animals give man better food, fur, fibre and other useful animal products and often also protect human health. A contagious cattle disease, pleuropneumonia, was by 1884 so crippling exports of U.S. cattle that congress for the first time authorized the department of agriculture to begin research on livestock problems. From such research has come a long series of victories against such livestock pests and diseases as new world hookworm, trichinosis, hog cholera and cattle-tick fever. Veterinarians developed a vaccine against brucellosis in calves that also, indirectly, protects man from this disease, undulant fever, which is transmitted by drinking raw milk from an infected cow. As recently as 1910, many doctors and public health officials regarded pasteurized milk as unsafe for babies. Years of bacteriological research proved it safe even for babies and invalids, and brought about general pasteurization of milk.

Modifying livestock to meet present or anticipated demands of consumers requires more than health protection. Research on the pig (*q.v.*), for instance, has changed its basic characteristics. Consumers demanded more meat and less fat in pork. The meat-type hog was developed in 16 years of research by crossbreeding. It has more lean pork, less lard and produces larger litters of bigger pigs that grow faster and require less feed to reach market weight than did the old-fashioned hog. Proper selection can produce such a hog in any breed. The Beltsville small white turkey

was developed for smaller refrigerators, ovens and families. The Columbia sheep was a breed made to order to yield more good wool and more meat in the intermountain area of the United States.

In attempts to breed dairy cows that can produce more milk during the long, hot summers of the region bordering the Gulf of Mexico, it has definitely been established that tolerance to heat can be bred into dairy cattle. Some of the most significant research on breeding of livestock has been done with dairy cattle, and has established the proved sire system of animal breeding (*q.v.*). Proved sires and artificial insemination enable the dairyman to constantly improve his herd. Advances in artificial insemination of swine point to more efficient pork production for the future.

Along with increased emphasis on performance testing—proving a sire by testing performance of his offspring—efforts have been made to predict at a progressively earlier age whether a young animal will grow into an efficient milk or meat producer. Success in predicting the future of dairy heifer calves, beef cattle and young chicks has made for early culling and better herds and flocks.

To understand how livestock converts plant food into milk, eggs, meat, bone, and fibre, scientists have undertaken broad investigations. Many discoveries—that feed flavours and odours are transmitted to milk directly through the body of the dairy cow, of ways to preserve the vitamin A and protein content of forage crops and to inject vitamin B₁₂, riboflavin and other growth-promoting supplements into poultry feed, that antibiotics stimulate growth in poultry and swine—have brought about better feeds. Study of life processes in farm animals—in the rumen of a cow, for example—may help in developing the perfect nutriment for each animal (*see* also FEEDS, ANIMAL).

Utilization Research.—In the early days, the main problems of United States research in agriculture were in production, but as export markets decreased and production rose beyond current needs, research turned to finding new and wider outlets for farm products. This utilization research was aimed at improving and extending the markets for existing foods, fibres and other farm products; at creating new products; and at finding new uses for farm output, including its wastes and residues.

The frozen juice industry was developed by utilization researchers, as were improvements in dried eggs that led to whole-egg cake mixes and similar convenience foods. Soybeans would not have become a major crop had not new food and industrial uses been found to stimulate a demand for greater production. Improvement of turpentine manufacture from pine-tree gum ushered in a new era in pine farming in the south Atlantic and Gulf coast states.

Large-scale methods for commercial production of penicillin were developed at one of the USDA utilization laboratories during World War II. This research aided in the discovery and production of many other antibiotics.

Finding uses for agricultural wastes, such as corn cobs, vegetable tops, inedible fats and fruit pulp, has been an important job of utilization research resulting in new products and industries.

Spruce pulpwood once furnished most of the country's paper. But scientists concerned with forest utilization found ways to use some of the more plentiful tree species, such as southern pine, and at the same time to increase their yields. Fastening together of small pieces of wood to form beams, arches and other structural members was brought to a high state of perfection as the large trees of the virgin forests disappeared. Plywood was transformed from a novelty product into a dependable material that could be used for a great variety of purposes. With research-developed glues the gluing of wood has progressed from a traditional and secretive process into a well-established commercial operation. Seasoning and preservation of wood have been vastly improved, swelling and shrinking of timber can be prevented and softwoods can be treated to closely resemble hardwood in appearance and performance.

Much has been learned about wood chemistry. Cellulose can now be changed to sugar and it in turn to ethyl alcohol, feed yeast, molasses or other products. Lignin, a substance in woody tissue that serves to bind together other constituents in the tissue, is a

potential source of alcohols and many other chemicals.

Home Economics Research.—The U.S. government's research in human nutrition began in 1894. To improve the nutrition of a nation, researchers must probe three unknowns—the exact nutrients the human body requires at different ages for growth and health; how much of each nutrient agriculture supplies in the various foods; and just what people are buying and eating. Changing people's food habits is difficult, but it can be done. A comparison of family diets in the U.S. in the second half of the 20th century and a century earlier shows the great strides made toward better health for all. (*See* also NUTRITION.)

Research at Work in Regulatory Programs.—The inadequacy of research organized along purely scientific disciplines became evident in the 1870s when the central United States was set upon by devastating hordes of grasshoppers. When congress established an entomological commission to study the problem, it was the beginning of economic entomology in government, using science to solve practical problems and as a weapon against insect pests. An even stronger endorsement for the problem approach came in 1884 when congress set up the bureau of animal industry to deal with the cattle disease, pleuropneumonia. It not only authorized research, but it granted regulatory powers to bring the disease under control. Thus, research and regulation were combined, and the pattern for future development was established. Research is frequently directed toward specific regulatory problems—such as pest control, for example. In the same way, pest control operations in the field provide practical tests for research findings and suggest directions for new research to take.

As speedy transportation shrinks the world, the danger of foreign crop and livestock pests threatens the remotest corners of the earth. Between the U.S. farmer and foreign livestock and crop insects and diseases stands a thin line of federal plant- and animal-quarantine inspectors. Second line of defense is a system of surveys and alerts for new pests made by veterinarians, entomologists and plant pathologists across the nation.

When foreign agricultural pests do invade, or when farmers or local agencies cannot control destructive native pests, large-scale federal-state control or eradication campaigns may be organized. Domestic quarantines are usually invoked to prevent spread. Latest research-proved weapons are used. Through such programs several livestock and crop diseases and pests have been eradicated from the U.S., and many another reduced to economic unimportance.

Since 1906, the meat marketed across state lines has been safeguarded by federal inspection, with close co-operation of industry. This continuing inspection has been maintained at a cost annually of less than ten cents per person.

Economic and Marketing Research.—Research economists of the USDA and the land-grant colleges help to supply factual economic data to aid farmers. They have also helped to combine the separate contributions of research on plants, animals and machines into efficient and profitable farm-management programs.

When farmers grew everything they needed and their wives made everything the family used, there were few marketing problems and little need for marketing research. As farming became a specialized business, the need increased for research in agricultural marketing relating to the entire range of activities that arose in moving products from farms to the consumer. Research assistance has been provided to farmers in organizing and operating co-operatives for marketing, purchasing, or other business service and continuous research has been conducted to improve the marketing, handling, storage, processing, transportation and distribution of agricultural products. (*See* also AGRICULTURAL ECONOMICS.)

COMMONWEALTH OF NATIONS

United Kingdom. — There are three types of agricultural education. (1) County farm institutes for vocational training (36 in England and Wales in the 1950s and 2 in Northern Ireland) give one-year courses. Students number about 2,000 in England and Wales. In April 1959 the institutes were transferred from the ministry of agriculture to that of education. (2) Five agricultural colleges, founded by private benefactors but now state-aided, provide two-year diploma courses. The Royal Agricultural college at Cirencester, founded in 1845, and the Shuttleworth college, Biggleswade, Bedford, are for men; Studley college, Studley, Warwick, is for women; the others, the Harper Adams and Seale-Hayne agricultural colleges at Newport, Shropshire, and Newton Abbot, Devon, respectively, are co-educational. (3) Most of the universities have faculties of agriculture and award degrees; Wye college, Kent, is the agricultural department of London university.

Extension services for those already farming include demonstrations and lectures arranged by the county authorities and farmers' organizations. The chief agency, however, is the National Agricultural Advisory service formerly under the county authorities but unified under the ministry of agriculture in 1946; its staff numbers about 1,300.

Central expert services are provided by the ministry at the National Institute of Agricultural Botany and Seed Testing station at Cambridge, the Plant Pathology laboratory at Harpenden, the Veterinary laboratories at Weybridge and at Lasswade (Scot.), and the station at Tolworth, Surrey, for control of large pests (rodents, birds, etc.).

For many years agricultural research in the United Kingdom was carried out by individuals or societies at their own expense. Sir John Lawes (*q.v.*) personally financed the Rothamsted Experimental station during its first 60 years. But in 1909 Lloyd George, then chancellor of the exchequer, set up a development fund of £3,000,000 to last five years, out of which research could be aided. A. D. Hall devised the plan. Autonomous agricultural research institutes were established on the basis of subjects, not commodities; they were associated with universities where practicable and linked at first through the ministry of agriculture, but later through a specialized autonomous body, the Agricultural Research council.

The oldest station, the Rothamsted Experimental station (*q.v.*) conducts unique field experiments in which the same crop has been grown on the same land with the same fertilizer for long periods. The investigations include the chemistry, physics and biology of soils, and the growth of the plant in health and disease. Since 1921 much work has been done on applications of statistical science to agricultural problems. The next oldest station, Woburn, is part of the Rothamsted organization.

The Long Ashton Fruit Research station (University of Bristol) was started in 1903 as the National Fruit and Cider institute (in succession to Butleigh court, 1893) but now deals with all fruit in the wetter western region; much work has been done on plant nutrition, especially on the trace elements, and on protection against disease and pests. Fruit problems of the drier, eastern part of England are studied at East Malling, Kent (established 1913). For crops grown under glass a station was established at Cheshunt in 1914 and transferred to Rustington, near Worthing, in 1954. The plant physiology department of the Imperial college, South Kensington (London university), is associated with the crop investigations of these various stations. Problems of vegetable growing are dealt with at Wellesbourne (established 1949), Invergowrie (1950) and the John Innes Horticultural institution (1910), Bayfordbury.

Three principal stations are devoted to plant breeding: (1) Cambridge (1912), which developed out of R. H. Biffen's work begun in 1899 and where success with wheat and barley has been outstanding and fundamental genetical studies have also been made; (2) Aberystwyth (1919) where Sir George Stapleton in-

augurated the successful work on grasses and clovers; and (3) Pentlandsfield (Scot.), in succession to Corstorphine, where potatoes and other crops are studied, especially in relation to disease resistance.

The nutritive value of pastures as affected by their botanical composition and management is investigated at the Grassland Research station at Hurley, near Maidenhead (1948, in succession to Drayton, 1941); one of its practical achievements has been a marked extension of the grazing season. The National Institute for Research in Dairying at Shinfield (1912) took the lead in the clean milk movement and has done much work on the chemistry and physiology of milk production. Animal nutrition is studied at the Rowett institute, Aberdeen (1914), special attention being given to its relation to animal health and to metabolism. Much work on the subject was previously done at the Cambridge school of agriculture by T. B. Wood and his colleagues.

The Agricultural Economics Research institute, Oxford (1912), has developed methods of farm bookkeeping and cost accounting that form the basis of the economic surveys now made in different parts of the country. The National Institute of Agricultural Engineering at Silsoe, Bedford (1948, in succession to Oxford, 1924) plays an important part in the revolution in implement design after World War II. The Macaulay institute at Aberdeen (1930) investigates soils, especially their mineral components including the trace elements. In addition to these major institutes there are several smaller and more specialized ones, and also some research units of the Agricultural Research council placed in appropriate laboratories for particular studies.

In 1927 a research station of a new type was set up by Imperial Chemical Industries, Ltd., at Jealott's Hill, near Bracknell, where products of modern technological chemistry have been tested for possible agricultural uses and fundamental work has been done and published. Among other discoveries was the first of the selective herbicides. Since 1950 other industrial organizations associated with agriculture have established research stations.

The Agricultural Improvement council was set up in 1941 to ensure that promising results obtained at the research stations should be applied in practice and also to report on agricultural problems needing further investigation. As agricultural research develops it becomes more abstruse and more in need of interpreters; and so massive, that no one person could hope to apprehend more than a fraction of it. The Commonwealth Agricultural bureaus were accordingly set up in 1929 to collect the results and pass them on. The bureaus supply other information on request and especially help those working in isolated conditions.

Canada. — Agricultural education in Canada is the responsibility of local or provincial authorities, while research is in charge of the central or federal authorities: this has the advantage that it can be based on broad ecological regions or on commodities of wide national importance.

The Ontario Agriculture college, Guelph, the oldest in the country, was established in 1874; later it was linked with the University of Toronto. In 1907 Sir William Macdonald founded the college in Quebec that bears his name and became the agricultural faculty of McGill university, Montreal, Que., with the largest postgraduate school in Canada. The French agricultural college at Ste.-Anne de la Pocatière, Que., is linked with Laval university. The three prairie provinces have their universities, each with its agricultural faculty. These provide staff for the experimental farms and the extension services; candidates for the higher posts usually do postgraduate work of doctorate level at one of the U.S. universities where greater facilities are available.

The experimental farms were established in 1886 as a federal responsibility: the central one is at Ottawa, Ont. and it had at the outset four branch farms in widely different parts of the country. The first director, William Saunders, recognizing that Canada's special climatic conditions would necessitate the breeding of crop varieties suited thereto, made crosses of wheat with the purpose of combining suitability, high quality and early ripening. Among them was marquis; its virtues were not immediately recognized but later it dominated the prairies and became the most famous variety of its day. The experimental farms proved so useful that

their numbers were increased and by the beginning of the 1960s had risen to about 40 with more than 20 substations and a staff of about 1,000 graduates in addition to technical and other assistants. The Ottawa and Charlottetown, P.E.I., stations are the plant breeding centres for the eastern provinces, and those at Winnipeg, Man., and Lethbridge, Alta., for the western. The new varieties of wheat bred at Winnipeg have markedly benefited Canada's economy. Progressive shortening of the period of growth enabled the wheat belt to be pushed further north, and greater resistance to drought facilitated western extension. Increased resistance to rust reduced greatly a serious hazard in the eastern prairies, and resistance to sawfly did the same in the western area.

Problems of soil management are studied at Swift Current, Sask. For conserving soil moisture no improvement on the old practice of fallowing every second or third year had been found by the early 1960s, but the action was much better understood and the procedure was more effective and safer. The older methods often led to soil erosion while modern ones evolved by research did not; they were based on strip farming, weed destruction and trash or rough-surface fallowing. Extensive rehabilitation of eroded lands was carried out under the Soil Conservation service.

The plant breeders of the eastern provinces have rendered great service to Canada's important and growing livestock industry by producing higher-yielding and disease-resistant grasses, large-seeded hybrids of wheat and agropyron (wheat grass, or couch grass), and earlier maturing strains of soybean. Other research activities deal with pasture improvement.

Fruit problems are studied at Kentville, N.S., and in the western and northwestern stations; other investigations deal with the possibilities of growing vegetables in the far north thereby mitigating the harsh conditions for its inhabitants; the program includes hydroponic methods.

The experimental farms always have been active educational agencies. They are the basis of the extension service which, modified to suit Canadian conditions, is patterned after that of the United States.

Closely linked with the experimental farms are a series of illustration farms, ordinary commercial farms on which promising new results can be tested under practical conditions. The experimental farms staffs are associated with the provincial departments and the universities in carrying out the soil survey.

Australia.—The first agricultural society in Australia was formed in 1822 at Parramatta, New South Wales, by a group of farmers with the purpose, among others, of "communicating their mutual experiences and benefiting by their reciprocal advice," and also of making experiments on the growth of products. Other societies followed, often short-lived; finally the Royal Agricultural Society of New South Wales was incorporated in 1869. Systematic agricultural education began in 1881 when the government of South Australia appointed a professor of agriculture who set up an experimental farm in 1882 which later became the Roseworthy Agricultural college. Victoria followed with the college at Dookie in 1885 and afterward another at Longerenong; New South Wales established Hawkesbury Agricultural college in 1891; Queensland set up the Gatton college (later called the Queensland Agricultural high school and college) in 1897; and last of all, in 1925, Western Australia established Muresk. There are also some agricultural high schools. Each of the universities has a faculty of agriculture; Sydney since 1910; Melbourne since 1911 (created 1905, but not staffed until 1911); the others later. These confer degrees in agriculture and prepare men for the higher teaching, advisory and administrative posts, while the college training is more vocational in character and suited to farmers and managers of large sheep stations.

The earliest systematic agricultural research in Australia was done by William Farrer at his home at Lambrigg near Canberra, New South Wales, between 1886 when he settled there and 1906 when he died: for the first 12 years the research was conducted at his own expense; later he had a post in the department of agriculture. There he bred varieties of drought- and rust-resistant wheats suited to the Australian environment which made a great expansion of wheat growing possible. But for nearly 20 years he

had no successors, and by 1920 unsolved difficult problems in soil management, animal health and other subjects were causing loss to agriculturists and sheep farmers, or pastoralists.

As in Great Britain, New Zealand and India, the first institute devoted entirely to research and free of departmental responsibilities resulted from the efforts of a private individual: in this case Peter Waite, a sheep farmer, whose benefactions to the University of Adelaide made possible the founding of the institute in 1924. It has since become Australia's greatest agricultural research station. Its investigations include the water requirements of the wheat crop, Australian meteorology and hydrology, soil surveys and the trace elements in plant and animal nutrition. Another independent research institute is in Western Australia, also associated with the university; it deals largely with the problems of the sheep industry.

In 1926 the Commonwealth Scientific and Industrial Research organization was established to ensure systematic investigation in all necessary directions. It set up a number of research institutes to study among other subjects the introduction and proper management of new fodder plants, the reclamation of soils hitherto infertile, problems of irrigation and factors determining the quality of wool. Each state has its experiment stations for dealing with problems of more local interest.

New Zealand.—New Zealand was fortunate in that its early settlers included a number of men and women who wanted to see education take an important place in the new country. The botanical flora was early studied by Sir Joseph Hooker; in 1864 a geological survey was organized; in 1867 the New Zealand institute (now the Royal Society of New Zealand) was founded, and in 1872, 100,000 ac. of pastoral land in the South Island were set aside to endow a college of agriculture. This was opened in 1880 and called Lincoln Agricultural college, but was later (1896) reorganized as the Canterbury Agricultural college. In 1920 the first agricultural research institute was founded by Thomas Cawthron at Nelson, also in the South Island. Educational and research activities expanded rapidly about this time as both soils and pastures began to show signs of deterioration, causing much anxiety about the future. In 1923 and 1924, two professorships of agriculture were established in the North Island, one each at the university colleges of Wellington and Auckland; they amalgamated in 1926 and transferred to Palmerston North where much more land was available; they were reorganized as the Massey Agricultural college. This and the Canterbury college became part of the University of New Zealand; both provide courses ranging from diplomas to doctorates.

Another reorganization took place in 1926: the various government research agencies were linked by the establishment of the department of scientific and industrial research on lines similar to those of the United Kingdom and Australia. This resulted in the setting up of research bureaus and institutes. Among them are: dairying (1927), grassland (1929, reorganized in 1936), and plant chemistry, all at the Massey college; cereals at Canterbury college where useful plant breeding has been conducted since 1910; soils at Rukuhia (North Island); horticulture at Te Kauwhata and Levin. Notable successes have been achieved: the dairy industry has become one of the most efficient in the world; new and highly productive strains of grasses and clovers have produced superb pastures; the cause of the sterility of large areas in the volcanic regions of the North Island (deficiencies of the trace elements boron, cobalt, copper and molybdenum) has been discovered and rectified, dramatically transforming this once dreary waste into a smiling and prosperous countryside. The pasture improvement investigations at Marton begun in 1928 opened the way for aircraft dressings of superphosphate on hills too steep for farm implements thereby greatly enriching them. Meanwhile the Cawthron institute has continued its studies of the intensive crops of the northern part of the South Island.

Rhodesia and Nyasaland.—The chief experiment station of the Federation of Rhodesia and Nyasaland is at Salisbury (1914); it is now also the centre for hybrid corn (maize) seed production: a separate breeding station has been set up at Panmuri. The Grassland Research station at Marandellas, about 50 mi. E. of Salisbury,

deals with the intensive production of milk and beef on the veld; there are also stations for tobacco at Kutsaga (financed by the industry), for cotton at Gatooma and for pigs near Salisbury: one for irrigated crops in the Sabi valley about 100 mi. S. of Umtali, another for low rainfall conditions at Matopos. Northern Rhodesia has a research station at Mount Makulu near Lusaka, and Nyasaland has one at Lilongwe.

The multiracial Federal university, opened in 1957 and associated with London university, has a faculty of agriculture and a farm adjoining the Henderson Research station where investigations are concentrated on the integration of crops, animals and pastures. A college for training young European farmers has been set up at Gwebi 18 mi. W. of Salisbury. All three territories provide some agricultural training for Africans. The federal department of conservation and extension advises European farmers in the Rhodesia and the territorial departments advise the Africans.

The establishment of an Agricultural Research council to serve the whole federation was proposed and a farm planning program was inaugurated for European farms as was a program for reallocation of land in the Native reserves and its planned use.

British East Africa.—The East African Agriculture and Forestry Research organization founded in 1948 with large and well-equipped laboratories and 1,600 ac. of land at Muguga, Kenya, deals with the fundamental problems of plant and animal growth in tropical conditions and is free of local and departmental responsibilities. The investigation include soil and water conservation, resistance of crops to disease and pests, the effects of changes in land use on the flow of rivers, water relationships of soils and plants, the plant nutrient status of African soils, and the nutritional value of African pasture plants. A parallel organization on an adjacent site deals with veterinary problems. Both are under the East Africa High commission and are partly financed out of the Colonial Development and Welfare funds.

The Commodity Research institutes of East Africa included two independent organizations dealing respectively with tea (Kericho, Kenya) and cotton (Namulonge, Uganda) financed by the industries, mostly with British capital (Namulonge, however, also receives government grants from Sudan and those British African territories that grow cotton), while the research stations for coffee (Ruiru, Kenya, and Lyamungu, Tanganyika) for sisal (Thika, Kenya, and Mlingano, Tanganyika) and for cereals (Njoro, Kenya) were financed partly by the growers and partly by the government. Coffee research in Uganda is financed wholly by the government as also are the pasture and horticultural research stations in Kenya. The department of agriculture in each of the three territories carries out field experiments with crops of local importance.

Agricultural education in Kenya is complicated by the dual nature of the agricultural community, the European and the African, differing so completely that no one system could serve both. The Egerton college at Njoro (European) gives practical courses much on the lines of an English agricultural college, and are designed for those who wish to farm. But, in the second half of the 20th century, the African who goes to college did not want to do this but desired a post under the government or other large organization, and the demand was so great that he had no difficulty in obtaining one. The multiracial Makerere University college, Kampala, Uganda, which serves all three territories and is linked with London university has a faculty of agriculture which provides the necessary training. The college also has a diploma course. All three territories have farm schools for Africans which do not, however, lead up to Makerere.

British West Africa.—No station for fundamental research comparable with that in east Africa existed in the four west African territories at the beginning of the 1960s. The university colleges at Ibadan (Nigeria) and Achimota (Ghana), linked with London university, had faculties of agriculture largely endowed by the cocoa marketing boards and provided facilities for investigation. Three commodity research stations were established to serve all four territories: the West African Cocoa Research institute at Tafo, Ghana, and Ibadan; the West African Institute for Oil Palm Research near Benin, Nigeria; and the West African Rice Research

station at Rokupr, Sierra Leone; there is also a research unit for maize at Ibadan. The arrangement is economical of staff and of appliances, suitable men being few and appliances costly. The territorial departments of agriculture maintain other experiment stations at Samaru (Nigeria), at Ibadan (Nigeria) and Kumasi (Ghana).

The educational organization resembles that of east Africa. The university colleges at Ibadan and Achimota have graduate courses and provide instructors and other staff for the departments; as in east Africa there is little desire for farming, and no farming college similar to Egerton in Kenya. Each region has an agricultural school for boys of 15 and upward with a capacity of about 100 pupils. They are not very popular, however; a boy with sufficient education to be accepted has a considerable choice of other work. They are not a ladder to university training in agriculture; that way lies through the secondary school. Research and education officers are kept in touch with developments in their subjects through the Commonwealth Agricultural bureaus.

India.—The teaching of better methods to the cultivator began in India as early as 1839 when the East India company, anticipating a modern method, brought in a group of American cotton planters to show how cotton should be grown. This and some similar efforts proved unrewarding and it was gradually realized that success could be achieved only by making investigations in the country itself. The Famine commission of 1880 discussed the problems and in 1889 J. A. Voelcker was called in to advise the commission. First a government agricultural chemist was appointed, then in 1892 a technical agricultural director for Bombay presidency. Six years later a sugar cane expert was brought from the West Indies to deal with the increasingly serious disease problems. Research on a broader basis free from routine duties became possible in 1903 when the Pusa Research institute was founded by a generous donation by Henry Phipps, of the United States; it attracted a very able British staff, and much work was done on the breeding of improved wheats and potatoes, on the control of insect pests, on the increase of milk yield and on other subjects. From 1905 departments of agriculture were established in the different provinces and states charged with the provision of agricultural education: they set up a number of colleges at some of which (*e.g.*, Nagpur, Poona, Lahore) useful research was also carried out. The Linlithgow commission of 1926 recommended the appointment of the Indian Council of Agricultural Research with ample funds for the proper organization of research over the whole country. This was done in 1929. The Pusa institute was destroyed by earthquake in 1934; it was replaced by a larger and better-equipped one at New Delhi which has an estate of 1,000 ac.; this was opened in 1936 and continues to deal with fundamental problems. A number of other institutes deal with specific crops or subjects, including sugar cane at Coimbatore, rice at Cuttack (this also has international responsibilities aided by the Food and Agriculture organization of the United Nations), potatoes at Patna, dairying at Bangalore (the home of the Indian Institute of Science) and veterinary problems at Mukteswar-Kumaun.

The several state governments foster research on crops specially important to their regions. In addition, various crop and commodity committees provide for research on their particular subject, financed either by a special tax, or cess, or by a government grant; tea research, for instance, is thus carried out at Tocklai.

Education and extension services are the responsibility of the state governments and are under the directors of agriculture. Much ingenious thought has gone into the task of teaching the cultivator better methods. The problem is complicated by the widespread poverty of the peasants. Most of the larger states have agricultural colleges affiliated to the appropriate university and provided with an experimental farm for demonstration and research.

The West Indies.—Introduction and acclimatization of plants was begun early in the West Indies. The Spaniards brought in cotton and sugar cane in the 16th century. The Botanic garden of St. Vincent was set up in 1763 and was enriched in 1783 by the collection made by Capt. William Bligh (of the "Bounty") in the south seas. Jamaica had a considerable establishment in the 1870s. In

the 1880s and 1890s subsidized beet sugar from Europe almost drove cane sugar out of the British market causing great distress to West Indian growers. A professor of chemistry, J. B. Harrison, was appointed in Barbados in 1882 but the economic situation grew so serious that a royal commission was appointed in 1896; on its recommendation a department of agriculture including a chemist, an economic botanist and entomologist was established in 1897. This organization grew and was able to effect considerable technical improvements; an unintended result was that some of the staff, having acquired experience with tropical crops, migrated to India where they rendered valuable service.

The West Indies were by the second half of the 20th century the chief training ground for tropical research workers. In 1921 the Imperial College of Tropical Agriculture was started, at first a centre for local advisory service and training, and later becoming a postgraduate institution for the whole British commonwealth. From 1946 it became the centre of research on bananas, cocoa, soils and sugar cane, chiefly for the West Indies, but in the case of cocoa for other countries also. It also provides a three-year diploma course for the West Indies; in addition there are farm schools in a number of the islands giving instruction at certificate level.

Malaya.—Malaya has its departmental educational and research organization as well as the Rubber Research institute at Kuala Lumpur which is financed by the industry.

Close association is maintained between the home and the colonial research organizations and a pool of specialists is organized in Great Britain to deal with problems for which the local resources are inadequate. The cost of agricultural research in the tropical and subtropical countries associated with the colonial office is largely borne by the British government out of a substantial fund it has set up for colonial development and welfare.

WESTERN EUROPE

France.—The problems of agricultural education and research are associated in France with the peasant structure of much of the rural community, desired on social and political grounds; also with the need to attain greater self-sufficiency in food supplies (especially wheat) and to foster production of certain valuable export products (notably wine). There is a long tradition of agricultural education and research: the *École Nationale d'Agriculture* at Grignon was founded in 1826, that at Rennes in 1830, and the *Institut National Agronomique* in Paris, largest of all, in 1848, and reorganized in 1876. There are other colleges at Montpellier, Beauvais and elsewhere and a horticultural college at Versailles.

Agricultural research is organized by the *Institut National de la Recherche Agronomique* in Paris in two main groups of institutes: those for soils and crops form the *Centre National de Recherches Agronomiques* at Versailles, and those concerned with animals and their products form the *Centre National de Recherches Zootechniques* at Jouy-en-Josas. The *Institut National de la Recherche Agronomique* also has an institute at Narbonne for research on wine (oenology), cider and fruit juices, and research laboratories attached to the colleges at Grignon (plant physiology). Rennes (crop improvement) and Montpellier (plant nutrition). Other institutes deal with machinery, farm buildings and irrigation, and there are seven regional institutes for studying local problems.

Belgium.—Higher agricultural education is provided by the agricultural institutes of Gembloux (founded 1860), of Louvain (Catholic university, 1838), and of Ghent (Flemish university, 1920). Research is concentrated in these institutes and is closely linked with the corresponding teaching section; it comes, however, under the ministry of agriculture while the teaching activities are under the ministry of education. The *Institut Agronomique de l'Etat* at Gembloux is the chief centre covering almost all the agricultural subjects.

The Institute for Encouraging the Application of Science to Industry (set up in 1944) organizes joint research on specific subjects by members of the various research institutes, providing funds and necessary facilities. Among its activities are the soil and vegetation survey of the whole country, research on sugar beet (Tirlemont), fruit trees, wines and other subjects.

Netherlands.—High quality in its agricultural exports is so vitally important to the Netherlands that it has developed very efficient systems of agricultural education and research. Farmers actively participate through their old-established societies for the improvement of agriculture, subsidized by the government. The centre for higher agricultural education and research is at Wageningen which began as an agricultural school in 1876, became an experiment station in 1877, when Dutch agriculture was behind that of neighbouring countries, and now comprises a group of important institutes dealing with all branches of agriculture. Other institutes in the appropriate districts deal with specific subjects: soils and plant production at Groningen, soil survey at Bennekom, soil testing at Oosterbeek, fruit and vegetables at Alkmaar, greenhouse crops at Naaldwijk and bulbs at Lisse. Animal husbandry is studied at Hoorn; livestock investigations at several stations include pasture problems and associated animal disorders such as grass tetany (*hypomagnesaemia*). Problems of the *Zuider Zee* (*IJsselmeer*) reclamation are studied at Kampen and elsewhere. About 500 graduates assisted by 1,500 technicians are engaged in research. The co-ordinating body is the National Council for Agricultural Research, a branch of the Central Organization for Applied Scientific Research in the Netherlands. The corresponding centre for Veterinary Research is at Utrecht.

SCANDINAVIA

Denmark.—Like that of the Netherlands, Denmark's economy depends on the export of high-quality agricultural products. Higher agricultural education was provided early in Denmark; the Technical university sent out its first agricultural graduate in 1849. The subject was transferred to the Royal Veterinary and Agricultural college when it was founded in 1858; this is now the centre for agricultural, dairying and horticultural education. At least three years work on a farm must be done by the student before entering; he must also have attended a nine months course at an agricultural school. Vocational training begins on farms at about the age of 14, day or evening classes being attended. After about four years a full-time five to eight months course is taken at an agricultural school or a Folk high school, where, however, the emphasis is on general education. The working farmer is helped by two advisory services, one provided by the state, the other by the farmers' organizations.

Research is centred at the Royal Veterinary and Agricultural college. Closely associated with it is the National Research Institute on Animal Husbandry (1883). The animal problems studied at the various stations include pig progeny testing, immunogenetics, blood grouping, etc. The first blood-typing laboratory in Europe was set up in Copenhagen.

A number of state institutes under the ministry of agriculture in different parts of the country deal with particular crops and local problems. The important group at Lyngby includes plant diseases and pests (founded 1905), plant research (1909) and variety testing. Fertilizer investigations are done at Askov; they were started in 1893 to compare farmyard manure and artificial fertilizers as agents for conserving soil productiveness. An experimental dairy has been set up at Hillerød and the Atomic research centre at Risø studies possible uses of radiation in plant breeding, meat conservation, etc.

Among the privately organized institutes are the Viborg station of the Danish Heath society founded by Enrico Dalgas in 1866; the Danish Farmers Co-operative Seed-Growing association's station at Øtoftogaard, and the Meat Research institute of the Federation of Co-operative Bacon Factories.

Sweden.—Agricultural education in Sweden began in 1862 at the Alnarp institute. In 1932 the Royal Agricultural college was founded at Uppsala and took over most of the subjects, leaving Alnarp with dairying and horticulture. Six agricultural schools train youths of 18 and over in one- and two-year courses for posts as instructors and farm managers, while more than 50 farm schools give courses for prospective farmers.

The advisory and extension work includes a correspondence school founded in 1943 by the Federation of Agricultural societies for the benefit of some of the 80% of the farmers who never at-

tended farm schools. These societies have long played an important part in the improvement of Swedish agriculture: the first was founded in 1791. Agricultural research is organized under the Swedish Agricultural Research council: since 1948 the chief institute has been attached to the Royal Agricultural college: its numerous departments cover most branches of crop and animal husbandry. Other institutes have been founded for dairying and horticulture (both at Alnarp), farm buildings (Lund) and economics (Stockholm). Two private plant breeding and seed stations operate at Svalov and at Landskrona, both receive state subventions. The Dairies association has also its well-equipped station.

Norway.—Norway's agricultural problems differ greatly from those of Sweden and Denmark; there are no agricultural exports, only about 2.5% of the land area is cultivated and the farms are very small. The Agricultural college at Vollebakk and the Veterinary college at Oslo provide higher education, and a number of schools for young farmers offer 6 to 18 months courses which, however, were not well attended. The advisory service is in three groups: state, county and district. Research is centred at the two colleges and there are state institutes (12 in all) distributed over the country to deal with local problems. The Agricultural Research council has general supervision: its distinguishing feature is that its activities are financed by the state football pools. Researches of special interest include those on fur-bearing animals (fox, mink, etc.), on the effects of sunlight on plant growth and on regrouping and re-allocating small holdings.

Finland.—Finnish agricultural problems derive from the fact that it is the only country lying wholly north of lat. 60° N. The agricultural faculty of the University of Helsinki (established 1902) provides higher education (though many entrants do not graduate) and formerly organized all the research, but in 1923 the ministry of agriculture took over the more practical and local sections leaving the university to develop the basic subjects, including soil science, plant pathology and dairying.

The ministry's stations are supervised by the Central Board of Agricultural Research and are distributed over the country. The most important group is at Tikkurila and includes the stations for soil management, grassland problems, pest control, dairy and animal production (including mink). The plant breeding centre is at Jokioinen as is also the state institute for dairying; the Frost research institute is at Pelsosuo. The Biochemical institute, well known for Artturi Virtanen's work on silage, is at Helsinki, as are also the centres for soil science and seed testing, and the Plant Breeding institute of the Co-operative Wholesale society.

CENTRAL EUROPE

German Federal Republic.—Germany has long been distinguished for the number and efficiency of its institutes for agricultural education and research. The agricultural faculty of the Munich Technische Hochschule was founded in 1803; the much larger ones at Bonn (Friedrich-Wilhelms university) and Stuttgart-Landwirtschaftliche Hochschule Hohenheim, go back to 1818. There were in the early 1960s eight university schools, many farm schools and about 250 research institutes. The latter are of four types: (1) federal, under the federal ministry of food, agriculture and forestry in Bonn, among which are institutes for investigating quality in crops (Giesenheim), dairying (Kiel), animal health (Dahlem), biology of crops and forests (Brunswick); (2) state, associated with agricultural colleges or faculties of universities and financed by the respective ministries of education—these include names well known in the history of agricultural science such as Giessen, Dahlem, Göttingen and others; (3) state, under the respective ministries of agriculture and usually dealing with crops or problems of local importance—these are the most numerous; and (4) private institutions run by manufacturing or other groups dealing with specific subjects. The German Academy of Agriculture has its research institute in Berlin.

Switzerland.—Higher agricultural education is a federal responsibility and has been provided at the Eidgenössische Technische Hochschule, Zurich, since 1871. and under the federal department of the interior. Its associated institutes are the chief

research agencies. There are ten federal institutes in different parts of the country for studying local problems, but they are also responsible for various control and advisory activities. The agricultural schools were provided by the cantons.

Austria.—The centre for higher agricultural education is the Hochschule für Bodenkultur (soil science) founded in 1872, and for livestock subjects at the Veterinary college, both in Vienna and under the ministry of education. There are a number of farm schools adapted to local requirements under the ministry of agriculture. Research is centred at the institutes of the Hochschule, of plant protection and of horticulture, all in Vienna. The Alpine institute is at Gumpenstein, Styria.

SOUTHERN EUROPE

Portugal.—Higher agricultural education is given at the Instituto Superior de Agronomia at Lisbon (founded 1852). Research on soils and crops in all branches is centred at Sacavém, on animal husbandry at Santarem and on veterinary subjects at Lisbon. There are stations for plant breeding at Elvas and Oeiras (industrial crops); for fruit at Setubal and Alcobaça; oenology (wine) at Lisbon, Regua and Dois Portos; and a port wine station run by the industry at Oporto.

Spain.—The highest centre for agricultural education is the Instituto Nacional Agronómico (founded 1855) in Madrid which offers a five-year course. Other centres were reorganized in 1957 in three groups: (1) higher level under the ministry of education—technical high schools with five-year courses, the last to be spent at a research institute; (2) medium level under the ministry of education for training experts (*peritos agrícolas*)—in 1958 there were five schools; (3) vocational schools under the ministry of agriculture (started 1949)—these are of several types selected respectively for prospective foremen on large estates, agricultural workers, administrators; etc.

Agricultural research is under a special council and is centralized at the Instituto Nacional de Investigaciones Agronomicas, Madrid, under the ministry of agriculture. A number of stations have been established in various parts of Spain for studying problems of the region or for special purposes: citrus fruits at Valencia, grapes at Barcelona, cereals at Cadiz. A parallel organization, the Consejo Superior de Investigaciones Cientificas, associated with the ministry of education, is responsible for the more fundamental studies: one of its stations, the Aula Dei at Saragossa, deals with plant breeding, cytogenetics, plant physiology and pathology; another deals with edaphology (the relation between the soil and the growing plant).

Italy.—Twelve of the Italian universities have faculties of agriculture but although the student entries are large only a small proportion graduates. Pisa is the oldest (founded 1840), Milan (1872) and Naples (1873) come next; the largest is Bologna (1900). Research is carried out at these centres and also at some 40 institutes of the ministry of agriculture dealing with local problems in different parts of the country. There are stations for wheats, especially macaroni sorts, at Rome, Pisa, Rieti and Catania; for rice at Vercelli; flowers at San Remo; sericulture (silkworms) at Ascoli Piceno and Padua; wine at Conegliano; and for soils at Rome, Turin, Udine, Gorizia and elsewhere.

Greece.—The physical conditions of Greece are ill-suited for many crops, but olives, vines, tobacco and citrus fruits grow well in places. The research problems consist in seeking for higher output, better quality and for new crops, including cotton, rice and wheat, to broaden the basis of production. The agricultural faculty of the University of Salonika (founded 1927) provides for higher agricultural education and research. The ministry of agriculture has a number of stations dealing with soil management and crops; at Salonika for cereals and cotton; at Larissa for fodder and leguminous plants; in the province of Attica for vegetables; at Drama for tobacco and at Pyrgos for raisins, the three last-named being helped by the industry. General supervision is exercised by the ministry's bureau of agricultural research. An important private foundation, the Benakeion, deals with insect and fungus pests; it is now subsidized by the state. The Fertilizers and Chemical company has its own station.

Turkey. — The agricultural faculty of the University of Ankara (founded 1933) provides higher education, and its associated research institutes cover the whole range of soils, crops and livestock problems. The ministry of agriculture has a number of stations distributed over the country dealing with agricultural and horticultural crops of local importance, with bees and silkworms, and also has live government studs. Research on wine and tobacco, however, is the responsibility of the ministry of monopolies. Veterinary research is similarly organized by the University of Ankara and the state stations, and that on forestry by Istanbul university.

EASTERN EUROPE

The organization of agricultural education and research in the Communist countries is generally similar to that of central Europe. So fees are charged at the teaching institutions, and the number of students is very large; many are women and a large proportion of the students complete the full four- or five-year course and graduate. Research for the development of a subject is commonly in the charge of the Academy of Agriculture which, except in Poland, is entirely distinct from the Academy of Sciences. Research on particular crops or problems of local importance is under the ministry of agriculture of the country concerned.

Poland. — Agricultural education and research began in Poland in 1818 at Marymont, a suburb of Warsaw. In 1862 the Russians transferred this institute to Pulawy, the estate of Prince Adam Czartoryski, confiscated by them and renamed Novo-Aleksandria; the institute was reopened in 1869. In 1916 the old name was resumed, the teaching work was given up and the institute was developed as Poland's chief centre of agricultural research. Higher agricultural education is given at seven colleges of which Warsaw, Cracow and Poznan were founded before World War I; all are under the ministry of higher education and award the qualification of *inżynier magister* ("master engineer").

Below the colleges come the technical schools of agriculture (126 in 1958). They are under the ministry of agriculture and most of them specialize in one main subject such as seed production, grassland, horticulture, economics, etc.; some of them conduct their five-year courses by correspondence. The diploma admits the student to the colleges. Other schools have two-year courses, both internal and correspondence, and confer the title of practical technician: this, however, does not admit the student to college. At still lower level are the residential schools offering one-year courses on agriculture and animal husbandry for men and home economics for women; also one or two-year courses for pupils of 13 or over, leading to admissions to the technical schools.

The Pulawy institute, now called the Institute of Soil Science and Plant Cultivation, has a farm of 7,000 ac. where much variety testing is done; it has several associated institutes in other parts of Poland and a widespread extension service which annually makes some 2,000 field experiments adequately controlled by a special statistical section. The extension service also appoints an agricultural inspector or adviser to each of the provinces, together with a scientific and technical assistant. Various unions, e.g., the Sugar Beet union, also conduct experiments.

Other research institutes include those for plant breeding and acclimatization in Warsaw, for plant protection in Poznan, and for agricultural economics in Warsaw, the two latter subjects being studied at Pulawy, too. The Veterinary Research institute is also at Pulawy.

Czechoslovakia. — There are four levels of agricultural education leading from one to another. (1) Apprentice schools for those leaving the elementary school at the age of 14 give two- or three-year courses, half the time being spent at the school and half on a training farm. Those wishing to specialize in practical branches can have two- or three-years training on co-operative and state farms, tractor stations or forestry establishments, according to their choice. Pupils can then pass to (2) schools for training group leaders on co-operative farms which give appropriate courses lasting two winters. (3) Agricultural technical schools give four-year courses for pupils from elementary schools. (4)

The universities of Prague, Brno and Nitra have agricultural faculties with a total of about 7,000 students. All these institutions provide correspondence courses leading to the same qualification as for residential students.

Agricultural research is immediately under the Academy of Agricultural Sciences which consists of 15 members and was established in 1953 in succession to the older Academy of Agriculture. It controls the 30 research institutes and 22 research stations and appoints the staff and awards honours. Each institute, however, has its own council for detailed management; each also has sub-stations. There are also 21 independent stations within the academy.

Rumania. — Five institutes of higher agricultural education exist in Rumania. The chief is the Nicolae Balcescu Agricultural institute at Bucharest founded in 1885 and one of the largest in the world, having for its five-year course between 2,500 and 3,000 students. The institutes at Iasi and Craiova have about 1,000 students each and that at Cluj more than 700; a high proportion graduate.

The chief research institute is under the Rumanian academy; set up in 1928 it covers the whole range of subjects dealing with crops and soils, including horticulture, forestry, agricultural economics and meteorology. The ministry of agriculture has some more specialized institutes for animal husbandry, forestry, corn (maize) production, and horticulture and viticulture. Research is also carried out at the teaching institutions mentioned above.

Yugoslavia. — Being a federation of six different countries. Yugoslavia has six universities each with faculties of agriculture: Zagreb (1919), Belgrade (1921), Ljubljana (1947), Sarajevo (1947), Skopje (1947) and Novi Sad (1954). Each faculty has specialized research institutes for different branches of agricultural science or technology. These are financed by the federal state. Another group of institutes carries out investigations for the regional and provincial authorities and is supported by them. The degree course at each university lasts four years for the *inženjer agronomije* ("agricultural engineer") qualification.

THE SOVIET UNION

Prior to the 1917 Revolution the volume of work on agricultural science in Russia was small, but it included some brilliant investigations which after many years are still proving fruitful: among others those on soil formation and classification by V. V. Dokuchaev (1846–1903), on soil bacteriology by S. N. Vinogradsky (*q.v.*) from 1890 onward (not all done in Russia), by M. F. Ivanov (1871–1935) in the early 1900s on artificial insemination, by K. K. Gedroits (1872–1932) on soil colloids in the years before World War I.

After the Revolution agricultural and other sciences came under the influence of political dogma, and scientific writings of the 1920s and 1930s had to conform to the tenets of dialectic materialism; they usually included quotations from the writings of Marx, Engels, Lenin or other political authorities. Geneticists suffered particularly; western ideas were banned; N. I. Vavilov (*q.v.*), their most brilliant exponent, who had assembled at what is now the All-Union Institute of Plant Breeding, Leningrad, the finest collection in the world of the wild species of cultivated plants with the purpose of carrying out genetical investigations, was accused by T. D. Lysenko (1898–) of ideological impurity and banished to the arctic regions where he died. Lysenko was elevated to the highest rank for a time and enjoyed great popularity as a man of peasant origin who rose to become an academician. Many scientific workers were required to devote much time to Stalin's grandiose plan for combating drought in the arid steppe region by planting protective forests and other devices. After Stalin's death agricultural science appeared to be allowed more freedom; the political quotations were fewer; the Stalin plan seemed to have faded out and western distrust diminished. Occasional short visits by western scientists were arranged and in some instances a longer stay became possible.

As in certain other European countries, the applied sciences (including agricultural science) are not studied at the universities but at special institutes, the chief of which, however, are of uni-

versity rank. These are widely distributed over all the constituent republics, but the most important are in Moscow. Of the institutes for higher agricultural education the best known was the Timiryazev Academy of Agriculture, Moscow, founded in 1865: this claimed in 1958 to have trained 17,000 specialists since the Revolution.

The separation of agricultural science from the pure sciences holds also for research: pure sciences come within the purview of the Academy of Sciences founded in 1725 while those concerned with agriculture are within the province of the V. I. Lenin All-Union Academy of Agricultural Sciences founded in 1929.

There are three main groups of agricultural stations. (1) The all-union institutes deal with fundamental studies and major problems of wide importance. Some are for subjects: *e.g.*, the Dokuchaiev Soil institute, founded in Leningrad in 1881 but greatly developed in 1926; the Institute of Plant Physiology, formerly in Leningrad but in 1934 transferred to Moscow in accordance with the centralizing tendency of the time; also the Institute for Fertilizers and Soil Science, Moscow, which has a large outside staff to organize fertilizer trials in many parts of the union. Others are for special crops; *e.g.*, the sugar beet station at Kiev. These institutes serve the whole of the U.S.S.R.: they are affiliated to the Lenin All-Union Academy of Agricultural Sciences except for the Timiryazev and the Dokuchaiev institutes which retain their old affiliation with the Academy of Sciences. (2) The regional institutes, of which each republic has at least one, are for the study of local problems; they collaborate with the all-union institutes when necessary. Other subjects studied have been the possibility of growing vegetables in northern latitudes, agricultural developments in Siberia and the acclimatization of livestock and its improvement by crossbreeding. (3) The state variety testing stations of which there are about 1,500 are under a special commission to deal with new varieties of crops.

The total output of work is enormous. Much of it, however, is little known outside the U.S.S.R. and its impact on the western scientific world has not been great.

THE FAR EAST

China.— Each province of the Chinese People's Republic has its agricultural college, some with about 5,000 students. There are two academies, the Academia Sinica (or Academy of Sciences) and the Academy of Agriculture. Each has its research institutes and journals (for agriculture, the *Journal of the Agricultural Association of China*). Plant improvement is studied in both groups of institutes; in the agricultural group the emphasis is on variety testing and regionalization. Research is also done at some of the colleges; *e.g.*, Fukien, Szechwan, Chekiang. Soils are studied at the Institute of Pedology, Peking, the Nanking institute and elsewhere. The volume of research is considerable and some of the titles of the papers are impressive, but because of the language difficulty the work is little known in the west.

Japan.— Japan developed its agricultural education in the second half of the 19th century. The Hokkaido university began it in 1875; Tokyo followed in 1889 and two other agricultural institutes were founded in 1909 (Kagoshima and Chiba). Others were set up after World War I, and at the outbreak of World War II there were 15 in all. After the war ended there was great activity, fostered by the U.S. authorities. The agricultural institutes were reorganized (1949) and new ones set up: by 1959 there were more than 50 institutes and university departments offering two- and three-year courses for masters and doctors degrees, while other junior colleges provided two-year courses but no title. Tokyo had three institutes: the largest, the faculty of agriculture of Tokyo university, had about 1,000 students, practically all males. The total number of all agricultural students was more than 30,000.

Fundamental research in the basic sciences is carried out at the universities. A research station for forestry was set up in 1878 and one for agriculture in 1893; later came stations for sericulture (1911), livestock (1916) and horticulture (1921). A comprehensive scheme was started in 1950. The National Research Institute of Agriculture (1946) deals with economics and the National Research Institute of Agricultural Sciences (1950,

when agricultural research was reorganized) deals broadly with them. There are eight regional institutes where these subjects are applied to the development of the local agriculture; eight fisheries research stations and also one (1955) which is devoted to cultivated pearls. All these are under the ministry of agriculture; the staffs numbered nearly 6,000. A co-ordinating council was set up in 1956.

Indonesia.— Under its old name of Netherlands Indies, Indonesia had one of the best tropical agricultural research services in the world. The work had begun early: a botanical laboratory was set up in 1884 in the old Buitenzorg (renamed Bogor) Botanic gardens (Java; 1817), the first to be established in the tropics, and was opened to visiting scientists. Later there followed a college of agriculture and an important group of agricultural research institutes dealing with soils, phytopathology and crops, and the planters set up special institutes for tea, rubber and cinchona. A sugar experiment station was established (1880) at Pasuruan (Java); Sumatra also had its Botanic garden and a tobacco experiment station. A steady stream of able young scientists came from the Netherlands to staff these stations and valuable work was accomplished. Much damage was done to these stations during the Japanese invasion. There are three university faculties of agriculture: at Bogor (University of Indonesia), Jogjakarta (Java) and a small one at Pajakumbuh (Sumatra).

THE MIDDLE EAST

Israel.— Agricultural research is organized by the Research Council of Israel set up in 1949: the chief centre was long at Rehovot (established 1921) but in 1958 began its transfer to Beth Dagan on the coastal plain: it deals with the basic sciences as applied to Israel's problems. Its experimental farm includes citrus and other irrigated horticultural and fodder crops. It has two other experimental farms; one, at Neveh Ya'ar, in the western Jezreel valley, near Haifa, is for dry land crops—cereals, unirrigated pastures and the breeding of hybrid corn (maize) and sorghum; another, at Gilat in the northern Negev, near Beersheba, is for studying the adaptability of crops to semidesert conditions. Another station, the Negev Institute for Arid Zone research, was founded with help from United Nations Educational, Scientific and Cultural organization in Nov. 1957; its program includes the utilization of solar energy and of dew, the desalting of saline waters, and the study of effects of desert conditions on human beings and animals and of the phenomena of acclimatization to them. Attempts are being made to reconstruct the conditions under which the region had supported a considerable Nabatean population for 1,000 years between the 2nd century B.C. and the 8th century A.D.

Agricultural engineering and food processing are both studied at Technion, Haifa. Higher agricultural education is given at the Agricultural college at Rehovot (founded in 1940) which in 1952 became the faculty of agriculture of the Hebrew university. There is also a two-year course for agricultural teachers and advisers for the advisory field service.

For children that have completed the elementary school course there are a number of agricultural boarding schools with more than 12,000 pupils at the beginning of the 1960s. The annual intake was planned to be at least 15% of all leaving the elementary school, this corresponding with the labour structure of the whole population. The ordinary course lasts for three years but a fourth-year course leads to the university.

There are also centres where unemployed young people are taught agricultural work. Evening classes are arranged for young people actually at work on farms. Transportation is organized to take them twice a week from their villages to study centres: the syllabus includes agriculture, arithmetic, Hebrew and social activities. The studies last four to five hours at a time and the course extends over two years.

Instruction has long been available for farmers and is well developed in the older villages. Special arrangements are required for the new villages because of the diversity of the settlers, many of whom are in great need of both instruction and guidance. The necessary efforts are organized jointly by the

ministry of agriculture and the Jewish agency, the body that had enabled many of the settlers to reach the country.

The Arab Countries.—The Arab countries had three kinds of universities: (1) the old institutions in Fez, Tunis and Cairo (see North Africa, below) teaching Islamic theology and jurisprudence; (2) the modern state universities in Cairo, Egy., Damascus, Syria, and Baghdad, Iraq; (3) foreign universities, French and American, both at Beirut, Lebanon. Only the last of these has an agricultural department. Iraq, however, has a college of agriculture at Abu Ghraib, founded in 1950. The courses last four years and there are no fees.

Iran.—Better provided than the Arab countries, Iran has a school of agriculture established in 1930 under the ministry of agriculture; it was transferred in 1944 to the University of Tehran and became a faculty in 1949. The university is under no ministry but has its own allocation in the budget: no fees are charged, and the course lasts three years.

NORTH AFRICA

Egypt.—A college of agriculture was established in 1890 at Giza on what had been the home farm of Ismail Pasha's palace: it became the faculty of agriculture of the Cairo university and has about 2,000 students including about 200 women. The Alexandria university also has a faculty of agriculture (1942) as has the Ain Shams university, Cairo (1950): each has about 500 students. In each case the course lasts for three years and leads to the B.Sc. degree.

Research began under the British with the formation of the Khedivial Agricultural society in 1898 which was given half the land at Giza. In 1903 its laboratories were built on the nearby Nile island of Gezira. After 1914 it became the Royal Agricultural society and built new laboratories on Gezira.

The Egyptian government took over the experimental farm at Giza for cotton research under the direction of the cotton board. More experimental farms since have been set up including one for the Alexandria university, and useful work on the development and productive powers of livestock under local conditions has been carried out.

Tunisia.—Tunisia started its independent career with an organization of agricultural education and research similar to that of France. The leading institute was the *École Supérieure d'Agriculture de Tunis* (founded 1890 as the *École Coloniale*, the name being changed in 1955) for training the higher staffs; lower in the scale came the *École Nationale d'Agriculture de Boghrana* (1946) for training advisers, and at a still lower level the three agricultural schools. Research is done at the *Service Botanique et Agronomique de Tunisie* and by a team of experts from France.

Algeria.—Higher education is given in the Algiers *École Nationale d'Agriculture* which is on a level with the three higher colleges in France and like them provides a three-year course for the diploma of *ingénieur agricole* ("agricultural engineer"). A branch establishment set up in 1957, the *École Supérieure d'Agriculture Africaine*, also with a three-year course, specializes in the problems of the Mediterranean and semiarid regions. At a lower level are the regional colleges and the agricultural schools. Agricultural research is done at the *Service Botanique et Agronomique* and the soil survey is by pedologists from the French Office of Tropical Scientific Research.

Morocco.—There is a school of agriculture at Meknès and a research organization at Rabat with stations for cotton at Tadla, and for hydraulics at Marrakesh, Tadla and Berkane. The soil survey is conducted by French pedologists.

CENTRAL AFRICA

Higher agricultural education is given at the *École Supérieure d'Application d'Agriculture Tropicale* in Paris and at agricultural schools in each of the former French territories. As production is entirely by small farmers a wide-ranging extension service has been developed including advisers, pilot schemes and *paysannat* ("peasant co-operative areas"). Pilot schemes (*section d'aménagement rural*) are large comprehensive schemes which may involve a whole village or even a canton of 5 to 15 villages, while a

paysannat is an area of small schemes, often 25 or 50 ac., entirely for African cultivators.

Research is centred in Paris in the Office de la Recherche Scientifique et Technique Outre-Mer and in several *instituts professionnels*, each for a special commodity. The office (*Orstom*) has two teaching and research institutes, one at Bondy near Paris, the other near Abidjan (Ivory Coast) and a few centres of wide scope; Tananarive (Malgasy Republic), Bamby (Senegal), Bouaké (Ivory Coast) and others. The *instituts professionnels* have stations for their special commodities: Pobé (Dahomey), Sibiti (Republic of Congo) and others for oil palm; M'Pésoba (Republic of Sudan), Bouaké and others for cotton; Divo (Ivory Coast) and one in Cameroun for coffee and cocoa. Some large production organizations have their own stations: the Office du Niger has one in the Republic of Sudan for cotton and rice, and there is one on the island of Casamance (Senegal) for peanuts (ground nuts).

Before world War II the Sudan Scientific service was almost unequalled in the tropics. The irrigation station at Wad Medani in the Gezira and the cotton-breeding station at Shambat carried out superior research work and the Gordon Memorial college at Khartoum rose to become a university giving degrees in association with London university. An upheaval followed the establishment of the new republic in 1956; the connection with London university was broken and most of the British staff left. Later, however, the government realizing the importance of research work re-established a research group.

General.—The commission, set up in 1948 by the governments of the countries south of the Sahara to secure technical co-operation for dealing with problems of wide geographical range, such as soil conservation and water resources, gives useful help in research. It organizes conferences, exchange of technicians and research workers and seeks to secure uniformity of procedure and nomenclature in surveying and mapping.

SOUTH AFRICA

Republic of South Africa.—Agricultural education began in South Africa in 1898 with the founding of the Elsenburg School of Agriculture in Cape Province. Research began in 1902 at the end of the South African War when two experimental farms were established, one at Cedara in Natal the other at Potchefstroom near Pretoria. Both agricultural education and research are now organized regionally on an ecological basis. Six regions are distinguished: (1) The winter rainfall region is served by the agricultural faculty of the University of Stellenbosch founded in 1926 by amalgamation with the Elsenburg School of Agriculture. (2) The Karoo and eastern Cape region has the Grootfontein College of Agriculture, established in 1911, and possessing a farm of 22,000 ac. and a flock of more than 6,000 sheep as well as Percherons and dairy cattle (Jersey and grade Frieslands). It deals with both crops and stock but it specializes in Merino sheep and wool. (3) The high-veld region has the Potchefstroom experiment farm to which in 1909 a college was added and later two outstations: it deals with all summer crops. (4) The South African plateau is served by the Glen college and experimental station near Bloemfontein. The rainfall averages only 20 in. a year and comes in summer when evaporation is high; the investigations include dry-land production of maize and other crops, beef production with Afrikandar cattle on the veld, and the combining of improved systems and methods of veld management with soil and water conservation. (5) Natal has an Agricultural Research institute at its university at Pietermaritzburg and also the Cedara college with a farm where winter crops, sown pasture and dairy farming are among the chief studies. The South African Sugar association has its wide-ranging experiment station at Mount Edgecombe (1924), with substations at Chaka's Kraal (1946) and Mtunzini, Zululand (1955). (6) The Transvaal region is served by the faculty of agriculture of the University of Pretoria associated with the government Soil Conservation and Extension services. Its outstations include one for grassland at Athlone, in the mistveld, cattle ranching stations at Mara and Messina where climatological reactions of cattle are studied; and one at Brits for the study of irrigation problems.

There is also a research station for wattle (acacia) in Pretoria. No systematic soil survey of the whole Union had been made but good work on soil conservation has been done; general soil problems are dealt with by the division of chemical services.

The most widely known of all South African institutions is the great Veterinary Research institute at Onderstepoort.

LATIN AMERICA

Most of the universities of South America have faculties of agriculture offering five-year courses and giving the *ingeniero agrónomo* ("agricultural engineer") qualification; there are also a number of agricultural schools of college rank, 34 teaching institutions in all. The results, however, are not impressive. A large proportion (80% or more) of the students entering fail to complete the course; among the various reasons are the low educational standards in rural areas, the inadequacy of secondary education, the poor reward for those who finally graduate (the remuneration for agricultural technicians in government service being low) and the consequent attraction of other professions enjoying a higher social standing.

Argentina.—There are six agricultural teaching institutes: the oldest and largest is the La Plata National university (founded 1882); the University of Buenos Aires also has an agricultural and veterinary faculty (est. 1904). Other? include the national universities of Cuyo, Tucumán and the North-East (Corrientes).

Brazil.—Brazil has the greatest number of agricultural colleges, the largest being that of São Paulo (founded 1901) with more than 300 students; schools of agriculture are also found at the universities of Ceará and Rio Grande do Sul. The facilities for training have generally exceeded the demand.

Chile.—There are four university schools: the oldest in South America is the faculty of agriculture of the University of Chile (1876). Others are the Catholic University of Chile, the Southern University of Chile and the University of Concepción.

Peru.—Lima university has the largest school of agriculture in Latin America, with nearly 700 students.

Uruguay.—An agricultural faculty exists at the University of Montevideo.

Paraguay.—The most recent school of agriculture in South America is that of Paraguay, founded in 1956, which, however, has only a few students.

Other Latin American Institutions.—Some provision for agricultural education and research is made in the other Latin American countries. The history of the stations had been chequered; some have been started and then closed before accomplishing anything. Useful work has been done in Venezuela at the Sosa station, near Caracas; at Majaguez under Atherton Lee; at the Insular station in Rio Piedras, Puerto Rico, under J. A. B. Nolle; and at the Tropical Forest station under Arthur Bevan. Mexico offers greater facilities for agricultural education, including more financial aid to the students, than any other of the Latin American countries. It has four agricultural colleges, the oldest and best-known being at Chapingo (founded 1854), which has a seven-year course. The path from school to university is smooth, the school certificate being sufficient qualification for admission.

INTER-AMERICAN AND UN INSTITUTIONS

The Inter-American Institute of Agricultural Sciences, mainly financed by the United States, founded and maintains a research station at Turrialba, Costa Rica, for studying major problems concerning livestock, pastures, coffee, forestry and other subjects. Another station is being set up at La Estanzuela, Urug., to serve the southern part of the continent. Two important stations deal with veterinary problems: the Pan-American Zooanosis centre at Azul, Arg. and the Pan-American Foot and Mouth Diseases centre at Rio de Janeiro, Braz., run by the Pan-American Sanitary bureau in association with the World Health organization. An international forestry research station in Venezuela is sponsored by the Food and Agriculture Organization of the United Nations.

In addition the U.S. Overseas Aid program, operated by the International Cooperation administration, in most of the coun-

tries provided missions which deal comprehensively with important development problems, including education and research, while Rockefeller and Kellogg Trust funds are both available for research and training in selected fields. The UN Food and Agriculture organization through its agricultural education and administrative branch advises on organization of educational, advisory and research activities.

For further discussion of agricultural education see ADULT EDUCATION; LAND-GRANT COLLEGES AND UNIVERSITIES; RURAL EDUCATION. For additional information on various aspects of agricultural research see ANIMAL BREEDING; PLANT BREEDING; PLANTS AND PLANT SCIENCE; VETERINARY SCIENCE and articles on crops and products, as CORN; ENSILAGE; PIG; etc. See also Index references under "Agricultural Education and Research" in the Index volume.

BIBLIOGRAPHY.—*United Kingdom:* Reports of the *Luxmore Committee*, Cmd. 6433 (1943); Ministry of Agriculture and Fisheries, *Report of the Loveday Committee* (1945, 1947, 1949); Ministry of Agriculture and Fisheries, *Report of the Working Committee on Agricultural Education* (1953); *Report of the de la Warr Committee*, Cmd. 614 (1958); E. H. Dale, *Daniel Hall: Pioneer in Scientific Agriculture* (1956).

Commonwealth of Nations: The results achieved at a number of the agricultural research stations in the Commonwealth during 1833-1958 are described in the *Empire Journal of Experimental Agriculture*, 26:77-194 (April 1958) and some later issues. Each of the larger countries issues a *Yearbook* annually containing information about agriculture and research. For the colonial territories see *Colonial Research* (H.M.S.O., annually).

Europe: Organization for European Economic Co-operation, *Agricultural Advisory Services in European Countries: Report of a Working Party of Experts* (1950); Food and Agriculture Organization, *Organization of Agricultural Research in Europe* (1953).

Other Countries: The subject is by its nature very fluid and the annual reports, published by most of the national research stations, are the safest guide.

(E. J. R.)

AGRICULTURAL ENGINEERING has become an increasingly important part of the technical foundation for supporting agricultural productivity well above the subsistence level.

Agricultural production involves many engineering problems and opportunities. Agricultural operations to aid biological productivity—soil conservation and preparation, planting, cultivation, pest control, harvesting, hauling, processing, packaging and storage—are in many respects precision operations involving large tonnages, heavy power and critical factors of time and placement. Homes and work buildings functionally designed to aid farm operations help farm families to minimize the time and energy requirements of routine jobs.

Farmers use some of the same products engineered for urban use, but many conditions, operations and problems of agriculture are specialized. There is no urban use for a combine harvester thresher or a mechanical cotton picker. The primary use of much other equipment—plows, sprayers, dairy barns, electric brooders and terracing graders, to mention only a few items—is in agriculture. Agricultural engineering has developed to serve this need for engineering of and for agricultural activities, guided by a practical and scientific knowledge of agricultural considerations.

Early History.—In the United States, the field for agricultural engineering was recognized in part by such early leaders as George Washington and Thomas Jefferson, in improvements on the equipment and structures on their plantations. The term agricultural engineering came into occasional use before 1900 and became firmly established early in the 20th century with the organization of agricultural engineering departments and professional curriculums at Iowa State college and the University of Nebraska. This was followed by the organization of the American Society of Agricultural Engineers (ASAE), acceptance of the term agricultural engineering by a number of other colleges, universities and experiment stations, recognition by the federal civil service and some industrial employers, provision in the laws of certain states for the registration of agricultural engineers and accrediting of some curriculums by the Engineers Council for Professional Development.

Branches.—Four primary branches developed within agricultural engineering, based on natural groupings of the types of problems encountered. They deal with the following subjects:

Farm Power and Machinery.—This branch is concerned with advances in farm mechanization in terms of tractors, field machinery and other mechanical equipment.

Farm Structures.—This includes the engineering necessary to provide shelter in houses, barns, livestock buildings and crop storage and special purpose buildings, as well as fencing.

Soil and Water Control.—Agricultural engineering deals with the problems of water and soil as they influence farm operations, in drainage, irrigation, soil conservation, hydrology and to some extent, flood control.

Electric Power and Processing.—Distribution of electric power on the farm and its application to a wide variety of uses present primary problems. They include engineering electric power use to improve results in established stationary power and lighting jobs; and development of the full potential of electric power for new functions that could not otherwise be performed economically on farms, such as lighting to control plant growth and insect pests, electric fencing to control livestock and automatic control of various operations.

In these fields the general pattern of progress toward the solution of specific problems is (1) research to more accurately define functional requirements to be served; (2) design and development of machines, structures, electrical equipment and operations to better serve the functional requirements; and (3) adult education and related measures to introduce improved equipment or methods.

Professional Education.—It proved generally more practicable to develop agricultural engineers by providing a sound basic training in engineering supplemented by training in agriculture, rather than by making agriculture the prime requirement, to be supplemented by something less than the usual basic training for engineers.

Early in the second half of the 20th century, recognized professional curriculums in agricultural engineering were offered in 46 schools in 41 U.S. states and in 3 provinces of Canada. Provision for graduate study in agricultural engineering to the master of science degree had been made by 34 of these schools and 8 offered graduate study for the doctor of philosophy degree. Comparable engineering education with specialized attention to agricultural applications is available in a number of universities in other parts of the world where engineering education is well advanced and agriculture is an important factor in the national economy.

Applications.—In addition to training professional agricultural engineers, college agricultural engineering departments serve three other main functions. These include the education of students in related departments; adult education; and research projects.

The agricultural engineering departments provide service courses for students of agriculture who need to develop familiarity with farm mechanical, electrical and structural equipment, and soil and water control from a practical operating standpoint without becoming professional engineers. In many cases, the same department handles extension work or adult education in agricultural engineering in close co-operation with the federal agricultural extension service.

Independently and in co-operation with the agricultural experiment stations and in some cases the engineering experiment stations, the college agricultural engineering departments conduct research to develop new information in their field. This generally represents a more specific definition of physical conditions favourable to efficient production and handling of high-quality agricultural products.

Comparatively few agricultural engineers are directly engaged in farming. About 60% are employed in private enterprise and the other 40% in public service, including federal, state and local agencies. Private employers include farm-equipment manufacturers, component materials and parts manufacturers, trade associations, electric utilities, distributors and dealers and farm product processors.

In the U.S. department of agriculture, the soil conservation service and the agricultural research service are the primary employers of agricultural engineers, with smaller numbers in several

other agencies. Land-grant universities and experiment stations are the largest state employers of agricultural engineers.

American Society of Agricultural Engineers.—This is a national professional organization having membership or representation in other engineering, agricultural, educational, scientific, governmental and trade organizations. The society was organized in 1907 with 17 charter members. In 1935 it was chartered in Michigan as a nonprofit membership corporation for scientific and education purposes. The objectives outlined in its constitution are to encourage, advance and improve (1) the science and art of engineering in agriculture; (2) agricultural engineering education; (3) the standards of agricultural engineering; (4) relations among agricultural engineers and with allied technologists; (5) the professional progress of its members; and (6) the usefulness of agricultural engineering. There are 27 regional branches in the United States and parts of Canada. The society publishes *Agricultural Engineering*, a monthly journal.

Agricultural Engineering Outside the United States.—A somewhat parallel development of agricultural engineering was taking place in other countries, modified by the composite influence of their agricultural problems, over-all economy, social customs, technical progress, educational and professional development and national outlook on material progress.

The extent of this development in the late 1950s was indicated briefly by the *International Directory of Agricultural Engineering Institutions* published in 1957 by the Food and Agriculture Organization of the United Nations. It listed 628 governmental services and institutes concerned with agricultural engineering in 75 countries. It also showed 41 national associations of manufacturers and distributors in related product fields, 33 related national meetings and shows, 54 technical and trade periodicals entirely or partly in this field and 129 reference books on various phases of the subject.

In its program of technical aid to other countries, the United States included teams of agricultural engineers to contribute to the development of agricultural resources. This usually involves considerably more than the transplanting of mechanization; it requires recognition of the existing agricultural, economic, scientific and social development of the country.

AGRICULTURAL ORGANIZATIONS. Agricultural associations range in scope from local clubs to national and international organizations that wield appreciable economic and political power and promote far-reaching technological programs. In the following discussion, the more important agricultural organizations are grouped geographically.

UNITED STATES

Farmer Movements.—Farmer movements in the United States can be grouped roughly into two types: (1) spontaneous mass efforts to change conditions regarded as intolerable by large numbers of farmers; and (2) the more closely knit continuing organizations designed for specific purposes. The first is well illustrated by the Greenback and Free Silver movements and the Populist revolt of the late 19th century, the second by such general-purpose, continuing organizations as the Grange (Patrons of Husbandry), the Farmers Educational and Cooperative Union of America (Farmers union) and the American Farm Bureau federation.

Movements of the first type have sprung up from time to time, sometimes locally, sometimes on a regional basis and at times on a scale that was almost nationwide. Among the early and local examples were Shays's rebellion (1786-87) (see MASSACHUSETTS: History), the Whisky insurrection (*q.v.*) in western Pennsylvania in 1794 and Fries's rebellion in eastern Pennsylvania in 1799, (see FRIES, JOHN). These were sharp, violent protests against such things as taxes and inadequate amounts of money and credit. Much broader agrarian and semiagrarian movements developed later. The movement which led to the election of Thomas Jefferson in 1800 had its roots in the rural areas of the west and south,

as did that which centred around Andrew Jackson and his opposition to the banking system in the period 1824-36.

From the 1830s until about 1870 there were no large-scale, general farmer campaigns of the protest type. In this period, farmers' clubs and rural fairs, organized mainly for social and educational purposes, sprang up in nearly all parts of the country, but they were almost exclusively independent and local. The most extensive and vigorous farmer movements were those of the late 19th century, from around 1870 to about 1896. The causes underlying them were, in the main, the poverty and hardships of pioneer life in the west and the flagrant abuses that characterized the railroad, marketing and political organizations of that period.

Immediately after the Civil War (1861-65) the most significant struggle was over the issuance of United States notes, known as greenbacks (*q.v.*). It was essentially a protest against deflation and a return to the gold standard. The Greenbackers, mainly the farmers of the west, demanded that the amount of paper currency issued during the Civil War be maintained or expanded, as a means of keeping money in circulation and helping to keep prices up. The movement gained enough strength to halt the retirement of greenbacks but was not able to prevent the return to the gold standard in 1879. It eventually merged with the Free Silver movement of the 1880s and 1890s, which had similar objectives but advocated the use of silver instead of paper currency.

The so-called Granger movement of the 1870s and 1880s included many of the same persons and was part of the general protest against low prices, high and discriminatory freight charges and corporate and political corruption. Largely as a result of it, railroad rates were brought under public control and a national regulatory body, the Interstate Commerce commission, was established in 1887. A later outgrowth of the movement, though not specifically spearheaded by the Grangers, was the Sherman Anti-Trust act of 1890.

The Farmers' alliance movement, mainly in the 1880s and early 1890s, was a more general protest against the railroads, middlemen, banks, "trusts and monopolies" and the major political parties. It consisted of many organizations, some of which were absorbed into while others merely joined forces with the alliance in the pursuit of common ends. The shift to political party status in 1890 and 1892 resulted in defeat at the polls and the disintegration of the movement.

No new large-scale farmer movements developed thereafter until the 1920s, except for the Nonpartisan league, which gained considerable strength in the northern plains region between 1915 and 1924. The league had many of the characteristics of the Populist movement, though its program looked more specifically to state socialism than did that of the alliance or the Populist party. It did not expand beyond a regional basis and its effective program was confined largely to one state, North Dakota.

A large-scale farmer movement of a different kind developed in the 1920s as a campaign for adoption of the McNary-Haugen two-price plan for farm products. It grew out of the severe decline in farm prices that followed World War I and was much more highly organized and ably led than the earlier protest movements. The plan itself lost out, but the strength developed by the farm groups in supporting it undoubtedly contributed to the actions later taken by the federal government in establishing the Federal Farm board (1929-33) and the Agricultural Adjustment administration of 1933 and after.

Smaller and less continuing farmer movements have sprung up from time to time, among them the Farmers' Holiday movement which swept over parts of the middle west in 1932 as a protest against low prices and farm foreclosures.

The movements described above were of the mass-protest type. In addition, U.S. agriculture has developed a vast array of more formally organized, continuing organizations including marketing and service associations numbering in the tens of thousands. At times their rate of growth has been such as to constitute something approaching a "movement," though usually they are looked upon as being merely a special type of business organization.

General Organizations.—The general farm organizations constitute an intermediate group. The oldest of them, the Grange

(Patrons of Husbandry), was started as a fraternal, educational and social organization in 1867. It expanded rapidly, achieving a membership of nearly 1,000,000 by 1875. It soon launched into many types of activity not contemplated by its founders. The railroad laws and related legislation passed in the 1870s and 1880s are commonly referred to as the Granger laws, though the Grange itself was merely the largest and most prominent of the many farm organizations that took part in this movement. The Grange later declined to a membership of little more than 100,000, but it grew again after 1900 and became one of the largest and most stable of the farm organizations.

The Farmers Educational and Cooperative Union of America was organized in Texas in 1902. Its early leadership consisted largely of former Farmers' alliance men and its strength in the early years was chiefly in the cotton states. Later its membership shifted to the northern plains states.

The other major farm organization, the American Farm Bureau federation was organized in 1919. It consists of state farm bureau federations, which in turn are made up of county farm bureaus originally organized as educational groups for collaboration with the agricultural extension services. By 1922 it had a national paid-up membership of 450,000 families. Its membership declined sharply in the late 1920s and early 1930s but increased appreciably thereafter. The federation and the state and local farm bureaus continued to work in close collaboration with the agricultural extension services and the state colleges of agriculture.

Other farmer organizations of similar type gained temporary followings at various times but either did not survive or did not become important nationally.

Improvement Societies.—Agricultural improvement societies constituted another group of organizations, composed both of farmers and of others interested in farming. The first of these societies in the U.S. of which there is a definite record was the Philadelphia Society for the Promotion of Agriculture and the South Carolina Society for Improving Agriculture and Other Rural Concerns, both organized in 1785. The pioneer in establishing societies that would reach the working farmer was Elkanah Watson of Pittsfield, Mass., who organized the Berkshire Agricultural society in 1811 to sponsor an annual cattle show or agricultural fair. County societies founded on the Berkshire plan multiplied rapidly until about 1825 when state aid was withdrawn and most of the societies disbanded. About 1840 interest in societies revived and both county and state societies were organized, many state governments appropriating funds for their support. From about 1840 to 1870 these societies bore virtually the entire burden of agricultural experimentation and instruction. After 1870 the number and influence of the societies declined as they were replaced by state and county boards of agriculture and later by state departments of agriculture, and their educational functions were taken over by other institutions (see AGRICULTURAL EDUCATION AND RESEARCH: United States).

COMMONWEALTH OF NATIONS

Great Britain.—In the latter half of the 18th century numerous societies were formed in Great Britain whose objects were entirely or mainly to foster agricultural development.

In Scotland the Edinburgh Society of Improvers in the Knowledge of Agriculture, founded in 1723, dissolved for financial reasons in 1764, but out of it developed the Highland and Agricultural Society of Scotland, formed in 1784. In 1787 the latter

society was granted a royal charter, and although its first aim was the development of the Highlands, its operations soon extended over the whole of Scotland. It offered premiums for plowing matches, land reclamation, plans for new villages and for the best-manured farms and encouraged research and education. It became known as the Royal Highland and Agricultural Society of Scotland.

In England, the Bath and West and Southern Counties society, founded in 1777, started by collecting information about the best farming practices, arranged a plowing match said to be "the first of its kind in any country," and offered premiums for improved livestock. In 1799 it acquired an experimental plot of ten acres, the forerunner of the research stations of today.

Before the end of the century local associations had sprung up in numerous counties. Among them was the Herefordshire Agricultural society, formed in 1797. In 1894 it was enlarged to include Worcestershire, and 28 years later the Gloucestershire Agricultural society, formed in 1829, joined with the other two counties to form the Three Counties Agricultural society.

In 1798 the Smithfield Cattle and Sheep society, which in 1802 became the Smithfield club, was founded to improve farm livestock and particularly to bring out the principle of early maturity by scientific farming and breeding. At its first show in 1799 prizes were offered in four classes, for the best beast and best sheep fed on grass, hay, turnips or cabbages, and for the best beast and best sheep fed on corn or oil cake.

In 1838 a meeting of landowners and farmers formed the English Agricultural society to encourage improvement in every branch of agriculture, by methods which ranged from the collection and distribution of available information to the award of grants and prizes for research, new equipment or better livestock. The society came to exert a great influence on the farming of England. During its first 50 years it undertook much of the work later done by government departments. In 1840 it was granted a royal charter as the Royal Agricultural Society of England (R.A.S.E.). Its recommendations to government on many occasions laid the foundations for new agricultural legislation, for example, the organization of a conference in 1944, the recommendation of which formed a foundation for the Agriculture act of 1947. In addition to its other activities one of the greatest tasks of the R.A.S.E. is the organization of the Royal show.

After World War II an important feature of its work was the organizing of conferences and of visits by its council members to overseas countries. Out of this developed the organization known as the Royal Agricultural Societies of the Commonwealth in which are represented the Royal Agricultural Societies of the United Kingdom and all the commonwealth countries. Its object is to encourage and arrange the interchange of knowledge and experience in the practice and science of agriculture to improve methods of crop growing, the breeding of livestock and the efficiency of agricultural machinery, and to encourage the exchange and settlement of young farmers within the commonwealth.

Besides the large societies concerned with all sides of agriculture, there are many that deal with specific sections of the industry, such as pedigree-breed societies for all the pure livestock breeds. The British Dairy Farmers' association, founded in 1876, was established to improve dairy stock and produce and to support the interests of dairy farmers. In addition to organizing the London Dairy show, it publishes a journal and, in conjunction with the R.A.S.E. and the Royal Highland society, forms the National Dairy Examination board. It has given financial assistance toward research in dairying. The National Cattle Breeders' association, formed in 1907, works in conjunction with the cattle-breed societies. The National Sheep Breeders' association, incorporated in 1892, represents all the 35 sheep-breed societies in England; and the National Pig Breeders' association, founded in 1884, incorporates nine of the pig-breed societies.

Ministry of Agriculture.—In 1793 a board of agriculture was created by royal charter. The government financed and patronized it but had no direct control. It was dissolved in 1822 and in 1889 a new board of agriculture was established by act of parliament and to the board were transferred the duties of the land

commission and the responsibility for ordnance (government) survey, agricultural research, education and statistics. In 1903 it took over the administration of the fishery laws. In 1919 it was reconstituted by act of parliament as the ministry of agriculture and fisheries, and its activities steadily increased. The minister of agriculture is assisted by two parliamentary secretaries, one in the house of lords and one in the commons. At the outbreak of World War II the ministry virtually assumed command of the country's farming resources, and war agricultural executive committees were formed in every county from representatives of farmers and farm workers. These committees acted as the ministry's agents in the county. Under the Agriculture act of 1947 they were reconstituted as permanent county agricultural executive committees.

The Agricultural Research council was established in 1931, and the Agricultural Improvement council was set up in 1941 by the ministry to encourage the application of research to practical farming. In 1946 the national agricultural advisory service of the ministry came into being, took over the existing advisory services and set up a chain of experimental husbandry farms.

The ministry's policy applies to Wales as well as England, but a Welsh department at Aberystwyth deals with problems specific to that country.

In 1911 the department of agriculture for Scotland was created and assumed all the ministry's functions in Scotland with the exception of animal health matters. Because animal disease does not stop at country boundaries, the authority of the ministry's animal health division extends over Scotland as well.

There is a separate ministry of agriculture for Northern Ireland

Farmers' Clubs.—Another type of organization for farmers which grew up in Britain in the 19th century was the farmers' clubs—local groups that met to read papers and exchange information on agricultural subjects. The largest of these is the Farmers' Club of London, founded in 1842.

The organization of young farmers' clubs in England began largely through the influence of Lord Northcliffe, who had studied the work of the 4-H clubs (*q.v.*) of the United States. The first club in England was formed in Devon in 1920. Later the movement was given financial assistance by the ministry of agriculture, and in 1932 the National Federation of Young Farmers' clubs was inaugurated. By 1953 it had about 1,500 local clubs in England, Wales and the Channel Islands, containing about 49,000 boys and girls between the ages of 10 and 25 years. Each club is a self-governing body arranging its own activities, but the county federations appoint organizers who arrange interclub and intercounty events. The object of the movement is to stimulate in young persons, both urban and rural, an interest in the soil, animals and plants and to promote a sense of citizenship. Similar youth organizations for young farmers are to be found in many other countries, including Australia, Belgium, Canada, Denmark, France, Finland, the Netherlands, Ireland, Luxembourg, New Zealand, Northern Ireland, Scotland, Sweden, Switzerland and The West Indies.

Farmers' Union.—The Chamber of Agriculture, founded in 1866 and intended to unite all organizations interested in agriculture, died out through lack of support. In 1904 nine farmers in Lincolnshire founded a local union of farmers, and the idea spread to adjoining counties. In 1908 these branches were incorporated in the National Farmers' union, which by the second half of the 20th century had more than 200,000 members in more than 1,000 local branches in England and Wales. The union promoted most of the existing marketing schemes and maintained close contact with overseas agriculturists.

Similar organizations are the National Farmers' Union of Scotland, founded in 1913, and the Ulster Farmers' union in Northern Ireland.

Agricultural Workers' Unions.—There are also unions which protect the interests of farm workers. In 1906 George Edwards, a Norfolk farm labourer, started in East Anglia a farm workers' union that, in 1919, became the National Union of Agricultural Workers. This union by the mid-1950s had more than 3,700 branches in England and Wales with a membership of 200,000.

In Scotland the farm workers are represented by the Scottish Farm Servants section of the Transport and General Workers' union, and in Northern Ireland this same union also has an agricultural section.

Australia.—The National Farmers Union of Australia, a nationwide federation of associations of agriculture founded in 1943, includes the great majority of farm operators in the country. It is represented in government committees and statutory authorities dealing with matters of production and distribution of primary produce as well as such related matters as immigration and taxation. Among its accomplishments was the appointment of a minister for primary industry with full cabinet status in the federal government.

Canada.—The Canadian Federation of Agriculture, which has a membership of most of the farm operators in the country, was formed in 1935 when all organizations of farmers in the provinces were invited to join in provincial federations and in one national body. The federation advises the government on agricultural matters and the government has followed the federation's policy of establishing marketing boards for various commodities.

India.—There are two main farmers' organizations in India: the Federation of Rural Peoples' Organizations and the Farmers' Forum of India. Of the former organizations, the biggest is the All India Kisan congress, which in the late 1950s had a membership of 750,000. The Farmers' Forum, founded in 1954 had the union minister of agriculture as its first president. It is a federal organization that affiliates the farmers' forums established in various states as well as the agricultural commodity organizations which have been established at national level.

Kenya.—The Kenya National Farmers' union was founded in 1947. The Kenya government consults the union on major decisions concerning agricultural policy; contact with the government is constant either through informal meetings with officers of the ministry of agriculture or by formal deputation to the minister himself.

New Zealand.—The organization called the Federated Farmers of New Zealand was founded in 1945 and took over the functions of the New Zealand Farmers union formed in 1900. About 80% of all farm operators in the country are members. It links all farming organizations in the country and has sections for every commodity of primary produce, each section having a large measure of autonomy.

Rhodesia.—The Rhodesia National Farmers union was formed in 1942 by a merger of a number of local farmers unions, some of which had been in existence since the beginning of the 20th century. In 1954, after the formation of the Central African federation there was a further merger with the Northern Rhodesia Farmers union. The organization deals with the government by direct negotiation with ministers, by meetings with members of parliament and by submission of evidence to government commissions.

Republic of South Africa (Commonwealth member until May 31, 1961).—Practically every farm operator in the country is affiliated with the South African Agricultural union by way of farmers' associations or agricultural co-operatives. The union presents the co-ordinated representations of the farming community to the government. The minister of agriculture recognizes the executive committee of the union, together with a few other officials, as his advisory board. The union substantially implemented progress toward the more orderly marketing of several agricultural commodities, not previously subject to statutory control.

EUROPE

Belgium.—The chief organization looking after the interests of farming in Belgium is Boerenbond belge, which has a large membership. Among its aims are the development and strengthening of the spirit of fellowship within the rural population; the maintenance of faith and morality in the country; the dissemination of agricultural skills; the improvement of conditions for farmers; and the economic and technical perfecting of agricultural and horticultural practices.

Denmark.—Nearly every farm operator in Denmark is a mem-

ber of the Agricultural council (Landbrugsraadet), founded in 1919 and composed of the Federation of Danish Co-operative societies and the Federation of Danish Agricultural societies. Negotiations are carried out with the government on behalf of agriculture and the council takes part in trade negotiations with other countries and represents Danish agriculture abroad.

Finland.—There are two main agricultural organizations in Finland: Pellervo-Seura, founded in 1899, and Maataloustuottajain Keskusliitto (M.T.K.), founded in 1917. In the late 1950s the former had a membership of 250,000 and the latter, 265,000. One of the most important accomplishments of Pellervo-Seura was the new Co-operative societies act that came into force on Jan. 1, 1955. The M.T.K. maintains close relations with members of parliament and with cabinet members. It is represented on the most important committees dealing with agriculture and forestry.

France.—The Confédération Générale de l'Agriculture (C.G.A.) was formed in 1945 as a free professional agricultural organization grouping the different branches of agriculture which were themselves formed into various federations.

German Federal Republic (West Germany).—The German Farmers' association (Deutscher Bauernverband) is the central organization of 15 independent regional unions. Another 19 specialized professional associations extending their activities over the republic are affiliated with the union. The Association of German Farmers' Co-operative Unions (Deutscher Raiffeisen-Verband) is the central organization of the 12 independent regional associations with more than 23,000 single co-operative unions of all kinds.

Netherlands.—The Dutch National Farmers union (K.N.L.C.) is a federation of ten provincial organizations. As with the other Dutch farm organizations (the National Catholic Farmers' union and the National Protestant Farmers union) most of its relations with the government are handled through the public body (Landbouwschap) that deals mainly with negotiations on price policy, agricultural wages and technical matters.

Norway.—The Norwegian Farmers' union (Norges Bondelag) was founded in 1896. It negotiates with the government when a long-term agreement regarding agricultural prices is to be fixed. The Norwegian agricultural co-operative marketing, purchasing and other organizations working on a nation-wide scale are eligible for membership in Landbrukets Sentralforbund. This organization carries out certain statistical services and has a special division dealing with current marketing and price reports.

INTERNATIONAL ORGANIZATIONS

The leading international agricultural organization, the Food and Agriculture Organization of the United Nations (FAO), came into being in 1945 with Lord Boyd-Orr as its first director-general. It arose after World War II when there was an urgent need to prevent starvation in some countries. The governments of 71 nations (77 nations by 1961) combined in FAO to increase food production throughout the world. The work was organized under five technical divisions—agriculture, economics, fisheries, forestry and nutrition. Technical advisers helped the member governments to improve their agriculture and social conditions by assisting such projects as land reclamation and drainage, the improvement of water supplies, the provision of improved varieties of seeds and plants, pest destruction and the control of disease, fish culture and forestry development.

The International Federation of Agricultural Producers was formed in 1946 at a conference called by the National Farmers' union of England and Wales. Its headquarters in Washington, D.C., and Paris kept in close touch with the FAO and it became the spokesman for agricultural interests in international negotiations. By 1957 it comprised 39 member organizations from 27 countries representing all six continents. In 1927 a laboratory was founded at Farnham Royal, Buckinghamshire, as an off-shoot of the Imperial Bureau of Entomology. It was primarily concerned with biological control of insect pests. This was later moved to Canada and became the Commonwealth Institute of Biological Control. In April 1929 the executive council of the Imperial

Agricultural bureaux came into being. In 1948 they were re-named Commonwealth Agricultural bureaux and in 1958 were 13 in number. All countries of the commonwealth contribute toward their financial support, and contributions are also received from Sudan and the Republic of Ireland.

The World's Poultry Science association, formed about 1914, and in the second half of the 20th century 30 nations were represented on its council. Its first world congress was held at The Hague, Neth., in 1921 and from that time, apart from a break during World War II, was held every third year in different countries. See also INTERNATIONAL TRADE ASSOCIATIONS AND CONGRESSES: *Agriculture*.

AGRICULTURE (ARTICLES ON). In spite of the industrialization of many parts of the western world, agriculture still drafts into its service more of the world's aggregate manpower than all other occupations combined. The article AGRICULTURE, below, deals with its changing methods of employing men and machines and gives a general view of its contemporary status. The history and current status of individual phases of the subject are treated in four additional survey articles: AGRICULTURAL ECONOMICS; AGRICULTURAL EDUCATION AND RESEARCH; AGRICULTURAL ENGINEERING; and AGRICULTURAL ORGANIZATIONS.

An additional background article, AGRICULTURE, PRIMITIVE, discusses the link between the origins of agriculture and of civilization. FOOD SUPPLY OF THE WORLD, dealing with the contemporary situation, describes regional production of various foodstuffs, outlines the nutritional patterns of various nations and explains why agricultural experts believe the world is capable of feeding its growing population. Significant basic material is contained also in the sections of NATURAL RESOURCES captioned *Vegetation; Soils; Animal Life; and Water*.

Agronomy, the branch of agriculture concerned with field-crop culture and soil management, is represented by many articles. Among these, CHEMURGY discusses new types of agricultural planning that have been stimulated by chemical research. SOIL deals with the natural processes by which soils are created, the methods by which they are classified and their physical and chemical properties, microbiology and productivity. Among other articles dealing with problems of agronomy are SOIL TESTING AND ANALYSIS; SOIL EROSION AND CONSERVATION; CROPS; ROTATION OF CROPS; FERTILIZERS AND MANURES; LIMING; IRRIGATION; LAND RECLAMATION; PLANT BREEDING; WEED; CEREALS; and GRAIN PRODUCTION AND TRADE.

Among the articles on individual grains are WHEAT; CORN; OATS; RYE; RICE; BARLEY; etc. Information on pastures and hay crops is given in GRASSLAND and in RANGE (IK AGRICULTURE). Articles dealing with forage and legumes are ENSILAGE; LEGUMINOSAE; and the specific crops ALFALFA; LESPEDEZA; PEANUT; etc. Articles devoted to fibre crops are FLAX; HEMP; JUTE; and COTTON.

Sugar crops are discussed in SUGAR and BEET. Other important crops are discussed in such articles as POTATO; TOBACCO; OIL PLANTS; TEA; COFFEE; and RUBBER.

HORTICULTURE surveys the principles and methods of the culture of fruits, vegetables and ornamental plants. This article is supplemented by FRUIT FARMING; VEGETABLE; and FLOWER, which has a section on *Commercial Flower Growing*. Additional information on floriculture can be found in LANDSCAPE ARCHITECTURE; and individual articles are devoted to various fruits, berries, nuts, flowers and shrubs. Soilless plant culture is discussed in HYDROPONICS; also in a section on hydroponics in PLANTS AND PLANT SCIENCE. Among the articles dealing with trees are ARBORICULTURE; FORESTS AND FORESTRY; and TREE.

Animal agriculture is treated in AKIMAL BREEDING; DAIRY INDUSTRY; FEEDS, ANIMAL; VETERINARY SCIENCE; POULTRY AND POULTRY FARMING; TURKEY; and FUR, which contains a section

on *Fur Farming*. Individual articles are devoted to the various types of livestock—HORSE; CATTLE; SHEEP; GOAT; PIG; etc.; also, to such specialized farm interests as RABBIT; GAME BIRDS; and BEEKEEPING.

Agricultural buildings, machinery and equipment are treated in FARM BUILDINGS; FARMSTEAD ARRANGEMENT. U.S.; GRANARIES AND GRAIN ELEVATORS; FARM MACHINERY; PLANTING MACHINERY; CROP-PROCESSING MACHINERY; HARVESTING MACHINERY; RURAL ELECTRIFICATION; TILLAGE MACHINERY; SPRAYING AND DUSTING MACHINERY; TRACTOR; etc.

Among the articles devoted to processed agricultural commodities are MILK; CHEESE; ICE CREAM; DAIRY INDUSTRY; FOOD PRESERVATION; CANNING, COMMERCIAL; JAMS AND JELLIES; OILS, FATS AND WAXES; FLOUR; CIDER; WINE; and HONEY.

Articles of specialized interest include TROPICAL AGRICULTURE; WEATHER FORECASTING; ENTOMOLOGY; FUNGI; MUSHROOM; BEEKEEPING; and SILK AND SERICULTURE.

Agricultural economics, treated in a survey article under that title, is discussed from various points of view in FARM MANAGEMENT; MARKETING; and FARM TENANCY. Among the articles dealing with social, legal and political considerations are FARM COLONY; LAND TENURE: ECONOMIC AND AGRARIAN ASPECTS; and LAND REFORMS. The historical uprooting of large populations because of land hunger is described in MIGRATION.

Information on the agricultural methods and products characteristic of various regions will be found in articles on nations, states and other geographical units

AGRICULTURE. In the second half of the 20th century the people of the world were living very largely on the produce of an area of cropland equivalent to about one acre per person. This suggests the extent to which the land had been made productive by man's efforts, for they could not have lived as they did, and where they did, on the native vegetation and wildlife. Agriculture, the art of making land more productive, is practised throughout the world—in some areas by methods not far removed from the conditions of several thousands of years ago; in others, with the aid of science and mechanization, as a highly commercial type of endeavour.

I. WORLD AGRICULTURE

A. ORIGINS OF AGRICULTURE

The earliest human societies subsisted by hunting and gathering. About 10,000 years ago there arose in the old and new worlds a

set of circumstances from which the discovery of plant and animal domestication became not merely a possibility but a likelihood. The glaciers were in full retreat. The next few millenniums were to see the continued extinctions of migratory Pleistocene fauna which had been the main food supply of Upper Paleolithic hunters. Humanity had begun a long period of settling down in various local environments, of learning to exploit particular plant and animal resources to the fullest. Above all, there was a new emphasis on the use of wild plants—roots and seeds. Speaking very generally of the origins of agriculture, archaeological evidence strongly indicates that the first use of cultivated plants was by societies which had achieved some degree of sedentary life through intensive collection of wild foods. Judging from observation of recent tribal peoples, it is also supposed that those early societies had a sustained practical interest in and a detailed knowledge of wild plants and their properties.

Knowledge of the specific times and places of the first plant domestications is derived from the study of present distributions of ancestral wild forms and from archaeological finds of preserved specimens of the plants and seeds themselves. The same methods are used to study the domestication of animals but less is known of the early stages of animal domestication than of plants because it is often difficult to distinguish the bones of the domesticated species from their wild counterparts.

In the second part of the 20th century information concerning the early development of agriculture was accumulating at an unprecedented rate as more archaeological explorations were being undertaken and in greater co-operation with botanists and zoologists. In consequence much that had been written only a few years earlier was becoming outdated. The evidence, however, suggests two major centres of plant domestication—southwestern Asia (the near east) in the old world and Mesoamerica (northern Mexico to northern South America) in the new. The old world centre from the beginning was also the scene of animal domestication. Plant and animal husbandry were early woven into the close relationship which characterizes western European farming. In the ancient Americas, however, animal domestication was less important, perhaps because of the absence of larger species which would be suitable as draft animals and which would submit to domestication.

The southwest Asia centre of plant and animal domestication has been described as a fertile crescent, extending from the alluvial plain of Mesopotamia through Syria and down the eastern coast of the Mediterranean to the Nile valley of Egypt. It is doubtful if all innovations in this region occurred at any single locale, and the most important evidence has come from two major sites: Jarmo (c. 6000 B.C.) in Iraqi Kurdistan, on the flanks of the Zagros mountains, and ancient Jericho (c. 7000 B.C.), by a gushing spring in the Jordan valley. Both localities indicate the goat as the first farm animal domesticated. Pigs, sheep and cattle—the major food animals of modern agriculture—were being hunted and eaten but were probably not domesticated at that time. Numbers of wild and cultivated grains were found in the excavations at Jarmo but by 1960 none had been discovered at Jericho. The suggestion that plants were grown there is based principally on the size and substantial character of the settlement, not a completely safe assumption.

At Jarmo occurred the large-grained wild wheat (*Triticum dicoccoides*), the small grained wild wheat (*T. aegilopoides*) and a two-row barley very like the wild species (*Hordeum spontaneum*). Cultivated grains included the large-grained emmer (*T. dicoccum*), which is ancestral to all other species of cultivated wheat except einkorn. The latter is the descendent of the small-grained wild wheat (*T. aegilopoides*). (See also WHEAT.)

Radiocarbon dating techniques suggested that plant and animal domestication probably were underway at Jarmo at 6000 B.C. and at Jericho perhaps 1,000 years earlier. Later between 6000 and 5000 B.C., farming villages spread over the Mesopotamian plain, Anatolia and Egypt. Emmer was adapted to the irrigated lands of Mesopotamia. Einkorn apparently was not, but continued with emmer in the agricultural settlements of the Danubian loessic lands of eastern Europe about 4500 B.C. Successive migrations of farm-

ers and herders were responsible for the introduction of plant and animal husbandry to western Europe. In the 3rd millennium B.C. club wheat, which had had an earlier sporadic occurrence in Egypt, was the main wheat crop in Switzerland. In the meantime, other farming communities had appeared to the eastward in Iran; it was probably from these that Indus valley agriculture was derived early in the 3rd millennium B.C. The Yang-shao period of northern China apparently possessed cultivated millet (*Setaria* and *Panicum*), kaoliang (*Andropogon*) and rice (*Oryza*) and probably had domesticated cattle, pigs, sheep and goats; the relationship between this well-developed Neolithic agriculture and the southwestern centre is not at all clear.

The independent development of agriculture in Mesoamerica was also a complex affair. An excellent archaeological sequence from Tamaulipas in northeast Mexico shows supplementary cultivation emerging about 6000 B.C. among peoples who relied mainly on game and wild plant foods. The cultigens at this time were the pumpkin (*Cucurbita pepo*), pepper (*Capsicum frutescens*) and the runner bean (*Phaseolus coccineus*). Unlike the old world situation, where the important plants, wheat and barley, were present from the beginning, corn (Indian corn or maize), the most important plant of Mesoamerican agriculture, did not appear until later. An early race of maize appeared in Tamaulipas and at Bat Cave, New Mexico, about 3000 B.C. An earlier view held that maize was derived from teocentli, or teosinte (*q.v.*); a more recent opinion is that a wild form was the ancestor of the cultivated species (see also CORN: Origin and History). In the meantime other varieties of beans (*Vulgaris*) were developed. Somewhat later the warty squash (*Cucurbita nzoschata*) appeared. Again, unlike the old world situation, several thousand years elapsed between the initial cultivation of plants (6000 B.C.) and the appearance of communities in which the main subsistence was derived from food production (1500 B.C.).

In the forests of the Amazon and Orinoco a tradition of cultivating tropical root crops—bitter manioc (*Manihot utilisima*), sweet manioc (*M. aipi*), and the yam (*Ipomoea batatas*)—arose sometime before 1000 B.C. On the Peruvian coast another series of cultivated plants had appeared by 2200 B.C.—squash, peppers, gourds, cotton, achira tubers and a local bean (*Canavalia*). These were in semisedentary shellfish and marine economies which utilized wild plants as well. In the northern Mississippi valley another group of plants which may have been cultivated as early as 1000 B.C. included gourds, pumpkin and squash, goosefoot (*Chenopodium*) and sunflower. The last two, at least, were local domesticates.

It is possible that the Mississippi valley and Peruvian centres somehow reflect an early diffusion of cultivated plants from the Mesoamerican region, but for the Amazonian root-crop tradition, there is, as in the case of the southeast Asia root-crop tradition, a greater likelihood of independent origin.

Whatever the case, the outward spread of Mesoamerican maize drew Peru, the North American southwest and the Mississippi valley into the orbit of Mesoamerican agriculture. In the southwest the eventual result was the establishment of village farming communities at about 300 A.D., or more than 3,000 years after the introduction of maize. During this long period of supplementary agriculture the bean, squash, pumpkin and improved races of maize were developed or introduced. In the northern Mississippi valley a certain amount of Mesoamerican maize was grown during the last centuries B.C. Again, not until 1,000 years later was heavy dependence placed upon cultivated plants. Indeed, nowhere in forested eastern North America did agriculture, which was essentially a part-time occupation of the women, play as decisive an economic role as in the farming villages of southwestern Asia and Mesoamerica.

The preceding discussion follows closely the views set forth in three distinguished papers in Science: H. Helbeck, "Domestication of Food Plants in the Old World," vol. 130, no. 3,372 (Aug. 1959); C. A. Reed, "Animal Domestication in the Prehistoric Near East," vol. 130, no. 3,189 (Dec. 1959); and G. R. Willey, "New World Prehistory," vol. 131, no. 3,393 (Jan. 1960).

(J.H., R. C.)

1. Cultivation and Land Use.—Early methods of cultivation were limited to the digging stick and the hoe. The stick was

the ancestor of the mattock, pick, spade and fork. Since a few years of cultivation of upland soil led to depletion, hoe culture was associated, in most places, with a seminomadic way of life. In fertile river valleys where irrigation was possible and where fruit trees could be grown, populations tended to be more stable.

The plow is believed to have originated in the eastern Mediterranean region, some time before 3000 B.C. The use of plows, even those of the simplest type, marks the beginning of some system of land tenure and the development of a more complex form of agriculture.

Iron plowshares were used in Britain about 400 B.C. and colters (cutters on plows) made their appearance about the 1st century B.C. Early Roman agriculture in Britain is believed to have been based on the colter plow and strip cultivation in contrast to the pointed plows and square plots which characterized the native farming. The pointed plows, giving rise to cross cultivation, resulted in a system of small squarish fields averaging from one-half to two acres in area and found throughout Europe. The plots, separated by lynchets or terraces, were clustered around villages. In Britain this form of agricultural economy is referred to as the Celtic field system. It appeared there during the late Bronze Age, about 1000 B.C., and lasted until the end of the Roman period, about A.D. 400. While it appeared to be the predominant system of community organization and land use then in effect there were exceptions, one of which, based on the Roman strip-shaped fields, has been noted.

With the coming of the Angles and Saxons, the Celtic field system was replaced by the open-field system of tenure which included the use of colter plows and strip cultivation. This was a co-operative system, the arable land being held in common but divided into strips which were apportioned among those entitled to them. The land was worked in common with plows and oxen owned by individuals. A man's holdings could be numerous and widely scattered. The plots were worked in rotation.

The Domesday survey, undertaken in Britain in 1086, revealed that the early Saxon form of tenure had been replaced by a manorial system. The land was owned by the king, by a lord or by the church, and the village community lived in serfdom upon it. Part of the land was operated as the home farm of the lord of the manor; the balance was operated by tenants who were required to perform military service and to work on the lord's demesne for a specified period each year. The land of the manor was divided into two or three large fields, each of which was subdivided into numerous strips. A serf or tenant had land in each field. The fields were tilled in rotation, one being in winter wheat, a second in barley, oats or beans and the third lying fallow. Livestock grazed on the fields after the harvest.

The Domesday survey recorded 9,000,000 ac. of arable land south of Yorkshire and Cheshire, 275,000 farm workers and 75,000 plow teams.

See FEUDALISM; MANOR; VILLEINAGE.

2. Livestock.—The domestication and raising of livestock in the eastern Mediterranean region was carried on by people who led a nomadic life. Bones found in early excavations indicate, however, that there was some association or trading of products between the herdsmen and those who raised crops.

By the time agriculture had spread over Europe the distinction between herdsmen and cultivators was disappearing and the two forms of agriculture were practised together. There were variations, however. The people of central Europe were nomadic cultivators who kept some cattle whereas the Breton was first and foremost a herdsman, for whom the cultivation of crops was a minor activity. The nomadic life of the herdsman was associated with tribal development and is not conducive to the creation of permanent habitations and institutions or to the leaving of records for archaeologists to discover.

The diffusion of knowledge of the plow and the discovery that manure would restore soil fertility gave a great stimulus to agriculture as contrasted with pastoralism. As the production of grain increased there was less need to raise cattle for food. There was also a change in the climate of Britain and northern Europe at the beginning of the Iron Age (500–400 B.C.). The much colder

climate necessitated some form of housing and the growing of crops for winter feeding. The slasher or leaf knife used for stripping leaves from trees and the scythe used for cutting hay for winter feeding are products of this period.

A system of modified pastoral nomadism has survived in Europe down to the present. In Spain, Italy, Switzerland, the Balkans,

Norway and Britain the presence of mountains and plains or valleys led to the cultivation of crops on the lowlands and the pasturing of cattle and sheep at the higher elevations. Transhumance—the migration of herds, herdsmen and even families from the lowlands to the uplands in the spring and back again in the fall—was and still is to some extent a custom. But the end of widespread herding in Europe began about 1750. When the common fields were enclosed and yields of grain and grasses increased, cattle and sheep could be enclosed in pastures in the summer and housed and fed in barns during the winter. With these changes the development of animal husbandry entered a new and interesting phase all over Europe, particularly in Britain.

The Romans had found large numbers of cattle in Britain and had also brought some of their own. Later, Anglo-Saxons brought cattle of the Devon type from western Germany. The Scandinavians contributed hornless or polled breeds. But it was in Britain that the characteristics of breed were established. The Shorthorn, Devon, Hereford, Aberdeen-Angus, Ayrshire and several other breeds of cattle are credited to contemporaries or followers of Robert Bakewell in 18th-century Britain (see *The United Kingdom*, below). As with cattle, so with sheep and pigs: selective breeding was applied in Britain during that same period and from it came the Leicester, Shropshire, Suffolk and Oxford breeds of sheep and Yorkshire, Berkshire and Tamworth pigs.

For details on the origins of various crops including those mentioned above see separate articles on those crops, as CORN; WHEAT; etc

For the story of livestock development see ANIMAL BREEDING and CATTLE; PIG; etc The history of the development of agriculture in early Britain and Europe is given in *United Kingdom: Early and Medieval Times*, below.

B. AGRICULTURAL EXPANSION TO THE NEW WORLD

The Industrial Revolution of the 18th and 19th centuries was accompanied by an agricultural revolution. With the growth of industry people gathered together in urban centres. The industrialist with his hired workers replaced the master and domestic craftsmen. The demand for food for this new urban population soon exceeded the capacity of the open-field tenure system, and husbandry and enclosure became necessary. Between 1750 and 1850 several thousand parishes were enclosed in Britain.

These changes were accompanied by great disturbances, aggravated by the Napoleonic Wars and the severe economic depression which followed. In some cases large farmers benefited but small holders, landless labourers, craftsmen and many others experienced difficulties. In the depression period, 1815-40, all of Europe suffered.

But this was also the period of spectacular development in the new world following two centuries of exploration and conquest. Britain, France, Germany, Spain, Holland, Portugal, Italy—the countries in which great progress had been made in agriculture—were also the countries that became associated in one way or another with the settlement and development of overseas territories. In some of these territories agriculture had to await the exploitation of other industries such as the fur trade, fisheries and forestry, but from 1750 onward agricultural growth was rapid.

The industrial and agricultural revolutions in Europe made not only the products of industry and agriculture available for export, but also millions of restless people who sought release from economic, religious and other restraints. They took with them the skills, the enterprise and the enthusiasm needed in the new world. They also took cattle, horses, sheep, pigs, fowl, seeds and plants which established these breeds and varieties in the new countries and led to a substantial export trade.

The agriculture that developed in the new world was a blend of the new and the old. Though influenced in all cases by the land-tenure practices and general farming experiences of the mother countries, it was also to a large extent the product of the local geography, climate and population. Plantation and estate farming became important in many tropical countries where a combination of native labour, climate and the adaptability of certain crops to that system existed. The production of coffee, tea, cocoa, rubber, coconut, cotton, pineapple, bananas, palm oil and similar products was the result. (See TROPICAL AGRICULTURE.) Side by side with the establishment of large estates and the employment of the native population, varying degrees of independent and small-holder operations came into being.

The seigniorial system of tenure was introduced from France to the St. Lawrence river region of North America. The plantation system came into being in the deep south. But in other parts of what is now the United States and Canada, the pattern of tenure and operation that was emerging in 17th- and 18th-century Britain took root. In the people who came to settle in these areas there was a deep-seated desire for the possession of land. Accordingly, during the colonial period and later, the selling or granting of land for free title became the dominant policy. This culminated in

the Homestead acts of the 1860s and 1870s. Based upon this policy the family farm became an institution in North America.

Land policies of somewhat the same general nature characterized New Zealand and Australia. There, shifts in emphasis between freehold and leasehold and variations in trend as regards small and large holdings occurred, but gradually the pattern shifted toward ownership and the family-farm type of operation. The family farm there, as in North America, may employ additional hired labour.

In Latin America the pattern of agriculture was predominantly monopolistic control and estate operation. In most if not all of these countries, however, some measure of small-holder operation also developed and in a few countries, such as Brazil, a family-farm type of tenure and operation prevailed.

C. LAND USE AND PRODUCTION

From the early beginnings of plant and animal domestication in southwest Asia and Europe, agriculture has spread to every part of the globe. The Food and Agriculture Organization of the United Nations (FAO) estimated the total world area of "arable land and land under tree crops" at 1,390,000,000 ha. for 1957 and permanent meadows and pastures at 2,494,000,000 ha., making a total of 3,884,000,000 ha. (Table I). The unused but potentially productive and built-on area, waste and other land was estimated at 5,662,000,000 ha. The area used for agricultural purposes was thus a little more than a quarter of the total land area of the world. The proportion of arable land to total area was highest (30.8%) in Europe and lowest (2.9%) in Oceania.

The arable land of the world is very unevenly distributed among countries and continents and in relation to population. Asia (excluding U.S.S.R.) in 1955 had more than one-half (55.6%) of the world's population with less than one-third (30.6%) of the world's arable land. North and Central America, on the other hand, with only about 8.9% of the world's population, had 18.6% of the arable land. In Africa and the Soviet Union the population percentages were almost the same (8.3% and 7.2%, respectively) as in North and Central America, and so were the percentages of arable land—16.97 and 15.9%, respectively. In Europe (excluding U.S.S.R.) and South America percentages of the world's arable land and population were about equal. Oceania had the most

balanced relationship between arable land and population but both were very small. Estimates of the world's potentially productive land vary from 400,000,000 to 3,500,000,000 ha.

The area in the world under major crops was substantially greater after World War II (1957) than in the prewar years 1934-38 (Table II). The area in wheat increased much less than world population during the period 1937-50 (Table V). The area in oats and rye declined slightly despite the larger population. The decline occurred mainly in North and Central America and in Europe. In Asia, on the contrary, the acreage of grain crops including rice increased by over 35%. These crops also increased in Africa. Increases in all other major crops also occurred in these regions. The data indicate that the per capita consumption of the bread grains and potatoes declined in Europe and in North America.

Crop yields vary from country to country and from continent to continent. In 1957, for instance, European countries harvested about 18.1 metric quintals (1 q. = 220 lb.) of wheat per hectare (2.471 ac.) but the average yield in other continents was considerably lower. The yield per hectare of rice (paddy) in Asia, where rice is the staple food of the people, was 18.5 quintals. Yields were highest in Europe—42.2 quintals—and lowest in Africa—15.3 quintals. The highest corn yields were obtained in North and Central America—25.4 quintals—and the lowest in Africa—9.0 quintals. Cotton yields at 4.5 quintals per hectare were also highest in North and Central America, but at 2.0 quintals per hectare were lowest in South America and Asia. Yields of potatoes

TABLE V.—World and Agricultural Population*
(population figures in 000,000s)

Continent	1937		1950		Percentage of agricultural population	
	Popula- tion total	Popula- tion agricul- tural	Popula- tion total	Popula- tion agricul- tural	1937	1950
Europe (excl. U.S.S.R.)	372	134	391	127	36	32
North and Central America	178	56	217	51	31	24
North America (excl. Hawaii)	(140)	(32)	(166)	(23)	(23)	(14)
Central America	(38)	(24)	(51)	(28)	(63)	(55)

and root crops vary greatly although these crops are usually grown under better conditions.

The average level of crop yields was considerably higher in Europe, North America and Australia in 1945-55 than in pre-World War II years. Average cereal yields in western Europe, for instance, were 17% to 18% higher in 1948-53; potato yields increased still more. Wheat and corn yields in the United States in 1949-53 were, respectively, 20% and 50% higher than in the period 1925-39. Potato yields in the same period were twice as great as before World War II. Wheat yields in Australia from 1949 to 1953 were 50% above the 1925-39 average. In the case of the other continents there is no clear evidence of general or substantial increases in crop yields.

Calculations made by the U.S. department of agriculture of the money value (relative prices in dollars) of world agricultural production show that in 1955-56 the United States and Canada produced 18.3% of the world's agricultural output; Asia (excluding the U.S.S.R.), 34.3%; Europe (excluding the U.S.S.R.), 19.6%; Soviet Union, 9.7%; Latin America, 8.8%; Africa, 6.6%; Oceania, 2.6%. The average annual world production of the principal cereals in 1956-58 was about 757,600,000 metric tons (Table III). Production of bread grains—wheat, rye and rice—which are uti-

lized mainly for human consumption was 449,300,000 metric tons or about 60% of the total grain output. Wheat represented 209,600,000 tons and was produced mainly in North America, western Europe, the Soviet Union, China, India, Argentina and Australia. Production of rice, about 203,500,000 tons annually, was concentrated mainly in the far east (India, China, Japan, Indonesia). Corn was third in importance with world production of about 172,900,000 tons in 1956-58. It is grown in North and Central America, South America, eastern Europe, India and China, and is used chiefly for feeding livestock. Barley and oats are also used for livestock feed; their annual production amounted to 71,300,000 tons and 64,100,000 tons, respectively, in 1956-58.

The output of sugar was about 52,000,000 tons in 1955-57. Cane sugar is produced mainly in Latin America (Caribbean area and Brazil) and the far east (India, Pakistan and mainland China) and beet sugar in Europe, the Soviet Union and North America. Lentils, beans and other pulses, important as a source of vegetable protein are raised mainly in Asia (China and India), South America and Europe. Vegetable oilseeds and nuts are produced in widely separated parts of the world: soybeans and cottonseed in North and Central America; sunflower seed in South America; peanuts, rapeseed and soybeans in Asia; and copra and palm oil in Africa (see OIL PLANTS). Cocoa is produced mostly in Africa and Brazil; tea in China. India and Ceylon; coffee in South America (particularly Brazil and Colombia); and tobacco in North America, Asia and South America.

Production of fruits is concentrated in various parts of the world. Commercial output of apples and pears occurs in Europe and North America, grapes in Europe, figs in Europe and the near east and bananas in Latin America and the far east. (See FRUIT FARMING)

Of the world's total milk production in the late 1950s, about 70%, 297,000,000 tons, came from Europe and North America. Meat production (beef and veal, pork, mutton and lamb) in the major producing countries amounted to about 43,300,000 tons, most of it beef and pork. For all meats, as for milk, Europe and North America are the most important producing regions. Foremost producers of eggs and poultry are North America, Europe and Asia.

Production of fibre crops has been localized in various parts of the world. Cotton production is concentrated in North America, South America (Brazil), Asia (U.S.S.R. and China) and Africa (Egypt). Flax is grown mainly in Europe, including European U.S.S.R., and in the United States, Argentina and India. Two-thirds of the world's sisal is produced in Africa and South America (Brazil); two-thirds of the hemp in Europe (including the U.S.S.R.); and almost all the manila hemp in the Philippines and the Caribbean area. Asia produced almost the entire world supply of natural rubber.

World numbers of livestock units by continents in 1956-57 are shown in Table IV. (A livestock unit is a measurement designation which permits the grouping of livestock in terms of feed requirements. Thus, using the FAO scale, 2 pigs, 10 sheep or 1 horse each represents 1 livestock unit and the 16 animals combined represent 3 livestock units.) The heaviest concentration of livestock units per 100 ha. of agricultural land was in Oceania and Europe, where the figures were 97.8 and 61.2, respectively. For other parts of the world the figures were as follows: Africa, 15.7; U.S.S.R., 16.2; North and Central America, 23.6; South America, 47.4; and Asia, 48.1. The total number of livestock units was greater in 1956-57 than before World War II although there had been a considerable drop in the horse and mule population. The number of cattle, pigs and sheep increased considerably in the postwar period.

The world population in 1950 was 2,503,000,000, of which 1,467,000,000 persons, or 59%, were engaged in agriculture. The lowest percentage of agricultural population in the total population was in North America (14%), followed by Oceania (31%) and Europe (32%). In other continents the proportion of agricultural population ranged from 60% to 74%. In several of the leading industrialized countries that are also major food exporters, the percentages of the population engaged in agriculture were low:

in the United States, 13%; the Netherlands, 14%; New Zealand, 19%; Canada, 20%; and Denmark, 24%.

D. POPULATION AND FOOD SUPPLIES

In 1798 the English economist Thomas R. Malthus published *An Essay on the Principle of Population*. His main thesis, that population would increase more rapidly than food supplies, had a profound effect on the thinking of the early 19th century and has been the subject of much discussion since that time. A hundred years after Malthus set down his views Sir William Crookes, in a presidential address to the British Association for the Advancement of Science, told his listeners that there seemed to be no possibility of increasing the wheat-producing area of the world sufficiently to provide for the wants of the rapidly increasing population of bread-grain eaters. This, too, had a pronounced effect—the more so because it came after a hundred years of advances in agriculture which seemed to have discredited the gloomy predictions of Malthus.

The experiences of the 1930s and of World War II and the subsequent widespread interest in the economic and social conditions of people throughout the world gave rise to the United Nations and its Food and Agriculture organization, World Health organization and other specialized agencies, all of which again stirred up interest in the matter of population and food supplies. The prediction of UN experts in 1958 that the world's population, then estimated at 2,737,000,000, would reach more than 6,000,000,000 by the beginning of the 21st century tended to extend the controversy.

The FAO draws attention to the fact that large numbers of people throughout the world are underfed, but FAO officials do not despair of the future, provided man continues his program of improving production in agriculture, fisheries and forestry. Food production in 1957 was increasing at the rate of 2% a year compared with a population rate running below that figure.

There are two or three ways of increasing the world's supply of agriculturally produced food. One is to increase the output on existing land; another is to add to the cultivated area. The third might be to extend or make better use of the foods produced. Increased output offers much hope for the foreseeable future. In many areas revolutionary changes are occurring. In the decade following World War II total output in many countries was increased by 25% to 50% and the output per worker by even greater amounts. These increases were made possible by advances in scientific achievement and by the acceptance and application of the knowledge available. In the temperate zones better seed, improved cultural practices and greater use of fertilizers and pesticides resulted in larger yields. Irrigation of dry lands, the drainage of wet lands, the introduction of new grasses and plants brought increased output. The development of earlier maturing varieties extended the area of production northward. In the tropical forest areas, drainage, better management of soils, improvement of varieties and substitution of crops raised production. Better breeding, care and management of livestock greatly increased the output per animal unit and per acre. In general, less human labour but more capital and improved management practices brought results that had not been foreseen even a generation earlier. These developments indicate that with known methods the output of food in many countries and on the lands now cultivated can be considerably enlarged, probably doubled.

It is reassuring to know that increased output need not be hampered by any shortage of fertilizers or pesticides. Raw materials are abundant, and the chemical and engineering facilities and technology necessary to production are available.

As regards potential land area, the soil scientist Charles E. Kellogg in 1955 summarized certain conclusions that he and others had put forward in a UNESCO report issued several years earlier. He said that with the general adoption of practices already being used by good farmers occupying the various kinds of soil, the acreage of cropland in the world could be increased by more than 50% or from 1,000,000,000 ha. to 1,500,000,000 or 1,600,000,000. The report indicated that while a part of this additional land lay in the temperate or cool temperate region, most of it lay in the

tropics of South America, Africa and some of the larger islands.

Much of this land, while potentially suited to agricultural use! will not be farmed for many years. In Canada, for instance, it was reported in 1954 that there were about 73,000,000 ha. of unoccupied land with agricultural possibilities of some sort. Probably not over a quarter of that area will be brought into farms in the foreseeable future, assuming economic conditions similar to those prevailing in the late 1950s. If population pressure becomes acute enough, however, more of such land may be brought into food production.

Kellogg stated that "the estimates of the available soils for agricultural use and the production possible from those soils are considerably higher than the prospective population of this century." Sir E. John Russell, too, completed his study of 1954 on an optimistic note, saying ". . . world agriculture is developing and its possibilities are vividly emphasized by the circumstances that at present (1) less than 10 per cent of the earth's land surface is cultivated; the rest is largely waste; (2) only about one-tenth to one half of 1 per cent of the sun's radiation received at the earth's surface is fixed as organic material; the rest is lost; (3) only about half or less of the organic material ultimately reaches the table as human food; much of the rest is wasted. Taking the earth's surface as a whole, for each million calories of energy received from the sun only one calorie is converted into human food. And lastly, little attention has been paid to the conservation and most efficient use of water, the factor finally limiting food production. The problem of improving our utilization of these natural resources is being studied in many countries and it offers the best method of increasing the total supply of human food." (*World Population and World Food Supplies*, George Allen and Unwin Ltd., London, 1954.)

It is probable that most agricultural authorities support the views expressed by Russell and Kellogg but there are others who are not so optimistic.

The third method of increasing food supplies will not be dealt with here. It is not strictly a method of increasing but rather of preserving and extending the foods that are produced. That means reducing loss in storage, improving transportation, eliminating waste and deterioration, improving methods of processing and preservation, increasing extraction rates and the like (*see CROP DRYING AND PROCESSING*). Attention to these matters could contribute substantially to the food supplies of the future.

E. SOIL CONSERVATION

The problem of maintaining and restoring soil fertility is one that is common to farmers the world over. Through the centuries changing climates and the cropping practices of man have resulted in the permanent or temporary loss of large areas of land to agriculture. The full extent of the vegetative cover in the eastern Mediterranean region during the pre-Christian period and at the beginning of the Christian era is not known but the available evidence indicates substantial areas of tree and plant growth. Much of that growth later disappeared and millions of hectares of land became desert. After 1945 extensive land development and reclamation projects were initiated by India, Pakistan, Iran, Israel and other countries in the area extending from India to the Mediterranean. In 1957 the FAO began a survey of conditions in the countries of the Mediterranean region, including France, Spain and Italy, where conservation and rehabilitation programs were in process.

Old Chinese records tell of land destruction and abandonment centuries ago. In later periods many thousands of hectares of land were either completely eroded or buried and abandoned. In south China nearly all of the cleared hillsides were stripped of their soil cover. In some areas soil on the upper slopes of hillsides became so thin that crops such as sugar cane and corn had to be replaced with sweet potatoes and peanuts. Records indicate that the Yellow river in 1934 carried silt equivalent to 145,000 ha. of land with soil one metre deep.

Much of the land in the densely populated parts of Latin America is extremely susceptible to erosion. Removal of the original cover and cultivation of the slopes and valley lands of the Andean

region has resulted in extensive soil loss. Wind erosion on the great plains of Argentina and Uruguay and in parts of Paraguay and southern Brazil has been the cause of much concern. Loss of soil from erosion is thought to have contributed to the low-calorie diet of the people in certain Central and South American countries, as revealed by the FAO world food survey of 1946.

In tropical countries where rainfall is heavy the removal of forest cover and the planting of land to coffee, bananas, pineapple and other crops results in heavy erosion, particularly where contour cultivation is not practised. In northern Thailand, Sumatra, Sarawak and elsewhere, large-scale soil erosion and floods result from the custom of felling virgin jungle, planting from two to four crops of upland rice and then abandoning the land to the elements. In Malaya upland tea production has developed on strip terrain where, on many estates and small holdings, good management and conservation practices are largely lacking. The sand and silt load of some rivers: the banks of which are being cultivated, has resulted in deposits that restrict navigation.

Wheat yields in medieval Britain are variously estimated at from six to nine bushels per acre. Some economic historians attribute these low yields to loss of soil fertility. With better husbandry and the use of manure and fertilizers, yields have been increased severalfold since then.

In the 18th century rapid settlement of the piedmont plateau of the southeastern United States led to the clearing of woods from land that went into cotton, corn and tobacco. With the land under clean cultivation and the rows running up- and downhill, the heavy rains of the region washed the soil away. This happened, too, on the heavy black soils of Alabama, Mississippi and Texas. Millions of acres were cleared and cultivated, a great proportion was seriously damaged and much of it was abandoned.

On the western Great Plains of the United States and Canada, farming practices involving large-scale mechanization led to severe loss of organic matter. In dry years, particularly during the 1930s, dust storms resulted in much drifting of soil and serious land and crop loss.

The conditions described have probably been experienced by new countries everywhere. Land is at first plentiful and cheap. Labour and capital are scarce and expensive. Economic conditions dictate that more of the cheaper factors of production be used than good husbandry would prescribe, so land is used extensively and production per acre is low. Production in terms of labour—a scarce factor—is high. Fertility is sacrificed to the building of capital goods.

In time the seminomadic and soil-depleting phase of farming passes. Population becomes more stable. Capital is acquired. Motor power and machinery supplement labour. Fertilizers, pesticides, weed killers and better seed can be purchased and used. Fence rows and stones can be removed, land can be leveled and tile-drained. In short, a better balance of production factors can be applied.

Along with these changes comes increased knowledge of how to prevent erosion. The scientist and experimenter have contributed new varieties of grass that provide better cover and sod, thus holding the soil in place. New techniques in cultivation—contour farming, the use of trash or mulch cover, the planting of windbreaks, alternate use of grain and row crops or summer fallow—help to control both wind and water erosion.

It would be a mistake to assume that these new techniques and aids to production are everywhere in use and that beneficial results are everywhere apparent, for they are not. But there are some very encouraging developments. Yields of grain in Britain and in the countries of western Europe have been increased very appreciably. There is evidence here and there of improvement in the newer countries where records are available for half a century or more. More and better animal husbandry is also contributing to soil conservation. With the knowledge of husbandry now available and with the power and materials of industry at hand it is actually possible not only to restore fertility but to build a more productive soil than nature provided originally.

One should not dismiss this topic without a reference to river basin or watershed development. Typically, the planning of a

river-basin development includes measures to prevent too rapid runoff of water from rain or melting snow. Preservation and restoration of forest cover may be involved. Land on the hill slopes may be farmed on the contour or even terraced. A portion of the land devoted to annual crops is converted to pasture and to forage crops. Sheet and gully erosion is checked by various kinds of restraining works. Destruction of riverbanks is impeded by tree plantations and brushwork. The rapid flow and destructive effect of streams and rivers is reduced by the introduction of dams and other built-in impediments.

The water of many river basins is used to irrigate land. In temperate zones where variations in rainfall require the storage of water from rain and melting snow to ensure supplies for the dry season, dams are built to create storage reservoirs. From these, water is conveyed in ditches to land prepared for irrigation. In parts of the world where rainfall occurs frequently and with more or less uniformity throughout the year, thus ensuring a fairly constant river flow, water is diverted into irrigation ditches with the aid of gates and simple weirs or barrages, no reservoir being required.

In addition to these conservation and irrigation aspects, a river-basin program may afford the basis for a forest products industry; provide electrical power and water supplies for both urban and rural use; prevent flooding and destruction of farmlands and urban property; contribute to navigation; improve sanitary conditions where urban or industrial waste is discharged by ensuring year-round supply and flow of water; and improve the fishing and hunting opportunities and provide water-front building sites and camping grounds for recreational purposes.

F. LAND TENURE AND AGRARIAN REFORM

Outdated systems of tenure often prevent the adoption of new methods of farming. Insecurity of tenure may result in lack of incentive to improve a holding—to maintain or build soil fertility or to improve buildings and fences. Rigid laws and customs may perpetuate cropping systems and practices which deplete the soil and reduce yields. Excessively large holdings may impede progress if the owners lack the desire, the ability or the capital to develop their property. Excessively small, fragmented farms lead to much waste of effort and prevent the adoption of modern methods of husbandry.

Land-tenure reform attracted attention following World War I and played a still more important role in agricultural development after World War II. The measures adopted concerned redistribution of land, consolidation of holdings, land registration, improved leasehold arrangements, control of rents and changes in land taxation. For discussion of the history and development of programs in this area see LAND TENURE: ECONOMIC AND AGRARIAN ASPECTS; LAND REFORMS.

G. PRODUCTIVITY AND INCREASED OUTPUT

World agricultural production in 1956-57, according to the FAO, was 17% above the average of 1948-52. Output was running slightly ahead of annual increases in world population. The increase in productivity, particularly in countries of the western world, following the mid-1930s is one of the striking achievements in agriculture. What has occurred might well be referred to as a second agricultural revolution.

In the United Kingdom productivity in agriculture in 1952-53, expressed in terms of labour, was 58% above the 1937-39 average per man-hour, at 1951-52 prices. Between 1940 and 1958 the total output of farm products in the United States increased about 36% while output per worker nearly doubled. The productivity increase per worker was greater than had occurred in the previous 120 years. In Australian rural industries the output per worker in 1951-52 was 12% above that of the late 1930s. The average for the years 1950-54 in Denmark was 49% above the 1935-39 average. In Canada the net product per unit of labour in agriculture averaged 80% more in 1953 than in 1942. Even after making reasonable allowance for the difficulty of measuring agricultural output and for the variations caused by weather, the record of production in much of the world was impressive.

The major part of these increases probably resulted from the use of more machinery, power and materials of production. Much of it, too, was attributable to science, technology, and education. For example, the increase already quoted for the United Kingdom was achieved with the aid of a 168% increase in farm machinery and very great additions in the amount of lime and fertilizer used. In Canada annual purchases of machinery by farmers from 1948 to 1954, with adjustments for changing prices, ran four to five times the purchases of the period 1935-39. World summaries exclusive of the U.S.S.R. provided by FAO indicate that in 1955-56 from 103% to 112% more of the major fertilizer ingredients were used than in 1938. There were 7,700,000 tractors in use in 1955-56 compared with 1,700,000 in 1949-52.

But back of the machinery and materials of production, the better husbandry and the use of available equipment to best advantage was research and experimentation. From the tropics to the subarctic, in hundreds of centres throughout the world, research and experimental effort were contributing to increased productivity. Advances were made through the development of new varieties of plants to withstand drought or mature quickly enough to avoid freezing; the creation of new fertilizers, pesticides, fungicides and weed killers; the development of new production techniques and improved farm management; improvements in breeding, feeding, housing and management of livestock; and better understanding of nutrition and disease control. Extension services spread the techniques of good farming. This together with progress in transportation and marketing greatly expanded the frontiers of production. (See also AGRICULTURAL EDUCATION AND RESEARCH.)

H. WORLD CENSUS OF AGRICULTURE

Censuses of agriculture are held periodically in many countries. Originally, each of the various national censuses followed its own pattern in accordance with national needs and conditions. To promote the collection of comparable agricultural statistics, the former International Institute of Agriculture (*q.v.*) launched a program for a world census of agriculture in 1930. Forty-six of the 42 countries and 24 territories participating took a census by farm holdings for the enumeration of areas under crops and livestock in one operation in accordance with a standard form. The institute presented a program for a 1940 census of agriculture, but the outbreak of World War II prevented its completion.

A flexible plan for the 1950 world census of agriculture was presented by the FAO, which took over this responsibility from the International Institute of Agriculture. The minimum program covered principal characteristics of the holding such as size; form of tenure, land use and means of production available, including numbers of residents and livestock. An expanded list (for those countries able to undertake it) included such additional items as number and characteristics of the people employed in agriculture and the volume of crop production and of wood and fishery products in the agricultural holdings. Fifty-two countries and 54 territories participated in this world census.

For the 1960 census the FAO proposed a more flexible program with considerable expansion of some sections including those relating to land tenure. The scope of information on certain other items, especially in the expanded list, was broadened in view of the increased possibility of obtaining data through the use of sampling techniques. While in the past information on all census

items was usually collected simultaneously from all holdings by interview and related to a predetermined point or period of time, by mid-20th century many countries had used a sampling approach. The 1960 census program recognized the value of this trend and of the study over a period of time of certain items such as employment in agriculture.

Ideally a census should include all agricultural holdings whatever their type (family or commercial), size and location. Practical considerations, however, have limited the enumeration to holdings that conform to certain criteria as to size of holding or operation or both. These criteria vary from country to country.

The 1960 world census of agriculture envisaged the collection of data for all individual holdings by direct enumeration wherever possible; but in countries lacking the necessary funds, personnel and physical facilities to prepare and carry out such operations, sampling methods were effectively substituted. In other countries where detailed information is needed for some census items and only national totals for the others, a combination of complete enumeration and sample survey was used.

Sampling helps ensure the quality of data. The measurement of sample areas for area statistics and the weighing of crops from small sample plots for yield statistics provide examples of such refinements. Such methods are particularly useful in countries where the majority of farmers are illiterate. Sampling methods are also used in assessing the accuracy of census data already collected, by making one or more follow-up surveys taken by specialists.

In addition to sampling, other methods and techniques are applied for improving the quality of national censuses. Special procedures often are needed in countries where agricultural practices are primitive. The use of independent sources of information to obtain or to check data is of great importance. To test the census questionnaire, definitions and enumeration procedures and to determine appropriate methods for the collection and processing of data, pilot censuses and pretesting surveys are useful, particularly in countries lacking previous experience in census work.

Participation in the world census project is promoted by the FAO through assistance to countries in planning, taking and tabulating the censuses in various ways. FAO has published reports on the experience gathered from past world censuses. FAO also advises countries on census questionnaires and instructions and has provided a number of studies of sampling procedures. Government officials are given training in special regional training centres on censuses set up for the purpose and experts in censuses and sampling are provided to countries requesting them. In view of the difficulties experienced by the countries in organizing and completing the tabulations of census data, FAO made a particular effort to assist various countries in data processing and tabulating by: (1) studying the existing facilities, methods and techniques for data processing, and the preparation and dissemination of informational and training materials on this subject; (2) developing plans to provide assistance, advice and special training on the organizing and operating of census tabulations through experts, and by organizing special training centres for census tabulations; and (3) exploring possibilities for central tabulation of agricultural census data by electronic equipment for those countries which may desire such a service. Several countries expressed interest in participating in such a scheme, provided the confidentiality of their census data is ensured by international supervision, and should there be savings in processing costs and time. (See also FOOD AND AGRICULTURE ORGANIZATION.)

See Food and Agriculture Organization, *Report on the 1950 World Census of Agriculture*, 3 vol. (1955 et seq.). Vol. i gives census results by countries; vol. ii is a study of various national censuses; vol. iii is an analysis of the main subjects included in the censuses. (A. H. BA.)

II. UNITED STATES

The first immigrants to America in the 17th century went not to set themselves up in farming but to trade with the natives, fish and search for gold. Trading and fishing from the outset absorbed

the attention of some, but most immigrants were soon forced to turn to agriculture, which continued to be the mainstay of colonial life thereafter. The agriculture they practised was very different from that of the old world. English practices influenced colonial agriculture everywhere, particularly in New England. but in the middle colonies the Dutch, Germans, Welsh, Scotch-Irish and Swedes and in the southern colonies the French Huguenots contributed to the developing agricultural pattern. All these groups brought with them agricultural practices, seeds, farm tools, livestock, cuttings and plants that varied widely and ensured a cosmopolitan mixture of methods, techniques, plants and livestock.

More important in shaping the growth of agriculture in the new world was the great abundance of land, its cheapness and ease of acquisition, the dissimilarities of soil and climate, the freedom of enterprise, the initiative of the settlers and new commodities and practices acquired from the Indians.

A. AGRICULTURAL BEGINNINGS

1. Indian Agriculture.—The agriculture practised by the Indians varied widely from section to section. Corn or maize: the Indians' greatest gift to the white man, was commonly grown throughout the western hemisphere, but in what is now the United States it had perhaps attained its highest state of cultivation and was grown on the largest scale in the Iroquois country of the Mohawk valley. There were found substantial fields of corn and storehouses filled with grain. Farther south, tobacco was grown for smoking, but corn constituted the principal food of the Indians other than meat and fish. Sweet potatoes, squashes and beans were other important foods in the Indian diet, as was wild rice in the lower south and in the upper Mississippi valley. In the semiarid interior basin, a highly organized form of communal irrigation was practised which was to point the way centuries later, for reclamation of dry lands.

Most Indian groups in the colonial period had a complex and fairly well-organized system of agriculture which was highly useful to the conquering Europeans. The Indians' clearings in areas of heavy forests were quickly seized for grain production, and their stores of grain were robbed or destroyed in the frequent wars. During some of the most trying times in the early days of Plymouth and Jamestown, these stores of grain were opened to the settlers for barter. The Indians' knowledge of the soil, their primitive methods of cultivation that required little labour, the vegetables and grains that they produced and their utilization of wildlife were all borrowed by the settlers struggling to adapt themselves to pioneer life.

In the first years of Jamestown and Plymouth the immigrants had considerable difficulty in adjusting themselves to the new country, ravaged as they were by disease and Indian conflicts. Though at first succoured by the Indians, the newcomers were actually close to starvation more than once. During this time they were dependent upon England for many of their foodstuffs, so slow were they to recognize and take advantage of the possibilities of the land surrounding them. At times malnutrition, dysentery, malaria and typhoid so weakened them as to make impossible the labour of clearing the land of its heavy forest cover for the planting of grain.

Gradually the first settlements became self-sustaining and even able to sell surplus foodstuffs to newer colonies. Better order was established through the use of more rigid political and social sanctions and the elimination of malcontents. Increased immigration of yeoman farmers and the coming of indentured servants and Negro slaves provided the labour essential to clearing land, preparing the soil and planting and harvesting the crops. Abandonment of communal and company ownership of the land and its fruits, the recognition of individual rights in land and the greater freedom allowed settlers further contributed to the progress of colonial agriculture.

2. Colonial Land Policies.—When the promoters of the trading companies were brought to realize that profits would not be forthcoming from company operation of the settlements, they turned to the land, from which they hoped, through sale, leasing or quitrents, to derive revenue. In Virginia and the Carolinas

some early investors came to control large tracts. Elsewhere, in Pennsylvania and Maryland, income from rents and sales was relatively large. Efforts to establish aristocratic systems of land tenure with great estates held by the few, and with tenants, servants and slaves performing the labour, however, were not so successful as anticipated. The existence of 13 colonies, all having virtual control over their own internal problems and long neglected by the British privy council, each attempting to attract population, develop its resources and settle its abundant lands, made difficult the kind of tenure from which land promoters might benefit.

Early plans, consequently, for establishing the manorial system or, if not quite that, at least for keeping ownership of land in the hands of an aristocracy were discarded in practice if not in law. Instead, full ownership was made easy in most colonies. In a few, notably New York, where huge grants were made by the governor's council to favourites and men of influence, a concentration of ownership was established which was to retard development for nearly two centuries.

The founders of New England favoured an orderly, systematic growth with a fairly tight rein being held by the controlling Puritan group. The movement of individuals helter-skelter to the frontier was certain to irritate the Indians and endanger peace and security. Better, it was thought, to ensure a compact movement by requiring that groups interested in establishing new communities petition the legislature for a grant of a township of six or eight square miles, in the centre of which a town would be laid out. After survey, the petitioners or proprietors would be assigned residence lots in the village and meadow and forestland outside for farming operations. The original proprietors could divide the land among themselves, whether they settled in the town or not, or they might admit later applicants to share in the division. Newcomers not having proprietor's rights would have to buy from existing owners. The system was not intended to be revenue producing, and access to land by discreet persons in good standing was not difficult. Though there was some speculation in proprietors' rights, the township grant to groups and subsequent division among the members tended to produce a widespread diffusion of land ownership that was in sharp contrast with the situation developing in the Hudson-Mohawk valley or in the southern plantation country where great estates were being created.

In the middle colonies, notably in Pennsylvania and Maryland, land distribution was planned to produce revenue. Manors and other large holdings were established, but so were the more numerous small holdings. Rents constituted a major source of revenue to the proprietors and their families throughout the colonial period, but they were not oppressive nor did they retard immigration and development. On the contrary, an enlightened policy of easy land distribution, the degree of freedom guaranteed and vigorous efforts to solicit immigration combined to make Pennsylvania the fastest growing and most prosperous of the colonies.

South of the Potomac a more aristocratic system of land ownership emerged, not so much the result of policy as of economic conditions. There the headright of 50 ac. was assured to each person coming into the colonies. Indentured servants were entitled to the headright when they had served their period and were ready to start farming. Ship captains, slave importers and others bringing servants or slaves were entitled to a headright for every person they transported. With these rights it was possible to accumulate large ownerships. Although large and small owners existed together, there is little evidence that the small farmer played an important role in the economy or politics of the south.

3. Colonial Agriculture.—The pattern of land ownership in the American colonies was shaped as much by the nature of the land as it was by land-disposal policies. New England is a plateau region extending from the mountains of the west and north to the narrow coastal plain, cut deeply by swift-flowing and unnavigable rivers with narrow valleys. Its soil is thin, rocky and infertile and could not produce the lush rural life of parts of the south. Unless he lived near the growing seacoast towns, where

there was a market for cheese, butter and vegetables as well as for grain and meat, the Yankee farmer usually could not specialize. Remote from markets and lacking transportation facilities, he could expect to sell only what he could drive to market—livestock. He had little income and could buy little; hence he had to produce most of the items he needed. In his near-subsistence condition, he became ingenious in making his own tools, clothing and furniture, and at the same time he learned how to wrest from the land the most that it could produce.

Fuel came out of the Yankee farmer's wood lot, sugar and sirup were made from the sap of the maple tree, forage in the summer and hay for the winter feeding of sheep, cattle and horses was provided by the meadows and patches of cleared land too rocky for cultivation. Corn, wheat and rye were produced on the more level upland plots. Steeper-sloped land was used for pasture. Such a diversified economy did not call for extensive tracts, and the average farm was small. This made possible a relatively dense rural population having no wide disparity in wealth.

In New York and Pennsylvania with their wider valleys, more level land and better soil and with navigable rivers such as the Hudson, Delaware and Susquehanna, farms operating on a commercial scale with wheat as their major cash crop were common. The large Hudson river estates farmed by numerous tenants were unmatched elsewhere in the north. On the rich limestone soils of southeastern Pennsylvania the Germans followed the best farming practices in America, though even they concentrated primarily on one crop—wheat.

Tobacco was the staple crop of Maryland and Virginia. An increasing demand for it in England and Europe and the adaptability of American soil and climate to its culture encouraged its widespread planting. Tobacco raising requires intensive labour in the preparation of the seedbed, the transplanting of the seedlings, frequent cultivation, elimination of worms, picking, curing, packing and transporting to market. On the tobacco farms and plantations, indentured servants in the 17th century and Negro slaves in the 18th provided labour for the planters. Eventually, favourable prices led to overproduction with attendant price declines. Efforts to control production took various forms, including legislation requiring that only superior grades be exported.

Tobacco and Negro slavery made possible the successful development of the plantation economy in Virginia and supported the fine homes, lavishly furnished and bountifully supplied with the best of food and drink for owners and guests. They made possible the leisure time which the southern planter could devote to travel and education, political activity and leadership at all levels. Except on the remote frontier, small farmers also made tobacco their major crop.

In Georgia and South Carolina, rice and indigo were the major staples. Rice cultivation required a greater capital investment than tobacco or wheat. After the arduous task of clearing the low tidal lands along the streams was accomplished, canals, ditches and control valves had to be constructed to flood fields in the early season and to drain them later. Heavy investments, moreover, had to be made in machines for hulling and polishing the rice. These requirements plus the necessity for rotating fields made large-scale operations essential. Men of small means were able to engage in tobacco or cotton raising but not in rice cultivation.

The backwardness of agricultural practices in colonial America impressed English and European travelers, who could not understand the reasons for thin plowing, absence of rotation, neglect of livestock and manures. They did not realize that the abundance of land, the ease with which it could be acquired, its cheapness and the high cost of labour made land expendable. Also, colonial farmers and planters, in building a new country which lacked capital, were erecting farms and plantations with their own labour and that of their servants, and had to make their capital out of the land. Hence, they followed practices long since abandoned in the old world. They exploited the land without regard to its future use, mining the soil of its mineral and vegetable matter.

Agricultural tools in use in the colonial period were primitive. (The history of farm machinery is covered in FARM MACHINERY.)

The sickle and cradle were both used in harvesting wheat. Threshing was still done by the flail or by treading out the grain. Hoes and mattocks were employed to prepare land for seeding, though crude plows replaced them on all but the most backward farms as draft animals were imported. Two-wheeled wooden carts hauled by oxen or horses carried produce to market in the summer; sleds were used in the northern colonies in winter. Great tobacco casks were rolled to the rivers for shipment. Hoes, axes, spades! simple harrows, pitchforks, scythes and wheelbarrows were improvised by the farmers themselves, with the ironwork being hammered out by nearby blacksmiths. Badly designed plows permitted only slight breaking of the soil. Not until Charles Newbold of New Jersey produced a cast-iron plow in 1797 and Jethro Wood of New York patented a plow with interchangeable parts in 1814 and 1819 was a practical, cheaply produced and light draft plow that worked well in most eastern U.S. soils available.

Livestock importations began almost with the arrival of the first settlers. Cattle, hogs, sheep and horses were brought from England, Sweden, Spain and the Netherlands and contributed their characteristics to American stock. Along with them were brought English grasses, for the native grasses, though rank, lacked nutriment. Fencing and stabling were not thought to be so essential as other factors in farm making and were among the last tasks to be undertaken. Beef became an item of export, though its quality was low, but for the most part cattle, sheep and swine were kept for domestic use.

British colonial policy, though based on the mercantilist idea that the colonies should supplement the economic life of the mother country, was doubtless more beneficial than it was harmful. Virginia and Maryland tobacco farmers found a ready market for their produce in England, where they had no competitors. Indigo and naval stores produced by Georgia farmers were subsidized. Rice was admitted free into the English market. The British-owned West Indian islands offered markets for wheat and flour, corn, beef and pork. Similarly, agricultural exports to the French and Dutch colonies flourished, in spite of the Navigation laws. After 1763, when enforcement of restrictive measures was tightened, farmers had more cause to complain of the imperial ties.

The loss of British and West Indian markets during and after the Revolution was a heavy blow to American farmers, particularly to producers of tobacco, rice and indigo. For a time the newly independent country was open to competition from imported goods, unable to shut them out or to bargain for concessions. Only with the adoption of the new constitution and the exercise by the national government of its treaty- and tariff-making powers did agriculture emerge from its post-Revolutionary disturbances and enter a new era of expansion with favourable prices. The long conflict between Great Britain and France in the Revolutionary and Napoleonic period assisted this development by creating a demand for American goods.

B. DEVELOPMENTS UP TO THE CIVIL WAR

1. Federal Land Policies to 1862.—With independence the 13 original states retained control over land within their immediate jurisdiction. Massachusetts kept its Maine lands, New York and Vermont fought over the New Hampshire grants, Virginia and North Carolina continued to grant lands in Kentucky and Tennessee, and Georgia, until 1802, sold, resold and forfeited the sales of its Yazoo lands in Mississippi. Ultimately, however, states with western land claims were induced to convey their rights in lands north of the Ohio and in Mississippi and Alabama to the federal government. With the adoption of the land ordinance of 1785, federal policy provided for the rectangular system of survey before sale, the offering of land at public auction and for private purchase after the auction.

The Federalists planned to make the public lands a major source of revenue by selling them at \$1, later \$2, an acre in large tracts which they expected would be bought for speculation. They also sought to control the westward movement of population by the high price and to make for orderly settlement by systematic and slow surveys and competitive bidding at auctions. There was

logic in their plans, but they ran counter to long-established traditions and could not be maintained. Squatting, the practice of moving to new areas before the surveyor had run his lines or the land had been offered for sale, was opposed by federal troops but not for long. It was too unpopular for an administration to evict hardy pioneers struggling to make homes for themselves. Slowly the emphasis upon revenue gave way to a policy of facilitating the development of the west and aiding pioneer settlers to become farm owners.

Between 1800 and 1820 credit was extended to purchasers of government land, but it was halted because it had induced speculators and settlers to buy beyond their means. From 1820 until the end of government land sales, \$1.25 an acre was the basic price. The minimum-sized tract subject to purchase was gradually reduced from 640 ac. in 1785 to 40 ac. in 1832. Pre-emption, the right to buy the land they settled on and improved, was extended to squatters in a series of special acts. In 1841 prospective pre-emption, or the right to settle upon surveyed public lands before they were offered at public sale, was conceded and in 1854 squatting was legalized on unsurveyed lands for which the Indian title had been surrendered. At the same time, lands which had been open to sale for 10 years or more were graduated in price in inverse proportion to the length of time they had been subject to purchase, the lowest price being 12½ cents per acre for tracts which had been on the market for 30 years.

In the meantime, congress granted land to subsidize state universities, agricultural colleges, roads, canals, railroads, swampland drainage and common schools. Beneficiary states, colleges and canal, railroad and construction companies all vied with each other for the sale of their lands. All were expected to get as much for their lands as the market would allow. Hence, while congress and the general land office were easing the path to ownership (the Homestead act of 1862 offered free land to actual settlers), the major grantees of the federal government were asking from \$2.50 to \$5 and more an acre.

Not until the Civil War did the federal government curb the speculative buying of public land and such restrictions were not to be altogether effective. Anticipating the settler, speculators invested heavily in the purchase of new land as it was placed on the market. Three great periods of speculation in which many millions of acres were thus acquired were 1816-19, 1835-37 and 1854-57. Speculators, whether small buyers who entered two or three quarter sections or individuals and companies that acquired from 10,000 to 100,000 ac., in no way contributed to the development of the west unless they also invested capital to improve their holdings. Instead, they slowed down progress by forcing settlers looking for cheap lands to go farther afield in their search, pushed the frontier deeper into the Indian country, aggravated the problem of transportation, delayed the extension of local government, the school and the church and made for greater isolation of the settlers. Most serious, the speculator, by intruding himself between the government and the settler, raised land costs substantially, aggravated an already serious credit problem in the west and contributed to the early development of tenancy.

2. Southern Staple Crop Production.—Staple crop production in the south was not the same after the Revolution. Indigo planting flourished for a time, but without subsidies it soon disappeared as a major crop. Two important new staples quickly pushed to the fore, attracting large capital investments and creating a constantly growing demand for slaves. Cotton had for its kingdom the region from North Carolina west through Tennessee to Arkansas and southwest to Louisiana and Texas. Sugar, like rice, was concentrated in a relatively small area, the lower Mississippi delta and lands adjacent to the bayous of Louisiana. Meanwhile, the other great staples, tobacco, flax and hemp, mere moving westward, following the streams of population into Kentucky and Missouri.

Perfection of the cotton gin in 1793 capped a series of inventions for the utilization and manufacture of cotton that so lowered the cost of separating the seed from the short-staple lint, spinning the thread and weaving the cloth as to enable cotton to compete with wool in the world market. Demand and prices shot upward

and farmers in Georgia, South Carolina and later elsewhere in the south soon began to raise cotton. From a crop of 10,000 bales in the year the gin was made workable, production increased 12-fold in the first decade and went on to make new records year after year. In 1835 the first 1,000,000-bale crop was raised. The record ante-bellum output was 4,508,000 bales in 1859. Cotton had become "king," having long since pushed tobacco aside as the principal staple crop.

Profits in cotton led to a scramble for land suitable to cotton culture. By the hundreds of thousands planters with numerous slaves and substantial bank credit and small farmers dissatisfied with their lot in older and perhaps declining areas sought out places in the piedmont of Georgia and the black prairie and alluvial lands of Mississippi, Alabama and Louisiana where they might plant cotton. These mushrooming cotton areas needed the surplus slaves who could no longer be profitably employed on the worn-out tobacco lands of Maryland and Virginia, and were responsible for the internal slave trade which so scandalized northern abolitionists and foreign travelers. The rapid engrossment of potential cotton land led southern leaders to feel the need for additional territory into which they could carry their slaves and their cotton economy. The annexation of Florida and Texas, the war with Mexico, the move to acquire Nicaragua and Cuba, the conflict over slavery in the territories and the Kansas imbroglio all resulted, at least in part, from the changed situation of cotton and the importance it had in the southern mind.

Cotton was raised by small farmers in 1- or 2-bale lots and by great planters with their many slaves in lots of 100 to 200 bales and more. It was an exacting crop which required much labour, from the planting early in spring throughout the long growing season to the picking, ginning, baling and shipping that extended into the next year. Because it provided work almost the year round, rough work such as chopping, picking, handling and baling, it was well suited to the use of slaves under the charge of overseers. The small farmer who worked in the field with his family and perhaps a slave or two did not count costs, including his own labour, as seriously as did the large planter. Yet he was eager to enlarge his operations, own more slaves and free himself from field work. The larger planter, trying to achieve efficient operation for his extensive capital investment, was even more anxious to expand. He could not capitalize his earnings and float securities to finance expansion as could the industrialist. Instead, he had to undertake expansion through the use of earnings of the land and slaves and such funds as he could borrow.

The ease with which farmers could shift to cotton and sell their crop and the adaptability of much of the southern land to its cultivation induced farmers and planters to lean ever more heavily upon it as their major crop. The high returns of the early period did not last long in the face of rapidly expanding production. From 33 cents per pound in 1818, cotton fell to 9 cents in 1827. In the middle 1830s the price recovered to 15 cents but continued expansion and declining economic activity forced it down to a low of 5 cents in the 1840s. In the late 1850s the price was again up to 11 and 12 cents. The economic pressure upon the planters for increased output was always strong. Capital costs of expansion, including the rising value of slaves, combined with the diminishing margin of profit to ensure the continued cropping that had so ravaged older portions of the south. Soil continued to be expendable.

Fearful of the results of constant cropping, planters tried to anticipate their future land needs by engrossing tracts far larger than they could expect to use for years. In the principal staple-producing areas all the better land not requiring expensive drainage and levees was in private ownership by the 1840s, but only a small part was in cultivation. Land engrossment by the planters dispersed the population, delayed the building of roads and railroads and prevented the compact and intensive development that was proceeding north of the Ohio. This is not to say that small farmers were not found in the south, but they were fewer and their progress was retarded by the scattered character of population, the distance between farms and the slowness with which transportation facilities were introduced.

Low cotton prices in the 1840s and 1850s, while stimulating planters to enlarge their output, also led to more careful attention to costs. Experiments were made with improved seeds, new varieties were introduced and low-yielding lands were abandoned for freshly opened tracts. The saving feature in the southern cotton economy seemed to be that the value of land and slaves was rising rapidly. Upon this increased value planters could finance their deficits.

Emphasis upon cotton did not mean that the planters raised little else. They tried to make their plantations self-sufficient by producing corn, pork and beef—sometimes on land that was not well suited to such purposes—and emphasis was placed on making the plantations independent of foodstuffs, clothing and even ironware from the north. A few leaders who were well in advance of current agricultural practices preached in the farm journals the need for rotation and manuring but they did not win many converts. On the other hand, the regionalists who were arguing for self-sufficiency no matter what the cost had great influence.

In the tidewater counties of Virginia, however, tobacco cultivation, having seriously depleted the soil, was replaced by wheat farming. An agricultural revival of these depleted areas, stimulated by the example and admonitions of John Taylor and by Edmund Ruffin in his *Farmer's Register*, brought about a notable recovery. Crop rotation, the application of marl, gypsum and guano and local animal manures, deeper plowing and better cultivation made possible large yields. The new tobacco region was in the piedmont of Virginia and North Carolina and across the mountains in the bluegrass country of Kentucky. Rice and sugar cultivation flourished in limited areas of Georgia, South Carolina and Louisiana, and it was there that the plantation aristocracy reached its highest development. In the sugar region of Louisiana, for example, 1,161 producers shared in the 1858 sugar crop that was worth \$25,000,000, and only 208 of these were large producers of 500 hogsheads or more. One hundred and six planters received an average of \$55,506 for their crops.

There has been much argument as to whether Negro slaves contributed to or detracted from the prosperity of the south. It is certain that the bulk of the immigrants, repelled by slavery, went elsewhere, and they constituted one of the greatest potential additions to the wealth of a community. It is also clear that the south was not able to hold its own population, for there was a substantial emigration from the slave states to free territory.

The south had been led by economic forces to invest its surplus capital in an institution which the rest of the civilized world was turning against. Not for long could the section stand against the tide of moral opinion that was demanding restriction and abolition of slavery. Yet the institution of slavery, or the presence of the Negro, so unified the south—the piney woods farmer, the southern mountaineer, the Cajun and the planter—as to enable it to fight four years of bloody civil war to protect itself against the northern interference it feared.

3. Northern Mixed Farming.—Farming in the north was more self-sufficient in character and less devoted to the production of staple crops than in the south. True, every farmer sought to produce marketable crops to finance capital improvements. Dairy farming near growing cities served this purpose. Wheat qualified as a staple cash crop for a few years until the accumulation of parasites, diseases and exhaustion of the soil necessitated rotation of crops. Livestock farming required capital investments that were beyond the reach of most farmers, who raised cattle, sheep and hogs as a side line.

In Virginia and Pennsylvania at the opening of the 19th century, wheat was the major crop. Its keeping qualities, value in relation to its bulk, the almost universal demand for it and the fact that it could be grown almost anywhere in the north with no great amount of labour led to its widespread distribution. Wheat was grown most extensively on the rich limestone lands of southeastern Pennsylvania by the descendants of the early Mennonite and Dunker immigrants. In the 1820s the Genesee valley of New York, which had a similar soil and climate, became a major wheat area. Later Ohio and, just before the Civil War,

Illinois became centres of wheat production.

Purchasers of or tenants on the lands of the Holland Land company, the Pulteney associates, the Livingstons, Schuylers and Van Rensselaers of New York sought to meet their obligations by tendering wheat. Like the southern planters, they were driven to plant their staple year after year with similar results. Disease and insect infestation, soil depletion and declining production with rising costs made it difficult for them to compete with farmers on the cheap virgin soils farther west. Troubles over collections and antirent wars resulted. Discouraged farmers by the thousands gave up the struggle, abandoned their farms and joined the westward trek. The older parts of the north were having to adapt themselves to the new competition of the west as English farmers after the repeal of the corn laws (*q.v.*) had to adapt their scheme of farming to the flood of cheaply produced U.S. grain. Abandoned farms soon dotted the hillsides of New York and New England, but there was no great loss. Much of this abandoned land was probably marginal when it was first settled and had been made to support families only by the hardest labour. When wheat as a major cash crop was no longer economically feasible for the better valley lands of New York and Pennsylvania, the farmers turned to dairying, sheep raising, vegetable crops and truck gardening and other specialties.

The flow of population from the older states was joined by increasing numbers of immigrants from England, Germany, Norway and Sweden. Some new immigrants, notably the Irish, stayed in the east to take construction jobs, but others sought the cheap and fertile lands of the west which were being brought to their attention by emigrant agents and representatives of land companies.

Most people moving westward took no great amount of capital with them. Some grabbed more land than they could develop, a common failing so agricultural authorities said, but the expense of farm making and the meagreness of their resources soon turned their operations into small-farm development. Following the quarter-section lines of federal surveys, tier after tier of farms were established, fairly compactly arranged except where the speculators intruded. These farms were not separated by the hundreds of acres of unused land found in the south and as a result, schools, churches, roads and local government all came earlier. Ohio, Indiana, Michigan and Wisconsin were filled with small, single-family farms, mostly owned by the operators. Despite the existence of speculative holdings and a few large estates, Jefferson's ideal of an agrarian democracy came closest to realization there.

As settlers moved out of the previously wooded region of the older states into the prairies of Indiana, Illinois and Iowa they met with conditions which called for greater capital investment. Lumber for building and fencing had to be brought into the treeless prairies. Heavy breaking plows hauled by a number of pairs of oxen were needed to break up the thick prairie turf, and lighter steel plows, first perfected by John Deere in the 1840s, were thereafter required for the annual turning of the soil. To meet the cost of the land and the improvements it was necessary to raise grain on a substantial scale, and this required expensive machinery. Some men of capital came to the west to develop estates manned by hired hands and tenants. They appeared in almost every community, where they provided jobs for less-fortunate immigrants not able to begin farming on their own. Some of these workers by hard labour and careful saving were able to attain ownership; but others remained permanently as labourers or tenants. A few great estates were thus established at an early date.

Seventy years after the constitutional convention of 1787 agriculture had changed greatly. The population had spread over large areas in the Mississippi valley, creating more than 1,000,000 new farms. Cotton, tobacco and wheat pouring from these farms found markets abroad which provided exchange to balance U.S. trade. England's reliance upon U.S. cotton and wheat was to be of importance in the shaping of U.S.-British relations during the Civil War. The building of roads, canals and railroads had opened up new areas previously inaccessible to farmers and had made it

possible for them to ship their surpluses to market. Commercial agriculture had made great strides. Farm machines such as the reaper, improved plows, drills and harrows and the substitution of the speedier horse for the cumbersome ox had contributed to this end. Farmers were getting to market more frequently; their families had easier access to the churches; schools were becoming available. The old type of near-subsistence farming and the old isolation were passing.

Increasing commercialization of agriculture made the farmer more subject to the fluctuations of the market and aggravated his distress in periods of low prices. This was the more true because the capital demands of agriculture made borrowing common, the mortgage a feature well known to most farmers. The depression years of 1858-61 brought hard times to many, particularly those who had bought land in the high-price period just preceding. Many failed in their efforts to become owners and were reduced to tenancy. Some moved elsewhere to try again, perhaps to Kansas, Nebraska or Minnesota where free homesteads were available.

4. Livestock. — From early times livestock constituted a minor yet significant feature of farm economy. Cattle, sheep, swine and horses—mostly grade (hybrid) stock in the colonial period—were given little attention as to breeding, feeding and housing. Cattle herding in North Carolina and Louisiana developed into a considerable business for a time. Hogs ran wild in the forests and swamps, living on mast (nuts), roots and seeds and providing, when dressed, pork of a distinctly inferior quality. Sheep likewise produced inferior wool which was used on the farms for homespun goods.

Before the end of the 18th century farmers and planters of wealth had imported purebred stock that contributed to raising the standards of cattle. First the Devons, then the Durhams were brought to Virginia; later Kentucky, New York and Ohio became centres for fine stock. Descendants of these early importations were popular for more than half a century until the better milk breeds and the Hereford and Angus replaced them. Early cattle fanciers prized heavy fat stock that took years to reach the desired weight, but pasture and corn were cheap.

The abundance and cheapness of grassland in Ohio, Indiana, Illinois and Missouri and the large surpluses of corn these states produced ensured that cattle and hog feeding would be centred there. Dealers bought the farmers' surplus stock, drove them to a central feeding ground where they were fattened and then drove them overland to market. Cattle droving thus flourished until the coming of the railroads to the middle west in the 1850s. The feeder-cattle industry was well under way before the Civil War, providing a pattern for corn-belt agriculture which, with the feeding of hogs, was to continue into the 20th century.

Everywhere the ox was an important beast of burden. In most of New England oxen were employed more commonly than horses, although the Morgan horse held sway in Vermont. Where time was of less importance and agriculture was more primitive the ox prevailed. Oxen could be raised and trained on the farm, while few small farmers could afford to enter horse breeding. Oxen, moreover when past their prime were useful for their meat. More progressive farmers in better areas, however, relied on the horse or mule.

The Morgan horse, a good all-purpose animal, and the Conestoga horse, a heavy draft animal developed by Pennsylvania Germans, were the best U.S. types at the opening of the 19th century. Later, Kentucky became famous for its fast driving horses and Missouri for its mules. The cost of rearing horses in the west was low because of the abundance of grassland.

The typical hog was a long-legged animal with a long snout, lean shanks and little meat. Much of the time hogs depended on their own ability to find food in the forests and to escape the wolves. On the southern plantations where droves of them were kept in the woods, unattended and unfenced, slaughtering was done by rifle in annual hunts. The pork was heavily salted, the poorer grades being doled out to the slaves. Only in the upper Mississippi valley was hog raising becoming a major feature of the farm economy. There, with rich pasture and cheap corn, hogs

could be fattened to considerable size, dressed and shipped by flat-boat down the Ohio and Mississippi rivers to markets at Natchez, Memphis and New Orleans; or they could be driven overland to Cincinnati, St. Louis or Indianapolis for slaughtering. Hog drovers worked through Ohio, Indiana and Illinois, buying the surplus stock of individual farmers. Improvement in the quality of swine came through the use of better breeds, confinement and grain feeding, and by 1860 the modern corn and hog belt was becoming well defined, stretching from Ohio into Missouri and Iowa.

The modern sheep industry began with the importation of fine-wooled Spanish Merino sheep in 1800-12, followed by the Saxon breed from Germany and the Rambouillet from France. Sheep farming flourished on the hillsides of Vermont and New Hampshire where clearings were being abandoned by grain farmers who could not compete with the Genesee and Ohio regions. For a time Vermont led the union in numbers of sheep in proportion to its population. The high quality of its purebred animals with their large yields of fine wool assured a demand for all the state could produce and brought high returns to the breeders. But New England farmers could not compete for long with sheep raisers in Ohio and Michigan where land was cheaper and pastures were richer, and by the 1840s sheep farming was moving westward into the newer states of the upper Mississippi valley.

5. Agricultural Journals.— Before the day of agricultural colleges and experiment stations, leadership in agricultural improvement was in the hands of a notable group of writers, editors and farm journalists. Among these were John Taylor of Virginia, who preached deep plowing, rotation and manuring; Edmund Ruffin, also of Virginia, who advocated the use of marl; Jesse Buel and Luther Tucker, prominent agricultural editors; John Johnston, vigorous advocate of tile draining, with which he experimented on his New York farm; Solon Robinson, a shrewd, noncontroversial writer; and, finally, the ubiquitous and effervescent Horace Greeley. Important journals were the *American Farmer*, *Genesee Farmer*, *Country Gentleman*, *Cultivator*, *American Agriculturist*, *New England Farmer* and *Prairie Farmer*. See also AGRICULTURAL EDUCATION AND RESEARCH.

6. Science in Agriculture.— Technical knowledge of the chemical composition of soils and the essential elements that make for good crops was transplanted belatedly to America through the writings of German and English scientists, the visits of eminent European agricultural scientists such as James F. W. Johnston of the University of Durham and the pilgrimages of Americans to England and Germany for study with men like Johnston and Justus von Liebig. At Yale notable work in agricultural chemistry was being done in the middle of the century by Benjamin Silliman, John P. Norton and Samuel W. Johnson. The latter, having established the essential elements for plant growth, examined the brands of commercial fertilizer then widely advertised and determined the truth or falsity of their claims.

The next step in the application of science to agriculture was the appointment of state geologists who made analyses of rock and soil structures to determine the productive capabilities of various types of soil, the details of which were extensively copied in the agricultural periodicals. Then came the appointment of specialists in the taxonomy of insects who, though they made little progress in developing insecticides of value, did provide useful information concerning ways of combating pests. Agricultural surveys by reputable authorities and government action in importing seeds, cuttings, shrubs and trees from all over the world contributed to the broadening of knowledge of modern methods of farming and to diversification of crops. Most important of the imported crops was sorghum, a cornlike cereal grown for the sweetness of its stalk and for its grain.

C. FROM THE CIVIL WAR TO THE 20TH CENTURY

1. The Civil War and Agriculture.— The Civil War was accompanied by major political and economic developments that had marked effects on agriculture. Southern staple production was brought to a low point by the destruction left in the wake of the armies and by the drafting of field hands. Fields became

neglected and weed infested and drainage ditches clogged and overgrown; livestock was destroyed; levees were breached and bridges and roads became impassable. The freedmen in many cases, refused to accept the work conditions their former owners offered. After a period of unrest they (and many poor whites) were compelled by circumstances to become sharecroppers instead of acquiring the elusive "forty acres and a mule" which radical Republicans had held out to them. Rice cultivation never recovered and sugar and tobacco came back only slowly.

By 1880 a new optimistic spirit pervaded the south. Cotton planting was pushed into central Texas and the northern delta of Mississippi and Arkansas. Diversification, better soil practices and increasing use of fertilizer along with expansion in beef and dairy cattle and the introduction of new crops all aided materially. But this improvement was followed by such problems as the boll weevil, overproduction and marketing problems that were to call for long-range planning and action by the federal government.

Northern agriculture prospered as that in the south suffered during the war. Army demands and renewed dependence of England upon U.S. wheat produced a scramble for the grain. Beef and pork also were in increased demand and prices rose to a level not witnessed since the Napoleonic Wars. Despite the drafting of younger men for the army, farmers met the demands upon them by substituting machines for the labour they were losing. Improvements were made in the reaper, mower, drills, plows, harrows and threshers, and the easing of credit and the rising price level enabled farmers to acquire such machines and actually to expand their operations.

War inflation brought high returns to farmers, but it also induced them to borrow heavily to acquire additional land, purchase needed machinery and build up their livestock. The roots of many of the western farmers' difficulties in the last third of the century lay in the fact that they had borrowed heavily in a period of marked inflation. In the meantime, the northern-controlled congress, freed of the strict constructionist views of the southerners, enacted a series of measures that profoundly influenced agriculture. The Homestead act of 1862 offered free 160-ac. tracts to persons who would settle upon and improve them over a period of five years. It was this offer of free land that was to draw to the new west hundreds of thousands of peasant farmers from Europe and perhaps as many discouraged and debt-ridden farmers and tenants from older parts of the United States.

The Land-Grant College (Morrill) act of 1862 granted lands to each state to aid in establishing colleges of agricultural and mechanical arts and led to the beginning of scientific education for farmers and mechanics (engineers). The subsequent Hatch act of 1887 and the second Morrill act of 1890 went further by contributing to the establishment of experiment stations, extension work and agricultural research. By these three acts congress provided for the development of technical knowledge in the fields of farm management, agronomy and animal husbandry. In 1862 congress also recognized agriculture's importance by creating the department of agriculture. This was an outgrowth of work begun by Henry L. Ellsworth many years earlier when, as commissioner of patents, he had initiated the practice of collecting and publishing, in an annual volume, statistics of agriculture and reports on innovations in farm practice.

Finally, in 1862 congress promised as much as 100,000,000 ac. to assist the building of railroads connecting the Mississippi and the Gulf with the Pacific coast. A decade earlier congress had given land to numerous railroads in the Mississippi valley. The beneficiary railroads, anxious to develop their areas, undertook elaborate advertising schemes to bring them to the attention of prospective settlers and to stimulate and direct emigration thither. Some of these land-grant railroads organized agricultural departments to aid the land buyers by disseminating information concerning modern farm practices, contributed to agricultural fairs, granted low rates for transportation of farmers' machines and exhibits and imported purebred bulls.

2. Agriculture in the New West.— The discharge of the veterans at the end of the Civil War, the rapid construction of west-

ern railroads (the Union Pacific was completed in 1869 and the other transcontinental lines were finished in 1883 and 1884), the extensive emigration-promotion work done by landholding companies in the eastern United States and in Great Britain, Germany and the Scandinavian countries, all contributed to a great migration to the west. Directed by the railroads, homesteaders swarmed over the undeveloped lands in Illinois and Iowa, took up the homestead and railroad lands of Kansas, Nebraska, North and South Dakota and the Pacific coast states and rushed into Oklahoma, where they crowded aside the Indians. By 1880 the modern corn belt was already sending out emigrants to seek land farther west. In the high plains the cattle kingdom had its brief but dramatic day, only to be pushed aside by the more prosaic wheat farmers. Before the end of the century this wheat belt was well on its way toward overflowing, and population was already crossing into the Canadian prairie provinces and into the interior basin of the United States, an area of limited rainfall where an agricultural pattern different from that farther east was developing.

The growth of the corn belt, which extended from Ohio through eastern Kansas and Nebraska, was accompanied by the emergence of tenancy and a small class of landlords owning from 2 to 60 and more farms. In Illinois, for example, only a generation out of the frontier stage, nearly one-third of the farms were operated by tenants; in the richer prairie counties tenants operated as many as one-half. Many of these tenant farmers were taking over the farms of their fathers, which they expected ultimately to inherit, but others were farming land they had no expectation of owning. This latter group of tenants might have considerable livestock and farm machinery and might, as on the hundreds of Scully farms in Illinois, Kansas and Nebraska, own the improvements. It was, however, the landlord who profited from the rise in real-estate values and who had the greater legal protection. As new immigrants pressed into the corn belt the demand for land further strengthened the position of the landlord, who felt justified in increasing cash rents or his share of the crops. Tension between landlords and tenants reached a high point in the late 1880s, with the latter seeking legislation to curb the growing concentration of ownership and to compel fairer treatment of tenants. (*See FARM TENANCY: United States.*)

Corn-belt farm practices continued much as before the Civil War. Increasing dependence was placed on farm machines. Corn was planted year after year on land the farmers thought was inexhaustible, and too many farmers neglected the need for manures, lime, phosphate and cover crops. Agricultural authorities continued to urge that farmers feed more livestock, particularly cattle, and thereby get the profits from feeding while providing the manure essential for the soil. Corn-belt farmers' prosperity, however, came more from the rise in land values and the swift utilization and exploitation of the soil than from intelligent long-range planning. A major development in the corn belt was the extension of tile draining, which made possible planting of corn on land previously too wet for anything but hay and pasture.

Removal of the Indians and the opening of the Kansas-Nebraska country by the railroads made possible the establishment of the cattle kingdom which flourished in the high plains area from the end of the Civil War to the droughts of the late 1880s. Texas longhorns, unmarketable during the war, were driven north in great herds to the railheads at Abilene, Newton, Dodge City or Ogalalla, feeding on the way on the unfenced public domain. When in good condition they were carried by rail to feed lots in the corn belt, where they were fattened for slaughter. The Texas cattle brought with them into the feed lots the tick *Boophilus annulatus*, which promptly infected the local cattle with the deadly cattle tick fever, also known as Texas cattle or Spanish tick fever. The prairie states retaliated by barring further imports.

The Texas cattle reservoir was huge but it consisted of inferior stock that produced low-quality beef. Efforts to improve cattle by importing purebred stock from England promised steady stock upgrading in the long run, but through the 19th century the bulk of the plains cattle remained inferior to the purebred herds that

were developing in smaller lots in the corn belt.

Development of the refrigerated car and artificial refrigeration made possible the shipment of beef to England, which, for a time, frightened the English into believing that such imports might have as serious effects on English agriculture as had the earlier flood of U.S. grain.

The Great Plains cattle kingdom lasted for a generation, but well before 1890 the region was being transformed into the wheat belt. Homesteaders advanced relentlessly into the short-grass country, taking up their quarter sections and pushing the open range farther west. Conflicts between the "nesters" and the cattlemen followed, but time was on the side of the former. What was once considered the American desert was proving to be productive wheat country. Displaced corn-belt tenants, Mennonite farmers from southern Russia, Germans, Swedes and Norwegians joined in this trek into the American frontier. They brought with them strains of hard winter wheat that were resistant to drought, disease and insects. Despite cold winters, grasshopper plagues, long droughts and low prices, the wheat farmers advanced to and beyond the 100th meridian, breaking into thin-grassed land as they proceeded—a development which subsequent events were to show was unwise. Unusually dry years and severe winters forced some of these hardy pioneers backward, but with more favourable weather and rainfall, western Kansas, Nebraska and North and South Dakota again proved attractive.

3. Agrarian Politics, 1870-96.—Post-Civil War agriculture, especially in the new areas of the west and southwest, was largely commercial with emphasis on one crop, such as cotton, corn or wheat. Heavy capital investments for land and its improvement, farm machinery and livestock, including horses and mules, and the high cost of farm credit, generally acquired when money was cheap and prices were high, made the position of the farmer particularly vulnerable when the downward movement of prices set in. With interest, taxes and the cost of the goods he bought made stable by the tariff and monopolistic practices, the farmer found his income shrinking badly while his necessary expenditures remained stationary. After 1873 distress was common among the farmers of the west and south. Since freight rates did not decline in proportion to the decline in agricultural prices, they absorbed an increasing amount of the Chicago price for wheat, hogs and cattle. This led the Iowa or Kansas farmer to blame the railroads for his plight.

There followed a series of agrarian movements that had as their object the ending of the monopolistic practices of the great trusts, the curbing of the railroads by rate-control legislation and inflationary legislation including the reissue of greenbacks and extensive silver purchase and coinage. The greenbackers, the Anti-Monopoly movement, the Farmers' Alliance and the Populists directed their demands to these ends. They also sought to encourage farmers' co-operatives and government farm credit institutions. The agrarian movements provided the only real opposition to the Democratic and Republican parties, which differed little on the fundamental issues of the time. Farmers learned to work together for common ends and won some important state victories; they also had a major share in the enactment of the federal Interstate Commerce act, but their successes were later weakened by the hostility of the supreme court to social control. (*See also AGRICULTURAL ORGANIZATIONS.*)

Great gold discoveries and the revival of foreign trade brought an improvement just before the turn of the century, and agriculture entered its halcyon days culminating in what have been called the "parity years," 1909-14, when farm commodity prices were most favourably related to other prices indexes.

4. Government Collection of Agricultural Data.—Collection of agricultural statistics by the U.S. government was first authorized in 1839 when an appropriation of \$1,000 was made to the commissioner of patents for this and other purposes relating to agriculture. Until the creation of the department of agriculture in 1862 this office continued to publish agricultural statistics that it compiled or that were borrowed from the census reports.

In the sixth census in 1840 the first detailed statistics were compiled of the number of farms, their ownership, acreage, im-

provements, crop yields, livestock and value. Unfortunately, the collection of the data was in the hands of federal marshals and temporary appointees having political influence. The work was poorly done and the data were carelessly transcribed, unscientifically tabulated and inaccurately checked, if they were checked at all. The results were replete with errors, some obvious and easily corrected by anyone using them seriously, others impossible to check without going back to the original manuscript schedules, many of which were lost.

Criticism of the 1840 census figures and methods of compiling them by the American Statistical association led to improvement, but for years the political selection of census takers and clerks resulted in large numbers of errors. Also, the number of inquiries was increasing steadily, making the burden of the questioners difficult. In 1840 the number of agricultural inquiries was 27; in 1850, 45; and in 1860, 55. In that year a misunderstanding between the census takers, the marshals and the tabulators led to the omission of large numbers of livestock—as much as 18%—from the totals of horses, mules, cattle, sheep and hogs. To rectify the blunder a second tabulation of omitted data was included under a cryptic and unclear caption that was only made understandable by a footnote. Most users, having overlooked the footnote, used the inaccurate schedule.

While all early censuses have to be used with caution, later censuses presented their own difficulties by breaking up and changing earlier inquiries, thus making comparisons with previous data difficult or misleading.

The first census in which advance thought and planning were given in the preparation of schedules, by congress and by a board of the census set up by congress, was that of 1850, and the results proved to be a marked reform. In 1870 Francis A. Walker, an outstanding statistician, brought a touch of professionalism to the gathering of statistics. Thereafter, continued improvement was made in collecting, processing and publishing data. In 1902 congress provided for a permanent census bureau to replace the previous temporary bureaus. Statisticians and other experts in various government bureaus, the universities and professional organizations were utilized in planning for data gathering but politics continued to be influential in the appointment of the census takers.

Before 1860 there had been considerable criticism of the agricultural censuses by various states on the ground that their production of farm goods and numbers of livestock were not properly recorded and hence the census minimized their rank in U.S. agriculture. On the eve of the Civil War the census was collecting data which showed that the public land system was not working as its framers and defenders maintained it was. The census of that year revealed a relatively high ratio of agricultural labourers to farms in the frontier states of Kansas, Minnesota, Iowa and Wisconsin. In 1870 the statistics of the amount paid farm labourers further revealed that many thousands of western land seekers had had to settle for farm jobs, not farm ownership. In 1880 the census bureau for the first time collected statistics of farm tenancy which shocked the country, so high was the proportion of tenancy in the new west. Finally, in 1890 the census bureau, under pressure from the west which was greatly concerned about the farm mortgage problem, collected statistics of the number of mortgaged farms, their acreage and the dollar value of the mortgages. These data confirmed widely held views that the west was deeply in debt to eastern creditors, and they contributed to the growing agrarian unrest in the west and the demand for reform of land policies and the establishment of government farm credit.

In the 20th century the statistics of agriculture were found useful in so many ways by governmental and private groups that after 1920 the collection of such data was made every five years.

D. FARMING IN THE 20TH CENTURY

U.S. agriculture has gone through a series of changes in the 20th century that have accentuated many of its problems. From "parity years" through the inflation of World War I to the distressing 1920s, the tragic 1930s and the recovery with World War II, farmers plunged from the heights to the depths and then

cautiously watched the recovery of the 1940s and the rising production accompanied by rising costs of the 1950s. During this period scientific farming as taught in the colleges of agriculture and practised in the experiment stations and on the more progressive farms was having its effect everywhere. Improved farm machines, the combine harvester and thresher, corn and cotton pickers, mechanical planters and milkers and, more than anything else, the introduction of the rubber-tired tractor and the extension of electricity worked a revolution in farming.

Twentieth-century homesteaders continued to press into the new west, mostly the semiarid lands of the region extending from western Texas, the panhandle of Oklahoma, western Kansas, Nebraska and the Dakotas to the Pacific coast. Wheat was their principal crop. Dry farming (*q.v.*) techniques were developed which enabled farmers to conserve the meagre moisture in the soil by a process of dust mulching and by permitting the land to lie fallow to build up moisture for the following crop year. Thomas D. Campbell developed a huge wheat ranch in Montana on which dry-farming techniques were practised, and gave wide publicity to the methods he used. Because the homestead unit was too small for the extensive farming the semiarid lands required, congress in 1904 allowed full section homesteads in the sand-hills region of western Nebraska, which Mari Sandoz was later to picture in *Old Jules*. In 1909 and 1916, 320- and 640-ac. homesteads were authorized. Free land available in such quantities, whatever its character, proved a powerful attraction. World War I brought high prices and a demand for wheat that furthered the movement into the region beyond the 102nd meridian. In a half century an area equal to ten states the size of New York was brought under cultivation.

In the older states of the northeast farming continued to contract, so far as the number of farms and acreage in farms was concerned. Despite certain alarmists, however, the contraction was regarded by most agricultural economists as just and sound. Poor, unproductive land was reverting to forest. On better land farmers were doing well. The growing demand for dairy products and the extension of hard roads made possible the enlargement of urban milksheds so that few regions in the northeast were too distant to feel the pull of the city market. Fast milk trains and milk trucks brought the milk from pasteurizing plants in the dairy centres to New York, Boston, Philadelphia and other cities. Sanitary improvements were made in the housing facilities for cattle and the care of the milk on the farm. Emphasis was placed on quantity of milk and the amount of butterfat it contained. Farmers were urged to cull their poorer stock and substitute high-producing cows and progeny-tested bulls and to follow the techniques being developed at the agricultural colleges for wiping out Bang's disease and tuberculosis. The perfection of the milking machine was a boon to dairy farmers, for it freed them from some of their hardest labour, made them less dependent on hired help, which was increasingly difficult to retain, and made possible the management of larger herds. Another near-revolutionary improvement was artificial insemination, which shortly accomplished much in herd improvement (see ANIMAL BREEDING).

Until settlers reached areas where rainfall was insufficient to make fruit flourish they set out apple trees, grapevines and small fruits such as raspberries and strawberries. Regions of specialization developed where the tempering effects of lakes encouraged peaches and grapes, as in the Finger lakes country of New York and on the shores of the Great Lakes. Truck gardening flourished in the Connecticut valley along with tobacco cultivation, on Long Island and in the muckland area of upstate New York. By the 1860s southern Illinois had become an important fruit-producing area, and special fast fruit trains were run to Chicago to carry the region's produce. In the 20th century Florida and California oranges, Texas grapefruit and lettuce and other early vegetables grown in the deep south were shipped north in refrigerated cars to the rapidly expanding urban markets. A complex transportation network of truck and train was employed to bring to the great cities the seasonal products raised in every part of the country. Specialty crops, including vegetables, fruit and nuts, had become a big business.

Migratory labour was common in the wheat belt until the coming of the modern combine which both cut and threshed the wheat. Threshing crews started in midsummer in Texas and worked north through Kansas, Nebraska and the Dakotas. The migratory labourer was paid a higher wage than the ordinary farm hand and he had his living where he was employed, but he lacked security and decent housing conditions. During World War I wheat threshers, apple and strawberry pickers in Washington and Oregon and other migratory workers were drawn into the Industrial Workers of the World (*q.v.*) a radical labour union that sought by violent and revolutionary means to gain better wages and working conditions for its members. In the early 1930s residents of Oklahoma, Texas and other parts of the cotton south, driven to desperation by drought, dust storms, credit difficulties, diminishing soil fertility and the consolidation of small cotton and wheat farms into larger units suitable for modern machine farming, migrated to California, where they joined other migratory workers in search of fruit- and vegetable-picking jobs. John Steinbeck's *Grapes of Wrath* painted a classic picture of this displaced group as it slowly worked its way westward. The rapidly expanding airplane industry of World War II absorbed these workers, and the "stoop-crop" work in the lettuce and onion fields and fruit picking in the citrus belt began to be done by Mexicans, including "wetbacks" who crossed illegally into the U.S. Farther east, Puerto Rico provided migratory labourers for truck-gardening jobs. Bad conditions in housing camps for them attracted attention, and improvements required federal and state action. (See AGRICULTURAL ECONOMICS: *Agricultural Labour.*)

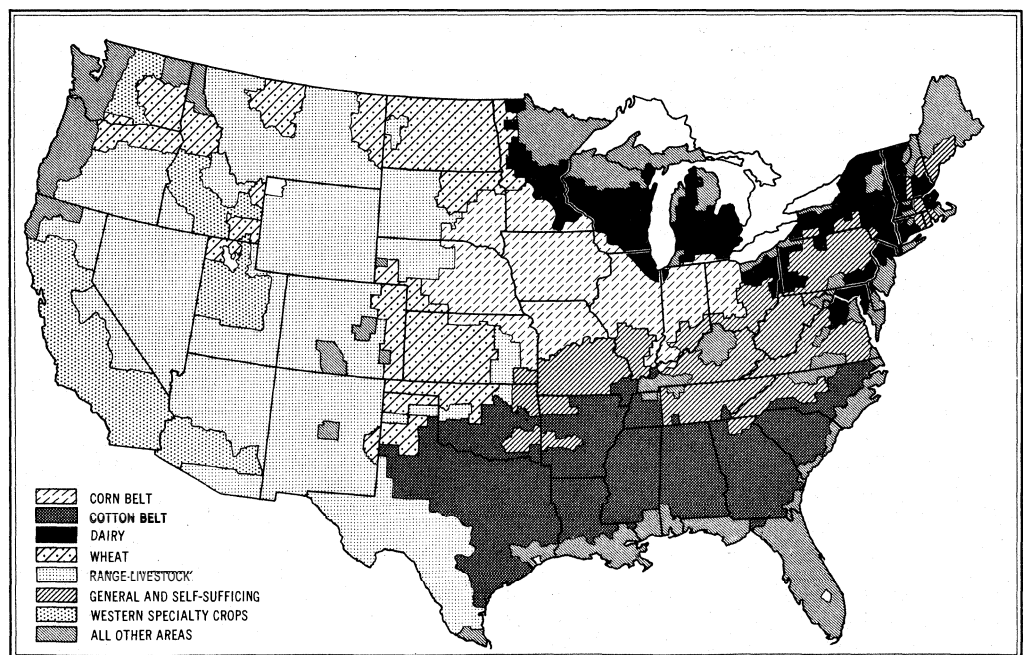

European dependence on U.S. grain, meat, fats and cotton in World War I and the accompanying high prices resulting from wartime demand made it possible to disregard costs and the economics of marginal land use and thereby to enlarge production strikingly. In accomplishing this, farmers bought, at war prices, expensive machines and land that had increased sharply in value, and borrowed heavily from banks and insurance companies. In 1920 the turn came. Prices dropped to prewar levels while the farmers' costs did not. The reasons for the collapse are diverse. European nations, in the throes of nationalism, sought to free themselves from dependence on U.S. foodstuffs, and the foreign market for wheat products and other exports dried up. The Fordney-McCumber and later the Smoot-Hawley tariff acts led to retaliation by Europe against U.S. imports that further cut demand. At the same time U.S. farming was becoming more efficient as a result of the teaching of the agricultural economists and extension agents, the increased use of fertilizer, the development and wide introduction of machines, notably the combine, the tractor and the corn picker, the substitution of hybrid corn for the open-pollinated variety, all of which brought better yields in the face of lower demand. The tractor freed millions of acres previously used for raising oats or grass for horses and mules for commercial crops. Farm surpluses became a major economic and political problem.

Corn, wheat, tobacco and cotton farmers grimly watched their incomes shrink and their purchasing power decline in a period of general prosperity. Mortgage foreclosures, increase in tenancy, unemployment among farm workers and sharply contracted sales to farmers reflected this distress. Political efforts to deal with the farm crisis through the

Nonpartisan league, the Farmer-Labor party, the McNary-Haugen movement and the farm bloc came to little for it was impossible, except in a few states, to get farmers and workers to agree on a common program.

Farm credit was extended in the 1920s, and in 1930, as a result of pressure by the American Farm Bureau federation, the Grange (Patrons of Husbandry) and the Farmers union, the Agricultural Marketing act was adopted. These organizations, in addition to being spokesmen for major groups of farmers, had set up co-operatively owned grain mills, processing plants and wholesale and retail stores to aid farmers in eliminating the middleman's profits. The marketing act provided for the establishment of a farm board which might lend funds to co-operatives to buy and hold nonperishable commodities the price of which had fallen below the cost of production. Lacking production controls, the measure slowed price declines only for a time.

After the election of Franklin D. Roosevelt as president in 1932, the Agricultural Adjustment administration was established to curtail production through the domestic allotment plan, whereby farmers were paid to withdraw from cultivation a portion of their land previously planted in major crops. A processing tax was levied at the point of ginning the cotton or milling the wheat and given to co-operating farmers in the form of benefit payments. Limitation of output and the tax and inflationary action, including the reduction of the gold content of the dollar, substantially raised the farmers' income. These steps were followed by the creation of the National Resources Board and Advisory committee to draw up long-range plans and make recommendations for the best use of various types of publicly and privately owned land. A major recommendation of the board that was soon acted upon was that several million acres of land classed as submarginal for farm purposes because of low yield, degree of erosion and soil depletion should be withdrawn from cultivation and placed in forests, parks, recreation areas or other controlled use. When the great drought of 1934 occurred and dust storms blackened the nation's skies, and land made productive by dry-farming techniques was stripped of every vestige of growth and left barren, the government took quick action to aid the ravaged area. Starving cattle were moved to better ranges or bought and slaughtered, and loans were extended to the distressed farmers. Mortgage foreclosures were stopped in 1933 by the swift extension of government credit. Soil erosion, long one of the gravest losses sustained by the country, was attacked by offering farmers payments to use cover crops, rotate their crops

BY COURTESY OF U.S. DEPARTMENT OF AGRICULTURE

REGIONALIZED TYPES OF FARMING IN THE UNITED STATES

and institute grass waterways, terracing, strip cropping, contour farming and better drainage practices. Lime was widely distributed, and fertilizer prices were reduced through the threat of prosecution of the fertilizer "trust." (See also IRRIGATION; LAND RECLAMATION.)

Tenancy had been somewhat complacently regarded by agricultural economists of an earlier day, but its rapid growth in the depression (the agricultural censuses of 1930 and 1935 each showed more than 200 000 new tenant-operated farms, a total of more than 400,000 additional in a ten-year period) created alarm. A land-purchase program was initiated for tenants to aid them in becoming owners, though congress was reluctant to vote substantial funds for the plan. During World War II farmers' income improved, the cycle was reversed and the percentage of farms operated by tenants diminished from more than 40% in the 1930s to less than 25% in the 1950s.

Subsidies to maintain prices, once introduced, proved difficult to end. Representatives of farm states fought for their continuation, despite the high prices farm commodities were bringing after World War II and the growing surplus. Vast quantities of wheat and cotton accumulated in government warehouses where the cost of maintaining them was high even while they depreciated in value. Neither major political party voiced opposition to subsidies and high parity prices, but by 1954, under pressure from some farm organizations, rigid price supports were breached. The administrative machinery for the soil conservation program was changed and the soil bank plan (not dissimilar from the old soil conservation procedure of the 1930s and 1940s) and government-subsidized sale of surpluses abroad at such prices as they might bring were pushed vigorously. The government attempts to have less-productive land withdrawn from cultivation, thereby reducing the yield of basic crops, and to unload unwanted surpluses abroad did not bring the hard-pressed farmer the relief he needed. Prices received in relation to prices paid by the farmer dropped below parity in the 1950s, while the federal government was spending substantial amounts in attempting, without notable success, to bolster farm income (see AGRICULTURAL ECONOMICS).

In the second half of the 20th century, high labour costs encouraged the use of corn pickers, wheat combines, cotton pickers, milking machines, bulk tanks and other large and expensive machines which, to be used efficiently, required larger farm units than had formerly been the norm. The average size of farms increased from about 150 ac. in the 1930s to almost 250 ac. in the 1950s, mostly through the elimination of small farms. In 20 years more than 2,000,000 farms had been eliminated and an equal number of farmers displaced. The resulting emigration from the rural areas was even more rapid than immigration to those areas had been in the 19th century. These kaleidoscopic changes in agriculture seemed to threaten the old concept of agriculture as a "way of life" and to reduce further the influence of the once-powerful farmers in national politics. For production and acreage statistics see separate articles on various crops, as CORN; RYE; WHEAT; etc. See also FARM MANAGEMENT; FARMSTEAD ARRANGEMENT, U.S.

E. TYPE-OF-FARMING REGIONS

There are eight major classes of farming area in the United States, commonly referred to as type-of-farming regions. The proportion of farm income in an area which is derived from a given commodity or combination of commodities determines to a large extent the type into which the area is classed. The major types are (1) cotton belt; (2) wheat areas; (3) corn belt; (4) dairy areas; (5) general and self-sufficing areas; (6) range-livestock areas; (7) western specialty-crop areas; and (8) all other areas, a residual category in which tobacco, sugar cane, fruits, vegetables and potatoes predominate. These broad areas are shown in the accompanying map. Hawaii and Alaska, being unique agriculturally and falling outside the eight major type-of-farming regions, are dealt with in separate articles (see ALASKA; HAWAII).

Although major type-of-farming regions when described graphi-

cally seem to end abruptly at their borders, their outer fringes are transitional zones which shade into the contiguous regions. Each major type-of-farming region has a core or heart in which the physical features and location produce a technology, economy and social life different from those found in the cores of the others. The common activities engaged in by rural persons in making a living in each region produce broadly similar interests, attitudes, values and life patterns. Although there are occasional groups within a region which are different from the group prototype (such as the Amish, whose culture prohibits the use of many types of farm machinery, or the Mormons, the only large group with a high birth rate as well as a relatively high income), each major region is in general homogeneous with respect to technological, economic and social factors in the core area and less so near the boundaries of adjacent regions.

1. Cotton Belt.—The main factors determining the location of the cotton belt of the old south and the new cotton-producing areas of the southwest are climate and water for irrigation. The core areas of the cotton belt are the high plains and Corpus Christi areas of Texas and the delta counties of Arkansas, Louisiana and Mississippi. By the second half of the 20th century cotton production was firmly established in the San Joaquin valley of California and on irrigated land in Arizona, and these states ranked third and fourth, respectively, in the production of the staple. In some areas of the cotton belt small, family-owned farms are found. In others the sharecropper system, with small acreages per family, persists as a remnant of slaveholding days. The commonest pattern, especially in the core areas; is that of large farms situated on level ground and operated by up-to-date machinery. Other crops are grown in the cotton belt. Grain sorghums, corn, oats, soybeans, peanuts, tobacco, sugar cane and rice, separately or in various combinations, are produced on cotton farms in different parts of the cotton belt. Pasture, livestock and dairy enterprises are also found. The cotton boll weevil, which spread over the cotton belt from 1892 to 1920, provided the strongest incentive toward diversification.

In the older cotton areas where mechanization has proceeded slowly the cycle of growing and harvesting cotton determines school vacations, social events, business activities and church revivals. In contrast with the slack period in winter and early spring, the heavy work period during the picking season from September to November absorbs the efforts of almost everyone. The original plantation organization permitted only a relatively few to initiate action, make important decisions or engage in concerted community efforts. Influence and control by relatively few persisted into the 1960s, and segregation of Negro and white persons prevailed throughout the whole cotton belt. The Farm Bureau became the strongest of the general farmers' organizations. The co-operative movement was particularly weak.

Use of the cotton picker and new systems of planting and cultivation made it possible to reduce greatly the amount of hand labour needed. This, together with the high birth rate of the people in the cotton belt, resulted in a steady exodus of white and Negro residents to the cities of the south and to the north. At the beginning of the second half of the 20th century approximately one-third of the farm population of the nation lived in the cotton belt, which matched its high birth rate with low standards of living, high proportions of native American stock and, except in the western portion, high proportions of nonwhites and non-owners. It is the most rural of the regions. According to the 1950 federal census, of the 17 largest cities in the United States not one fell in the cotton belt, which contained only 3 of the 25 largest cities. True cotton-belt cities like New Orleans, Dallas, Fort Worth, Houston, Baton Rouge and San Antonio were growing phenomenally, however. Some of the most solid neighbourhoods in the entire country, often organized around a church, are found in the cotton belt. This is particularly true of Negro neighbourhoods. In general the interaction between groups is largely informal, with traditional and religious activities dominant. Rural religion is generally fundamentalist. Discussion meetings which permit participation of large segments of neighbourhoods or communities are extremely rare. (See also COTTON BELT.)

2. **Wheat Areas.**—Although wheat is grown in most parts of the United States, approximately three-fourths of the nation's wheat crop comes from the 250 counties delineated on the map as the wheat areas. In these areas there is insufficient moisture for heavy corn or row-crop yields. In terms of acreage and production the southern wheat area in central and western Kansas, southwestern Nebraska, eastern Colorado and northwestern Texas and Oklahoma, known as the hard winter wheat region, excels the others. The spring wheat area in western Minnesota, North and South Dakota and Montana ranks second in production. In the eastern part of this spring wheat area farms are smaller than elsewhere in the wheat areas. Toward the west rainfall decreases, summer fallow becomes more important and acreages become larger. The wheat area of north central Montana is characterized by extensive farming operations and, as in most of the other wheat areas of the high plains, range livestock production is common. In the Pacific northwest region in the Columbia river basin both soft red and soft and hard white wheats are produced. There rainfall ranges from 20 in. annually in eastern Washington and northern Idaho to a low of 10 in. to the west in the Big Bend area.

The rural culture of the wheat areas stands in sharp contrast to that of the cotton belt. Levels of living and income are high, the birth rate is low, relatively little of the produce is consumed by the family and the proportion of operators owning tractors is high. Like the cotton belt, the wheat areas are highly rural. Unlike the cotton belt, however, the neighbourhoods are weak with comparatively few open-country churches. The trade centres are relatively important gathering points for economic and social life. Farms are large, and people are settled sparsely. Towns are few and there are no large cities. The maintenance of adequate rural schools, libraries and similar agencies is a critical problem. Churches are usually in the towns, and the differences between rural and town people are inconspicuous.

In many of the wheat areas rainfall is uncertain and hailstorms and pests are common. The farmers are familiar with crop failure and have been characterized as willing risk takers. The Great Plains portion has been called the dust bowl. Farm tenancy is comparatively high even though farm enterprises are usually managed by families. Tenants have relatively high status. More than three-fourths of the work involved in wheat production is concentrated in the four months of planting and harvesting. In some instances "suitcase farmers" who live on the farms only during planting and harvesting are the operators, but townspeople and country people all sense their dependence on the wheat crop and the weather. The Farmers union became the strongest organization in these areas, particularly in the northern part, which was settled largely by northern Europeans.

3. **Corn Belt.**—Although corn (maize) is the dominant crop of the so-called corn belt, a more descriptive title and one frequently used is the feed-grains and livestock region. Soils there are deep, warm, fertile and rich in organic material and nitrogen and the land is relatively level. This is the area of warm nights, hot days and rainfall well distributed throughout the growing season—ideal conditions for corn. In practically all parts of the region the feed crops—corn, oats, grasses and legumes—form the basis for the farming system. Corn is used chiefly for feeding hogs, beef cattle and sheep.

The chief subdivisions of the region are determined by the basic relationship between the grains and the livestock fed from them. Thus much of the level, fertile land of central Iowa and east central Illinois is devoted to grains and farmed with relatively little livestock. Share renting is common. On the more rolling areas where there is considerable permanent pasture, livestock raising is combined with grain farming. Hogs, which convert concentrated feeds into meat efficiently, get most of the corn fed to livestock. On the boundaries of the area the chief products of the adjoining type-of-farming regions are mingled with and influence the combination of feed grain and livestock.

Grain-livestock farms are usually family-operated commercial enterprises, averaging between 150 and 200 ac. A large part of the family's food supply is produced on the farm, and the value of land, buildings, implements, machinery and livestock is nearly

double the national average. Tenant improvements are commonly inferior to those on owner-operated farms.

Approximately 14% of the nation's farmers lived in the corn belt at mid-20th century. High standards of living and large farm incomes coupled with low birth rates characterize the area. In no other major type-of-farming region is the proportion of extremely rich and poor lower. The one-room neighbourhood school is still fairly common, but in other social and economic activities the trade centre is very important and neighbourhoods located near the centres are dying out. Rural churches are more frequently built near the trade centres than in the cotton belt. The Farm bureau became strongest in this area, but special-interest groups are usually organized around farm commodities. Producers' co-operatives also flourish. The farm work is distributed through the whole year, with the busiest seasons in the spring and fall, when the work days are long.

4. **Dairy Areas.**—Dairying is centred in the northeast, in the Great Lakes states, in small areas on the northern Pacific coast and in smaller areas adjoining large cities. There the soils and the terrain are not suitable to cereal farming, but the cool climate and plentiful, well-distributed rainfall are favourable to hay and pasture. Proximity to large cities provides markets for fluid milk in most of the areas.

The core dairy areas are the central northeast, eastern Wisconsin and northeastern Illinois. All these areas supply fluid milk to urban centres and to cheese factories and condenseries. A large proportion of the grain and other concentrates fed to the dairy herds are produced on the family farms. Other enterprises, most commonly poultry, fruit and truck farming, are usually combined with dairying.

The relationship between a common manner of earning a living and basic attitudes and habits is illustrated in the dairy areas. These areas are widely scattered and they vary considerably in climate, soil type and terrain. Settlement history, forms of local government, ethnic composition and other cultural factors also differ greatly, but the activities involved in producing dairy products stamp the farmers and their families with distinctive characteristics not found elsewhere. The general orientation of the farmers of the dairy and wheat areas may be compared. In the former, the income and work load are relatively constant and predictable throughout the year and from generation to generation; in the latter, principally because of the vicissitudes of the market and weather, great fluctuations occur within the year and through the years. In the dairy areas the work and marketing pattern lead to a high evaluation of thriftiness and hard work, the outward signs of which are solvency and attainment. There is little chance for making a "killing" in a short period of time. The gambling spirit is less apt to appear under these conditions. Soil building and conservation are common. In this respect, the dairy areas resemble the corn belt except for livestock feeding in the latter areas, which involves considerable risk.

The Grange, the Farm bureau and numerous co-operatives flourish in the dairy areas. Many special-interest groups, including various dairy herd and breed associations and artificial insemination co-operatives, exert considerable influence. There are some factory farms, but by and large dairy farming is a family enterprise. Small operations are also few, most of the herds ranging from 10 to 50 cows.

This is the most urban major type-of-farming region. Within its boundaries as depicted on the map are many of the nation's largest cities. In the area as a whole, seven-tenths of the people live in cities and another two-tenths are rural but do not farm. The most rapidly growing segment of the population is the suburban nonfarm, most of which lives in the fringe areas extending out from the metropolitan centres along the main highways.

5. **General and Self-sufficing Areas.**—These are the areas which are left over after the major type-of-farming regions which are dominated by one or two agricultural enterprises are delineated. In the eastern areas as indicated on the map, corn, wheat, oats, hay and to a lesser extent soybeans, tobacco, fruit and truck crops are grown and much of the rougher land is kept in pasture and hay. Hogs, beef cattle and poultry are found on the majority

of the farms, with some scattered dairy cattle and sheep. Live-stock, truck crops and cotton are important in the southern Ozark and Ouachita mountain area. A detailed type-of-farming map with subregions would show numerous small general farming areas under irrigation in western Nevada, the lower Snake river basin in Idaho and Oregon, central Utah, southeastern Idaho, western Montana, the upper Arkansas valley, the San Luis valley and San Juan basin in Colorado and northwestern New Mexico and the Yakima valley in Washington. Other irrigated areas lie in Nebraska and central and northern New Mexico. There are small-scale and part-time general farming areas along the Atlantic and Gulf coasts where forest products, truck crops and cotton are common. Other small, nonirrigated general farming areas are in northeastern New Mexico and northwestern Texas.

The larger areas as shown on the map contain the most rugged terrain east of the Rockies. It is this terrain which makes isolation play such a dominant role in the lives of the people. Folk dances, music and crafts still live in the most remote sections. Traces of Elizabethan English are still evident. These areas are characterized by limited land resources, small, uneven fields and badly eroded, hilly land. Population pressure is great, and many marginal lands have been opened for cultivation, resulting in the depletion of game and forest resources. Outward migration is significant, as many as one-fourth of the people having left some mountain counties during World War II—many never to return except for an occasional visit. Others returned because of the strong family and locality ties characteristic of the region. Although the region is varied and the culture as a whole difficult to characterize, it may be said in general that a high premium is placed on independence among the people, an apparent heritage of the Anglo-Saxon rural culture which produced men like Daniel Boone, Davy Crockett and Andrew Jackson. Most of the farmers trace their ancestry to England, Scotland and Northern Ireland, although some are descended from Germans, Welsh or Dutch or the French Huguenots.

In general, relationships in business and politics are extremely personal. Special-interest or formal organizations are less widespread than in other regions. Tools are simple, life is unhurried and leisure is no luxury. The bulk of the farm work comes in the spring plowing and planting season and in the fall harvesting period. Emotional revival meetings are held frequently before the harvest begins. Most farmers supplement their incomes with off-farm work, and home production of food is relatively important.

6. Range-Livestock Areas.—This region comprises approximately 30% of the land area of the United States and carries 14% of the cattle and 45% of the sheep. Forming a band 500 to 1,000 mi. wide, it stretches from Mexico to Canada and has the roughest and most varied landscape of any region. It is made up mainly of areas which are too infertile, high or dry for other agricultural uses. About half the western range is federal- and state-owned land, a considerable portion of which is in federal grazing districts and national forests. In Nebraska, Kansas, Oklahoma and Texas private ownership is dominant. Elsewhere ranchers lease grazing rights on public lands, usually to supplement their private holdings. Throughout the ranch country there are mining enterprises, irrigated farming areas and recreation centres including dude ranches. The most important subregions of the range-livestock region are the areas of (a) year-long grazing; (b) seasonal grazing for non-migratory use; (c) seasonal grazing for migratory use, and (d) up-land summer grazing.

The cultural influence of the range-livestock areas upon American life is out of proportion to the number of persons and value of products within its boundaries. The only agricultural life of the United States generally known in many countries of the world is the life of the ranch country.

The range-livestock areas provide farmers and ranchers with more leisure time than any other farming region. Busy periods occur when animals are dipped to remove insect pests, calves castrated and branded, yearlings prepared for market and, in the migratory areas, when livestock is transferred from one area to another. The great climatic changes and the fluctuations of the market require adjustments which dominate the people every-

where. The old traditions of the "wild and woolly west" are kept alive through such events as rodeos, but ranchers who make their living from their agricultural operations have little use for dude or luxury ranches.

In social life the dominating factor is distance. The range or "spread" is usually measured in square miles called sections and towns are small and far apart. In no other agricultural region do schools, libraries, public health units, road maintenance divisions and other social and economic agencies suffer so much from lack of an adequate population base. (The population gains in these states shown in the 1960 census was accounted for by the spectacular growth of certain urban areas, and depended on industrial development rather than agriculture.) There are few open-country churches. All parts of the range-livestock areas have relatively high rates of operator ownership. Birth rates are high, but because of migration rural population was decreasing in the second half of the 20th century. Levels of living are relatively high, except in the Spanish American and Indian areas.

7. Western Specialty-Crop Areas.—The areas falling in this category are similar chiefly because they are devoted to specialty crops rather than diversified farming and because they are irrigated areas in arid territory. The 88 counties designated as belonging to this type-of-farming region are chiefly in California, Idaho, Utah and parts of Washington. They cover 8,000,000 ac. on which the major portion of the nation's almonds, apricots, alfalfa, asparagus, carrots, cantaloupes, cherries, lettuce, prunes, walnuts, lemons and grapes are grown. There are wide variations in climate and soil in the region.

Utah and the irrigated and specialty-crop areas of Idaho under the influence of the Mormon culture produced a distinct social and economic life. Relatively high birth rates are coupled with rural levels of living which are among the nation's highest, an exceptional relationship. The family-type farm prevails, and family and religious life are of great importance.

The irrigated specialty-crop section of California falls in a subarea sometimes called the factory-farm area. There a very high plane of living for operators is coupled with a very low birth rate. Approximately 40% of the population is foreign-born. As in the other non-Mormon parts of the western specialty-crop areas, farming is industrialized and commercialized. Approximately 35% of the crops harvested in California are grown on farms of 1,000 ac. or more. Corporate ownership and operation of farms there reaches its high point. Four-fifths of the farms in the United States are between 70 and 259 ac. as compared with only two-fifths for California.

Producers of citrus fruits, vegetables and nuts attempt through their specialized associations to control and regulate marketing. Even though irrigation reduces dependence on climate, the perishability of the crops places the producer at the mercy of the markets. The Farm bureau, Grange and Associated Farmers are strong organizations on the west coast.

Outside the Mormon areas, class distinctions are accentuated and dependence on transient labour is great. Tenants hold about the same social-economic position as owners. Transient labourers—largely Mexican—are the lowest in the social scale and are not accepted as equals by the established residents. Although the areas have excellent schools, the children of migrant workers are handicapped in obtaining a good education and in becoming integrated into the communities in which their families work.

8. Other Areas.—The cutover area of the Great Lakes states is often classified as part of the dairy areas, but it is more like the general and self-sufficing areas. New sources of income have been opened up by tourist and recreation industries, and a large proportion of the rural nonfarm inhabitants are dependent on off-farm work, especially in the mines and woods. There low farm incomes are associated with a high birth rate; a considerable proportion of the people are foreign-born.

The tobacco-growing counties of Kentucky, Tennessee, Virginia, North Carolina and Maryland stand out on the map as areas outside the seven major regions. In these areas people are dependent on the intensive cultivation of the cash tobacco crop mixed with the crop of the surrounding major type-of-farming region. To-

bacco requires a great deal of carefully directed labour for preparing the soil, seeding, transplanting, cultivation, harvesting, curing and marketing. These operations set the rhythm of life for the areas. Otherwise, the life of the people resembles that of the general and self-sufficing areas.

The Gulf coast fringe and much of Florida is the largest sub-area outside the seven major type-of-farming regions. There sugar cane, citrus fruits and vegetables are grown. The areas resemble the western specialty-crop areas, especially in the need for transient labour. Small family operations are common. The Atlantic seaboard portion is a small but important vegetable-producing section.

Noted for its potato production, the northern portion of Maine also falls outside the seven major regions. Another such area, on the northern Pacific coast, includes commercial orchards, part-time farming operations for rural nonfarm dwellers and dairy enterprises. Potatoes, sugar beets, peanuts, rice and dry beans are grown under varying conditions in small enclaves scattered throughout the other regions.

III. BRITISH COMMONWEALTH

A. THE UNITED KINGDOM

1. Early and Medieval Times.—The first food producers in Britain were the peoples who arrived about the middle of the 3rd millennium B.C. bringing seeds of cereals—and their accompanying weeds. They probably cleared patches of ground by burning the vegetation and scattered their seeds among the ashes; there is no evidence of the use of hoes or other implements. They kept cattle, pigs and a smaller number of sheep and goats. Their Bronze Age successors (c. 1500 B.C. onward) were pastorally minded. Sheep predominated over pigs and were relatively abundant in the early Iron Age. The Bronze Age people in Europe used the ard or scratch plow. It is not known when this reached Britain but its presence is indicated by the spread of small, rectangular, "Celtic" fields in the last phase of the Bronze Age. No remains, however, have been found. Ards and Celtic fields were in full use during the pre-Roman Iron Age (450 B.C.—A.D. 54) and persisted throughout the Roman period (into the 5th century). Meanwhile plows with iron shares had been brought in, perhaps by the Belgae (jo B.C. onward); they are associated with long rectangular fields. Probably both systems were in operation in Roman times! the ard being used by the peasants and the plow by the villa farmers.

Sir Mortimer Wheeler's estimate of 1,000,000 inhabitants at the height of the Roman period implies a cultivated area of about 2,000,000 ac.—a considerable proportion of the more easily cultivable land then available. There followed a period of decay. Recovery began under the Anglo-Saxons who made many clearings in the forests for their village settlements. By the end of the 11th century agriculture had developed sufficiently to carry a population of about 4,000,000. Over much of the country—Wessex, the midlands, Lindsey and Deira—the arable land was in large unenclosed

areas called open fields. These were divided into three or, on heavy soils, two sections, and each peasant's holding was in a number of strips scattered in such a way that he had approximately an equal area in each section. In the eastern districts of the country—Kent, much of Essex and probably East Anglia—each of the original settlers had his own compact area which, however, became much subdivided by inheritance. The chief crop was winter-sown bread grain (wheat where possible, but rye in wet districts with acid soils), or oats in the north. This was usually followed by a spring-sown crop of barley, peas or beans. A fallow period was then necessary. On heavy soils the fallow might be needed in alternate years. All strips in the same section carried the same crop, and the rotation went round the two or three sections.

The livestock grazed on the stubbles after harvest and on the untended common land, each eligible person having his allowance or "stint" of animals. There was, however, insufficient food to carry all the animals over the winter, and a number had to be slaughtered and salted down in the autumn when, as Thomas Tusser wrote in his *Five Hundreth Pointes of Good Husbandry* (1573), the husbandman's feasting began. The management was communal and it was almost impossible to effect changes, however desirable they might be.

The manorial system of the Normans after the Conquest gave farms to the lord of the manor and to the monasteries. On some of these farms! especially the monastic ones, improvements were made, but in general the system was static. Not infrequently a man's aggregate holding in the three fields would be about 30 ac., one-third being in wheat yielding approximately 10 bu. per acre; 2 bu. would be needed for seed leaving 8 bu. per acre, or, reckoning the weight of a bushel at 60 lb. (later it rose to 62-63 lb.), about 4,800 lb. for his disposal, reduced, however, by harvesting losses. But there were often local failures and records of hunger are not infrequent.

The peasants held their land from the lord of the manor and owed him certain obligations, though, as Walter of Henley (13th century) shows in *Le Dite de Hosebondrie*, they had their ways of evasion and deceit. Gradually changes set in, hastened by the Black Death of 1348-49. Villeins commuted their services for cash and so became free to leave the village. Enclosures began and by the time of Queen Elizabeth I were already causing concern as peasants suffered through the loss of grazing rights. However, the enclosed land was in individual farms managed by their owners (or by a tenant) and improvements could thus be introduced.

2. The Era of Improvement.—By the 17th century the south of France and Flanders each had well-developed and productive systems of agriculture. Sir Richard Weston, a royalist landowner in Surrey who fled to Flanders during the Great Rebellion, learned something of these methods and described them in a letter to his sons which Samuel Hartlib published under his own name in 1650 as *A Discours of Husbandrie*, though acknowledging Weston's authorship in the enlarged edition of 1651 (His legacie). The methods included a four-year rotation: first flax, next turnips, and then oats undersown with clover. This produced so much food for the animals that larger numbers could be kept in better condition providing more meat and more manure, thus greatly enriching the soil. Improvement became a mounting spiral: more crops gave more manure which in turn gave still more crops.

In the south of France Jethro Tull had seen cultivation implements which suggested to him the idea of the seed drill whereby the turnips could be sown in rows and kept free from weeds by hoeing, thus much increasing their yield. In 1730 Charles Townshend, 2nd Viscount Townshend (1674-1738), retired from political life to Raynham, Norfolk, and, adopting these improvements, worked out a new farming technique including the four-course rotation of crops. Thomas Coke, earl of Leicester, elaborated it from 1778 onward and made it into a highly productive system.

Meanwhile Robert Bakewell (q.v.; 1725-95) of Dishley near Loughborough had been carrying out his famous experiments on the improvement of livestock by selective breeding. He had the vision of the perfection he wished to attain and an artist's eye for recognizing the animals he should use. He developed the Leicester breed of sheep and stimulated Charles Colling of Ketton near

Darlington to improve the Shorthorn breed of cattle (see CATTLE; SHEEP).

A flourishing period began about 1780. Agricultural improvements became the fashionable occupation of great landowners and King George III had his own model farm at Windsor. A board of agriculture was set up that organized the most complete set of agricultural surveys of Great Britain ever made. Its secretary was Arthur Young (*q.v.*), whose vivid accounts of his farming tours in England, Ireland and France are classics. Sir John Sinclair, the president of the board, arranged a detailed survey of Scotland. The surveys revealed considerable differences in farming efficiency in different parts of the country, but also showed where and how improvements had been made.

Then came the French Revolutionary and Napoleonic Wars (1793-1815) during which 14 bad harvests and only 2 really good ones forced wheat prices up to a height that stimulated further improvement. After the wars came a long period of severe depression when many farms were abandoned and their occupants ruined. These included a large number of freeholders of small farms, which in many instances had been in their families for generations. England became a land of large estates and tenant farmers.

3. Victorian Prosperity.— Recovery began in the late 1830s. The Royal Agricultural Society, founded in 1838 and incorporated by royal charter in 1840, exerted a great influence by its shows, its premiums for high-quality animals and useful inventions, its journal and its advisory staff. In 1842 John Bennet Lawes of Rothamsted (see ROTHAMSTED EXPERIMENTAL STATION) set up the first fertilizer factory, greatly facilitating the enrichment of the soil. Methods of drainage were developed and agricultural implements and machines were improved. The new iron plows were lighter than the wooden ones and could be drawn by a pair of horses instead of the larger team, often of slow-moving oxen. They could, moreover, do the work more easily and at a greater speed. The yield of wheat, which had risen from about 10 bu. an acre to 20 bu. through the improvements of the late 18th century, rose still further to about 30 bu. an acre. By the 1860s British agriculture was so productive that visitors came from overseas to admire and to learn.

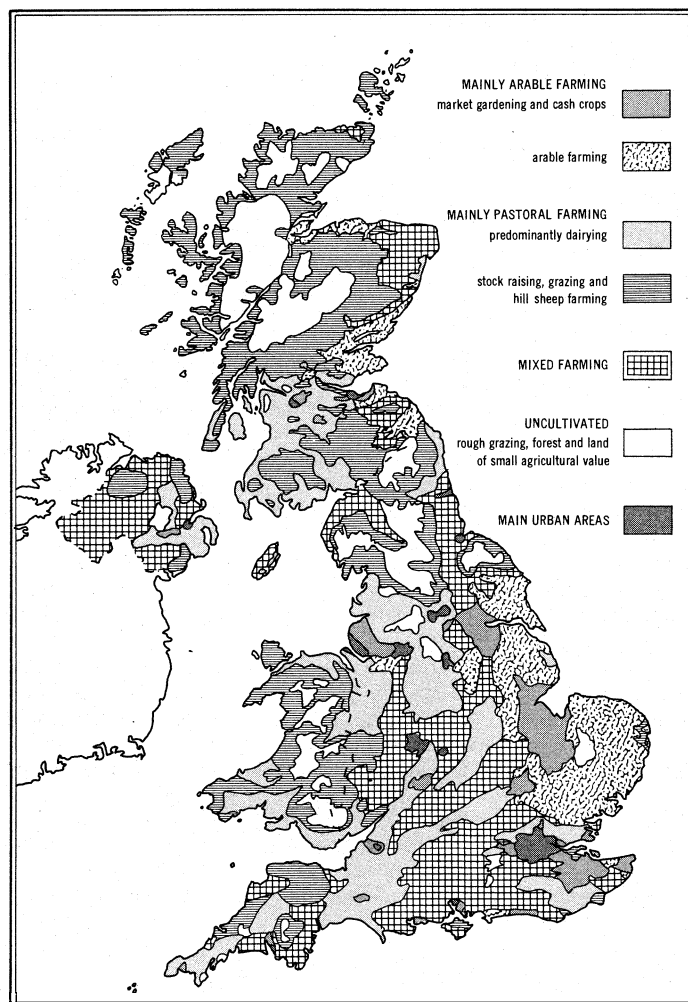

4. Depression and Its Aftermath.— In the late 1870s came a collapse. The North American prairies were opened up by the completion of the transcontinental railways and linked by steamer services to British ports. Wheat, the most easily managed crop for the pioneer farmers, began to pour into British markets. Its price fell from 58s. 8d. per imperial quarter (480 lb.) in 1873 to 31s. in 1886 and 22s. 10d. in 1894; 1879 was the wettest season and its harvest the most disastrous that farmers had ever known. Then came the shattering blow. Throughout the years prices of meat had generally been high when those of corn were low and vice versa: "Down horn, up corn" was an old adage. But in 1882 a refrigerator vessel brought the first frozen mutton and lamb from New Zealand to England, and in the following year frozen beef began to arrive from the Argentine. The quantities rapidly increased, and the selling prices were so low that British farmers could not compete. They asked for protection by tariff but this ran counter to the political theories of the time.

In this long run of bleak depression two periods were especially bad: 1875-84 and 1891-99. During each of these a commission of inquiry was held, each made very gloomy reports, especially the second, for in the interval the value of farm produce had fallen by nearly one-half while the cost of production had, if anything, risen. This second period was one of the saddest in the history of the countryside; it crushed out of existence those many conscientious farmers who regarded themselves as trustees of the land with the duty of leaving it in at least as good a condition as they had found it, and if possible, better. Their motto had been "Live as if you are going to die tomorrow, but farm as if you are going to live for ever." They tried but went bankrupt.

Thousands of acres in Essex and other wheat-growing districts became derelict. Farm rents had to be reduced so much that landlords could no longer maintain buildings or drainage systems in proper order and were fain to make a little money by accepting

shooting tenants. The board of agriculture was re-established in 1889 but achieved little. A high official was heard later to say that British agriculture was dead and the business of the board was to give it a decent burial. Certain advanced politicians thought that it was in any case superfluous: food could be imported more cheaply than it could be produced in Britain; it could be paid for by British manufactures and the land could be used for recreation by the people.

Salvation came from within the farming industry. It was the grain farmers who had suffered most; the grass farmers, producing milk and meat were less affected. British meat was of higher quality than imported, and a sophisticated urban population then emerging was prepared to pay a higher price for it. A number of young farmers from the west of England and from Scotland, hear-

ing of derelict farms in Essex to be had for little or no rent, took them and started producing milk and potatoes for London and other towns. There was no overseas competition, and the rising standard of living was creating new and expanding markets. Arable farming gave place to low-level grass farming. There had been 14,900,000 ac. of arable land in England and Wales in 1871, but only 12,100,000 in 1901. The area of grassland, however, rose from 11,400,000 to 15,400,000 ac., an additional 1,200,000 ac. having been recorded. With the shrinkage of arable land came a fall in the number of workers required. The numbers of cattle rose from 4,270,000 to 5,530,000 while those of sheep fell from 20,230,000 to 19,000,000.

Agricultural education had greatly expanded. More and better machinery was becoming available and prices were improving. By about 1909 tenants were seeking farms and by 1912 rents were

rising from their subeconomic level. When A. D. Hall made his well-known tours in 1910, 1911 and 1912 he found much good farming and quiet prosperity. The Agricultural Holdings acts gave farmers sufficient security to justify their spending money on improvements. Hall was, however, critical of the "low mental calibre" of some of the farmers and noted with regret the poverty of the workers: wages were low, hours long and holidays few. There was as yet no trade union to look after the interests of the farm labourers.

5. World War I.—For the first two years of the war there was little interference with food supplies, but by the end of 1916 the depredations of German submarines were creating a very serious situation. A food production department was therefore set up with T. H. Middleton as its technical director. The basic need was for calories. These were most economically supplied by wheat and potatoes, the production of which on the necessary scale

TABLE VI.—United Kingdom: Utilization of Land
(in 000,000 ac.)

Type of land	England and Wales		United Kingdom	
	1939	1956	1939	1956
Arable land	8.93	13.45	12.91	17.61
Permanent grass	15.71	11.02	18.77	13.47
Total cultivated	24.64	24.49	31.68	31.09
Rough r a n	5.54	5.14	16.54	16.77
Total agriculture	30.18	20.67	48.22	47.86
Nonagriculture	7.16	7.71	11.93	12.29
Total all land	37.34	37.34	60.15	60.15

meant the plowing up of 3,000,000 ac. of grassland. The department was given powers to achieve this. Farmers were helped to obtain equipment and guaranteed against serious loss on their wheat and oat crops; a labour force, including a women's land army, was also organized. By 1918 output of wheat, potatoes and oats (required for army horses) was 50% above the 1909-13 average. Wheat increased from 7,000,000 to 11,600,000 quarters, oats from 21,600,000 to 31,500,000 quarters and potatoes from 6,500,000 to 9,200,000 tons. But production of milk fell from 1,900,000,000 to 1,500,000,000 gal., and that of beef and mutton from 1,000,000 to 830,000 tons. Nevertheless, the total calorie output rose by nearly 25%.

6. Years Between the Wars.—The anxieties of the closing months of the war had greatly disturbed the nation's equanimity about food supplies and in 1919 a royal commission was appointed to advise in regard to increased home production. Its recommendation for permanent adoption of the principle of guaranteed prices for wheat and oats was embodied in the Agricultural act of 1920. Unfortunately there followed almost immediately a catastrophic fall in prices that would have necessitated unexpectedly

TABLE VII.—United Kingdom: Area and Production of Chief Crops

Crop	1939		1953-56	
	(in 000,000 ac.)	(in 000,000 tons)	(in 000,000 ac.)	(in 000,000 tons)
Wheat	1.86	1.65	2.29	2.60
Barley	0.93	0.76	2.32	2.94
Oats	2.40	1.94	2.56	2.71
Sugar beet	0.33	2.74	0.43	4.56
Potatoes	0.72	4.87	0.92	6.28
Seed hay	1.94	2.68	2.88	4.19
Meadow hay	4.92	5.00	3.26	3.53

heavy disbursements and the act was repealed within a few months. Wheat fell from 80s. 10d. a quarter in 1920 to 42s. 2d. in 1923. Farmers were left to bear the full force of the economic blizzard as in the 1880s, with the same results. Many went bankrupt, especially those who had tried to keep their soils in good condition and their men in good heart. Much arable land was put down to grass. In 1925 a subsidy was given to encourage the cultivation of sugar beet, then only recently introduced. Farmers in the eastern counties learned to combine this with milk production, and derived some benefit thereby. They had been the worst sufferers in the crisis (as in the 1880s) because low rainfall made establishment of grass on their land difficult. Farmers elsewhere benefited less. It was hoped that better marketing would help; in general farmers

were receiving only about one-half of what the consumer paid. A marketing act was passed in 1931 encouraging the organization of producers' co-operative selling agencies, and marketing boards for milk and for hops were established. But food production at home continued to shrink and the international situation was deteriorating. The drastic step was therefore taken of abandoning the old policy of free trade in food adopted in 1846, and substituting instead some degree of control. Horticultural products were subjected to a tariff, bacon imports were restricted, wheat had a guaranteed price and sugar production a subsidy. Even these measures did not suffice, however, for prices continued to fall and land to go out of arable cultivation. By 1938 the arable area was down to 8,880,000 ac., the lowest on record. In May 1939, therefore, the further step was taken of giving a subsidy of £2 an acre for all grassland seven or more years old converted to arable. Subsidies were given also for various land improvements including the application of lime and fertilizers.

7. World War II.—By Sept. 1939 each county had an agricultural committee and one or more trained agricultural advisers, while nearly all farmers were enrolled in the National Farmers' union. Organization for production was therefore simpler than in 1914. No food production department was set up. Instead there were county agricultural war committees with the ministry of agriculture in general charge. Each county was given a target. Much rehabilitation of the farms was needed to repair the losses of the previous 15 years and much land had to be reclaimed. The committees were empowered to do this and any other necessary work that the farmers could not undertake. They could also impose cropping programs and remove unco-operative farmers. The expenditure was colossal and still burdened the country in the late 1950s, but the food was produced. The calories supplied per annum from the farms of the United Kingdom rose from the prewar average (1936-39) of 16,700,000 to 26,300,000 in 1943-44 without any reduction in the output of milk—an all-time record.

8. British Agriculture After World War II.—The profound political, social and economic changes consequent to the war revolutionized British agriculture. The old sense of national security disappeared. It was felt that the country could no longer rely on importing so much of its food, much more must be produced at home, and agriculture must be maintained in such efficient condition that expansion could be rapidly achieved should the need arise.

Previous periods of depression had proved very costly. That of the 1880s had snalloned up the reserves accumulated in the 1860s and 1870s, and when World War I broke out heavy government grants for re-equipment became necessary to carry out the food-production program. But this and much privately owned capital was lost in the depression of the 1920s, and rehabilitation and re-equipment on a large scale at government expense were needed in World War II. Further, difficulties about balance of payments were compelling agriculture to become more self-supporting and to reduce imports of foods for livestock. The new policy necessitated the continued cultivation of marginal and hill land, and also keeping many marginal farmers in business with farm subsidies and control of food imports. No control was imposed on farmers, but agricultural production was steered by a system of support prices (subject to annual review) that applied to about 80% of the total produce. The change in utilization of land is shown in Table VI.

Another result of World Wars I and II was a radical change in the structure of village life. The landowning and county families were so impoverished that estates had to be broken up and many farmers were compelled to purchase their holdings, raising the money on long-term loans far more costly than rents and having imposed on them charges and obligations previously borne by the landlord. The growth of urbanism and industrialization continued to take land from agriculture, at first with but little control. In the 1930s the loss had been estimated at 60,000 ac. a year but this caused so much apprehension that a ministry of town and country planning was set up and given considerable power of action. In the 1950s the loss was reduced to 30,000 ac. a year, but it was estimated that 500,000 ac. were lost between 1939 and 1956 (Table

*"Improved" land is arable and tended grassland (1951 and 1956 censuses). †"All cereals" includes wheat, oats, barley, mixed grains and rye.

I) This might be less serious than it appears since no account was taken of holdings of less than one acre, some of which were very productive.

Motors and tractors replaced horses, farming became highly mechanized and the work was speeded up. A plowman with horses usually plowed less than an acre a day; with a tractor he could do from half an acre to two acres an hour. Earlier sowing and planting thus became practicable, in many instances increasing the yields, especially of cereals, sugar beet and potatoes. Harvesting was similarly expedited, thereby saving much grain in bad weather. Mechanization was much more economical of man power: one man for 2 j ac. was needed for a horse-drawn reaper; with a tractor and combine one man sufficed for 100 ac. and the grain was not only reaped but threshed. Wages rose accordingly; by Oct. 1957 the minimum was £7 10s. weekly and the actual usually higher. The numbers of regular workers on the farms of Great Britain fell from 600,000 in 1939 to 527,800 after World War II, but the value of the output rose.

After World War II farming efficiency increased the output in spite of the loss of land and workers. Full advantage was being taken of educational and advisory services (see AGRICULTURAL EDUCATION AND RESEARCH). Crops and seeds were improved at plant-breeding stations at Cambridge (cereals and others), Aberystwyth (grasses and clovers), Pentlandfields (potatoes) and by some of the seed firms. Much help was provided by the National Institute of Agricultural Botany at Cambridge. Fertilizers were more extensively employed. In terms of plant nutrients the quantities used (1955-56, prewar figures in parentheses) were: nitrogen 248,000 tons (60,000); phosphate 386,000 tons (170,000); and potash 385,000 tons (75,000). Weeds, pests and diseases were more effectively controlled by the new products of technological organic chemistry and yields continued to rise. The average yield in hundredweights per acre of wheat rose from 17.8 before World War II to 26.7 in 1956-57, that of barley from 16.5 to 2j.6 and that of oats from 16.1 to 21.0. An efficient farmer obtained considerably higher yields (see Table VII). The output from grassland did not increase so much as from the arable, although investigations at Xberystwyth, Hurley, Jealott's Hill and elsewhere showed great possibilities.

The management of livestock improved. Artificial insemination was raising the quality of animals. Fuller knowledge of the nutritional requirements in the various phases of the lives of animals led to improvements in their rations. Concentrated foods can be fortified with the necessary minerals and vitamins, and farmers can adequately control the supplies of carbohydrates and protein equivalent. Milking parlours facilitated the clean handling of milk and the adjustment of food to performance besides saving labour. Inoculations, modern insecticides and vermicides and more efficient management improved the health of the animals and reduced wastage.

Tuberculosis and mastitis were eliminated from many herds although foot-and-mouth disease continued to give trouble. In consequence of these better conditions animal performance improved: the average gross yield per cow in milk-selling herds rose from 560 gal. in 1938-39 to 720 gal. in 1956-57, and the total production from 1,293,000,000 to 2,194,000,000 gal.

The numbers of livestock in the United Kingdom early in the second half of the 20th century,

with totals for England and Wales only shown in parentheses, were: cattle 10,910,000 (8,250,000); sheep 23,590,000 (15,200,000); pigs 5,470,000 (4,390,000); and poultry 92,460,000 (71,770,000).

The gross value of the annual agricultural output before 1939 was estimated at £290,000,000 and after World War II at £1,339,400,000. The net output rose by 56%. Of the total calorie requirement of the nation 43%, sufficient for the needs of 21,600,000 people, was produced at home, as compared with the prewar 32% of total requirements, sufficient for a population of 15,000,000.

Of course these achievements were costly: in the 1950s subsidies, grants and deficiency payments amounted to £239,200,000 (1956-57). Deficiency payments under the price guarantees were 65% in 1956-57 and 70% in 1957-58.

B. CANADA

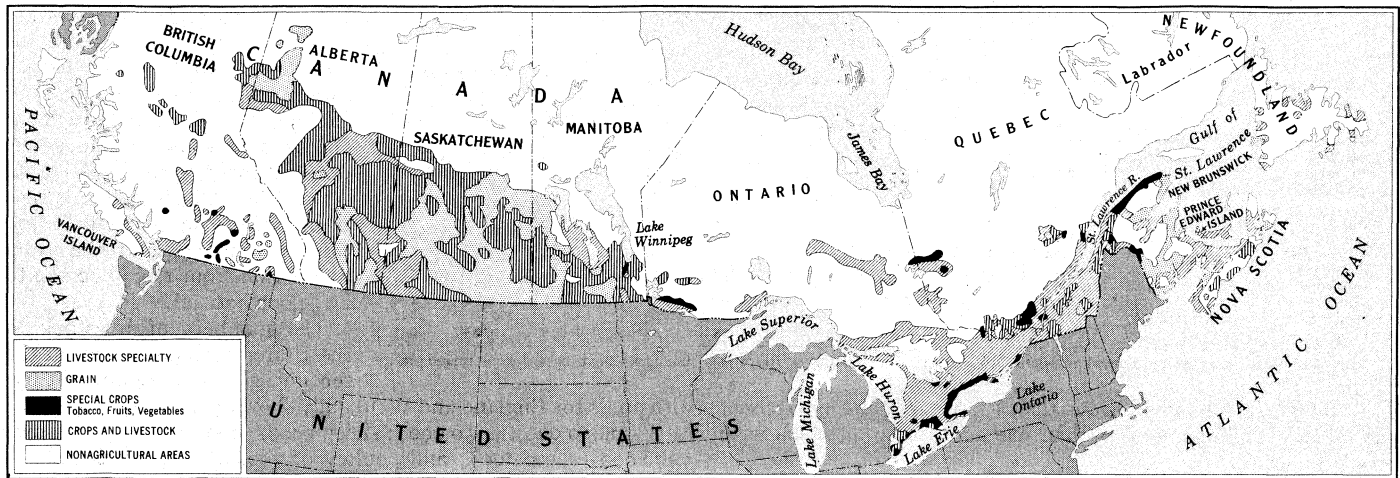

1. General.—Most of Canada is physiographically unsuited to agriculture, and climatic factors restrict it chiefly to the southern regions. The Pre-Cambrian shield occupying more than half the country and the Cordilleran region occupying about 20% contain little land suitable for arable cultivation. The main agricultural areas of eastern Canada lie south of the shield, roughly south of latitude 45° N.; and those of western Canada are the great plains between the shield and the Rockies, mainly south of latitude 55° N., with some possibilities of extension as far north as latitude 62° N.

Eastern Canada was the first part of the British empire to be developed agriculturally. The first settlers were French *émigrés* of the 17th and 18th centuries. Starting from the rivers, the chief means of communication, they cut their farms out of the forest, so founding the linkage of agriculture and forestry still so important in the eastern provinces. The farming at first was necessarily for subsistence: as the population increased, more forest had to be

GENERALIZED AGRICULTURAL AREAS OF CANADA

cleared and more farm produce was sold.

2. **Quebec.**—Most of the farming is still in the hands of the French habitants, and much of its old pattern survives, but with great improvements. About 95% of the province is forest and waste for reasons stated above, and of the 5% in farms (most of which lie south of the St. Lawrence river) only about half is in crops or tended grassland. Forest and grass constitute the natural vegetation, and the farmland includes both. About 60% of the sown area is grass lea usually left down for four years followed by two years of cereal crops, chiefly oats, leaving only about 8% for other crops including fodder crops, potatoes and, in favoured districts, apples. Livestock thus became the chief interest, and butter, cheese, eggs and meat the chief products. This type of husbandry is well suited to the small farms that the social structure encourages; three-quarters of them are between 10 and 180 ac. The forest provides work during the winter.

3. **Ontario.**—This province was settled later, chiefly by the British. Its climate is milder than that of Quebec and productivity is greater. But the agricultural pattern is broadly similar in the two provinces, for both are naturally grass and forest regions. About 90% of Ontario is in forest and waste, and of the area farmed only about 60% is arable and tended grassland. Approximately half the arable area is in cereals—chiefly oats and mixed corn with a little winter wheat—and 40% is in leas. The remaining 10% includes a great variety of crops: soybeans, tobacco, apples and, in a limited area on the north shore of Lake Ontario, peaches, apricots, pears, cherries, grapes and, around St. Catharine, wine. The chief products are livestock, meat, including bacon, dairy produce and eggs.

4. **New Brunswick.**—About a fifth of the land is farmed; the rest is mainly forest, which also occupies about half the farmland and provides useful winter work. The chief crops are sown grass and oats for dairy cattle; potatoes are also important.

5. **Nova Scotia.**—This province has a similar integration of forestry and agriculture but, as it is almost entirely surrounded by the sea, the climate is better and yields are higher. The richest section is the Annapolis valley, where good-quality apples can be grown.

6. **Prince Edward Island.**—This is the most fully farmed of all the provinces, nearly 80% of the total land being utilized. About half the improved land is in grass and half in tillage; the system is mainly dairying combined with pig production and potato growing. Yields are high, in some years the highest in Canada. Farms are small, the average being about 100 ac., and there is considerable prosperity.

Crops and livestock of eastern Canada are shown in Table VIII.

7. **Manitoba.**—The agricultural history of western Canada differs completely from that of the east. The first settlers, brought into the Winnipeg district by the earl of Selkirk in 1812, tried to grow English winter rheat but failed. After four years of heroic effort and pitiful suffering the settlement was abandoned. Subsequently the Hudson's Bay company, to which the prairies had been

assigned, transferred vast areas to the Canadian government in 1869 for £300,000. Later it was discovered that Red Fife wheat, a hard spring variety which was popular with the bakers and had gotten into Canada in 1842 by an almost incredible chain of accidents, grew well on the prairies and was indeed the only known type that would. The opening of the transcontinental railway in the 1870s and 1880s made wheat farming practicable and a wheat-fallow system of farming entirely for market, fundamentally different from the system of eastern Canada, was adopted. The farms also were larger, usually 160 ac., and as labour-saving machinery was invented they became larger still: 640 ac. is usual.

8. **Saskatchewan.**—This province lies farther west and at a higher level than Manitoba. It has a higher evaporation rate and lower rainfall: about 18 in. a year in the east and 12 in. in the west, fortunately coming in late spring or early summer when the crop most needs it. Plant breeders, agronomists and engineers have enabled Saskatchewan to achieve by far the largest acreage of wheat and other cereals of all the provinces, although yields are lower than those of Manitoba. (See Table IX.)

The general system is that a one-year fallow is followed by two cereal crops, the first being wheat while the second may be either wheat, oats or barley. An area in the south is particularly liable to dry seasons. The farms are large, commonly a section (640 ac.; *i.e.*, 1 sq.mi.) in area.

9. **Alberta.**—This is the farthest west and highest in altitude (much is about 3,000 ft.) of the three prairie provinces and has the least and most precarious rainfall. In its western part the uncertainty is so great that cattle ranching replaces arable cultivation. The cropping system is very similar to that of Saskatchewan but yields are lower. The cattle are largely beef animals and many are sold as stores to the United States.

The movement of wheat growing has been westward. In 1891, out of a total wheat area of 2,700,000 ac., 53% was in Ontario, 33% in Manitoba and only 4% in Saskatchewan and Alberta together. During 1951-55, when the total average wheat area was 24,500,000 ac., only 3% and 9% were in Ontario and Manitoba, respectively, while Saskatchewan had 63% and Alberta 25%.

Considerable soil erosion had resulted, however, especially in Saskatchewan and Alberta. The virgin prairie soil usually had a good crumb structure formed during the long years of undisturbed vegetation. The continuous arable cultivation breaks the crumbs down to dust, which is easily blown away by the hot dry wind. This can be considerably checked by strip farming and tillage practices that retain most of the stubble on the surface. Some of the land, however, has suffered serious losses. Rehabilitation is effected by sowing suitable grasses followed by proper management of the resulting pasture.

10. **British Columbia.**—This province is a region of lumbering and fishing rather than cultivation. In some of its delightful valleys apples are grown and in others dairying is practised.

11. **Canada's Agricultural Production.**—The total area of wheat increased up to about 1928 but then remained fairly stable

at about 24,000,000 ac. until World War II. It was pushed up to 28,000,000 ac. in 1940 and remained about 26,000,000 ac. until 1952 after which it began to fall. By 1957 it was down to 21,000,000 ac. The yield fluctuates from year to year between extremes of 7 and 26 bu. per acre depending on the rainfall. Usually it is between 1 j and 20 bu. (between 8.3 and 11 cwt.) and there is no clear indication of any increase in spite of the great amount of good scientific work. Production fluctuates between about 3,500,000 and 19,700,000 tons a year. There is little possibility of irrigation and the climate remains the unconquered element determining production. The occasional high yields put a great strain on transport, storage and marketing services. The acreage of oats fell as tractors largely displaced horses, but the area under barley increased.

Livestock is next to cereals in importance for Canada's agriculture. In the five years after 1950 cattle increased from 8,360,000 to 11,000,000, about a third being milch animals; poultry from 67,900,000 to 73,000,000. Pigs, however, were unchanged at 4,800,000. The production of milk increased from 1,532,000,000 to 1,730,000,000 gal. and the quantity used in manufacturing dairy products rose from 908,000,000 to 1,730,000,000 gal. About 60% was used for manufacturing in each year, most of it (67% in 1950 and 70% in 1955) for creamery butter, the output of which rose from 2,330,000 to 2,840,000 cwt. There was, moreover, a diminishing production of dairy butter. Production of cheese fell slightly from 926,000 to 907,000 cwt., cheddar cheese suffering especially, but the amount of milk going into the various concentrated forms, particularly evaporated milk, increased from 74,000,000 to 91,000,000 gal.

Canada plays a vital part in the feeding of Great Britain and the question was arising as to whether its agriculture could expand sufficiently to continue supplies despite its own growing population. In the survey of 1956 the total land area of 2,272,000,000 ac. was used as follows: total farm area 174,000,000 ac.; improved (i.e., tilled land) 100,300,000 ac.; under crops 62,900,000 ac.; summer fallow 24,600,000 ac.; pasture (a) "improved" 10,100,000 ac., (b) native 35,900,000 ac.; and woodland 19,500,000 ac. Less than 8% of the total area is in farms and it is not clear that this could be much increased. Perhaps another 200,000,000 ac. could be utilized if the causes of their infertility could be discovered and remedied. A more hopeful prospect would be to increase the area of improved land; i.e., arable and tilled grassland on the farms. In 1941 this had been 91,600,000 ac. and within 1 j years it had increased to 99,100,000 ac.: it remained, however! only 60% of the total farm area.

The demands of urban and industrial expansion in eastern Canada were absorbing more and more useful land from farms. During the 1 j years 1941-56, 1,780,000 ac. of improved land were lost, reducing the gain of 10,950,000 ac. in western Canada to a net gain of 9,160,000 ac. These losses continued. The excellent scientific and technical services have shown great possibilities of pasture improvement and of rehabilitation of eroded lands although little could be hoped for from irrigation. The area in the late 1950s was 628,000 ac. and no great increase seemed feasible, though some progress continued. Consumption of fertilizer increased, and in 1955 in terms of plant food was: nitrogen 45,000 tons; phosphate 114,000 tons; and potash 68,000 tons. Herbicides were increasingly effective against weeds, which in the past much reduced cereal yields.

C. AUSTRALIA

1. General Survey.—The agriculture of Australia is both population and agricultural tradition and there were no indig-

enous food plants or animals of use on farms. Everything had to be introduced, much of it within living memory. The older agricultural exports were wheat and wool from the fine-wooled Merino sheep introduced by John Macarthur in the 1790s. Later, as refrigerator transport developed, dairy products, fruit and frozen meat were added. Later still the meat was chilled only, which improves its quality.

The northern part of Australia is tropical; the southern has a mediterranean climate. The rain in the southern part comes mostly during the winter months, from April to September, and is fairly reliable; in the northern part it comes chiefly in summer, from October to March, and is more erratic. It is highest—50 in. or more a year. 160 in. in the far north—on a narrow belt along the east coast. It decreases going inland; the inner core, two-thirds of the continent, has only 20 in. or less, and half of this area is desert or nearly so.

There is much intensive and varied farming in the well-watered coastal zone; fat-lamb production and dairying and, in places, fruit production are widely practised. In the adjacent inland zones (rainfall 15 to 25 in. yearly) farming is commonly restricted to wheat, barley and wool. The early settlers grew English varieties of wheat and suffered considerable losses until William Farrer in the 1880s and 1890s started breeding drought- and rust-resistant varieties. This work has been continued with great success.

In the lower-rainfall regions Merino sheep are kept for wool production. The rate of stocking is low: from 5 to 30 ac. per head, and dams are constructed for storing water against the long dry periods. The farms or stations have to be very large, and while some of the older and more accessible ones are extremely pleasant habitations, many of the others suffer from being isolated. This is mitigated; however, by radio and by air transport.

Because of rainfall deficiencies little more than 1% of the total area is sown, and another 1½% is under improved pastures. The great areas involved and the low manpower have led to the invention of some very ingenious labour-saving farm implements.

The Australian land surface is geologically very old and with some exceptions, e.g., the Darling downs, the soil is poor, highly deficient in phosphate, nitrogen, organic matter and the trace elements. Important and far-reaching investigations on the latter have been made.

The agricultural utilization of land in the various states is shown in Table X.

2. Queensland.—This state produces most of Australia's beef and sugar. The main beef areas are the Earkly tableland and the Cape York peninsula. Dairying is largely confined to the coastal regions and the Darling downs. Sheep are in the dry central regions and the Darling downs. Sugar cane is grown in the wet coastal sections. Its production has increased by about 80% since the decade before World War II and a decade after the war the area has 480,000 ac. (30,000 ac. irrigated! and the yield of raw sugar, 9,250,000 tons. Other important crops are pineapples, bananas, cotton, peanuts and tobacco.

3. Northern Territory.—This is the most tropical and least populous region in Australia and produces beef cattle either fat or as stores for neighbouring states. The chief areas are Alice Springs, the Barkly tableland and Victoria river districts. The

*Including Australian Capital Territory (Canberra). †During 1955-56 approximately 120,000,000 bu. were exported. ‡During 1955-56 total Australian wool production was estimated at 1,565,000,000 lb. §Total does not add because of rounding.

uncertain rainfall makes production hazardous. Severe droughts such as occurred in 1944-46 and 1952 cause appalling losses. Productivity is very low: of the 335,000,000 ac. of Australia's tropical north having 20 or more in. of rain, the carrying capacity of the utilizable land is only about ten bullocks per square mile.

4. New South Wales.—This is the most populous and productive of all the states, and produces half of Australia's wool, mainly in the central division and in the drier western districts of the Riverina. No food is grown for the sheep and the carrying capacity of the land is very low, being limited by the amount of native vegetation available during the hot dry summer. The stations have to be very large.

Much wheat is grown, chiefly in the 15- to 20-in. rainfall zones of the central region and in the Riverina. In the well-watered coastal belt there is considerable dairying, especially in the northern section of good summer rainfall. Bananas and citrus fruits are also grown. About 525,000 ac. in the Murray-Murrumbidgee basin are irrigated, about half being sown pasture.

5. Victoria.—Victoria is the chief dairying state. The dairying is carried on in the higher-rainfall areas of Gippsland and else-

FROM R. D. WATT'S "THE ROMANCE OF THE AUSTRALIAN LAND INDUSTRIES"; REPRODUCED BY PERMISSION OF ANGUS & ROBERTSON LTD., SYDNEY

PRINCIPAL USES OF LAND IN AUSTRALIA

where, and on the irrigated pastures of the north. Much wool is produced on the western plains (rainfall 20 to 30 in.). After World War II Victoria had more land under irrigation than any other state (855,000 ac. in 1956-57), partly because of its geographical position and partly because of the advocacy of Alfred Deakin, a former prime minister. Two-thirds of this area was under pasture, mainly for dairying, and the remainder under orchards, vines and market gardens. Important fruit-canning and grape-drying industries had been developed.

Victoria shares with New South Wales the Snowy mountains irrigation project, one of the most remarkable in the world since it involves decapitating the river which flows uselessly to the Tasman sea and diverting its headwaters into the Murray-Murrumbidgee irrigation system.

6. South Australia.—The chief products of this state are wool and cereals, especially barley, and in favoured districts dairy produce and fruit. The wine industry (about 20,000,000 gal. annually), established by British settlers from 1838 onward, was expanded in the Barossa valley in the 1850s by German immigrants

Reclamation on more than 500,000 ac. of the former Ninety Mile desert, barren in spite of suitable rainfall, was being effected in the second half of the 20th century, the sterility having been

traced to deficiencies of phosphorus, copper, zinc and, in places, molybdenum. This was rectified and sheep grazing and dairying are successfully practised. The region has been renamed Coon-alpyn downs. Once they were recognized, these deficiencies were found to be widespread in the southern coastal regions of Australia, and large areas have been reclaimed or improved.

7. Western Australia.—This is the newest state to be developed, chiefly in the southwest. The coastal region produces apples and other European fruits, in association with dairying and timber. The section of the tableland lying beyond and averaging about 1,000 ft. in altitude, with annual rainfall between 10 and 20 in., produces wheat and sheep in alternate husbandry. The wheat area is the largest in Australia and the only one that increased after 1949.

8. Tasmania.—The island of Tasmania is Australia's chief exporter of apples and pears, produced with small fruit in the southern river basins. There is much mixed farming in the northern coastal area including dairying and production of fat lambs, potatoes and vegetables; in the midlands and east coast region wool is the chief product. About half the island, however, is too mountainous or heavily timbered to be agriculturally or pastorally useful.

9. Further Development.—Australia's great difficulty is the widespread shortage of water. Only the Murray-Murrumbidgee basin is suited for large-scale irrigation. Queensland has a greater potential supply of water (runoff), but its rivers are very difficult to harness economically. There seems little scope for tube (drilled) wells anywhere. By 1957 the total irrigated area was 1,620,000 ac.; the Snowy mountains scheme was planned to add 2,000,000 ac. to this.

The 1949 marketing agreements with Great Britain encouraged the export of meat. The numbers of cattle rose from an average of 14,500,000 during 1947-52 to 17,000,000 five years later, and those of sheep from 111,000,000 to 150,000,000.

Except in the low-rainfall, unirrigated areas pasture improvement was progressing rapidly. By 1957, 32,000,000 ac. had been sown. Some useful grasses and other forage crops have been introduced, at first accidentally (e.g., subterranean clover), but later on a planned scientific program. The rabbit population was for a time almost completely controlled by the myxomatosis virus liberated in 1950, but the older methods were having to be used again. The area under crops did not increase because the wheat area fell from 13,000,000 ac. before World War II to 7,900,000 in 1957, but as the yields had risen the total output did not correspondingly suffer. For a long period agricultural output appeared to stagnate but there were signs of an upward trend in the second half of the 20th century.

D. NEW ZEALAND

1. General.—The two main islands of New Zealand form a crescent about 1,100 mi. in length facing westward, but tilted somewhat to the northwest, and so narrow that no part is far from the sea. The north end is subtropical and produces citrus and other warm-climate products; the south end is cooler but still mild.

New Zealand has always been predominantly a pastoral country. In the mid-19th century the main product was wool for export to Great Britain. The invention of refrigerator transport in 1873 and its practical development in the 1890s permitted the much more lucrative export of lamb, dairy produce and fruit in addition to that of wool. Production difficulties during the 1920s led to the development of scientific services, and these, combined with labour-saving methods, greatly increased the value of the output from the land. The land is cultivated as shown in Table XI.

Production steadily increased. New Zealand became Britain's chief supplier of dairy produce, lamb and mutton, besides sending an important quantity of crossbred wool. Consumption of phosphatic and potassic fertilizers rose rapidly, and by 1956 was 210,000 tons of phosphate (P₂O₅) and 24,400 tons of potash, compared with pre-World War II averages of 102,000 and 6,000 tons, respectively. Nitrogenous fertilizers, however, are but little used (4,700 tons of nitrogen before World War II and 3,400 tons in 1955-56).

A considerable area of pines (more than 900,000 ac. in 1958) was planted with a view to developing a paper-pulp industry. About 75% of the crops are in the South Island.

TABLE XI.—New Zealand: Land Utilization (1956-57)
(in 000,000 ac.)

Total area units	Arable and planted crops	Permanent grass	Forest and scrub	Unused: potentially productive	Urban roads, works, etc.
66.4	1.21	30.9	21.2	1.0	11.4

About 90% of the cattle and 55% of the sheep are in the North Island. Numbers of all livestock have continued to rise (see Table XII). On the other hand the acreage under wheat has fallen so heavily as to reduce the total sown acreage, and though the average yield has risen it has not offset the drop in acreage (see Table XIII). Up to 1911 wheat was exported; after that imports increased to about 8,000,000 bu. after World War II.

TABLE XII.—New Zealand: Livestock Production

Item	1947-52 average	1956-57 average	Item	1955-56 average	1956-57 average
Total cattle (000,000 head)	4.96	5.81	Wool (000,000 lb.)	.462	.491
Milch cows (000,000 head)	1.85	2.0	Butter (000 tons)	200	198
Sheep (000,000 head)	33.4	42.38	Cheese (000 tons)	96.3	94
Pigs (000,000 head)	.564	.68	Lamb and mutton (000 tons)	352	335
			Beef (000 tons)	225	240

Acreage and output of oats also fell; on the other hand production of barley increased.

New Zealand is famous for its highly productive small farms, but they occupy only a small proportion of the total area. In 1950 the holdings of between 1 and 320 ac. numbered 68,000 but had only 6,500,000 ac. out of a total of 43,200,000 ac. of occupied land.

2. North Island.—The North Island has the higher rainfall (35 to 70 in.) and so little difference between summer and winter temperature that the cattle can be out all year. The soils are naturally poor, lacking phosphate, often lime, and some of the trace elements, cobalt, molybdenum and others; but they become extremely productive when the deficiencies are rectified. Some of the native tussock grasses, especially *Danthonia pilosa*, have a limited pastoral value, but perennial rye grass, cocksfoot and

white clover introduced from Great Britain thrive amazingly, yielding 9,000 to 12,000 lb. or more dry matter per acre (even 16,000 lb. under spray irrigation) and making the grazing lands among the richest in the world.

The dairy farms are small: a usual range is from 50 to 200 ac. A hundred acres has been a common size but the tendency is toward the 150-ac. farm. Stocking is heavy—at least 60 or 70 and, on the best farms, 100 cows (mostly Jerseys) per 100 ac.—and so well mechanized and organized that where, as is usual, there is no hand stripping one man can look after 60 cows and two men after 100 to 120. The animals live almost entirely on grass—either green or as hay or silage. The yield of milk is

usually about 350 to 400 gal. per acre, giving about 200 lb. of butterfat. Up to 400 lb. has, however, been obtained.

The cream may be separated on the farm and sent to the co-operative factory to be made into butter, the separated milk going to the pigs; or the whole milk may go to be made into cheese, milk powder, casein or other products.

New Zealand stands highest among the world's exporters of butter and cheese. These go chiefly to the United Kingdom. Fruit is grown in Hawke's Bay province.

Much of the North Island (about 20,000,000 out of 25,000,000 ac.) is hilly, even mountainous, and unsuited for dairy farming or, in its natural state, fat-lamb production. Spectacular improvements have, however, resulted from the application of superphosphate and trace elements by airplane, and where necessary also white clover seed. Farms at 1,000 ft. elevation can now produce fat lambs (Romney Marsh crossed with Southdown).

Many thousands of barren acres in the central volcanic plateau were being reclaimed at the end of the 1950s by treatment with superphosphate and the appropriate trace elements.

3. South Island.—The South Island is cooler and drier, the rainfall being about 25 to 45 in. in the settled areas. The northern part is very attractive with long hours of sunshine. It produces hops, tobacco, fruit and a variety of canning crops. The central part includes the 1,000,000-ac. Canterbury plains, where much of the land is arable, producing rape or leas for the fattening of lambs (Southdown crossed with Corriedale) and for maintaining the productivity of the land. High winds have caused erosion but this has been checked by erecting windbreaks.

In the far south (Otago district) grass farming using improved strains (e.g., H1 rye grass) has become more important. Fat lamb is the chief product; stone fruit is also grown. Much of the hill country is too dry for this system of husbandry, the rainfall being only 15 to 12 in. or less a year. It is in large holdings for Merino or crossbred sheep. The native vegetation is coarse and poor; production of wool is low but quality is high.

The Corriedale is an inbred half-breed, based on the Merino ewe and the English Long wool ram. It is a valuable dual-purpose animal (carcass and wool) whereas the Merino is kept only for its wool.

E. INDIA

1. General.—The agriculture of India is dominated by the amount and distribution of the rainfall. This comes mainly during the southwest monsoon, from June to September. It is highest (80 to 100 in. or more a year) in the region at the head of the Bay of Bengal and on a strip of the southwest coast. It is low and uncertain in the south central Deccan region and lowest in the northwest. The main crop in wet regions is rice; in the drier but irrigated regions of the north, wheat; and in the dry central region, the millets. The utilization of the land early in the second half of the 20th century (in millions of acres) was as follows: geographical area 806; reporting area (Indian statistics have relation only to the "reporting area") 778; forest area 125; agricultural 380 (including sown area 323 and fallows 57); noncultivated areas 68; and area not available for cultivation 205. The area of irrigated land in 1954 was 54,000,000 ac. net and 61,000,000 ac. gross (i.e., total crops), whereas in 1950 it had been 49,000,000 ac. net.

Most of the former large estates have been broken up and the agricultural land is mainly in peasant cultivation. The holdings are small (averaging 7.5 ac.) and become smaller as the population increases. At the beginning of the second half of the 20th century, about 80% were under ten acres except in the Punjab and Bombay state (northwest and west), where the percentages were respectively 50 and 70. This small size results in great poverty and makes improvements difficult. The soils are naturally poor, yields are low and the greater part of the land has to be in human food crops, chiefly cereals (see Table XIV). Not all the increased out-

put of 1955-56 resulted from human effort, however; more than half is attributed to two very favourable monsoons, an unusual feature in so short a period.

2. Crops.—Rice.—This is the most important of the human foods. By long experience cultivators have picked out from the many Indian varieties those best suited to their local conditions and most acceptable to their tastes. Some varieties tolerate dryness, but most grow in well-watered or even swamp conditions. The best are grown in low-lying areas with standing water. The grain as reaped is called paddy and when dehusked it becomes rice. One hundred parts of paddy give 66.7 parts of rice. The average yield is about seven hundredweight of rice per acre but far higher yields are obtained in good areas.

Millets.—The millets are all tolerant of drought and soil poverty and they replace rice in regions of low and uncertain rainfall. Jowar (*Sorghum vulgare*) is the most important, followed by bajra (*Pennisetum glaucum*) and ragi (*Eleusine coracana*). Lower-yielding smaller varieties with even higher tolerance of drought and poverty are grown in poor districts.

Wheat.—Wheat does not grow well in hot or very wet conditions. It is confined to a belt in the drier part of the north and

is grown only as a winter crop; about a third is irrigated. Average yields range about five or six hundredweight per acre. Severe losses are periodically caused by rust and smut, and much effort has been devoted to the breeding of resistant varieties. (See Table XV.)

Pulses.—Many kinds of pulse are grown. The chief are gram (*Cicer arietinum*), nearly half the total production, and pigeon pea (*Cajanus cajan*), about a fifth. The total area is about 55,000,000 ac. and the product about 10,000,000 tons.

Vegetable Oils and Fats — Peanuts, an early introduction (16th or 17th century from South America), are the chief crop. They also provide a good deal of protein. They are grown mainly in the states of Madras (in the south), Andhra Pradesh (central India) and Bombay (west). The others, chiefly rape and mustard (treated as one crop) and sesamum, are much more widely distributed. (See Table XVI.)

crushed out by mills), a very popular product. The average yield of 3,000 lb. of gur per acre gives the highest calorie return per acre of any crop in India. In the 1950s, 1,900,000 tons of refined sugar were produced.

The 300,500,000 ac. of food crops recorded in Table XIV amount to about 90% of the total cropped area.

TABLE XVII.—*India*: Area and Production of Cash Crops, Beginning of the Second Five-Year Plan (1956)

Crop	Area	Production
Cotton (bales)	20,200,000	4,000,000
Jute (bales)	1,700,000	4,200,000
Tea (lb.)	800,000	648,600,000
Coffee (lb)	230,000	58,700,000
Rubber (lb.)	170,000	49,000,000
Tobacco (tons)	920,000	300,000

Cotton.—This is grown mainly in the drier districts and occupies about 80% of the total area of the cash crops. Short-staple Asian varieties are grown in rain-fed districts and medium-staple American varieties in those irrigated. The surplus seed furnishes edible oil and a residual cake which can be fed to animals (usually milch buffaloes) or used as manure.

Jute.—This requires enormous quantities of water and is con-

finned to the low-lying Gangetic delta in the northeast where floods and high rainfall furnish ideal conditions. It yields 600 to 1,000 lb. of yarn per acre and as textiles and yarn it heads India's list of export commodities.

Other Crops.—Tea comes second in importance as an export. It is grown in three regions where high rainfall has made the soil sufficiently acid: the hills of Assam, of the Darjeeling district and of Kerala and the Nilgiris in the south. The drier parts of the Nilgiris also produce coffee. Both crops are more suited to large plantation companies than to small farmers. The demand is not greatly expansible and neither area nor product has changed much since 1950.

Two other cash crops, however, have increased in area and output: tobacco and rubber. (See Table XVII.)

3. Livestock.—Cattle are the main source of power on the farm, but they provide little milk and no meat. Slaughter is prohibited by the Hindu religion and castration is far from common. A vast cattle population, estimated at 203,700,000, has, therefore, grown up and for most of it, apart from the working animals and the milch buffaloes, there is no food beyond the farm wastes and the quite inadequate grazing on wasteland or forest verges. Over most of the country there is sufficient drought for eight or nine months in the year to prevent the growth of natural herbage. The animals are half starved and very inefficient; the milk yield is a few pints daily and even the dung does not get to the farmed land but is dried into cakes for domestic fuel. Meanwhile the grassland is overgrazed and eroded. The 22,000,000 milch buffaloes provide most of the milk. This is used for making the staple cooking fat, ghee, a kind of butter.

4. Food Production and Population: the Five-Year Plans.—At the beginning of the second half of the 20th century India's diet was definitely poorer than before World War II and the rising population threatened a further reduction. The five-year plans of 1950 and 1955 aimed at averting this calamity by increasing food output, lowering the birth rate and increasing industrial development. The agricultural methods included more irrigation, soil conservation and reclamation, greater use of fertilizers, better farming techniques and reduction of wastes and losses. An additional 2,769 tube wells were drilled, benefiting 830,700 ac., and about 5,000,000 ac. were added to the total irrigated area. By the end of the first five-year plan 34,000,000 ac. had been added to the food-crop area, and the population of 380,000,000 had 0.79 ac. per head—an increase on the 0.73 ac. of 1951—and crop yields were higher. In consequence of these developments the food production part of the first five-year plan, as Table XIV shows, was accomplished. Import of cereals fell from 4,300,000 tons (1951–52 average) to 770,000 tons (1954–55 average) and the calorie consumption per head per day in 1955–56 rose from 1,700 (FAO estimate) to 2,200. The second five-year plan aimed at still further progress. Its calorie target for 1960 was 2,400 per head per day, but drought in northern India in the late 1950s gravely affected the food supply.

F. PAKISTAN

1. General.—Pakistan, which lies in the north of the Indian subcontinent, comprises two provinces, West Pakistan and East Pakistan, widely different from each other and separated by 1,000 mi. Its total area is 364,373 sq.mi. (233,198,720 ac.), but only about 00,700,000 are in agricultural use. About two-thirds of this area is sown, but since some of it carries two or three crops a year the area of crops exceeds 51,000,000 ac. (47,000,000 in 1949–50). About 12,000,000 ac. are fallow and 6,000,000 are forest.

2. West Pakistan.—West Pakistan is the larger but less populous of the two provinces (area 197,912,960 ac.; pop., 1961, 40,815,000), much of it mountain and desert. The agricultural part is about 60,000,000 ac., mainly on the plain of the Indus system running north and south for approximately 800 mi., with a fall over the whole distance averaging only a foot a mile. The hold-

ings average about five acres. There is, however, much division and fragmentation, especially on the unirrigated land. The rainfall is low—about 40 in. in the foothills and 4 in. at the sea—and comes mostly in July and August. The rivers are fed by the snows and glaciers of the Himalayas and are in spate during summer and early autumn, sometimes causing destructive floods when the embankments are breached. The land is admirably suited for irrigation and some impressive systems were set up under the British administration, notably the great Sukkur barrage designed to water 7,500,000 ac. The canal system, the longest in the world, commands about 23,000,000 ac., 35% to 55% of which can be cropped in winter and 30% to 40% in summer. Projects were under construction at the beginning of the second half of the 20th century which would bring in another 3,000,000 ac.

Wheat (11,700,000 ac.) and cotton (3,600,000 ac.) were the two chief crops. The annual production of wheat used to be about 4,000,000 tons and the yield about 7.5 cwt. per acre; later it fell and averaged only 6 cwt. per acre during the early years of the second half of the 20th century. Wheat, pulses, oilseeds and berseem, the fodder for the cattle, are winter crops. Those grown in summer include cotton, the millets, some oilseeds and rice. Most of the millets, about a third of the wheat and some of the cotton are grown on barani or unirrigated land; the other crops are irrigated.

The output of cotton is about 1,800,000 bales annually, of which about 1,500,000 are medium-staple, American, upland types and the rest (10% of the cotton area) are native short-staple varieties. The average yield is fairly steady at about 200 lb. of lint per acre.

Weeds cause considerable loss; the native implements were designed for bullock power and are not very effective. Insect pests also cause serious trouble.

Since the partition of India, Pakistan has had to import both wheat and rice, with the aid of considerable overseas subventions. Sugar also is imported. Experimental yields are considerably higher than the average, showing that improvements are possible. Unfortunately many peasants have to burn their farmyard manure for fuel and cannot afford adequate fertilizers. Serious irrigation troubles cause increasing anxiety: waterlogging and accumulation of salt in the surface soil are making it sterile. About 2,000,000 to 3,000,000 ac. are affected, and the area is extending at an increasing rate. By the late 1950s it was about 40,000 ac. a year. Great extensions of irrigation were planned, but three of the important rivers, the Sutlej, the Beas and the Ravi, begin their courses in India, and the Indian government was carrying out vast projects to deflect water onto Indian soil. The allocation of water between India and Pakistan had not been agreed upon.

3. East Pakistan.—East Pakistan is much the smaller of the two provinces but by far the most populous (area 35,285,760 ac.; pop., 1961, 50,844,000). It lies on some of the mouths of the Ganges and Brahmaputra, and stretches up into the hill region of the east. The rainfall varies from about 50 to 135 in. a year, and as the riverbanks are not protected by levees, the floodwaters spread uncontrolled over the low-lying land.

These conditions suit rice and jute admirably, and in summer every available acre is cropped. In winter there is little rain and only about 20% of the land carries crops. The government was, however, promoting extensive schemes of pump irrigation. There is a little lift irrigation on some of the land bordering the rivers but none by canals. About 20,000,000 ac. are cropped, some of the land twice and some even three times a year, making the total area of crops about 25,300,000 ac.

Rice occupies 90% of the cropped area. About 75% of it is a kharif or summer crop (the *aman* varieties), sown in nurseries in March and June and transplanted to catch the monsoon rains (July to September). It is harvested about December. About 20% is broadcast during March–May (*aus* varieties) and, being harvested during July–August, can be followed by a winter crop. These varieties do best on good high land. The remaining 5% (boro varieties) is a winter crop started in nurseries, transplanted during October–January and harvested during March–May. Many types are grown including some adapted to flooded areas, which can

grow two or three feet a day so as to keep the heads above the rising flood, and can attain a height of 20 or 30 ft. The yields fluctuate about 11 cwt. of paddy, or unmilled rice, per acre (in Pakistan 100 lb. of paddy is estimated to give 70 lb. of rice). The total area of rice in the two provinces is about 22,500,000 ac.

The other food crops are the pulses, mainly grain, occupying nearly 1,000,000 ac., and oilseeds, chiefly rape and mustard, occupying a little over 500,000 ac.

Jute is the chief cash crop. It is confined entirely to the low-lying districts of East Pakistan because of its great need of water. The fibre is contained in the stems which may be ten or more feet high. The area, about 1,600,000 ac., is fixed annually to avoid overproduction and the yield per acre is about four bales of 400 lb. each.

There are also some minor crops: betel nuts (260,000 ac.) used for chewing, some being exported to India, tobacco and small areas of potatoes, tea and cotton. Because of the dense population the holdings are very small; the average size is about two acres. In the two provinces numbers of livestock in the early 1950s were about 31,000,000 cattle, 7,000,000 buffaloes, 10,000,000 goats and 6,000 sheep.

4. Summary.—Pakistan has had to face many difficulties. Nevertheless, food production per head of population was for many years higher in Pakistan than in India, giving (on the average of East and West Pakistan) 2 000 cal. a day. The protein supply also is better: beef (but not pork) is permitted to Moslems. In East Pakistan both inland and marine fish are available, and there is great scope for development. The Punjab is probably the best-fed region in the Indo-Pakistan subcontinent. The cattle, having between 2,000,000 and 3,000,000 ac. of fodder crops, are among the best producers.

G. FEDERATION OF RHODESIA AND NYASALAND

1. Southern Rhodesia.—Southern Rhodesia was developed late. Much of it is high-lying savanna (the high veld and middle veld), which contains the farming area. Its rainfall is moderate but unreliable. It comes in the summer months from October or November to March or April, and is higher in the east and north-east and lower toward the south and west. Much of the soil is light and poor. The low veld, a region of wide river valleys with low rainfall and often high temperatures, occupies about 40% of the country. It is unsuitable for ordinary farming and is used for large-scale cattle ranching. Irrigation was, however, being introduced in the second half of the 20th century.

The European-farmed area is about 30,000,000 ac., of which less than 1,000,000 are cropped. The acreages of the chief crops early in the second half of the 20th century (1955–56, with 1950–51 figures shown in parentheses) were: maize 342,000 ac. (343,000 ac.); tobacco 195,000 ac. (169,000 ac.); green manure 150,000 ac. (110,000 ac.); other leguminous crops 76,000 ac. (93,000 ac.); and other crops 85,000 ac. (77,000 ac.).

The most distinctive feature of the farming is that green manuring, chiefly with leguminous crops, is more extensively used than in any other country. Three and four years' leas of selected and improved grasses are grown to restore soil structure destroyed by cultivation, especially on the light tobacco soils, and also to provide food for early maturing mutton sheep. Yields per acre were rising, indicating a steady improvement in the farming. These were in 1955–56, with 1951–52 figures shown in parentheses: maize 18 cwt. (12); tobacco 849 wet pounds (523); and peanuts (unshelled) 10.4 bags (5.9).

Tobacco, nearly all blue-cured Virginian, is commercially the most important crop and it is admirably suited to Rhodesia's great stretches of poor sandy soil. The other main crops are peanuts, potatoes (both summer and winter grown) and fodder. There is very little wheat. Sugar and citrus fruits are grown on the irrigated land in the low veld and tea along the high eastern border districts. Also grown in high districts is Hibiscus cannabinus, needed for local sack and bag manufacture, and in the lower rainfall areas, castor beans for export.

Cattle are the most important of the livestock. Their numbers increased from 2,960,000 in 1951 to 3,280,000 in 1956, more than

half (1,940,000) being on the African farms. Beef production increased from 35,400 tons to 44,500. An ample store of food must be provided for the long dry season and in years of drought losses may be heavy. Sheep are far fewer. They are liable to suffer in the high-lying districts because of the high rainfall and heavy mists, and everywhere they may pick up internal parasites. Properly managed, however, and given clean water and good pasture, they do well. Pig husbandry was expanding in the early part of the second half of the 20th century.

Soil erosion is an ever-present danger, but vigorous steps are taken against it. Practically all the arable land on European farms is protected, and the African farmers are becoming more co-operative. The area under irrigation was slowly increasing. In 1951 it was only 17,600 ac. but by 1955 it had risen to 31,200 ac. and some larger schemes were projected, including dams at the Kariba gorge and on the Sabi river.

2. Nyasaland.—This is the smallest but most populous member of the federation. Maize and the sorghums are the chief food grains, and tobacco, tea, cotton and tung oil the chief cash crops. Of all these except tobacco Nyasaland produces more than Southern Rhodesia.

3. Northern Rhodesia.—Northern Rhodesia is really a mining country but it was developing its agriculture in the 1950s, and a useful ecological survey had been made.

H. WEST AFRICA

1. Introduction.—Agricultural development in west Africa followed naturally from its opening up by the British in the latter part of the 19th century. There was already a primitive agriculture based on bush fallow (leaving exhausted land to cover itself with natural vegetation for several years and then cropping it again) or shifting cultivation (abandoning the exhausted land and moving on elsewhere). Africa is very poor in native food plants. Sorghum, various millets and roots, yams, etc., are indigenous. The Portuguese Jesuit fathers in the 16th and later centuries introduced some others from America, including maize, cassava and peanuts. The only implements were the hoe and a large knife. There were no plows, wheels or carts; transport was on human heads. The agricultural system was very inefficient and served only because famine, pestilence and tribal warfare kept the population low. The British policy was to improve the native crops and methods and to develop cash cropping so that Africans could purchase goods and services from outside countries.

2. Nigeria.—The coastal zone combines high rainfall (50 to 150 in. a year) with high temperature and is a region of tropical forest giving the impression of high production potential. Actually the soils are poor. The luxurious forest growth is due to the fact that the leaves falling to the ground decompose rapidly, liberating plant nutrients which are absorbed by the tree roots and so used over and over again. This region produces tree crops: oil palm (the most important), cocoa, rubber and, locally, kola, besides timber. The oil palm is a native tree and is usually wild, not cultivated. Both the pericarp oil and the kernels are valuable. Cocoa and rubber were both introduced and are grown from seed. The chief food crops are yams (*Dioscorea* species), coco yams (*Colocasia* species) and cassava, and all are interplanted with maize. Other crops include cowpeas, beans and bananas. Bush fallow is at present the best method of dealing with the soil poverty, and experiments are being made to improve it.

Farther inland is a belt of country with lower rainfall (60 to 80 in.), formerly mostly deciduous forest. As a result of much burning and clearing, it has become a man-made savanna where the crops are maize, sorghum, yams and cassava. Still farther north, beyond about latitude 11° N., is a drier and healthier zone where some of the best farming is found. This is the grain belt (millet and sorghum) and the chief source of cotton and peanuts. Fertilizers, particularly phosphates, markedly increase the yields. Their application is especially needed because the large export of peanuts permanently removes much phosphate from the soil.

Still farther inland the rainfall is too low and uncertain for much crop production except on some of the river flats. Most of Nigeria's cattle are there. The forest regions cannot carry them

because of the prevalence of tsetse fly and other disease-bearing insects. Only the small imported Ndama breed appears to be resistant.

About two-thirds of Nigeria is forest, uncultivated bush or waste, and less than 10% is under farm crops. Farms are small and there is much interplanting of food crops.

3. Ghana.—Ghana is much smaller than the Federation of Nigeria but its physiography is generally similar, except that it has a rather dry coastal belt and does not stretch inland beyond the savanna. It has no semiarid or desert region. In the wet forest zone cocoa is by far the most important product. It is not a native tree but was brought to the island of São Tomé about 1822, apparently from Brazil. Propagation did not begin, however, until about 50 years later and even then it was slow. The taste for chocolate is a 20th-century phenomenon. Once expansion began it proceeded rapidly and by 1926 the export of cocoa beans amounted to 228,500 tons, around which it has fluctuated ever since. Nigeria produces about 100,000 tons and the two together amount to 40% of the world total. When the contribution of French West Africa (66,000 tons) is added the total comes to nearly half of the total world output. However, diseases and pests gradually have come in, and Swollen shoot, a serious virus disease, has caused great difficulties in cultivation. The Cocoa Research institute at Tafo, set up in 1944, investigates technical problems and the Cocoa Marketing board deals with business matters.

The savanna country beyond the forest produces, as in Nigeria, maize, peanuts, yams and, in places, rice.

The dry Northern Territories contain most of the livestock. As elsewhere in Africa burning and overgrazing have led to soil erosion and deterioration of the herbage; steps for control have, however, been taken.

Some large reclamation projects were planned in Ghana, the most impressive being the Volta river scheme to irrigate 400,000 ac. for the cultivation of rice, cotton and grass in the dry eastern plains.

4. Sierra Leone.—This small but interesting country has the highest rainfall in west Africa, and grows the same crops as Ghana except that rice is far more important and cocoa less so. Bush fallowing is widely practised, but is being shortened because of the increasing population.

5. Gambia.—This is the smallest of the west African countries. It has a low rainfall and the tree crops cocoa and oil palm are of very little importance in its economy. Peanuts are the chief export crop, millets and rice the chief food crops. Depredations by baboons, other monkeys and wild pigs formerly caused considerable losses, but have been kept down by a well-organized shooting campaign.

I. BRITISH EAST AFRICA

1. General.—British East African territories lie mainly on the great African plateau. The rainfall is less than in the west and it is seasonal and irregular. There is a long dry season and the rivers offer little scope for irrigation. There is some forest on the higher ground and a good deal of scrub, but much of the land carries grass that varies in height from six feet or more to short tussocks, according to the rainfall. Some of the tribes are settled cultivators, others are cattlemen grazing over considerable areas. Hopes have sometimes been raised that a livestock industry might be developed, as in South America. But the conditions are completely different. Rinderpest is still prevalent and this excludes the possibility of an export trade. The carrying capacity of the pasture is low, and it is difficult to accumulate sufficient reserves of fodder to carry large numbers of animals over the dry season. The cattle tribes do not in general regard their animals as merchantable commodities but as marks of wealth and rank. They are also the price of a bride. For these purposes quantity rather than condition is important. Numbers were kept down so long as diseases remained uncontrolled, but with the introduction of veterinary services they increased, the land was overgrazed, bush encroachment and erosion were much intensified.

This same result followed the introduction of health services for the people. More land was needed for food crops; the period

under bush fallow had to be reduced or eliminated and the land became impoverished and much of it eroded. Remedial measures were necessarily unpopular and for various reasons it has not always been possible to combat erosion as effectively as the methods allow.

2. Kenya.—Kenya is agriculturally extremely important because the highland region, a relatively small block of country 6,000 to 10,000 or more feet in altitude, much of it in grass, has a cool climate suitable for European settlement. Being devoid of surface water it was almost uninhabited when the British went there toward the end of the 19th century. The numerous African tribes remain on the lower land. Of the cultivating tribes the Kikuyu are among the most numerous and efficient. They grow maize, potatoes, beans, bananas and yams for subsistence, and vegetables, pineapples, coffee, pyrethrum and wattle for cash. Much of their soil is a fertile red loam, sufficiently supplied with water and capable of giving good yields. Their land system, however, includes the fragmentation and scattering of the holdings and is wasteful both of land and of effort. The British agricultural staff worked out a much more effective system, including consolidation of the scattered holdings, the collection of the people into villages, anti-erosion measures, especially terracing, planned cropping, rotations and proper cultivating implements. Persuasion failed to secure its acceptance. The Mau Mau disturbances, however, compelled the government to remove the leaders and to build villages to which the people could be transferred. The advantages of village settlement and land consolidation were then so obvious that the cultivators themselves applied to the department of agriculture to have their scattered land consolidated, and this proceeded as rapidly as was practicable. The aim was to make compact holdings, providing food for the family and the livestock and a cash income of not less than £100 a year. It was necessary that industrial development proceed simultaneously to provide work for those not needed on the land.

To help the cattle tribes markets are being established and steps taken to ensure honest dealing. The meat can be sold for the mine workers in the Rhodesias and the Union of South Africa and efforts are made to induce the owners to improve their stock.

The European farming is entirely for cash and the products include wheat (the chief arable crop), maize and other cereals, meat and dairy produce and, in regions suited to them, coffee (*Coffea arabica*), tea (best as plantation crops), pyrethrum and sisal. Coffee grows best on the deep red loam with moderate rainfall—about 3j in.—little mist and good sunshine. Tea grows well in regions of mist, high rainfall and acid soils. Pyrethrum must have a period of low temperature to stimulate the formation of flowers and sisal grows well in dry conditions. Much effort is devoted to the search for improved varieties of crops and of grasses, better management of pastures and better modes of cultivation of the arable land and avoidance of erosion, an ever-present danger in Africa. Dairying, bacon production and other livestock industries are being developed. The farms are large—500 ac. and more—and much labour and expense have been incurred in carving them out of the waste and in sinking bore holes for water, which may be 200 to 600 ft. deep. As methods are improved some of the larger arable farms are subdivided and the system intensified. A considerable amount of work is provided for Africans. These farms not only add greatly to the national income, but also furnish valuable information about possibilities of increasing output from the land, which will always be Kenya's crying need, there being no valuable minerals or fuels for mining.

The total area of Kenya is 143,026,000 ac., of which 90,000,000 ac. are unsurveyed crown land and about 8,000,000 ac. are owned by non-Africans, mainly British. Of this nearly 1,000,000 ac. are under crops, the chief of which, in the 1950s, were (in thousands of acres): wheat 291; sisal 190; maize 174; wattle 77; coffee 78.6; and sugar 18.6. The numbers of livestock on non-African farms by the mid-1950s were (in millions, with 1945 figures shown in parentheses): cattle 7.65 (5.28); sheep 3.33 (2.69); pigs .36 (.35 [1947 figure]); and poultry .183 (.181). In 1955, 9,900,000 lb. of factory butter was produced compared with 5,000,000 in 1945.

See R. J. M. Swynnerton, *A Plan to Intensify the Developments of African Agriculture in Kenya* (1955).

3. Uganda. — The agriculture is almost entirely African. Over most of the country the rainfall is very reliable. The Baganda area is very fertile. The export products are cotton, coffee (mainly *C. robusta*), tobacco, peanuts and maize. The food crops include bananas, maize, sorghum and cassava, roughly in that order. The small area of non-African farming produces sugar, tea and coffee.

4. **Tanganyika.**—The export products are plantation sisal, tea, sugar, maize, African coffee and cotton. By far the greater share of the export is produced by a small number of white cultivators.

J. THE SMALLER TROPICAL COUNTRIES AND ISLANDS

The agricultural problems are generally set by the circumstance that while an acre of land may grow enough food to provide an adequate, if uninteresting, diet for one or two persons it will, if growing a remunerative cash crop, provide for the purchase of a fuller and better diet as well as other requirements for a larger number. Search is therefore made for suitable cash crops and for means of securing higher yields of better quality. The West Indies produce sugar and its products rum and molasses, cotton, and, in Jamaica, bananas, citrus fruits, cocoa and coffee. Ceylon produces tea, coconuts, rubber and smaller quantities of cinnamon, citronella and cocoa. Malaya produces rubber, palm oil, coconut oil and copra. Mauritius produces sugar, tea and some tobacco. Fiji produces sugar and copra. All, however, import food. See TROPICAL AGRICULTURE; see also Index references under "Agriculture" in the Index volume. (E. J. R.)

AGRICULTURE, PRIMITIVE. Agriculture, the cultivation of fields (Lat. *ager*) for the production of a regular supply of crops for food and other needs, is the technical foundation on which the development of stable and sedentary human communities and the elaboration of most other arts and crafts has almost everywhere depended. Ethnographical records include a number of instances of primitive hunting and foraging peoples who sought to increase their supply of one or more of their collected vegetable foods by establishing proprietary rights over naturally productive tracts, by protecting seedlings, by burning the bush at certain seasons to inhibit the growth of unwanted plants and even by diversion of streams to promote the growth of seed-bearing grasses and wild roots by irrigation. But the crucial step toward cultivation consists in the deliberate and regular planting of stored seeds, tubers or cuttings in ground which has been sufficiently cleared and prepared to yield a crop.

Considerable empirical knowledge of the sprouting of seeds and tubers and of vegetative reproduction has been reported from collecting peoples. But for agriculture, however primitive, an element of foresight, planning and an established routine of cultivation is also necessary. The archaeological record shows that agriculture was a late development in the history of mankind. For by far the greater part of their existence, human communities were limited to small, widely dispersed and often migratory encampments of food gatherers.

Some natural environments have afforded an abundance of wild plant supplies that agriculture at a primitive level could not surpass. But under most conditions the successful cultivation of one or more staple crops, which can provide the greater part of the food supply, greatly reduces the extent of territory on which a given population needs to rely to secure its food. At the same time it can provide, according to the crop and climatic conditions, a harvest of storable supplies for the rest of the year or, as in the humid tropics, an almost continuous supply of maturing tubers and fruits. Both induce a greater fixity and concentration of settlement.

With the regular replanting of the more rewarding crops, incidental selection in favour of higher-yielding or otherwise desirable varieties takes place so that, over considerable periods of continuous cultivation, new mutant and hybrid plants may come to preponderate and thus effect a general improvement and an increase in the number of varieties adapted to different conditions. Already before the spectacular advances achieved by the genetically controlled methods of modern plant breeding, a wide range

HULTON PRESS LTD

PRIMITIVE METHOD OF PLOW CULTIVATION BEING PRACTISED ON AN ALGERIAN FARM

of improved and locally adapted varieties of cereals such as wheat, rice and corn or maize, of tropical root crops such as yams, taro and cassava and of many other cultivated plants had been developed in primitive agriculture.

EARLY AGRICULTURAL COMMUNITIES

Evidence for the antiquity of agriculture and the character of the earliest known farming communities has been derived from several sources. Archaeological discoveries of carbonized grains and other plant remains, or their impression, accidental or deliberate, on pottery before firing, together with other less-certain indications of cultivation, such as flint sickles, grindstones, mortars and hoelike tools, have been recovered from prehistoric settlements. Estimations of the absolute dates of some of these have been obtained by carbon-14 dating (see RADIOCARBON DATING). The geographical distributions and especially the clustering within limited regions of many varieties of some cultivated plants have been interpreted to indicate the probable areas of their first cultivation, while genetic studies have yielded valuable information on the course of the development of cultivated mutants and hybrids. (See AGRICULTURE: *Origins of Agriculture*; ARCHAEOLOGY.)

Old World.—Modern man (*Homo sapiens*) has existed from at least the period of the late Pleistocene glaciation and he survived as a food gatherer for more than 50,000 years before any human community began to rely on the effective and regular cultivation of plants for its food supply. In the old world the earliest known agricultural communities probably developed only about 7,000 or 8,000 years ago in the seasonally watered and lightly wooded grasslands to the east of the Mediterranean. The Natufians of Palestine with their harvesting sickles and mortars appear to exemplify an incipient agricultural community that heralded this development. The details of the process and the conditions in which these advances were achieved remain to be determined. But by at least 4000 B.C. the cultivation of wheat and barley, with which was combined the raising of goats, sheep and, later, cattle, was spreading widely over southwestern Asia, northeastern Africa and Europe to effect the Neolithic revolution—so called because these early agricultural communities, unlike their Paleolithic predecessors, generally employed ground stone "axes" as chopping and sometimes as digging tools.

While most early Neolithic settlements were still small communities of 20 or 30 households, they were more stable than those of Paleolithic hunters and the agricultural economy afforded time and energy for other activities including the new crafts of potmaking and weaving, as well as for the regular construction of durable dwellings. The potentiality for further development afforded by agriculture is shown by the comparatively rapid extension of such settlements over wide areas. This points in turn to a growth of population, made possible by a more assured food supply, and a recurrent hiving off of segments of expanding communities to

establish new settlements.

Some similarities in the cultivated plants and farming methods of the Indus civilization in northeastern India and of Neolithic sites in Honan and Kansu in eastern Asia with those of the ancient near east suggest that the former may owe their beginnings to an early eastward diffusion of Neolithic farming. But at the beginning of the 1960s there was no archaeological or other evidence to indicate whether any links with southwestern Asia underlay the development of rice cultivation in southern and southeastern Asia which was well established before the Christian era. In the latter region, too, the cultivation of root and tree crops, notably yam and taro, the coconut palm and the breadfruit tree, which were subsequently introduced as food staples in Oceania, was also developed at an early but unknown date.

Little is known of the antiquity of agriculture in trans-Saharan Africa. Yam cultivation was established in the tropical forests of western Africa long before European penetration. Some of the African varieties of yams and other forest crops are common to southern Asia and were probably introduced. But others are unknown elsewhere and it is uncertain whether these result from an independent agricultural development in Africa or are secondary additions. Bananas and plantains, which are widely cultivated and afford the staple crop in some areas, are on botanical grounds to be regarded as introductions and may not have reached Africa before the development of the Arab trade down the east coast. From the 15th century European traders also introduced many plants from the far east and the new world which spread rapidly and widely through tropical Africa.

The cultural history of another group of food grains including sorghum (*q.v.*) and collectively known as millets (*see* MILLET), which have become staples over the dryer tropical and subtropical areas of Asia and Africa, remains largely unknown, but in the absence of archaeological evidence for their great antiquity it is assumed that their first cultivation was a secondary development in areas marginal to the ancient east; from there they spread through central Asia and over the tropical savannas of eastern and western Africa.

New World. — The archaeological record in the new world shows that agriculture was first established in the tropical and subtropical areas of central America where maize became the food grain. Detailed studies have shown that maize has a long and complex genetical history including the hybridization of distinct species.

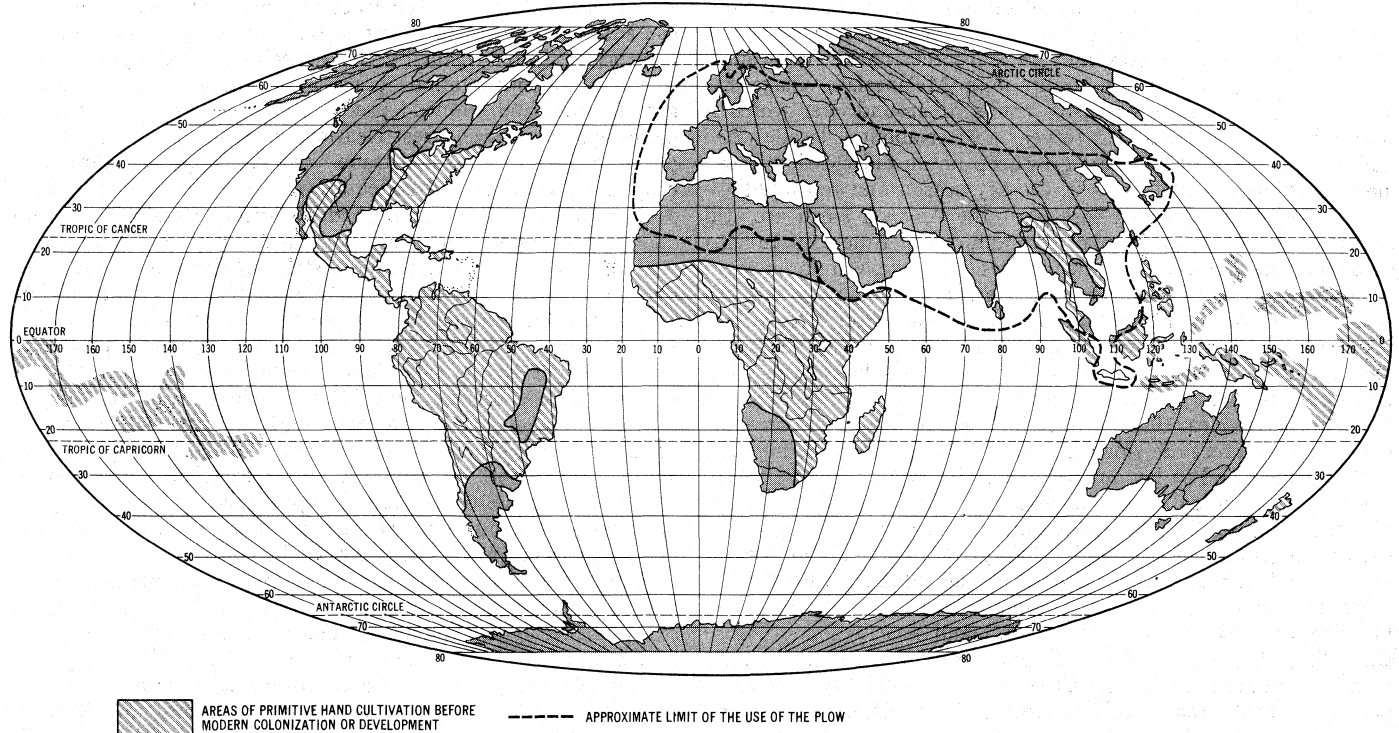

Although the basis for any absolute chronology is limited to carbon dating of only a few sites, settlements based on primitive maize cultivation may have existed 4,000 years ago. By 1000 B.C. farming communities that also cultivated beans, gourds and cotton as a textile material were established over a wide region extending from coastal Peru to Arizona, suggesting a rapid proliferation of the new and more productive economy analogous with but—as far as is known—independent of the Neolithic revolution in the old world. Maize growing was later introduced throughout the eastern woodlands of North America, and by the time of European discovery its cultivation had extended north and west to the climatic limits of cold and drought. In the west, on the other hand, although grown along the lower Colorado river, it had not been adopted by the Indians of the Californian woodlands who continued to rely on an abundance of wild acorns, nuts and seeds.

Although maize was known and cultivated under rather unfavourable conditions over much of the Amazonian tropical forest, an indigenous root, *Manihot* (cassava), had also been brought under cultivation at an unknown date to provide a continuously yielding food staple. On the high plateaus of the Andes beyond the climatic limits of maize cultivation, the potato became a cultivated food staple. (*See* INDIAN, NORTH AMERICAN; INDIAN, LATIN-AMERICAN.)

DIFFUSION OF PLANTS AND TECHNIQUES

In the course of the growth and movements of human populations and the secondary development of new food crops, a very wide range of combinations of cultivated plants had been established in the farming patterns of different regions. Crops that may have been originally secondary and minor sources of food have, like the sago palm in parts of Melanesia or the banana in parts of eastern Africa, become the food staple in new areas. World-wide voyaging and trading by Europeans added greatly to the range of crops available to primitive cultivation by introducing plants from other continents, some of which, like cassava in western Africa or maize in southern Africa, displaced the older staple foods.

But primitive forms of cultivation with simple hand tools were superseded well before the Christian era in the areas of early agricultural development in the old world. In southwestern Asia the harnessing of draft animals for plow cultivation and large-scale basin irrigation in the riverine lowlands had been developed by the and millennium B.C. Plow cultivation and the rotation of

PRIMITIVE AGRICULTURE: WORLD DISTRIBUTION OF HAND AND PLOW CULTIVATION

fields extended through the Mediterranean, central and western Europe in the Iron Age to provide the economic foundation of the classical and medieval civilizations of Europe. Intensive agriculture with regular manuring and continuous cultivation was also developed in the higher civilization of southern and eastern Asia.

CONTEMPORARY AGRICULTURAL COMMUNITIES

It is only in remote hill areas of southern Asia, in some of the islands of Indonesia, in the Melanesian and Polynesian archipelagoes of Oceania, in trans-Saharan Africa and in the new world that hand cultivation has survived into modern times (see map). Such areas do, however, include a wide range of physical environments and great diversity of crops. Techniques of cultivation and the organization of labour for the planting, tending and storage of crops are equally diverse in detail. It is therefore illusory to conceive of any single pattern of culture or form of social organization to which primitive cultivators will conform. The techniques involved range from the crudest dibble planting in sloughs or partially burned-over ground to the careful preparation of seed-beds, fertilizing with ash and sweepings, the terracing of hill slopes with stone revetments, ridge and mound cultivation and the irrigation of plots enclosed by bunds (embankments). Successful hand cultivation does not depend on any great elaboration of implements. Land can be sufficiently cleared by burning in the dry season, the scattered ash increasing the fertility of the soil. Simple digging sticks can, as in Oceania and the Americas, suffice for dibbling in seeds or tubers.

On their forested tropical islands the Melanesians practised a highly successful yam cultivation before iron tools were introduced and they continue to rely mainly on their digging sticks for planting. In the eastern Solomons they maintain coconut and bread-fruit groves along the coast and make yam gardens on the rising ground inland. Groups of kinsmen co-operate to ring the trees and burn the undergrowth over acre-sized clearings which are fenced with the larger logs against the depredations of their domesticated pigs. Within the clearing the separate gardens of each household are marked out but all co-operate to rake over the ground and plant the yams of each garden in turn. The details of cultivation manifest an intimate empirical knowledge of the requirements of good farming and a strong spirit of emulation in the effort to obtain a good harvest of large yams. In the display of the harvests and the reciprocal gifts of food among kinsfolk great prestige is gained by the successful and social obligations are fulfilled. After one or two seasons a new clearing has to be made since fertility rapidly falls off and weeds choke the ground. But each co-operating kin group in a Melanesian village has claims to one or more extensive tracts of ground over which it shifts its clearings from year to year. After about a decade when saplings and dense bush have grown up on an old clearing it can be burned and cleared again in the dry season and replanted.

The vast river-threaded forests of the Amazon basin are still occupied by innumerable small communities of American Indians who successfully maintain themselves with even more meagre equipment. Stone axes are extremely scarce and many groups can obtain them only one at a time by infrequent barter. Nevertheless patches of forest extending over several hundred yards are periodically cleared of all but the largest trees by burning and prizing, using heavy stakes as levers. A whole season's work is often needed to clear this charred wilderness of trunks and creepers sufficiently to erect the single communal dwelling for the hundred or so villagers and to lay out plots in which crops can be planted. These include several root crops including yams and sweet potatoes but the food staple is cassava flour. A continuous supply of cassava roots can be obtained, for a plant will yield for several seasons and cuttings can be taken from the old growth for further plantings. But the tubers are poisonous in their raw state. They have to be soaked, fermented, grated and squeezed dry before the edible flour is obtained. Beans, pineapples and sometimes maize are planted in and around the cassava plots as well as tobacco and coca shrubs that yield narcotics. When, after four or five years, the yield of cassava tubers falls off markedly work on a new clearing must begin. An old site vacated a decade or so

before is usually chosen since although the undergrowth is denser this can be burned and there will be fewer large trees. Thus, as in Melanesia, a community migrates over a familiar tract of country occupying a series of clearings in succession.

This pattern of shifting cultivation by slash-and-burn methods is characteristic of primitive tropical-forest root-crop farming in all parts of the world, and is also used for dry rice cultivation in forested hill country in southeastern Asia. It allows for the development of settled village communities surrounded by their farming tracts within which plots are periodically cleared and planted. But the large total area per household that it entails limits their growth to a few hundred persons. Where, as in western and north central Africa, iron tools—especially machetes—are used for the effective clearing of the forest and hoes for the deep cultivation and mounding of the soil, considerably higher production can be obtained. Heavier dressings of fertilizing ash are obtained and fully cleared plots can be more closely cultivated, so that population densities of over 100 to the square mile and sometimes much higher can be maintained under shifting cultivation. Where the settlement pattern is compact, villages several thousand strong are established under favourable conditions.

In parts of the forest belt of west Africa, for instance, where the growth of trade, population and larger political organizations has also been stimulated for over four centuries by coastal commerce with Europe, intensive patterns of shifting cultivation have been established by large settled communities. Yams are usually the staple crop and extensive areas can be hoed into yam hills to provide the depth of soil required for these large tubers. A household plot will vary from one to several acres according to the size and other resources of the family. A wide range of secondary crops including coco yams, beans and gourds are grown on and between the yam mounds, while groves of bananas, peppers and fruit trees are established along the paths leading to the plots and round the large open barns in which the bulky yam harvests are stored on scaffolding to protect them from pests. Such intensive cultivation rapidly exhausts tropical soils and fresh plots are needed each year. But once a sufficient area of high forest around a settlement has been gradually cleared, the close secondary growth that develops on untilled ground can be cleared fairly rapidly in the dry season by teams of kinsmen with machetes and burning. Thus a system of rotating bush fallowing can be established whereby a given tract of land is farmed for one season and then allowed to revert to bush for four or five years before being cleared again by the household or kin group which retains continuous rights to its use for farming and as a collecting area for wild and semiwild produce. The latter includes the oil palms which colonize forest clearings and are of outstanding importance for both food and trade. On the better soils permanent crops such as cocoa and coffee are grown specifically for export overseas in plantations established by further clearing of the forest. Household surpluses of foodstuffs and produce for export are sold at recurrent village and district markets at which a wide range of imported manufactures are available for purchase. Both men and women engage in trade, some on a considerable scale in export produce, while local shortages of farm labour in productive areas are met by seasonal and periodic immigrations of farm workers from poorer regions. Dense sedentary populations are thus maintained, whether in large villages or spread over innumerable neighbouring hamlets that are connected by forest paths and focused on local markets. In southern Nigeria local population densities commonly exceed 200 per square mile and may rise much higher where substantial cash crops can be grown for export or where seasonal wage labour is available in accessible commercial centres. With such pressures of population, land rights for hoist sites as well as farms become increasingly important and the successive rights of the individual holder, his heirs, his wider group of kin and his local community become the subject of precise rules in customary law which are enforced according to the judgments of courts in the local community or chiefdom. Although the explicit sale of land is usually excluded by the collective rights of kin groups supported by religious sanctions, the needs and op-

portunities for land transactions between individuals in these more commercialized economies are met by forms of land pledging which result in permanent transfers. The division and organization of labour and the allocation of rights to the produce are similarly defined with increasing precision both within the household and within the groups of kinsfolk and villagers who co-operate in farming both for subsistence and for the market.

In the Mato Grosso and similar regions in South America the tropical wooded grasslands and scrublands proved very intractable to primitive agriculture before the advent of iron tools. Although the tall grasses could be burned after the long dry season, the hard ground was difficult to break and dibble with wooden sticks and the maize crops were often washed away by torrential rains. But in tropical Africa where the craft of ironworking was widely known and practised long before modern European penetration, millet cultivation was successfully established throughout such areas with the aid of the iron hoe. The problem of fertility on the characteristically poor and leached soils was met throughout much of central Africa by lopping trees over a wide area round the plot to provide the wood for heavy dressings of ash.

The steppes or temperate grasslands with their short growing season and root-matted soils appear never to have been conquered by the primitive hand cultivator. In the old world, prehistoric cultivators only penetrated the fringes of the Pontic and Siberian steppes which remained hunting and grazing territories well into historic times. The Great Plains and the pampas of North and South America were only opened up to agriculture by the steel plows of European pioneers in the 19th century. But primitive cultivators established themselves early in the semidesert areas of the new world and in a few of them the obstacles to European colonization have enabled them to survive. The Indian pueblos of New Mexico and Arizona preserved an essentially pre-Columbian pattern of primitive agriculture into the 20th century.

These small but compact Indian villages of the American southwest, to which the name pueblo, originally given by their Spanish discoverers, is generally applied, are dispersed over the semidesert intermontane plateaus from the Rio Grande to the Little Colorado. These are climatically marginal lands for agriculture, since the direct rainfall is inadequate for growing the staple crop, maize, and late winter frosts at these high altitudes of several thousand feet severely curtail the growing season. But, by taking advantage of the runoff and seepages from the higher plateaus which receive more rain and by deeply planting crop varieties that, as a result of centuries of practical selection, are resistant to drought and mature quickly, it is possible to secure good harvests on the wide alluvial basins lying below and between the mesas or plateaus.

Along the larger streams with permanent flow, such as the tributaries of the Rio Grande, irrigation channels can be taken off to lead water to the farmlands. Elsewhere, as in the Hopi pueblos of Arizona, fields can be made in the valleys at places where the floodwaters of intermittent streams from the mesas spread over the flats to produce natural and temporary inundations after rains in the higher ranges. Along the lower slopes at the foot of the mesas small but frequent natural springs afford opportunities to make irrigated gardens and seepages provide sufficient moisture for further cultivation. The scantiness of the vegetation of shrubs and cacti at lower altitudes and the friability of soils make it possible to clear and plant the ground with the simplest of wooden tools to uproot bushes and dibble in the seeds. Brushwood fences can be erected to afford some protection against the washing out of crops by heavy floods or their destruction by wind-blown sand. Plants are widely spaced and soil fertility is restored by the deposition of new soil so that a suitable area can often be used indefinitely for cultivation. The shortness of the season has induced careful attention to the timing of agricultural activities which is regulated by a calendar based on the daily shift in the position of sunrise along the southern sky line. By these means the Hopi, Zuñi and other Pueblo peoples have for centuries raised crops of maize, beans, squashes, melons, peppers: onions and formerly cotton between April and September in the various tracts of better-watered land which have been appropriated by the kin groups of which the villages are composed. But the hazards of farming are

such that a prudent household endeavours to keep most of a year's maize harvest in reserve, storing it on the ear in dry inner chambers of the house. The securing of the donkey and some new crops such as peaches from the Spaniards and of steel tools and wagons from Americans has not greatly altered the general pattern of Pueblo farming in which individual households still raise their crops by hand cultivation within the framework of village organization.

In addition to the references given above, see also articles on the various plants mentioned (such as CORN and POTATO) and on geographical regions (such as AFRICA; MELANESIA; NORTH AMERICA).

AGRICULTURE, TROPICAL: see TROPICAL AGRICULTURE.

AGRI DECUMATES, a name given by Tacitus to the Black Forest and adjoining areas of southwestern Germany between the Rhine, Danube and Main, which Rome began to annex under the Flavian emperors, starting in A.D. 74. Tacitus, writing in A.D. 98, does not explain the name, but it probably derives from a pre-Roman term whose meaning had been forgotten; it may imply earlier occupation by a tribe with ten cantons. The area was once owned by the Helvetii (*q.v.*) but later was precariously inhabited, so Tacitus says, by vagabonds from Gaul. The Roman advance was doubtless due to the desire to secure better communications inside the imperial frontier by moving it farther east so as to include behind it the territory partly encircled by the loop of the Rhine as it changes its course from westward to northward. The Alamanni occupied the territory c. A.D. 260.

AGRIGENTO (formerly GIRGESTI; AKRAGAS of the Greeks, AGRIGENTUM of the Romans), an ancient and wealthy city near the south coast of Sicily. Founded c. 582 B.C. by Greek colonists from Gela on the site of an existing native settlement, it prospered rapidly, reaching its peak in 480, when Theron (488–472), in alliance with Syracuse, won the decisive battle of Himera over the Carthaginians. In 470 the tyranny that had existed until then was replaced by a democracy. It was the birthplace of the philosopher-politician Empedocles and under the tyranny it was a considerable centre of the arts. Pindar, who calls it the "fairest of mortal cities," and Simonides of Ceos were frequent visitors, and its wealth, founded on agriculture, stockbreeding and commerce, was a byword. Neutral in the struggle between Athens and Syracuse, it was sacked by the Carthaginians in 406 B.C., a disaster from which it never really recovered. It was refounded by Timoleon in 338 and achieved some local importance under the tyrant Phintias (289–279), but soon after fell victim to the rivalry of Rome and Carthage. It was sacked successively by the Romans (262) and the Carthaginians (255), and fell finally to the Romans in 210. Under Roman rule its agricultural wealth and the exploitation of the nearby sulfur mines ensured a modest prosperity, and it was not until late antiquity that the inhabitants withdrew to the relative security of the medieval hilltop town of Girgenti, the nucleus of the modern town of Agrigento. In 828 Girgenti was occupied by the Saracens and colonized. It was captured in 1086 by the Norman conqueror of Sicily, Roger Guiscard (Roger I), who established a Latin bishopric.

The site is beautiful and unusual, occupying a basinlike plateau, encircled on three sides by the low-cliffs that overlook the junction of the ancient rivers Hypsas and Xkragas (now called Drago and San Biagio respectively), and dominated from the north by a ridge with twin peaks, the so-called Rock of Athena and the eminence later occupied by Girgenti. Which of these peaks was the acropolis (*q.v.*) has been disputed, some scholars maintaining that the latter lay outside the town. However, reasons of defense seem to

PLAN OF ANCIENT AGRIGENTUM (AKRAGAS), SHOWING SITE OF THE MODERN CITY OF AGRIGENTO

demand its inclusion, and the remains of an early 5th-century Doric temple under the church of Sta. Maria dei Greci may well be those of the temple of Athena, known to have been founded on the acropolis by Theron. That of Zeus Atabyrios perhaps underlies the cathedral. Except to the north and northeast the site is not one of great natural strength, but it was readily defensible by means of a wall which can be traced almost continuously from the Rock of Athena round to the head of the valley south of the hill of Girgenti, a distance of more than 4 mi.; in this stretch there are the remains of eight gates.

The principal excavated remains of the Greek city are its temples, of which no less than seven formed an almost continuous sacred area along the ridge that carries the south line of the city's defenses. All are Doric buildings. (For explanation of terms see GREEK ARCHITECTURE.) All except for the temple of Heracles (peripteral, hexastyle; late 6th cent.; eight standing columns) belong in their present form to the great burst of building activity that followed the victory at Himera in 480. The best preserved are the two very similar peripteral, hexastyle temples conventionally, though wrongly, attributed to Hera and to Concordia; the latter temple, which lacks little but the roof, owes its remarkable conservation to having been converted into a church in A.D. 597. In front of the temple of Hera stood a huge altar, as long as the façade of the temple itself, a feature which is repeated in the temples both of Heracles and of Zeus. This latter temple (3681 x 184½ ft., a double square) was planned on a scale to which temple C at Selinus (*q.v.*) offers the only parallel in the field of Doric architecture, and it is one of the most original of all Greek buildings. The huge figures of Atlas, one of which has been recomposed on the site, supported the trabeation between the half-columns of the exterior order, which was unique in consisting not of columns but of half-columns linked by a continuous partition wall. The façade was heptastyle and the cella was open to the sky. Still unfinished in 406, its ruins were quarried in the 14th century to build the jetties of Porto Empedocle and very little is now standing. The sanctuary of Demeter and Persephone, founded on the site

of a pre-Hellenic shrine, is notable for the many remains of its archaic cult-buildings; the familiar standing structure (formerly known as the temple of Castor and Pollux) is largely a 19th-century pastiche. Of the temple of Hephaestus (hexastyle, peripteral; built c. 430) only the platform and two columns have survived. The little Doric temple of Aesculapius outside the walls, in antis (see ANTA), with a false rear porch indicated by half-columns, is notable for its architectural refinements, the lines being all slightly convex. Another simple Doric temple in antis is that of Demeter, underlying the church of S. Biagio; the cave sanctuary at the foot of the cliffs beneath goes back to pre-Hellenic times. The Agora, later the Roman forum! probably lay just north of the temple of Zeus, but apart from the extensive remains of aqueducts and cisterns little is known of the civil or domestic architecture of the Greek city. The "Tomb of Theron" just outside the south gate is a late Hellenistic funerary monument; and the "Oratory of Phalaris," adjoining the picturesque 13th-century Cistercian church of S. Nicola (the setting of Pirandello's *Il Signore della Nave*), is a *heroon*, or heroic shrine, of the 1st century A.D. A short distance to the east of it a considerable quarter of the Hellenistic and Roman town has been excavated. It is laid out on a strictly rectangular plan and includes houses of both Greek peristyle and Italic atrium type.

Although by late antiquity the cemeteries were invading the temple area (the many tombs around the temple of Concordia include a Christian catacomb) the earlier classical cemeteries lay on the slopes and in the valleys beyond the walls to the east and west. The earliest of these, on the low hill of Montelusa, west of the river mouth and the ancient harbour, offers clear evidence of a Greek trading settlement before the formal establishment of the colony.

The modern town, whose name was changed from Girgenti to Agrigento in 1927, is the capital of the province of Agrigento and an episcopal see, 58 mi. south by east of Palermo direct and 84½ mi. by rail. Pop. (1957 est.) 44,338 (commune). The old quarter contains many historic buildings, notably the cathedral (14th century), the medieval churches of S. Giorgio and S. Spirito, and a number of baroque churches and palaces; there is a large modern quarter spreading over the Rock of Athena. The museum contains fine vases, sculptures, terra cottas, etc. Porto Empedocle (pop., [1957 est.] 17,513 commune), 5½ mi. S.W. by rail, was founded in the 18th century by Bishop Gioeni of Agrigento. It is the best harbour on the southwest coast of Sicily, and serves the important sulfur mines in the hills just to the north of Agrigento. It was heavily bombed by the Allies during World War II.

See P. Griffo, *Guide to the Monuments of Agrigento* (1956).

(J. B. W.-P.)

AGRIMONY, a slender perennial herb (botanical name, *Agrimonia eupatoria*, family Rosaceae), 1½ to 3 ft. high, growing in hedge banks, copses and borders of fields. The leafy stem ends in spikes of small yellow flowers. The flower stalk becomes recurved in the fruiting stage, and the fruit bears a number of hooks which enable it to cling to rough objects, such as the coat of an animal, thus ensuring distribution of the seed. The plant is widely spread through the north temperate region. The underground woody stem is astringent and yields a yellow dye.

The name has been unsystematically given to several other plants; for instance: bastard, Dutch, hemp or water agrimony (*Eupatorium cannabinum*); noble or three-leaved agrimony (*Anemone hepatica*); water agrimony (*Bidens*); and wild agrimony (*Potentilla anserina*).

AGRIONIA (the "gathering"), an ancient Greek festival celebrated annually at Orchomenus in Boeotia and elsewhere in honour of Dionysus by women and priests at night. The tradition is that the daughters of Minyas, king of Orchomenus, having despised the rites of the god, were driven mad by Dionysus and ate the flesh of one of their children; as punishment they were turned into bats, or birds. At this festival it was originally the custom for the priest of the god to pursue a woman of the Minyan family with a drawn sword and kill her.

AGRIPPA, a skeptical philosopher to whom are ascribed the "five tropes" (types of skeptical argument) which, according to

Sextus Empiricus, summarize the attitude of the later ancient skeptics. His date cannot be accurately determined but he must have lived later than Aenesidemus. He argued: (1) there is a clash of opinions, both in daily life and in the debates of philosophers; (2) nothing is self-evident—what is called a proof is a second proposition which itself needs demonstration, and so on ad infinitum; (3) perceptions and judgments are relative in a double sense—each is relative to a subject, and each is affected by concomitant perceptions; (4) dogmatic philosophers, to avoid the infinite regress, simply offer hypotheses which they are unable to prove; and (5) philosophers are involved in the vicious circle of proving the sensible by the intelligible and establishing the intelligible in its turn by the sensible.

The general result is that we have no starting point for knowledge. No perception or judgment guarantees its own truth, and the methods of proof which philosophers have attempted to use are all invalid. The ten tropes of Aenesidemus (*q.v.*) were concerned mainly with presentations of the senses and occupied a subordinate place in his defense of skepticism. Agrippa's tropes are integrated with one another and deal not merely with perceptions, but also with modes of proof. See also AENESIDEMUS.

For sources see Diogenes Laertius, ix, 88 *et seq.*, and Sextus Empiricus, *Hypotyposes*, i, 164–169. (D. J. A.)

AGRIPPA, HEINRICH CORNELIUS (AGRIPPA VON NETTESHEIM) (1486–1535), German writer, soldier and physician whose works on occult subjects gained him a reputation as a magician, was born at Cologne on Sept. 14, 1486, of the lesser nobility. From 1501 to 1507 he was a captain in the emperor Maximilian I's army. In 1509 his lectures at Dôle university, in the Franche-Comté, on the *De verbo mirifico*, Johann Reuchlin's liberal treatise on religion, roused ecclesiastical opposition. In 1510 he left Dôle for London, where he stayed with the humanist John Colet. He married his first wife in 1514, at Cologne. Eustache Chapuys, later imperial ambassador to England, stood godfather to their son. In 1515 Agrippa was lecturing at Pavia university and remained in Italy until 1518, when, recommended by William VI of Montferrat, he became public orator and advocate at Metz. His defense of an accused witch brought him ecclesiastical condemnation, and in 1520 he left Metz for Cologne, where his first wife died. In 1524 he went to Lyons as physician to Louise of Savoy, but in 1527, having received no salary, he again moved. He was appointed historiographer to the emperor Charles V at Antwerp in 1529. Imprisoned for debt in Brussels in 1531, he was rescued by Chapuys. He died at Grenoble in Dauphiné, on Feb. 18, 1535, having been three times married and leaving seven children.

Agrippa's principal works are *De occulta philosophia*, written about 1510 in Cologne and published in revised form in Antwerp in 1531; and *De incertitudine et vanitate scientiarum et artium atque excellentia Verbi Dei declamatio*, written between 1527 and 1528, and published at Antwerp in 1531. The latter work, influenced by Pico della Mirandola and Reuchlin, is a biting satire on the state of science, attacks the belief in witches, denounces the accretions which had grown up around the simple doctrines of Christianity and attacks the reactionary schoolmen of his time. The *De occulta philosophia*, a fascinating mixture of Neoplatonic and Christian beliefs, contains a system of cabalistic-mystical philosophy in which magic emerges as the most perfect science which can lead men to a knowledge of nature and God. It contains Agrippa's doctrine of the three worlds—those of the elements, of the stars and of the spirits, corresponding to the physical world, to the heavenly world and to the world of the mind—and postulates a fifth element (quintessence) that presides over the four elements. Agrippa displays many features later to be embodied in Goethe's Faust. An edition of his works was published at Leiden in 1550. Book I of *De occulta philosophia* was also reprinted in *Three Books of Occult Philosophy*, ed. by W. F. Whitehead (1898).

AGRIPPA, MARCUS VXPSANIUS (63–12 B.C.), Roman statesman and general, the chief agent of Octavian in his rise to

power and chief support of the Augustan monarchy. Agrippa was with Octavian at Apollonia when the news arrived that Julius Caesar had been assassinated, and went with him to Rome to claim the inheritance (44 B.C.). Their path led through hazard and violence. Before long Agrippa helped Caesar's heir to recruit a private army. No action of his is recorded in the campaigns of Mutina and Philippi, but he played an important role in the War of Perusia (41–40).

Two years later, while governing Gaul for Octavian, he crushed a rebellion of the Aquitanian tribes and led an expedition across the Rhine. The consulate was his reward (37). Meanwhile Octavian had been calamitously defeated by Sextus Pompeius, who commanded the seas adjacent to Italy. Agrippa's help was needed. He trained fresh crews and constructed a great harbour on the Bay of Naples, using the Lucrinus (Lucrino) and Avernus (Averno) lakes. Then in the next year an attack was launched against Sicily, Pompeius being overcome by Agrippa at the battles of Mylae and Naulochus. When at last the uneasy alliance that apportioned the Roman world between Octavian and Mark Antony broke down, it was Agrippa's talent that won the decisive victory at Actium (31).

Agrippa proceeded to a second consulate as colleague of Octavian in 28 (when they held a census together and purged the Roman senate), likewise to a third in 27. In January of that year Octavian announced that normal government had been restored to Rome and took the cognomen Augustus. For the next 15 years Agrippa seems to have functioned as deputy to Augustus, alternating between Rome and the provinces; the two men were seldom in the same place. The year 23, in which occurred a conspiracy against the principate and the grave illness of Augustus, was critical for the new system of government, but it did not shake the power or diminish the utility of his ally. Agrippa went to the east (presumably on some important mission the nature of which is not recorded). In 23 the young Marcellus, nephew of Augustus and husband of his daughter Julia, died, and when Agrippa was recalled in 21 he received the widow as his bride. He then went to Gaul and Spain, where he completed the subjugation of the north and northwest.

In 18 Augustus admitted Agrippa to partnership in some of the special powers of the principate; and the sons whom Julia had borne him, Gaius (b. 20) and Lucius (b. 17), were promptly adopted by Augustus, who was anxious for the dynastic succession. In 17 Agrippa went away to supervise the provinces of the east, with extensive powers. He stayed there for four years during which he settled the affairs of the Bosporean kingdom, planted veteran colonies at Berytus (Beirut) and Heliopolis (Baalbek) and pursued a policy of friendship with Herod the Great. He came back in 13 to open operations against the Pannonians in Illyricum, but died early in the next year.

Agrippa was not merely a great general, but an organizer and an engineer. When aedile at Rome in 33 he had carried out many improvements, repairing sewers and aqueducts. He built a new aqueduct, the Aqua Julia. The Pantheon (built in 25) is also his. He prepared a map of the world and left behind notes on geography and a record of his own life.

Agrippa was a parvenu of obscure parentage. He is represented as self-effacing and tireless in his loyalty to Augustus. He was married three times, first to Caecilia Attica, the daughter of Cicero's friend T. Pomponius Atticus; a daughter of this marriage, Vipsania, married Tiberius Claudius Nero (later the emperor Tiberius). The death or divorce of Attica c. 29 qualified him for a dynastic match with Augustus' niece, the elder Marcella, whom he divorced in 21 in order to become the son-in-law of the *princeps*. Julia had three sons, Gaius, Lucius and Agrippa Postumus, and two daughters. Julia and the elder Agrippina (mother of Caligula and grandmother of Nero).

AGRIPPINA THE ELDER (c. 14 B.C.—A.D. 33), daughter of Marcus Vipsanius Agrippa and of Augustus' daughter Julia, was born about 14 B.C. and married her second cousin Germanicus Caesar (*q.v.*) about A.D. 5. She accompanied her husband to Germany and

to the east and after his death at Antioch in A.D. 19 promoted the trial of Gnaeus Piso for his murder. The death of Tiberius' son Drusus in 23 brought her sons into direct hope of the succession, and she became the object of attacks from Sejanus (*q.v.*), who had his own alternative designs. Finally in 29 she was exiled to Pandateria off the coast of Campania, where on Oct. 18, 33, she died, starved to death by herself or, according to some, by order of Tiberius. Her two elder sons, Nero and Drusus, had already died violent deaths. Of her nine children by Germanicus one son and three daughters survived her, the son being the emperor Gaius (Caligula) and the most famous of the daughters being Agrippina the mother of Nero. Her arrogance had moved Tiberius to protest that she must not take it as an insult that she was not actually queen of Rome, but her private life has escaped reproach.

There are several fine portraits of her, the most famous in the Capitoline museum at Rome, and a coin issue of which there are examples in the British museum commemorates the return of her ashes to Rome under Gaius' order.

BIBLIOGRAPHY.—Tacitus, *Annals* i–vi; Suetonius, *Tiberius*; *Cambridge Ancient History*, vol. x and volume of plates, iv (1934). (G. E. F. C.)

AGRIPPINA THE YOUNGER (A.D. 16–59), daughter of the elder Agrippina, sister of the emperor Gaius (Caligula) and mother of Nero, was born at Oppidum Ubiorum on the Rhine, afterward named in her honour Colonia Agrippinensis (mod. Cologne). By her first husband, Gnaeus Domitius Ahenobarbus, she was the mother of the emperor Nero; her second husband was Passienus Crispus, whom she was accused of poisoning in 49. In 39 she was involved in a conspiracy against Gaius and exiled, but returned to Rome in 41.

In 49, after the death of Messalina, she married the emperor Claudius I (*q.v.*), her uncle, and induced him to adopt the future Nero as heir to the throne in place of his own son (Britannicus). She also protected Seneca and Burrus, who were to be Nero's tutors and advisers in the early part of his reign. In 54 she is said to have poisoned Claudius and secured the throne for her son. She exercised a considerable influence on political life during the first years of Nero's reign, but later her power declined. She quarreled with Nero about his private life and opposed his liaison with Poppaea. Nero thereupon decided to get rid of his mother. Pretending a reconciliation, he invited her to Baiae, where an unsuccessful attempt was made to drown her on a vessel constructed to founder. Eventually he had her put to death at her country house. Agrippina wrote memoirs, referred to by Tacitus and Pliny the Elder.

AGRONOMY. In the middle 1890s the term agronomy, used to designate the branch of agriculture dealing with climate, soils, fertilizers and crops (plant production), was introduced into the agricultural colleges and experiment stations of the United States. The term later came to be used generally to indicate that branch of agriculture dealing with the science and the art of field crop culture and soil management. However, in some institutions the term agronomy is limited to the culture of field crops. See also Index references under "Agronomy" in the Index volume.

(A. D. T.)

AGUADILLA, a municipal district that forms the northwest corner of the island of Puerto Rico. Its population in 1960 was 47,864. The town of Aguadilla itself is located on the west coast of Puerto Rico, on the Mona passage that connects the Atlantic ocean with the Caribbean sea. The excellent port facilities provided by a deep bay, formed on the south by Point Jigüero and to the north by Point Boriquén, the northwest tip of Puerto Rico, are strategically located close to the shipping routes. The agricultural area around Aguadilla produces principally sugar, coconuts and tropical fruits such as avocados and grapefruit. Excellent roads lead to Mayagüez to the south, east to San Juan, the capital of Puerto Rico, and into the interior towns of San Sebastián and Lares. Slightly to the north of the town is Ramey air force base, one of the largest U.S. air bases in the Caribbean zone. Overlooking the town, the bay, and Mona passage is a well-serviced and popular tourist hotel.

Although the town was not founded until 1775, its historical tradition dates from 1493 when Columbus, on his second voyage, supposedly refilled the fleet's water casks from a spring which still flows in the centre of the town.

(T. G. Ms.)

AGUASCALIENTES, an inland state of Mexico, bounded north, east and west by the state of Zacatecas, and south by Jalisco. Pop. (1950) 188,075; (1960) 236,574. Area 2,499 sq.mi. The state occupies a part of the plateau of central Mexico about 6,000 ft. above sea level, extending from two spurs of the Sierra Madre, called the Sierra Pinal and Sierra de Laurel, eastward to the rolling fertile plains of its eastern and southeastern districts. It is well watered by numerous small streams and one large river, the Aguascalientes or Rio Verde, and has a mild healthful climate with a light rainfall. The fertile valleys of the north and west are devoted to agriculture and the plains to stock raising. Indian corn, flour, cattle, horses, mules and hides are exported to the neighbouring states.

The area was explored by the Spaniards in the 16th century and was a mining centre of colonial days. Its name, Aguascalientes, meaning "hot waters," stems from the many thermal springs in the vicinity. The state is one of the smallest in Mexico; its present boundaries were delineated by the constitution of 1857. During the revolution of 1910–20 it was the centre of bitter fighting and was occupied by successive factions in the struggle. The capital city, also named Aguascalientes (see below), was a military prize because of its important rail terminals.

Aguascalientes is the centre of many beautiful orchards and vineyards, and produces excellent wines and fruits. Irrigation projects carried out in the 1950s greatly increased the productivity of the land. The state is also noted for its mining products: zinc, copper, gold, silver, lead and antimony. The ranches of Aguascalientes raise bulls for the *corridos* all over Mexico. The state and capital city have excellent rail, air and highway connections with all parts of Mexico.

(J. A. Cw.)

AGUASCALIENTES, a city of Mexico and capital of the state of the same name, 364 mi. N.W. of Mexico City. Pop. (1960) 122,809. Altitude 6,261 ft. Aguascalientes was founded Oct. 22, 1575, and became the state capital when the area was created a separate state during the 1850s. The city contains cotton and other textile factories, potteries, tobacco factories, distilleries and other industries. It is also the centre of a rich agricultural region producing many varieties of fruits and vegetables. The city contains many fine public buildings and churches. The most notable churches are San Juan de Dios, San Francisco and La Parroquia, each of which possesses outstanding examples of colonial religious art. The city is sometimes called La Ciudad Perforada (the perforated city) because of a labyrinth of tunnels beneath it excavated in pre-Columbian times by some unidentified tribe.

(R. B. McCk.)

AGUE, the common name given to a form or stage of malarial disease; the ague fit is the cold, shivering stage, and hence the word is also loosely used for any such paroxysm.

See *MALARIA*.

AGUESSEAU, HENRI FRANÇOIS D' (1668–1751), French jurist and statesman who as chancellor of France made many important reforms in his country's legal system. He was born at Limoges, Nov. 27, 1668, the son of Henri d'Aguesseau, who held a number of high positions in the government. Educated for the law under Jean Domat, he distinguished himself as an advocate and in 1700 was appointed procurator general. As such, he defended the rights of the Gallican Church against Rome in the controversy over the promulgation in France of the papal bull *Unigenitus*. The regent Philippe d'Orléans made him chancellor and keeper of the seals in 1717 but withdrew the seals and exiled him to Fresnes in 1718 because of his opposition to John Law's projects. D'Aguesseau recovered the seals on his recall in 1720 and then, reversing his original attitude, helped Guillaume Dubois in his efforts to register the bull *Unigenitus*. However, he opposed other measures of Dubois and forfeited the seals again when Dubois became chief minister (1722). After five years spent in study at Fresnes, he was recalled by Cardinal Fleury in 1727 (though G. L. de Chauvelin was garde des sceaux till 1737). D'Aguesseau failed

in his attempt to codify French law, but formulated several enactments concerning donations, testaments and successions and also introduced regulations for improving the forms of procedure and for effecting a greater uniformity in the execution of laws. He died in Paris on Feb. 9, 1751.

The chancellor's grandson, HENRI CARDIN JEAN BAPTISTE, MARQUIS D'AGUESSEAU (1752–1826), who was born in Paris on Aug. 23, 1752, became advocate general in the *parlement* of Paris (1772), a member of the Académie Française (1787) and a deputy in the estates-general (1789). Under the consulate he was appointed president of the court of appeal of Paris and then minister to Denmark (1803). He was a member of the senate from 1805 to 1814, in which year Louis XVIII made him a peer of France. He died in Paris on Jan. 22, 1826.

BIBLIOGRAPHY.—A selection of H. F. d'Aguesseau's own works ed. by E. Falconnet, 2 vol. (1865), includes a biographical notice. See also Charles Butler, *Memoir of the Life of Henry Francis d'Aguesseau* (1830); F. Monnier, *Le Chancelier d'Aguesseau*, 2nd ed. (1863).

AGUILAR, GRACE (1816–1847), English poet and novelist who wrote on Jewish history and religion, was born in London on June 2, 1816, of a family of Spanish-Jewish origin. An early book of poems, *The Magic Wreath*, appeared when she was 19. In *The Spirit of Judaism* (1842) she wrote in defense of her faith. She died, Sept. 16, 1847, at Frankfurt am Main, Ger. Many of her works were published posthumously. A branch of the New York public library is named after her.

AGUINALDO, EMILIO (1869–), Filipino leader who fought first against Spain and later against the United States for independence of the Philippines. He was born on March 23, 1869, near Cavite, Luzon, of Chinese and Tagalog parentage. He completed his education at the University of Santo Tomás, Manila. In Aug. 1896 he was mayor of Cavite Viejo and was the local leader of the Katipunan, a revolutionary society which fought bitterly and successfully against the Spanish. In Jan. 1898 he signed an agreement called the pact of Biac-na-Bat6 with the Spanish governor-general. He agreed to leave the Philippines and to remain permanently in exile on condition of a substantial financial reward from Spain coupled with the promise of liberal reforms. While in Hong Kong and Singapore he made arrangements with representatives of the American consulates and of Commodore George Dewey (*q.v.*) to return to the Philippines to assist the United States in the war against Spain. (See PHILIPPINES: History; SPANISH-AMERICAN WAR OF 1898.)

After the power of Spain was destroyed in the Philippines, Aguinaldo broke with the U.S. authorities because he wanted complete independence for his country. His followers adopted their own flag, organized an army, assembled a congress and proclaimed the first Republic of the Philippines at Malolos, Bulacan, just a few miles away from the U.S. headquarters in Manila. After three years of costly fighting, General Aguinaldo was captured on March 23, 1901, and the insurrection came to an end. Aguinaldo took an oath of allegiance to the United States, was granted a pension from the U.S. government and retired to private life.

In 1935 when the commonwealth government of the Philippines was established in preparation for independence, Aguinaldo ran for president but was decisively beaten. He returned to private life until the Japanese invaded the Philippines in 1941. The Japanese used Aguinaldo as an anti-American tool. They caused him to make speeches, sign articles, and to address a radio appeal to Gen. Douglas MacArthur on Corregidor to surrender in order to spare the flower of Filipino youth. When the Americans returned, Aguinaldo was arrested and, together with others accused of collaboration with the Japanese, was held for some months in Bilibid prison until released by presidential amnesty.

As a token vindication of his honour, he was appointed by Pres. Elpidio Quirino as a member of the council of state in 1950. In the later years of his life, he devoted his major attention to veterans' affairs, the promotion of nationalism and democracy in the Philippines, and the improvement of relations between the Philippines and the United States. (C. A. B.)

AGUIRRE, LOPE DE (1518–1561), a Spanish adventurer, born in Oñate, in the province of Biscay in 1518, and known as the

"traitor." Arriving in Peru in 1544, he took part in the internal strife among the Spaniards that followed the defeat of the Incas. In 1560 he joined the expedition that Pedro de Ursúa organized to search for the legendary "El Dorado." After reaching the headwaters of the Amazon, Aguirre incited a rebellion which resulted in Ursúa's death. Fernando de Guzmán met the same fate at the hands of Aguirre after failing to co-operate in the latter's plans for renouncing allegiance to Spain. During the course of travel to Venezuela by way of the Amazon and a tributary of the Orinoco, Aguirre was responsible for the death of about 80 persons, including women, priests and his own daughter. Aguirre was captured and executed at Barquisimeto in 1561. (J. L. Tr.)

AGUSAN, a province in northeastern Mindanao, Republic of the Philippines, with a land area of 4,120 sq.mi. Its population in 1960 was 271,973. After 1950 there was rapid immigration from Cebu, Bohol and Leyte as new lands were opened and new roads constructed. The economy of the province is related to the forest and the farm. There are many lumber mills; the one at Nasipit is among the largest in the far east and operates a kiln dryer and a hardboard plant. Agricultural products are principally corn, coconuts and abaca (in the southern part of the province).

The area is drained by the Agusan river, which is navigable for river craft and log rafts throughout the length of the province. The river and a newly constructed highway that parallels it at a distance of a few miles are the routes to the interior settlements.

The capital, Butuan, lies on the west bank of the Agusan, near its mouth. It has several sawmills and is a regional depot for a few petroleum companies. Pop. (1960) 82,755. (AN. C.)

AHAB (in the Douai version of the Bible, ACHAB), son of Omri, king of Israel from c. 875 to c. 852 B.C. (I Kings xvi, 29–xxii, 40). In some respects his reign represented the high-water mark of the success of the northern kingdom. In the reigns of Omri (*q.v.*) and Ahab the northern kingdom for the first time took an important part in international politics. Omri left to his son an empire which comprised not only territory to the east of Jordan, in Gilead and probably Bashan, but also the land of Moab, whose king was tributary. Judah (and probably Edom also), if not actually subject to Omri, was certainly a subordinate ally. Ahab's marriage with Jezebel (*q.v.*), daughter of Ethbaal of Sidon, revived an alliance which had been in abeyance since the time of Solomon.

Throughout the reign of Ahab, however, a fierce border war was waged with Damascus in which Israel, in spite of occasional victory, proved the weaker, while Meshah, king of Moab, successfully revolted and occupied the southern portions of the territory of Gad. The forces of Israel retained strength enough to contribute the second largest contingent of soldiers (the largest force of chariots) to the combined armies which, under the leadership of Benhadad of Damascus, checked the westward movement of Shalmaneser III of Assyria at Karkar. After the Assyrian repulse, however, the alliance broke up, and Ahab met his death fighting the Syrians in a vain attempt to recover Ramoth Gilead.

Domestically, contact with a wider world and, especially, the alliance with Phoenicia had far-reaching results for the kingdom of Israel itself. Jezebel attempted to introduce into religion and government elements which were common enough elsewhere in the ancient world but strange in Israel. She endeavoured to set up the worship of the Tyrian Baal in Samaria and to maintain the familiar oriental principle of the absolute despotic power and authority of the sovereign. This roused the bitter hostility of that conservative party, which clung to the sole worship of the national god, Yahweh, and at the same time held to those democratic conceptions of society which the Hebrews had brought with them from the wilderness and had consistently maintained. The spirit of this party found expression in the prophet Elijah (*q.v.*), who protested alike against the establishment of the Baal priests and the judicial murder of Naboth. He and those who came after him seem to have been successful in eliminating the foreign worship, though in the end their purpose was achieved only by a bloody revolution, but they were powerless to stem the tide of social and moral deterioration. To the reign of Ahab may be traced the beginning of that sapping of the national life which led to the condemnations of the 8th-century prophets and to the downfall of

Samaria.

(T. H. R.)

AHAD HAAM (literally "One of the people"; real name ASHER GINZBERG) (1856–1927), Hebrew writer and leader of "spiritual Zionism." Born Aug. 18, 1856, in Skvira, Ukraine, and reared in a strictly orthodox family, he acquired a mastery of rabbinic literature but was early attracted to the rationalist school of medieval Jewish philosophy and soon turned to the writings of the modern Jewish "Enlightenment" (Haskala). At the age of 22 he went to Odessa, the centre of the Jewish nationalist movement, Hoveve Zion ("Lovers of Zion"). There he came under the influence of both Jewish nationalism and the teachings of the Russian thinker D. I. Pisarev and the English and French positivists. He joined the central committee of Hoveve Zion and published his first essay "Lo ze ha-Derekh" ("This is not the Way," 1889), which opened a new epoch in Jewish nationalist ideology. It contained all the basic features of what was later called "spiritual Zionism" and, though praised and welcomed by many, was also severely criticized by the more practically minded. Ahad Haam thus became involved in controversy and was thereafter to remain so. In 1891 and 1893 he visited Palestine to study the movement's colonizing methods, and recorded his impressions and reflections in two critical essays, "Emeth me-Erez Yisrael" ("The Truth from Palestine"). In 1895 he published a collection of essays, *Al Parashat Derakhim* ("At the Crossroads"), followed by three further volumes (1903, 1904, 1913). In 1897 he founded the periodical Ha-Shiloah in which he severely criticized Theodor Herzl's political Zionism. He remained outside the Zionist organization, although in deep sympathy with the goal of a Jewish national centre in Palestine. In 1908 he moved to London and in 1912 visited Palestine a third time, later describing his observations in the essay "Sakh ha-Kol" ("Sum Total"). His last years he spent in Palestine editing his Letters (Zggeroth *Ahad Ha-Am*, 6 vol., 1923–25). He died on Jan. 2, 1927, in Tel Aviv. Further letters, notably from the last phase of his life, and his memoirs were published in *Ahad Ha-Am: Pirge Zikhronoth we-Zggeroth* (1931).

Ahad Haam's doctrine blends an idealist conception of Judaism with a positivist and sociological approach. He interprets the Jewish religious and ethical teachings as expressions of Jewish culture and stresses the rational and moral character of Judaism. Unlike the Jewish reformers in western Europe and America, however, he also stresses that the national spirit is essential both for Jewish survival and as a means of expressing moral values in a distinctly Jewish way of life. He therefore calls for a renaissance of Hebrew culture and to this end urges the creation of a Jewish national home in Palestine as the centre and model for Jewish life in the Diaspora. He believes that this goal cannot be achieved by purely political means but primarily through spiritual rebirth. He rejects the solutions of thinkers who sought to recreate Jewish nationhood by a radical "transformation of values." Though himself deeply affected by secularizing tendencies, he retains a passionate love for what he regards as the essence of traditional Judaism. He is convinced that the Jewish people have not lost their creative capacity and proclaims his faith in the establishment of a Jewish culture in Palestine embodying the ideals of social justice and righteousness.

He expressed his lofty program in language of superb clarity and precision. His Hebrew style, though employing to some extent the allusive imagery (*meliza*) of an earlier period, paved the way for modern Hebrew prose and was a very important formative influence. Above all, his high moral pathos had a tremendous impact on his contemporaries. A more critical attitude to his ideology later began to assert itself, however, chiefly because of his excessive rationalism.

BIBLIOGRAPHY.—His collected writings appeared in 1947, 1 vol. (German trans., 4 vol., 1923). For a full bibliography in Hebrew see Arye (Sir Leon) Simon and Yosef Eliyahu Heller, *Ahad Ha-am, Ha-Ish, Poalo we-Thoratho* ("The Man, His Work and Doctrine," 1955). For English translations see *Selected Essays* (1912) and *Essays, Letters, Memoirs* (1948) translated by Arye (Sir Leon) Simon. (A. AN.)

AHAGGAR MOUNTAINS, a large plateau region, also spelled HOGGAR, in the north centre of the Sahara (*q.v.*), lies on the Tropic of Cancer between longitude 5° and 7° E., about 900 mi. S. of Algiers. Its height is above 3,000 ft. culminating in Mt.

Tahat (9,842 ft.). The plateau is rocky desert composed of rocks with low dips. The main caravan route from Algiers to Kano in northern Nigeria passes along the western margin through the important oasis town of Tamanrasset. There has been exploration for oil northwest of the plateau. (J. I. P.)

AHASUERUS (in the Douai version of the Bible, ASSUERUS; in the Septuagint, ARTAXERXES), a royal Persian name occurring in Ezra iv, 6, Dan. ix, 1 and throughout the book of Esther. Its occurrence in Tob. xiv, 15 in some Greek manuscripts is the result of a copyist's error. In Ezra iv, 6 Ahasuerus is mentioned as a king of Persia, to whom the enemies of the Jews sent representations opposing the rebuilding of the temple at Jerusalem. He thus occupies a place in a chronological series of those Persian rulers who were directly concerned with events of Jewish history. (See EZRA AND NEHEMIAH, BOOKS OF.) Immediately preceding Artaxerxes I Longimanus, he is evidently to be identified with Xerxes. In the book of Esther the king, at whose court the scene is laid, bears the same Hebrew name. Probably Xerxes is again the king intended. (See ESTHER, BOOK OF.)

In Dan. ix, 1 "Ahasuerus" is the father of "Darius the Mede," who is said to have become king over Babylonia upon the death of Belshazzar. The name seems impossible here, however, and may be the result of some accident in the literary transmission. No other name resembling Ahasuerus, nor any name like Darius, is to be found in the list of Median kings. It is known, moreover, that the immediate successor of Nabonidus and Belshazzar as ruler of Babylonia was Cyrus. Comparison with the list of Persian kings in the book of Ezra seems to show that in the Jewish tradition Darius I Hystaspis was placed before Cyrus as "Darius the Mede." (C. C. T.; X.)

AHAZ (Assyrian JEHOAHAZ; in the Douai version of the Bible, AHAZ), king of Judah. After the death of Menahem, Pekah, king of Israel, and Rezin (Rasun), king of Syria, allied against Assyria and invaded Judah. At the same time the Edomites recovered Elath on the Gulf of Akabah and Judah was isolated. Notwithstanding the counsel of Isaiah (*q.v.*), Ahaz called in the aid of Tiglath-Pileser I who, after attacking the Philistines, destroyed the power of Syria and exacted heavy tribute from Judah. It was as a vassal that Ahaz presented himself to the Assyrian king at Damascus, and he brought back religious innovations described in II Kings xvi, 10–18.

See W. R. Smith, *Religion of the Semites*, 2nd ed. (1894).

AHAZIAH (in the Douai version of the Bible, OCHOZIAS), the name of two biblical kings. (1) Ahaziah, eighth king of Israel, was the son and successor of Ahab and reigned for less than two years. On his accession the Moabites refused to pay any further tribute. Ahaziah lost his life through a fall from the lattice of an upper room in his palace (II Kings i, 2–17). (2) Ahaziah, sixth king of Judah, son of Jehoram and Ahab's daughter Athaliah, reigned one year. He, together with Joram, king of Israel, was slain by Jehu, son of Jehoshaphat (II Kings viii, 25–ix, 28). See also ELIJAH; ELISHA.

AMENOBARBUS, the name of a distinguished plebeian family of the Roman gens *Domitia*, members of which held consulships in 192 (from which time the family had the status of nobility), 162, 122, 96, 94, 54, 32, 16 B.C. and A.D. 32.

GNÆUS DOMITIUS AHENOBARBUS (consul 122 B.C.), helped to subdue southeastern Gaul and gave his name to the Via Domitia, the highway from Italy to Spain; his son of the same name (consul 96) opened the office of *pontifex maximus*, the head of the official religion, to popular election and was himself elected in 103.

LUCIUS DOMITIUS AHENOBARBUS (consul 54; d. 48 B.C.), was a die-hard member of the class of optimates (families whose power in the later republic was due to wealth and to distinction in public office throughout successive generations). A bitter enemy of Julius Caesar, he took Pompey's side in the civil war of 49 (when he was appointed to succeed Caesar in Gaul), although a kinsman had been put to death by Pompey as a supporter of Gaius Marius in 81. He tried to secure the loyalty of 10,000 or more troops under his command by promising each man 25 ac. out of his own estates, but his men went over to Caesar. Domitius was spared by Caesar, but resumed the struggle; he raised Massilia (Marseilles) against Cae-

sar and fell fighting against him at Pharsalus.

GNÆUS DOMITIUS AHENOBARBUS (d. 31 B.C.), a son of Lucius, was, according to Suetonius, the best of a family notorious for its pride and cruelty. He had taken the same side as his father, and after Caesar's death he espoused the cause of Brutus and Cassius and commanded their fleet in 42. After their defeat by Mark Antony at Philippi he held out as a privateer, but was reconciled to Antony in 40 and became one of his chief partisans. A consul in 32, the year when the final breach occurred between Antony and Octavian, he fled from Italy to the east. But he could not brook Cleopatra's dominance over Antony and deserted him just before the battle of Actium (*q.v.*), only to die soon after, allegedly of remorse. The Enobarbus of Shakespeare's *Antony and Cleopatra* portrays him imaginatively but unhistorically.

LUCIUS DOMITIUS AHENOBARBUS (consul 16 B.C.), son of the last-mentioned Gnaeus, was promoted by Augustus to high commands, despite his family's past record. About A.D. 1 he carried Roman arms to the Elbe river. He was married to Antony's daughter by his wife Octavia, Augustus' sister, and their son Gnaeus was given in marriage to the younger Agrippina (*q.v.*). A son of this union, adopted by Agrippina's third husband, the emperor Claudius, became the emperor Nero (*q.v.*), the last Ahenobarbus.

See R. Syme, *The Roman Revolution*, reprint (1951). (P. A. BR.)

AHIKAR, WISDOM OF, the title of a story and collection of proverbs connected with the wise Ahikar, originating almost certainly in Babylonia, probably about 550 B.C. The oldest version of the text is in some 5th-century B.C. Aramaic papyrus fragments. In it the Assyrian kings Sennacherib and Esarhaddon are mentioned. Two other persons in the narrative bear Babylonian names: Ahikar's nephew Nadin (Nadan) and Nabusumiskun, who is known to have been one of Sennacherib's officers. Ahikar's own name appears as Ahiyaqar. The collection of proverbs is chronologically the fourth oldest extant, following the Egyptian, Mesopotamian (cuneiform) and Old Testament ones.

The Aramaic version relates how Ahikar was the counselor of the kings of Assyria. As he had no children of his own he brought up his sister's son, Nadin, as his heir. But he was ill rewarded, for Nadin aroused the suspicions of King Esarhaddon against Ahikar. He was sentenced to death, but managed to escape. At this point the story breaks off, but later versions tell how Ahikar regained his position, and Nadin was put in prison, where he had to listen to the proverbs and moral sayings of his uncle. It is not known if this is how the proverbs were originally attached to the story.

The story and sayings of Ahikar enjoyed great popularity. His name, in the form Achiacharus, is mentioned in the book of Tobit (i, 21, 22; xiv, 10), and some passages in both the Old and the New Testaments perhaps show acquaintance with episodes from the story. A life of Aesop takes material from it, and Theophrastus and Democritus were reputed to have known and used the sayings. Ahikar is also mentioned in the Koran. More or less complete versions, exhibiting minor and sometimes fantastic variations, are extant in Aramaic, Syriac, Arabic, Ethiopic, Armenian, Slavonic, Old Turkish and Rumanian.

BIBLIOGRAPHY.—Aramaic version with Eng. trans. in A. E. Cowley, *Aramaic Papyri of the 5th century B.C.*, pp. 204-248 (1923); versions (save for the Rumanian) translated with Introduction in F. C. Conybeare, J. Rendel Harris and A. S. Lewis, *The Story of Ahikar*, 2nd ed. (1913); Syriac, Arabic and Armenian versions translated in R. H. Charles, *The Apocrypha and Pseudepigrapha of the Old Testament*, vol. ii, pp. 715-784 (1913), *cf.* vol. i, pp. 189-192 (1913). See also R. Smend, *Alter und Herkunft des Achikar-Romans und sein Verhältnis zu Aesop* (1908); T. AHITHOPHEL (in the Douai version of the Bible, ACHITOPHEL), one of David's most trusted advisers, whose counsel was "as if one consulted the oracle of God." He took a leading part in Absalom's revolt, and his defection was a severe blow to the king, who prayed that God would bring his counsel to "foolishness." At Ahithophel's advice Absalom (*q.v.*) first took the precaution of asserting his claim to the throne by seizing his father's concubines. The immediate pursuit of David (*q.v.*) was then suggested, but Hushai recommended waiting till the levies of all Israel could be called up. This advice was adopted, and David had time to escape

across the Jordan. Finding that his policy was neglected and foreseeing the disaster which actually occurred, Ahithophel went home and hanged himself. (II Sam. xv, 31-37; xvi, 20-xvii, 14, 23.)

AHLEN, a town of Germany which after partition of the nation following World War II was located in the *Land* (state) of North Rhine-Westphalia, Federal Republic of Germany. It lies on the Werse river, 17 mi. S.E. of Münster, on the northeastern edge of the Ruhr district. Pop. (1959 est.) 38,893. Ahlen is on the main Cologne-Hanover-Berlin railway and about 5 mi. from the Cologne-Hanover autobahn. A coal-mining town, its chief manufactures are enamelware (it once had the biggest enamel works in Germany), shoes, and industrial and agricultural machines. The town charter was granted in 1224 and industrial development began about 1900. St. Bartholomew is the patron saint of Ahlen.

AHMADOU (d. 1898), the ruler of a Toucouleur empire in the western Sudan, celebrated for his resistance to the French occupation. Succeeding his father Omar el-Hadj in 1866, Ahmadou ruled over a great empire centred on the ancient Bambara kingdom of Ségou (his first capital) and including (1), in the west, the Kaarta country and the fortresses of Niore, Koniakory, Diala, Koundian and Mourgoula; (2), farther to the south, the fortress of Dinguiraye; and (3), in the northeast, the Macina country around Bandiagara. Despite his great religious authority, Ahmadou could not count on the obedience of all his vassals or even on those of his own family. By the treaty of Nango signed with the French commander J. S. Gallieni in 1881 Ahmadou granted France most-favoured-nation status. Then, after the advance of the French to Kita and Bamako, he abandoned Ségou as his capital and accepted a French protectorate (treaty of Gouri, May 12, 1887). In 1888, however, Col. Louis Archinard, supported by the "colonial party" in Paris, took the offensive against Ahmadou. By 1891 Archinard had seized most of Ahmadou's strongholds in the south and west. When Ahmadou retreated into the Macina, Archinard pursued him and seized his remaining fortresses. Ahmadou sought refuge in the mountains to the east. He died in 1898 in the province of Sokoto (Nigeria). (J. E. B.)

AHMAD SHAH (1725-1775), Mogul emperor in India from 1748 to 1754, son and successor of Mohammed Shah, was born in Delhi on Dec. 24, 1725. His father had kept him in penurious obscurity, so that on his accession he was wholly inexperienced in affairs and ready to fall victim to the opportunities for sensual gratification which was almost all that the throne then offered.

Twice during Ahmad Shah's reign, in 1748 or 1749 and in 1751-52, the Afghan Ahmad Shah Durrani (*q.v.*) invaded the Punjab, obtaining grants of revenue and territory from the Mogul. Further, in 1750, the Mogul wazir Safdar Jang was defeated by the Afghans of the Doab and, enlisting the aid of the Marathas, provided him with the spectacle of "his" servants struggling over the spoils of "his" empire.

In Delhi, Ahmad Shah fell first under the control of his mother Udham Bai and the eunuch Javid Khan. Safdar Jang had Javid murdered in 1752, only then to emphasize his own greed and incapacity. In 1753, Safdar Jang was ousted as wazir by Intizam ud-Daula and withdrew to Oudh. Then Imad ul-Mulk, grandson of Asaf Jah, first nizam of Hyderabad, won the alliance of the Marathas and, in 1754, expelled Intizam ud-Daula and deposed and blinded Ahmad Shah. Ahmad Shah lived in confinement until Jan. 1, 1775.

See Sir Jadunath Sarkar, *Fall of the Mughal Empire*, vol. i, 2nd ed. (1949). (P. H.)

AHMAD SHAH DURRANI (1722?-1772?), founder of the state of Afghanistan and ruler of an empire which stretched for a time from the Oxus (modern Amu-Darya) across Baluchistan to the Indian ocean and from Khurasan into Kashmir, the Punjab and Sind. He was born, probably at Multan late in 1722, in the noble and sacrosanct Sadozai clan, the second son of Mohammed Zaman Khan, a hereditary chief of the Abdali tribe of Afghans. When Nadir Shah of Persia conquered the Afghans in 1738, Ahmad entered his personal service and rose to command an Abdali contingent of cavalry. On the assassination of Nadir in 1747 his Afghan troops returned home; their chiefs declared themselves independent and elected Ahmad as shah. He took the title Durr-i-

Durrān ("Pearl amongst Pearls"), changed the name of the Abdali tribe to Durrāni, and from it chose most of his high officers. He was crowned that year near Kandahar, which became his capital. The spirit of his government was essentially Afghan and tribal but his administration and army were modeled largely on those of Nadir Shah. To gain prestige and wealth, to unify his people and to satisfy their marauding proclivities, he adopted a policy of raids and limited conquest toward his then chaotic neighbours. In 1747–48 he invaded India, capturing guns, horses and much wealth, but was finally repulsed near Sirhind, north of Patiala. He returned to Afghanistan; but in 1748, or 1749, he again invaded India and won from the Mogul emperor what had formerly been granted to Nadir Shah: India west of the Indus and the revenues of four districts of the Punjab. About 1750 he took Herat; in 1751 Nishapur and Meshed in Khurasan, as ruler of which he confirmed Shah Rukh, the blinded grandson of Nadir Shah. Balkh and Badakhshan were gained for him that year. The revenues from the Punjab were not paid, and in 1751–52 he returned and extorted the virtual grant of the Punjab from the Moguls. They attempted to reassert their supremacy and provoked a fourth invasion in 1756–57. He plundered Delhi; sacked with great slaughter the Hindu holy cities, Mathura and Vrindaban; confirmed the weak Alamgir II as emperor; and allied himself and his son Timur by marriage with the imperial family. Cholera among his troops forced him home that summer. Timur was driven out of the Punjab in 1758 by a force of Sikhs, Moguls and Marathas, the latter having intervened at the invitation of Imad ul-Mulk, wazir in Delhi. In 1759, however, Ahmad Shah swept the Marathas from the Punjab and joined forces with the Afghans settled in Rohilkhand; and on Jan. 14, 1761, at Panipat north of Delhi, they destroyed a large Maratha army sent from the Deccan (enabling the British in Bengal to strengthen their position decisively). In 1762, 1764–65, 1766–67 and 1769 Ahmad Shah marched to crush the Sikhs, but they were elusive and had local support, whereas his empire was restive: he lost control of the Punjab to them.

Ahmad Shah died at Maruf, or perhaps at Margha, east of Kandahar. He had been a bold yet careful general, a rapacious and cruel conqueror. The Sadozais ruled Afghanistan until 1818, when the Barakzai branch of the Durrānis succeeded them. See also AFGHANISTAN: History.

BIBLIOGRAPHY.—Ganda Singh, *Ahmad Shah Durrani* (1959); J. Sarkar, *Fall of the Mughal Empire*, 2nd ed., vol. i and ii (1949–50); T. S. Shejwalkar, *Panipat: 1761*, in the "Deccan College Monograph Series" (1946). (P. H.)

AHMAD SHAUQI (1868–1932), one of the outstanding Arab poets and dramatists of his time, was born in Cairo in 1868 of a family attached to the khedival court. A brilliant pupil, he was sent by the khedive to study at Montpellier and Paris universities and on his return the path of quick promotion lay open to him. By 1914 he was the leading literary figure in Egypt. He was exiled to Spain during World War I but on his return continued to dominate the Egyptian literary scene. In 1927 he was proclaimed *amir al-shu'ara* ("prince of poets"). He died in Cairo on Oct. 13, 1932.

He was a prolific writer with a fine command of Arabic rhyme and poetic diction, his themes varying from conventional encomia to poetical plays following western models (*e.g.*, Shakespeare, Corneille, Racine). His efforts, however, to copy the ancient Arabic poets were not successful. He was, in fact, an innovator and his poem *Muluk al-Arab* shows him as a precursor of modern Arab nationalism. A pioneer, too, of the modern movement in Arabic poetry, he attempted to adapt traditional metres to dramatic dialogue in his remarkable poetical plays.

Ahmad Shauqi's collected poems were published in Cairo in four volumes (1948–51). (A. EL-T.)

AHMEDI (1590–1617), Ottoman sultan of Turkey, was born at Manisa (Magnesia) on April 18, 1590, and succeeded Mohammed III, his father, on Jan. 22, 1603, in his 13th year. When his first child was born, Ahmed wished to put his brother Mustafa to death, but was restrained by the ulema. His authority was weakened by wars, rebellions and misrule but, despite his youth, he took an active part in the government. The peace of Zsitvatorok (1606) which he signed with Austria was a blow to Turkey's pres-

tige, and he was compelled to renew the capitulations (*q.v.*) with France and Venice and to conclude a capitulation with the Dutch, by which the Dutch merchants were able to introduce the use of tobacco into Turkey. Ahmed tried to re-establish order in the country and administration: he put down the rebellion of the army deserters in Anatolia and the revolts of Fakhr al-din in the Lebanon and of the *sipahis* in Istanbul; he executed some of the viziers and exiled many palace dignitaries for bribery and intrigue; and he introduced a new regulation for the improvement of land administration.

Ahmed was strong willed and pious and he succeeded in rescuing his authority by skilful and drastic action. He made many donations, especially to the holy places of Mecca and Medina, and he built the great Blue mosque near the church of Hagia Sophia. He died on Dec. 22, 1617, leaving seven sons, of whom Osman II, Murad IV and Ibrahim I eventually succeeded to the throne.

(E. Z. K.)

AHMED II (1642–1695), Ottoman sultan of Turkey, son of Ibrahim I, was born on Aug. 1, 1642, and succeeded his brother Suleiman II in 1691. Continuing the war against the "Holy league" (Austria, Poland and Venice), the Turks sustained a crushing defeat in the battle of Slankamen (Szalankamen) at the hands of the Austrians under Louis, margrave of Baden (Aug. 19, 1691); the grand vizier Mustafa Koprulu was killed and the Turks were driven from Hungary. Crete also was attacked and Chios taken by the Venetians. Ahmed tried to retrieve these disasters, by changing grand viziers, but without success. He died on Feb. 6, 1695, in Edirne and was buried in the mausoleum of Suleiman I, in Istanbul.

(E. Z. K.)

AHMED III (1673–1736), Ottoman sultan of Turkey, son of Mohammed IV, succeeded to the throne in 1703 on the deposition of his brother Mustafa II. He cultivated good relations with England and France and afforded a refuge to Charles XII of Sweden after his defeat by Peter the Great at Poltava (1709). Forced into war with Russia (1711–13), he came nearer than any other Turkish sovereign to breaking that power. His grand vizier, Baltaji Mohammed Pasha, encircled the Russians near the Pruth (1711), and Russia had to agree to retrocede Azov, to destroy the Azovian forts and to abstain from interference in Polish or Cossack affairs (Turkish discontent at the leniency of these terms nearly brought on a renewal of the war). In 1715 the Morea (Peloponnesus) was taken from the Venetians, but when Austria intervened the Turks suffered reverses, losing Belgrade in 1717. Under the peace of Passarowitz (1718), concluded through Anglo-Dutch mediation, Turkey retained its conquests from the Venetians but ceded Hungary and part of Serbia.

Both Russia and Persia seized the opportunity to invade Turkey. Peace was made with Russia in 1724, but the struggle with Persia for Azerbaijan continued. Deposed during the uprising led by Patrona Khalil in 1730, Ahmed died in captivity in 1736. His reign was known as the Age of Tulips (see TURKISH LITERATURE; NEDIM, AHMED) and saw the first steps taken toward the westernization of Turkish institutions. (E. Z. K.)

AHMEDABAD (AHMADABAD), a city in Gujarat state, India, and headquarters of Ahmedabad district, lies 275 mi. N. of Bombay on the Sabarmati river, crossed there by four bridges, including the 1,450-ft. Nehru bridge. Pop. (1961) 1,149,852. Urban area 20 sq.mi. The city presents a conflict between bustling mills and factories and ancient architectural glories. A local peculiarity is the planning of some sections in pols, self-contained blocks of houses sheltering several thousand people. Some are virtually small townships, crossed by a street with gates at either end. An attractive feature of the city is Lake Kankaria, with promenades, boating and a hill garden. The museum was designed by Le Corbusier. Ahmedabad is also the seat of Gujarat university (1950) and 20 of its 43 affiliated colleges. On the northern boundary is the military cantonment. Sabarmati, a suburb west of the river, became well known as the seat of Mahatma Gandhi's *ashram* or religious retreat.

Ahmedabad is at the junction of main roads giving access to Bombay and central India, the Kathiawar (Saurashtra) peninsula and the Rajasthan border. It is a major junction on the Western

W. SUSCHITZKY

HEADQUARTERS OF THE ASSOCIATION OF COTTON MILLOWNERS, AHMEDABAD: DESIGNED BY LE CORBUSIER (C. E. JEANNERET). 1955

railway: a double-track route (309 mi.) goes south to Bombay; other lines run to Delhi via the Rajasthan metre-gauge system and into Kathiawar.

About one-half of Ahmedabad's population depend on the cotton industry. There are about 70 cotton mills and 50 other major plants for oil, flour and silk milling, soap, match, glass, tobacco and hosiery manufacture, carpet weaving and tanning. The city's handicrafts include brocades, "atlas" and tinsel lace, copper and brassware, jewelry and wood carving.

History and Monuments. — Ahmedabad was founded in A.D. 1411 by the Moslem ruler of Gujarat, Sultan Ahmad Shah, next to the earlier Hindu town of Ashawal. It grew in size and wealth until the death in 1511 of Ahmad's grandson Mahmud Begara, the most (and last) eminent sovereign of the line. Then dynastic decay and anarchy brought decline until the city's capture by the Mogul emperor Akbar in 1572. Its renewed eminence under the Moguls ceased only with the death in 1707 of the last notable emperor, Aurangzeb, who had been viceroy at Ahmedabad in 1645–47. Further decline under the later Moguls and the Marathas was arrested by the British annexation of Gujarat in 1818. Ahmedabad's subsequent rise to the rank of India's sixth largest city and biggest inland industrial centre was promoted by the opening of the first cotton mills in 1859–61. In 1960 Ahmedabad became the temporary capital of Gujarat.

Dynastic changes made Ahmedabad the meeting place of Hindu, Muslim and Jain architectural traditions. Ahmad Shah and his successors ordered the dismantling and adaptation of Hindu temples in order to build mosques. This and the employment of Hindu artisans gave many of Ahmedabad's mosques and tombs a Hindu flavour in motifs and planning. The dense "forest" of 260 richly carved columns within the Jami Masjid or Great mosque (completed 1423) recalls the *mandapa* or hall of a Hindu temple (from which it has probably converted). At the mosque's entrance is the domed tomb of Ahmad Shah (completed 1441) and on the road leading to it the Tin Darwaza or triple arch (c. 1425), a triumphal gate through which the sultan was borne to worship. Among the city's many other fine Muslim buildings are the delicate mosque (c. 1505) at Rani Sipri's tomb; the Sidi Said mosque (1510–15), with minutely pierced arch-screens in the "palm and parasite" design; and the exuberantly rich Rani Rupmati mosque (1515). (For others see P. Bronn, *Indian Architecture: Islamic* Perzod, pp. 48–58, 1942.) A notable later building is the Jain Hathi Singh temple (1848)

AHMEDABAD DISTRICT (3,461 sq.mi.; pop, 1961, 2,231,534) extends across the neck of the Kathiawar peninsula. The north-eastern part is dotted with low hills, which gradually give way southwestward to a great plain subject to floods at its western end. Except in this latter area, the soil is fertile, the chief crops being

millet, cotton, wheat and pulses. Some parts are wooded. The main rivers are the Sabarmati and its tributaries, flowing southward into the Gulf of Cambay. (D. G. K.)

AHMEDNAGAR (AHMADNAGAR), a city and district, in Maharashtra state, India; till April 30, 1960, in Bombay state. The city lies on the left bank of the Sina river, 130 mi. E. of Bombay. Pop (1961) 118,266. It was founded in 1490 on the site of a more ancient city, Bhinar, by Ahmad Nizam Shah, who established a monarchy which lasted till its overthrow by Shah Jahan in 1636. Thereafter it passed into the hands of the Marathas, but during the war with them in 1803 it was captured by General Wellesley. Restored to the Marathas, it again became a British possession in 1817 under the treaty of Poona.

The city has a commonplace appearance and is surrounded by a dilapidated earthen wall with decayed bastions and gates. Monuments of interest are the fort about half a mile to the east, numerous specimens of Mohammedan architecture including the Damji Masjid, and several other mosques, a palace, the Paria Bagh (fairy garden), the tomb of Ahmad Nizam Shah, and Alamgir's Dargah (tomb). The city is a military station of the Poona district and an important mission station. It has a municipality established in 1854, and a college affiliated to the University of Poona. There is a large trade in cotton and silk goods. The chief industries are weaving of saris, cotton ginning and pressing, manufacture of copper and brass pots, indigo works and tanning. Ahmednagar is on the Dhond-Manmad loop line of the Central railway.

AHMEDNAGAR DISTRICT is a comparatively barren tract with a small rainfall. Area 6,591 sq.mi.; pop. (1961) 1,771,066. On the north the district is watered by the Godavari and its tributaries, the Pravara and the Mula; on the east by the Sephani which flows through the valley below the Balaghat range, and in the extreme south by the Bhima and its tributary the Dor. The Sina river, another tributary of the Bhima, flows through the Nagar and Karjat talukas. The Western Ghats, which cross the western end of the district from north to south, are its principal geographical feature. The staple food grains grown are the millets jowar (*Sorghum vulgare*) and bajri (*Pennisetum typhoideum*). Other crops include cotton, millet, pulses, wheat and ragi (*Eleusine coracana*). The forest cover consists of characteristic tropical dry deciduous and thorn trees. The chief industries are weaving, dyeing, and the manufacture of copper and brass pots. (M. R. P.)

AHMED VEFIK PASHA (1823–1891), Ottoman Turkish grand vizier and man of letters, was born in Istanbul on July 6, 1823, and educated in Paris. Appointed to a post in the translation office of the ministry for foreign affairs, he devoted his leisure to translating Molière's plays into Turkish and to compiling dictionaries, historical and geographical manuals, etc., for use in schools. In 1847 he brought out the first edition of the *Salnameh*, the official annual of the Ottoman empire.

Ahmed Vefik was appointed imperial commissioner in the Danubian principalities in 1849 and ambassador to Persia in 1851. After his return he was appointed a member of the grand council of justice and entrusted with the revision of the penal code and the code of procedure. In 1860 he was sent as ambassador to Paris, to avert the intervention of France in the affairs of Syria. Ahmed Vefik was president of the first Turkish parliament (1877) and twice prime minister (1878 and 1882), but the position in which he rendered his most distinguished service was as vali (governor) of Bursa (1879–82).

The drainage of the pestilent marshes, the water supply from the mountains, the numerous roads, the suppression of brigandage, the multiplication of schools, the vast development of the silk industry through the substitution of mulberry plantations for rice fields, the opening out of the mineral springs of Chitli, the introduction of rose trees, the production of attar of roses and the foundation of the first Turkish theatre—all these were Ahmed Vefik's work. A few days after his return he was again appointed grand vizier (Dec. 1, 1882), but he made conditions that were unacceptable to the sultan and Said Pasha was appointed in his place. For the rest of his life Ahmed Vefik, by the sultan's orders, was practically a prisoner in his own house at Rumili Hisar on the Bosphorus, where he died on April 2, 1891. His library was sold

for the payment of his debts.

AHMOSE (AAHMES; Gr. AMASIS or AMOSIS), from the Egyptian Iah-mose, "the moon has begotten him," the name of two Egyptian pharaohs, one in the 18th dynasty and one 1,000 years later, in the 26th.

AHMOSE I (reigned c. 1570–1546 B.C.), the first king of Manetho's 18th dynasty, bore the praenomen Neb-pehti-RE, "the sungod Rē is lord of might." His predecessor Kamose, who may have been his brother, began the war of liberation against the Asiatic invaders known as the Hyksos, but died, perhaps in battle, before capturing their stronghold Avaris in the eastern delta. Ahmose took the city after a siege and pursued the fleeing Hyksos into Palestine; the occupation of Sharuhen after three years' siege laid the foundations of Egypt's future empire in Asia. Before proceeding to further conquests there Ahmose had to reorganize the newly reunited kingdom and to carry Egyptian arms into the long-abandoned province of Nubia, whose paramount chief had been an ally of the Hyksos. Nubia was subdued in three campaigns in which the Egyptian frontier was pushed at least as far south as Toshkeh. Later the king campaigned in Phoenicia. He appears to have done little large-scale building, but the dynasty that he established was one of the most glorious in Egyptian history.

AHMOSE II (reigned 569–526 B.C.) is generally known as Amasis. Herodotus in his second book draws a vivid portrait of the shrewd, convivial soldier king. He was the general sent by Apries (*q.v.*) to quell a revolt among the Egyptian troops who had been sent on an abortive expedition to Cyrene in 570 B.C. The Egyptians proclaimed him king, and in a battle at Momemphis against the Greek mercenary army of Apries the latter was defeated and taken prisoner. In Amasis' third year, according to a stele in the Cairo museum, Apries again raised an army but was killed in battle. As champion of the native Egyptians Amasis at first played the role of xenophobe, but had the good sense to cultivate the friendship of the Greeks and other neighbouring powers. He married a Greek princess, Ladike of Cyrene, contributed 1,000 talents to the rebuilding of the Delphic shrine and made Polycrates of Samos and Croesus of Lydia his allies. Early in his reign he sustained an attack by Nebuchadrezzar of Babylon, but Egypt was apparently saved from invasion. Later he conquered Cyprus and was master of part of Phoenicia. Herodotus avers that under his wise administration Egypt was very prosperous. His last years, however, were disturbed by the threat of Persian invasion.

See A. Wiedemann, *Herodots zweites Buch* (1890); F. K. Kienitz, *Politische Geschichte Ägyptens, vom 7 bis zum 4 Jahrhundert* (1953). (M. S. Dr.)

AHO, JUHANI (real name JOHANNES BROFELDT) (1861–1921), a writer of central importance in the development of Finnish literature, was born in Lapinlahti, Sept. 11, 1861. A country clergyman's son, he studied at Helsinki university, worked as a journalist and was an active member of the liberal group Nuori Suomi ("Young Finland"). Aho's early realistic stories and novels describe with humour life in the Finnish backwoods he knew so well. His novel *Rautatie* ("The Railway," 1884; Swedish trans. 1920), the story of an elderly couple's first railway trip, is a Finnish classic. Influenced by contemporary Norwegian and French writers—Ibsen, Björnson, Maupassant and particularly Daudet—he described the life of the educated classes in *Papin tytär* ("The Clergyman's Daughter," 1885; German trans. 1899) and *Papin rouva* ("The Clergyman's Wife," 1893; German trans. 1896). In the 1890s he was drawn toward romantic nationalism: the long novel *Panu* (1897; German trans. 1899) dealt with the struggle between paganism and Christianity in 17th-century Finland and *Kevät ja iakatalvi* ("Spring and the Untimely Return of Winter," 1906; Swedish trans., 2 vol.) with the national awakening of the 19th century. His soundest romantic work, *Juha* (1911), is the story of the unhappy marriage of a cripple in the Karelian forests. Aho's short stories, *Lastuja* ("Chips," 8 series, 1891–1921; partial Swedish trans. *Spånor*, 4 vol., 1891–99; selection in French trans. *Copeaux*, 1929), have lasted best: they are concerned with peasant life, fishing and the wild life of the Finnish lakelands. In these, as in his reminiscences of childhood, *Muistatko?* ("Remember?" 1920), Aho's quiet lyricism is at its best. He died in Helsinki, Aug. 8,

1921.

See G. Castrén, *Juhani Aho*, 2 vol. (1922); A. J. Aho, *Juhani Aho*, 2 vol. (1951). (K. L. K. L.)

AHOM, an offshoot of the large family of Tai-speaking peoples whose migration from the Chinese province of Yunnan southward into Indochina and upper Burma began in the first centuries A.D. A tribal group called the Ahoms moved from the Irrawaddy region of Burma into the upper Brahmaputra valley of Assam early in the 13th century. Under the leadership of kings, whose names and deeds are recorded in chronicles originally written on strips of bark, the Ahoms began a long struggle with the indigenous Bodo peoples such as the Kacharis, and by the end of the 16th century controlled the whole of upper Assam. (This country's name is derived from the word Ahom.) Their system of government was based on a balance between the power of the king and that of an aristocracy, which elected the king from among the members of the royal lineage. This aristocracy also furnished three ministers of state, whose offices were the monopoly of five clans. By the end of the 18th century the Ahom kingdom, which had beaten back repeated attacks by Mogul armies, had extended its power also over lower Assam. Its end came in 1838 with the establishment of British rule.

Ever since the 15th century the Ahoms had been influenced by Hinduism, but they formally embraced the Hindu faith in 1714 and even then continued to practise the old tribal religion without hindrance. Yet traditional Ahom culture rapidly changed. While as late as the 16th century the Ahoms had lived in pile dwellings, they now built houses on solid foundations in Indian style. Similarly, cremation replaced burial and Hindu marriage rites the ancient ritual. The traditional division of Ahom society into a number of exogamous groups persists to the present day, however, and groups of different status do not intermarry. The original Ahom language and script (the latter akin to that used by the Siamese (Thais) and other Tai-speakers) have become extinct and the Ahom now speak Assamese, an Indo-Aryan language related to Bengali. No longer a nation of distinct identity, they are today a Hindu caste of good status. Their Mongoloid physical features, however, still distinguish them from the Assamese castes of Indian origin.

F.-H.)

AHRENS, FRANZ HEINRICH LUDOLF (1809–81), German philologist, was born at Helmstedt, June 6, 1809, and died Sept. 25, 1881. His most important work is *De Graecae Linguae Dialectis* (1839–43, new ed. by Meister. 1882–89), which, although unfortunately incomplete, dealing only with Aeolic and Doric, and in some respects superseded by modern research, remains a standard treatise. A volume of his minor works (ed. by Haeblerin, 1891) contains a complete list of his writings.

AHRIMAN (ANGRA MAINYU, the "Destructive One"), the principle of evil in the dualistic doctrine of Zoroaster. As the Evil Spirit, representing untruth, unrighteousness and disorder, he is contrasted with the Wise Lord, Ahura Mazda. He is the all-destroying, the source of all evil in the world; eventually, in the great world catastrophe, he will be defeated by Ahura Mazda and disappear. See AHURA MAZDA; DUALISM; ZOROASTER.

AHUACHAPÁN, department and city in northwestern El Salvador. Population of the department (1958 est.) 122,682; area 472 sq.mi. Except for Pacific coastal plain about 8 mi. wide, the department consists of deep valleys and mountains, which include several volcanoes, the highest being Cerro Chichicastepeque, altitude 6,075 ft. The Rio Paz to the west forms the natural boundary with Guatemala. Coffee is grown on volcano slopes 1,800 to 4,000 ft. altitude. Corn, beans, other food crops, livestock and blooms from the flower garden of El Salvador, Apaneca, are sent to all parts of the country.

Ahuachapán city (pop. [1958 est.] 37,934), the departmental capital, is a manufacturing and distributing centre. Coffee is the most important product. It is noted for its hot mineral waters which are drawn from mountain springs, notably below Mala-

catiupan falls nearby. Ahuachapán is connected by rail and highway (64 mi.) with the national capital, Sari Salvador. (C. F. J.)

AHURA MAZDA, the supreme god, "Wise Lord." in the religious system of the Iranian sage Zoroaster (7th century–6th century B.c.), worshiped by the Persian king Darius (reign, 522 B.C.–486 B.C.) and his successors as Auramazda, greatest of all gods and protector of the just king.

According to Zoroaster, Ahura Mazda created the twin spirits Spenta Mainyu and Angra Mainyu, the former beneficent, choosing truth, light and life, the latter destructive, choosing lie, darkness and death. Their struggle against each other makes up the history of the world.

In the developed religion reflected in the Avesta (*q.v.*), Ahura Mazda became identified with the beneficent spirit and directly opposed to the destructive one; the two being conceived as mutually limiting, coeternal beings, the one above and the other beneath, with the world in between as their battleground. There was thus lacking an infinite principle, and this sometimes was supplied by Zurvan, "Time." In late sources (3rd century AD onward) Zurvan is made father of the twins Ormazd (Ahura Mazda) and Ahriman (Angra Mainyu) who, in orthodox Mazdaism, reign alternately until Ormazd forever triumphs.

Something of this conception is reflected in Manichaeism, in which God is sometimes called Zurvan, while Ormazd is his first emanation, Primeval Man, who is vanquished by the destructive spirit of darkness and rescued by God's second emanation, the Living Spirit.

The modern Zoroastrians of India, the Parsees (*q.v.*), tend to diminish the importance of Ahriman by explaining him away as an allegory of man's evil tendencies, thus restoring omnipotence to Ormazd. See also DUALISM; ZOROASTER. (J. D.-G.)

AHVAZ (AHWAZ), a city of southwestern Iran and capital of the sixth province or ostan (Khuzistan), is situated on both banks of the Karun river where it crosses a low range of sandstone hills. The climate is dry and very hot in summer. Pop. (1956) 119,828.

Ahvaz has been identified with the Aginis of Nearchus, and approximate? occupies the site of a once extensive and important city of which very few traces remain. Its old Persian name was Hurmuz Shahr. Arab historians of the 12th century describe it as the centre of a large sugar-cane, rice and silk growing area irrigated by a system of great canals from a stone weir constructed across the river on solid rock. It exported its products all over Persia and to the west.

Since the opening of the Karun to foreign commerce in 1888 a new settlement, called Bandar Nasiri in compliment to Shah Nasr-ed-Din (d. 1896), has arisen on the left bank one mile below the rapids. Steamers anchor there. The town was well laid out in a grid pattern between 1903 and 1925. Extensive new quarters including the seat of government and the main railway station developed on the right bank after the construction of a concrete road bridge, whereas the workshops, stores and workers' quarters of the former Anglo-Iranian Oil company were built north of the old centre, near Karun station.

Ahvaz is the junction of the two branches to the termini of Khorramshahr and Bandar-e Shahpur of the Trans-Iranian railway. The Bandar-e Shahpur line crosses the river on a steel bridge more than 1,000 yd. long. Motor routes connect Ahvaz with Abadan (78 mi.), Khorramshahr (85 mi.), Shushtar (64 mi.), Dezful (94 mi.) and the oilfields. Air services to Teheran are frequent. The pipelines from the oilfields of Masjed Soleyman,

Naft-e Safid and Haft Gel meet there, and the pipeline (1959) from Abadan to Teheran passes by. The town was scheduled for industrialization under the Khuzistan development program. A faculty of agriculture was founded in 1959. (H. Bo.)

AHVENANMAA or **ÅLAND ISLANDS**, an archipelago at the entrance to the Gulf of Bothnia, separated from the Swedish coast by the 25 mi.-wide Åland sea and from the archipelago of Turku (Åbo) by the islanded strait of Skiftet. Area 581 sq.mi. Pop. (1959 est.) 22,144. The islands (Finnish Ahvenanmaa, Swedish Åland) comprise the smallest of the ten *lääni* (counties) of Finland, but have unique autonomy in the republic. The county consists of about 80 inhabited islands, about 6,000 other identifiable islands and a large number of rocky reefs. The bedrock is primarily granite of varying age and character which supports depositional features of glacial and marine origin. The surface, depressed in the shallow central Bay of Lumparn, rises to upstanding heights toward the north coast, e.g., Ardalsklint (423 ft.). There is much evidence of land upheaval in both archaeological remains and place names. Soils are principally of clay or sand. Pine, spruce and birch are the chief trees, but there are also groves of oak, alder, maple and hazel. For the latitude, natural vegetation is remarkably varied and reflects the relatively mild climate. Mariehamn (Maarianhamina), the administrative centre and chief port, has average February temperatures of 25° F., July temperatures of 61° F. Rainfall is about 22 in. annually.

Population is concentrated in Åland "mainland," on which Mariehamn is located; founded in 1861, it has a population (1959 est.) of 4,511. The Ålanders, who are Swedish-speaking, are mostly farmers, seamen and fishermen. Farms are small, intensively operated, well-mechanized and centred upon substantial buildings. The chief crops are spring and autumn, wheat, oats, barley, sown grasses and clovers, potatoes, rape, beet, cucumbers and onions. There are nearly 700 ac. of apple orchards. Ayrshire cattle dominate the dairy farms. Sea-going enterprise is represented by a fleet of 100,000 gross registered tonnage and is reflected in an excellent maritime museum. The fisheries are a relatively declining source of income. Wland is linked by daily ferry and steamship services to the Finnish and Swedish mainlands, and by air services from Mariehamn airport. Icebreakers aid winter shipping. Workshop industry is mostly concerned with processing farm and forest products, and surplus grain and softwoods are exported. A shaft has been sunk to undersea iron workings at Nynas, near Mariehamn. Depopulation and desertion of the outlying parts of the archipelago are social problems. There is also steady emigration to Sweden.

History.— The higher parts of Åland archipelago display ample evidence of Bronze and Iron Age settlement, while, as in adjacent

AHVENANMAA (ÅLAND ISLANDS) BETWEEN FINLAND AND SWEDEN IN THE BALTIC SEA

parts of Sweden, Viking age graveyards are common. Aland was a steppingstone on the way to Finland during the crusades of the middle ages and has impressive granite churches with a wealth of medieval wall paintings. Kastelholm has the remains of a major Swedish fortress restored as a museum. In early 18th-century campaigns, the islands were harried by Russians and, as church records attest, most people fled to Sweden. When the grand duchy of Finland was ceded to Russia in 1809, the islands were included; but Sweden was able to secure a provision that they should not be fortified. Nevertheless, fortification of the islands was initiated by Russia in the 1830s when the garrison of Bomarsund with its outworks was created. Bomarsund became the principal objective of the Anglo-French force during the first phase of the Crimean War. In Aug. 1854 the fortress was destroyed. A special Aland convention between Britain, France and Russia of March 30, 1856, stipulated that "The Aland Isles shall not be fortified and that no military or naval establishments shall be maintained or created on them." By article 33 of the treaty of Paris (1856) this convention was given "the same force and validity as if it formed part thereof." With the growth of German rearmament in the early 20th century, Russia again debated the status of the islands.

The Aland question assumed a new character when Finland declared its independence in 1917. The Alanders claimed the right of self-determination and unofficial plebiscites showed an overwhelming vote in favour of union with Sweden. Finland granted the islands autonomy on May 7, 1920, but refused to contemplate their secession. In June leaders of the secession movement were arrested for high treason and Finnish troops were sent to the islands. On June 19, 1920, the attention of the council of the League of Nations was formally drawn to the serious tension prevailing between Finland and Sweden. With the consent of Finland and Sweden, the council asked a special commission of jurists whether the question was international or the exclusive concern of Finland. It was declared international and a commission of inquiry was dispatched to Aland. The commission reported against the claim to secede from Finland, but declared that the Alanders formed a distinct group within the Finnish state. The commission also reported in favour of a new convention of neutralization and demilitarization to replace the international convention of 1856. This report was accepted by the council and the two nations. The new neutralization convention came into effect on April 6, 1922. The U.S.S.R. called for no concessions in Aland either in 1940 or 1944. Aland flies its own flag.

AI, the name of a Canaanite town destroyed by Joshua (Josh. vii–viii). Since biblical references agree without exception in locating this town (whose name in Hebrew, Ha-'ay, means simply "the ruin"), just east of Bethel (modern Beitin in western Jordan), there can be no doubt that it is to be sought in the unusually large Early Bronze Age site now called et-Tell. Excavations were conducted there by a French expedition led by Mme Judith Marquet-Krause in 1933–35, and very important remains of the 3rd millennium B.C. were recovered, including especially a large temple (believed at first to be a palace) with smaller adjacent shrines. This early occupation came to an end c. 2500 B.C., after a great conflagration, and there was no later reoccupation except briefly in the 12th–11th centuries B.C., whereas the events described in the book of Joshua are assigned by biblical scholars to a period between c. 1400 and c. 1200 B.C. A widely accepted solution of the dilemma is that early Israelite tradition identified the Canaanite town which was buried under the Israelite Bethel (and which is known to have been destroyed by fire about the time of Joshua) with the imposing ruins of the still earlier et-Tell, only 1½ mi. E.

See J. Marquet-Krause, *Les Fouilles de 'Ay (et-Tell) 1933–1935* (1949); G. E. Wright, *Biblical Archaeology*, pp. 80 ff. (1957).

(W. F. A.)

AICARD, (FRANÇOIS VICTOR) JEAN (1848–1921), French poet, novelist and dramatist known as a writer on Provence, was born at Toulon in 1848. In his youth he was influenced by Lamartine, and his *Poèmes de Provence* (1874) brought to French literature the most sensitive evocation of the Provencal scene since Hilistrals' *Mierèio*. The most successful of his 14 plays was *Le Pkre Lebonnard* (1889). Most of his novels, the best of which is *Maurin des Maures* (1908), are also based on Provencal life. Aicard became a member of the Académie Française in 1909. He died in Paris on May 13, 1921.

See C. Jullian, *Jean Aicard, la Provence et le félibrige* (1925).

AICHI, Japanese prefecture (area 1,953 sq.mi.; pop. [1960] 4,206,282) on the Pacific coast of central western Honshu. More than one half its area lies within the Nōbi plain and two smaller plains to the east. The irregular coast line is marked by the Chita and Atsumi peninsulas. In addition to growing food, Aichi is a leading industrial prefecture. Its capital, Nagoya (*q.v.*), and surrounding industrial satellite cities constitute Japan's third-ranking industrial concentration. Cotton textiles are the leading product, but ceramics, automobiles, wood products and many other items are made. Main port facilities are in Nagoya.

(J. D. EE.)

AICHINGER, GREGOR (1564–1628), German composer of church music. Born at Regensburg in 1564, he may have been a pupil of Orlando di Lasso (Lassus) before taking holy orders and becoming organist to the family of Jakob Fugger at Augsburg from 1584. He visited Italy (1584–87) and Rome again in 1599–1600. He died at Augsburg, Feb. 21, 1628. His music is chiefly choral and ecclesiastical: to Latin words; and shows a conservative taste influenced by the Venetian school of composers, especially Giovanni Gabrieli. His motets were well-known, and frequently appeared in contemporary collections.

(C. P. Co.)

AID, the name for a wide variety of taxes levied in the middle ages. The underlying idea was that they were granted (Lat. *dona*, "gifts"; Fr. *dons gratuits*) in aid (*auxilia*, "help"; aides) by persons or communities to someone in authority who asked for them or assessed them. Aids could be demanded (1) by the crown from its subjects; (2) by a feudal lord from his vassals; and (3) by a manorial lord from the inhabitants of his seignior.

All over Europe princes had to resort to forms of direct taxation since the other revenues of the crown were insufficient, especially in emergencies. In Carolingian times "gifts" (*dona*) were regularly offered to the king. In the later middle ages the crown negotiated with various sections of the population for aids. Thus on pressing occasions (wars, etc.) towns (or communes) would be asked for certain lump sums by the crown. It was up to them to collect the money from their burgesses. This way of obtaining aids from separate communities was superseded by the more practical method of negotiation with the representatives of the whole country assembled in "estates." How much the sovereign could in fact obtain depended on various incidental considerations, such as the actual strength of the crown, the real urgency of its financial needs and its willingness to make concessions in exchange. Thus the negotiation over aids in the assemblies of estates played an important role in the development of representative institutions in Europe. Attempts to limit the amount that could be asked were occasionally made by communes, but were never really successful against the overriding financial needs of the crown.

A feudal lord could ask his vassals for an aid, as they owed him *auxilium* et *consilium* (help and counsel). In course of time, however, the occasions on which a lord could ask for a subsidy came to be limited (1) to the knighting of his eldest son; (2) to the first marriage of his eldest daughter; (3) to the payment of his ransom; and sometimes (4) to his going on crusade. These feudal aids should be distinguished from the feudal relief (*relevium*), which was a tax due to the lord by a new vassal upon entering into possession of a fief. They were also different: at least in origin, from scutage (*q.v.*), which was a payment in lieu of the military service due by a feudal tenant.

For the aids which a lord could demand from the inhabitants of his seignior, see **TAILLE**; **TALLAGE**.

For England, aids were dealt with expressly in Magna Carta

(*q.v.*). Clause 12 established that the king should demand no aid or scutage without the common counsel of the realm, except for the payment of the king's ransom, for the knighting of his eldest son or for one marriage of his eldest daughter; and even in these cases the aid would have to be reasonable. Clause 15 extended this regulation between the king and his tenants in chief to all feudal lords and their respective vassals. Before, they had taken aids at their own pleasure. The last English king to levy these feudal aids was James I.

From early times the crown occasionally levied tallages or aids (also called *dona*) on the royal demesne lands including the towns of the realm. Exemptions were sometimes obtained by charter or custom. Lords could tallage their lands if they had in the past been royal demesne lands. From the reign of Henry II onward aids consisting of a certain proportion of movables (one-tenth, one-fifteenth, etc.) were levied at irregular intervals. Their frequency was reduced after the accession of Edward I, mainly because of the progress of taxes on movables and the effective liability of towns and rural demesne to them. The replacement of tallages by aids on movables and revenues occasionally had taken place earlier; thus in 1188 practically all the unpaid tallages of 1187 were pardoned and the aid on movables and revenues substituted. The yield of the latter was found more satisfactory. The fact that various sections of the country had to consent to the aids was an important factor in the history of parliament. By a statute of 1340 it was provided that the nation should not be called upon "to make any common aid or sustain charge" except by consent of parliament. The important but controversial document *De tallagio non concedendo* of 1297 said that no tallage or aid was to be imposed by the king without the common assent of the prelates, earls, barons, knights, burgesses and other freemen of the realm, thus turning the demesne tallage from a due into a gracious aid. Its text was more sweeping than the official confirmation of Magna Carta by Edward I, which merely stipulated that no aid levied for a special emergency should ever be regarded as establishing a precedent for a customary due. Whatever the nature of *De tallagio*, tallage on the demesne was only levied twice thereafter.

Finally there also existed in England the so-called sheriff's aid, which was a local payment of a fixed nature paid in early days to the sheriff by the county.

Mitchell, *Taxation in Medieval England* (1951). For particular aspects see F. W. Maitland, *Domesday Book and Beyond* (1907); W. S. McKechnie, *Magna Carta*, 2nd ed. (1914). (K. C. V. C.)

AIDAN, SAINT (d. 651), first bishop of Lindisfarne, was a monk at Iona when in 635 Oswald sent there to ask for a new bishop for his kingdom of Northumbria. Northumbria had only recently been converted to Christianity by Paulinus, a missionary from Rome. Aidan was appointed bishop, and settled on the island of Lindisfarne (Holy Island; *q.v.*). He founded churches and monasteries, and a school where 12 boys were trained for the ministry.

Aidan was successful in spreading Christianity throughout Northumbria, partly because he was building on foundations laid by Paulinus, partly because of Oswald's friendship, but chiefly because of his own character. Bede praises him for his learning, generosity, simplicity of life and the way he practised what he preached. After the defeat and death of Oswald at Maserfield (642), the kingdom was divided, but Aidan retained his see. He always kept to the practice of the Celtic church on the date of celebrating Easter. He died at Barnburgh on Aug. 31, 651, and his feast day is Aug. 31.

See R. H. Hodgkin, *A History of the Anglo-Saxons*, 3rd ed., ch. 8 (1952); *Butler's Lives of the Saints*, ed. by H. Thurston and D. Attwater, vol. iii, pp. 451-452 (1956). (PL. GN.)

AIDE-DE-CAMP (Fr. for camp assistant or perhaps field assistant), an officer on the personal staff of a general, admiral or other high-ranking commander who acts as his confidential secretary in routine matters. On Napoleon's staff such officers were frequently of high military qualifications and acted both as his "eyes" and as interpreters of his mind to subordinate com-

manders, even on occasions exercising delegated authority. In modern times they are usually of junior rank and their duties largely social. Traditionally, however, there are military, naval and air force officers, frequently of high rank, who act as aides to the president of the U.S.; governors of states also have aides-de-camp with the title of colonel. In Great Britain, the office of aide-de-camp to the king or queen is given to senior officers of the three services as a reward or honorary distinction. Civil governors serving the British crown, such as the governor of Northern Ireland, have also, as a rule, officers on their staffs with the title and functions of aide-de-camp.

In many countries, the word adjutant (*q.v.*) is used for aide-de-camp and adjutant general (*q.v.*) for a royal aide-de-camp. The common abbreviation for aide-de-camp in the U.S. is aide and in Britain A.D.C.

AIGUES-MORTES, a town of southeast France, *département* of Gard, 24 mi. S.W. of Nîmes. Pop. (1954) 3,470. It is a well-preserved medieval port now silted up. Situated at the western extremity of the Rhône delta, it was named for the *aqueae mortuae* (dead waters) of the surrounding marshy plain. Aigues-Mortes is 3½ mi. from the Gulf of Lions, to which it is connected by a canal. The Rhône—Sète canal also serves the town.

Aigues-Mortes is almost entirely enclosed by medieval walls, forming an oblong roughly half a mile by a quarter. The crenelated walls are 25 to 30 ft. high, and are dominated by towers, the chief being the Constance tower once used as a prison for Protestants after the revocation of the Edict of Nantes. The main street leads from the central gate to St. Louis square and the other streets run parallel with or at right angles to it. Notre Dame du Sablon (1248) and the chapels of the Pénitents Gris and Blancs are interesting old churches.

Aigues-Mortes is on a branch railway line and has bus services to Nîmes and Montpellier. The salt marshes provide the main industry, the salt being extracted, processed and exported. The vineyards are preserved from disease by periodic submersion. Fishing and soda manufacture are other industries, and there is trade in coal, fruits and wine.

Louis IX (St. Louis) embarked from Aigues-Mortes in 1248 and 1270 for the 7th and 8th crusades. Only the Constance tower dates to his day and the fortifications were completed by Philip III. Although of declining importance, Aigues-Mortes remains as an example of medieval town planning. (G. Bo.)

AIGUILLON, EMMANUEL ARMAND DE VIGNEROT DU PLESSIS DE RICHELIEU, DUC D' (1720-1788), French statesman, whose career illustrates the difficulties of the central government of the *ancien régime* in dealing with the provincial *parlements* and estates, the extent to which powerful ministers were at the mercy of court intrigue and how French diplomacy suffered under Louis XV as a result of secret diplomacy. Born on July 31, 1720, he succeeded in 1750 to the peerage duchy of Aiguillon (created for his great-great-grandfather's sister, a niece of the cardinal de Richelieu, in 1638). In 1753 he was appointed military commander for Brittany, where his wife, Louise-Félicité de Bréhan-Plélo, had numerous family connections. In the governor's absence he was the chief representative in the province of the central government and so incurred the hostility of the *parlement* of Rennes and of the provincial estates, which resisted the government's fiscal reforms of 1764-65. He also aroused the personal enmity of L. R. de Caradeuc de La Chalotais (*q.v.*) the powerful *procureur-général* of the *parlement*. These quarrels led to his recall in 1766. D'Aiguillon, however, was a man of great ambition and, after the fall of the duc de Choiseul, was appointed minister of foreign affairs (June 1771), though he had neither taste for nor experience of diplomacy. He was closely associated with the chancellor, René de Maupeou, and with the controller-general, the *abbé* J. M. Terray, in the so-called "triumvirate," which attempted to destroy the political powers of the *parlements*. As foreign minister he was unable to prevent the rapid decline of French influence in central and northern Europe. Though this was partly due to the rising power of Prussia and Russia, he gave no firm direction to French diplomacy and could not save Poland from being partitioned in 1772. His only—

dubious—success was the help that he gave to Gustavus III of Sweden in effecting his *coup d'état* of 1772. Dismissed from office on the accession of Louis XVI in 1774, he died in Paris on Sept. 1, 1788.

AI-HUN (AIGUN), a Chinese city on the south bank of the Amur river in the province of Heilungkiang (49° 58' N.; 127° 35' E.). Opposite it is the Russian city of Blagoveshchensk (Hailanpao in Chinese). Ai-hun became an important entrepôt after the treaty of Aihun concluded in 1858 between China and Russia, dealing in the shipment of cattle, meat and food grains across the Amur to Blagoveshchensk. But after the building of the Chinese Eastern railway at the turn of the century its importance was reduced. Aihun is one of the major gold-producing districts of Manchuria, with important placer deposits. It is also a timber centre, getting supplies from the Little Khingan ranges. (KN. C.)

AIKEN, CONRAD POTTER (1889—), U. S. poet and man of letters, explored the subconscious mind in symphonic poems and meditative prose. Born of New England stock in Savannah, Ga., on Aug. 5, 1889, he was the oldest son of a physician who killed his wife and himself when the boy was eleven. Sent to live with relatives in New Bedford, Mass., he was educated at private schools and at Harvard (class of 1911), where he was a friend and contemporary of T. S. Eliot. Most of his mature life was divided almost equally between England and the U.S., but after 1947 he was permanently established at Brewster, Mass.

Aiken was never anything but a writer. After three immature collections of verse, he entered an extremely fruitful period. 1915-20, during which he wrote five "symphonies" in an effort to create what he called "a sort of absolute poetry" that would resemble music. Then came a period of narrative poems, then several volumes of lyrics and meditations, and after World War II a return to the musical form, in poems that were simpler in conception than the symphonies but had richer overtones of philosophical and psychological meaning.

Besides his poems, Aiken produced distinguished work in many fields. He wrote five novels (beginning with *Blue Voyage*, 1927) and four books of short stories (notably *The Short Stories of Conrad Aiken*, 1950), many of them dealing with inhibited characters studied almost psychoanalytically. He also wrote many critical essays, a play (*Mr. Arcularis*, with Diana Hamilton, 1949) and an experimental essay in autobiography (*Ushant*, 1952). He worked in obscurity, sometimes in extreme poverty, during much of his career.

Although his *Selected Poems* received a Pulitzer prize in 1930, it was not until 1953, when his *Collected Poems* appeared in a volume of 900 pages, that he was widely recognized as a major writer.

Kcsides *Ushant*, see Houston Peterson, *The Melody of Chaos* (1931). *Wake 11: Conrad Aiken Number* (1952) contains an extensive bibliography. (M. CV.)

AILANTHUS (more correctly *ailantus*, from *ailanto*, an Amboyna word probably meaning "tree of the gods," or "tree of heaven"), a genus of trees belonging to the quassia family (Simaroubaceae). The best-known species, tree of heaven (*Ailanthus altissima*), is a handsome rapidly growing tree with spreading branches and large pinnately compound leaves bearing many lance-shaped leaflets with conspicuous glandular bases. The small greenish flowers are borne in branched panicles; the staminate (male), upon opening, exhale a most disagreeable odour. The fruit is a samara with a single centrally disposed seed in the elliptical, twisted, fibrous wing. This tree, which is a native of China and Japan, was introduced into England in 1751 and is a favourite in parks and gardens. It has been planted extensively in the eastern United States and is one of a few trees capable of thriving in smoky atmospheres adjoining industrial centres. Two other species, *A. imberbiflora* and *A. punctata*, are Australian trees of secondary importance; *A. excelsa* is a common tree in

India.

(E. S. HR.)

AILLY, PIERRE D' (1350-1420), French churchman, cardinal and scholar, the chief aim of whose life was to heal the great western schism of 1378-1417, was born at Compiègne and studied at the College of Navarre of the University of Paris, where he became doctor of theology (1380) and soon acquired a position of leadership. Although he recognized the Avignon pope as early as 1379, D'Ailly advocated the conciliar theory as early as 1380. According to this view, also adopted by the University of Paris, a general council is superior to the pope, whom it may, if necessary, depose. Acting as spokesman of the university before the royal council in 1381, D'Ailly advocated the convocation of a general council to end the schism. After temporary retirement, he became master of the College of Navarre in 1384, where he had as one of his pupils Jean de Gerson (*q.v.*). He became chancellor of the university as well as the king's confessor and almoner in 1389, but displeased the university by supporting Benedict XIII after the latter's election to succeed Clement VII (1394). Benedict appointed him bishop of Le Puy in 1395 and then bishop of Cambrai in 1397. Although D'Ailly opposed withdrawal of French allegiance from Benedict, he worked for the voluntary abdication of both pontiffs. He gradually broke with the intransigent Benedict XIII and returned to his old conciliar doctrine, which steadily became more extreme. He played a prominent part in the general council of Pisa (1409), which declared both popes deposed and elected a third, Alexander V. John XXIII, who succeeded Alexander the following year, made D'Ailly a cardinal (1411) and bishop of Orange, as well as his legate to Germany. But since the schism persisted, D'Ailly supported the convocation of a new general council at Constance (1414-18), where he was influential in its decisions to insist on the abdication of John XXIII, condemn the Hussites, vote by nations, support conciliarism and compromise concerning the parts of the council and the cardinals in the election of a new pope. He was also an advocate of church reform. (*See* CONSTANCE, COUNCIL OF.) The possibility that D'Ailly might be elected pope was ruled out by a hostile coalition of Italians, Germans and English. Since he was unacceptable to the English and Burgundians, who were now in control of most of France, he was forced to retire to Avignon, where he was legate for Rlartin V.

D'Ailly was the author of numerous works, several of which were very influential. Although many of his views on the constitution of the church, such as the independent superiority of the general council, the autonomous jurisdiction of bishops and the reservation of infallibility to the universal body of believers, were later rejected as heretical, they became temporarily ascendant as the only apparent way of ending the great western schism, and were later echoed by Protestant reformers. In philosophy, D'Ailly supported Ockhamistic nominalism (*q.v.*), which became ascendant at the University of Paris and later influenced Luther. Interested in science, he advocated calendar reform, later effected by Gregory XII; and his *Image of the World*, which supported the idea that India could be reached by sailing west, encouraged Columbus. Several of his works were printed in the 15th and 18th centuries; others remain in manuscript.

Biographies of D'Ailly have been published by P. Tschackert (1877), L. Salembier (1886) and John McGowan (1936). (D. D. MCG.)

AILSA CRAIG, an island rock at the mouth of the Firth of Clyde, 10 mi. W. of Girvan, Ayrshire, Scot. Pop. (1951) 14. "Paddy's milestone," as it has been called because it is about halfway between Glasgow and Belfast, is cone-shaped and rises abruptly to a height of 1,114 ft.; it is 3,900 ft. long and 2,600 ft. wide. The only side from which the rock can be ascended is the east, the other sides generally presenting lofty columnar forms. The island is composed of microgranite with riebeckite—a rare type in Britain. Pebbles were carried far south (*e.g.*, to Wales and Ireland) by the retreating glaciers. The rock is a favourite material for curling (*q.v.*) stones, hence their popular name of "Ailsas" or "Ailsa Craigs." The rock is also used for paving stones. A columnar cave exists toward the north of the island, and on the east are remains of a toner. The Garry loch is 800 ft. above sea level. Two springs occur near the summit and some

scanty grass affords subsistence to goats. After myxomatosis was introduced in 1956 the rabbit population almost died out, but it had risen again to about 10% of its former numbers by 1959 when the disease recurred. The precipices have large breeding colonies of gannets and other sea birds; the brown rat is firmly established. A lighthouse on the south flashes a light visible for 13 mi. and there are two alternating foghorns.

AIMAK, a Mongol term which Genghis Khan applied to a tribal group fighting as a military unit. In the 18th century the Chahar Mongols of Inner Mongolia comprised a single aimak, whereas in the 20th century the four major administrative divisions of the Khalkhas of Outer Mongolia were called aimak. Among the Kalmuks, who migrated to southern Russia in the 17th century, the aimak was a comparatively small subtribal group sharing a common territory. In western Afghanistan the term originally meant "nomadic tribe," but later was used only in the name Chahar Aimak ("Four Tribes"), which includes the Djamshidi, Firuzkuhi, Hazara and Taimani. Of these only the Hazaras (western Hazaras) are Mongol. The Firuzkuhi have a tradition of Persian origin. (EL. B.)

AIMARD, GUSTAVE (pseudonym of OLIVIER GLOUX) (1818–1883), French novelist who wrote adventure stories of the American frontier, was born in Paris in 1818. He went to sea at 12 and witnessed local wars and conspiracies in Turkey, the Caucasus and South America. He took part in the 1848 revolution in Paris, returned to America in an unsuccessful armed expedition to Sonora, Mex., under Count Raousset-Boulbon in 1854 and shortly afterward began a series of novels that extended to his death. Many of them, first published in serial form, were translated into English, including *The Border Rifles*, *The Trappers of Arkansas* and *The Missouri Outlaws*. Aimard fought in the siege of Paris in 1870 and died in Paris on June 20, 1883.

AIMOIN (c. 960–c. 1010). French Benedictine monk whose history of the Franks was highly esteemed in the middle ages. Having entered the abbey of Fleury-sur-Loire (between 979 and 985), he devoted much of his time to writing on St. Benedict, the second and third books of the *Miracula sancti Benedicti* were written by him in 1005. Encouraged, however, by the abbot Abbon (d. 1004), whose biography he also wrote, Aimoïn began to compose his *Historia Francorum* or *Libri IV de gestis Francorum* from various texts on the Merovingian period (notably the works of Gregory of Tours), which he collected and rewrote in better Latin. Left incomplete, his history ends at the year 653. Later writers adapted, lengthened or expanded it, and its substance reappears in a number of 12th-century works.

BIBLIOGRAPHY.—For the *Miracula* see *Les Miracles de Saint Benoît*, ed. by E. de Certain (1858). For the life of Abbon, valuable for its use of authentic letters, see the *Annales ordinis Sancti Benedicti*, ed. by J. Mabillon, vol. vi, pt 1 (1668). The *Historia* is printed by J. P. Migne, *Patrologia latina*, vol. cxxxix (1844). (JE H.)

AIMORÉS, SERRA DOS, known as a *Territorio em Litigio* (litigated area), is a region of southeast Brazil claimed by the states of Minas Gerais and Espírito Santo. Pop. (1950) 160,072; area 3,914 sq mi. It is bounded west and south by Minas Gerais, north by Minas Gerais and Bahia and east by Espírito Santo. It is crossed by the São Mateus river and several smaller streams, and the Rio Doce follows closely its southwest border. In surface characteristics Serra dos Aimorés is mainly crystalline hilly upland, covered with semideciduous forest; elevations average close to 3,000 ft. Rainfall is in the range of 40 to 60 in. annually. It is a frontier region with fertile soils capable of producing coffee, beans, cereals, vegetables and livestock. The proximity of the Rio-Bahia highway and the Estrada de Ferro Vale do Rio Doce enhance the economic value of the region. Mantena is the principal town. (J. L. TR.)

AIN, a *departement* of eastern France, formed from Bresse, the Pays de Dombes on the lowland and the Pays de Gex, Valromey and Bugey among the high parallel ridges of the Jura (*q.v.*) reaching south to the Rhône river between Geneva and Lyons. Pop. (1954) 311,941. Area 2,249 sq mi. The Ain river roughly separates the lowland areas from the other districts, running north to south at first between outer hill ridges and then along the foot of the highland to join the RhBne. The western boundary is the

SaBne river, the southern the Rhône, the eastern Switzerland and the northern the *départements* of Saône-et-Loire and Jura, the boundary over against the latter being closely linked with that of old between Burgundy and Franche-Comté. The Pays de Gex includes some of the highest Jura scarps (Crêt de la Neige 5,653 ft.), the Pays de Valromey flanks on the west the deep RhBne gorge below Bellegarde, the Pays de Bugey is the south-pointing triangle of the Rhône focussing on Belley. West of the hills, Bresse occupies the fertile north part of the *departement* and is effectively drained to the SaBne, thus contrasting with the Pays de Dombes, mantled in boulder clay, with innumerable pools and marshes and, still, a good deal of consequent malarial trouble. The summers are warm in the lowland but the winters, generally, are cold; the precipitation rises above 40 in. per annum in the highland.

The farms of Bresse are famous for pigs and poultry and the latter (especially geese) are bred in Dombes, which also raises horses. In the Jura hills are extensive forests and pastures. Cheese is a noteworthy product. Bresse produces considerable cereal and other crops but the rest of the *departement* is concerned mainly with stockraising, activities connected with its forests (of fir and oak) or with extensions of the silk industry from Lyons, made possible by the water power available from the rivers among the gorges of the limestone country.

Bourg (*q.v.*) is the capital of the *departement*; the four *arrondissements* take their names from Bourg, Belley (the seat of a bishop in the archiepiscopal province of Besançon), Nantua and the Pays de Gex. The departmental appeals are heard at the court of Lyons and the *département* is also under Lyons educationally. Bourg is a market town specially known for the famous church of Brou. Among silk towns are Jujurieux, Tenay, St. Rambert and St. Bernard en Bugey; Bellegarde and St. Rarnbert make wood pulp; and Oyonnax, a rather larger town than several of the others, north of Nantua, makes articles in wood and horn and is specially well known for its combs. Seyssel, on the far east, yields asphalt, and many parts of the *departement* produce building stones, cement or potter's clay. There is a thriving tourist industry for winter sports, angling, etc., and some of the gorges and ridges are very striking. Near Bellegarde, at the Perte du RhBne, the river formerly disappeared down a fissure. Though the main Sud-Est (formerly Paris-Lyon-MCditerranCe) railway from Dijon to Lyons lies west of the SaBne, and so outside the *departement*, the main line from Paris to Geneva runs through Bourg and Am-bérieu to Bellegarde; both the Saône and the Rhône are navigable for considerable lengths along the confines of the *dkpartement*. Historical aspects may be found in BRESSE; BURGUNDY; DOMBES; GEX; parts of which comprise Ain. (AR. E. S.)

AIN RIVER, of eastern France and a tributary of the RhBne (*q.v.*), flows through the *départements* of Jura and Ain. Rising in the Jura (*q.v.*) plateau above Champagnole, it flows southward for 124 mi. through the limestone plateau in a deep valley, receiving left-bank affluents from the Jura mountains. Approaching the Rhône, it emerges from its gorge to flow past Pont d'Ain across the hummocky moraine country of the Dombes. Several hydro-electric power stations are located along the courses of the Ain and its tributary the Bienne in the Jura mountains. (AR. E. S.)

AINSWORTH, HENRY (1571–c. 1622), English Nonconformist theologian and rabbinical scholar, a leader of the English Separatist colony in Amsterdam, was born at Swanton Morley, Norfolk, in 1571. He was a scholar of Caius college, Cambridge, and joined first the Puritan and eventually the Separatist party in the church. Driven abroad in the persecution of 1593, he found a home in "a blind lane at Amsterdam." He acted as "porter" to a scholarly bookseller in that city who, on discovering his skill in Hebrew, enabled him to continue his Hebrew studies. When part of the London church, of which Francis Johnson (then in prison) was pastor, reassembled in Amsterdam, Ainsworth was chosen as their doctor or teacher.

In 1596 he drew up a confession of their faith, which he re-issued in Latin in 1598. Johnson joined his flock in 1597, and in 1604 he and Ainsworth composed *An Apology or Defence of Such True Christians as Are Commonly but Unjustly Called Brownists*. In 1610 he was forced reluctantly to withdraw, with a large part

of the church, from Johnson and his adherents on a question of church government. Ainsworth taking the more congregational view. (See CONGREGATIONALISM; BROWNE, ROBERT.) He died in Amsterdam, probably in 1622.

The fruit of Ainsworth's rabbinical learning appeared in his *Annotations — on Genesis* (1616), *Exodus* (1617), *Leviticus* (1618), *Numbers* (1619), *Deuteronomy* (1619). *Psalms* (including a metrical version, 1612) and *Song of Solomon* (1623). These were collected in folio in 1627 and again in 1639. From the outset the *Annotations* took a commanding place, especially among continental scholars.

BIBLIOGRAPHY.—H. M. Dexter, *Congregationalism of the Last Three Hundred Years* (1880); W. E. A. Axon, *H. Ainsworth, the Puritan Commentator* (1889); F. J. Powicke, *Henry Barrow and the Exiled Church of Amsterdam* (1900); J. H. Shakespeare, *Baptist and Congregational Pioneers* (1906).

AINSWORTH, WILLIAM HARRISON (1805–1882), English writer of popular historical romances, was born in Manchester, Feb. 4, 1805. In 1824 he went to study at the Inner Temple, but abandoned law for literature and collaborated with J. P. Aston in writing *Sir John Chiverton* (1826). Success came in 1834, with *Rookwood*, which includes a vivid description of Dick Turpin's famous ride. It was followed by many other historical novels, of which *Jack Sheppard* (1839), *The Tower of London* (1840), *Old St. Paul's* (1841), *Windsor Castle* (1843) and *The Lancashire Witches* (1849) are the best known.

In 1839 Ainsworth became editor of *Bentley's Miscellany*, which he owned from 1854 to 1868, and in 1842 he founded *Ainsworth's Magazine*. He later edited the *New Monthly Magazine*. His fame as a writer, and his generous encouragement of other authors, gave him social standing. His books brought him wealth, but his ventures as editor and publisher were not financially successful. He died at Reigate, Jan. 3, 1882.

Ainsworth's novels, lacking coherence of plot or subtlety of characterization, excel in conveying a sense of the bustle and pagantry of history and in their historical accuracy and local colour.

AINU, a people living in Hokkaido, Sakhalin and the Kuril Islands, who are physically unlike their Mongoloid neighbours and may be descendants of early Caucasoid type peoples once widely spread over northern Asia. The Ainu of modern times are extremely reduced in numbers and appear to be dying out except as they are intermarried with Japanese and other settlers. Formerly they may have extended southward to the Ryukyu Islands. Some scholars see relationships between the Ainoid (Ainulike) type and the Australoid type aboriginal peoples of Australia and New Guinea. Short statured and brunette, they have the most profuse body hair of any known human group. Japanese migrations northward involved centuries of sporadic warfare with Ainu groups before final pacification of the remnants in the Hokkaido area. Ainu speech, with a number of dialects, has no known relation to any other language. The Ainu live in small villages near the sea, with hunting, fishing, gathering wild plants and, in modern times, minor gardening as an economic base. Houses are of reed thatch, and formerly included pit dwellings. Men usually have heavy beards, and women moustachelike tattooing around the mouth. Traditional clothing consists of bark cloth or skin

BY COURTESY OF CONSULATE GENERAL OF JAPAN, NEW YORK, N. Y.

AINU COUPLE IN CEREMONIAL DRESS

drapes often decorated with geometric designs characteristic of their art. Village chiefs and kin elders provide leadership. Religion centres around local forces of nature and a cult of ancestors, with a bear sacrifice ritual as a high point. Many aspects of Ainu life show past Japanese influences, and the younger generations of Ainu in north Japan show extensive adaptation to modern Japanese culture. See JAPAN: *The People*.

AIR is the gaseous envelope that surrounds the earth. It is a mixture of gases, the most abundant of which are nitrogen and oxygen. Near the end of the 18th century the word air was applied to several common gases; e.g., nitrogen was known as phlogisticated air, oxygen as dephlogisticated air, hydrogen as inflammable air and carbon dioxide as fixed air (see CHEMISTRY: *History of Chemistry: The Understanding of Combustion*). The name air is used ordinarily only for the mixture of substances which constitute the gaseous components of our atmosphere.

The composition of the air is not constant. The principal variable components are water and carbon dioxide. If these substances are removed from samples of air collected in many places and at many times, the compositions of the remainders of the samples are virtually constant. Table I shows the concentrations of the non-variable components of air.

TABLE I.—Nonvariable Components of Air From Which Water and Carbon Dioxide Have Been Removed

Constituent	Formula	Volume %*
Nitrogen	N ₂	78.110
Oxygen	O ₂	20.953
Argon	Ar	0.934
Neon	Ne	0.001818
Helium	He	0.000524
Krypton	Kr	0.000114
Xenon	Xe	0.000087
Hydrogen	H ₂	0.00005
Methane	CH ₄	0.0002
Nitrous oxide	N ₂ O	0.00005

*Volume per cent of any gas is the volume of that gas isolated and purified in a total of 100 vol. of gas mixture.

Table II contains a list of other gases commonly found in air. The last four probably arise from industrial sources and perhaps should be regarded as contaminants rather than as constituents of natural air.

The amount of moisture in the air is very variable and has important effects on climate, radiation, weather and comfort (see HUMIDITY, ATMOSPHERIC). The absolute humidity may be as high as 7 volume per cent of water vapour if the temperature is 40° C. (104° F.) and if the relative humidity is 100%.

TABLE II.—Variable Components of Air

Constituent	Formula	Volume %
Water	H ₂ O	0 to 7*
Carbon dioxide	CO ₂	0.01 to 0.1; average 0.033
Ozone	O ₃	0 to 0.00007
Formaldehyde	CH ₂ O	?
Sulfur dioxide	SO ₂	0 to 0.0001
Nitrogen dioxide	NO ₂	0 to 0.000002
Ammonia	NH ₃	0 to trace
Carbon monoxide	CO	0 to trace

*Approximate value for 40° C. (104° F.) and a relative humidity of 100%

The ozone concentration is highly variable. Ozone is both produced and destroyed by absorption of ultraviolet radiation. Most of it is found at great altitudes. It is important in meteorology largely because it absorbs ultraviolet and infrared radiation.

Variations in the carbon dioxide content of the air are interesting and some of them are very important. Carbon dioxide concentration is relatively high over decaying leaves of forest floors and in enclosed spaces such as crowded rooms, city subways, caves and wells. It is relatively low over fields of growing vegetation, in polar regions not covered by ice and in regions where the air has recently passed over the ocean.

Carbon dioxide in the air reduces the loss of heat by infrared

radiation from the earth. The widespread burning of fossil fuels (*e.g.*, coal and oil) increased the carbon dioxide content of the air by about 12% during the first half of the 20th century. This, in turn, caused an increase in the average temperature of the earth of 1.1° C. during the same period. It is estimated that all of the fossil fuels will be consumed in about 1,000 years, if the present rate of consumption is maintained. It has been further estimated that this will cause the temperature of the earth to rise 7° to 14° C. (13° to 25° F.), giving most of the earth a tropical and semitropical climate by the end of the period.

Density.—The density of the air can vary greatly. It is reduced by the lowering of barometric pressure, rise of temperature and increase of humidity. Since lowered density greatly reduces the lifting capacity of airplanes, density must be considered whenever planes are being prepared for flights with near-maximum loads.

Particulates.—Suspended in the air are liquid droplets and a wide variety of small solid particles called particulates. A very prominent class of particulate is salt raised by winds from ocean spray and carried to great altitudes and great distances over the earth. The salt particles are highly important in the condensation and precipitation of water. See ATMOSPHERE; LIQUEFACTION OF GASES; see also Index references under "Air" in the Index volume.

AIR (AYRE). In general the musical term air (like its cognate forms in French, *air*, and Italian, *aria*) signifies a tune or song, and hence a type of music in which the upper (melody) line predominates. In the 16th century in particular these terms (*e.g.* as used in the compound *air de cour*, of a particular type of courtly song) indicated forms of art song, simpler in texture than the polyphonic madrigal (*q.v.*). The spelling "ayre" is used to refer to the rich and clearly defined repertory of late Elizabethan and Jacobean songs for solo voice, usually with lute accompaniment, inaugurated by John Dowland's *First Books of Songes or Ayres of Foure Parties, with Tableture for the Lute* (1597) and ending with John Attey's similarly named collection of 1622. This brief period saw the publication in London of more than two dozen collections of "ayres." The principal composers were Dowland (four books), Robert Jones (five books), Thomas Campion (four books), Philip Rosseter and Thomas Morley (one book each). Not only do their songs run the gamut of expression from gaiety to mourning, passion to frivolity; they also represent a relationship between music and poetry more intimate than any to be found in English song writing before the 20th century. Of the composers only Campion is known to have been a poet, but many of the texts of these collections were written by the finest poets of the day.

BIBLIOGRAPHY.—The complete repertory was edited by E. H. Fellowes, *The English School of Lutenist Song-Writers*, 32 vol. (1920-32). See also P. Warlock, *The English Ayre* (1926); B. Pattison, *Music and Poetry of the English Renaissance* (1948). (J. J. N.)

AIR BLADDER, a structure present in most bony fishes (teleosts) and somewhat homologous with the lungs of land vertebrates. The function of this organ, which contains atmospheric gases, is varied and to some extent obscure. In some fishes it is hydrostatic and in others respiratory in function. In some fishes a duct connects the air bladder to the alimentary canal, through which gases pass. In others no duct exists. In the latter type gæses enter and leave the air bladder through a vascular gland (*rete mirabile*). In these bladders high concentrations of oxygen have been found. In some fishes air bladders connect with the internal ears, suggesting they are concerned with hearing.

(F. G. HA.)

AIR-BORNE TROOPS, soldiers who enter combat from the air. The term comprises three main types of soldiers—paratroopers, glidermen and those who are landed in the combat zone from air transports. In the last group are those who use assault air transports during the initial shock wave of an attack. They are especially valuable for making sudden surprise attacks on the enemy's flank or rear. Because their tactics have much in

common with those of cavalry, they are often referred to as "sky cavalry."

Air-borne troops have participated in all major operations since their first combat use by the Russians in 1939 and by the Germans in the spring of 1940. During World War II, entire divisions, corps and field armies were organized as air-borne units. They made a decisive contribution to the outcome of most of the major battles. United States air-borne troops acquired picturesque nicknames that were associated with their divisions. Members of the 11th air-borne division, for example, were called "The Angels," those of the 82nd division the "All Americans" and those of the 101st "The Screaming Eagles." British air-borne troops collectively were known as "The Red Devils" because they wore red berets, both in and out of combat.

Entry into combat from the air was first accomplished by using parachutes. The largest portion of U.S. air-borne troops still enter combat by this means, and are called paratroopers. They carry on their persons the essentials for combat—a knife, grenades, a rifle or machine gun, medical gear and, frequently, bazookas, mines and radio equipment. But, in order to fight successfully, they also need artillery and heavy equipment. In World War II artillery weapons were broken down into separate pieces, dropped by parachute and were later assembled on the ground. Because this task was sometimes difficult, the needs of paratroopers for heavy equipment were met by the use of gliders. Jeeps, antitank guns and in some cases light tanks were delivered to paratroopers by gliders.

The idea of entering combat from the sky was suggested by Benjamin Franklin as early as 1784. It was seriously proposed by Gen. "Billy" Mitchell in World War I. The U.S. army first dropped machine gun crews by parachute as an experiment in 1923, but the idea was not pursued further in the United States until World War II. The British army did not organize any air-borne forces until 1940. The Russians developed techniques for dropping large numbers of individual paratroopers and in 1936 demonstrated their ability to conduct large-scale parachute operations. But during World War II they attempted only a few air-borne operations, and the results were not impressive.

The first combat use of paratroopers did not occur until the Russians used them against Finland. The Germans used sky soldiers in large numbers in the Netherlands in 1940. Later, in May 1941, they captured the Island of Crete by a large-scale paratroop assault. Gliders and supporting forces landed on air fields in ordinary air transports after the fields had been captured by paratroopers. This established the pattern for paratrooper operations for World War II and by the end of the war combined operations of this type were identified as "air-borne operations."

Early in the war the Allies revived their dormant interest in paratrooper operations and conducted several small-scale and behind-the-lines drops. The United States formed its first parachute battalions in 1941. These units expanded rapidly and the first paratroop divisions, the 82nd and 101st, were formed in the fall of 1942. These divisions combined both paratroopers and gliders and were known as air-borne divisions.

In July 1943 a brigade of the British 1st air-borne division was dropped by parachute and glider to seize a vital road bridge and other objectives south of Syracuse. Simultaneously, the U.S. 82nd air-borne division was used in combat in the assault on Sicily. This division also participated in the battle of Salerno. Three parachute divisions, the United States 82nd and 101st and the British 6th, spearheaded the 1944 assault in Normandy.

Corps-size air-borne units were formed early in 1944 and later that year the 1st allied air-borne army was created. This army planned and carried out the large air-borne assault at Arnhem, Nijmegen and Eindhoven in the Netherlands in Sept. 1944. The largest concentrated air-borne assault of the war took place in March 1945. A total of 17,122 troopers, 614 jeeps and 286 artillery pieces, plus tons of gasoline, food and ammunition, were parachute-delivered and air-landed within a space of two hours in the seizure of crossing sites of the Rhine river near Wesel, Ger. Parachute operations also took place in the Pacific theatre—although on a smaller scale. A most significant operation was

the capture of Corregidor in the Philippines from the Japanese in 1945.

After World War II more efficient parachute delivery systems were developed, and by 1957 loads up to ten tons were dropped by parachute. Thus paratrooper units were able to include all the necessary weapons and vehicles for heavy combat. These included self-propelled tracklaying guns, trucks, radio vehicles, medium artillery, missiles and nuclear weapons.

Immediately following World War II it became necessary to develop means for delivering heavier combat equipment to meet the demands of new and more complex patterns of warfare. World War II gliders made of fabric and wood were replaced by all-metal gliders capable of carrying heavier loads. These in turn were replaced by assault air transports. The latter were designed for delivering heavy cargo up to eight tons in unimproved or cultivated land areas. With such assault air transport it was possible to move and air-land large composite units consisting not only of combat infantrymen but including also their ordnance, signal, medical, engineer and quartermaster support. Armoured vehicles suitable for participation in armoured warfare could also be air-landed in an assault. Thus, air-borne troops gradually acquired a capability of engaging in sustained combat of either a nuclear or nonnuclear type.

Paralleling this improvement in air-landing vehicles, there was an improvement in air-borne unit communications and in their ground vehicles. Thus, it became possible for units to disperse over much greater areas than in World War II and still maintain effective combat control. In addition, they could take larger numbers of vehicles into combat and thus enjoy extensive land mobility. The combination of these new developments enabled air-borne troops to adapt themselves to the challenge of tactical nuclear warfare. During the 1950s the Soviet Union gave special attention to improving its air-borne equipment and techniques. Soviet military leaders emphasized the value of air-borne troops in launching surprise attacks. They developed light weapons that could be transported by helicopters or cargo aircraft for the support of air-borne forces.

In the missile age, air-to-air and surface-to-air missiles have a significant impact upon air-borne combat. To meet this challenge, air-borne troops rely to an increasing extent upon unusual air vehicles of rotary wing and short take-off characteristics. Thus they are able to avoid the risks of flying at vulnerable altitudes and at the same time to retain a high degree of air mobility.

AIR BRUSH: see SPRAY GUN AND AIR BRUSH.

AIR CONDITIONING, the control of temperature, humidity, purity and motion of the air in an enclosure. Air conditioning is used for industrial processes as well as for human comfort. The production of uniformly good quality cotton yarn requires nearly constant temperature and high moisture content of the air in the cotton mill. During the manufacture of extremely delicate equipment, such as inertial guidance systems for rockets, airplanes or submarines, temperature and humidity must be closely controlled and air purity maintained at an extremely high level. Air conditioning for human comfort is employed in both large and small installations, such as theatres, office buildings, department stores, residences, airplanes, railway cars and submarines.

History.--In a broad sense the fires of the cavemen might be considered as the first attempts of air conditioning for human comfort. The Romans used panel heating systems (see HOUSE DESIGN), and for centuries in India wetted grass mats were hung over the windward openings of houses to cool the incoming air.

The beginnings of modern air conditioning occurred in the textile industry, where the term "conditioning" was applied to the determination of the moisture content of textiles. In order to reduce breakage and the effects of static electricity, the air in the textile mills was humidified by evaporating water from steam pots.

In 1842 Dr. John Gorrie of Apalachicola, Fla., designed and built for the treatment of yellow-fever patients an apparatus that

used air as a refrigerant. In the latter part of the 19th century, cotton mills used atomized sprays of water for simultaneous humidification and cooling. In the same period, methods of controlling the ambient air were used in other industries also; e.g., printing, candymaking, wood production, tobacco manufacturing and the storage of food or other perishable products. In 1897 Joseph McCreary of Toledo, O., patented an air washer which cooled and humidified in addition to its primary function of cleaning the air.

In 1906 Stuart W. Cramer of Charlotte, N.C., and Willis H. Carrier of Buffalo, N.Y., working independently, made two important contributions. Cramer used individual spray heads in a room and controlled humidity by a system that depended upon the relation between the wet- and dry-bulb temperatures (see below). He first suggested the use of the term "air conditioning." Carrier devised the "dew point control," a central air-conditioning unit of the air-masher type which saturated the air and also controlled automatically the saturation temperature. This system thus determined the moisture content of the air supplied. Carrier initiated the scientific approach to air conditioning in his paper "Rational Psychrometric Formulae" presented to the American Society of Mechanical Engineers in 1911.

The form of air conditioning used first in textile mills was extended to other industries. In the early 1920s new refrigerants began to appear, enabling the manufacture of lighter, safer and more efficient refrigerating equipment. Air conditioning for human comfort was first used in 1922 in a motion-picture theatre. Its great success caused the widespread use of air conditioning in other public buildings, such as department stores, hotels and restaurants.

The early 1930s saw the development of the first small unitary air conditioner for railway coaches and the beginning of the scientific study of human comfort requirements. The John B. Pierce Laboratory of Hygiene, the U.S. bureau of mines and the American Society of Heating and Ventilating Engineers, together with the United States department of public health, started studies of man's relationship to his thermal environment from both the physical and physiological standpoints.

After World War II the air-conditioning industry expanded at an extremely rapid rate. The use of air conditioning became universally accepted in various applications, particularly in the United States. New public buildings, office buildings and factories are almost always built with air conditioning included in the original design. Ships, particularly passenger vessels, use air conditioning. Medium-size unitary systems find widespread use in residential central units, offices, restaurants and in specialized applications such as buses, airplanes, submarines and space vehicles. Examples of the smallest units are air conditioners installed in the windows of homes and in automobiles.

Psychrometric Properties of Air.—Psychrometry is essentially the thermodynamics (*q.v.*) of air and water-vapour mixtures as applied to air conditioning. Atmospheric air is considered to be a perfect gas consisting of a mixture of dry air and water vapour. At the usual temperatures and pressures encountered, each of these components can also be considered as a perfect gas; *i.e.*, each component as well as the mixture follows the relation $p v = RT$, where p is absolute pressure in pounds per square foot, v is specific volume in cubic feet per pound, R is the gas constant of the particular gas in foot-pounds per pound-degree Fahrenheit (for air, $R_a = 53.35$; for water vapour $R_w = 85.71$) and T is the temperature in degrees Fahrenheit. In addition, Dalton's law of partial pressures holds. Accordingly, atmospheric, barometric or total pressure is equal to the sum of the pressures exerted by dry air and water vapour independently of each other. The maximum partial pressure that water vapour can exert at any temperature is equal to its saturation pressure at that temperature (see VAPORIZATION). This saturated condition also determines the maximum quantity of water vapour that air can hold at any temperature.

Humidity per se denotes the water vapour mixed with dry air. Absolute humidity is the actual mass of water vapour in one cubic foot of space, and is equivalent to the density. It is usually expressed in pounds or grains per cubic foot (1 lb. = 7,000 gr.

avoidrupois). Specific humidity or humidity ratio is the mass of water vapour in pounds or grains that is mixed with one pound of dry air. Relative humidity is the ratio of the actual partial pressure of water vapour to the saturated vapour pressure at the same dry-bulb temperature. It is usually expressed as a percentage. (See HUMIDITY, ATMOSPHERIC.)

Percentage saturation is 100 times the ratio of the actual mass of water vapour mixed in one pound of dry air to that required to saturate one pound of dry air at the same dry-bulb temperature and absolute total pressure.

Dry-bulb temperature of the air is measured by a clean, dry thermometer properly shielded against radiation.

Wet-bulb temperature of the air is indicated by a wetted thermometer bulb when evaporation from its surface occurs in an air stream moving with a velocity of at least 1,000 ft. per minute. For dry-air and water-vapour mixtures this temperature is essentially equal to that of adiabatic saturation; *i.e.*, the temperature the same air would reach if brought in contact with a large surface of water inside a well-insulated chamber through which no heat flows and inside of which no work is done.

Sensible heat is the heat absorbed by a body when its temperature is changed. Latent heat (*q.v.*) is the heat absorbed by a body when it changes its physical state without change of temperature; *e.g.*, ice melting to form water.

Psychrometers are devices for measuring dry-bulb and wet-bulb temperatures.

Dew point is the temperature at which condensation of the water vapour in the air begins. Consequently, it is the saturation temperature corresponding to the partial pressure of the water vapour.

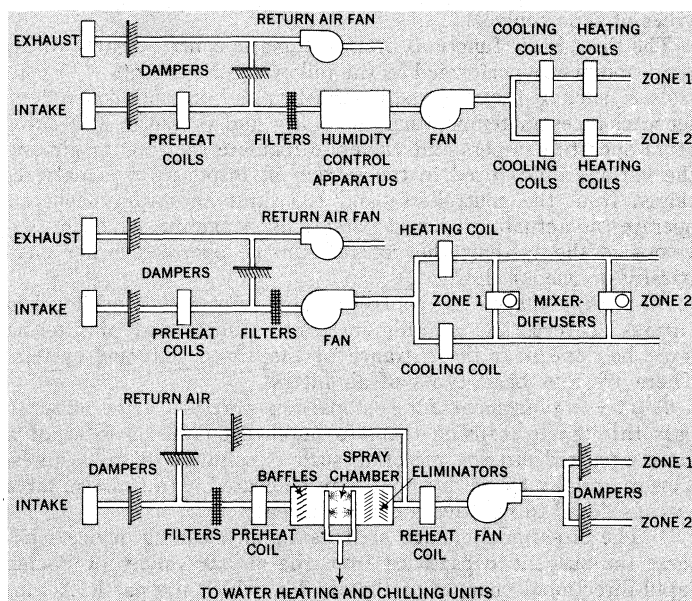

Enthalpy of a substance is its internal energy plus the product of its absolute pressure times its specific volume expressed in consistent units, usually B.T.U. per pound. In psychrometric calculations enthalpy is the measure of the energy that can be converted into heat. For dry-air and water-vapour mixtures the enthalpy per pound of dry air depends almost exclusively on the wet-bulb temperature.

Psychrometric charts present graphically the relations between the various properties of dry-air and water-vapour mixtures. They are of great help in air-conditioning calculations, providing not only a quick way of finding properties but also allowing convenient presentation and calculation of processes.

Air-Conditioning Equipment.—Air-conditioning systems may be classified in several ways. According to their purpose, they can be described as winter, summer or all-year systems. (For a discussion of winter systems, see HEATING AND VENTILATION.) Considering their basic design, they are called unit or central air conditioners.

Summer air-conditioning equipment can lower the dry-bulb temperature in several ways. In hot, dry climates, evaporative coolers are very effective and are also the most economical to install and to operate. These coolers use recirculated water to saturate adiabatically the air passing through. Such a process lowers the dry-bulb temperature and increases the humidity; it is of little effect when the outside humidity is above 40%.

In hot, humid climates air can be cooled and dehumidified by passing it through either a finned cooling coil or a spray of chilled water in an air washer. The air leaving either of these units is usually too cold and has to be passed through a reheat coil to bring it up to the desired dry-bulb temperature. The finned cooling coil can be of the direct expansion type when it serves as an evaporator of the refrigerant, or it can be cooled by chilled water that is refrigerated elsewhere. The latter arrangement has the advantage of permitting the use of the coil for heating applications if hot water is circulated through it. The self-contained cooling units are usually of the direct expansion type, which require only electrical connection to operate the compressor and fan motors if the condenser is air cooled but need both electrical and water connections if the condenser is water cooled. The air washer is essentially an all-year unit because it can provide heating, cooling, humidifying and dehumidifying by changing the temperature of the water spray. Dehumidification can also be achieved with absorption by a hygroscopic material, such as a lithium

SCHEMATIC DIAGRAMS FOR REPRESENTATIVE ALL-YEAR AIR-CONDITIONING SYSTEMS

(Top) Zone control by individual cooling and heating coils; (centre) dual-duct system controlled by mixer-diffusers; (bottom) air-washer system with individually controlled zone dampers

chloride solution, or with adsorption by such substances as silica gel or activated alumina. With these types of systems, bypass arrangements and additional means for cooling and heating the air are usually required to obtain the desired final dry-bulb temperature.

All-year air-conditioning systems must provide means for performing all the processes required for winter and summer air conditioning. The basic pieces of equipment are the filters, preheat coils, humidifiers, dehumidifiers, reheat coils, additional cooling coils (if chemical dehumidification is used), fans and controls. The figure shows typical arrangements of all-year central systems.

Special Systems.—Special designs include the so-called high-velocity, the induction and the heat-pump systems. The high-velocity systems, with air moving up to 6,000 ft. per minute, require relatively small ducts, but their operating cost is high and the noise problem is severe. Special diffusers have to be used in the rooms to reduce air velocities and thus obtain a lower noise level.

The induction-type systems combine the principles of self-contained units and central systems. Primary conditioned air is supplied to a nozzle in the induction units in the rooms, where it is mixed with secondary air drawn from the room. The principal advantages of this system are individual controls for each room, reduced power cost due to the small amount of centrally supplied air and (usually) better circulation of the air in the rooms.

The major disadvantage of this system is the difficulty of providing enough fresh air to all rooms at all times.

The heat pump system is essentially a vapour compression refrigeration cycle system (see REFRIGERATION). For cooling, the air is passed over an evaporator coil. The heat from the condenser is rejected either to the outside atmosphere or to cooling water. For heating, the air is passed over a condenser coil, while heat can be absorbed in an evaporator from the outside atmosphere, from the ground or from some other available source. Such a system requires a rather complicated layout of ducts, pipes, dampers and valves.

Control Methods.—The control of unit or induction-type air conditioners is done directly from the room in which they are located. In central air-conditioning systems control can best be achieved by dividing the total space into zones and arranging the equipment so that the condition and quantity of air supplied to each zone can be controlled individually. The figure indicates

types of zone controls.

The three basic functions of an automatic control system of air conditioning are performed by the following instruments: (1) controllers, such as thermostats, humidistats and pressure controllers, sense changes in temperature, humidity and pressure; (2) actuators operate dampers and valves to regulate the flow of air and the various fluids used in the system in response to signals received from the controllers; and (3) limit and safety controls operate the actuators when a potentially dangerous condition develops in the system; the controls can be operated either electrically or pneumatically.

Air Purification.—The control of air purity can be achieved in various degrees. As a minimum control, some sort of filtering must be done near the entrance of the air-conditioning system. There are four basic types of air filters.

1. The impingement filter stops dirt particles attempting to pass through by causing them to impinge on the surfaces of a closely packed filtering material, such as cellulose or glass fibres. This material may be dry or it may be coated with some suitable viscous liquid to improve filtering efficiency.

2. The directional-change or dynamic air-cleaning device separates the suspended particles from the air stream by producing rapid directional changes of the air flow which the particles cannot follow. A typical example is the so-called cyclone separator.

3. Possibly the most efficient (and most expensive) filtering device is the electrostatic precipitator. With this device, the particles in the air are charged by passing the flow through a strong electrostatic field, and are then precipitated on alternately placed, positively and negatively charged plates.

4. The air washer also acts as an air cleaner, but it can eliminate only contamination which can be wetted, such as ordinary dust.

Specialized air-purification problems include the removal of odours, most effectively done by activated charcoal filters, and air sterilization by ultraviolet rays or germicide sprays (see ANTI-SEPTICS).

Load Calculations.—In order to establish the size and operational requirements of an air-conditioning system, the maximum probable heating and cooling demands have to be calculated. These depend on the required conditions inside the enclosure, the expected outside design conditions and the various heat losses and heat gains occurring. The maximum probable heating demand is usually for winter air conditioning and it involves heating and humidifying. The maximum probable cooling demand is generally for summer applications and requires cooling and dehumidifying.

In calculating the various loads it is important to distinguish between sensible loads, which involve only a change in dry-bulb temperature, and latent loads, which involve only a change in humidity. The operating conditions of the air-conditioning system have to be so established that the air supplied to the enclosure will be able to satisfy the requirements of both sensible and latent loads. For example, if cooling and dehumidifying are required in the enclosure, the supply air has to be colder and drier than the inside air to such a degree that, as the supply air reaches the design conditions during its diffusion in the enclosure, it absorbs just the required amounts of sensible and latent heats.

Design Conditions.—The inside design conditions depend entirely upon the purpose for which air conditioning is used. Certain industrial process requirements and human comfort are the two major factors encountered. If the installation is for human comfort the usual inside design conditions for winter differ from those for summer. Summer air conditioning requires a closer control of humidity and higher dry-bulb temperatures (76°–80° F.) to reduce the cooling load on the equipment and lessen the temperature difference experienced by the people when they leave the air-conditioned space. The maximum outdoor-indoor temperature difference used is about 20° F.

The outside design conditions depend entirely upon the geographic location of the enclosure and should follow established local practices. If no local standards are available, the outside design dry-bulb temperature may be taken as 10 to 15 degrees above the minimum ever recorded in the winter and 5 to 15 degrees

below the maximum ever known in the summer.

Heating Load.—The heating load is generated by the following phenomena:

1. Sensible heat is conducted through the walls, ceilings and floors in proportion to the dry-bulb temperature difference between inside and outside, and also in proportion to the over-all coefficients of heat transmission and the areas of these boundaries. If proper vapour barriers are installed, no latent heat will pass through these surfaces.

2. Outside air entering by ventilation and by infiltration through window and door cracks constitutes both sensible and latent loads since it has to be both heated and humidified.

3. Any process in the enclosure which absorbs heat and/or moisture contributes to the load.

Cooling Load.—The cooling load results from the following phenomena:

1. Sensible heat is conducted through the boundaries because of the dry-bulb temperature difference. This is the same effect described under item 1 of the heating load phenomena except that the heat flows in the opposite direction.

2. Sensible heat is conducted through exterior surfaces because of absorption of solar radiation. This effect depends upon the altitude of the sun, the clearness of the atmosphere, the position of the surface with respect to the direction of the sun's rays, the thermal absorptivity and construction of the surface, and the temperature of the surroundings with which radiant heat exchange may occur. Exact calculation of the resulting heat flow is difficult due to its periodic nature and the many variables involved. The usual design method is to determine the so-called sol-air temperature on the outside and the corresponding equivalent temperature differential, which gives the actual heat flow through the surface when multiplied by the over-all coefficient of heat transmission and the area. These equivalent temperatures depend upon all the factors enumerated above. Consequently, they have to be found specifically for each application.

3. Sensible and latent heats are given off by the occupants. Representative values are given in the accompanying table.

Rates of Heat Emission from Occupants of Conditioned Spaces*

Degree of activity	Sensible heat, B.T.U./hr./person	Latent heat, B.T.U./hr./person
Seated at rest	195	155
Seated, very light work	195	205
Moderately active office work	200	250
Standing, light work; walking slowly	200	250
Sedentary work	220	330
Light bench work	220	530
Moderate dancing	245	605
Walking 3 m.p.h.; moderately heavy work	300	700
Heavy work	465	985

*Tabulated values are based upon 80° F. room dry-bulb temperature. For 78° F. room dry-bulb total heat remains same, but sensible heat values should be increased by approximately 10% and latent heat values decreased accordingly.

Source: American Society of Heating, Refrigerating, and Air-Conditioning Engineers, *Heating, Ventilating, and Air Conditioning Guide* (1960).

4. Sensible and/or latent heats are given off by lamps, motors, machinery, appliances, industrial processes, etc. To find the heat liberated in B.T.U. per hour, the electric power in watts which is converted into heat must be multiplied by 3.416. In the case of electric motors driving equipment within the air-conditioned space, the heat load can be calculated from the equation

$$\text{heat gain} = \frac{\text{horsepower rating} \times \text{load factor} \times 2,545}{\text{motor efficiency}} \quad (\text{B.T.U./hr.})$$

The load factor is the fraction of rated load actually used under normal continuous operation. Allowances must be made if only the driving motor or only the driven machinery is within the air-conditioned space.

In calculating the latent heat load the number of B.T.U. required to either condense or evaporate one pound of moisture from or into the air is taken as 1,076.

AIRCRAFT CARRIER, a naval vessel specially designed to serve as a floating base from which airplanes may take off and on which they may land.

The outstanding development in warfare during the first half of the 20th century was the rise of aviation. The airplane exercised perhaps an even more decisive effect on naval than on land warfare. At sea, air power reached its greatest effectiveness in the planes flown from aircraft carriers. In fact, by the end of World War II the carrier had succeeded the battleship as the dominant type of combatant vessel in the principal navies of the world. (See AVIATION, NAVAL.)

Evolution of the Carrier.—As early as Nov. 1910 a U.S. civilian pilot, Eugene Ely, flew a plane off a specially built platform on the deck of the cruiser "Birmingham" at Hampton Roads, Va. On Jan. 18, 1911, in San Francisco bay, Ely landed on a platform built on the quarterdeck of the cruiser "Pennsylvania," using wires attached to sandbags on the platform as primitive arresting gear, and then took off from the same ship. Lieut. T. G. Ellyson of the U.S. navy experimented with a catapult launching device in 1912 at Annapolis, Md.

The British navy had meanwhile also been experimenting with the airplane, and during World War I developed the first aircraft carrier. The first true carrier, distinguished from other aircraft ships of the time by its unobstructed flight deck, joined the Royal Navy in 1918, but the war ended before it was actually used in operations. This vessel, H.M.S. "Argus," displaced 14,000 tons and had a flight deck approximately 560 ft. long by 64 ft. wide.

Built on a merchant ship hull converted during construction, the "Argus" was one of three carriers begun in 1917. A second, the "Eagle," was built on a battleship hull originally intended for the Chilean navy, while the third, H.M.S. "Hermes," had been designed from the keel up as a carrier. With the signing of the Armistice on Nov. 11, 1918, construction of the "Eagle" and the "Hermes" was suspended until more could be learned about the requirements for carrier operations from trials with the "Argus."

Prior to the start of World War I in 1914, naval opinion had looked to seaplanes, *i.e.*, planes that could alight on and take off from the water, as the type of aircraft best suited to accompany the fleet to sea. As early as 1912 the Royal Navy converted an old cruiser, also named "Hermes," to accommodate three seaplanes. Although these planes were generally hoisted over the side for take-off from the water, there was a deck built forward from which the planes could be launched by means of dollies.

After the outbreak of hostilities, the Royal Navy converted more ships for use with seaplanes and employed them successfully in all theatres of war. The seaplane of that time, however, was no match for land planes, so it became increasingly evident that to achieve full effectiveness for aviation some means of taking land planes to sea would have to be devised. In 1916 the Royal Navy selected one of its larger vessels, the battle cruiser "Furious," on which to erect a flight deck both fore and aft with the conventional bridge structure between. Land planes flown off forward conducted successful raids against zeppelin sheds at Tonder, Den., on July 19, 1918. Landing on either deck, however, had proved impracticable as an operating procedure, although under favourable conditions it could be done. The result of these experiments was the carrier construction program of 1917 of which the "Argus" was the first product.

With the end of hostilities the United States and Japanese navies followed the British lead. The first United States carrier, a converted collier renamed the U.S.S. "Langley," joined the fleet in March 1922. The Japanese, on the other hand, chose to design a ship especially for the purpose of operating aircraft. This vessel, the "Hosyo," entered service in Dec. 1922, thus allowing the Japanese to claim that they had the first operational aircraft carrier designed as such from the keel up. The British completed the "Hermes" a few months later in 1923.

Like the "Argus," the "Langley" and the "Hosyo" were frankly experimental. Upon their decks the fundamental techniques of take-off and landing were worked out. Particularly important was the development of arresting gear that would bring an airplane to

a halt after a short run along the deck. The lack of any sort of bridge structure on these ships proved an impediment to running the ship or controlling air operations. The need was first recognized by the British who added a temporary bridge to the starboard side of the "Argus." This bridge, called the island, was soon made permanent and was adopted by all navies. Only the Japanese continued to operate a small number of flush-deck carriers and on two of their ships located the island to port rather than starboard.

Obviously, the lessons learned aboard the three experimental carriers influenced all carriers built in later years. An equally decisive influence came from the Washington naval treaty of 1922. Among the provisions of the treaty were a total carrier tonnage allowed each signatory and a limitation on the size of newly built carriers to 27,000 tons. An escape clause, however, allowed the conversion to a carrier of any ship up to 33,000 tons that might otherwise have to be scrapped under the terms of the treaty. All signatories, except Italy, took advantage of this clause to obtain large carriers quickly. The United States converted two battle cruisers, and Japan one battle cruiser and one battleship. Britain completed the "Eagle," reworked the "Furious" into a flush-deck carrier to which an island was later added, and converted two other battle cruisers, sister ships of the "Furious." France turned the battleship "Normandie" into the carrier "Béarn." British, French and some Japanese aircraft carriers differed from United States fleet carriers in having lightly armoured flight decks for added protection against aerial bombs.

Having used a large share of their total tonnage on conversions, the naval powers faced the problem of obtaining a maximum number of effective ships from the remainder. As a result, carriers built in the latter 1920s and early 1930s were under 20,000 tons and formed the basis for a class of light fleet carriers. The 27,000-ton limitation also had a lasting effect on carrier size. Except for the earlier conversions and the Japanese "Shinano," converted from a battleship hull during World War II, fleet carriers used in that conflict were all built in conformity with the 27,000-ton figure.

In addition to fleet carriers and light fleet carriers, a third class developed under the stress of conflict. No belligerent had sufficient fleet carriers to meet all its needs. The solution was found in the conversion of merchant hulls by the addition of flight decks, antiaircraft guns and basic equipment needed for air operations. The resulting ships, known as escort carriers, varied greatly in size and characteristics. Organized into task groups with screens of destroyers and destroyer escorts (mainly for antisubmarine protection), they supported troops in amphibious operations.

The development of flying techniques accompanied the development of the ships themselves. Fundamentally, the carrier was an airfield at sea with many special features imposed by size and by the medium on which it operated. To increase air speeds over the deck, the ship turned into the wind for take-off and landing. Catapults flush with the flight deck were also devised to assist in launching aircraft when wind was insufficient or the plane was overloaded. Since no more than half the deck was available for landing, the aircraft was fitted with a retractable hook which engaged one of a series of transverse wires, thus bringing it to a quick stop.

During intensive operations, planes could be rearmed and refueled on the flight deck. Rapid handling under combat conditions required large deck crews of specialists; each specialty had jerseys of a distinctive colour to indicate its function. Aircraft in need of more extensive attention could be lowered to the hangar deck. This large space contained equipment to replace engines, guns and all types of gear and do other maintenance work. Extensive repair and overhaul, however, were not usually done aboard carriers; badly damaged aircraft were returned to shore bases.

The vital nerve centres of a carrier were centred in the island, the only part of the superstructure extending above the flight deck. There the ship was controlled and operated, and there all flight operations were handled. Due to the din of dozens of motors connected with any flight operation, spoken conversation was practically impossible, and various hand signals were used by plane crews and plane handlers, although orders from the island could be given to the flight deck with a "bull horn," an electrical am-

plifier capable of magnifying the voice hundreds of times.

The actual landing of the planes aboard the carrier was under the control of one officer stationed at the after end of the flight deck. Highly experienced in the operation of carrier aircraft, he watched the approach of each plane, indicating to the pilot through a series of hand signals the proper moves to make in bringing the plane in to a landing. At any time that the landing officer judged the approach unsafe, he waved the plane off and the pilot withdrew into the landing circle of other planes to await his turn to come in for another landing.

History of Operations.— Before World War II, prevailing opinion held that the battleship would continue to dominate naval warfare. Although the increasing power of aircraft tended to enlarge the role of aviation, carriers were still believed to have a supporting rather than a principal function in naval tactics.

Doctrines for their employment stressed air defense of the battle fleet, control of the air over the enemy's fleet, and attacks on his surface units, not so much with the expectation of sinking his ships as of slowing them down so that they could be overtaken by other units and brought to a decisive engagement. Carriers were also to be used for scouting and to conduct surprise raids on enemy bases. The use of carriers in antisubmarine warfare seems not to have been extensively contemplated.

Carrier aircraft were developed with these roles and missions in mind. There were three principal types: fighters, torpedo planes and dive bombers. The dive bombers also had the additional role of scouting and reconnaissance. Because of the time required to design and produce new models of aircraft, World War II was fought with aircraft that had, at least, been on the drawing boards before hostilities began. In a word, although the concepts of carrier employment changed, both the ships and the airplanes continued to be those originally produced to meet the theories of the 1930s.

In the first phase of World War II, from the outbreak of hostilities in Europe, Sept. 1939, to the Japanese attack on Pearl Harbor, Dec. 1941, many of these theories seemed to be well-founded. At the battle of Matapan, in March 1941, the Royal Navy used its carrier aircraft to track the enemy, and hits on an Italian cruiser slowed down certain units until British surface vessels could engage them. This experience was repeated when the German battleship "Bismarck" sortied into the North Atlantic during May of the same year. Airplanes from the carriers "Victorious" and "Ark Royal" brought the "Bismarck" to a virtual standstill with aerial torpedoes and left it to be finished off by the big guns of the fleet. Raids on Italian naval bases were also effective, particularly a daring night attack against Taranto on Nov. 11, 1940, that resulted in so much damage that the Italians withdrew their heavy units to less exposed bases to the north.

Carriers played a minor role in the Norwegian campaign of early 1940, but their real test came in the Mediterranean after Italy entered the war in June of that year. Although they did useful work against the Italian fleet and in raiding bases, superior German and Italian land-based airpower forced the British to withdraw their carriers from the eastern Mediterranean. Operations, however, were continued from Gibraltar. There, the principal task was to provide air cover for Malta-bound convoys. This was dangerous and difficult work, but the carriers performed their duties well, aided by the British possession of radar and the adaptation to carrier defense of the fighter direction techniques first successfully employed in the battle of Britain.

During this period the British lost four carriers. Two were sunk by submarine torpedoes in the Mediterranean while engaged on convoy duty. A third likewise fell victim to submarine attack, this time in the Atlantic. The fourth was lost to the fire of German surface ships while ferrying a deck load of Royal Air Force fighters from Norway to Britain.

Because of the priority in aircraft production given to planes for the defense of Great Britain, the Royal Navy had on the whole inferior equipment with which to work. Its carriers, however, did remarkably well, and in the development of radar techniques it helped to prepare the way for United States success against the Japanese in the Pacific.

Japan opened the Pacific war on Dec. 7, 1941, with a devastating surprise attack on the United States base at Pearl Harbor, Hawaii. Its carrier force then turned westward to strike at Allied bases and concentrations of air power in the East Indies, Australia and Ceylon. The force was seldom sighted and never attacked.

Whatever may have been its prewar theories about the relative roles of battleships and carriers, the United States navy had no choice in the opening months of the war. Its carriers had escaped destruction by being absent from Pearl Harbor while the Japanese were rendering the battleline largely inoperative. To the three carriers already in the Pacific, two others were quickly added by transfer from the Atlantic. During the first seven months of the conflict these five ships steamed more than 180,000 mi. in their successful effort to check the Japanese offensive.

Their early operations, a series of raids against enemy positions in widely scattered areas of the central and South Pacific, while skilfully executed, failed of their principal purpose to divert the Japanese from their drive through the East Indies toward Australia. Two fleet engagements fought a month apart finally checked the Japanese offensive. In the first, the battle of the Coral sea, May 4-8, 1942, each side lost a carrier, and the Japanese turned back from an invasion of Port Moresby in New Guinea. The second occurred off Midway Island, located in the sea approaches to Hawaii, between June 6 and 8, 1942. The Japanese lost four carriers and the United States one. In neither engagement did the surface fleets sight one another; both were exclusively carrier actions.

After Midway, United States forces went over to the offensive on a limited scale, seeking to dislodge the Japanese from the southern Solomons. The Japanese reacted violently to the landing of Aug. 7, 1942, and in the confused naval fighting that followed the United States lost two additional carriers and the Japanese one. Total carrier losses for the first year in the Pacific were six of their original ten for the Japanese and four of the original eight for the United States.

With the end of the naval engagements in the Solomons both sides withdrew their remaining carriers. In the months that followed the belligerents hastened to outfit more ships, train additional aircrews and prepare to resume the conflict. In any production race the United States had great superiority, and in this instance it also excelled in applying the lessons of the conflict.

In laying its plans for the offensive, the United States navy acknowledged that the carrier would play the dominant role in future fleet engagements. It also recognized the lesson in the Japanese sweep of early 1942 from Hawaii to Ceylon. If sufficient carriers were concentrated their aircraft could overwhelm enemy air power at the point of contact and, by preventing the enemy from bringing up reinforcements, maintain control of the air in the objective area. For these purposes it organized fast carrier task forces. Each force was composed of one or more task groups made up of three or more fleet and light fleet carriers and an accompanying screen of battleships, cruisers and destroyers.

The task group had the added advantage of increasing defensive power by concentrating antiaircraft fire, providing better protection against submarines and permitting a smaller number of fighters to carry out an effective air defense than if the carriers were operated singly. The task group, however, would have been impossible without radar, which not only gave early warning of air attacks but also made possible accurate station keeping by the ships under all conditions of visibility. Finally, the technique of replenishment at sea, by which the force received fuel, munitions, supplies, replacement aircraft and fresh aircrews without return to port, allowed the carriers to remain in operation for periods up to 70 days.

With its forces organized, the United States began its great central Pacific offensive in Nov. 1943. Less than a year later, it had reached the Philippines and in two great battles had destroyed the Japanese navy as a cohesive fighting force. Beginning in early 1945, the offensive turned northward through Iwo Jima and Okinawa toward the Japanese home islands, which were first attacked in February. During the closing phases of the campaign, United States carriers were reinforced by a fast carrier task force of the British Pacific fleet.

The U.S.S. "Card," an early escort carrier, relatively small in size, built on a merchant ship hull

H.M.S. "Centaur," with sister ship, H.M.S. "Albion," in the background, British light fleet carriers with canted (oblique) decks

French aircraft carrier "Béarn," an early carrier converted from the battleship "Normandie," showing a parasol-type airplane taking off from the flight deck

H.M.S. "Eagle," 37,000-ton British fleet carrier designed after World War II to accommodate jet fighter planes

The U.S.S. "Essex," the principal type of fleet carrier used by the United States during World War II

The U.S.S. "Enterprise," the first nuclear-powered carrier, launched Sept. 24, 1960. The 83,350-ton ship had guided missiles in place of antiaircraft guns for defense

The U.S.S. "Shangri-la," an attack aircraft carrier of the Improved "Essex" class

LAUNCHING AND LANDING OPERATIONS

Fast carrier task forces formed the principal striking element of the Allied navies, overwhelming the Japanese whenever they were encountered and seizing and maintaining control of the air over wide areas of naval operations. Some idea of their size may be had from the force that attacked Tokyo during Feb 1945. It was composed of 11 fleet and 5 light fleet carriers with more than 1,200 aircraft on board and accompanied by 8 battleships, 17 cruisers and 81 destroyers. No such assemblage of naval power had ever been gathered together before.

The war in the Atlantic was quite different. The use of carriers in amphibious operations was the exception, although British and United States carriers were used to cover the North African landings of Nov. 1942 and those in southern France during Aug. 1914, and British carriers participated in the Salerno, Italy, landings of Sept. 1943. The British also achieved considerable success in laying aerial mines in Norwegian waters. Principally, however, the carriers were employed in antisubmarine operations. In this type of warfare hunter-killer groups composed of an escort carrier and a number of destroyers or destroyer escorts proved especially valuable in searching out and destroying packs of submarines that waylaid convoys in the mid-Atlantic beyond the range of land-based aircraft. Escort carriers also helped to run supplies through to the U.S.S.R. on the northern route around the North Cape to Murmansk.

The outstanding characteristic of carriers as employed in World War II was their ability to move quickly into an area, overwhelm opposing air power and maintain this control once gained. They also greatly extended the sphere of fleet action by attacking enemy naval units at great distances, sinking merchant shipping, raiding objectives for considerable distances inland and supporting troops in land operations.

They had many of the attributes of a tactical air force, which in part they were. This fact led to efforts to compare carrier-based and land-based aircraft. Exact measures of comparison, however, are difficult to establish because of the differences in manner and purpose of operation. Each has its distinctive sphere of activity, even though at times they complement one another.

Perhaps the clearest measure of the tactical effectiveness of carrier aviation is the record of the United States against the Japanese in the Pacific. From Pearl Harbor to V-J day, carrier aircraft destroyed 12,000 enemy aircraft, about 6,500 in air combat and the remainder on the ground. They accounted for 168 enemy warships, totaling more than 778,000 tons and including 11 carriers, 5 battleships, 19 cruisers and 31 destroyers. They also sank 359 merchant vessels of more than 1,390,000 tons, a total exceeded only by action of U.S. submarines.

Carrier losses to accomplish these results were not excessive. The United States had 10 carriers sunk in the Pacific and 1 in the Atlantic and lost only 451 planes in air combat. The accompanying table shows carrier losses of all belligerents.

Carrier Losses by Cause of Loss, World War II

Cause	United States	Britain	Japan	Total
Carrierair	6*	1	11†	18
Submarine	3	7	8	18
Carrier air and submarine	1	—	1	2
Naval gunfire	1	1	—	2
Carrier air and naval gunfire	—	—	1	1
Accidental	—	1	—	1
Total	11	10	21	42

*Includes one loss to Japanese carrier aircraft probably flown from a land base.

†Includes one case of U.S. carrier and U.S. army air forces planes combined.

It is noteworthy that after the task force system was introduced in 1943 neither the British nor U.S. navies lost a fleet carrier and only the C.S. lost a light fleet carrier.

Postwar Developments.— With the end of World War II in 1945, the Japanese navy ceased to exist and the United States and British navies sharply reduced their carrier fleets to a peacetime basis. Many vessels were disposed of and others laid up in reserve. Except for a few ships nearing completion, building programs were either canceled or suspended. Notable among the completions were three United States fleet carriers of the new

45,000-ton "Midway" class. The 930-ft. flight decks of these ships were armored, an innovation in United States carriers introduced because of wartime experience with light bombs and Japanese suicide planes.

Size alone, however, would not solve the problems presented by post-World War II aircraft. The new jet-propelled airplanes were not only heavier than their predecessors but also were slower to accelerate, had higher landing speeds and consumed greater quantities of fuel. From the first trials by the Royal Navy with "Vampire" jets on Dec. 4, 1945, and by the United States with "Phantoms" on July 21, 1946, it was evident that World War II fleet carriers had marginal characteristics for jet operation. Programs were immediately inaugurated to extend the usefulness of existing carriers by strengthening the flight decks to carry heavier loads, increasing the aviation fuel capacity and making other improvements.

Due to their flight characteristics, jet aircraft had to be catapulted from the deck. Their relatively short time in the air and rapid fuel consumption also made traditional landing procedures obsolete. Three British developments, widely adopted by the United States, greatly increased the effectiveness of carriers in these respects. The first, a steam-powered catapult, made possible the successful launching of any plane in production or under design. The second was the angled or canted flight deck, permitting planes to land and take off simultaneously. The third, the mirror landing system, relieved the pilot of dependence upon an officer who formerly had directed approach and landing by means of hand signals.

These innovations were back-fitted into older carriers, including the "Midway" and its sister ships. They were likewise incorporated in new carriers that appeared during the 1950s. The British resumed work on two 37,000-ton fleet carriers, construction of which had been suspended in 1945. The first of these ships, a second "Eagle," joined the fleet in 1952, while the other, named "Ark Royal" after a carrier also lost during World War II, went into service during 1955. On Oct. 1 of the same year the United States commissioned the "Forrestal," first of a new class of aircraft carriers of postwar design. This ship displaced about 60,000 tons and had a flight deck in excess of 1,000 ft.

When the communists invaded the republic of Korea on June 25, 1950, the United States fleet carrier "Valley Forge" and the British light fleet carrier "Triumph" were in the far east. Both ships were immediately ordered to join the United Nations naval forces, and they commenced operations with simultaneous strikes at the communist capital of P'yongyang on July 3, the first occasion on which carrier-launched jets entered combat. From that date forward aircraft carriers played an important role in Korea. British and United States carriers covered the amphibious landing at Inchon in Sept. 1950 and United States carriers the withdrawal of United Nations forces from Hungnam in Dec. 1950. Their principal contribution, however, was in support of general land fighting and in the campaign to keep the enemy from bringing up supplies and reinforcements.

From Oct. 1950 a United States fast carrier force operated continuously off the east coast of Korea until the conclusion of hostilities on July 27, 1953. The force was replenished at sea, and individual ships were relieved on station. On the other side of the peninsula, a United States escort carrier with marine corps pilots on board alternated with a British light fleet carrier, including the Australian ship "Sydney," in supporting ground troops and maintaining the naval blockade.

Later Trends.— Except for the Soviet Union, the principal navies continued to operate aircraft carriers. By 1960 France had three carriers, Australia two, Canada and the Netherlands one each. Argentina and Brazil were also reported to be obtaining one carrier each, and training air groups. These vessels were primarily equipped for antisubmarine warfare. The British navy had on active service three fleet carriers and three light fleet carriers, all but one fleet carrier completed after 1950. An additional light fleet carrier was under construction.

In the United States, light fleet and escort carriers, with one exception, had by 1960 ceased to engage in air operations. Four

of the escort type were still in use as aircraft transports and a number of both types were held in reserve for similar duty in an emergency. Of 24 "Essex" class fleet carriers, the basis of World War II task forces, 20 were still active early in 1960, 8 of them as attack carriers, 10 as antisubmarine carriers and 2 as amphibious assault ships. The last of these categories was a new one and involved the modification of the ship to handle helicopters and marine combat teams. The first experiments with this type of vessel were begun in 1956 on an escort carrier. In addition to the "Essex" class carriers, the United States navy had available the three "Midway" class ships completed shortly after the war. Five of the "Forrestal" class, the first truly postwar design, were also in service. A program of gradual replacement was keeping the fleet modernized.

At the same time, the aircraft carrier of the future was taking shape. On Sept. 24, 1960, the first nuclear-powered carrier, the "Enterprise," was launched. Displacing 83,350 tons, this ship had a flight deck 1,101 ft. by 252 ft., providing about 4,000 sq.ft. more operating space than aboard "Forrestal." Great size and almost unlimited cruising range without sacrifice of speed was only one of the advantages sought in the design. Ship's fuel ceased to be a problem, and the bunker space could be devoted to additional aviation fuel. Removal of the smokestacks and the elaborate system of ducts for elimination of gases increased safety, reduced chances of detection and eliminated the flying hazard of gas-induced turbulence across the deck. Named after a famous World War II carrier, the "Enterprise" possessed improved radars and all the latest equipment, including guided missiles in place of anti-aircraft guns for defense. The place of the carrier in the atomic age seemed assured.

AIRCRAFT INSTRUMENTS. There are three main classes of aircraft instruments: flight instruments, navigational instruments and power plant instruments. Flight instruments assist the pilot in maintaining the desired attitude of the craft and include the air speed indicator, rate of climb indicator, turn and bank indicator and gyro horizon. The flight instruments make blind flying possible; that is, control of the aircraft when the pilot cannot see where he is going. Navigational instruments are analogous to those of a ship with the addition of altimeters (barometric, radio and sonic) that help the pilot to fly his vehicle at the proper

Bottom row: speed brake position indicator

height above the earth or at a suitable distance above or below other aircraft. Navigational instruments include compasses (magnetic, gyro and astro), the air speed indicator, which is also a flight instrument, and various radio direction and position finding systems. (See NAVIGATION.) Power plant instruments are comparable to those used on an automobile to show fuel supply, oil pressure and engine temperature. (See also AERONAUTICS.)

Flight Instruments.—The attitude of an airplane is determined by the positions of its fore-and-aft or longitudinal axis, its thwart-ship or lateral axis and its rudder axis, relative to a horizontal plane and to an axis perpendicular to the horizontal. Attitude in relation to all three axes is shown by the horizon flight direction indicator. An attitude indicator, which forms the background of this instrument, provides a pictorial horizon reference. Horizontal and vertical bars move in response to motion of the airplane about its lateral and rudder axes. By maintaining the two bars centred the pilot keeps the airplane on the desired flight path.

Another indication of attitude is provided by the turn and bank indicator. In this instrument a gyroscope rotates on an axis normally parallel to the lateral axis of the airplane within a frame pivoted on an axis parallel to the longitudinal axis, about which it is restrained by a spring. Turning of the airplane about its rudder axis causes the gyroscope to precess, moving the frame against the force of the spring and causing a pointer to indicate the rate of turn.

The bank indicator consists of a ball in a curved glass tube. When the airplane is not turning the ball remains in the centre of the tube so long as the wings are level. If one wing drops, the ball rolls to the side with the low wing. When the airplane is turning the ball remains in the centre of the tube when the angle of bank is correct: that is, when the resultant of the force of gravity (vertical) and of the centrifugal force (in a horizontal plane) is parallel to the rudder axis of the airplane. If, in a turn, one wing is lower than it should be for a correct bank, the ball rolls to that side.

The air speed indicator provides information both for maintenance of attitude and for navigation. It is a pressure gauge in which the position of the hand indicates the difference between the dynamic pressure generated by a pitot tube (a tube with its open end pointed into the air stream) and the static pressure corresponding to the altitude at which the airplane is flying. The instrument's dial is graduated in knots for standard sea-level air.

The air speed indication is a measure of the support provided by the passage of the airplane's wings through the air. In taking off and landing, the pilot observes this instrument to maintain the air speed of the airplane above the stall speed where the flow of air over the wings is just sufficient to maintain support.

In navigation, the indicated air speed must be corrected for reduced air density to give true air speed. A true air speed indicator is a computer that correlates indicated air speed and air density to show true air speed. The true air speed must be corrected for the effect of the wind to give the airplane's speed relative to the ground.

Navigational Instruments.— The altimeter is an indicator of atmospheric pressure. Its dial is graduated in feet of height according to the following formula which relates altitude to pressure:

$$H = 221.152 (273 + T_{ms}) \log \frac{29.921}{P_h}$$

in which H is the altitude in feet, T_{ms} is the standard mean temperature in degrees Centigrade of the air from the ground to the altitude H, and P_h is the pressure at the altitude H in inches of mercury absolute. This formula assumes standard air, with a sea-level barometric pressure of 29.92 inches of mercury absolute. To determine the correct altitude when the barometric pressure is other than 29.92, the altimeter may be adjusted to indicate the actual elevation of the airport above sea level when the airplane is on the runway. At other altitudes the altimeter will show the actual height above sea level only when the temperature is standard, that is, the temperature assumed in the pressure-altitude formula. When the temperature drops below standard, the air contracts and the actual height is then less than that indicated by the altimeter.

The climb indicator (or rate of climb indicator or vertical speed indicator) is a pressure gauge with a dial graduated to show rate of climb or descent in thousands of feet per minute. It comprises a sensitive differential pressure element, one side of which is connected directly to the ambient static pressure, and the other side connected to static pressure through a constriction. Hence, the differential pressure across the element is a function of the amount the static pressure has changed in a unit of time, and the indication is in rate of change of altitude. Pilots use the climb indicator to keep on a level course and to maintain a constant rate of climb or descent.

The magnetic compass, when corrected for the effects of magnetic materials on the aircraft, gives the heading of the craft in relation to magnetic north. Mechanical compasses comprise magnets, supported on a pivot, which move to align themselves with the earth's magnetic field. Electrical compasses utilize the interaction of the earth's field with that of an electrically induced flux

field pattern.

Except at the equator, the earth's magnetic field is not horizontal, but is inclined, becoming vertical at the poles. As the compass indications are used for navigation in a horizontal plane the instrument is useful only to the extent that its indications correspond to the horizontal component of the earth's field. The magnetic element is therefore stabilized, either by making it pendulous or by associating it with a gyroscope.

The gyrosyn compass comprises a remote compass transmitter (flux valve), a directional gyro, and a compass indicator, together with the necessary servo amplifiers. The magnetic heading is sensed by the flux valve, depending on the orientation of its sensitive element to the horizontal component of the earth's magnetic field. The directional gyro provides directional stability to the compass system, with the flux valve transmitting signals to correct for any wandering of the gyro. At high latitudes, where the earth's magnetic field is unsuitable for a directional reference, the flux valve is disconnected from the system. The compass indicator also incorporates radio-actuated direction pointers.

Two factors must be allowed for in using the gyrosyn compass. First, because the earth's magnetic poles are located at some distance from the geographic poles, compass readings must be corrected for variation: the angle by which the magnetic direction differs from the geographic direction. Second, both types of compass give the heading of the aircraft. To it must be added or subtracted the angle of the drift caused by the wind to obtain the direction in which the airplane is moving relative to the ground.

Radio position finding systems, based on the transmission of signals from two or more transmitters, permit the continuous computation of position (latitude and longitude) of the aircraft.

Mach meters are used on high-speed airplanes to indicate the Mach number: the ratio of the speed of the aircraft to the speed of sound. The Mach meter is a computer, the inputs of which are air speed pressure, static pressure and temperature of the air. The permissible top speed of the airplane is stated in Mach number rather than in terms of indicated air speed as on slower airplanes.

An aid to landing is the pictorial deviation indicator that is actuated by radio signals from the ground and from the gyro direction system. This instrument pictorially presents the position of the airplane relative to the radio guidance beams and its displacement from the glide path beam. A pointer moves with aircraft

heading changes, or lateral departures from the correct path. A horizontal bar moves up or down as the airplane goes below or above the radio-beamed glide path.

The automatic pilot substitutes for the human pilot in flying the airplane. Horizontal and directional gyro sensors transmit signals to servomotors that operate the airplane's controls to maintain straight and level flight. Sophisticated versions of the automatic pilot provide controlled flight at a pre-set altitude or on a radio-monitored glide path.

Power Plant Instruments.— These instruments indicate engine speed (revolutions per minute) and, for reciprocating engines, manifold pressure, oil pressure, oil temperature, fuel pressure, cylinder-head temperature and propeller blade pitch. For jet engines, in addition to speed (usually shown as per cent of rated speed), indicators show thrust (pressure ratio) and exhaust temperature.

On large aircraft, indicators of fuel flow (in thousands of pounds per hour) to each engine, fuel quantity remaining in each tank, and of ram and static air temperatures are also provided. Other indicators show the positions of trim tabs, flaps, speed brakes and landing wheels.

I. INTRODUCTION

Lighter-than-air craft (balloons, dirigibles) need expend no power to remain aloft, but unless one is content to drift with the wind, a propulsive device is necessary. To be an effective machine for transportation it is necessary that an aircraft be able to make headway against the winds ordinarily encountered. This requirement calls for a substantial amount of power. Even the most highly developed rigid airships sometimes found themselves being carried backward by the wind in spite of their propulsion engines. Early prints show balloons with sails blowing full. This, of course,

is an artist's misconception because a balloon drifts freely with the wind and in this situation sails can only hang slack and useless. Propulsion of a balloon by human effort is possible, but the speed that can be achieved in this manner is very low indeed and thus this method of propulsion is little if any better than drifting. Drifting can be controlled to a certain extent by controlling the altitude at which the balloon flies by valving gas or throwing out ballast, thus taking advantage of the fact that the direction and velocity of the wind vary with height. (See BALLOON.)

In 1851 a Frenchman, Henri Giffard, built the first engine to power a manned aircraft. It was a steam engine which, with its boiler, weighed 350 lb. and developed only 3 h.p. Nevertheless, it made possible the first controlled flight of the air on Sept. 24, 1852, when Giffard piloted his airship from Paris to Trappes at an average speed of 6 m.p.h. (see AIRSHIP). The first internal-combustion engine was flown in 1872 when a German, Paul Haenlein, piloted an airship powered by a four-cylinder engine using coal gas as a fuel. The first use of gasoline in aircraft was in a two-cylinder engine designed by David Schwarz to propel the first rigid airship in 1897. All of these engines turned screw propellers, which were well known as devices for marine propulsion.

All of the more modern dirigible airships have been powered by reciprocating internal-combustion engines burning gasoline, diesel oil, hydrogen, or a combination of these. Blaugas is a combustible oil gas with approximately the same density as air and having the advantage of leaving the lifting power of the machine unaltered as the fuel is consumed.

Heavier-than-air craft (airplanes, helicopters), unlike their lighter-than-air counterparts, require power to remain aloft. The power requirement of an airplane ($q.v.$) is considerable. Gliders without means of propulsion can remain aloft only if they are flown in a rising current of air (see GLIDING).

In the days of the Wright brothers, the screw propeller was universally recognized as being suitable for providing the necessary thrust for aircraft propulsion. The missing element needed to complete the propulsion system was a lightweight engine to turn the propeller. The Wright brothers' attempt to find a builder for such an engine took them to Europe, but they could find no one who would undertake to build an engine which they considered sufficiently light. An engine of their own design and construction powered the first controlled flight of an airplane on Dec. 17, 1903. It was a four-cylinder gasoline engine which developed 12 h.p. and weighed 179 lb.

In the same year Charles M. Manly designed and built a noteworthy engine for the ill-fated Langley "Aerodrome." Manly's engine developed 52 h.p. for 151 lb. weight. Its weight/power ratio of 2.90 lb./h.p. was remarkably low at that time and compares not unfavorably with the weight/power ratio of modern engines of similar power. Furthermore, this engine in later tests demonstrated durability and reliability far beyond that demonstrated by any comparable contemporary power plant. In Manly's engine there were five water-cooled cylinders arranged radially around a single crank. The radial form was an excellent design choice and contributed substantially to the light weight of the machine. All large air-cooled piston engines are now built in this form.

II. AIR RESISTANCE

A body moving in still air experiences a "drag"; *i.e.*, a force opposing and tending to reduce its velocity (see AERODYNAMICS; MECHANICS, FLUID). In the case of a body with wings, such as an airplane, a portion of the drag force is the result of the lifting force on the wings ("induced drag") while the remainder is the result of fluid friction and of pressure waves in the air caused by the body's motion. In the case of a lighter-than-air machine, such as a dirigible, virtually all the drag force results from friction. On the other hand, a large part of the drag force of a vehicle that travels near or above the speed of sound may be due to wave making. For modern aircraft at cruising conditions the drag force is somewhere between one-sixth to one-fortieth of the weight. The former figure applies to supersonic machines, the latter to highly developed gliders. The modern transport machine has a drag amounting to about one twenty-fifth of its weight.

A propulsive device is required to provide a "thrust"; *i.e.*, a force on the body opposing the drag force. In order for the aircraft to fly horizontally at constant speed, the thrust force must be equal and opposite to the drag force. Additional thrust must be supplied if it is desired to accelerate or climb.

III. PROPULSION THEORY

There are a number of possible methods of applying a propulsive force to an aeronautical vehicle. Perhaps the simplest method is to pull the vehicle with a tow rope from a ground vehicle or from another air-borne vehicle. A rope tow is a standard method of launching gliders. Gliders towed by airplanes were used during World War II for the purpose of delivering troops and supplies to places without landing fields adequate for powered airplanes. Another possible method of propulsion is to make use of a force acting at a distance, such as electrical attraction, magnetic attraction or gravitation. Electrical and magnetic attractive forces are much too weak when acting at the long distances required for aerial navigation. Gravitation can be used only if the destination is at an altitude considerably lower than the origin of the flight.

The only practical means of propulsion so far devised is to take advantage of Newton's third law of motion. (Before Newton, Leonardo da Vinci enunciated a similar law specifically applied to flight: "An object offers as much resistance to the air as the air does to the object." His notes remained unpublished and unknown for nearly 300 years.) Usually this law is stated as "action and reaction are equal and opposite" (see MECHANICS). This somewhat cryptic statement may be explained as follows. It is observed in nature that forces ("pushes" or "pulls") never occur singly but always in equal and opposite pairs. Thus the existence of a force on a body requires the coexistence of an equal and opposite force. Two equal and opposite forces acting on the same body have no net effect upon its motion. The saying that a man cannot lift himself by his bootstraps is an expression of this observation.

If a pair of forces acts between two separate bodies (and if no other forces act) the bodies will be impelled to separate or come together depending upon whether the force pair is repulsive (a push) or attractive (a pull). Combining Newton's second and third laws shows that the resulting motion of the two bodies can be expressed by the statement that "the change in momentum of the two bodies is equal and opposite" and along the line of action of the force pair. Momentum is the product of mass and velocity, and because (at aeronautical velocities) the mass of any body remains constant, a force pair acting between two (otherwise free) bodies produces a change in the velocity of each. It is clear that in order to propel a body it is necessary to find something to push against. All aircraft propulsion devices except the rocket push against the air itself. If air is used as the propelling medium it must experience a change in momentum; that is, it must be accelerated toward the rear of the airplane and thus discharged rearward with increased velocity.

When an airplane is in flight, air appears to approach it at the flight speed, V . If a portion of this air is subjected to a steady rearward force it leaves the vehicle rearwardly with a velocity V_j , which is greater than V . If all particles of air are assumed to be identical, it may be shown by using Newton's second law that the propulsive force or thrust T is

$$T = \frac{m}{g_0}(V_j - V)$$

FIG. 1.—PROPULSION IN PROPELLER-DRIVEN AIRCRAFT

Rotation of the propeller results in the increase of air velocity (V) to the higher value (V_j) and produces thrust (T) in propeller shaft, which pulls the plane forward

where m is the mass of air flowing per unit time which is subjected to acceleration and g_0 is the proportionality constant (depending upon the units used) in Newton's second law:

$$g_0 \times \text{force} = \text{mass} \times \text{acceleration}$$

The agent that applies the force to the stream of air can be a propeller or a jet engine. If it is a propeller the situation can be pictured as shown in fig. 1. In this diagram the thrust, T , appears as tension in the propeller shaft.

A jet airplane produces thrust in the same way, except that in this case air is taken into an opening in the front of the engine and discharged to the rear (fig. 2).

The power, P_i , required to increase the velocity of the air from V to V_j is, if all losses incident to the process are neglected,

$$P_i = \frac{m}{2g_0}(V_j^2 - V^2)$$

while the power required to accomplish the propulsion by pulling with a rope would be

$$P_p = TV = \left[\frac{m}{g_0}(V_j - V) \right] \cdot V$$

The propulsive efficiency E , is the ratio of these two powers, or

$$E_p = \frac{P_p}{P_i} = \frac{\frac{m}{g_0}(V V_j - V^2)}{\frac{m}{2g_0}(V_j^2 - V^2)} = \frac{2}{\frac{V_j}{V} + 1}$$

The quantity E , is known as the Froude efficiency after R. E. Froude who, with W. J. M. Rankine, first advanced this theory. As stated, V_j must be larger than V for a propulsive force to exist; however, it may be seen that high efficiency can occur only if the ratio V_j/V is close to unity.

For propeller-driven airplanes that cruise at 200–400 m.p.h. V_j/V is nearly 1 and propulsive efficiency can be 80%–90%. Propellers maintain their efficiency reasonably well at the low speeds encountered during take-off. Turbojet-propelled aircraft in general have higher jet velocities and hence lower propulsive efficiency

FIG. 2.—PROPULSION IN JET AIRCRAFT

Burning gases in the combustion chamber produce the increase in air velocity (from V to V_j), yielding the thrust to propel the plane

at cruising speed and particularly at take-off. This fact accounts, in part, for the long runways required for getting turbojet-propelled airplanes into the air (see AIRPORT).

IV. PROPELLERS

The principle of the aircraft propeller is essentially similar to that of the marine propeller, which was reasonably well understood at the time of the Wright brothers. There are, however, outstanding differences in the requirements of aircraft and marine propellers which made the problem of designing and constructing an air propeller quite different from that of a marine propeller. The most important difference is the relatively low density of air. Water is about 800 times as dense as air at standard sea level conditions. For a given thrust, an air propeller must therefore be much larger in diameter than a marine propeller. It can also run at a very much higher peripheral speed. The combined effects of these differences make stresses due to centrifugal force more important, and those due to fluid pressure less important, in air propellers than in marine propellers.

1. Materials.—For early airplanes, hardwood was a suitable propeller blade material, and up to the mid-1920s wooden blades

were universally used. With the advancement of the aluminum industry came techniques for rolling and forging the relatively large sections of high-strength aluminum alloys which made it possible to construct propeller blades of this material (originally Duralumin). Aluminum-alloy blades are not affected by weather and are not eroded by water drops, as are wooden blades. Propeller blades have also been made of compressed wood, laminated plastic (Mica) and hollow steel.

2. Pitch. — The first metal propellers were made of a single piece of rolled aluminum alloy twisted and machined to form a two-bladed propeller. Later, individual blades were forged separately and assembled into a steel hub. By loosening a clamp, the propeller blade could be turned about its own longitudinal axis and clamped again at any desired position, thus changing the angle of attack of the blade relative to the air. This adjustment of pitch (the distance advanced by the propeller in one revolution) made it possible to use one hub design and one blade design for several different airplanes or even for different engines. Furthermore, hubs could be constructed for any number of blades.

The advantages of adjustable pitch pointed the way to even larger advantages which could be obtained by a pitch-changing mechanism that could be controlled in flight. The increase in speed of airplanes made a controllable-pitch mechanism even more desirable.

A propeller of fixed pitch subjected to a constant turning force will turn faster as altitude increases and air density decreases. A fixed propeller designed for high-altitude operation will turn too slowly at sea level, and if designed for sea level it will turn too fast at high altitude. The advent of supercharged engines that could maintain sea-level power up to high altitude made the controllable-pitch propeller essential.

In the early 1930s a suitable controllable-pitch propeller was perfected and was (along with propeller reduction gearing, wing flaps and retractable landing gear) one of the important reasons for the superiority of the Douglas DC-2 and DC-3 transport airplanes. The mechanism was arranged so that the propeller could operate in either of two pitch positions under the control of the pilot—a low-pitch position primarily for take-off and climb and a high-pitch position for cruise and high flight speed. The angle through which the blade was turned was about 20° .

Continuously-Variable Pitch. — In the mid-1930s the mechanism was improved to make the pitch continuously variable. The pitch setting was controlled by an engine speed governor. The pilot had merely to set the desired engine r.p.m. and the governor then controlled the propeller pitch to maintain this r.p.m. This ar-

angement made it possible to provide for greater range of control of propeller pitch without danger of overspeeding the engine. The range of pitch change for a constant-speed propeller is about 50° .

Feathering. — A further improvement was made when the "feathering" propeller was perfected in the late 1930s. This development made it possible to increase the pitch to a "feathered" position and thus stop the rotation of a damaged engine which would otherwise be rotated by the propeller acting as a windmill in flight. The drag of a windmilling engine is large. In addition, an important safety advantage was gained because damaged windmilling engines often catch fire. The total change of pitch necessary with the feathering feature is about 90° .

Reverse Pitch. — A still further increase in the amount of pitch change (to about 115°) was brought about by the incorporation of reverse pitch—an arrangement which made it possible to reverse the thrust of the propeller (without reversing the direction of rotation), which thus served as a brake. This feature, which

first appeared in the late 1940s, has also contributed greatly to the safety of air transport by making it possible to stop an airplane quickly on the ground without relying on mechanical brakes, which, on an icy runway, can be nearly useless.

Pitch-Changing Mechanisms. — With all variable-pitch propellers there is a gear mechanism to ensure equality of pitch of all blades. Some mechanisms accomplish pitch change by means of one or more hydraulic pistons, others by electric motors. Modern pitch-control mechanisms often use a combination of electric and hydraulic elements. A typical hydraulic pitch-changing mechanism is shown in fig. 3.

3. Counter-Rotating Propellers. — Experiments have been conducted with counter-rotating propellers. The counter-rotating propeller consists of two coaxial propellers, one ahead of the other, rotating in opposite directions. Mechanical complications and difficulty with vibratory stresses have so far proved a barrier to its adoption. In theory it can provide a slight improvement in efficiency over a conventional propeller.

4. Supersonic Propellers. — Because of the rotation, the speed of a propeller blade relative to the air is higher than the forward speed of the airplane. This fact may be seen from the velocity diagram of fig. 4. Thus the propeller must contend with sonic velocity and the attendant wave-making losses before the airplane itself attains sonic velocity. This is one of the major reasons why propeller-driven airplanes do not ordinarily fly at speeds much greater than 400 m.p.h. Efforts have been made to improve the efficiency of propellers at high speed, but the jet engine appears to offer an easier solution to the problem of high speed and no supersonic propeller has come into use. Some aircraft of the 1930s were not equipped with propeller reduction gearing and had propeller tip speeds approaching the velocity of sound at the take-off condition when high revolutions per minute were used. These airplanes were very noisy and it seems probable that any supersonic propeller would constitute a severe noise problem.

5. Propeller Strip Theory. — The theory of Froude is unsuited to the calculation of the performance of propellers, and another theory, the strip theory, was developed for this purpose. In this theory, the propeller blade is divided into thin transverse slices and each slice is assumed to behave like a section of a wing. In the original strip theory each section was assumed to be uninfluenced by the remainder of the propeller. The velocities and forces on a strip are shown in fig. 4. The advantages of adjustable pitch may be seen by careful study of this figure.

The engine must supply turning effort (torque) to balance the

FIG. 4.—APPLICATION OF PROPELLER STRIP THEORY

Forces and velocities involved are (in velocity diagram) Ωr , rotational velocity; V , speed of air approaching propeller; V_{rel} , speed of air relative to the section; and (in force diagram) L , lift; D , drag; F , force resulting from lift and drag; F_x , forward thrust; F_θ , tangential force

FIG. 3.—HYDRAULIC PITCH-CHANGING MECHANISM OF VARIABLE-PITCH PROPELLER

contributions of all sections to the torque sum of the quantities rF_{θ} . The resulting thrust is the sum of all the axial forces F_x .

With some modifications, the strip theory can predict the performance of propellers adequately and hence can be useful in design. A more rigorous theory, the vortex theory, is considerably more cumbersome and will not be treated here.

6. Vertical Take-Off.—A propeller offers an economical way of obtaining large thrust at low speed. It is therefore a natural choice for an airplane that can take off vertically without a preliminary run. A helicopter (*q.v.*) is, of course, such a device and the rotor of a helicopter is indeed a kind of propeller. Airplanes have been built that take off vertically by using a conventional propeller on a vertical axis and then switch to a propeller mounted on a horizontal axis for cruising flight.

V. PISTON ENGINES

1. Advantages of Gasoline Engines.—During the 40 years following the Wright brothers' first flight, the gasoline piston engine was highly developed as a power source for turning an aircraft propeller and thus completing the propulsive machinery. Although a few diesel engines were built for aircraft use (notably the Packard aircraft diesel, a nine-cylinder radial air-cooled engine, and the somewhat more successful Junkers six-cylinder opposed-piston two-stroke aircraft diesel engine), the gasoline piston engine was for 40 years virtually the only power plant used for aircraft. The success of the gasoline engine was due to a number of inherent advantages it had over other forms of power plants.

The steam engine has often been considered for aircraft. In fact, as has been noted, many of the early experiments were with steam power plants. The steam engine (see STEAM) is an external-combustion engine; that is, while it derives its energy from the combustion of fuel with the oxygen of the air, the energy thus made available must be transferred to the steam in the form of heat by means of a boiler. The surfaces of the boiler must be somewhat hotter than the water (or steam) inside in order for heat to flow. Thus, steam can be heated no hotter than the highest temperature that the material of the boiler can withstand. Although this temperature limit is slowly rising as better materials are developed, there seems little likelihood that it will ever approach the temperatures in common use in gasoline internal-combustion engines, these latter temperatures being limited only by the temperature attainable by the combustion of hydrocarbon and air (roughly 3,500° F.). In the case of the internal-combustion engine, there need be no heat-transfer device comparable to the boiler. The products of combustion are themselves used as the working fluid to push the piston and thus deliver power to the crankshaft. The walls of the cylinder and piston which contain the products of combustion are cooled by circulation of air or liquid on the outside of the cylinder so as to maintain these parts at a low temperature, and there is thus no need to limit the combustion temperature. (See INTERNAL-COMBUSTION ENGINE.)

The amount of power that may be obtained by burning fuel at a given rate (*i.e.*, the thermal efficiency) depends upon the ratio of the highest to the lowest absolute temperature of the working substance; hence there is great advantage in the high temperatures that can be used in the internal-combustion engine. Furthermore, the elimination of the boiler results in an important saving of weight, but even more important for weight saving is the elimination of the need for a condenser. Early aircraft steam engines did not use a condenser but exhausted the used steam to the atmosphere. Since the airplane must carry its water as well as its fuel this is an intolerably wasteful process. The combustion of one pound of fuel (*e.g.*, kerosene or gasoline) releases enough energy to evaporate about 18 lb. of water. A condenser to recover this water becomes essential in an aircraft steam engine—another heavy piece of equipment which is unnecessary with an internal-combustion engine. In view of these facts it is not surprising to find that even today all aircraft power plants (including jet engines and turbo-propeller engines) are of the internal-combustion type. In all these devices the products of combustion are the agents that push the piston or turn the turbine.

It does not seem possible to use the internal-combustion prin-

ciple in conjunction with an engine powered by a nuclear reaction. The necessary limitation of maximum temperature and the weight of the necessary heat-transfer device are two of the many obstacles in the way of a practical nuclear-powered airplane.

Every engine that uses atmospheric air to burn fuel is limited in power essentially by the amount of air that can be passed through the machine. The spark-ignition (gasoline) engine is the only engine that can successfully use all of the oxygen in the air for combustion. The diesel engine can burn only about 60% of the oxygen in the air. Consequently, a diesel engine is, in general, larger and heavier than a gasoline engine of the same maximum power.

The gasoline engine, then, has great advantage for aircraft, and it is not surprising to find it used for 40 years to the virtual exclusion of all other types of prime mover. During this period great progress was accomplished in making airplane engines powerful, reliable, light in weight and economical of fuel.

2. Types of Gasoline Engines.—The first 20 years of this 40-year period were occupied mostly in perfecting details of design and manufacture and in experimenting with almost every conceivable arrangement of the cylinders around the crankshaft. One of the more interesting forms, which was extensively used during World War I and subsequently abandoned, was the rotary engine. This had a radial arrangement of cylinders around a single crank similar to Manly's engine, with the difference that the cylinders were attached solidly to the propeller and the crank was fixed to the airplane frame; because of this the cylinders revolved and the crank remained stationary. This arrangement was used to eliminate the necessity for a flywheel (which proved unnecessary in any case) and to improve the cooling of the engine by the motion of the cylinders, thereby making air cooling easier. One of the early rotary engines, the Gnome Monosoupape (see Table I), had an unusual valve arrangement which necessitated controlling the engine by means of the ignition switch. When the pilot required reduced power (*e.g.*, for landing) he shut off the ignition, turning it on again at intervals in order to keep the engine running. It is not difficult to see the disadvantages of this technique, not the least of which was that it entailed releasing a quantity of unburned fuel from the exhaust. Later rotary engines did not have this objectionable feature, but as time went on it became clear that other engine forms were simpler and lighter, and the rotary form was abandoned shortly after World War I.

TABLE I.—Some Important Aircraft Piston Engines*

Approx. date first engine	Name	Horse-power	Weight, lb.	Displacement, cu. in.	Cylinder arrangement and number

*With exception of Manly, all rotary and radial engines are air-cooled; others liquid-cooled.
 †Sleeve valves.
 ‡Water injection.

Several other forms enjoyed brief popularity. The V-8 was made in sizes up to 300 h.p. immediately after World War I (both air- and water-cooled) and was moderately successful, although it vibrated badly, a fault corrected in later automobile V-8s by using a different arrangement of cranks together with counterweights on the crankshaft.

The three-cylinder radial type appeared and disappeared (it also had excessive vibration) as did the five-cylinder fan engine. Four- and six-cylinder in-line engines were used in both air- and liquid-cooled forms. Many small air-cooled, four-cylinder, in-line engines were made in the late 1920s and early 1930s for light planes. Some engines of these types are still being produced in Europe, but in the U.S. these forms have been superseded by horizontally opposed four- and six-cylinder air-cooled engines.

In later years the search for better forms (and the desire to increase power by putting more cylinders on a single crankshaft) led to the 12- and 18-cylinder and the 24-cylinder X forms. Single-row radial air-cooled engines appeared with 5, 7, 9 and 11 cylinders, two-row radials with 6, 10, 14, 18 and 22 cylinders, a four-row radial with 28 cylinders and finally a six-row radial with 42 cylinders, this latter design establishing the record for the highest number of cylinders on a single crankshaft. Horizontally opposed (flat) 12-cylinder engines were designed with the object of making an engine that could be placed within the wing, thereby eliminating unnecessary drag; however, wings became thinner faster than the engines could be developed and therefore these engines were abandoned. In addition there were engines having two crankshafts (24-cylinder H engines and a 24-cylinder double V engine).

By 1927 three very successful forms of aircraft engines had evolved: the air-cooled single-row radial engine of 7 or 9 cylinders, the double-row radial with 14 cylinders and the liquid-cooled 12-cylinder vee. All of these types were in production in Great Britain at this time, all but the two-row radials were being produced in the U.S. and some of the types were being produced in France. The gear-driven centrifugal supercharger was in production in the C.S. and the propeller reduction gear, by means of which the propeller was made to rotate at a speed lower than that of the engine crankshaft, had made its appearance in France and was spreading rapidly to England and the U.S. The original Wright brothers' airplane had a chain drive incorporating a speed reducer, but the speed of later airplanes was sufficiently great that this feature gave insufficient advantage to warrant its extra weight. Still later, with the advent of engines having a large number of cylinders and running at higher revolutions per minute, the reduction gear again became worthwhile.

The nonstop transatlantic flight of Charles A. Lindbergh in 1927 dramatized air transportation in a way not achieved by the previous nonstop flight of Sir John William Alcock and Sir Arthur Whitten Brown (1919). The U.S. navy had announced its decision to back the air-cooled radial engine and to abandon the development of liquid-cooled engines. In the United States fierce competition between the Pratt and Whitney company and the older Wright Aeronautical corporation led to a period of rapid development of the air-cooled radial engine, culminating in engines having more than 3,500 h.p.

3. Superchargers.— A supercharger is a blower that raises the pressure of the air entering the engine and thereby makes it possible to get more air into the engine in a given time and hence obtain more power. Because the density of air decreases rapidly with increasing altitude, an engine normally has less power available at higher altitudes. Also, a certain amount of power is required to overcome engine friction, primarily friction of the pistons. The net result is that for piston engines the power available goes to zero at about 53,000 ft. altitude. Below this altitude power increases approximately linearly with air density. The supercharger was originally conceived as a device to be used to increase the amount of air passing through the engine at altitude to make up for the loss in power. A small amount of power is sufficient to drive the supercharger.

A supercharger normally is geared to turn three to ten or more times crankshaft speed. The gear ratio is selected for operation at a certain altitude, but because the supercharger operates at all altitudes, it is necessary to operate the engine with the throttle partly closed below the design altitude in order to prevent damage to the engine. (The regulation of power of a gasoline engine is accomplished by a valve or "throttle." By closing this valve, the pressure in the inlet of the engine can be reduced. This in

turn reduces the quantity of air [combustible mixture] entering the engine and thus the power. It would seem that the throttle could undo the effect of the supercharger in raising the inlet pressure. Except for the power required to drive the supercharger and the increase in temperature of the entering air resulting from this expenditure of power, this assumption is indeed true.) This fact required a complete change of attitude on the part of the engine operator (the pilot). The power that an engine could produce was no longer limited to what could be obtained with the throttle fully opened but was limited by what the structure of the engine could withstand without damage or too rapid deterioration. The pilot therefore had the added responsibility of seeing that this limit was properly observed. The limit was ordinarily set by the tendency of the fuel to "knock" or detonate. When the spark ignites the gasoline-air mixture in the cylinder, normal burning takes place progressively, the flame spreading from the source by a process of conduction of heat from the flame front to ignite the adjacent mixture. During this process the pressure rises and the unburned part of the mixture is progressively compressed. If compressed too much, it burns with explosive violence. The result is a pressure wave within the gas in the cylinder which causes the audible "ping" familiar to automobile drivers and known variously as knocking, fuel-knock, spark-knock or detonation. In an aircraft engine, detonation can be very destructive, resulting in erosion of pistons, piston rings, cylinder heads or valves which can lead to catastrophic mechanical failure. The tendency to detonate increases with increased inlet pressure and temperature and therefore with supercharging.

Another limiting factor (in air-cooled engines, at least) was the tendency of the cylinder temperature to rise above a safe value when extra power was called for. Knocking, but not overheating, can be controlled by altering the fuel composition, as measured by "octane number" (see *Aircraft Fuels*, below). The advent of the supercharged engine put additional importance on fuel composition and led to a revolution in methods of producing fuel.

Although some earlier engines had blowers running at crankshaft speed and a few experimental engines had been equipped with geared superchargers, the first production engines with geared superchargers appeared (in both England and the U.S.) in 1927. The amount of supercharging of these engines was trivial, still both the principle and the mechanism were present and in a very few years the gear ratio was increased to produce significant supercharging.

Even before the 1920s, Rateau in France and General Electric in the U.S. had demonstrated in-flight superchargers driven by turbines operating on the exhaust gases, but the development of these devices was slow because of various difficult problems connected primarily with control and with the very high temperatures of the exhaust gases.

The years from 1927 on were marked by great increases in power from an engine of given size. These increases were largely due to increases in supercharging, which was found to be effective at sea level as well as at altitude. The horsepower ratings of many engines more than doubled during this period. Increase in power made it necessary to strengthen and redesign practically every part of the engine. Redesigning for the most part was based upon endurance testing, which more often than not ended in failure of one or more engine parts. These failures were studied, corrective measures taken and the tests repeated. This technique still remains the cornerstone of the development of successful aircraft engines.

4. Post-1927 Developments.— Developments of the reciprocating engine after 1927 resulted in the 18-cylinder two-row radial engine—a logical step from the 14-cylinder design—and later the somewhat more daring 28-cylinder four-row, radial, air-cooled engine. In the early 1930s the principles of aerodynamic design of a cooling system became known, and the amount of drag caused by the cooling system of an air-cooled engine was greatly reduced by the Tomnend ring, NACA cowl and pressure baffles, all these devices being used for guiding air through the cooling fins of the engine and subsequently directing it rearward. These advances also pointed the way to reductions in the drag caused by cooling of

liquid-cooled engines, but the problem here was not so severe and the improvement not so marked.

Other improvements during this period were fully lubricated valve mechanisms; greatly improved carburetors; two-speed superchargers, which allow supercharging to higher altitudes; fuel injection, which improves the metering of fuel to individual cylinders and eliminates the danger of fire in the inlet system; and water injection, used for take-off, which suppresses knocking and relieves the cooling problem, thus allowing the throttle to be opened further to obtain more power.

VI. TURBO-SUPERCHARGERS

The turbo-supercharger is of importance not only as a useful accessory to a piston engine but also because of the part it played in the development of the jet engine. In 1911 the Swiss firm of Brown-Boveri constructed and tested one of these devices, using the design of Alfred Biichi. The first aircraft turbo-supercharger was built five years later by Rateau in France. A Le Père biplane powered by a Liberty engine equipped with a turbo-supercharger of General Electric design broke the world's altitude record in 1920.

The turbo-supercharger consists of a turbine, operating on the exhaust gases from the engine (see TURBINE: GAS), which directly drives a centrifugal compressor used as a supercharger. This device is attractive for several reasons. First, it provides an easy means of varying the revolutions per minute of the supercharger and thus the pressure supplied to the engine. This is accomplished by a "waste-gate," a valve in the exhaust pipe between the engine and the turbine which, when open, allows some of the exhaust to escape without passing through the turbine. Second, because the supercharger is not connected to the engine crankshaft, full engine power is available for driving the propeller.

Originally, the turbo-supercharger was conceived as a device for providing the engine with a sea level environment when operating at altitude and thus alleviating the reduction in power which otherwise accompanies increasing altitude. To accomplish this end it was necessary that the turbine and compressor be efficient enough to provide compressed air at sea level pressure at the engine inlet, with sea level pressure also maintained at the engine exhaust and turbine inlet. In addition, an intercooler cooled by atmospheric air was used to reduce the high temperature of the supercharger discharge before the discharge entered the engine. This objective could be accomplished with only modest efficiency of turbine and compressor. The temperature of the exhaust of a gasoline aircraft engine can easily exceed 2,000° F., and the development of the turbo-supercharger required the development of turbine nozzle and blade materials that were able to withstand high temperatures. Turbo-superchargers were successfully used on several bombers (Boeing Fortress and Superfortress and Consolidated Liberator) and on the Republic Thunderbolt fighter, all of World War II.

As the design of turbines and compressors improved, it became evident that an efficient turbo-supercharger could provide sea level pressure at the engine inlet and exhaust and have some power left over which could be used to help turn the propeller. This led to the development of the turbo-compound engine, which is essentially a reciprocating engine with an integral supercharger and one or more exhaust turbines geared to the crankshaft. Engines of this type have remarkably good efficiency and high power-to-weight ratio and consequently are useful for long-range aircraft.

Before the advent of the turbojet airplane, most of the improvement in speed of transport airplanes came from flying at higher and higher altitudes, where the air resistance was less because of lower density. High-altitude flight required the successful utilization of several devices—the high pressure-ratio supercharger, the controllable-pitch propeller and the cabin supercharger. These three devices are all essential to modern piston-engine transport planes.

VII. JET ENGINES

1. Turbojets.— From 1903 to 1939 the reciprocating internal-combustion engine with propeller was the sole means used to propel

both heavier-than-air and lighter-than-air craft. On Aug. 27, 1939, the first jet-propelled airplane flew in Germany. The engine was designed by Hans von Ohain (patented by von Ohain and Max Hahn), who had conceived the idea when he was a student at the University of Gottingen. Unknown to von Ohain, Frank Whittle in England had arrived at the same concept some years earlier and was actively working on it when von Ohain's engine first flew. Whittle's engine had its first flight on May 15, 1941.

Whittle's and von Ohain's devices were both what have come to be called turbojet engines. The basic idea of this engine is simple. Air taken in from the atmosphere is compressed to 3 to 12 times its original pressure in a centrifugal or axial compressor. Sufficient fuel is added to the air and burned to raise the temperature of the fluid mixture to between 1,200° and 1,700° F. The resulting hot air is passed through a turbine whose sole function is to drive the compressor. If the turbine and compressor are highly efficient, the pressure at the turbine discharge will be nearly twice atmospheric, and this excess pressure is used in a propelling nozzle to produce a high-velocity stream of gas and hence a thrust.

The most important advantage of the jet engine is that it is extraordinarily light compared to an engine-propeller combination having similar thrust at cruising speed. This advantage makes it possible to use much more powerful engines in jet planes. In addition, the elimination of the propeller makes possible a simpler, lighter and aerodynamically cleaner (*i.e.*, more streamlined) air frame. Furthermore, the propulsive efficiency of a propeller is low at high (above 500 m.p.h.) forward speed while the propulsive efficiency of a jet is particularly good at very high speed. All these advantages taken together have made it possible to build turbojet-powered aircraft having a speed advantage over their engine-propeller counterparts of more than three to one.

In order to produce a large thrust, a turbojet engine must be capable of handling a large flow. At the same time it must not be excessively heavy or bulky. Unless the compressor, combustion chamber and turbine of a jet engine are highly efficient, the machine will be heavy and will use an excessive amount of fuel. It is also necessary for the temperature of the products of combustion entering the turbine to be high, otherwise the ratio of thrust to weight will be low.

The requirements faced by the turbojet pioneers were clear:

1. A light machine with a high capacity for air flow.
2. Highly efficient compressor, combustion chamber and turbine.
3. A turbine which could withstand high temperatures.

Centrifugal Compressor Development.— Both Whittle and von Ohain used centrifugal compressors for their first machines (see Table II). The alternate choice was an axial compressor. During those years the performance of the axial compressor was less predictable, and in the interest of rapid development the choice was undoubtedly well made. Von Ohain's machine was abandoned for an entirely new design (which used an axial compressor), but Whittle's was developed and was the direct ancestor of the Rolls-Royce Welland, Derwent, Nene and Tay engines, the General Electric 1-16 and 1-40 engines, and the Russian engine used in the MiG-15 fighter in the Korean War. The first two Rolls-Royce types were built in quantity during World War II and were used in the Gloster Meteor fighter against German V-1 rockets.

TABLE II.—Some Important Turbojet Engines

Name	Thrust, lb.	Weight, lb.	Type
Whittle W-1	850	623	Centrifugal
Junkers 004	1,980	1,630	8-stage axial
Rolls-Royce Derwent	4,000	1,250	Centrifugal
Bristol Siddeley Sapphire AS5a-7	11,000	3,050	13-stage axial
Pratt and Whitney J-57 (JT3C-6)	13,000*	4,234	2-spool 16-stage axial
Rolls-Royce Avon RA.28	10,000	2,890	15-stage axial
Pratt and Whitney J-75 (JT4A-3)	15,800	5,020	2-spool 16-stage axial
General Electric J-79	11,000	3,190	17-stage axial

*Water injection

During the 1940s a significant improvement in the performance of centrifugal compressors was accomplished. Efficiency was increased from somewhat better than 70% to over 80%. The ratio

of discharge pressure to inlet pressure was raised from less than 3 to 1 to more than 4 to 1 and the flow capacity of a given size machine has greatly increased. These improvements were made largely by empirical methods, with little guidance from theory. From the beginning it was clear that the pressure ratio of the centrifugal turbojet compressor was limited to about 5 to 1 without using two compressors in series (two "stages"), an arrangement that involved a heavy and awkward construction.

Axial Compressor Development.—In the axial compressor, air passes axially through alternate sets of rotating and stationary blades. The rotating blades are arranged to increase the tangential component of velocity of the air, while the stationary blades are arranged to remove this increase and thus prepare for similar action by the following row of rotating blades. One set of rotating blades and its accompanying set of stationary blades is called a "stage." If it has a large number of stages, the axial compressor can be made to produce a much higher pressure ratio than a centrifugal machine can produce. Furthermore, it can be made very much smaller in diameter (about one-half), a factor that is important in reducing the aerodynamic drag of externally mounted engines. Moreover, axial compressors can be made with extremely high efficiency. These obvious advantages led to the design of axial turbojet engines by Junkers and BMW in Germany and by the Royal Aeronautical establishment in England even before the first jet-powered flights. During the 1940s these engines and others, notably the General Electric TG-180, were developed. The Junkers 004 was produced in quantity late in World War II and used in the Messerschmitt 262 fighter against Allied bombers with considerable effect.

The empirical development process, with slight assistance from theory, did not succeed nearly so well in the case of the axial compressor as it had in the case of the centrifugal machine. The Junkers engine was a very effective machine for its time, but it had a very low pressure ratio (about 3 to 1). Its development was stopped with the end of World War II in Europe. It was necessary to build up theoretical and practical knowledge before it was possible to design efficient high pressure-ratio axial compressors with confidence that engines with these devices could operate satisfactorily, or indeed at all. By the early 1950s such a background of knowledge had been built up by several manufacturers. The design processes involved complex theories and the use of large electronic computers. By such processes a sufficiently good first approximation to the final design is possible, so that with a reasonable amount of experimental work and subsequent modification a satisfactory machine can be expected. The efficiency of the best axial machines was about 5% better than the best centrifugal machines throughout the period when both were under development. In the 1950s a large number of axial machines were developed in England, France, the U.S. and the U.S.S.R. It appears that the centrifugal turbojet has become obsolete for all but small engines.

The demand for increased pressure ratio led to trouble in the form of instability of flow in the machine, a phenomenon called surge. Surging can occur in centrifugal compressors but it is a much more serious problem in high pressure-ratio axial machines. This trouble ordinarily occurs at revolutions per minutes that are lower than those for which the machine is designed. Three methods of alleviating the difficulty have been devised:

1. Blow-off valves which allow some air to escape part way through the compressor.
2. Two-spool machines which consist of two separate compressors, each driven by its own turbine and thus capable of operating independently at different revolutions per minute.
3. Stator blades which can be controlled as to angle in a manner similar to the pitch-changing in a controllable-pitch propeller.

Combustion.—The combustion chamber of a turbojet engine is required to raise the entering air temperature uniformly to the desired turbine inlet temperature without imposing too great a restriction on the flow of air. This problem turned out to be considerably more difficult than at first anticipated. Theoretical analysis that could be used as a guide to its solution was practically nonexistent, and experimentation was almost the sole means of

progress. The problem was complicated by the fact that to attain the desired temperature less than one-third of the available oxygen in the air had to be burned. Further, the combustion chamber was expected to operate smoothly and efficiently over a wide range of pressures and fuel flow. Early troubles with hot spots in the combustion chamber itself causing distortion and cracking and hot spots in the turbine causing nozzle and blade failures were remedied, only to be followed by troubles with low efficiency and extinction of fire at high altitude. Although the theory of combustion is still too complex to be of much assistance, the early troubles of the combustion chamber have been satisfactorily solved for present purposes.

Two types of combustion chambers are used. In the spray type, fuel is introduced in the form of a fine spray, mixed with sufficient air for its combustion, evaporated and burned. The products of combustion are then diluted by mixing with excess air to produce the desired temperatures. The vaporizing type of combustion chamber is similar except that the fuel is introduced in a stream and evaporated by contact with a hot surface. Either type can be made to give good service and to burn efficiently up to very high altitudes. At normal operating conditions efficiency of combustion, as measured by the amount of unburned fuel discharged, can be expected to be very nearly 100%. Combustion chambers of reasonable size can be made with a pressure drop of less than 4% of the entering pressure.

Turbines.—The steam turbine industry provided much background experience which could be drawn upon by the designers of turbojets. The principal new problems were the necessity of operating at very high temperatures and of keeping the weight down. These problems were also present in the turbo-supercharger, and materials developed for this device were useful (particularly in the U.S.) for application to early turbojets. Later developments involving materials, notably vacuum melting, have helped to make modern turbine blades more reliable.

Centrifugal engines require only a single turbine stage, but the increase in pressure ratio made possible by the axial compressor requires two or more turbine stages. Some minor improvements in turbine efficiency have been made by the application of the methods of aerodynamics to turbines, but for the most part improvements have been metallurgical and mechanical rather than aerodynamic.

Bearings.—Another problem facing the designers of turbojets was that it was necessary to use large-diameter bearings running at very high revolutions per minute. These bearings were of the antifriction (ball or roller) type and in early engines gave considerable trouble. Close attention to quality control together with improved methods of feeding lubricant has successfully solved these problems.

Afterburner.—The afterburner is a device that capitalizes on the fact that less than one-third of the oxygen of the air is consumed in the turbojet engine. It is merely a second combustion chamber placed after the turbine and before the propelling nozzle. By means of this device the temperature of the gas ahead of the propelling nozzle can be increased to 3,000° F. or more. The velocity of the propelling jet is approximately proportional to the square root of the absolute temperature of the gas entering the propelling nozzle. The result of the increase in temperature is an increase of nearly 50% in thrust at take-off and much larger increases at high speed. This increase in thrust is gained at the expense of three to four times the fuel consumption without the afterburner, but it is useful for short duration requirements such as take-off and also for extreme speeds, where the increase in thrust nearly matches the increase in fuel consumption. The very loud noise accompanying afterburning has thus far restricted its use to military airplanes.

When the afterburner is ignited, the propelling nozzle must be made larger (in proportion to the square root of the gas temperature) in order to accommodate the increased volume of gas. Thus an adjustable propelling nozzle, automatically controlled, is part of every afterburning system.

Water Injection.—A somewhat more modest increase in thrust can be obtained by injecting water either before the combustion

chamber or before the compressor. The cooling effect of the water can be counteracted by burning additional fuel to bring the temperature back to the limit, and the result is about a 20% increase in thrust without the large increase in noise of an afterburner. A very large flow of water is required, and this method of operation is useful for take-off only. Some modern jet transports use water injection for this purpose.

Thrust Reversal.—The reversible propeller is highly effective in reducing the length of landing run of propeller-driven airplanes. Jet-propelled aircraft normally land much faster and need a retarding device even more than do propeller-driven airplanes. Thrust-reversing devices, which reverse the direction of the jet after landing, have been developed and are used in commercial jet transports.

2. Turboprops.—The turbo-propeller engine, called a turboprop, was another important development of the 1940s. In a certain sense it was the result of the development of the jet engine, because the same problems (high-efficiency compressor and high-temperature turbine) had to be solved before the turboprop could be successful. Although the concept of the turboprop engine is much older than that of the turbojet, the basic problems were first solved for the turbojet engine. Like the turbojet, the turboprop engine comprises a compressor, combustion chamber and turbine, but in this case nearly the full pressure drop is used to run the turbine, which therefore develops more than enough power to drive the compressor. The excess power is used to drive a propeller through reduction gearing. The turboprop is very much lighter in weight than a reciprocating engine of comparable power and is easier to construct in very large sizes (over 4,000 h.p.). Compared with a turbojet engine, the turboprop has better propulsive efficiency at flight speeds below about 500 m.p.h. It seems particularly suited for a helicopter engine, where its very light weight is an especially great advantage and where fuel consumption is not so important because the duration of flight is usually short.

In the development of the turboprop engine, two severe problems arose which had not been encountered with the turbojet. Because a turbine turns about ten times as fast as a propeller, a reduction gear is essential. No previous experience was available with light reduction gears having such large power capacity coupled with high input revolutions per minute. While no new principles were needed to make a successful reduction gear, a considerable improvement in the art of gear making was required before such a gear was successfully made. The other problem was associated with the control of the machine. Overspeeding is particularly serious in the case of a turbine engine, and special attention to both the engine control and the propeller pitch-control system is necessary in order to provide safe operation at all times. This problem needed only the intelligent application of known principles for its solution, but it required considerable development time.

TABLE 111.—Some Important Turboprop Engines

Name	Max. h.p.	h.p./lb.	Type	Application
Rolls-Royce Dart Mk 525	1,990	1.6	2-stage centrifugal	Vickers Viscount transport
Bristol Siddeley Proteus 765	4,445	1.5	12-stage axial and 1 centrifugal	Bristol Britannia transport
General Electric T-58-GE-8	1,350	4.5	10-stage axial	Helicopter engine
Pratt and Whitney T34-P-3	6,000	2.3	13-stage axial	Douglas military transport C-133
Allison 501-D13	3,750	2.1	14-stage axial	Lockheed Electra transport

Turboprop engines appeared in commercial airliners in the middle 1940s, several years before successful turbojet service was inaugurated. At least one of these transport airplanes, the Vickers Viscount (see Table 111), was notable for its quiet and vibration-free operation. This was partly due to the absence of the low-frequency exhaust noise of the reciprocating engine and partly to the smooth operation of the turbine power plant. Intelligent placement of the propeller with respect to the airplane also considerably reduced the noise and vibration.

Both the power and the efficiency of turboprop engines would be greatly improved if the turbine inlet temperature could be raised, and improvement in this direction could well result in the efficiency of the turboprop engine exceeding that of the reciprocating engine. The efficiency and power of the turboprop is also sensitive to atmospheric temperature, the highest power and efficiency being available at low temperature. For this reason the efficiency of the turboprop is best at high altitudes.

3. Pulse Jets.—The German V-1 weapon used in World War II was a pilotless airplane provided with an intermittent jet propulsion device called a pulse jet. In this device air entered at the front through a nonreturn valve and passed into a combustion chamber, where it was mixed with a suitable quantity of gasoline and ignited. Because return of the air was prevented by the valve, the resulting combustion raised the pressure in the chamber and forced the products of combustion to flow out of a nozzle at the rear. Inertia of the flowing gas in the nozzle caused the gas to continue to flow until the pressure in the combustion chamber was reduced below atmospheric pressure, at which time the non-return valve opened and allowed a new charge to enter. It was found that residual fire from one explosion would ignite the next, hence an ignition device was necessary only for the first explosion. This device was simple, cheap and effective for its intended purpose. It has never become a propulsive device for manned aircraft because of its inherently high fuel consumption and because it produces an almost intolerable noise.

4. Ram Jets.—The simplest of all aircraft propulsive devices is perhaps the ram jet. It is essentially a turbojet in which the rotating machinery has been omitted. It functions only at high airplane speed. Air entering the front of the device at flight speed is slowed to a low velocity (relative to the airplane velocity) by providing a properly shaped inlet passage. If this process is done efficiently the pressure will be raised. Fuel is added and burning takes place at the higher pressure. The hot products of combustion are re-expanded to atmospheric pressure and flow out at high velocity through a rearward-facing nozzle. Because of the higher temperature of the gas after combustion the velocity at the nozzle exit is higher than the flight speed; therefore a thrust is produced. The ram jet can be an efficient device only at very high speeds. It can produce no thrust at standstill and very little at low forward speed. It therefore needs some form of assisted take-off. Rocket-assisted ram jets are used in guided missiles (see MISSILES).

5. Turbofans.—Ducted fan, ducted propeller and turbofan are all names for a hybrid form intermediate between the turbojet and the turboprop engine. Turbofan engines can be looked upon as turbojet engines in which a portion of the energy normally used in the propelling nozzle is employed by a turbine which in turn drives an additional compressor. This additional compressor functions exactly like a propeller but only a fraction of the available power is used in the fan; a large part of the thrust is still supplied by the propelling nozzle in the jet engine. Troubles caused by the near sonic velocities are reduced by lowering the speed of the air in a diffuser ahead of the fan. The fan is very much smaller and lighter than a normal propeller and runs at turbine speed, thereby eliminating the need for reduction gears. The turbofan is somewhat more efficient than the turbojet at low speeds, and is also quieter. Compared with the turboprop it is lighter, less economical at low speed and more economical at high speed.

6. Rockets.—Rockets (*q.v.*) have been used in the propulsion of aircraft. One use of rockets is to provide additional thrust for the purpose of shortening take-off distances. Many such rockets were used in World War II. German rocket assist take-off devices of World War II used hydrogen peroxide as a fuel. Those of U.S. manufacture use solid propellants. Rockets have also been used as the primary power plant in interceptor aircraft, such as the Messerschmitt 163 used by the Germans in World War II. Experimental high-speed aircraft, such as the United States' X-1 and X-15, use rockets to achieve very high speeds and altitudes.

The advantage of a rocket is that it provides very high thrust for its weight. On the other hand, rockets use fuel at a very rapid rate (approximately 16 times as fast as a turbojet engine of the same thrust). For this reason rocket power can be used only

for a very short duration. Rocket engines used for primary aircraft power plants differ from rocket engines used for other purposes in that in aircraft it is essential to be able to turn the thrust off and on again and also extremely desirable to be able to adjust the thrust. This feature makes it necessary to use liquid propellants.

(E. S. T.)

VIII. AIRCRAFT FUELS

Until the advent of the gas turbine essentially all aircraft fuel was of the gasoline type (see GASOLINE). A few diesel engines were used but diesels never became important for aircraft propulsion. As a result of the gas turbine, development of high-power aircraft piston engines and of aviation gasoline largely ceased by about 1947.

Improvement of aviation gasoline was an essential factor in the development of the piston-engine aircraft, which reached their most advanced stages about 1950. At the end of World War II an engine of given size was producing at least four times as much power as at the end of World War I. Supercharging was a major factor in this power gain and was made possible by fuels having at least four times as much resistance to knocking as World War I fuels. Increased knock resistance permitted marked reduction in fuel consumption at the cruise condition, thereby increasing aircraft range. Increased knock resistance permits increased density of the fuel-air mixture in the cylinder at the time the spark passes. This increased density can be obtained by increase of cylinder compression ratio (as in automobiles) or by means of supercharging. The power output of a gasoline engine is closely proportional to the weight of air consumed per unit time, and supercharging may increase this by at least 200%.

1. Fuel Composition. — Data are lacking regarding the composition of aircraft fuels used prior to World War I, but they are probably straight-run motor gasolines; *i.e.*, hydrocarbons naturally occurring in crude oil and produced by simple distillation.

Gasolines, for both motor and aviation use, consist of mixtures of hydrocarbons of different types and boiling points. Motor fuels may contain thousands of different compounds with boiling points varying from about 30° to over 400° F. Aviation gasoline is much more restricted in both types of compounds and their boiling points. The types of chemical compounds in aviation gasoline are paraffins of straight and branched chain types, aromatics (the ring type compounds, of which benzene [benzol] is the simplest) and naphthenes. The compounds in aviation gasoline have boiling points ranging from about 85° to about 350° F., with the great majority boiling below 275° F. Both motor and aviation gasolines often contain antiknock agents (usually tetraethyl lead) in small concentration.

2. Fuel Development. — After World War I perhaps the most important development concerning aviation gasoline was standardization of quality so that an aircraft landing almost anywhere in the world could obtain suitable fuel. Standardization and improvement of distillation range (volatility) was also an important factor. The fuel must be sufficiently volatile so that it evaporates readily in the air taken in by the engine. The volatility, however, must not be too high, lest it cause the formation of ice in the carburetors (from atmospheric moisture) or boiling in the engine and aircraft fuel systems (vapour lock).

The increase in knock resistance has resulted from selection of gasolines, blending selected gasolines with benzol and other aromatics, and development of suitable methods for measuring and expressing knock resistance. The discoveries of tetraethyl lead and of the knock-resisting properties of the branched chain paraffins were the most important advances. The branched chain paraffins (octanes) were synthesized on a large scale during World War II.

Knock resistance is expressed in octane numbers (ON) for motor and aviation gasolines and in performance numbers (PN) for aviation gasolines of over 100ON. In World War I U.S. aviation gasoline was often only of 50 ON (largely straight chain paraffins), and the best used by the Allies was only about 75 ON. By the end of World War II grade 1151145 fuel was in use. This fuel had 115 PN under cruising conditions and 145 PN at maximum power conditions. Grade 1151145 has about four times the knock resist-

ance of 50 ON fuel at maximum power conditions and three times as much at the cruising condition. During World War II the Germans used highly leaded fuels of about grade 901130.

During World War II and subsequently the maximum power available with grade 100/130 (which preceded grade 115/145) and with grade 1151145 was insufficient. Injection of a 50–50 mixture of water and methanol (wood alcohol) into the carburetor, in addition to the fuel, enabled power to be increased by about 20%.

Four grades of aviation gasoline of uniform volatility and varying knock resistance are in use. They are grades 80187, 91/98, 100/130 and 115/145.

3. Turbine Fuels. — When the aircraft gas turbine first came into use it was believed that any liquid that would burn and that had a low enough freezing point would constitute a suitable fuel. Experience proved, however, that the combustion characteristics of aircraft turbine fuels were very important. The initial work with aircraft gas turbines was conducted mostly with kerosene (frequently known in Europe as lamp oil or paraffin oil). This is a straight-run product distilling between about 325° and about 525° F. Kerosene, as sold for use in lamps, proved to have too high a freezing point and sometimes possessed unsatisfactory combustion characteristics. Consequently, aircraft kerosene had to be modified somewhat from the lamp oil grade. Aromatics are undesirable in turbine fuels because they produce carbon deposits in the combustion system. The aromatic content of kerosene is frequently too high for satisfactory combustion. Modified kerosene has been used in the majority of the world's turbine civil transport aircraft.

The world supply of kerosene appears to be insufficient for it to be used in the pure form for military use; consequently, what is essentially a mixture of 65% gasoline and 35% kerosene, known as JP4, is widely used in military turbine-powered aircraft.

In turbine aircraft the fuel is often used to cool the engine lubricating oil. Fuel that is used for cooling purposes should not cause deposits in the cooling system. (S D. H.)

AIR DEFENSE, a term that denotes defensive measures taken against attack by aircraft or other flying objects. It consists of two types of activity—active measures to prevent or to interfere with air attacks and passive measures to reduce the effect of enemy air action. In general, active air defense includes the detection, identification, interception and destruction of attacking aircraft. It is a military responsibility carried out by a unified system of aircraft control and warning radar stations, interceptor aircraft and antiaircraft artillery. Some passive measures, such as control of air traffic, are performed jointly by military and civilian agencies. Other passive measures, including evacuation, dispersal, camouflage, provision of air-raid shelters and fire fighting, are civilian responsibilities. An effective air defense system requires close co-operation between military and civilian organizations.

AIR DEFENSE IN TWO WORLD WARS

Air defense became important in World War I when the airplane (including the German zeppelin) was introduced as a significant military weapon. (See AIR WARFARE.) As its potential became evident, particularly after the zeppelin raids on London, the necessity for air defense was realized. The first requirement for such a defense was advance warning of the enemy's approach. To provide this warning, the British had by mid-1918 devised an air-raid warning service based upon visual observation and communication by telephone augmented by airplane patrols. Attempts were also made to develop antiaircraft weapons mainly by elevating regular field artillery to fire skyward. In common with the aircraft it was designed to combat, the World War I air defense system was crude

and unreliable.

Following the war, while air power advocates struggled to gain acceptance of their weapon, all nations disarmed rapidly. Airmen could do little toward improving air defenses. Yet, for the future of air defense, by 1935 the British had made a most important development — "radio detection and ranging" or radar. By means of radar a ground operator could detect air-borne objects far beyond the range of human eyes and ears. Radar enabled a ground operator to pick up hostile aircraft on a radar scope and track them at great distances. The operators could direct (vector) interceptor planes toward the enemy aircraft while they were still miles from their targets. Radar revolutionized the art of air defense. (See RADAR: *The Development of Radar*.)

By the outbreak of war in Europe in 1939 all nations had begun the construction of air defense systems. But only Great Britain had built a radar early-warning network capable of alerting and controlling the air defense system. When World War II began, Great Britain had a network of 20 radar stations. Warning of approaching German bombers was relayed from these stations, or from ground observers, through filter centres to operations rooms which controlled interceptor planes and anti-aircraft artillery. This radar network allowed the few Royal Air Force fighter squadrons to remain on the ground until the last possible moment before taking off to intercept the bombers. Largely because of the British early-warning network and other radar developments such as GCI (ground-controlled interception), AI (air-borne interception) and IFF (identification, friend or foe), the "battle of Britain" of 1940–41 was won by a numerically inferior fighter force.

Less important, but nevertheless of some significance, were captive balloons, often with wire or netting attached. They were flown at varying heights up to several thousand feet above targets on land, and occasionally also from naval vessels. They forced enemy bombers to keep their distance and drop their bombs from a considerable height. Balloon barrages were set up in London during World War I and again on a much more extensive scale during World War II.

The British also led in the development of passive defense measures. Civil defense in Great Britain was a community business carried out on a territorial basis. Directed by various governmental agencies, some steps to cope with possible air raids had been taken before the war began. Although their efforts were unpopular, civil defense advocates succeeded in having air-raid shelters built, passive defense workers trained and an extensive organization formed. Within a few years the passive defense made possible by this foresight saved many lives. During the war the British civil defense organization, which included over 1,000,000 people, greatly reduced the effect of German bombing attacks.

The experience of the British in defense against air attack contributed to the development of air defense in other nations, friend and foe. The prewar German air defense was largely composed of anti-aircraft weapons. When the British bomber command quickly proved the weakness of this defense, Germany began construction of an air defense similar to the British system. By 1942 Germany had established an effective air defense which the Allies overcame only by jamming or confusing German electronic signals (electronic countermeasures) and by using American-developed long-range escort fighter aircraft.

Air defense in isolation-minded United States was of little importance during the 1920s and 1930s, for prospects of enemy bombing of cities in the western hemisphere seemed remote. Some attention was paid to civil defense, however, and by 1937 the United States had organized a limited civilian air-raid warning service which was later tested in several exercises. Nevertheless, the nation was virtually without air defense when World War II began in 1939.

During the next two years, while the Axis nations overran Europe, the United States made some progress in developing an air defense system. Air force observers went to Great Britain to study British air defense under actual combat conditions and an air defense command was established early in 1940 to make air defense plans. In the following year the army air forces, which

had emerged as the military agency responsible for continental air defense, undertook the construction of an early-warning network patterned after the successful British radar screen. By Dec. 7, 1941, work on the network had barely begun, but after the Japanese attack on Pearl Harbor the project was rushed to completion, a system of ground observers was expanded and a small force of pursuit aircraft was deployed. About 9; radar sets were sited—6j on the Pacific coast—but not more than 75 were ever operational at one time. Attempts were also made to strengthen the air defenses of two strategic American outposts, Alaska and the Panama Canal Zone. By early 1943 the danger of enemy air attack had passed and in the following year the continental air defense system was dismantled. Great Britain and the Axis nations, on the other hand, retained their air defense systems until the end of the war.

POSTWAR AIR DEFENSE SYSTEMS

During the early years of peace that followed the defeat of Germany and Japan, air defense seemed unnecessary. The victorious western Allies quickly demobilized and scrapped or stored most of their air defense weapons. However, by 1948 the cold war had begun and, as the split between the free world and the Communist nations widened, most governments began to rearm. With the world's two strongest powers armed with nuclear weapons of tremendous destructive power, defense against air attack assumed new importance. Nations on both sides of the "iron curtain" felt compelled to erect the most effective air defense system possible.

By the mid-1950s the free world under the leadership of the United States had made substantial progress in constructing an early-warning radar network around the periphery of the Soviet Union and its satellites. Inside the "iron curtain" another radar network was poised to alert the Communist air defense system. Into these air defense systems went a substantial part of the defense budget of each nation.

GENERAL PRINCIPLES

Basic to the U.S. air defense system, and all others, was the early-warning radar equipment. Although restricted in its ability to "see" long distances because it operated on a line-of-sight principle and did not follow the curvature of the earth, radar in the air defense system of the 1950s was able to detect aircraft at distances of nearly 250 mi. and at heights of 50,000 ft. With a network of one or more lines of radar sets, a nation could hope for enough warning of approaching bombers to alert its defenses.

Because a serious limitation of radar is its inability to detect objects at low altitudes, all air defense systems continued for some years to rely upon ground observers to augment the radar networks. Ground observer posts were placed at points in the network where gaps in radar coverage existed or where the importance of the defended area warranted additional protection. Information on aircraft spotted by ground observers was flashed immediately to filter centres for evaluation.

When unknown aircraft were detected by the early-warning radar network, the air defense system had to determine whether they were friendly or hostile. Since no reliable electronic means of identification existed, the United States adopted an elaborate system of correlating flight plans. Areas called air defense identification zones (ADIZ) were established around the nation's borders or vital areas. Each aircraft flying through an ADIZ was required to file a flight plan and to fly a prescribed course. Accurate identification depended upon correlation of data from the radar site with flight plan data from the air movements information section (AMIS) of the Civil Aeronautics Administration. Any variation of an aircraft from its prescribed course in an ADIZ called for investigation by the air defense forces.

The means for investigating unknown objects, or for acting upon any information gathered by the early-warning network, was the interceptor plane. When warning of unknown or hostile aircraft was flashed from the radar station—or filter centre if the aircraft had been spotted by ground observers—to a GCI (ground-controlled interception) station, usually called an air defense direction centre (ADDC), the air defense system was alerted. The ADC

notified the interceptor pilots standing at readiness who, when air-borne, were directed by ground controllers toward the oncoming aircraft. With the electronics equipment carried by all-weather interceptors it was possible for an interceptor pilot to complete his mission without seeing his target. When the interception had been completed, the ground controller directed the pilot back to his base.

After World War II the performance of interceptors improved greatly. The typical interceptor of the 1950s was a jet-propelled aircraft capable of flying close to the speed of sound in all kinds of weather. It was filled with radar equipment and armed with radar-controlled cannon, rockets and air-to-air guided missiles. Once air-borne, the interceptor's success largely determined the success or failure of the entire air defense system.

Backing up the interceptor force was the ground-based anti-aircraft artillery (AAA). The primary role of AAA in the air defense system of the early 1950s was point defense (defense of a specific location, such as a city) since its armament consisted primarily of conventional guns like the 120-mm. and the American-developed, radar-controlled 75-mm. Skysweeper. (See ARTILLERY.) The future of XAA in air defense depended upon the development of short-range surface-to-air guided missiles such as the U.S. Nike. AAA units, which in the U.S. military structure were assigned to the army, were under the operational control of the air defense commander. When controlled by the air defense commander, AAA was an integral part of the air defense system.

GREAT BRITAIN

The leader in air defense in World War II, Britain maintained the nucleus of its wartime system during the postwar years. The peacetime system was centred around London with the radar network facing the continent of Europe. By World War II standards, the British air defense system was satisfactory.

Beginning in 1955, however, Great Britain adopted a new defensive concept. Realizing that the best air defense system it could develop with current resources would not be effective against supersonic bombers and guided missiles, Great Britain decided to abandon gradually its conventional defenses. The anti-aircraft command was inactivated in 1955. Two years later the government announced that the fighter force would be phased out slowly. Until reliable guided missiles were developed, the safety of the British Isles would depend upon the deterrent effect of thermonuclear weapons with bomber bases protected by a limited early-warning network and a shrinking fighter force.

Long before the British decision was announced, the defense of the free world had come to depend more and more on the U.S. strategic air command (SAC). Military plans of the non-Communist nations were based largely upon the retaliatory power of thermonuclear weapons carried by SAC intercontinental bombers. Protection of bomber bases, as well as the tremendous productive capacity of the United States and Canada, made imperative a strong defense for North America.

NORTH AMERICA

To provide the greatest amount of early-warning for North American defenses, the U.S. and Canadian governments co-operated in placing three radar lines in operation across Canada. Near the Arctic circle was the Distant Early Warning (DEW) line of over 50 radar stations, completed in 1957. The DEW line was constructed and manned by the United States. Backing up the DEW line was the Mid-Canada line built and operated by Canada at about the 55th parallel. To the south was the joint Canadian-American Pinetree line, which was integrated into the permanent U.S. radar system. To fill gaps in the radar coverage afforded by these lines, small automatic radar sets were installed at appropriate sites. To extend early-warning coverage seaward, air-borne early-warning aircraft, picket ships and "Texas towers" (stationary radar platforms resembling those used for well-drilling) were in operation. All of these radar sets were tied into the combat operations centre at the headquarters of the joint command at Colorado Springs, Colo.

In addition to the extensive North American radar network,

which would alert the defensive forces of the United States and Canada, the U.S. air force provided or helped maintain radar networks in most of the world's non-Communist nations. Early-warning radar stations operated in such outposts as Greenland and Iceland as well as in western Europe, the middle east and in Japan. It was possible to foresee that someday all these radar stations might be integrated into a world-wide network that would enable all of the free world's air defenses to be alerted by any radar set.

Aiding the North American radar network were the ground observer corps (GOC) of the United States and Canada. Scattered throughout the United States were 16,000 ground observer posts manned by almost 400,000 unpaid volunteers and operating through more than 70 filter centres. After 1952 a considerable portion of the GOC was on 24-hour duty, called Operation "Sky-watch." In Nov. 1958 the U.S. air force announced that its radar network had reached a point that made continuance of the GOC unnecessary.

Method of Operation.— To make full use of information gathered by the early-warning system, an extensive organization was established in the United States under the continental air defense command (COX-AD) and the North American air defense command (NORAD). CON-AD, a joint command including army, navy and air force personnel, was created in 1954 and was augmented by Canadian units. NORAD, an integrated headquarters designed to direct the air defense of North America, came into being in May 1958 when the U.S. and Canadian governments reached formal agreement. Headquarters of both organizations were in Colorado Springs, Colo. Data on approaching aircraft were passed from the radar station of the filter centre to the air defense direction centre (ADDC), which controlled the interceptors and anti-aircraft artillery. In turn, the ADDC passed the information to an air defense control centre (ADCC). There were 16 ADCC's in the United States, each the centre of a CONAD division area. The CONAD division commander was the battle director. From his control room he directed the operations of the interceptors and AAA units in his sector and was responsible for alerting civilian defense organizations. Each XDCC was tied into a combat operations centre in one of the three CONAD regions. At the summit was the combat operations centre at CONAD headquarters.

Information concerning hostile aircraft was sent from the ADCC's to civil defense personnel through civilian-manned air defense warning centres, at least one in each state. One of three types of warning could be passed by the ADCC, or by higher headquarters: warning Yellow which meant that an attack was likely; warning Red indicating that an attack was imminent; or the "all clear" warning White. At the same time the military organizations would receive warning through the military air-raid warning service. When warning Yellow was received, civil defense authorities instituted evacuation plans or alerted civil defense workers to stand-by for instructions. Upon receipt of warning Red, expected to be from one to three hours after warning Yellow, the general public was alerted and preplanned defense measures were taken by both military and civil defense organizations.

Once defense officials had been alerted, several actions were to be taken simultaneously. A plan for the security control of air traffic, known as SCAT, was to be placed in operation. The SCAT plan provided for the temporary diversion or grounding of all civil or military aircraft not essential to the defense. When it was safe to allow air traffic to resume, the flow would be regulated on a priority basis.

In order to deny use of friendly radio or other electronics facilities for navigational purposes to the enemy, a "Plan for Control of Electromagnetic Radiation," or Conelrad, went into operation upon declaration of warning Yellow. Conelrad was designed to control commercial broadcasting stations, allowing only those essential to civil defense to operate. Nationwide tests of Conelrad yielded encouraging results.

Other passive defense measures were to be instituted by the Federal Civil Defense administration (FCDA), which also had responsibility for co-ordinating all federal agencies in natural disaster relief. Working closely with military air defense officials,

FCDX and its state counterparts had many plans and carried on an educational program designed to stimulate volunteering and arouse the interest of the general public in civil defense. Officials responsible for the nation's defense found the latter to be their greatest problem.

In the mid-1950s the passive air defense program of FCDA was based upon the principles of dispersion, evacuation and shelter. A national policy for industrial dispersion, with federal financial aid, was announced in 1951. Evacuation—the movement of the population from threatened areas—was deemed necessary because of the great destructive power of thermonuclear weapons and the large resultant fall-out area. But it posed many difficult problems and encountered much public criticism. Success of mass evacuation depended upon the amount of prior warning received from the military air defense system and the effectiveness of plan for speedy evacuation.

The Sage System.—By 1957 the U.S. air force had begun the installation of a system designed to cope with the problem of intercontinental supersonic bombers and guided missiles. By centralizing air defense functions! the semiautomatic ground environment (SAGE) system simplified air defense operations. Men continued to make the basic decisions while the SAGE machines performed the complex tasks of computation.

The SAGE system was to consist eventually of a vast interconnected network of electronic computing machines into which information was to be fed by the early-warning radar network, weather stations and Civil Aeronautics administration air traffic centres. Installed at strategic locations, SAGE computers were to store information, perform intricate calculations and present a televisionlike display of the results for use by human controllers. Based upon the data fed into it, SAGE would indicate to the controller the best solution to the air defense problem. It would monitor the air situation so that the SAGE operator would be able to follow the air battle at all times. SAGE would also transfer control of the air battle to adjoining sectors, if necessary, and would keep higher headquarters informed of the battle's progress.

The principal advantages of SAGE lay in the speed with which it could solve air defense problems and display the results. Also, the system might function as a vast air traffic control device in time of peace. On the other hand, the cost of SAGE was great. Since it depended to a great extent on civilian communications facilities, only the United States and Canada had civilian communications networks capable of supporting such a system.

Ballistic Missiles.—The advent during the 1950s of intercontinental ballistic missiles capable of carrying H-bomb warheads marked the beginning of a new era in air defense. Many observers were at first filled with a feeling of hopelessness when confronted with the task of providing a defense against such weapons. Published reports stated that ocean-spanning missiles could travel at a speed of 15,000 mi. per hour and could be guided to their targets with a fair degree of accuracy. Though the work of military and civilian scientists engaged in developing a defense against such weapons was shrouded in secrecy, it was well known that some form of defense was considered feasible. See MISSILES.

AIRDRIE, a large burgh of Lanarkshire, Scot., 11½ mi. E. of Glasgow by road. Pop. (1961) 33,620. Area 3.2 sq.mi. The Monkland canal (constructed 1761-90 and now derelict) connected Airdrie with Glasgow and the Forth and Clyde canal near Maryhill.

Airdrie, originally a farming and weaving village, became a market town after 1695; its later prosperity was due to local coal and ironstone beds and its proximity to Glasgow. Its chief industries include the manufacture of tubes, boilers, paper, electrical equipment, foodstuffs, chemicals, clothing, drugs and cigarettes.

The parish of New Monkland, in which Airdrie lies, was formed (with Old Monkland) in 1640 out of the barony of Monkland, land

granted by Malcolm IV in 1160 to the monks of Newbattle. Airdrie became a burgh of barony in 1820. It was the first (1856) town in Scotland to adopt the Free Library act.

AIREBOROUGH, an urban district (1937) in the Pudsey parliamentary division of the West Riding of Yorkshire, Eng., 8 mi. N.W. of Leeds and 7 mi. N.E. of Bradford. Pop. (1961) 27,643. Area 10.7 sq.mi., of which nearly one-third is moorland. The residential village of Rawdon contains large 16th- and 17th-century houses, a Baptist college (1859) and orchid nurseries. The textile-making town of Yeadon has an airfield, and two fine old mansions, Hawksworth hall (Elizabethan) and Low hall (1624). The district is connected with the Bronte family, Charlotte having taught for a time in Rawdon and her parents having been married in Guiseley church. Many members of the Longfellow family, ancestors of the poet, are buried in the churchyard. In Guiseley are woolen mills and factories for metal goods, baby carriages, bricks, etc. These places, with parts of Esholt and Menston, form the urban district of Aireborough.

AIR ENGINE. The practical drawbacks to employing air as the expanding substance of a heat engine are so great that its use has been very limited. Such attempts as have been made to design air engines on a large scale have been practical failures, and are now interesting only as steps in the historical development of applied thermodynamics. In the form of domestic motors, air engines had some application prior to the development of the internal-combustion engine and the extended use of electricity. The type survives in a few motors of very small power.

One of the chief practical objections to air engines is the great bulk of the working substance in relation to the amount of heat that is utilized in the working of the engine. Another is the difficulty of getting heat into the working air through the walls of the containing vessel.

Air takes up heat from such a surface with much less readiness than does water. The waste of heat in the chimney gases is accordingly greater; and further, the metallic shell is liable to be quickly burned away as a result of its contact at a high temperature with free oxygen.

STIRLING'S AIR ENGINE

The working parts shown are: (A) externally fired heating vessel; (B) working cylinder; (C) cooling pipes; (D) displacer; (E) regenerator; (F) connecting flange to another heating vessel

A form of air engine invented in 1827 by R. Stirling embodied the earliest application of what is known as the regenerative principle, namely, the principle that heat may be deposited by a substance at one stage of its action and taken up again at another stage with but little loss, and with a great resulting change in the temperature of the substance at each of the two stages in the operation. The principle later found wide application in metallurgical and other operations.

AIR FORCE ACADEMY, UNITED STATES: see MILITARY, NAVAL AND AIR ACADEMIES.

AIR FORCES. Modern air forces may be defined as military organizations that maintain, control and operate all types of aircraft and long-range missiles used for military purposes. These forces have usually taken one of three general forms: air services attached to armies; air services attached to navies; and air services enjoying an autonomous or independent status.

Early History.—It was natural that the flights of Montgolfier balloons in the 1780s should suggest military employment of balloons. A balloon school was organized in the early days of the French revolutionary wars, and the French victory at Fleurus in 1794 has been ascribed largely to the advantage of balloon reconnaissance. The unit or units that were trained to operate these air-borne objects—which obviously required special skills and, for those who went aloft, special courage—comprised the first air

force.

In land warfare, the possession of high points on the battlefield had always conferred a tactical advantage, partly for the view they gave; in war at sea the disposition and power of the enemy was usually determined first by the lookout at the masthead. Thus, aviation would have played a vital part in modern warfare even if its employment had been limited entirely to reconnaissance. However, the force of gravity which the aircraft apparently defied gave it the means: without additional armament: of propelling missiles of large size toward targets on the surface of the earth. Thus: as soon as the aircraft proved itself capable of carrying some weight besides its minimum crew of one man, and of doing so for an appreciable distance, it was seen to have important combat as well as reconnaissance potentialities.

World War I began just 11 years after the first manned flight by the Wright brothers (*q.v.*) in a heavier-than-air flying machine. In that short time the military services of the United States and all the important powers of Europe had developed organizations for the military use of aviation. Under the stimulus of their interest the airplane became in the few years before the outbreak of war in 1914 a machine capable of over 100 mi. of sustained flight and able to carry, besides its pilot, respectable amounts of weight.

The U.S. army had operated balloons for military purposes in the Civil War and had also organized in 1892 within its signal corps a balloon section that later conducted experiments with heavier-than-air flying machines. On Aug. 1, 1907, less than four years after the Wright brothers made their first successful flight, the U.S. army organized an aeronautical division, still within the signal corps. Its original personnel consisted of one officer, Capt. Charles de F. Chandler, and two enlisted men. Two years later, on Aug. 2, 1909, the army, urged on by Pres. Theodore Roosevelt, purchased its first heavier-than-air machine from the Wrights. In 1913 the aeronautical division had grown to a strength of 23 officers; 83 enlisted men and 15 flying machines. In 1914 congress gave statutory recognition to the air arm as the aviation section of the signal corps, and later as the air service, independent of the signal corps. The first U.S. aero squadron was used in the pursuit of Pancho Villa in Mexico in 1916, but its aircraft were by then obsolete and broke down in the early stages of the campaign. By that time the war in Europe was entering its third year.

Although ground forces led in the adaptation of aircraft to military purposes, the major navies of the world were not far behind. At the beginning of 1911 an aircraft had alighted upon and taken off from a special platform, with arresting gear, mounted on a ship, the U.S.S. "Pennsylvania." (See AIRCRAFT CARRIER; AVIATION: NAVAL.) Airplane designers also quickly developed a seaplane or "hydroairplane" type, with floats or buoyant hull instead of landing wheels. In the year 1912, in both the U.S. and the British navies, airplanes were being tested for launching torpedoes, and in the same year catapults were successfully tested for launching both land and sea planes. In the U.S. navy the first aircraft were bought and operated by the bureau of construction and repair (later the bureau of ships), but by an order of July 1914 the office of aeronautics was created in the division of operations.

Similar developments were meanwhile taking place abroad. In Great Britain the air battalion of the royal engineers was established in 1911. After this was converted to the royal flying corps, a naval wing was attached to it but was soon transferred to the royal naval air service. Germany, France and the other major powers of Europe proceeded along similar lines. The pattern was thus established of having in each country an air service attached to the army, and for the major naval powers, a separate and distinctive air service attached to the navy. Russia was an exception to the rule. During the civil war in 1917 all aviation was put under centralized control as adjuncts of the Red army, a policy that was to continue long after the war ended.

Being more alert to the possibility that a major war would soon occur, the European military air services quickly outdistanced their U.S. counterparts in the volume of their equipment, number of trained pilots and development of airplane types. By the time World War I began, European military aircraft were already in

advance of those of the United States, where the airplane had first taken wing. Their advantage was especially marked with respect to power plants.

Aircraft were tried out during World War I in every role they were later destined to play on a much greater scale in World War II. Used in the beginning strictly as reconnaissance vehicles, and playing in that role an important part as early as the first battle of the Marne, planes soon began to mount machine guns in order to shoot each other out of the skies. Most of the last three years of the war were marked by an intense struggle to secure supremacy in the air by having a superior type of fighter, or "pursuit" plane, preferably in greater numbers. Aircraft also began dropping bombs during the first year of the war, and the great German dirigibles, or rigid lighter-than-air craft known as zeppelins after their creator Count von Zeppelin (*q.v.*), began in their raids against England what was later to become known as strategic bombing. The British retaliated with bombing raids against the zeppelin bases, but the best weapons for attacking these behemoths of the air turned out to be the machine guns of fighter aircraft. (See also AIRPLANE; AIRSHIP; AIR WARFARE.)

In air units attached to armies of World War I, the basic unit was the squadron, a term borrowed from sea warfare where it meant a small fleet of ships. The squadron varied in size depending on the types of aircraft operated, but it might have from 20 to 50 planes. Within the squadron there were usually smaller tactical formations known as flights, but they were not separately based and maintained as the squadrons were. The squadron was about the equivalent of a battalion in the army, and the rank of squadron leader later developed by the British was equivalent to that of army major. As squadrons increased in number the group was organized as a higher echelon, and was comparable to a regiment. The British later created the rank of group captain equivalent to a colonel. A still higher echelon of organization added by the Allies in 1918 and called the wing was roughly comparable to a brigade. After World War I the group and the wing came in time to be completely interchangeable terms. The British retained the term group where the Americans favoured the designation wing. British (including the dominions) ranks above group captain equate with U.S. ranks as follows: air commodore with brigadier general (one star); air vice-marshal with major general (two stars); air marshal with lieutenant general (three stars); air chief marshal with general (four stars); and marshal of the Royal Air Force with general of the air force (five stars).

Evolution of Separate Air Forces.— Even before World War I ended, the British adopted an organizational change of far-reaching consequence, one which was to be imitated in some degree by most of the other air forces of the world. Spurred by the difficulty of supplying aircraft to two competing services in the army and the navy, the British cabinet appointed a committee under Lieut. Gen. (later Field Marshal) Jan C. Smuts to reconsider the entire question of air force organization. Stimulated also by some of the developing ideas concerning the independent mission of future air forces, the committee recommended the formation not only of a separate air ministry to take over the development and procurement of aircraft but also of a separate air force, to be formed by a merger of the royal flying corps and the royal naval air service. As a result of the appropriate act, the Royal Air Force (R.A.F.) was formed on April 1, 1918, as an independent military organization coequal with the army and the navy. It was this organization for which the distinct designations of rank mentioned above were later developed.

This change was later found to be excessively ambitious. Over the next 20 years both the older services tried to regain their own air arms on the grounds of tactical need, and the Royal Navy finally succeeded in demonstrating that its special needs in both aircraft and crew training simply could not be taken care of by an independent organization. A fleet air arm manned by naval personnel was formed and attached to the navy, but supply of aircraft to the navy remained a responsibility of the air force. It later became clear that the R.A.F. was not keenly interested in developing aircraft for fleet carriers. Over the years, the planes of the Royal Navy became conspicuously inferior to the naval aircraft of

the U.S. navy.

For some years the British example in the creation of an independent air force was not followed by any other nation, other than the British dominions, especially Canada and Australia, which formed the R.C.A.F. and the R.A.A.F. respectively. The next to follow suit were the Italians, who, clearly stimulated by the writings of their own great theorist of air warfare Brig. Gen. Giulio Douhet, created the Regia Aeronautica in 1923. The French followed their example in 1923, with the creation of an air ministry (later organized as L'Armée de l'air), and the Germans, in violation of the restrictions of the 1918 peace treaty, created the *Luftwaffe* in 1936. By the start of World War II, the great nations which had not followed suit were the United States, Japan and the Soviet Union. The United States was not to do so until, the end of World War II, though, in the Army Reorganization act of 1920, the Air Corps act of 1926 and the war department action creating the general headquarters air force in 1935, it had given increasing recognition to the air force within the army.

The significance of organizational separateness can easily be exaggerated. Although the German, French and Italian air forces entered World War II as independent organizations, they were in fact oriented toward tactical use in close collaboration with their armies. The *Luftwaffe* had to adjust itself to the needs of the German army; it did not have enough additional strength to engage in large-scale independent air operations.

What was true of the German air force was even more true of the French and Italian, both of which had been allowed to decay in the interwar years. On the other hand, the U.S. army air forces were later to fight in World War II with about as much independence of control as the R.A.F. By war department Circular 59 of March 2 (effective March 9), 1942, the army air forces were made one of the autonomous and co-ordinate commands under the army chief of staff, the others being the army ground forces and the services of supply (later army service forces). Thus the air arm was given equal status with the ground forces: if not with the army itself. Its nominal status under the army did not prevent it from putting its major effort into strategic bombing, the independent mission that air power theorists have always stressed. Its autonomous status within the army was stressed by the fact that its leader during World War II, Gen. Henry H. Arnold, not only ranked immediately under the army chief of staff, Gen. George C. Marshall! but also enjoyed a position with him on the joint chiefs of staff (*q.v.*).

Interwar Years.—Although the organizational controversies described above were keenly fought within the armed services, they had on the whole little to do with developments in military aviation during the interwar period. The decade of the 1920s was the period of the naval limitation conferences and treaties, which reflected on all sides the effort to cut back armaments, both for the sake of enhancing the prospects of peace and for economy. An incidental result of the Washington naval limitation treaty of 1922, however, was that two large and fast ships then being built in the United States as battle cruisers were converted to aircraft carriers, the "Lexington" and the "Saratoga." In all other respects, military aviation languished.

The tremendous development in aircraft types that had characterized the four years of World War I was thus followed by a period in which neither military nor commercial orders were great enough to encourage much technological progress. The Liberty engine, the famous 400-h.p. water-cooled engine which had been the major American contribution to the contest for superior performance in aircraft, had been built in such huge numbers in the last year of the war that surplus engines mere powering U.S. airmail planes for 12 to 14 years after the war. However, slow development progress continued in the field of air-cooled engines, and the Schneider trophy races each year provided some stimulus to the various nations to develop fast aircraft that were to become the prototypes of World War II fighters. The U.S. air force, inspired by the Douhet philosophy, pushed as far as its resources permitted the development of a long-range bomber for the much-sought-after independent mission.

The decade of the 1930s brought a great acceleration of develop-

ment. The biplanes with fabric-covered wings of World War I gave way during the late 1920s and early 1930s to the modern all-metal monoplane. The rise of Hitler to power in Germany in 1933 brought new fears of war and thus increased interest in military aviation, while the feats of Charles A. Lindbergh (*q.v.*) and others had stimulated interest also in civil aviation. It is more true in the case of aircraft than in most other kinds of equipment that military and civilian development reinforce each other, but because of the far greater investment by the military organizations of the world most aircraft and engine development has come in response to military rather than commercial needs.

During the decade of the 1930s the air force of each major power concentrated on its own specific needs. The German air force was almost as much imbued with the ideas of Douhet as any other, but Germany was a land power and had to think first of the requirements of its army. Thus, most of its effort was concentrated on building small, relatively slow bombers for close support of ground troops. The British, starting late in the race, had to concentrate on building fighters for air defense, but they also developed long-range bombers for strategic bombing. The United States put most of its development effort into the long-range bomber. The French and Italian air arms were simply stagnating, while the Soviet and Japanese aviation services, like the German, were concentrating on the needs of their ground troops and, in the case of the Japanese, of their navy as well.

World War II.—World War II was the first war in history in which air forces played dominant roles in some of the most important campaigns. The four important parts into which air operations divided were: (1) tactical air operations in support of ground troops; (2) naval air operations; (3) strategic bombing, with related defense operations; and (4) military transport and supply. As already suggested, the apparent organizational structure of the various national services had little to do with the efficiency of the several tasks they pursued. The first spectacular demonstrations of modern military air power were by the Germans in the brief Polish campaign of Sept. 1939 and in the campaign in the following spring that ended with the fall of France. In these campaigns the contribution of the German air force, nominally independent, was mostly the close support of ground troops during which groups of aircraft functioned as mobile artillery in response to requests by the ground forces. After the fall of France the *Luftwaffe* tried, in what was supposed to be a precursor of a projected German amphibious operation given the code name "Sea Lion," a strategic bombing campaign against the United Kingdom, but it proved lacking in the appropriate aircraft. The British, aided by their search radar, which comprised one of the great technological surprises of the war, turned their few but efficient fighters of the Hurricane and Spitfire types against the small, slow, inadequately armed German bombers and cut them down by scores. The Germans had to shift to night bombing with its much lesser accuracy, where their inadequate numbers made it impossible for them to accomplish anything strategically noteworthy.

The Royal Air Force was divided operationally into several commands according to function, the most important being bomber command, mostly concerned with strategic bombing; fighter command, concerned mostly with defense against enemy bombers and with army support; and coastal command, which collaborated closely with the Royal Navy in over-water operations by land-based aircraft, especially against enemy submarines. The Royal Navy operated the fleet air arm, comprised almost entirely of carrier-borne air units.

In the United States the navy carried out, without using an autonomous organization (the bureau of aeronautics being strictly a supply organization), all the functions that in Britain were conducted by coastal command and the fleet air arm. There was one interesting difference between the United States and the British navies: in the former an aircraft carrier could be commanded only by an officer who was or had been a naval aviator; in the Royal Navy he did not need to have such experience. In the latter navy the functions of ship officer and aircraft pilot were thus kept more distinct.

The enormous proportions to which the U.S. army air forces ex-

panded in World War II is best reflected in numbers of aircraft absorbed. Of the nearly 300,000 military aircraft built by the United States during the war for army, navy and Allies, the army air forces accepted delivery of about 159,000. Of this number, over 51,000 were bombers and 47,000 mere fighters. The peak inventory in aircraft was about 80,000 planes in July 1944. To handle these aircraft the army air forces expanded in March 1945 to 243 tactical groups, of which 224 were then overseas. The largest units were the numbered air forces, including the 20th air force which led the bombing of Japan with B-29s. The next unit under the air force was the command. The army air forces reached their peak personnel strength in March 1944 with over 2,411,000 officers and men, or about 31% of the entire strength of the U.S. army. The organization governing its operation for the latter part of the war was that determined by the war department circular of March 1942, described earlier.

The Japanese air forces were sharply divided between army and navy contingents, with the latter playing the more important role in most stages of the war. It was Japanese naval aviation, for example, that struck such a devastating blow at Pearl Harbor. The Soviet air force, on the other hand, remained an adjunct of the army. The overwhelming proportion of its combat missions were of the close-support type. Even the long-range force formed in April 1942, under Maj. Gen. (later Chief Air Marshal) A. Golovanov, the *Aviatsiia Dalnego Deistvia* (A.D.D.), devoted most of its missions to long-range tactical uses, such as interdiction of enemy supply lines and attacks on air fields. At the time of its formation the A.D.D. possessed under 1,000 aircraft, none of them large. During the last two years of the war some raids, rarely of more than 100 to 150 planes, were made on Königsberg, Danzig, Tilsit (now Sovetsk), Berlin, Bucharest, Budapest, Warsaw, Stettin and Constanta. More important functions of the A.D.D. included supplying partisan groups in distant areas, particularly those under Tito in Yugoslavia.

Post-World War II Air Forces.—With the end of World War II only three nations had appreciable air power: the United States, the Soviet Union and, falling increasingly behind in the ensuing race, the United Kingdom. The only important organizational change during this period was the change in status of the U.S. army air forces from an autonomous organization to a fully independent one. An act of congress dated July 26, 1947, created the department of the air force and within it was the U.S. air force. The chief of staff of the USAF at that time, Gen. Carl Spaatz, became one of the three joint chiefs of staff at the top of the U.S. military structure. The first secretary of the air force (under the secretary of defense, who became the only cabinet member representing the military establishment) was Stuart Symington. The creation of the strategic air command, tactical air command and the air defense command on March 21, 1946, had provided the fundamental framework for a lasting organization of the air force. The remainder of the framework consisted of five supporting commands in the United States and five overseas commands. Foremost among the latter were the U.S. air forces in Europe and the far east air forces. Important new commands added after 1947 were the air research and development command, the continental air command and the joint military air transport service. The Air Force Organization act of 1951 established by law the organization which the air force had already achieved. At the Key West, Fla., conference in March 1948, the services had already agreed that the air force should have control of the strategic bombing mission and also the responsibility for providing close combat and logistical air support to the army.

Although the Soviet army and navy have been represented sometimes by separate and sometimes by combined ministries, the air forces have never had their own ministry. On the other hand, the Soviet organization is distinctive in that all air forces, including naval, are for administrative purposes under one marshal of aviation, who has the status of a first deputy minister of defense. However, this officer has direct operational control only of the important tactical or "army" air force, termed frontal aviation of the air forces, which has the largest number of aircraft of any air command. The other operational commands, headed by "deputies"

to the senior air officer, are the long-range air force, the fighter aviation of the air defense forces, the aviation of the air-borne troops and naval aviation. It must be supposed that inasmuch as the Soviet Union has no aircraft carriers, its "naval aviation" must be comparable to coastal command of the R.A.F., and thus it is not so anomalous to have it largely autonomous from the navy.

The Korean war, which broke out in June 1950, was the first modern limited war fought on a fairly large scale; i.e., the first modern military campaign of appreciable magnitude in which at least one side withheld from action its strategic bombardment strength with nuclear bombs. In this war the United Nations air forces were mostly British and American naval aviation operating from carriers, and tactical contingents of the USAF. Their contribution in close support was certainly crucial in keeping the initially outnumbered UN forces from defeat and, inasmuch as air superiority over the battlefield was never lost, in providing for later victories. A traditional distinction in combat philosophy between the USAF and U.S. naval and marine aviation was later reflected in their conduct. The naval contingents were eager to give the ground forces the kind of support the latter requested, which was mostly close support, while the USAF greatly preferred to engage in so-called "interdiction" operations, which involved a cutting of communications far behind enemy lines. For several months the USAF and the naval air forces co-operated in Operation "Strangle," intended to cut off supplies from the enemy front lines, but that campaign was later generally conceded, because of the peculiar nature of the war, to have failed in achieving its objective.

The two great developments that affected air forces in the post-World War II period were the tremendous development of nuclear weapons and the almost equally spectacular development of long-range guided missiles.

The nuclear weapons had in the first instance the effect of greatly increasing the relative importance of the strategic bombing forces because they quelled any doubts about the efficacy of strategic bombing. After the appearance of thermonuclear weapons in 1952, however, the trend started in the other direction. It was observed that strategic bombing with such weapons might be too effective to be borne, so long as there was any chance that the enemy would strike back in kind. Thus, an interest developed in attempting to keep wars limited, with nuclear weapons either ruled out or kept to very small sizes. In such limited wars, aircraft would very likely again serve in a role ancillary to the ground forces.

Despite the considerable development of jet-powered aircraft of all combatant types during the post-World War II period, a development that greatly increased the cost of individual units, the coming of ballistic missiles threatened to diminish the role of aircraft even within the air forces. For the first time it appeared that the air forces would be operating vehicles that were not piloted by human beings with specialized flying training, such as had given the air forces their major distinctiveness. In 1956 the secretary of defense decided that the USAF should be responsible for intermediate and long-range missiles, limiting the army to missiles of less than 200 mi. range.

On both the offensive and defensive side of operations the ground-to-air missile supplanted manned aircraft as the chief instrument for shooting down enemy bombers. The high speeds and altitudes of modern jet bombers gave the manned interceptor too little opportunity to maneuver into a good firing position; the fact that interceptors at the end of the 1950s cost something like \$1,000,000 each helped to make them a relatively poor buy as compared with defense missiles. Against enemy long-range missiles, the fighter-interceptor obviously had no value whatever.

The continental air defense command (CONAD) set up in 1954 became in 1958 the North American air defense command (NORAD), embracing the air forces air defense command and the army anti-aircraft command as major units, with comparable contributions from Canada. The post of commander was given to a USAF officer. It became increasingly clear, however, that the special and difficult skills long associated with the aircraft pilot would soon be of little relevance to the entire operation. (See AIR DE-

FENSE).

It is important to note that ground-to-ground missiles of shorter range, when placed in the hands of the ground forces, freed the latter in some measure from dependence on the air forces for tactical support. This problem of dependence had never been satisfactorily solved, since the distinctive indoctrination of the airman was such as to put him somewhat out of sympathy with the requirements of the ground forces. When his own budget was threatened, he was naturally more concerned with preserving units that contributed to his independent mission than those most adaptable to army support.

Aircraft were still of great military value because of their ability to carry out armed reconnaissance—the pursuit of targets whose exact location is not well enough known to make them available for missiles—and also because of their greater bombing accuracy and greater load-carrying characteristics. Military planners assumed that planes would remain a military necessity for a considerable period in the future. They were looked upon as being especially necessary for limited wars, in which nuclear weapons were proscribed or were kept to small dimensions, and for the transport of ground troops. With this in mind the United States in 1961 combined tactical air command and strategic army corps forces into a single command headed by an army general.

AIRGLOW is the faint luminescence of the earth's upper atmosphere. Unlike the aurora, airglow does not exhibit structures such as arcs, and is emitted from the entire sky at all latitudes and at all times. The nocturnal phenomenon is called nightglow. Dayglow and twilightglow, or twilight airglow, are analogous terms. Little is known about dayglow, as it cannot be studied from the ground because of the solar radiation scattered by the lower atmosphere.

Nightglow is very feeble in the visible region of the spectrum, the illumination it gives to a horizontal surface at the ground being only about the same as that from a candle at a height of 300 ft. It is possibly about 1,000 times stronger in the infrared region. Considerable variations of intensity occur. The spectrum of nightglow contains the following features: the forbidden green line and the forbidden red lines of atomic oxygen at 5,577Å; 6,300Å and 6,364Å; the pair of yellow lines of atomic sodium at 5,890Å and 5,896Å; the Meinel band system of hydroxyl (OH) in the visible and infrared regions; the Herzberg band system of oxygen (O₂) in the ultraviolet region and a single member of the atmospheric band system of the same molecule in the infrared; and, finally, a continuum beginning just below 4,000Å and extending indefinitely toward longer wave lengths. From the rocket and other research completed up to the end of 1959 it appeared probable that the altitude of the source of the red oxygen lines was very great, perhaps about 150 mi., and that the altitudes of the sources of the other spectral features were within 10 mi. of 50 mi. Nightglow represents the release of solar energy which has been stored in the upper atmosphere. It is thought that the red oxygen lines are emitted as a result of recombination between oppositely charged particles in the F layer of the ionosphere, and that the other spectral features are emitted as a result of a variety of chemical reactions.

Twilightglow differs from nightglow mainly in that the red oxygen lines and the yellow sodium lines are much enhanced. In the case of the latter the mechanism responsible has been identi-

fied: it is simply resonance scattering of solar radiation by free sodium atoms. Each sodium atom in the illuminated portion of the atmosphere acts, in effect, as a tiny mirror reflecting the characteristic yellow light. See also ATMOSPHERE: *The Terrestrial Atmosphere*. (D. R. B.)

AIR GUNS, weapons in which the force employed to propel the bullet, shot charge or dart is derived from compressed air, liquid carbon dioxide, or an ignitable fuel combined with compressed air. They are developments of the basic principle employed in the primitive blowgun (*q.v.*). Air guns are often called gas guns, spring-operated guns or BB guns. Most are relatively inexpensive and are usually thought of as children's toys, but many are used for target shooting or training in marksmanship. Although the term air rifle is loosely applied to all toy shoulder arms that use compressed air as a propellant, the term applies in strict accuracy only to weapons with rifled bores. Other varieties are air pistols, which are small enough to be held and fired with one hand, and air shotguns, which are shoulder weapons that shoot a quantity of small pellets at each firing. Total annual sales of air weapons throughout the world run into the millions.

The common forms of air gun are charged by compressing a spiral spring, one end of which actuates a piston working in a cylinder. When released by a pull on the trigger, the spring expands and compresses air which forces out the projectile. More complex air guns incorporate a reservoir of compressed air permitting one or several discharges. Gas guns utilize liquid carbon dioxide in a reservoir attached to or within the guns. A pull of the trigger opens a valve allowing a portion of the carbon dioxide to escape as a gas and propel the projectile from the barrel. Combination air and ignitable fuel guns utilize highly volatile gases pumped into the compression chamber where they form an ignitable mixture with air which is exploded by compression.

Elastic-operated guns utilizing the springiness of synthetic or natural rubber bands to propel a projectile may be considered in the spring-gun category. The projectile is ejected from a sliding carrier rather than through a barrel.

For historical background and detailed data on types and systems of operation see W. H. B. Smith, *Gas, Air and Spring Guns of the World* (1957). (M. D. W.; X.)

AIR LAW, the law governing use of the airspace and occurrences therein. Although radio waves, projectiles and other objects may traverse the airspace, air law has usually been related to aircraft, including operation thereof in the airspace or on the surface, rights therein, persons or property thereon, and events connected therewith. (For the meanings of airspace, aircraft and spacecraft, see *Space Law*, below.)

Sovereignty.—A fundamental principle of international law is that of national sovereignty over the airspace.

Early in the 20th century many jurists thought that airspace, like the high seas, should be free and outside national sovereignty; others regarded the airspace as part of the territory of the subjacent state; yet others attempted to reconcile "freedom of the air" with national rights in the airspace. Around 1910 it appeared that governments would regard control over the airspace as essential to national safety. Eventually the principle of state sovereignty became firmly established and was recognized in the Convention Relating to the Regulation of Aerial Navigation (Paris, 1919). That convention was replaced by the Convention on International Civil Aviation (Chicago, 1944) which also recognized that: "Every State has complete and exclusive sovereignty over the airspace above its territory."

Transit Rights.—Over the high seas there is freedom of air navigation, but aircraft cannot fly over any state without its permission. However, in the Chicago convention (following a similar principle of the Paris convention) each contracting state agreed that civil aircraft of the other contracting states would have the right, when not operating scheduled services, to fly across its territory or halt therein for nontraffic purposes, subject to the rules of the convention. As regards scheduled (regularly operated commercial) air services, privileges of transit and landing for nontraffic purposes were extended to one another's aircraft by the states that were parties to the International Air Services Transit

agreement of 1944.

Traffic Rights.— Aircraft may not exercise traffic rights, that is, pick up or set down passengers or cargo, in any country without its authorization. Under the Chicago convention aircraft of a contracting state may exercise traffic rights in the territory of another contracting state on nonscheduled flights, but the privilege is subject to the latter's right "to impose such regulations, conditions or limitations as it might consider desirable." The International Air Transport agreement was formulated in 1944 to enable aircraft on scheduled services to exercise traffic rights in foreign territory, but it proved unacceptable to most states. Consequently, bilateral agreements were made by states to enable their airlines to pick up and set down traffic in each other's territory.

Territorial Law.— An aircraft must comply with the laws of the country where it flies, including the rules of the air and air traffic control, and regulations relating to entry, clearance, immigration, passports, customs, health and documents relating to the aircraft, crew, passengers and cargo. However, the states that were parties to the Chicago convention must apply their air regulations, including any which levy airport and similar charges, to the aircraft of all contracting states without distinction as to nationality.

National Legislation.— The common law was inadequate for regulation of aircraft operations and almost all nations enacted legislation for that purpose. These laws generally provided for carrying out international obligations, such as the Chicago convention, for ensuring safety of air navigation, registration of aircraft and verification of their airworthiness, licensing of crew, establishment of airports and acquisition of land or rights over land, provision of radio aids and other air navigation facilities, control of air traffic, investigation of accidents and for the administration of such regulations. Legislation also provided for economic regulation and licensing of commercial flying and for specifying conditions of commercial carriage of passengers or goods. In many states air transport was wholly or partly nationalized by legal enactments. National legislation in many instances included provisions governing the liability of the air carrier in respect of passengers or goods and third-party insurance.

Usually such legislation was supplemented by detailed regulations promulgated by the governments under delegated powers. For example, in the United Kingdom the Civil Aviation act of 1949 (consolidating and replacing earlier enactments) was a comprehensive statute but it authorized the government to promulgate orders in council to make provision for multifarious matters and "generally for regulating air navigation."

In the United States federal competence to enact air legislation was questioned as late as 1918 but eventually was justified on the basis of the interstate commerce clause of the constitution. Such legislation concerning rules of flight, navigation lights and licensing of aircraft personnel was held valid for purely intrastate operations also, on the ground that departure therefrom would present hazard to interstate air navigation.

The Air Commerce act of 1926 authorized the secretary of commerce to make safety regulations, grant licences and registrations and install and operate facilities necessary to safe navigation, such as airway lights and radio stations. Such rule-making powers were transferred by the Civil Aeronautics act of 1938 to a board with a view to promote development of safe, efficient air services at reasonable charges under regulated competition. The Federal Aviation act of 1958 continued the board and created a Federal Aviation agency to control use of the navigable airspace and develop and operate air navigation facilities and air traffic control.

Private Ownership in Airspace.— In the case of private ownership in airspace, the trend was opposite to that in national sovereignty: it was toward freedom of flight. The right of the landowner to make unlimited use of the superjacent airspace was maintained, with only a few exceptions (see *The Law of Airports*, below), but judicial decisions and national legislation denied him any right to forbid, or to receive compensation for, the mere passage of aircraft, without producing material damage, through that part of the airspace of which he was making no effective use. In the United States the supreme court (*Causby v. United States*,

1946) observed: "It is ancient doctrine that at common law ownership of the land extended to the periphery of the universe . . . but that doctrine has no place in the modern world. The air is a public highway, as congress has declared. . . ." The court, however, upheld the landowner's claim for compensation since he suffered actual material damage from frequent flights of aircraft over his land. In the United Kingdom a law of 1920, re-enacted in 1949, provided that no action would lie in respect of trespass or nuisance by reason only of the flight or the ordinary incidents of flight of an aircraft over any property at a reasonable height if the flight was conducted in accordance with regulations. However, if aircraft operations resulted in material loss or damage to any person or property on land or water, then (unless the complainant negligently caused or contributed to the damage) compensation would be recoverable without proof of negligence or intention.

The Law of Airports.— Actions for aerial annoyance usually come from people domiciled near airports where aircraft operate frequently and at low altitudes. Courts have prohibited the establishment or the continued operation of airports where a strong showing of injury to the neighbours was made. The British Civil Aviation act of 1949 met the resultant hazard to airport operation by providing that no action would lie in respect of nuisance by reason of the noise and vibration caused by aircraft on any airport where the terms of an order in council regulating such matters had been complied with.

The owner of property adjacent to an airport may be prevented by legislation from using his property in a manner which would create a hazard for air navigation. In the United States local regulations prohibited the erection of structures of more than a limited height in the neighbourhood of airports. Such zoning was not to entail serious hardship to landowners. If it did, as for example if safety of flight required that the structures on a given piece of land be only a few feet in height, compensation would have to be paid. The acquisition of the owner's rights in the airspace above his property, subject to compensation, is a possibility where such extreme restrictions are necessary; but airport zoning ordinarily imposes only moderate restrictions and entails no compensation.

In most countries airports are nationally licensed, and unlicensed places can be used for the landing and taking off of aircraft only under restrictive conditions, if at all. In the United States no such licensing exists, and any attempt to establish it might encounter constitutional difficulties on the ground that an airport is purely an intrastate activity. Federal control over airports is possible, however, through conditions attached to the grant of national aid to airports.

Codification of International Air Law.— The extreme mobility of aircraft and their frequent crossing of international boundaries make it particularly necessary that air law should be uniform. This can be achieved by international agreement. Certain rules of public air law are codified in the Chicago convention: for example, that aircraft have the nationality of the state where they are registered and that such state has to ensure that the aircraft is airworthy, that its crew is competent according to international standards, and that it complies with the laws in force wherever the aircraft may be. Considerable uniformity in the aeronautical regulations, standards and procedures of states that are parties to the Chicago convention results from their endeavour to follow the international technical standards and procedures formulated from time to time by the council of the International Civil Aviation organization (I.C.A.O.) (*q.v.*) established by the convention. That convention and the International Air Services Transit agreement mentioned above embody international agreements for aerial transit.

The function of developing studies with a view to unification of private air law was performed by C.I.T.E.J.A. (Comité International Technique d'Experts Juridiques Aériens) from 1926 until 1947 when that body was dissolved and its work taken over by the legal committee of I.C.A.O. Drafts prepared by those bodies resulted in the adoption of international air law conventions.

Warsaw Convention.—The convention for the Unification of Certain Rules Relating to International Carriage by Air, adopted at Warsaw in 1929, provided that the carrier would be liable for accident, in such carriage, to passengers or goods, unless he proved that all necessary and possible measures were taken to avoid the accident. However, his liability would be limited, except in cases of willful misconduct, to specified maxima.

The Hague Protocol.—In 1955 a protocol was formulated at The Hague, Neth., to effect amendments to the Warsaw convention, including one to double the limit of liability in respect of a passenger.

Rome Convention.—A convention on Damage Caused by Foreign Aircraft to Third Parties on the Surface was adopted at Rome in 1952 (replacing one of 1933 and a 1938 protocol). It made the operator absolutely liable for such damage subject to specified limits.

Geneva Convention.—In 1948, the convention on the International Recognition of Rights in Aircraft was formulated at Geneva, Switz. Its objective was that proprietary and other rights in aircraft would be protected in all countries participating in it.

Precautionary Attachment.—A convention was drawn up at Rome in 1933 to protect certain aircraft against attachment before judgment in pursuit of private interests.

Drafts and Projects.—In 1957 the I.C.A.O. legal committee prepared a draft convention on the unification of certain rules relating to international carriage by air performed by a person other than the contracting carrier. Projects on which the legal committee was engaged included study of the legal status of the aircraft, particularly with a view to formulating rules applicable to events happening on board aircraft: such as crimes, commercial transactions, torts, births, deaths and marriages. A closely related subject was that of the status of the aircraft commander. Another concerned the principles of liability and any limitation in cases of collision between aircraft.

Space Law.—The launching of the first artificial space satellites by the C.S.S.R. in Oct.–Nov. 1957 aroused popular interest in legal problems that for some years previously had been studied by jurists in many countries. The problems involved the legal status of spacecraft and of the outer space they would traverse. The primary question was whether national sovereignty extended to outer space. The declaration of state sovereignty over the airspace contained in the Paris convention of 1919 and the Chicago convention of 1944, as well as in the legislation of many countries, did not appear conclusive, since those instruments spoke of "airspace," but did not define or delimit it, or make any reference to outer space. Furthermore, those conventions and statutes were essentially linked with aircraft. The accepted technical definition of aircraft was "any machine that can derive support in the atmosphere from the reactions of the air." Thus it could be argued that the sovereignty of a state extended from the earth's surface as high as aircraft could fly, but no higher. Technical indications were that such height could not exceed 50 miles. On the other hand, there was no international agreement placing a maximum height for state sovereignty.

It was argued that the failure of any state to object to the actual launching of satellites by the U.S.S.R. and the United States evidenced consent. But "consent" obviously implied existence of a legal right on the part of the nations. In any case the military potential of spacecraft or of the establishment of a space-station by one state above another's territory was very grave, and nothing indicated that nations, mindful of considerations of national safety, would forgo, or refrain from claiming, sovereignty over several hundred miles of space above their territories.

Preoccupation over the military aspects was evident when, in Dec. 1957, the United Nations general assembly adopted a resolution on disarmament including a provision calling for a joint study of an inspection system designed to ensure that the sending of objects through outer space would be exclusively for peaceful and scientific purposes.

The legal status of satellites or spacecraft was clearer: they were not "aircraft" since they could operate without deriving

"support in the atmosphere from the reactions of the air" and could ascend to infinite heights above the earth's surface where air is nonexistent. However, they would use the airspace while ascending or descending, possibly endangering the safety of navigation of aircraft, and would therefore become liable to be controlled at such time by air law.

General legal opinion tended to regard as insupportable the extension of state sovereignty literally to infinity or even thousands of miles above the earth. Various theories were advanced in regard to the height up to which state sovereignty extended: thus, one stipulated the height of 50 miles above the earth because of certain mathematical calculations concerning gravity and centrifugal force, and another a height of 300 miles. In Dec. 1959 the United Nations established a committee to co-ordinate and promote all activities for the peaceful uses of outer space and to study the nature of the legal problems arising from exploration of outer space.

AIR LOCK, a device to permit passage between regions of differing atmospheric pressures, most often used between the outside air and working places in compressed air, such as pneumatic caissons and subaqueous tunnels. A typical lock consists of a cylinder of steel plate with air-tight doors at both ends, one opening from the outside into the lock, the other from lock into

AIR LOCK IN VEHICULAR TUNNEL DRIVEN UNDER COMPRESSED AIR

compressed air, together with valves to admit or to exhaust compressed air into or from the lock. One of the doors must always be closed; before opening the other the pressure within the lock must be equalized with that on the opposite side. The employee who operates valves and doors is known as the lock tender.

Two types of lock are in general use, the horizontal, for tunnels, in which the doors are hinged on vertical axes, and the vertical, for caissons; in the latter the door arrangement must make provision for the cable which hoists material from working chamber to surface; several forms have been developed. On a large caisson the lock consists of a horizontal cylinder with a closed end mounted on a caisson shaft. See **CAISSON, TUNNEL**. (F. DN.)

AIR MASS. In synoptic meteorology, air mass is the designation for a vast body of air in which certain physical properties—mainly those of special value in analysis for weather forecasting purposes—vary but slightly in the horizontal.

The basic properties of air masses which determine characteristics of the weather are the vertical distribution of temperature and moisture content. These properties determine the actual or potential development of clouds and precipitation. Two air masses of similar horizontal homogeneity and similar average temperature and moisture at the ground may have very different vertical distribution of these properties. The practice of air mass analysis for weather forecasting therefore requires upper-air soundings to determine the vertical distributions, although it is possible to infer to some extent the latter from the conditions measured at or seen from the ground.

The origin and persistence of distinctive air masses are explained by the facts: (1) that there are certain large source regions of

the earth's surface where conditions are sufficiently uniform so that the overlying air can acquire similar characteristics; *i.e.*, horizontal homogeneity, throughout the region; and (2) that the general circulation of the world's atmosphere has large-scale streams that are more or less steady and permit the travel of the air masses over long distances without being dispersed into small eddy branches.

The primary source regions are the polar areas and the subtropical belts (around 10° – 30° latitude). The middle latitudes are the scene of interactions between the polar and tropical air masses, which intertwine and over- or under-run one another in great spiral trajectories that constitute the traveling cyclones and anticyclones (*q.v.*).

Such interactions produce the major weather variations in these latitudes (see METEOROLOGY). There is a subsidiary class of source regions in middle latitudes where the effects of the prevailing difference in temperature between ocean and continent surfaces tend to transform originally polar or tropical air masses passing over them into subtypes with distinctive and important characteristics.

Thus polar (or tropical) maritime and polar (or tropical) continental air masses are created, which also may interact in cyclones and anticyclones as a result of the large-scale air circulation bringing them together.

Near the coasts very rapid and striking transformations in air mass properties often take place when, for example, warm continental air moves onto cold ocean waters (in summer) or (in winter) cold continental air moves onto warm ocean waters; although such effects do not reach to very high levels in the atmosphere and are usually limited in area, locally they may play a dominant role in the weather.

Small-scale phenomena, such as sea and land breezes, mountain and valley breezes, may be considered as the result of contrasting local or pseudo air mass source regions. (See WIND.)

Although the air mass concept was recognized in a general way by H. W. Dove and others before the middle of the 19th century, its practical significance in weather forecasting was first realized in 1917 by Norwegian meteorologists hard pressed for a new technique to compensate for their lack of foreign weather reports withheld by the neighbouring warring nations. In less than two decades thereafter it had been adopted in most advanced countries. It greatly improved accuracy of forecasting, but only for periods up to 24 or 36 hr. in advance, and clarified the understanding of many familiar weather phenomena. (See WEATHER FORECASTING.)

In physical meteorology, air mass is the term for unit of mass of the atmosphere passed through by the sun's rays in reaching from outside the atmosphere to the earth's surface. Air mass of value 1 is defined as the amount of air passed through by the vertical rays when the sun is in the zenith. Then for lesser elevations of the sun above the horizon, the air mass m is nearly proportional to the secant of the sun's zenith distance, and may be described as the equivalent number of atmosphere² of air mass 1 which the rays would pass through at any given solar elevation.

Tables of m values for various zenith distances are required for convenience in calculating the absorption of solar energy by the atmosphere.

In order to avoid confusion with the expression air mass as used in synoptic meteorology, E. W. Woollard and I. F. Hand suggested the word air path for m . (R. G. SE.; X.)

AIR NAVIGATION: see NAVIGATION.

AIRPLANE. The concept of mechanical flight was almost a century old before modern aeronautical terminology began to take definite shape. During the early part of the 19th century, inventors referred to aerial vehicles variously as aerial ships, flying machines, aerial machines or aerial steam carriages. As late as 1903 the American inventor Samuel Pierpont Langley called his machine an aerodrome, from a combination of Greek words meaning aerial runner.

According to Svante Stubelius, the term aeroplane was first used by F. H. Wenham in England in 1866 to describe a wing, or "a plane in the air." From 1873 onward, the word was used to refer

to the whole aircraft. In British usage this term is still employed. In the United States, however, the simplified form airplane was officially adopted by government agencies in 1916 and subsequently came into general use.

An airplane is a power-driven, heavier-than-air craft, usually manned, which derives its lift, *i.e.*, its support in the air, from the dynamic reaction of air flow over a system of fixed surfaces, or wings.

The essential components of an airplane are a wing system to sustain it in flight, tail surfaces to stabilize the wing, moveable surfaces to control the attitude of the machine in flight and a power plant of some kind to provide the necessary thrust to push the machine through the air. Some sort of provision also must be made to support the machine when it is at rest on the ground or on water, or during take-off and landing operations. In addition, to make it a useful device, an enclosed body (fuselage) to house the crew, passengers and cargo must be provided, as well as controls and instruments for the pilots and navigators.

These general characteristics distinguish the airplane from other common forms of aircraft, such as balloons and airships, which derive their support from the displacement of large volumes of air by large containers (bags) of lighter-than-air gas; gliders and sailplanes, which resemble airplanes in form but which do not carry power plants; helicopters and Autogiros, which derive their lift from systems of rotating wings; and rocket craft or space craft, which usually are wingless vehicles designed to operate outside the boundaries of the earth's atmosphere. (Discussions of these types of aircraft may be found in the articles AIRSHIP; BALLOON; GLIDING; HELICOPTER; ROCKETS; and SPACE EXPLORATION.)

Airplanes may be classified into two broad categories by: (1) their design configuration; or (2) the mission that they are intended to perform. The various types of airplanes are discussed in this article under the following headings:

- I. Classification by Configuration
- II. Classification by Mission
 - A. Civil Airplanes
 1. Commercial Transport
 2. Industrial or Executive Transport
 3. General Utility Airplanes
 4. Private Airplanes
 5. Training Airplanes
 - B. Military Airplanes
 1. Fighter Airplanes
 2. Attack Airplanes
 3. Bombing Airplanes
 4. Reconnaissance Airplanes
 5. Transport Airplanes
 6. Training Airplanes
 7. Research Airplanes and Special Types

An account of the development of the airplane may be found in the article AVIATION, HISTORY OF. For a discussion of the physical principles upon which mechanical flight is based, as well as the practical applications of these principles, see AERODYNAMICS and AERONAUTICS. The nonmechanical flight of the more talented animals is described in FLIGHT (NATURAL).

I. CLASSIFICATION BY CONFIGURATION

Most modern airplanes are monoplanes; *i.e.*, their lift is derived from one horizontal fixed-wing system. The biplane (using two horizontal wing systems, one above the other, connected by a series of struts and wires) was the almost universally accepted form up to the mid-1920s, but it later virtually disappeared from use. The few that remained were employed for primary pilot training, for sport flying or for agricultural crop dusting. During World War I, several multiplane designs appeared (triplanes, quadriplanes, etc.), but they subsequently disappeared entirely.

Modern monoplanes may be further catalogued by the plan form of their wings, which may be rectangular, tapered, swept-back or delta. The theoretical considerations on which the selection of various plan forms is based, and the resulting characteristics, are discussed in the article AERONAUTICS.

Another observable variation in modern airplane configuration lies in the number and location of the power plants. Airplanes are driven by means of the thrust developed by engine- or turbine-

driven propellers, or from the reaction of streams of hot gases (jets) developed by gas turbines. For single-engine designs, the engines (or turbines) are usually located in the body, or fuselage. For multiple-engine designs, the power plants are usually distributed outboard along the wings, either in nacelles projecting from, or in pods suspended below, the wing. In a few cases, pods housing turbine power plants have been attached to the rear of the fuselage.

Finally, as to over-all configuration, airplanes are either land based or water based. In the first case, they are equipped with wheels or skids; in the second, they are mounted on floats, or the main hull is so designed as to permit take-off or landing on water.

There is no one best solution to any given design problem. The general size, shape and configuration of an airplane are closely related to the mission for which it is intended. The final design is always a series of compromises among many interrelated elements. This is why airplanes designed for different purposes have varying external characteristics. For example, a long-range, high-altitude photographic mission calls for minimum total weight and large wing area (low wing loading); a high aspect ratio (ratio of wing span to wing width) for long-range cruising efficiency; a single engine, economical in fuel consumption; and a fuselage just sufficiently large to house the necessary equipment and a single pilot.

On the other hand, maximum speed calls for small, compact machines with very small, thin, swept-back or delta wings (*i.e.*, high wing loadings), high landing and take-off speeds, large, uneconomical (in fuel) power plants and restricted crew accommodations.

If comfort, convenience and safety for a large number of passengers are paramount, lower wing loadings for slower landing and take-off speeds must be selected, and higher over-all drag (air resistance) must be accepted because of the necessity for larger fuselage (for passenger, crew and cargo accommodations), multiple power plants, large quantities of fuel, etc.

In making up specifications for an airplane of any category, the basic mission must be clearly defined and all design factors carefully studied to effect proper compromises to yield the desired result. It is impossible to attain the ideal in aircraft design. The "safest" airplane would be one that could not fly at all. The "fastest" airplane would have no practical utility except to establish speed records. The "highest flying" airplane would be merely a complicated and expensive research tool designed only to make a shallow penetration of outer space. And the "farthest flying" airplane would have very little practical utility except to establish endurance records.

Modern airplanes are so complicated, and such a large number of variables enter into their design, that many hundreds of thousands of engineering man-hours go into their specification, design, construction, testing and evaluation. After the mission has been defined and the basic configuration agreed upon, thousands of hours of detailed study must be spent upon the preliminary design before prototype construction can begin. Carefully built, geometrically and dynamically accurate scale models must be tested in wind tunnels to test the flying characteristics and to furnish information on the air load distribution in different flight conditions. Vibration and flutter induced by fluctuating air-flow patterns on wing, body and tail surfaces must be identified and evaluated.

Because designers are always pushing the state of the art to extreme limits and must work to the highest attainable strength-to-weight ratios in the use of materials, calculations must be exact. Margins for error are very small. Rule-of-thumb methods cannot be applied to airplane structural design. Simply to double the thickness (and therefore the weight) of any structural element to be certain of its strength or rigidity would be unthinkable. Each part must be examined in detail and then be designed for maximum efficiency. The problem is made doubly difficult because of uncertainty in determining the magnitude and exact location of points (or areas) of air loads on airplane structures. Often, actual full-scale structural components must be built and tested to destruction in laboratories to be certain that they will stand up under the dynamic and vibrational loads to be encountered in flight.

This detailed process may be repeated many times before the

final design is accepted and the first prototype built. The assembled airframe is then subjected to many complicated load and vibrational tests to be certain that it will meet the intended strength specifications. Finally, after the power plants and all other auxiliary equipment are thoroughly tested for functional integrity on the ground, the complete machine is ready for flight testing.

This is always a critical operation. In spite of endless computations, the testing of components, and the experience and expectations of the designers, the actual performance of the airplane in flight cannot always be predicted with accuracy. In earlier days the question was whether or not the machine would fly at all; now it is whether or not the machine will fulfill all the expectations of the designer. A long series of well-engineered, well-instrumented test flights is usually required to guarantee that the original specifications for performance and safety have been met. For large aircraft this phase may last a year or more.

Even after such long and careful testing, it is not always possible to anticipate and to provide for all conditions that may be encountered in flight. On at least two occasions, large commercial airplanes that were exhaustively studied in design stages and subjected to rigorous testing on the ground and in the air subsequently experienced catastrophic failures in service. When working far out on the fringes of human knowledge, a totally unanticipated combination of events may lead to disaster. In such cases, the experience can only be recorded for future guidance.

II. CLASSIFICATION BY MISSION

Airplanes of any of the configurations discussed in the preceding section may be classified also by the use for which they are intended. The two broadest categories are civil and military. In some classes—for example, training and transport—the general appearance of civilian and military airplanes may be quite similar. In many details, however, they are different, and the specifications to which they are designed and manufactured differ materially.

A. CIVIL AIRPLANES

1. Commercial Transport. — This type of airplane is intended for carrying passengers or cargo, or both, for a profit. Commercial transports must be fast, efficient and reliable. For passenger service they must provide comfortable seating, proper air conditioning (at all altitudes), and proper food services and toilet facilities consistent with the length of flights for which they are employed.

For short-haul service, where flights may be no more than one to two hours in duration, personal conveniences can be minimized. For long runs, however (transcontinental or intercontinental), passengers will be aboard from 6 to 12 hours; thus more space per passenger and more service facilities will be required. Such airplanes, moreover, must be provided with all available safety services and equipment. Extensive navigation and communication equipment must be supplemented by emergency gear for rapid and safe evacuation of the airplane on the ground or for emergency landings at sea.

Large airplanes for overseas or transcontinental use also require considerable crew space. In some cases as many as ten crew members are carried, including pilots, navigator, radio operator and cabin attendants. For the short-haul services two pilots and one cabin attendant make up the usual crew complement.

One of the most significant characteristics of commercial transport aircraft is the complete pressurization of the passenger and crew compartments. Modern airplanes, particularly if jet powered, operate most efficiently when flying at very high altitudes (25,000–35,000 ft.). At such heights the oxygen content of the atmosphere and the atmospheric pressure are both far below the limits of human tolerance, and it is necessary to supercharge all personnel spaces to somewhere near sea-level conditions. This means that the fuselage must be airtight, and air compressors must be provided to force sufficient extra air into the cabin to provide tolerable living conditions. Usually no attempt is made to reproduce actual sea-level conditions, but most airplanes maintain cabin temperatures and pressures equivalent to those prevailing at about 8,000 ft. above sea level, regardless of the actual flight altitude. Pilots and

crews are readily conditioned to work at such equivalent altitudes, and the average passenger, if in normal health, can tolerate such conditions, particularly if seated and not doing any physical work.

All high-flying airplanes carry emergency oxygen supplies so that if the pressurizing system should fail, each passenger can be supplied with oxygen at least until the airplane can descend to a lower altitude.

Most passenger airplanes, in addition to carrying the passengers' personal luggage, carry also a certain amount of cargo, usually mail or freight. Cargo and luggage commonly are carried in unpressurized compartments at the bottom of the fuselage, easily accessible from the ground through doors and hatches.

Airplanes intended only for cargo carrying dispense with all the comforts and conveniences that are provided for passengers. The pilots' compartments are usually of the same design and arrangement as for passenger airplanes, but the interior equipment of the fuselage is reduced to a minimum. Sound insulation, an essential for passenger carriers, is usually nonexistent. Suitable anchor points are provided in the deck and interior walls so that cargo of a variety of shapes and sizes (barrels, boxes, crates, oil drums, etc.) may be safely secured. In addition, cabin doors are much larger than those required for passenger accommodation; in the case of very large airplanes designed to handle heavy equipment, built-in cargo hoists and rear-opening doors are provided.

During the period of transition from propeller-driven to jet-powered transports, many airlines used the older, internal-combustion-engine airplanes for cargo carrying. The passenger accommodations were removed, and the airplanes were modified with facilities for carrying cargo.

2. Industrial or Executive Transport. — With the world-wide spread of commerce and business enterprises and with the availability of good airports in many parts of the world and an extensive system of government-controlled airways, many commercial firms came to own and operate their own airplanes or fleets of airplanes. Such machines are used to transport personnel or goods from plant to plant or country to country. Many of the twin-engined airplanes that made up the fleets of air transport companies in the late 1940s or early 1950s were sold to nontransport business enterprises because they were largely replaced by four-engined or jet-powered airplanes on the airlines. A number of large companies (steel manufacturers, petroleum refiners, parts manufacturers, etc.) maintain their own fleets, their own pilot and flight personnel and even their own maintenance facilities.

Their airplanes operated under the same general conditions and operating requirements as airline airplanes. They carried suitable navigation and communication equipment to operate safely anywhere in the world. Many of them provided luxurious office and living accommodations for traveling executives.

3. General Utility Airplanes. — Certain specialized forms of airplanes have been developed for commercial purposes apart from the transportation of passengers and goods.

One of the most common forms is the so-called crop duster, designed to be flown at very low altitudes over growing crops to distribute insecticides or other forms of chemicals for the improvement or protection of crops. Such chemicals may be in the form of aerosols or finely divided powders. The airplanes must therefore be provided with proper containers and means of distribution and control, such as hopper valves, spray heads, etc.

These airplanes usually are single-engine craft of relatively small dimensions, flown by a single pilot. Primary requirements are good control at slow speeds and low altitudes, and safe maneuverability. Another very desirable characteristic is in the ability to land and take off: from small, unprepared fields. This is one of the few categories of modern airplane in which the biplane type still persists.

Many farmers and cattle raisers in countries where large land holdings are commonplace use small airplanes for general survey and inspection purposes. These aircraft can also carry light equipment and supplies to outlying farm areas. Aircraft for such use are commonly of the ordinary pilot-owner types and are not specially designed for such purposes.

Oil companies, mining interests and professional aerial photog-

raphers use small airplanes in their businesses, but the airplanes generally are standard types in which specialized equipment has been installed. One such specialized use of aircraft in the more sparsely populated areas of the world is the Australian "Flying Doctor" service. Airplanes for such purposes must be sturdily built and dependable. In lake country they are often mounted on floats for off-water operations.

4. Private Airplanes. — The ownership of airplanes for pleasure or for personal convenience (entirely apart from business usage) is growing. Airplanes in this category range from small, single-seated, single-engined types, used purely for sport flying, to twin-engined airplanes capable of carrying eight to ten people in all types of weather along established airways.

At the lower end of the scale such private airplanes are relatively inexpensive and simple, designed to be flown only under fair conditions in the vicinity of suitable airports. At the other end of the scale, airplane ownership is expensive—comparable, indeed, to the ownership of seagoing yachts. Such airplanes are similar to small airliners and must be equipped with the same kinds of communication, navigation and survival gear. Between these two extremes is a wide range of aircraft for the private owner.

The majority of these airplanes are single-engined, cabin-type monoplanes, usually designed for two to four people, including the pilot. They are generally powered with air-cooled reciprocating engines, driving fixed-pitch propellers. Landing gear is simple, strong and, in some of the larger types, retractable in flight. Ease of control and ability to get in and out of small fields are highly desirable. A few private airplanes are mounted on floats for operation from water.

5. Training Airplanes. — In civil aviation the training airplane, as such, has practically disappeared. Pilots (or potential customers for private-aircraft purchases) are usually trained on the machines they intend to fly. These generally are in the small, private-owner class described above.

The essential element in a training type is the fitting of dual controls so that the instructor and pupil each can fly the airplane. Students usually begin by following through. The motions are made by the instructor, and the student gradually takes over control of the machine as he develops experience.

Good visibility for the pilot and pupil, ease of control, and sturdy landing gear are generally considered essential for training airplanes.

B. MILITARY AIRPLANES

Until well into the middle of World War I the principal requirement of a military airplane was simply the ability to fly. If it proved successful in that particular, it was expected that it might replace cavalry or scouts as a means of collecting battlefield intelligence. Military leaders soon discovered, however, that the airplane had many more capabilities than simply to act as "flying eyes" for the army. Fighter aircraft evolved from the necessity of arming airplanes for their own protection. Specialized forms then began to be developed for many specific missions.

Generally speaking, whether for the army, navy or air force, all military aircraft fall into one or another of the following categories: (1) air-to-air combat (fighters); (2) ground support (attack); (3) air-to-ground bombardment (bombers); (4) surveillance (reconnaissance and command); (5) logistical support (transport and cargo carriers); (6) training (trainers); and (7) special missions (including research).

1. Fighter Airplanes. — The primary mission of fighter airplanes (for either air force or navy) is to secure the control of essential air spaces by attacking and destroying all types of enemy aircraft which may be operating in their area.

The opposition may consist of high-performance fighters of equal capability, or of high-altitude, high-speed bombers carrying armor or protective armament. For such purposes fighters must be capable of the highest possible performance in order to be able to out-fly and outmaneuver opposing fighters; in addition, they must be armed with specialized weapons capable of hitting and destroying enemy aircraft.

At the speeds and altitudes at which such aircraft can operate,

Engraving of the design of an early dirigible balloon, or airship, a lighter-than-air craft lifted by hot air and propelled by means of sails. About 1807

Montgolfier hot-air balloon carrying Pilâtre de Rozier and the Marquis d'Arlandes across Paris on the first manned free balloon flight, Nov. 21, 1783

EARLY ATTEMPTS AT FLYING

AIRPLANE

Biplane glider, 1895, one of two built by Otto Lilienthal, Germany

Modified no. 3 glider by Orville and Wilbur Wright, 1902, at Kill Devil hill, N.C.

Model of the "Aerodrome," 1903, by Samuel P. Langley, U.S. This tandem-winged airplane never made a successful flight

Wright brothers' "Flyer" rising from ground at Kill Devil hill, Dec. 17, 1903, to become the first powered airplane

EARLY ATTEMPTS AT MECHANICAL FLIGHT

Bristol box kite, 1910, with a 50-h.p. Gnome engine, a British design which was a derivative of the Henri Farman biplane

Glenn Curtiss' seaplane of 1911, the first U.S. aircraft successfully to take off from, and land on, water

Glenn L. Martin at the controls of his biplane at Wahpeton, N.D., in 1912

BIPLANES AND FIRST SUCCESSFUL U.S. SEAPLANE: 1910-12

Captured German Fokker D.VII, 1918 (shown with British markings), a fighter plane remarkable for its maneuverability and rate of climb

Twin-engined Handley Page 400, 1917. The first British heavy bomber, it flew at 60–80 m.p.h. carrying a bomb load of 1,800 lb.

AIRPLANES USED DURING WORLD WAR I

French Nieuport biplane, with British markings, the first Allied scout fighter able to compete with the German Fokker

S.P.A.D., 1918, French fighter plane also flown by U.S. pilots in Capt. Eddie Rickenbacker's squadron

The Curtiss JN-4 "Jenny," one of the series of Curtiss single-engined planes used to train U.S. pilots during World War I

FRENCH FIGHTER PLANES AND U.S. TRAINER USED IN WORLD WAR I

"Spirit of St. Louis," Ryan monoplane in which Charles A. Lindbergh made the first solo nonstop flight between New York and Paris, May, 1927

De Havilland Albatross, British four-engine transport of 1937, a low-wing monoplane which seated 20-30 passengers

Supermarine S6, British seaplane, designed by R. J. Mitchell, which won the international Schneider trophy races for seaplanes in 1929

Focke-Wulf Fw 200 Condor, German four-engine reconnaissance bomber converted from a commercial airliner in 1940

Potez 63, French reconnaissance fighter-bomber monoplane, powered with tws Hispano-Suiza engines

AIRPLANES BETWEEN WORLD WARS I AND II

Ford Stout, 1925, first successful U.S. airliner. The all-metal trimotor was derived directly from the Fokker transport

Douglas DC-3, 1935, most successful airliner in history, which eventually flew in the service of nations throughout the world

U.S. AIRLINERS: 1925-35

German Messerschmitt 109, single-seat fighter with cannon and machine guns

Japanese Mitsubishi Zero, highly maneuverable, high-speed fighter plane

British Supermarine Spitfire MK XII, single-engined, single-seat fighter

U.S. P-51H Mustang, single-seat fighter built around Rolls Royce engine

Captured German Messerschmitt 262 (with U.S. markings), first production jet-propelled fighter plane carrying cannon and rockets; first flight, 1942

FIGHTER PLANES USED DURING WORLD WAR II

AIRPLANE

Junkers Ju 87 Stuka, 1937, German two-seater dive bomber which saw action in the Spanish civil war and World War II

Consolidated B-24 Liberator, U.S. air force four-engined, long-range bomber, also used by the R.A.F. during the early years of World War II

Avro Lancaster, 1942, four-engined British heavy bomber. Designed for night bombing without escort, it could carry a bomb load up to 22,000 lb.

Boeing B-29 Superfortress, 1944, U.S. four-engined bomber. It had a radius of over 2,000 mi. and carried a maximum bomb load of 20,000 lb.

BOMBERS USED DURING WORLD WAR II

Lockheed Constellation, 1943. This four-engine airliner carries up to 65 passengers at 260–300 m.p.h. for 2,000–3,000 mi.

Vickers Viscount, 1948. The first turboprop airliner, this British model used by U.S. lines carries up to 48 passengers at 315 m.p.h. for 1,400 mi.

Sud-Aviation Caravelle, French jetliner, 1955. With twin engines by Rolls Royce, Ltd., it carries up to 80 passengers at 480–500 m.p.h. for 1,200 mi.

Boeing 707 Intercontinental, 1959. This U.S. jet carries up to 160 passengers at 550 m.p.h. for 3,500 mi.

U.S., BRITISH AND FRENCH AIRLINERS: 1943–59

British Hawker Hunter, swept-wing, jet-propelled fighter powered with Rolls Royce Avon or Siddeley Sapphire engines

U.S. Lockheed F-104 Starfighter, supersonic fighter-interceptor. one of the fastest combat aircraft in the air forces of many nations

Russian Myasishchev "Bomber," largest known supersonic bomber. It is accompanied by two "Fishbed" (NATO assigned names) jet fighters

U.S. Convair B-58 Hustler showing delta wings and weapons pod. A supersonic bomber, it is powered by four turbojet engines

MILITARY AIRCRAFT OF THE MID-20TH CENTURY

B-52 Stratofortress bomber at 45,000 ft. dropping the X-15 space research rocket plane after pilot has ignited the engine

Drawing of the B-70 Valkyrie, delta-winged bomber designed to fly three times faster than the speed of sound, 15 mi. above the ground

AIRCRAFT OF THE 1960s

the problem of striking and destroying enemy aircraft becomes extremely complicated and requires an array of electronic, navigational and computing gear. A single-seated, high-performance fighter of the 1960s might weigh as much as, and be vastly more complicated than, many of the multiengine bombers of World War II. In many cases the search and attack functions are completely automatic, the pilot's role in combat being virtually reduced to monitoring the operation of the equipment. Indeed, with the most modern jet-powered fighter airplanes, a point has been reached where the performance capabilities of the machine far exceed the capabilities of a human pilot to control it.

In the so-called dogfighting aerial combat of World Wars I and II pilots could recognize enemy aircraft and maneuver themselves into positions for combat by visual means. They controlled their machines manually and operated their guns by pressing triggers when they were in proper firing position. In supersonic aircraft at extremely high altitudes, such maneuvers were no longer possible. Human eyes and human reaction time are neither acute enough nor quick enough to bring two opposing aircraft within combat range or to aim and fire accurately and effectively. The modern fighter airplane must therefore be an almost completely automatic weapons system that will detect, identify, close with and open fire upon an enemy with very little help from the man in the cockpit. The pilot must rely upon electronic devices to find his enemy and upon electronic computers carried in his plane to lock onto his target and fire his guns at the proper moment. It is still his responsibility to take off and to fly his plane into combat areas, to decide when to engage in or to break off combat, and to return safely to base after combat; but during actual engagement (which may be a matter of only a few seconds) the pilot really is little more than a passenger.

In appearance a modern supersonic fighter bears a close relationship to a guided missile, with embryonic wing and tail surfaces. The fuselage is usually long, narrow and pointed, with the pilot's cockpit well forward in the nose. Wings are of short span, generally well swept back, frequently of delta configuration. Because of the somewhat peculiar weight distribution in the fuselage; with pilot and armament well forward and the heavy jet engine aft, the wing systems are generally located well to the rear of the fuselage, giving a characteristic long, needle-nosed look. The wings themselves are quite thin, and their surfaces are smooth and free from protuberances.

Very little space is available for the comfort of the pilot in a fighter airplane. Every available cubic inch in the airplane is utilized for the storage of fuel, ammunition, guns, computers, power plant and miscellaneous equipment.

The pilot's cockpit is heated and pressurized for high-altitude operation, but he must also wear protective pressurized clothing to enable him to withstand the high accelerations to which he is subject during high-speed maneuvers, together with a protective helmet for crash survival. Automatic ejection-type seats which incorporate parachutes are installed to provide emergency means of escape from fighter airplanes. When such equipment is operated, seat and pilot are literally blown out of the airplane, after which a parachute opens automatically.

Fighter airplanes for air force and naval use are basically similar in design and appearance. Fighters designed to operate from, and to land on, aircraft carrier decks, however, must be more stable, land at slower speeds and be fitted with proper catapult attachment gear and tail hooks to engage arresting gear for deck landings.

2. Attack Airplanes.— Attack airplanes closely resemble fighters but are designed to operate at lower altitudes and to carry rockets or other forms of missiles for use against ground targets. They may also be used as dive bombers.

They are generally somewhat larger than the high-altitude fighters, with one or more engines mounted either in the fuselage or outboard on the wings. They are sometimes designed for extremely low-level attack, approaching their targets by profiling the ground at altitudes of 50 to 100 ft. They may thus effect surprise by their ability to approach under defensive radar screens and get safely away before defensive armament can be brought to

bear from the ground.

3. Bombing Airplanes.— Conventional bombers are designed to make high-altitude attacks against ground targets, using nuclear or conventional weapons. Prior to the era of nuclear warfare, bombers were usually relatively large and heavy, needing protection by high-speed fighter escorts against enemy attack.

With the advent of powerful jet engines, however, and the introduction of nuclear weapons of relatively small physical dimension and weight, it became possible to design long-range bombardment aircraft with performance capabilities approaching those of the best fighter types. Mach-2 and Mach-3 bombers (see MACH NUMBER) became theoretically possible, and with nuclear power plants, their range would be almost unlimited.

The long-range, high-altitude bomber is the basic offensive weapon of strategic air forces. By refueling in the air from flying tankers, such aircraft have flown around the world nonstop. However, it was claimed by some that intercontinental ballistic missiles rendered the long-range, high-altitude, manned bomber obsolete. Proponents of the bomber, on the other hand, argued that the presence of the crew on board the airplane provides an element of judgment lacking in the missile. Human navigators can make corrections in the flight plan which might be dictated by local conditions for which the unmanned missile could not possibly make allowance.

4. Reconnaissance Airplanes.— A knowledge of the enemy's whereabouts and intentions has always been of paramount importance in warfare. The airplane gave military commanders entirely new opportunities for reconnaissance, opportunities ranging from low-altitude observation of a battlefield, from light, single-engined airplanes, to the continuous observation of an entire nation's industrial and military complex, using specially designed airplanes flying at very high altitudes and carrying highly refined photographic and other recording apparatus.

The classic method of aerial reconnaissance has been high-altitude photography, using techniques that were developed to a high degree during World War II. By taking photographs of a certain area at intervals and comparing them by very accurate photogrammetric techniques, it is possible to determine with a high degree of accuracy the kind and character of military installations or operations that may be in progress at the time (see PHOTOGRAMMETRY).

Later reconnaissance techniques, using radar, infrared or electronic radiations from ground targets, made it possible to identify certain military activities over very great distances. Such information is invaluable in determining the state of readiness or the intentions of a potential enemy. Modern high-speed airplanes of almost every type may be fitted out with photographic or other sensing apparatus for surveillance of enemy operations.

Except for certain specialized operations that are mentioned below, the external configuration of the airplane is generally unaffected.

Internally, cameras and associated equipment simply replace the guns and ammunition of the ordinary attack or fighter airplanes.

Two marked exceptions to this general rule are the early-warning patrol airplane and the antisubmarine warfare machines. In the first case there is needed a large airplane that can be sent out on extended patrol flights over land or sea. An example of such operations is the patrolling of the North Atlantic and Pacific oceans to extend the coverage of the U.S. Distant Early Warning system (DEW line) across northern Canada.

Large, four-engined airplanes, capable of remaining "on station" for 15 hours at a time: are equipped with elaborate radar antenna arrays connected to sensitive detecting apparatus so that they can pick up and track the approach of unidentified aircraft or missiles.

The detection of submerged submarines is a very difficult task, for which special airplanes were developed. A submarine traveling with only its snorkel above water is extremely difficult to detect on surface radars, and airplanes patrolling areas in which the presence of a submarine is suspected must be equipped with radar antennas of very large size if they are to be at all effective.

The housing of such radar antennas on a moving airplane presents a difficult aerodynamic problem and results in airplanes of

unusual configuration. However, these ungainly looking machines play an essential part in antisubmarine warfare.

An example of a very specialized design for surveillance purposes was the American Lockheed U-2 airplane that was shot down over the territory of the U.S.S.R. early in 1960. This airplane represented an excellent design solution for the mission for which it was intended. Efficient cruising performance at very high altitudes was achieved by careful attention to aerodynamic and structural details. The machine had a very high aspect ratio, characteristic of high-performance sailplanes or gliders, for long-range cruising efficiency. Structural and equipment weights were kept to a minimum to yield a low wing loading (pounds per square foot of area) for the same reason. Its single turbine power plant was designed for long-range fuel economy at cruising speed at the design altitude. This is an example of a highly specialized design, of little practical value apart from the specific mission for which it was designed.

5. Transport Airplanes.—Although in general configuration military transport airplanes may resemble those used on civil airlines, the basic requirements differ greatly. Airline airplanes operate on regular schedules, along prescribed routes and between fixed terminals, where routine maintenance and servicing operations can be carried out regularly. Military transports, on the other hand, may be called upon to operate in any part of the world, in a wide range of climatic conditions, along unmarked routes and often from poorly prepared fields.

The character of the cargo handled also is different from that carried in ordinary commercial services. Passenger accommodations need not be as spacious or luxurious and must be readily removable, in whole or in part, to accommodate cargo. In fact, for combat troop carrier operations personal comfort is a minor consideration.

For general cargo carrying, the facilities and equipment are similar to those described above for commercial cargo airplanes. Where air drop of military equipment (by parachute) is contemplated, airplanes are arranged so that large cargo packages or heavy equipment items (up to and including field artillery and light tanks) may be jettisoned from the rear of the airplane over the designated drop zone. For dropping paratroops extra doors are generally provided in the rear of transport airplanes so that the parachutists and their equipment can be evacuated from the airplane in the shortest possible time.

Very large military transport airplanes are capable of handling a number of trucks, tanks or other motor vehicles—or a complete intercontinental ballistic missile—in a single load. The cargo space of such airplanes may be of the order of 70 ft. in length and 15 to 20 ft. in diameter. Access to the cargo compartment is through large, double doors in the nose or near the tail of the airplane. Hoists and ramps are provided for easy loading of large and bulky pieces of equipment.

In the late 1950s the U.S. navy developed large cargo-carrying flying boats for operation at sea almost in the same way as light, cargo-carrying surface vessels. They were designed to load and discharge cargoes directly on beaches through doors and ramps at the bow. It was found, however, that loading, servicing and refueling were too time-consuming to be practical, and flying boats were abandoned in favour of large land-based airplanes.

A wide range of small civil-type airplanes are used in a number of ways by both the ground and air forces. Light, single-engined, two-seated airplanes may be used in battle areas for rapid transport of staff officers or the evacuation of wounded. Four, six- or eight-seated airplanes (single- or twin-engined) are also used for transporting military personnel or equipment. Built to more exacting specifications than the commercial versions, these light military transports are capable of operating successfully under difficult and hazardous conditions all over the world.

One highly specialized type of logistical support airplane is the flying tanker. The technique of refueling fighters and bombers in flight became commonplace after World War II. It is obvious that the tanker must be compatible with the airplane it is intended to serve; *i.e.*, it must be capable of flying at a range of speeds and altitudes at which the fighters and bombers fly.

Planes to be refueled approach the tanker from below and from the rear, where trailing tubes or a refueling hose can be picked up. With the planes flying in close formation, connections are established between the tanker's pumps and the aircraft to be refueled, and the required amount of fuel is transferred from one airplane to the other. One bomber or as many as three or four fighter airplanes may be refueled at the same time by a single tanker. Such operations came to be performed as a matter of routine by military aircraft. The record-breaking around-the-world flight of a U.S. bomber in 1958 was accomplished by refueling the airplane in this way.

6. Training Airplanes.—The complicated modern military airplane requires a high degree of skill on the part of pilots. Military training programs commonly make use of single-engined, piston-powered aircraft for primary training phases, with twin-jet trainers for transition stages. However, the British Royal Air Force in 1959 dispensed with piston-engined trainers and began initial pilot training on jet aircraft.

Primary training airplanes are generally of simplified construction, with a minimum of complicated equipment. The transition trainers are considerably more complicated. They are fast and highly maneuverable and can be fitted with a variety of complicated equipment found also in combat types.

Training in navigation is generally given on a class basis, in which groups of students are taken aloft in "flying classrooms," usually a twin-engined transport airplane containing a number of navigator's stations at which each student can make his own observations and computations while in the air.

Because the use of high-speed, high-performance military airplanes for training purposes is expensive, difficult and dangerous, a great deal of pilot and crew training came to be done on flight simulators. These consist of a completely instrumented airplane cockpit or flight deck installed in a classroom. By properly setting electronic controls, the instructor can present to the student, through the ordinary flight and navigation instruments, problems representing any conditions that may be encountered in actual flight. Some training machines are equipped to simulate visual and sound effects and even the motion of the aircraft. Flight simulators are expensive to build, but the saving of time and equipment is considerable, and invaluable hours of experience closely resembling that encountered in flight can be accumulated by the trainee on the ground. Not only military air services but the larger commercial airlines as well came to rely on flight simulators as an important training aid.

7. Research Airplanes and Special Types.—Apart from prototype and development models of airplanes designed for specific military uses, research projects involving special types of airplanes are sometimes sponsored by military departments. Such airplanes are not in themselves useful from the military standpoint, but they may lead to the discovery of new principles on which future military aircraft can be based. Such projects may range from a packaged single-engined, inflatable rubber airplane to the supersonic U.S. X-15, designed to explore the fringes of outer space. One strictly military application is the unmanned target drone. Any operational airplane, from a fighter to the largest bomber, may be fitted with radio-operated controls and used as a target by other airplanes using live ammunition. Sometimes drone airplanes have been flown through nuclear-bomb clouds, or in close proximity to nuclear explosions, to register the results of such explosions on the aircraft and on equipment carried by it. More frequently, however, small, high-speed, relatively inexpensive unmanned airplanes are designed, built and flown as targets for air-to-air or ground-to-air gunnery or rocket practice. Many of these airplanes are powered by small turbojet engines.

Specialized research aircraft include ground-effect machines, heavily slotted and flapped airplanes designed for short landings and take-offs, and "convertiplane" configurations designed for vertical take-off and high-speed horizontal flight by the rotation of complete wing and propeller systems from vertical to horizontal positions.

Two of the more important of these nonconventional types are the STOL (Short Take-Off and Landing) and VTOL (Vertical

Take-Off and Landing) aircraft. The exact definition of a short take-off and landing aircraft has not yet been standardized. Two definitions that have been employed are: (1) take-off and landing over a 50-ft. obstacle in less than 500 ft.; and (2) take-off and landing over a 50-ft. obstacle in less than 5 aircraft lengths. In either case such take-off and landing performance requirements confront the designer with a unique set of problems.

A conventional airplane derives the majority of its lift from its relative motion with respect to the air. In order to take off it must accelerate until its minimum speed is sufficient to keep it airborne. In its landing maneuver it decelerates from a similar speed. If conventional lifting systems were to be employed for STOL aircraft, the resulting accelerations and decelerations would in all probability be unacceptably great unless the minimum flight speeds were very low. As a consequence, STOL aircraft endeavor to utilize appreciable amounts of their thrust in a vertical direction to reduce the lift load that must be generated by their conventional lifting systems (wings, flaps, slats, etc.). For vertical flight the entire vertical force is achieved by some power-driven device that produces a vertical thrust equal to the weight.

Many arrangements for achieving successful vertical flight or short landings and take-offs have been designed or are under investigation. The first and so far the most successful of these is the helicopter. In this design the rotor produces the necessary lift, and translational motion is achieved by tilting the rotor plane in the desired direction. Greater thrust can be achieved by the addition of separate propulsive engines driving conventional propellers.

In some designs attempts have been made to reduce the high-speed vibration and drag of the rotor by the addition of stub wings that produce appreciable lift loads at high forward speeds, thereby unloading the rotor in this critical regime. The disadvantage of such arrangements is that, in hovering, the down-wash of the rotor produces large down loads on such wings, thereby compromising the hovering performance. In an attempt to avoid this difficulty, several alternate approaches have been attempted. These have ranged from tilting the entire aircraft through 90° after a vertical take-off from a tail sitting position, to tilting the power plants or the power plants and wings in combination. Propellers and rotors have been employed in many designs, and pure jet aircraft have also been used.

Irrespective of the technique employed to achieve the vertical thrusting force, all of these machines have certain problems in common. The first of these is the highly detrimental effect of the high-energy slip stream or jet striking the ground. Any loose material is thrown around with violence and forms a severe hazard both to the machine and to any personnel in the vicinity.

Because the entire lifting force arises from the engines in the hovering or low-speed regimes, power failure might prove to be catastrophic. The designer must therefore strive for the highest possible reliability and also provide adequate emergency systems to ensure the safety of the machine and its occupants.

The last major problem is that of low-speed stability and control. Because there is little or no flow over the normal control surfaces, entirely different types of controls must be utilized in the low-speed regime. Many different control systems, ranging from auxiliary jets and fans to differential control of the engines and propellers, are under study, but no single system has demonstrated clear superiority.

All of the aeronautical configurations described above are manufactured in small numbers and are then put through exhaustive test and evaluation programs at civil and military test centres.

(S. P. J.)

AIRPORT, a land or water area on which aircraft may land, and from which they may ascend. Airports are also called aerodromes (aerodromes), air terminals, air parks and air fields. In addition to the basic provision of a runway for aircraft operations, an airport must provide additional facilities in varying degree according to the functions and volume of operations planned for the airport. Airport runways, locations, control towers, passenger and cargo terminals, lighting, and standards for construction and operation are the major topics discussed in this article.

Runways.—A conventional heavier-than-air craft requires forward speed through the air in order to sustain flight. Attainment of the required speed is accomplished by means of a runway on which the aircraft is accelerated forward from a standing position to the take-off speed. The runway is used in the opposite manner for a landing. The aircraft is brought down to the runway at a speed which will just barely sustain flight, and then after the airplane is on the ground it is braked to a stop.

The runways are strips of the over-all airport area and are usually hard-surfaced with concrete or asphalt. In the case of a water surface for seaplane operations, the principles involved are the same, and protected strips of water are utilized for transferring the seaplane from water to air and return. In the case of ground facilities for helicopters, advantage is taken of the fact that these aircraft can rise and descend vertically. Even so, a limited area of land must be made available for maneuvering and landing purposes in helicopter operations.

Configuration.—An aircraft's speed is relative to the speed of the air in which the aircraft flies. Thus if an airplane is coming in to make a landing at a speed of 100 m.p.h. and is flying directly into a wind of 20 m.p.h., the airplane's speed over the ground is only 80 m.p.h. When this airplane touches a runway the heading of which coincides with the wind direction, the airplane must slow down to a stop from 80 m.p.h.; in this case, the wind helps it to slow down. If the airplane had landed with the wind, it would have been going over the ground at 120 m.p.h. It can be seen that a basic advantage is gained in bringing an airplane to a stop by heading it into the wind.

In the early days of aviation large open fields, grass-covered, were normally used for airports. Known as landing fields, these airports allowed a pilot to head directly into the wind to aid take-off and landing operations. The early aircraft were light in weight and could be supported by grass turf. Furthermore, the early aircraft were very sensitive to wind currents, and it was important for them to be headed directly into the wind for both take-off and landing. Under these circumstances an open field which could be utilized for take-off or landing in any direction became the most desirable type of airport.

In the 1920s, when aircraft became so heavy that hard surfaces were required to keep them from sinking into the turf or mud, efforts were still made to allow take-offs and landings in any desired direction. Several airports were constructed with large pads or hard surfaces in the middle of the landing fields, which allowed the aircraft to head in any direction for take-off or landing. Most airports, however, met the need for hard surfaces by the construction of concrete or asphalt runways. The aircraft of the 1920s—and to a lesser extent, of the 1930s—were still sensitive to cross winds, and most airports were provided with several runways in order that pilots could choose one having a minimum amount of cross wind at the time of take-off or landing. Furthermore, a study of wind directions and velocities for a particular airport location always preceded runway layout—as it still does today. These studies allow the runways to be so laid out as to minimize the amount of cross-wind operations required.

As aircraft have become heavier and faster, they have become less sensitive to cross winds. As a result, the number of runways required per airport has been reduced. A good example of this trend is shown by the experience at LaGuardia airport, New York city. When this airport was designed and constructed in the late 1930s, it was equipped with four runways, enabling pilots to land or take off in eight different directions. In the mid-1940s one of the runways was closed because it was too short for the large four-engined planes then being introduced. This deserted runway was

then converted to aircraft parking purposes. In the late 1950s a second runway at LaGuardia was closed, leaving just two runways, with four possible directions for take-off or landing.

In some localities it has been found practical to operate from a single runway. The runway at Hong Kong is an example of single runway operation. This particular runway was commissioned in the late 1950s.

In addition to the matter of numbers of runways to provide orientation with respect to the wind, there is the matter of numbers of runways to provide adequate capacity for heavy traffic areas. By the late 1950s a number of airports had been equipped with dual runways which permit simultaneous handling of incoming and outgoing traffic or provide extra capacity for the handling of heavier traffic in one direction. Other configurations include tangential schemes, where the runways in effect radiate tangentially from a centre area which serves as the terminal area. Simultaneous operations are carried on, with incoming aircraft landing toward the terminal area, and outgoing aircraft taking off in a direction away from the terminal area.

Lengths.—As aircraft have become faster, heavier and of longer-range operation, the requirement for runway length has grown. Table I shows how this growth has taken place for commercial passenger aircraft. The trend has been similar for military aircraft.

TABLE I.—Runway Lengths

Aircraft description	Time of introduction	Runway length required
Twin-engine 20 passenger plane with 180 m. p. h. speed and 24,000 lb. weight .	Mid-1930s	3,000 ft.
4-engine 50-passenger plane with 240 m. p. h. speed and 65,000 lb. weight .	Mid-1940s	4,500 ft.
4-engine 60-passenger plane with 325 m. p. h. speed and 85,000 lb. weight .	Late 1940s	5,500 ft.
4-engine 80-passenger plane with 360 m. p. h. speed and 120,000 lb. weight .	Early 1950s	6,500 ft.
4-engine 110-passenger jet plane with 550 m. p. h. speed and 300,000 lb. weight .	Late 1950s	8,500 ft.

The runway lengths shown in this table are based upon standard sea level conditions; actually, the length of runway required for take-off depends somewhat upon the density of the air. When the temperature is high, the density of the air is relatively low and the aircraft requires a longer than usual run along the runway before it can take off. The altitude of the airport also affects the air density. The airport at Denver, Colo., must have much longer runways at its altitude of over 5,000 ft. than would be required were Denver at sea level.

The lower air densities at high altitudes require all aircraft to run for a longer distance along the runway before attaining flight speed. The airplane must move along the runway at a sufficient speed to deflect downward a given mass of air. If the air is of relatively low density (high temperature or high altitude), the airplane must move faster to deflect the same mass of air, and to move faster the airplane must run along the ground for a longer distance.

In addition to providing sufficient length for the ground run on take-off and landing, a runway must be sufficiently long to allow for emergency conditions, such as an engine failure. Under governmental regulations prevailing in most countries, all aircraft designed and constructed after 1940 must have the capability, should an engine fail during take-off, of being able to either continue its take-off successfully with the power remaining from those engines still operating or of being able to come to a stop. These regulations thereby establish on the runway a point before which an aircraft taking off must be brought to a stop should an engine fail, and after which the aircraft must be capable of continuing and sustaining flight with its remaining power.

Some airports utilize arresting gear at the ends of runways for emergency purposes. This gear is designed to stop an airplane should it for any reason not be able to complete take-off or come to a stop on the runway. Military operations of the gear have been highly successful.

Surfaces.—Both asphalt and concrete have been used extensively for airport runway surfaces and for secondary surfaces, such as taxi ways and aircraft parking ramps. Each of these surfaces has

its own advantages. For example, concrete is more visible under nighttime landing conditions, while the black surface of asphalt aids snow clearing during winter months by absorbing heat and thereby speeding the melting process.

The friction (resistance to motion) of runway surfaces began to assume increasing importance during the late 1950s because of the long runway requirements of new aircraft being introduced at that time. In the Scandinavian areas an instrument which indicates values of the coefficient of friction of runway surfaces when the surfaces are covered by snow or rain water has been used. This instrument has been considered as a useful means for advising the pilot in the air as to what braking action he could expect at a runway. Such meters, if found fully practical, would be of use at airports all over the world.

Location of Airports.—The utility of an airport in serving a community is partially determined by its convenience of location to the businesses and residents served. Whereas the major transportation terminals for railroads, steamship lines and bus companies have been located in central metropolitan locations, the comparatively large land area required for airports, together with the need for a minimum of surrounding obstructions, has required relatively remote locations.

Most airport locations for the major cities of the world were selected and activated in the 1920s and 1930s. At the time of selection they generally represented a compromise between convenience of location and requirement for space and minimum obstructions. As aircraft have become larger and faster, they have required larger airports, and in a number of instances new locations became necessary. In the 1940s London, New York, Los Angeles, Calif., Baltimore, Md., Paris and other cities moved commercial air traffic to larger airports usually located more remotely than the previous airports. In the 1950s a few new airports were opened, but by and large the expansion of aviation facilities took the form of runway lengthening and terminal building enlargement or replacement. The locations and distances of a number of the major commercial airports of the world in the late 1950s are given in Table II.

TABLE II.—Major Commercial Airports

City	Airport	Code	Miles from city
Brussels Belg.	Melsbroek	BRU	3½
Buenos Aires, Arg.	Ezeiza	BUE	32
Chicago, Ill.	Midway	MDW	9
	O'Hare	ORD	16
Denver, Colo.	Stapleton	DEN	5
	City	DET	5½
Detroit, Mich.	Willow Run	YIP	31
	Metropolitan	DTW	19
Geneva, Switz.	Cointrin	GVA	3

	Heathrow	LON	15
London, Eng.	Gatwick	GWK	27
	Croydon		12
New York City, N.Y.	Wall Street (heliport)	JRB	0
	LaGuardia	LGA	8
	International	IDL	17
Paris, France	Le Bourget	PAR	9½
	Orly		9½
Zurich, Switz.	Kloten	ZRH	7½

The situation at Detroit represents an interesting example in the trends of location. In the 1930s the airlines used the City airport. In the mid-1940s, however, it was necessary to move to a larger airport because of the requirement for longer runways by the new aircraft then being introduced. The only available airport with suitable runway lengths was Willow Run, which is 31 mi. from Detroit. The need for a more conveniently located airport was felt keenly throughout the late 1940s and early 1950s. In the late 1950s a number of airlines moved their operations to the "Metropolitan" airport.

In the case of London the movement was from Croydon before World War II to Heathrow in the late 1940s, with Gatwick coming into service in the late 1950s to share the commercial load with Heathrow. Croydon could not be enlarged; it accommodated private flying until it was closed as an airport and converted to other purposes in the late 1950s.

Airport Communities.—Large airports have proved to be centres of self-created business and commerce. In a number of instances

London airport (Heathrow), showing the runways and terminal buildings. One of two commercial airports serving London, it is equipped with two separate terminal areas, one for short-haul European flights, the other for long-distance intercontinental flights

New York International airport (Idlewild), Queens. Under construction since 1942, it has facilities for accommodating all types of aircraft traffic, ranging from local commuter helicopters to long-distance transcontinental jet planes

TWO OF THE WORLD'S BUSIEST AIRPORTS

Zürich airport at Kloten, Switz., 7½ mi. from Zürich, showing the terminal building, with built-in control tower, and the passenger loading area

Expressway leading to the main entrance of the terminal building (foreground) of Orly International airport, Paris. The major airport construction was completed in the early 1960s

Gatwick airport, London, showing the 7,000-ft. runway. Built alongside the London-to-Brighton railway (foreground), it was the first airport in the world to contain road, rail and air services in one unit

Runway at Kai Tak airport, Hong Kong. The airstrip, built on a man-made promontory in Kowloon bay, is 8,350 ft. long and equipped to handle the heaviest jet aircraft traffic

O'Hare International airport, Chicago, Ill., showing the airfield (background), passenger terminals (centre) and aircraft parked along the loading tunnels. Major construction was completed in 1963

OTHER MAJOR AIRPORTS OF THE WORLD

Electronic flash approach system at Cleveland-Hopkins airport, Cleveland, O. Moving bursts of light (top) supplement the regular approach lights to guide plane under poor visibility conditions

T-shaped landing apron of Westland heliport, on the Thames, London. Opened in 1959, it was designed to accommodate all types of British and U.S. helicopters currently in use

New York downtown heliport on the East river, showing the 80- by 85-ft. landing strip. Manhattan's second heliport, put into operation in 1960, it provided 22 daily flights to and from LaGuardia, Idlewild and Newark (N.J.) airports

View of the main terminal building and loading area at Orly International airport seen from inside the control tower. Originally located at the eastern end of the field, the tower eventually was to be rebuilt on top of the terminal building

Newark, N.J., airport control tower at night. The 150-ft. tower, located between the two active runways, is electronically equipped to guide air and ground aircraft traffic

SPECIALIZED AIRPORTS AND CONTROL OPERATIONS

where airports have been constructed in relatively remote areas, housing has been constructed to accommodate airport workers, motels and hotels have been erected to accommodate travelers, businesses have found that travel and shipping advantages are obtained by having airport locations for offices and manufacturing plants, and airport communities have therefore grown into being.

Drainage and Soil.—One of the most important considerations governing the location and selection of an airport site is the nature and composition of the soil and subsoil upon which the airport is to be built. For the economical development of the area for aviation purposes, and especially for the life and durability of paved runways, taxi strips and aprons, detailed knowledge of the soil at the site, and especially its behaviour in contact with water, is vitally important.

Adequate drainage is especially essential to the proper maintenance of paved runways, for experience shows that more runway paving failures occur because of unstable subsoil conditions caused by lack of proper drainage than for any other reason.

Airport Control Towers.—In order to keep the air traffic within the immediate vicinity of the airport on an organized basis and to provide maximum protection against collision, a control tower, usually equipped with radar, is located at any airport having an appreciable amount of air traffic. The control tower operators normally talk by radio with pilots of arriving and departing aircraft to give them traffic directions and to notify them of the exact positions of other aircraft in the area. They also assign landing positions to incoming aircraft when there is more than one aircraft in the so-called landing pattern. The landing pattern represents the traffic flow of aircraft existing at any one time under the existing wind conditions. Thus a typical landing instruction from a control tower operator might be: "Eastern 33, you are number one to land; American 42, you are number two to land, follow Eastern in . . ." Under these circumstances the pilot of the American Airlines plane makes sure he sees the position of the Eastern Air Lines plane, and pilots of any following planes conduct their operations likewise. Tower operators watch the progress of the aircraft on the radar scanning screen.

In addition to directing the traffic flow in the air, the control tower operators must direct aircraft on the ground. When traffic becomes too heavy for one set of control tower operators to handle both air and ground traffic, the job is divided between two different groups of tower operators, one group directing traffic in the air, the other group directing traffic on the ground.

Passenger Terminals.—Purchase or confirmation of tickets, checking of baggage and boarding of aircraft are accomplished at the passenger terminal. In addition to these basic functions, the modern terminal building is being used more and more not only to accommodate waiting passengers but also to house shops, banks, restaurants, drug stores, hotels, etc.

Boarding Systems.—The systems for boarding passengers onto their aircraft have undergone extensive analysis and development, but as of the early 1960s there was no standard system for getting passengers from the terminal to the aircraft. Two systems have been in prevalent use: the trickle system and the group movement system. In the trickle system the airplane is parked at the gate approximately 20–30 minutes before departure and the departure time is announced. The passengers then trickle onto the airplane with check-in procedures stretched out over the trickle period. In the group movement system the passengers are assembled in a group. All processing is then completed before they are moved in a group to the aircraft immediately before departure. The latter system was extensively used in Europe during the 1940s and 1950s, while in most other parts of the world the trickle system was used.

Ownership.—Passenger terminals and the airports on which they are located are normally owned and operated by some agency of the state or city government. In some instances they are operated by publicly owned authorities (such as the Port of New York authority, which operates the airports of metropolitan New York city) which function under the administration of the state or other governmental appointed administration.

Cargo Terminals.—During the period immediately after World War II there was serious discussion about the possible establish-

ment of separate airports for use by cargo aircraft exclusively. Detailed consideration of the problems involved showed that such establishment would not relieve air traffic congestion or airport congestion because the heavy traffic periods for passenger traffic and cargo traffic do not coincide. Cargo nearly always moves at night. The shipper wants the cargo to be removed from his dock in the late afternoon and to be on the dock of the consignee early in the morning. Such a schedule calls for the cargo aircraft to be departing about midnight, when passenger traffic is at a low ebb. Also, much of the cargo moves on combination passenger-cargo aircraft, and it is therefore advantageous for both cargo and passenger terminals to be located at the same airport.

Cargo terminals are utilized largely for processing and sorting cargo as to destination. Through the late 1950s the vast majority of cargo moving by air did so in less than plane load shipments; therefore the terminals were being used as marshaling points for full plane loads, as well as distribution points for transfer to combination passenger-cargo aircraft. The means of transfer from terminal to aircraft were many and varied. They included fork-lift trucks with pallets, cargo cart trains, endless belt conveyors and lift-bed trucks.

Delivery of cargo at the terminals was practically 100% by truck, and the usual air cargo terminal was equipped with a truck level floor, at least for its receiving dock. The eventual use of full plane load shipments would permit the development of cargo terminals having direct transfer design features.

Airport Lighting.—Of increasing interest to airport operators and those who use airports is the matter of lighting. The revolving searchlight with green on the reverse side of the white beacon has long been the mark of an active airport. (See BEACON; LIGHT-HOUSES. Aerial Lights.)

Of maximum interest to pilots are the high-intensity approach lights which were introduced in the late 1940s and have become a standard installation item for all busy airports. These lights are normally installed along a line leading up to the runway, thereby directing the pilot to the active runway. The line of lights is normally along the centre-line extension of the runway and may extend beyond the bounds of airport property.

Other lighting installations at airports include runway lights which can be turned on or off by individual controls for each runway. The control tower operator can therefore turn on a set of lights which outlines both sides of the runway in use at the time. Runway lights are white, slightly elevated from the ground and are spaced 200 ft. apart along each side of the runway. Green threshold lights are placed across the ends of runways. Lights are installed along taxi-ways (along which aircraft move between runways, terminal areas and maintenance hangar areas) for guidance of pilots at night. By international agreement, these taxi-way lights are blue in colour.

Red obstruction lights clearly mark all obstructions surrounding an airport. High obstructions, such as radio towers, which extend more than 70 ft. above their surroundings are marked by lights at the top and at the one-third and two-third levels.

Air markers, signs painted or constructed on roofs or on the ground or painted directly on highways, are especially valuable to private flyers. The marker letters should be 10–20 ft. high and legible under good visibility conditions from a height of at least 3,000 ft.

Standards for Construction and Operation.—In order that logical construction criteria may be applied generally to airports, the governments of individual countries normally establish airport construction standards. The Federal Aviation agency has classified airports in the United States as follows:

Intercontinental express: airports serving major transoceanic flights.
 Intercontinental: airports terminating long international flights.
 Continental: airports serving aircraft making long nonstop flights.
 Express: airports at important cities or at junction points on trunk routes.
 Trunk line: airports serving smaller cities on air-line trunk routes.
 Feeder: airports serving certified feeder air lines,

Respective standards adopted in 1959 by the U.S. government for these classifications are given in Table III.

TABLE III.—Construction Standards for U.S. Airports

Airport classification	Runway		Taxi-way	Landing strip	Pavement loading (lb. per wheel X 1,000)	
	Length* (ft.)	Width (ft.)			Width (ft.)	Width (ft.)
Intercontinental express . . .	8,400	200	100	500	100	125
Inter-continental . . .	10,500	150	75	500	100	100†
Continental . . .	7,500	150	75	500	75	80†
Express . . .	5,000	150	60	500	45	60
Trunk line . . .	6,000	150	75	500	60	40†
Feeder . . .	3,500	150	40	300	15	20

*At sea level elevation and zero gradient.

†All loading based on single wheel.

While the construction standards establish various categories of airports, the purpose to which each individual airport is to be put is determined by the airline operators. Whereas a given airport may have been classified for short domestic flights, traffic demand and airline planning may require the airport's use for long-range flights. Under these circumstances, the airport runway length or surrounding obstructions may be restrictive to the aircraft operation. Also, an aircraft with relatively limited airport performance may not be able to operate at full design weights out of existing airports.

Limitation of airport funds, as well as natural and physical limitations to expansion programs, impose airport limitations upon scheduled airline operation. In order for an airline to operate safely and efficiently under these conditions, it is necessary for it to establish and maintain specifications for take-off weights and landing weights at each airport on its system. These specifications establish weights based upon existing temperature and wind at time of take-off for each operating runway at each airport. Analyses to establish and maintain such specifications are extensive and time consuming. They are a measure, however, of the care and attention which is given every aspect of commercial air transportation to assure the highest possible standards of safety. See AVIATION, CIVIL; see also Index references under "Airport" in the Index volume. (R. D. Sp.)

AIR POWER. Since the end of World War I, the definition of air power has taken either of two major forms. The first, which conforms with the popular conception, was expressed by Brig. Gen. William Mitchell when he said that air power is "anything that flies." The second narrows the conception of air power to the force that carries out what has become known as strategic bombing. This term denotes aerial attack upon targets usually well beyond the zones of ground and naval fighting — targets which represent mainly the sources of enemy strength (or his war potential) rather than his mobilized military strength.

The latter conception of air power emphasizes its independence from land and naval power in structure, operations and mission. It is thus differentiated from other forms of military aviation, such as naval aviation operated from ships or naval shore stations and the so-called tactical aviation; i.e., the operations of military aircraft in direct support of fighting ground forces. As one might expect, in practice these forms tend to merge. Thus, naval aircraft operated from aircraft carriers may be used to attack enemy strategic targets ashore. Also, aircraft operating in direct support of armies will usually be operated and controlled by the same national air force which controls the strategic bombing force, and they may, in fact, comprise segments of that force. Besides, the type of attack known as "interdiction" bombing falls somewhere between strategic and close-support bombing; it is directed against targets, such as transportation bottlenecks, that are usually far behind enemy lines.

The implements of air power formerly comprised only military aircraft and supporting facilities, such as air bases. Now air power must be considered to embrace also guided missiles wherever those missiles (q.v.) have taken over the functions of aircraft rather than merely of artillery. The difference is, of course, one of range. There is some tendency to use the term "space power" for long-range or intercontinental ballistic missiles, but space power has not yet and may never become operationally distinct from air

power.

A final problem of identification concerns the defense against strategic air attack, especially the so-called active defenses. Active defenses comprise instruments for shooting down attacking planes, as differentiated from passive defenses, which are concerned rather with the protection of targets through various forms of dispersion, concealment and "hardening" (or armouring, as in shelters). One would logically suppose that active defenses against attacking air power would also be considered to be an essential part of air power, but in these matters logic rarely prevails. Traditionally, the part of the active defenses that comprised fighter aircraft, known as interceptors, was identified with air power, whereas the operation of anti-aircraft guns was entirely an army function. When ground-to-air missiles of various ranges began to take over the functions of both anti-aircraft guns and interceptors, the mission allocation became blurred. In the United States the short-range defense missiles, such as the Nike-Hercules, were operated by the army; the long-range missiles, such as the Bomarc, were operated by the air force.

Origins of Theory. — Practically all theorizing about air power, as distinct from operations doctrine, has been concerned with establishing and emphasizing the importance of strategic bombing as a way of war. Because of the opposition in the older services to this point of view, much of the literature on the subject has, in fact, been polemical. Outstanding among the air power polemicists have been the American Brig. Gen. William Mitchell (q.v.) and the Italian Brig. Gen. Giulio Douhet. But only the latter was sufficiently gifted dialectically to be able to develop a coherent philosophy of the use of air power as a distinctive and independent method of warfare.

The basic ideas that Douhet was later to elaborate were, however, advanced in British and U.S. official circles more than a year before the end of World War I. In Great Britain a committee under the nominal chairmanship of the prime minister, but actually headed by Lieut. Gen. Jan C. Smuts (q.v.), presented to the war cabinet on Aug. 17, 1917, a memorandum recommending that a separate air ministry be formed without waiting for the war's end. That recommendation was acted upon favourably, and the air ministry, together with the Royal Air Force, was formed within a year. The memorandum contained also the following observation: "As far as can at present be foreseen there is absolutely no limit to the scale of its (air power's) future independent war use. And the day may not be far off when aerial operations with their devastation of enemy lands and destruction of industrial and populous centres on a vast scale may become the principal operations of war, to which the older forms of military and naval operations may become secondary and subordinate."

The British officer usually credited with prompting the advanced thinking reflected in the quotation above was Hugh M. Trenchard (q.v.), then commander of the royal flying corps with the rank of major general, and later to become Marshal of the Royal Air Force Lord Trenchard. Trenchard is supposed also to have influenced Mitchell, who, as a young major, visited him in May 1917.

The effect of his new thinking on Americans was also absorbed and exercised through the Bolling mission (headed by Col. R. C. Bolling) that left for Europe in the middle of 1917 to gather information about military aviation in Britain, France and Italy. Its members were considerably influenced by the Italian plane designer Giovanni Caproni, who was a close friend of Douhet and also of another Italian air theorist, Nino Salvaneschi. Salvaneschi, obviously sponsored by Caproni, whose commercial and intellectual interests coincided, had already published, in 1917, in English, a little book advocating strategic bombing as a means of ending the war. It was entitled *Let Us Kill the War; Let Us Aim at the Heart of the Enemy*.

Influence of Douhet. — All this, however, was merely a prelude to the work of Douhet, whose rather stormy wartime career (he was jailed for a year for his published criticism of the Italian general staff, but officially vindicated when the Caporetto disaster was held to have confirmed his criticisms) demonstrated his penchant for courageous and original thinking.

Douhet is, in fact, the philosopher or prophet of air power, en-

joying in this respect an ascendancy in the field comparable to that possessed by Alfred T. Mahan (*q.v.*) in the field of naval strategy. Mitchell was, by contrast, not a strategic theorist at all, being simply concerned with asserting the importance of military aircraft in all military uses, tactical as well as strategic. He was, like Douhet, intensely in favour of an independent air force, but more because he distrusted the conservatism of the older services than because he thought in any profound sense of an independent mission. He produced many original and valuable tactical ideas, but they are now of strictly historical interest, while Douhet's ideas are in their main outlines still very much alive.

Douhet's principal work was an essay published in Rome in 1921 under the title of *Il dominio dell' aria: saggio sull' arte della guerra aerea* (*The Command of the Air; Essay on the Art of Aerial Warfare*). The version published in 1927 was somewhat enlarged. This, plus several other essays published between 1927 and 1930, constitutes his major published work, all of which can be gathered into a single volume of rather modest size. A French translation in 1932 of a substantial part of the second edition of *The Command of the Air* was, in turn, translated into English in 1933 and put into mimeographed form for officers of the U.S. army air corps, where, in this critical formative period of American air power development, it was bound to be well received. In Britain the Royal Air Force was hardly less predisposed in its favour. The German air force, being revived in the 1930s under Hermann Goring, also fell into line.

The only major air forces that seemed at the time of World War II not to be inoculated with Douhet's ideas were the Japanese and the Russian, and the reasons for these two exceptions are obvious. In Japan, not only were there two air forces, one under the army and the other under the navy, but the conservative army and navy leaders were in control of the government. Besides, the heart of any enemy great power was bound to be a very long distance away from Japan, so that Douhet's ideas about strategic bombing were largely inapplicable to Japanese policy.

In the Soviet Union the control of the armed services by the government was absolute and complete. The purge of leading military officers that took place in the late 1930s swept away Lieut. Gen. V. B. Khripin, deputy air force commander up to 1937 and chief Soviet air theoretician. He had written, in 1935, the introduction to the Russian translation of Douhet's major work, and shortly before the end of his career he had been named first commander of the short-lived "Army of Special Designation," a combined long-range bombing and air-borne forces organization. A purge environment is not generally conducive to new ideas, and the special identification of Khripin with Douhet did not help the spread of the latter's ideas in the U.S.S.R.

Douhet's ideas were enormously influential, especially in Great Britain and the United States, but he was never widely read in those countries nor did his followers universally recognize their indebtedness to him. The method of the military profession of transmitting doctrine usually minimizes the importance of the original contributor. Thus, the influence of Douhet has sometimes been specifically denied by officers whose own thinking betrays strict conformity with his, not merely in such basic essentials as an over-all stress upon strategic bombing but also in details. Many of these details, as well as the essentials, helped to make up the philosophy with which the U.S. army air forces entered World War II, including, for example, a general lack of interest in fighter aircraft, either as interceptors or as escort planes for bombers, and an insistence upon bombing in daylight. The U.S. Flying Fortress or B-11 came the closest of any aircraft existing in its day to exemplifying the Douhet ideal of the battleplane.

Basic Tenets of the Douhet Philosophy. — To Douhet the old military maxim, derived from Jomini, that "methods change but principles are unchanging" had no sense. To him the advent of the airplane changed the basic character of war. For that reason he was totally uninterested in pre-World War I military history. He was even prepared to reject as irrelevant—presumably because it was too much concerned with the aerial duel—the experience in the military use of aircraft which that war had provided, and which was the only such experience available at the time of his writing.

The lessons he did draw from World War I were of an entirely different order. He was convinced, first of all, that that war proved the ascendancy of the defensive in ground warfare. Because of the strength of ground defenses, inferior forces could easily hold the enemy on the frontiers or wherever else they pleased, and he felt they should not try to do more. In the air, however, the offensive was not only the stronger form of war, it was the only valid form. Thus, his first and most basic tenet was: "Resist on the ground in order to mass in the air!" The nation's military resources, he held, ought to be mainly concentrated in air power, and all its air power ought to be concentrated in what he called the independent air force, rather than being dispersed in naval and army air arms.

The enemy air forces were to be destroyed where they could be most easily met and where they were most vulnerable, which was not in the air but on the ground. They should therefore be attacked immediately, in full force, at their bases. Douhet scorned air defenses and felt the attackers had nothing to fear from them. The side that moved first and most aggressively would, if it had the requisite strength, quickly win the air battle, after which everything else would fall into order. The morale of the enemy population was the next target, and because it involved civilians rather than professional military people, he assumed that it would be extremely vulnerable. He felt there would be no real occasion for air support of armies and navies, but in so far as it might prove useful he greatly preferred interdiction bombing to close support of ground troops.

Thus, the correctness of Douhet's position depended on: (1) the existence of static land fronts, relatively easily held by inferior forces; (2) a high incidence of physical damage and hence strategic and moral effects from each ton of bombs dropped; (3) the ineffectiveness of air defenses; and (4) the great vulnerability of civilian morale.

The Test in World War II.—World War II is of more importance historically as a test of strategic bombing than of Douhet's special theories, and the two should not be identified. Whether or not the general emphasis on strategic bombing was vindicated, it was clearly demonstrated that ground fronts need not remain static; that conventional bombs (excluding the nuclear variety) produced smaller physical effects than Douhet supposed; that, largely because air forces had to make repeated sorties to achieve their results, aerial defenses were of much greater effectiveness than he had thought likely; and that neither civilian morale nor the economy of any great nation was as vulnerable as Douhet thought. Thus, the frequent assertion that Douhet was proved right by World War II cannot be accepted. It is nevertheless true that Douhet deserves credit for having foreseen more vividly than his critics the enormous importance of strategic bombing in the future and also the importance of fighting the air battle by hitting appropriate targets on the ground rather than in the air.

It is difficult to assess the real contribution of strategic bombing in World War II. Against Germany it seemed to produce decisive results only in the very last stages of the war, when, first, the German oil and chemical industries and, later, the transportation system were effectively paralyzed. However, by that time the German armies had been defeated in the field, and the disasters at home contributed rather little to that defeat. The part of the strategic bombing campaign that contributed most directly to the success of the Allied armies was the destruction of the German air force, due less to the bombing of aircraft production than to the aerial fighting which attended the bombing forays and to direct attacks on German airfields. Also, in the late stages of the war the Germans were putting something like one-third of their total military resources into defense against Allied bomber attacks. Had it not been for the bombing raids these resources could have been added to Germany's already formidable ground strength.

It is also clear that in the strategic bombing of Germany the Allies made many critical mistakes, largely because of lack of experience. They made mistakes in their choice of industrial target systems, in their choice of actual aiming points, in the size of the bombs dropped (which were usually too small) and in the early rejection of fighter escort for daylight bombing (later remedied for

the U.S. forces with the introduction of the P-51 long-range fighter). If the Allies could have assumed fewer critical mistakes because of more experience or better planning, there can be no doubt that the effects of the strategic bombing of Germany could have been decisively felt much sooner.

Some of the lessons of the German experience were absorbed early enough to be applied with profit to the bombing of Japan. It is clear that far fewer tons of bombs did far more damage to the industry and population of that country than was true of Germany. However, Japan was a defeated country, and recognized to be such by some of its own military and naval leaders, before the strategic bombing campaign was well begun in the early months of 1945. The destruction wrought by the bombers did, however, put urgency into the work of the peace party in Japan and forced the recalcitrants to recognize that further resistance would be hopeless and extremely costly.

The great and unequivocal successes for air power in World War II are to be found rather in the fields of tactical military aviation, both on land and at sea, than in strategic bombing. Many of the sea battles in the Pacific were mainly battles of carrier-borne aircraft against ships. In the Atlantic, aircraft played an important role in the fight against the German U-boat. And in the European war their tactical role in support of ground troops was often the dominant feature in the battle. The most spectacular demonstration of direct air support to ground troops took place in the air operations incident to the landing in Normandy on June 6, 1944. The Allied air forces based in the United Kingdom, including the strategic bombing forces, through their interdiction bombing successfully isolated the battlefield before the landing; they also prevented the German air force from offering any real opposition to that enterprise.

One could say that if airmen were inclined to repeat their successes and recoil from efforts which were less successful, the experience of World War II would have caused them to drop their preoccupation with strategic bombing in favour of tactical operations. Instead, they remained loyal to ideas which antedated that war. However, the atomic bombs which appeared at the very end of the war actually vindicated them in their continued adherence to the Douhet philosophy. (For further analysis of World War II air operations see AIR WARFARE.)

Nuclear Weapons and Missiles.—There can be no doubt that the coming of nuclear and especially of thermonuclear weapons established the dominance of strategic bombardment in any unrestricted war of the future. If Douhet exaggerated the effects of high explosive bombs, then nuclear weapons far more than made up the difference. Nor can there be any doubt that the results of strategic bombing would now be achieved most swiftly. Because each weapon can accomplish so much damage, it is now agreed with Douhet that aerial defenses have an exceedingly difficult job to accomplish and very little time in which to do it. Moreover, because a small load of weapons can be so profitable to the attacker, distance to the target no longer has the significance that it had in World War II, when every extra pound of fuel meant one less pound of bombs in an exchange which, if it went too far, eliminated the worth of the transaction. Finally, with thermonuclear weapons, one of which can destroy an entire city with all its industry, the problem of selection of target systems and of aiming points presents none of the special difficulties it did in World War II.

In fact, it could be said that because of other technological trends affecting both the offense and the defense in strategic bombing, Douhet's philosophy and indeed the whole idea of strategic bombing would now be absolutely dead if it were not for nuclear weapons. Advances in jet propulsion and in the effectiveness of the defense have been such that bombers, in order to overcome that effectiveness, have had to attain a performance which has made them exceedingly costly to purchase and to operate. In repeated wartime sorties their attrition would undoubtedly be very high. Such sorties could hardly begin to be worth while if they could carry only chemical weapons. But so long as each aircraft can carry one or more nuclear weapons, the whole perspective of costs and attrition changes in favour of the offensive operation.

However, another change has apparently clinched the issue. The development of guided missiles, especially of the long-range ballistic variety (of which the German V-2 in World War II was the prototype), makes the prospect for successful active defense exceedingly dismal, if not hopeless. Passive defenses in the form of shelters can offer useful protection, but clearly the thing most important to protect is one's retaliatory force. Thus a new conception of protection has appeared that depends primarily on the deterrence residing in the threat of retaliation, a kind of protection which can aspire to high, but not absolute, effectiveness because of the dread consequences of that amount of retaliation which even a relatively small surviving enemy force could effect. (See also AIR DEFENSE.)

The Philosophy of Limited War: the Korean Experience.—It may be said, in short, that the nuclear bomb no sooner eliminated doubts about the effectiveness of strategic bombing than it began to stimulate questions about whether it had not become too effective. Is not strategic bombing too dread a sanction to be invoked in any but the most desperate circumstances where sheer survival is threatened? Would it not be possible for each side to stand down the strategic bombardment forces of the other by its threat of retaliation, while forcing the more or less inevitable outbreaks of local violence to be settled by local limited means? It would hardly have been possible to ask such questions, in view of the previously prevalent dogma that all modern wars must be total wars, if it had not been for the Korean experience of 1950–53, when the United Nations unexpectedly found itself in what turned out to be a limited war. The fact that it remained limited despite an enormous American superiority in strategic bombing forces and nuclear weapons, which were not used, could not have been predicted.

However, the idea of limited war leaves many questions unanswered. It has been easily assumed in some quarters that total wars are now impossible and that all attention can henceforward be devoted to finding ways of conveniently winning limited wars. For that reason many have advocated even the fighting of limited wars with nuclear weapons. The fact is, however, that very little is known about how to keep wars between great powers limited. The special circumstances which kept the Korean war limited are not likely to obtain on a similar occasion in the future. There are a number of reasons why the danger of total war is likely to remain real and substantial, and the dangers will definitely increase if they are ignored.

In limited wars, which may have to be fought with nonnuclear weapons, there was by 1960 no important experience more recent than the Korean war. In that war, air power made an important contribution in a tactical role, especially that part of it devoted to close support. Naval and marine aviation as operated from U.S. and British aircraft carriers had no doctrinal reluctance to engage in that kind of support, as well as in interdiction bombing and even some strategic bombing. The U.S. air force, however, found itself uncomfortable in a close-support role and insisted on placing its major effort into an interdiction operation informally known as Operation "Strangle." This effort, carried on for some months with the co-operation of U.S. naval aviation, finally proved to be a failure, chiefly for three reasons: (1) the ground fighting during that period was relatively quiescent, and the Communist troops were, therefore, not forced to use up their ammunition and supplies as fast as they would have in more active fighting; (2) the attacks on vehicles being necessarily halted at night, the Communist traffic limited itself to nighttime hours; and (3) the masses of cheap coolie labour available to the Chinese and North Korean Communists for hand transportation were extremely difficult to attack.

For the future it may be said with assurance that in an unrestricted nuclear war the role of air power, carried out both by manned aircraft and ballistic missiles, will be dominant and decisive. It will be destructive to the point of annihilation, at least to one side if not to both. The only political objective that can be served thereby is the elimination of the enemy who poses an intolerable threat to one's existence, and this presupposes that one can hit first and also hard enough to reduce drastically, if not

eliminate his chances of retaliation.

So far as limited war is concerned, everything depends on the kind and degree of limitation. If the use of nuclear weapons can be avoided, then the manipulators of air power have to reconcile themselves to playing a role ancillary to ground forces. In that case the doctrinal preference for interdiction, which had Douhet's sanction and which permits an independent mission to the air force, deserves to be re-examined. A movement in this direction was made in 1961 in the United States when strategic army corps and tactical air command forces were combined under the command of an army general. However, the use of nuclear weapons is bound to increase the relative importance of air power, and the air forces may thus be expected to have a bias for their use. The chief danger in their use is that it will be more difficult to keep wars limited. See also AIR WARFARE; MISSILES.

AIRSHIP, or dirigible balloon, a self-propelled aircraft that can be inflated with a gas lighter than air and can thus be sustained aloft by buoyancy. To distinguish it from the simple balloon, which has similar aerostatic characteristics but no propelling or steering system, the dirigible balloon is sometimes referred to simply as a dirigible.

Consisting of an elongated gas-filled streamlined hull, and possessing propulsive power, stabilizing surfaces, and altitude and directional control, an airship is classified by its structural type as nonrigid, semirigid or rigid. The body of a nonrigid airship, or blimp, consists of a fabric envelope highly impervious to lifting gas or air. The envelope maintains its streamlined form by the interior pressure of both the lifting gas and of air, the latter being contained in variable-volume compartments called ballonets which inflate and deflate to compensate for changes in lifting gas volume. The semirigid airship similarly depends upon internal gas and air pressure to maintain its envelope form but has, in addition, a supporting structural keel extending longitudinally along the bottom of the envelope.

Nonrigid and semirigid airships are known as pressure airships because of the pressure differential used to maintain envelope rigidity. This distinguishes them from the rigid airship, which maintains its shape through a rigid structural framework independent of internal gas pressure. This framework has an outer cover (generally fabric), and on the inside, individual lifting gas cells are placed throughout the ship's length, an installation that is comparable to the watertight compartmentation of water-borne vessels.

EVOLUTION OF THE AIRSHIP

Human flight was first made possible in 1783 by the invention of the free balloon, and there immediately followed a period of intensive balloon development (see AVIATION, HISTORY OF; BALLOON). Man's desire to contrive an aircraft which could be steered and propelled independently of the wind inevitably led to the airship. Thus, between 1783 and 1852, when the first airship was flown, numerous unsuccessful attempts were made to steer and propel balloons. These efforts failed primarily because of dependence upon primitive forms of manual power in the absence of suitable mechanical means of propulsion.

Finally, in 1851, Henri Giffard, the French inventor of the steam injector, overcame the airship power-plant problem by developing a 350-lb. steam engine of 3 h.p. which could drive a propeller 11 ft. in diameter at 110 r.p.m. The following year he constructed an 88,000-cu.ft. airship, 144 ft. long and 10 ft. in diameter, and mounted his engine on it. Giffard ascended in this hydrogen-filled

craft on Sept. 24, 1852, from the Hippodrome in Paris and, at an estimated speed of 6 m.p.h., demonstrated in a light wind the first appreciable control ever exerted on a lighter-than-air craft.

Initial application of the internal-combustion engine to airship flight was made by the German engineer Paul Haenlein, who, in 1872, completed and flew an airship propelled by a gas engine which drew its fuel from the envelope. The French brothers Albert and Gaston Tissandier were the first to build an electrically powered airship; their 37,500-cu.ft. craft, powered by a 1.5-h.p. electric motor, made a successful initial flight on Oct. 8, 1883.

The first airship to possess control sufficient to enable it to return to the point of ascent was the electrically powered 66,000-cu.ft. "La France," constructed of an envelope of Chinese silk and a car of bamboo trelliswork. Powered by an 8-h.p. electric motor and piloted by its constructors, Charles Renard and A. C. Krebs, this French airship made its first trial flight on Aug. 9, 1884, at Chalais-Meudon, completing a circular flight of about five miles.

A 130,000-cu.ft. aluminum-hulled airship, built and tested in Germany in 1897 by David Schwarz, was the first of the rigid type. Having an aluminum framework covered by aluminum sheeting, it was also the first airship powered by a gasoline engine. Meanwhile, Alberto Santos-Dumont, a Brazilian living in Paris, had become interested in lighter-than-air flight and in 1898 completed his first of a series of 14 nonrigid, gasoline-powered airships. These small airships performed a number of record-making and unusual flights which won world-wide fame for their constructor. In 1905 Santos-Dumont abandoned airship development to turn his inventive genius to heavier-than-air craft.

Of great importance was the first Zeppelin airship (LZ-1), a rigid type, which made its initial flight from a floating hangar on Lake of Constance, near Friedrichshafen, Ger., on July 2, 1900. The 388,140-cu.ft. LZ-1 was 420 ft. long and 38 ft. in diameter. Its designer was Count Ferdinand von Zeppelin, a retired German army officer, who, while serving as a balloon observer with the Union forces in the American Civil War, conceived the idea of placing a number of balloons in line within a streamlined structure which could be propelled and steered. The cigar-shaped aluminum frame of the LZ-1 consisted of 23 longitudinal girders, extending from nose to tail, set within 16 transverse frames or rings and braced by diagonal wiring. The entire framework was covered by a cotton cloth to protect the inner structure and to present a smooth outer surface. Inside the framework, between the transverse rings, were separate hydrogen-filled gas cells of rubberized cloth, while beneath the craft there was a keel-like structure connecting two external cars. In each of the cars there was a 16-h.p. engine geared to two propellers. A sliding weight secured to the keel was designed to afford vertical control by raising or lowering the nose, while rudders were provided for horizontal control. Despite structural weaknesses, the LZ-1 proved the practicability of the Zeppelin design and attained speeds approaching 20 m.p.h.

AIRSHIP OPERATION AND CONSTRUCTION

Flight Principles.—The Archimedean precept (see MECHANICS, FLUID) is the fundamental principle of airship flight. Airships lighter than the air they displace experience a buoyant force tending to make them rise; those which are heavier will tend to descend. An airship or balloon floats in the air whenever the sum of the weight of the gas container and other weights appended to it, plus the weight of the lifting gas itself, is the same as the weight of the air displaced by the gas. The lift acquired by an airship from the buoyancy of its gas is known as static lift. When a lighter-than-air aircraft is buoyant, it is said to be light. When its weight and static lift are equal, it is in equilibrium. It is heavy when its weight exceeds its static lift. Airships and simple balloons are most accurately described as displacement aircraft.

An airship is also subject to aerodynamic or dynamic lift derived from its motion through the air, its body and horizontal surfaces or stabilizers producing an appreciable lifting effect when driven through the air at an inclination. The airship utilizes this dynamic lift to meet either a heavy or a light condition in flight, a heavy ship flying in a nose up attitude and a light one flying nose down. The static condition of an airship varies in flight, depending

upon the amount of fuel consumed, the rain or snow loads acquired and the temperature of the lifting gas. Extreme heaviness can be remedied by jettisoning ballast, while excess lightness can be overcome by releasing lifting gas or by taking on sea water or other ballast. Large helium-inflated airships use equipment whereby water may be recovered from the fuel consumed to compensate for the weight of the latter.

Normal control of altitude by airships is maintained by putting the elevators (movable surfaces attached to the horizontal fins) in their up position or in their down position. Horizontal steering is similarly accomplished. The airship and the submarine are somewhat analogous in design and operational features.

Lifting Gases and Pressure Control.— In simple terms the buoyancy, or lift, equals weight of air minus weight of lifting gas. Under standard conditions (32° F., 29.92 in. pressure), 1,000 cu.ft. of dry air weighs 80.72 lb., 1,000 cu.ft. of pure helium weighs 11.14 lb. and the same quantity of hydrogen weighs 5.61 lb. Although coal gas is often used in sport ballooning, it is not light enough for airship use. Thus, under standard conditions 1,000 cu.ft. of pure hydrogen will lift 75.11 lb., while the same quantity of pure helium will lift 69.58 lb. Helium, therefore, possesses 92.67% of the lift of hydrogen. Under operating conditions 68 to 70 lb. for 1,000 cu.ft. of hydrogen and 62 to 65 lb. for 1,000 cu.ft. of helium are used as average lift values. The lesser lift of helium is offset by its complete nonflammability, an advantage which caused the U.S., in 1922, to adopt a "helium only" policy in airship operation.

Because the rigid airship is not dependent upon internal pressure to maintain its form, openings in the hull permit ready flow of air in and out to equalize internal and external air pressure. However: in the nonrigid and semirigid types, too much internal pressure places undue strain on the envelope or automatically releases lifting gas; too little pressure might cause the envelope to fold or buckle. The fluctuations in gas volume (and hence pressure, the pressure of a gas being proportional to its volume at like temperatures) are compensated for by varying the air pressure in ballonets that are separated from the lifting gas by fabric diaphragms. There are generally two ballonets, one forward and one aft, so that they may also be used for trimming purposes (attitude control).

Construction Details.— Rigid airship structures were usually made of aluminum alloys. Outer cover fabrics were generally of cotton, with linen sometimes used on the fins and movable surfaces. Gas cells were originally lightweight cotton fabric lined with goldbeater's skin for gastightness, but synthetic materials replaced the latter.

Nonrigid airship envelopes originally consisted of long-staple cotton fabric impregnated with rubber, but synthetics, such as neoprene and Dacron, superseded the cotton-rubber combination. An aluminum-pigment paint on the outside reflects the sun and reduces the amount of heat absorption by the lifting gas. Battens of stiff material around the blimp's nose reinforce it against buckling at cruising speeds.

In rigid airships the control car and other cars containing the propulsion plants usually were hung beneath the hull. In the U.S. navy's "Akron" and "Macon," however, the engines were located within the hull, driving outside propellers by means of shafting. In blimps the latter practice was followed in a few designs, but generally both the engines and propellers were mounted as units on the car in outside nacelles. In early blimps, cars were suspended by wires leading from suspension patches on the outside of the envelope. This practice was later succeeded by a system of internal and external catenary curtains.

Personnel, armament, power plants and virtually all the equipment of a nonrigid airship are carried by its car, which is equipped with a retractable wheel to make possible running take-offs and landings. Airship cars provide space for excellent habitability and for communications, navigational and other equipment.

Airships are equipped with lines used in ground handling operations to steady the ship and hold it in position or to pull light craft to earth. At the extreme bow of the airship is a disk mounting a horizontal spindle to which a hinged cone is attached. Moor-

ing is accomplished by drawing this cone into a cuplike device at the top of the mooring mast. With its nose held in this manner, the airship is free to rotate about the mast as the wind shifts, and if the mast is mobile, the airship can be docked, undocked and "walked" over the landing field.

DEVELOPMENT OF NONRIGID AND SEMIRIGID TYPES

Germany.— Despite the prominence of (rigid) Zeppelins in Germany, other types of airships also received attention there. Maj. August von Parseval, in 1906, constructed the first of about 28 Parseval pressure airships for the German army. In 1907 a semirigid airship was constructed by Maj. Hans von Gross and Nikolas Basenach; the last of four additional Gross-Basenach ships, completed in 1913, saw service with the German navy.

Great Britain.— Prior to World War I, Great Britain made little contribution to airship development, although a few private British experimenters, notably Henry Spencer, Dr. Barton and E. T. Willows, aroused sufficient interest to cause the government to begin airship construction in 1907. From that date to the outbreak of hostilities in 1914, about eight British pressure airships were constructed, varying in volume from 21,000 to 180,000 cu.ft., while an additional five were purchased from France and Germany. During the war period of 1914–18 seven nonrigid types were evolved for antisubmarine, antimine and coastal patrol duties. Great Britain built or used 207 nonrigid airships in 1914–18; of these, 56 were in active service from June 1917 to Oct. 1918. More than 9,000 patrol and 2,200 escort missions were made from 17 airship stations and 12 mooring-out sites. After the war, non-rigid activity ceased, but one commercial blimp, the 60,000-cu.ft. AD-1, was constructed in 1929.

France.— French interest lapsed considerably after Santos-Dumont demonstrated his series of airships. The first significant modern airship of native French design was the Lebaudy brothers' "Jaune" (1902). The Lebaudy success encouraged others. From 1904 until the outbreak of World War I, pressure airships for private use and for export were constructed for the French government in appreciable numbers by the Astra, Clément-Bayard, and Zodiac firms and by the government's factory at Chalais-Meudon.

The French army abandoned its airship activity in 1917, transferring eight ships to the navy. With an additional 52 airships, the French navy in 1917–18 performed more than 3,300 flights. These airships attacked about 60 U-boats and sighted about 100 mines. French naval nonrigid and semirigid airship activity continued after the war until 1937. During that period the French naval airship service operated an average minimum of two ships from the main operating base at Rochefort.

All airships built during this period were constructed by the sole remaining French airship manufacturer, Zodiac, which from 1924 to 1937 produced six nonrigid and four semirigid airships, varying from the 130,000-cu.ft. Vedette to the 350,000-cu.ft. Escorteur. In 1936 Zodiac developed for the French army a 35,000-cu.ft. motorized observation balloon with an attachable power and control gondola. It went into production in May 1910, and 21 were completed. The termination of navy airship activity by government decree in 1937 and of similar army activity by the German conquest in 1940 was made all the more complete by Allied bombings of airship hangars and by other war destruction.

Italy.— Italian airship construction embraced mainly the semirigid type. Several P- and N-type airships, 166,000 cu.ft. and 424,000 cu.ft., respectively, were designed and built by Gen. A. Crocco and O. R. Ricaldoni prior to World War I; several Forlanini semirigid airships had similarly been completed by the beginning of hostilities. During the period 1914–18 additional types were developed, primarily to increase altitude performance during bombing missions. In 1921 a 1,240,000-cu.ft. semirigid type, the "Roma," was sold to the U.S. army; this 410-ft. airship was shipped disassembled to the U.S., where it was re-erected. During a test flight on Feb. 21, 1922, the "Roma" crashed and burned, resulting in the death of 34 persons.

The well-known N-type Italian semirigid airship, developed by

Maximum speed, knots.....	53	53	67	69
Cruising speed, knots.....	40	40	50	50

Gen. Umberto Nobile, was the last airship type undertaken under government sponsorship. Italy officially terminated its airship program in 1927. On May 11, 1926, the 654,000-cu.ft. "Norge" (N-1), carrying an expedition headed by Roald Amundsen, Lincoln Ellsworth and Nobile, left Spitsbergen, passed over the north pole on May 12 and, continuing its 3,000-mi. flight, landed two days later at Teller, Alaska, where it was dismantled. The N-3, third of the Nobile series, was sold to Japan, where it was destroyed during naval maneuvers in Oct. 1927. Using the "Italia" (N-4), Nobile attempted another polar flight in May 1928, but after reaching the north pole, the ship crashed on its homeward journey with the loss of seven lives.

Russia.—Although Russia before World War I had shown an interest in airships by purchasing semirigid types from France, there was little concerted activity until about 1931, when a public subscription of 15,000,000 rubles toward an airship program was announced. The second five-year plan provided for the operation of airships on civil air routes within the U.S.S.R., and the services of General Nobile were secured. A number of small pressure airships were subsequently constructed, and in 1933 plans were announced to construct two larger commercial airships and a large metal-clad airship.

The Dirigiblestroï (Dirigible Construction trust) in 1936 began the 353-it.-long, 882,829-cu.ft. semirigid DP-9. In 1937 a Russian airship commission visited the United States to study American airship efforts and expressed a desire to purchase the U.S. navy's German-built rigid airship "Los Angeles." Russia operated a regular airline before World War II, using small airships in a service connecting Moscow with Sverdlovsk. It has been stated that Russia had 15 nonrigid and semirigid airships in operation and was seriously considering larger craft of the rigid type.

A Soviet request for U.S. blimps on a lend-lease basis late in World War II was refused by the U.S. In late 1945 it was disclosed that a small civil airship, the "Victory," had made an 80-hour demonstration flight over the Black sea. In Nov. 1946 the existence of another Soviet airship, the "Patriot," was announced; this 150-ft.-long craft was reported to be dual engined and capable of carrying 12 passengers with a one-man crew.

United States.—In the United States a few small privately owned pressure airships were built and flown by Capt. Thomas S. Baldwin, Lincoln Beachey and Roy Knabenshue immediately following the beginning of the 20th century. The first practical U.S. airship was Baldwin's "California Arrow" (1903), while the first U.S. government airship was a 19,500-cu.ft. craft purchased from Baldwin by the U.S. army in 1908. Two unsuccessful attempts to fly to the north pole were made in 1907 and 1909 by the explorer Walter Wellman in his airship "America." Using the same craft, Wellman in 1910 attempted a transatlantic flight which similarly failed. In 1912 Melville Vaniman took off from Atlantic City, N.J., for a transatlantic flight in the "Akron," but within 15 minutes after departure the airship caught fire and was destroyed with the loss of its entire crew of five.

U.S. naval airship activity began when the 175-ft.-long, 114,800-cu.ft. DN-1 was contracted for in 1915. Erected in a floating hangar at Pensacola, Fla., the DK-1 (later redesignated the A-1) was completed in April 1917; the craft proved unsatisfactory because of excessive gas leakage and was abandoned after three flights. In 1917 serious attention was given to the development of nonrigid airships for antisubmarine and coast patrol. The navy ordered 15 B-type airships (77,000 to 84,000 cu.ft.), which were completed in 1917-18 by the Goodyear Tire and Rubber company, Goodrich Tire and Rubber company and Connecticut Aircraft company. The B-class was followed by the 182,000-cu.ft. C-type, for which 30 (reduced to 10 after the Armistice) were contracted with Goodyear and Goodrich: the first C-ship was completed in Sept. 1918. During U.S. participation in World War I, U.S. navy blimps were based at seven Atlantic coast air stations, ranging from Chatham, Mass., to Key West, Fla., while other airships, acquired from the French, were operated from Paimboeuf, France. In May 1919 the C-5 attempted a transatlantic crossing. After flying from Montauk, Long Island, N.Y., to Newfoundland in 23 hours, the blimp was lost and never again sighted when strong winds tore it

away crewless from the hands of the ground crew and blew it to sea.

Five D-type airships (189,000 cu.ft.) were then built. A considerably modified D-ship, the D-6, was later produced for the navy. In 1918 and 1919 two small, single-engined, nonrigid airships were built, designated the E-1 and F-1, and purchased by the navy. A 400,000-cu.ft. "G" design was completed in 1919, but no ships of this type were constructed. A later class of utility and training ships (183,000 to 196,700 cu.ft.), which began with the G-1 (ex-Goodyear ("Defender")), was acquired in 1935. The only navy semirigid airship was the O-1, erected at Cape May, N.J., in Sept. 1919. Imported from Italy, this craft saw only three months' service. In 1921 the navy acquired the 43,000-cu.ft. single-engined H-1 airship, which could be towed or used as a kite balloon. The next naval airship type was the J-class, of which the first unit was completed in 1922.

Meanwhile, the U.S. army, which also had flown both observation (kite) balloons and blimps in Europe during World War I, proceeded with nonrigid and semirigid development from main airship bases at Langley field, Va., and Scott field, Ill. To investigate the semirigid design, the army purchased the "Roma" from Italy in 1921 and the 719,000-cu.ft. RS-1 from Goodyear four years later. The hydrogen-filled "Roma" was destroyed by fire, with the loss of 34 lives, on Feb. 21, 1922, after striking an electric power line at Langley field, Va. The RS-1, after several years of intermittent service, was dismantled and the army concentrated thereafter on nonrigid types and motorized balloons. Finally, in 1937, the army terminated its airship program and turned over its nonrigid airships to the navy.

In the period between World Wars I and II, United States civil airship activity was primarily limited to the operation of commercial and advertising blimps by the Goodyear company, constructor of virtually every significant U.S. airship after 1911. After experimenting with a small "pony blimp," Goodyear in 1925 began the operation of from one to six of its own nonrigid helium-inflated airships, which pioneered many airship flight and ground handling improvements. The capacity of these Goodyear blimps varied from 51,000 cu.ft. to 183,000 cu.ft. but was later standardized at 123,000 cu.ft., a size which carried six passengers. These craft were taken over by the U.S. navy for service in World War II. In civil employment through 1958, the Goodyear blimp fleet had carried more than 483,000 passengers and made over 178,000 flights without a single passenger injury or fatality.

In 1935, with rigid airship activity interrupted by the sinking of the "Macon" (see below), naval lighter-than-air efforts again centered about nonrigid development and operation of the 210,000-cu.ft. J-4, the 320,000-cu.ft. K-1 and the 202,000-cu.ft. ZMC-2. The J-4 was an open gondola ship completed in 1924, and the experimental K-1 was built in 1931. The ZMC-2, the first successful all-metal airship, was constructed in 1929 by the Metalclad Airship corporation of Detroit, Mich. Its hull consisted of 24 longitudinal and 12 circular frames to which an 0.0095-in.-thick outer cover of an aluminum-base alloy sheet was riveted. Although possessing certain rigid construction characteristics, the ZMC-2 was, nevertheless, a pressure airship, depending upon internal pressure to maintain hull strength in flight. Although the craft had a long successful life prior to dismantlement, no other metal-clad airships were built. The 183,000-cu.ft. Goodyear-owned "Defender" was acquired by the navy in 1935 and designated the G-1.

Increased airship strength was authorized as the entry of the United States into World War II drew near, and at the time of the Pearl Harbor attack the navy was operating four K-type patrol airships and three small L-type trainers (all built in 1938-41), as well as the G-1 and the ex-army TC-13 and 14. The airship building program was accelerated, and an improved G-type and new M-type ship evolved. During the war the navy operated a total of 134 K-type (425,000 cu.ft.) and 4 M-type (647,500 cu.ft.) patrol airships, 22 L-type training ships of 123,000-cu.ft. capacity and 8 G-type (196,700 cu.ft.) training and utility blimps.

Except for those used primarily for training and experimentation, U.S. navy airships of World War II were grouped into 14 U.S. fleet blimp squadrons, which, operating from more than 50 main and

auxiliary bases, performed antisubmarine patrol and escort operations in a 3,000,000-sq.mi. area along the U.S. Atlantic, Gulf and Pacific coasts, in the Caribbean, along the South American coast from Panama to Rio de Janeiro and in the Mediterranean. A fleet blimp utility squadron operated similarly from five bases along the Atlantic seaboard. These 15 squadrons flew a total of 55,900 flights for 550,000 hours and escorted 89,000 ships without the loss of a single vessel to enemy action. Of the blimps assigned to fleet units, 87% were in operational readiness at all times, thereby establishing a record availability for military aircraft.

The first nonrigid airship transoceanic flight was made in 1944 when blimp squadron 14 was ordered based with six K-ships at Port Lyautey (now Kenitra), former French Morocco, for patrol of the Straits of Gibraltar. The blimps were ferried across the Atlantic in pairs from South Weymouth, Mass., via Newfoundland and the Azores. The first flight (3,145 mi.) was made on May 29–June 1, 1944, by the K-123 and K-130 in a total flight time of 58 hours. In 1945 two additional K-ships were flown to Port Lyautey from Weeksville, N.C., via Bermuda and the Azores; the 3,532-mi. flight was completed in a flight time of 62 hours.

Although antisubmarine operations were the main duties of U.S. navy airships during the war, their unusual flight characteristics were valuable in general utility missions. Used in shipping control to direct and facilitate the rendezvous, formation and breakup of merchant convoys, airships saved a great deal of shipping time. Torpedo recovery, aerial photography, observation, special equipment calibration, search operations, rescue work and other services requiring slow speed and low-altitude operations for extended periods of time were performed in great numbers and variety for fleet and shore units. In the Mediterranean, airships assumed unprecedented importance in mine sweeping operations by spotting and marking otherwise undetected mine fields and through saving a number of mine sweeping vessels by diverting them from collision courses with mines the mine sweepers could not see.

With the end of World War II, U.S. naval airship activity was materially reduced, only to be expanded upon the outbreak of the Korean war in 1950 and then reduced again. Various configurations of the K-patrol-type blimp were evolved, with increased volume up to 670,000 cu.ft. On Nov. 2, 1946, the 725,000-cu.ft. XM-1 (formerly the 647,500-cu.ft. M-1) completed a 170-hr. 17-min. world's aircraft endurance record for continuous unrefueled flight. In 1953 the first N-type blimp, subsequently designated the ZPG-2 type, was placed in service. This 1,000,000-cu ft. ship resulted from a project begun late in World War II to achieve increased blimp performance mainly in amount of equipment carried. The ZPG-2W was a configuration intended specifically for airborne early warning service. On July 1, 1957, one airship squadron took its place in early warning service at sea and quickly demonstrated the airship's all-weather reliability, economy and high technical efficiency in such service. Other blimp units continued as part of the antisubmarine warfare team. In March 1957 a ZPG-2 airship completed an unrefueled flight of 264 hr. 14 min. for a new record distance of 8,216 nautical (9,448 statute) miles over the North Atlantic and the Caribbean. This also broke the 6,980-mi. nonstop record made by the airship "Graf Zeppelin" between Friedrichshafen and Tokyo in 1929. On July 21, 1958, the first of the ZPG-3W type of over 1,500,000-cu.ft. volume, largest blimp ever built, made its maiden flight. Its most unique feature was the installation within the envelope of a large radar antenna, giving this craft valuable early warning service capabilities.

DEVELOPMENT OF RIGID TYPES

Germany. — In the category of rigid airships Count Zeppelin's only competitors were Johann Schütte and Heinrich Lanz, who evolved a rigid design using a spirally disposed wooden girder type of construction. Their first ship, a 700,000-cu.ft.-capacity, 430-ft.-long, 60-ft.-wide craft, was completed in 1911 and attained a speed approaching 50 m.p.h. During World War I the Germans standardized on the Zeppelin type, and a total of only 20 Schütte-Lanz airships were built and flown. At four fabrication plants 88 Zeppelins were built, a production rate of one ship per two weeks being achieved. These ships operated with the German army and navy

in bombing strategic areas and in North sea scouting and patrol (see AIR WARFARE). Their bombing activities, however, were gradually rendered ineffective by improvement of Allied defense measures, particularly the employment of incendiary devices for setting the Zeppelins' hydrogen afire. To get greater range and larger bomb loads and to fly higher and faster, the Zeppelins underwent remarkable improvements during this period. By 1918 their size had increased to 2,400,000 cu.ft., their speed to 80 m.p.h., their useful lift to 50 tons, and their ceiling to over 20,000 ft. They were armed with machine guns mounted in the cars and atop the hull for protection against airplanes. They also had a car or "spy basket" which could be lowered beneath the clouds to permit the observer in this car to navigate or direct bombing while the airship remained hidden above. Of German naval airship employment, only about 10% was in bombing raids, 90% having been on strictly naval missions. Zeppelin activity ceased temporarily with the capitulation of Germany in 1918. Existing Zeppelins were dismantled or delivered to France, Italy, England, Belgium and Japan. A few were sabotaged by their crews.

Success of the Zeppelin type had led to the formation in 1910 of the Delag, or Deutsche Luftschiffahrts-Aktien-Gesellschaft, which provided commercial and pleasure flights in airships up to the outbreak of World War I in 1914. During those five years, Delag's five small airships made 1,588 flights, carrying 34,228 passengers without injury. Two small commercial Zeppelins built immediately after the Armistice carried 2,380 passengers, all in safety, in 103 flights before being surrendered — the "Bodensee" to Italy, the "Nordstern" to France. Under Allied terms, later lifted, the Germans were prohibited from undertaking further airship construction.

The next Zeppelin airship was the 2,470,000-cu.ft. LZ-126, which was constructed as a war reparations payment to the U.S. Later christened the "Los Angeles," it was delivered to the U.S. in a transatlantic flight in Oct. 1923. The "Graf Zeppelin" (LZ-127), a 3,308,600-cu.ft. ship completed in Sept. 1928, saw nine years of successful continuous service. When decommissioned in 1937, the "Graf Zeppelin" had made 590 flights (including 144 ocean crossings) and had flown 1,053,391 mi., carrying 13,110 passengers and 235,300 lb. of mail and freight. In 1929 Hugo Eckener, successor to Count Zeppelin, who died in 1917, commanded the ship on a 21,255-mi. world flight that was completed in an elapsed time of 20 days 4 hr. 14 min.

The LZ-128 did not progress far beyond the blueprint stage and was followed by the 7,063,000-cu.ft. "Hindenburg" (LZ-129), completed in 1936. This 804-ft.-long airship, of conventional Zeppelin design with 36 longitudinal girders and 15 wire-braced main transverse frames, was powered by four 1,100-h.p. Mercedes-Benz diesel engines, giving it a maximum speed of 84 m.p.h. At a cruising speed of 78 m.p.h., the "Hindenburg," which contained accommodations for 50 passengers, had an 8,750-mi. range. In 1936 this airship inaugurated commercial air service across the North Atlantic by carrying 1,002 passengers on ten scheduled round trips between Germany and the U.S.; westbound crossings averaged 65 hours; eastbound, 52 hours. On May 6, 1937, while landing at Lakehurst, N.J., on the first of its 1937 schedule of North Atlantic crossings, the hydrogen-inflated "Hindenburg" burst into flames and was completely destroyed, with a loss of 36 lives — the first passenger fatalities in the history of commercial airship operation. The fire was generally attributed to a discharge of atmospheric electricity in the vicinity of a hydrogen leak; however, the possibility of sabotage cannot be overlooked.

The LZ-130, bearing again the name "Graf Zeppelin," was completed and tested in Sept. 1938. Designed for helium operation, this slightly modified sister ship of the "Hindenburg" was built for transatlantic commercial service, but the tense international situation at the time, together with the refusal of the U.S. to export helium, prevented the use of the ship for that purpose. Inflated with hydrogen, the LZ-130 made 30 exhibition and test flights for a total of 400 hours but saw no commercial or war service.

With the completion of the LZ-130 in 1938, work was begun on the LZ-131, but as the outbreak of World War II approached, the German government in July 1939 directed the Zeppelin company to

discontinue all lighter-than-air manufacture. Finally, in April 1940, another Nazi directive ordered the dismantlement of the LZ-130, the old decommissioned "Graf Zeppelin" (LZ-127) and the main zeppelin operating terminal at Frankfurt am Main; the reason given was the war need for duralumin and steel. Later, in July 1944, Allied bombings of Friedrichshafen resulted in the destruction of the hangars, shops and production facilities of the Zeppelin company, then engaged in the production of miscellaneous war materials.

Great Britain.—In 1911 the British 660,000-cu.ft. "Mayfly," modeled along zeppelin lines, was completed but never flown; it broke in two while being brought out of its shed at Barrow. Rigid construction was not undertaken again until 1914 when work was begun on the R-9; this airship was completed three years later. Six rigid airships (two modified to abolish external keels) of the R-23 class were next laid down, followed by the R-31 and R-32, which were of wooden construction. None of these, however, equaled the products of the experienced Zeppelin designers and constructors. The German Zeppelin L-33, shot down in good condition over Essex in 1916, served as a model for the next British rigid airships, the R-33 and R-34. They were completed in 1919 and were of marked improvement; in fact, the R-34 made a transatlantic flight from East Fortune, Scot., to Mineola, N.Y., in July of the same year and returned to England, the first aircraft to cross the Atlantic nonstop from east to west and the first to complete a transatlantic round trip by air.

Two additional rigid airships, the R-80 and R-36, were launched in 1920 and 1921. They were followed by the 2,700,000-cu.ft. R-38, which was to be purchased by the U.S. navy. On its fourth flight, on Aug. 24, 1921, this craft, designed for high altitude operation, broke in two under severe handling at low altitude and fell into the Humber river, killing 44 British and U.S. officers and men. The R-38 disaster brought British service airship activity to a halt, but in 1924 an empire communications scheme was undertaken, calling for British construction of two commercial 5,000,000-cu.ft. rigid airships, the R-100 and R-101. Both were completed in 1929, the former by the Airship Guarantee company at Howden and the latter by the Royal Airship Works at Cardington. The R-100, with accommodations for 100 passengers, was built on a modified Zeppelin design with six gasoline engines. Its two-year life was relatively uneventful, although in July 1930 it flew to Montreal, Que., in 78 hours, returning in 58 hours. The R-101, lengthened after completion to increase its lifting capacity, accommodated about 50 passengers and deviated substantially from Zeppelin practice by using steel girders and five diesel engines. During an attempted flight on Oct. 5, 1930, to India, the R-101 crashed into a hill near Beauvais, France, and burst into flames, killing 48 persons. (The unreadiness of the ship for such an undertaking had been no secret.) Following this disaster, the government scrapped the R-100 in 1931 and abandoned airship activity indefinitely.

France.—After the World War I Armistice considerable interest in rigid airships was shown by the French government. Only one of this type had previously been constructed in France, the none too successful "Spiess," a privately owned wooden type built by the Zodiac firm in 1912. Three Zeppelins, the L-72, LZ-113 and the small commercial "Nordstern," were turned over to France by Germany in 1920-21. The last two saw little active service prior to dismantlement, but the 2,470,000-cu.ft. L-72 (renamed the "Dixmude" by the French) established an endurance record of 118 hr. 41 min. in Sept. 1923.

In December of the same year the "Dixmude" was lost over the Mediterranean with its entire complement, ending rigid airship activity in France.

United States.—In 1919 the U.S. navy began construction of the 2,115,174-cu.ft. ZR-1. Fabricated at the Naval Aircraft factory, Philadelphia, Pa., and assembled at the Naval Air station, Lakehurst, N.J., this ship, christened the "Shenandoah," was largely a copy of the German Zeppelin L-49 design, modified mainly for mooring mast and helium operation. Her maiden flight on Sept. 4, 1923, was followed by a number of noteworthy flights, including a 9,000-mi. transcontinental round trip in Oct. 1924. On Sept. 3, 1925, the "Shenandoah" failed structurally in a thunderstorm near

Ava, O., and 14 members of her crew of 43 were killed.

On Oct. 15, 1924, the German Zeppelin Airship Works delivered the 2,470,000-cu.ft. ZR-3, later christened the "Los Angeles," to Lakehurst, N.J., after a 5,000-mi. flight from Friedrichshafen, where the ship had been constructed as a war reparations payment to the U.S. This 658-ft.-long dirigible was used extensively for experimental work on flight and mooring problems and developed a means for hooking-on and releasing airplanes in flight. After 331 flights, consuming a total of 4,320 hours, the "Los Angeles" was decommissioned at Lakehurst in 1932 and dismantled seven years later.

The German Zeppelin patents and processes, together with the services of key Zeppelin personnel, were acquired in 1924 by the Goodyear Tire and Rubber company, which then formed a subsidiary, the Goodyear-Zeppelin corporation, in Akron, O. In 1928 Goodyear-Zeppelin (later Goodyear Aircraft corporation) began the construction of two 6,500,000-cu.ft. rigid airships for the navy. Both ships were 785 ft. long and 133 ft. in diameter, with a cruising range of 6,500 mi. and a maximum speed of 72 knots. The novel power plant installation consisted of eight 560-h.p. Maybach engines mounted in separate engine rooms within the hull and driving propellers so mounted on outriggers that they could be swiveled to produce a vertical lifting component. To compensate for weight lost through fuel consumption, water recovery apparatus was installed, with exhaust condensers mounted on the hull above the engine rooms. Each ship also carried a trapeze for the landing and launching of airplanes and had an internal hangar for five planes. The "Akron" (ZRS-4) was completed in 1931 but, after about 1,700 hours of service, crashed, with the loss of 73 lives, on April 4, 1933, in a storm off the New Jersey coast. Her sister ship, the "Macon" (ZRS-5), was launched the same month and operated primarily from the new airship base at Sunnyvale, Calif. On Feb. 12, 1935, while returning from fleet maneuvers, the "Macon" suffered failure of her upper fin structure, resulting in loss of control. With severe gas leakage and accompanying structural collapse, the "Macon" settled to the sea and slowly sank off the California coast; all but two crew members were rescued. She had flown 1,798 hours.

The loss of the "Macon" left the navy without an operational rigid airship and led to numerous naval, governmental and civil investigations to determine the safety and practicability of rigid airships. Since the results of these investigations endorsed further dirigible construction, a 3,000,000-cu.ft. navy rigid airship was authorized in 1938. However, money appropriated by congress to begin its construction reverted to the treasury after delays in selecting the design and size; subsequent funds were not voted, and the ship never progressed beyond the drawing board stage.

AIR SICKNESS: see MOTION SICKNESS.

AIR UNIVERSITY, U.S.A.F., a centre for the professional education of air force officers, was established in 1946 at Maxwell air force base near Montgomery, Ala. It includes three general service schools at Maxwell—the squadron officer school offering a 14-week course for company grade officers with approximately 5 years of service; the command and staff school offering a 9-month

course for field grade officers with about 10 years of service; and the air war college offering a 10-month course for selected officers with 15 years of service. A warfare systems school offers instruction in the employment of aerospace vehicles and weapons. The air university is also the home organization for air force officers who instruct in, or attend as students, schools of the other armed services. Associated with the university is the school of aviation medicine at Randolph air force base, near San Antonio, Tex., which instructs medical officers and airmen and conducts research on the physiology of flight. Another associated activity is the air force institute of technology at Wright-Patterson air force base, near Dayton, O., an engineering school that offers some resident courses and sends selected officers to civilian colleges and universities for special instruction. The air force reserve officers training program (R.O.T.C.) in civilian colleges and universities is administered by the air university.

The extension course institute of the air university offers correspondence courses related to the resident courses of both the air university and the air force training command. The research studies institute includes the arctic, desert, tropic information centre, the documentary research division and the historical division. The air force reserve officers training program in civilian colleges and universities also has its headquarters at Maxwell air force base. The Air University Quarterly Review is a professional journal published at the air university. (J. C. SH.)

AIR WARFARE. As understood during the first half of the 20th century, air warfare was based on the use of armed and armoured flying machines capable of carrying bombs. Strategic air warfare was concerned with bombing attacks against an enemy's industrial home front, although the strategic bombers themselves were also used for other purposes. Tactical air warfare was concerned with operations by fighter bombers, light bombers and transports in the immediate vicinity of ground or naval battles.

The air warfare of the 20th century was faintly but unmistakably foreshadowed when Louis Blériot (*q.v.*) flew across the English channel from Calais, France, to Dover, Eng., on July 25, 1909—less than six years after the first flight of Orville and Wilbur Wright in the United States. Most of the important world powers at once took steps to organize air arms, but many military men still looked upon the airplane with little respect; Ferdinand Foch declared before 1914 that the airplane would never be more than a sporting device.

World War I quickly proved the military value of the airplane, first for observation and later for various other purposes, especially support of ground troops and bombing. The Germans bombed London during the war and the Allied air forces attacked industrial centres in western Germany. But major efforts of both air forces were devoted to the support of the massive ground battle.

World War II saw use of the air weapon on an enormous scale by all major powers. From the time the Germans attacked Poland in Sept. 1939 until the second atomic bomb was dropped on Nagasaki, Jap., on Aug. 9, 1945, air power was a major weapon in every campaign of the war. The appearance of jet aircraft and guided missiles in 1944 provided the means whereby the air warfare of the future would be revolutionized. Meanwhile, the concept of strategic air warfare as a means of destroying an enemy's will and capacity to resist was tested.

In the period after World War II, technological developments pointed to the emergence of long-range missile warfare. The leading nations of the world worked to produce intercontinental guided missiles equipped with atomic and thermonuclear warheads which could devastate urban areas. Neither guided missiles nor atomic weapons were used in the Korean war of 1950–53, but this war hastened the shift from conventional to jet-propelled aircraft by all major air forces of the world. (See also AIRCRAFT CARRIER; AIR FORCES; AIRPLANE; AIR POWER; WORLD WAR I; WORLD WAR II; KOREAN WAR.)

AIR WARFARE IN WORLD WAR I

Although there were some who recognized the potentialities of the airplane as a weapon prior to 1914, the military leaders of the major powers did little to make the airplane a practical, effec-

tive military weapon. Progress in the development of such important items as bombsights and aerial machine guns, for instance, was made by individual inventors on their own initiative, frequently in the face of lack of interest or encouragement from the military leaders.
