Meanwhile monasteries had multiplied and grown both in size and in wealth, and were often great institutions with many ranges of buildings and manifold activities (see MONASTICISM; MONASTERY). though in wilder districts, such as northern England, simpler establishments continued to exist. During the six centuries following the death of St. Benedict these monasteries were the sole repositories of learning and literature in western Europe, and almost the sole executants of the small-scale arts and crafts of civilization, such as the writing, binding and illumination of books. They were also the principal educators, their recruitment coming largely from the children committed to their care, and at certain times and in certain regions they also maintained schools for outside pupils. As a result of these employments, and of the increasing frequency with which monks proceeded to holy orders, the practice of agricultural and heavy craft work ceased.

Charlemagne had endeavoured to unite all the monasteries of his empire in a great federation governed by the rule and a single code of customs. The attempt was too grandiose for the age, but the code was widely applied and imitated and the monks came to have a new sense of family relationship, though each abbey remained autonomous. The first real attempt at closer organization came from the Burgundian abbey of Cluny, founded near Mbcon as a reformed house in 910 by William the Pious, duke of Aquitaine. Cluny often was approached to reform other monasteries, and a succession of saintly, able and long-lived abbots, outstanding among whom were Odo, Maieul, Odilo, Hugh and Peter the Venerable, gradually built up in every country a great network of monasteries that followed the Cluniac customs and looked to Cluny for the maintenance of discipline. In time this control was tightened and regulated; the dependencies, most of which either were founded as or degraded into priories, were under the direct jurisdiction of the abbot of Cluny, to whom the monks took their vows and who had the right of appointing all superiors. The daughter-houses'depended in a similar way upon their founders, and the whole "order," as it came to be called, formed a great quasi-feudal family long distinguished by strict discipline and a rich and exacting round of liturgical services. Nevertheless, though Cluniac houses were found as far apart as England, Spain and Italy, the monasteries of certain groups and regions, including (with a few exceptions) England, Germany, Normandy and southern Italy, remained outside the Cluniac organization, though they adopted, to a greater or less extent, the Cluniac customs.

Meanwhile, in England the character and rhythm of the monastic movement had been somewhat different. The only monastery known with certainty to have been founded by Augustine was at Canterbury, and there, very probably, the rule was known, but the monasteries that later were founded throughout the country seem either to have been modeled on pre-Benedictine abbeys in Gaul or, as in Northumbria, to have been offshoots of Celtic monachism. The rule was first introduced into the north by St. Wilfrid, but the real father of Benedictine monachism in England was Benedict Biscop, a Northumbrian who visited Rome and Gaul and in 668 was appointed abbot of St. Peter and St. Paul at Canterbury; later he went to Northumbria, where he founded Wearmouth (674) and Jarrow (682) in the primitive simplicity recorded by Bede, but equipped with books and a zeal for learning that made them, for more than 50 years, the brightest centre of letters and art north of the Alps. In them Bede and his disciples. and the artists of Lindisfarne, set up a tradition of learning and artistic achievement that influenced, through Alcuin and others, the whole of north-

western Europe. At the same time, learning of a more strictly classical kind had spread from Canterbury to houses in the west such as Malmesbury and Glastonbury. This first phase of English Black Monk life came to an end in the 9th century as a result of the Danish invasions. but a revival took place in the 10th century under Dunstan, Ethelwold and Oswald, assisted by King Edgar (959–975). It was then that the majority of the celebrated Black Monk abbeys — Glastonbury, Westminster. Winchester, Worcester, Ely, Abingdon and others — began or renewed their life.

During the "monastic" or "Benedictine" centuries the Black Monks were often also apostles of the faith. The work began with the mission to England, and in the two centuries that followed many of the notable apostolic bishops of England were monks, such as Paulinus of York and Wilfrid of Ripon, as were also the Celtic Aidan and Cuthbert of Lindisfarne. But the Benedictine missionaries who changed the course of European history were those of the 8th century, Willibrord the Northumbrian, the apostle of Frisia (northern Holland), and Boniface the Devonian, the apostle of Germany, with his successors Willibald and Wynbald of Wessex, who gave to the continent not only Christianity but also a church organized in the Roman tradition and the existing Anglo-Saxon monasticism. English monks, indeed, converted all Germany west of a line from Bremen to Regensburg on the Danube, and two centuries later English monks were the first successful missionaries in southern Scandinavia.

11th-Century **Reforms.**—When, therefore, the great age of revival and reform came in the 11th century, it found western Europe well supplied with great abbeys of the Black Monks, rich and populous. They had preserved classical and patristic literature, they had built great churches and filled them with precious and beautiful ornaments. They had given to the church all the writers and most of the outstanding bishops for more than 300 years; as feudal lords, with wide lands and extensive immunities, they were a social factor of the first importance. But their life, even when carefully regulated, might seem to differ from that supposed by the rule they professed to keep. A "family" of moderate size, composed principally of laymen, in which all the members contributed some kind of work to the common good, and in which the liturgical prayer in common was simple in form and relatively short, had given place to a large establishment of priests and clerics, who devoted a great part of their waking life to liturgical and intercessory prayer in common, and spent the residue either in sedentary literary work or in administering a large complex of buildings and estates. It is understandable, therefore, that one of the characteristic features of the reform movement was the appearance of new kinds of monastic life, usually simpler, more solitary and more austere in character. Several of these, such as the Vallombrosians (*q.v.*), Savignacs and Cistercians (*q.v.*), claimed to follow the rule more exactly or more strictly than the existing monasteries; but, since they speedily formed "orders" of their own more closely organized than the Cluniacs, they were regarded as having separated themselves from the traditional Benedictine monachism.

Yet despite these and other new forms of the religious life, the last of the monastic centuries was distinguished by the literary, intellectual and artistic achievements of the Black Monks. Lanfranc, Anselm and Abelard, who in succession led the van of the scholastic pioneers, were Black Monks, as were also the chroniclers Edmer, Orderic Vitalis and William of Malmesbury and the canonist Yves de Chartres. Throughout Europe the Romanesque style of architecture and sculpture achieved its masterpieces in Cluniac and Norman monasteries, and at St. Denis, near Paris, Abbot Suger encouraged and in some ways initiated the new style that was to become Gothic. Lanfranc in England and Suger in France also were statesmen of great eminence.

Nowhere, indeed, was the monastic order more powerful than in the domains of the Anglo-Norman monarch. At the time of the Conquest, Norman monasticism, a plant of recent growth, was reaching its height of maturity at Bec, Jumièges, St. Evroul and other abbeys, and William I drew heavily upon its resources to reform and rejuvenate the old English abbeys. Thus Bec and its daughter Caen gave no fewer than five bishops (three to Canterbury) and 13 superiors to England. At Bec in its heyday under Anselm a type of Black Monk life developed that became the model for many and is still recognizable in French and Belgian monasteries. In England at St. Albans, at Canterbury. at Westminster and at many another house, the century after the Norman Conquest was a time of material, intellectual and spiritual expansion. It was the moment, also, when the abbots of the larger monasteries of England were drawn into the feudal system, with its obligations of military service and the duty of attendance at the meetings of the great council, held three times a year.

Despite a growing entanglement in the social and political life of their world, and the competition of the new and more austere orders. the Black Monks remained throughout the 12th century in Europe the most numerous, the most wealthy and also the most active of all the orders in literary work and in the illumination of manuscripts.

From the middle of the 11th century onward there had been a tendency for a celebrated abbey to organize an "order" among its dependencies and allies for the preservation of good observance. In Normandy, Bec had an association of this type. This, however, was the work of private leaders, and in canon law, as in practice. the majority of the abbeys of Europe were still independent of any external ecclesiastical authority. In time, however, the example of the newer orders such as the Cistercians, and a certain decay of fervour in their own body, together with the tightening of organization throughout the church, led to some modification of their autonomy. In particular, the Cistercian institutions of annual chapter and visitation had proved so effective that at the fourth Lateran council (1215) they were imposed on all Black Monks, who were to be grouped for the purpose in each ecclesiastical province. The English took this decree more seriously than most, and for three centuries chapter and visitation functioned regularly. The bishops also claimed and often exercised the right of visitation, save among the newer orders, which generally were "exempted" from their control by the papacy, and in a number of individual houses that by ancient royal or more recent papal grant had secured exemption from all episcopal control.

Benedictine Monasticism in Decline. — Until after the middle of the 12th century the numbers of houses and monks continued to increase, and a constant stream of benefactions added to the Benedictines' extensive estates. Then, slowly but surely, they began to lose their paramount position all over Europe, and the centuries between the expansion of the Cistercians and the Reformation were for the older orders an autumnal season. The Black Monks had ceased to be the spiritual, intellectual and artistic leaders of western Europe, and they were ceasing also to provide great bishops and statesmen. As monks they had been outbidden by the Carthusians and the Cistercians, and the monastic ideal itself was soon to be challenged by the friars, while the new universities were drawing away the ablest young men.

Nevertheless the Benedictines, firmly established on great estates, were as wealthy and as socially important as ever. Their churches and buildings, constantly growing in size and splendour reflected every change in architectural style and were full of precious and beautiful objects and vestments, and until the pestilences and wars of the 14th century there was no lack of recruits, though the number of monastic saints and writers was notably smaller than before. From time to time, especially in Italy, new families of reform appeared, such as the Silvestrines and Olivetans (see below), and the monks somewhat tardily attempted to keep abreast of the times by frequenting Paris, Oxford and other universities, though they never made a great mark in the schools. At the same time, they were ceasing to have a monopoly in the copying and illuminating of books, and the crafts and arts of bookmaking were becoming commercialized in the towns.

Within the monasteries, meanwhile, the austerity. the solitude and the communal simplicity of life were modified; fasting and abstinence were decreasing, travel and regular periods of rest or holiday were becoming common. In many regions, of which England was one, the monks found it profitable to exploit their estates and to farm for the market, and themselves directed the

economic policy of their estates. This, and the multiplication of monastic officials, each with his own quota of land and revenues, gave employment, outside the routine of the cloister. to more than one-third of a large community. At the same time, the abbot, who in early times had shared the life of his monks and devoted himself to pastoral care of their welfare, became more and more an independent prelate with lands and a household of his own. Worse still, all over northwestern Europe (save for England) the practice grew up of popes, and later monarchs with papal privileges, bestowing abbeys in commendam to a secular prelate or lay magnate who then occupied the abbot's lodgings and enjoyed his revenues while the community was governed by a prior of his appointment. In France in particular, where the disasters of war had borne so hardly on the religious houses, the practice of *commendam* was universal in the 15th century.

These evils were attacked in several countries long before the cataclysm of the Reformation. Reformers had two objects in mind: the betterment of observance and of discipline in general, a return to a more regular and austere life, and, second, the provision of effective machinery to guarantee permanence to good endeavour. This machinery was found in the congregation, a development of the conciliar legislation of 1216 by which a group of like-minded or neighbouring houses came together not only for periodical chapters and visitations but as a permanent association, adopting a fixed set of constitutions and governed by a prelate or a council. Generally speaking, in Latin lands the plague of *commendam* drove reformers to take the revolutionary step of dropping the abbot and resting authority in an elected chapter, whereas in German lands the abbot remained but was made accountable to the chapter. The first and most important member of the former class was the congregation of Sta. Giustina of Padua (1424). In this congregation abbots were elected for three years, and the monks no longer took vows to a house but to the congregation; the ruling authority was general chapter acting through a small executive committee and a standing group of visitors under a president. This radical reform spread within a century to all the Black Monks of Italy and became known as the Cassinese congregation. The German reforms were less revolutionary. In that of Bursfeld in Westphalia (1434) the observance was based on Sta. Giustina: the abbot's domestic authority was retained, but over-all powers rested with the abbot president at Bursfeld, controlled by an annual general chapter. There were other smaller reforms in France and Hungary, and in Spain the congregation of Valladolid (1390–1492) came to resemble that of the Cassinese. A feature of most of these reforms was emphasis on private prayer and on creative intellectual work to replace the obsolete pursuit of writing and illuminating manuscripts.

The Reformation and After.—These reforms were powerless to hinder either the gradual decline of the church or the course of the 16th-century revolt. Within a few years (1525–60) the monasteries disappeared almost entirely from west Germany, Switzerland, Holland and Great Britain, and for almost a century there was a steady wastage in France and central Europe owing to the wars of religion; by 1600 only Italy and the Iberian peninsula remained intact. A revival began almost at once, and the century that followed was one of the brightest in Benedictine annals. France, in the epoch of its greatest splendour, took the lead with the congregations of St. Vanne (Verdun, 1604) and St. Maur (Paris, 1621), based on the model of Sta. Giustina, with temporary superiors and vows taken to the congregation rather than to the house. These remained for a century observant and well-disciplined, and are notable as having found an answer, at least for their country and century, to the problem of employment. They organized a higher education for their monks, undertook preaching and education, and above all encouraged creative historical and critical work. For more than a century the French monks, and above all the Maurists (*q.v.*), practised a vast literary activity that won for the whole Benedictine body the undeserved title of "learned." Meanwhile the Cassinese and Spanish congregations continued to flourish, as did a number of smaller bodies in German lands. Mention also may be made of the English congregation, consisting of four houses of exiles, modeled on the congregation of Valladolid; the monks took a special vow to go on the English mission, and for 70 years (1619–88) a steady flow of recruits, many of distinguished birth or talents, kept the houses at full strength.

In the early 18th century the blight of Jansenism and the chilling wind of rationalism withered the monasticism of France, and much of the spirit of fervour had vanished both there and in Italy before the Revolution, while in the Habsburg dominions the program of the emperor Joseph had reduced both numbers and hopes for the monks. What enlightenment had begun the Revolution and Napoleon completed, and the cataclysm that followed seemed at the time even more complete than that of three centuries earlier. The liberal revolution in Spain and elsewhere completed the ruin. In the third decade of the 19th century there were probably fewer Benedictine houses in existence than at any time since the days of Gregory the Great. Only in the German-speaking lands a few ancient abbeys managed to survive, and in them there was little enthusiasm.

The renascence came with unexpected rapidity, taking place principally in four foundations in France, Germany and Italy. In two of these a characteristic feature was the re-establishment of a fully liturgical life, reminiscent of the abbeys of the middle ages; in the other two the aim was to reproduce as nearly as might be the monastic life of the rule.

Solesmes.—The first in time was Solesmes, in the diocese of Le Mans, founded in 1837 by Prosper Guéranger (*q.v.*), one of the leaders of ultramontanism and author of popular works on the liturgy. His aim, continued by his successors, was to renew the tradition of learning of the Maurists and to revive a rich liturgical life with the accompaniment of plain chant in its purest form. There Guéranger began a tradition that was raised to the high level of scholarship and execution by J. Pothier and **A.** Mocquereau. The monks have produced successive critical editions of the Roman and monastic gradual and antiphoner that have been recognized by the Holy See as official. Solesmes became mother abbey of a congregation of autonomous houses, and remains celebrated for its performance and editions of the chant. At other abbeys—such as Ligugé (France), Silos (Spain), Farnborough (England) and Clervaux (Luxembourg)—higher studies in history and liturgy were developed. Monks of this congregation have worked also on the revision of the Vulgate, since 1932 in the abbey of St. Jerome at Rome. The names of Fernand Cabrol, J. Besse, Henri Leclercq, André Wilmart and Henri Quentin are among their scholars.

Beuron.—In Germany the ancient Bavarian congregation was revived in 1858, but a more notable event was the foundation of Beuron (Hohenzollern) by the brothers Wolter, and the inauguration of a congregation (1868) noted for its liturgical life and observance, with lay brothers for farm and craft work. The Beuronese, whose expansion coincided with the decades of German expansion before 1914, had houses in England, Portugal, Brazil and Belgium; in the last-named Maredsous became noted for its scholarship with A. Janssens, Germain Morin, J. Chapman and U. Berlière, the first editor of the Revue *Bénédictine.*

A third German congregation, that of St. Ottilien in Bavaria, devoted itself to foreign missions, with abbeys in east Africa, Manchuria, Venezuela and other places.

Subiaco.—Meanwhile in Italy Don Casarello established (1851) a group of houses forming the Subiaco congregation of Primitive Observance, with the restitution of the night office and the traditional monastic fasts; secularization in Italy and foreign foundations soon transformed this into an international body with regional provinces. Subsequently, under revised constitutions and a more traditional form of government, this congregation spread widely, especially in and from the French abbey of Pierre-qui-Vire which stands, if the phrase may be allowed, at the extreme left wing of the order, almost indistinguishable from the reformed Cistercians.

England.—The English monks, who had continued to work as individuals on the English mission, returned corporately during the French Revolution, and throughout the 19th century St. Gregory's (Downside), St. Laurence's (Ampleforth) and St. Ed-

mund's (in Douai in France until 1903 and now in Berkshire) slowly developed. After 1900 the growth was more rapid. and by 1960 the congregation numbered eight autonomous houses in Britain, several of them running large boarding schools. Downside, with F. A. Gasquet, Cuthbert Butler, R. H. Connolly and others, gained a reputation for scholarship.

Other Countries.—In North America a foundation was made by the Bavarian congregation among German immigrants at St. Vincent's (Beatty, Pa.) in 1846, which later became archabbey of the American-Cassinese congregation, counting 17 houses in the early 1960s. Shortly after, Swiss monks from Einsiedeln settled at St. Meinrad's (Indiana) in 1855, which also became head of a congregation with 11 houses. Both of these subsequently made foundations in Canada. In South America foundations made by the Portuguese congregation (1827) were revived in Brazil by Beuronese monks; Silos (Spain) and Einsiedeln have houses in Argentina. In Africa and India (and until 1939 also in China and Korea) quasi missionary abbeys exist, and there are Spanish monks in northern Australia.

Summary.— The Benedictine world map is therefore something of a mosaic. Not only do national congregations exist side by side with international and missionary congregations, but the national congregations themselves have foundations abroad (*e.g.*, the English in the United States, the French in England and Canada). Similarly, observances and occupations of all kinds exist— the austere quasi Cistercian regime of Pierre-qui-Vire, the claustral liturgical life at Beuron and Solesmes, the more extroverted life of the English, American and Swiss congregations. It is easy to understand that Leo XIII, after his success with the Cistercians, should have desired to bring about some sort of unity among the Benedictines. The age-old spirit of the Black Monks, however, stood strongly for individuality and for what might be called the biological evolution of the monastic species. After building the international college of Sant' Anselmo at Rome (1890), the pope was content with the establishment of an abbot primate as its head, without direct jurisdiction over any other monks, but available as an arbiter, papal visitor and *officieux* representative of the Black Monks to the Holy See. After that date his office remained undeveloped; elected by the abbots of the order, he would probably always represent conservative opinion.

Despite two world wars with their casualties and moratorium on recruitment, and despite the dissolution of three colonial empires, the Benedictines continue to grow: the 6,000 of 1910 became the 12,000 of 1957. The survival and constant rejuvenation of the oldest and in many ways the most flexible religious institute is an interesting historical phenomenon. The Benedictines have remained, if the phrase be allowed, the least "professional" (one had almost said the least "clerical") of the militia of the church. They have never been identified with a particular school of theology or spirituality, or with a particular social or political program. Their faults throughout the ages have been the accumulation of wealth, the immobility of conservatism and the tendency to sink from the true golden mean to a mediocrity of comfort or even luxury. To the outside world they have stood for the beautiful performance of the liturgy, for the acquiring and imparting of learning and for a courteous and humane life in community.

INDEPENDENT ORDERS

When the expansive force of the Cistercians was exhausted, the middle ages saw the rise in Italy of three Benedictine reforms that in time became independent orders outside the main stream of Black Monk life.

Silvestrines.—The Silvestrines (Congregatio Silvestrina O.S.B.) were founded in 1231 by St. Silvester Gozzolini (1177–1267), a lawyer and canon, who when converted settled with his associates on Montefano near Fabriano in Italy. They followed the Benedictine rule, interpreted strictly with an emphasis on abstinence and poverty, and flourished in the middle ages in Italy, with later foundations in Portugal and Brazil. They founded half-a-dozen small houses in Italy, and after 1855 also organized a missionary abbey that administers the diocese of Kandy in Ceylon. They wear a Benedictine habit of dark blue cloth.

Celestines.—The Celestines were founded by the hermit Peter of Morrone (c. 1215–96), who took the name Celestine V when elected in 1294 to the papal office, and subsequently six months later made the "great refusal" and returned to his monks. Earlier approved by Urban IV (1264), the hermits of Monte Morrone, who applied the Benedictine rule to an eremitical institute, spread rapidly in Italy. France and the Netherlands, and numbered at one time 150 houses. Henry V of England proposed to make a foundation in his country, but the scheme fell through. The head house at Sulmona in the Abruzzi alone had an abbot, and the cqnstitutions of the order, with its regular general chapters of priors and delegates under the abbot general, resembled those of the Franciscans. The Celestines, who wore a white tunic with black scapular and hood, disappeared in the Revolutionary era.

Olivetans.— The Olivetans (O.S.B. Montis Oliveti) owed their origin to St. Bernard Tolomei (d. 1348) of Siena, who retired in 1313 to Monte Accona in Umbria with two companions as hermits. They adopted the rule of St. Benedict, strictly interpreted, and were approved by Pope Clement VI in 1341, changing the name of their home to Monte Oliveto in honour of the Passion of Christ. Despite their austere regime they multiplied rapidly to about 100 houses, mostly in Italy, among which was S. Miniato at Florence. There are several houses in Italy and France with an abbey in Brazil and a colony in England (Cockfosters). From the beginning their superiors were elected for short periods only: the abbot general is elected for life. They wear the Benedictine habit of white wool; it is familiar from the frescoes of the life of St. Benedict by Signorelli and Sodoma at Monte Oliveto. Olivetan nuns exist in Italy, Switzerland, England (Cockfosters) and in the United States (Jonesboro, Ark.).

BENEDICTINE NUNS

Benedictine nuns count as their patroness Scholastica, the sister of St. Benedict who, as St. Gregory the Great tells, was a dedicated virgin living by her brother's counsel. There is no certainty, however, that the rule was applied to women before the 7th century. Thenceforward it spread. for women as for men, in Merovingian France and Anglo-Saxon England, though often alongside other customaries. In the 8th century English nuns corresponded with St. Boniface and followed him to Germany, where numerous important houses were founded. Later still in the English revival of the 10th century several abbeys, fully Benedictine, came into being in the kingdom of Wessex, among them Shaftesbury Wilton, Romsey and Winchester. In the great monastic revival of the 11th century a rapid growth took place. when many celebrated nunneries were founded all over Europe and many great abbeys of monks had a corresponding house at no great distance. Thus Marcigny became a centre of Cluniac influence. and several of the new orders had from the beginning a sister institute. In France the aristocratic abbey of Fontevrault and in England the house of Sempringham became head houses of orders that included groups of chaplains and brothers but followed the rule of St. Benedict. Highly educated in the Anglo-Saxon age and in the 12th century, and throughout the middle ages serving as *pensionnats* for daughters of the well to do, the choir nuns were recruited almost entirely from the landed families and rich bourgeois. certain houses being strict preserves of the aristocracy. Germany in particular during the 12th and 13th centuries saw a golden age of spiritual achievement at Admont, Schönau and many other great abbeys, illustrated by the mystics Hildegard. Gertrude the Great and the two Mechtilds of Hackeborn and Magdeburg.

Save for the nuns of recognized "orders," women following the rule were normally under episcopal jurisdiction, though a few were directly governed by a neighbouring abbot. Isolated for the most part, they declined in fervour in the later middle ages when many houses became asylums for unmarried women with little or no sense of vocation, but the level of observance and virtue was generally higher than that of the contemporary monks. In the lands lost to the church at the Reformation, the nunneries, often unwillingly, were disbanded; in Catholic countries reformed and decadent houses existed side by side until the widespread revival of the 17th century.

The Council of Trent, by decreeing strict enclosure and other reforms, inaugurated a period of magnificent expansion. directed by Jesuits and Capuchins as well as by monks; France, south Germany and Austria were favoured countries, and new congregations came into being such as those of Perpetual Adoration in Paris (1653) and the penitential group of Our Lady of Calvary (1617). Though not unaffected by wealth, the nuns of Europe were in better heart than the monks when the Revolution came. Englishwomen had made several foundations in exile in France and the Low Countries; some of these in due course returned to England, among them that at Cambrai. which moved to Stanbrook, Worcestershire, and that at Brussels, which moved to Haslemere, Surrey.

The nuns followed the rhythm of the 19th-century monastic revival, and many of the new congregations, such as Solesmes and Beuron, had nunneries under their jurisdiction. In the late 19th and 20th centuries all kinds of new institutes following the rule arose; while the *moniales*, the traditional Benedictines, retain strict enclosure and the full liturgical, contemplative life, numerous groups of sisters *(sorores)* followed the rule while engaged in teaching, nursing and other social and missionary work all over the world, some under monastic superiors, others under bishops. By 1960 the total number reached about 20,000, almost treble the figure in 1900.

BENEDICTION, strictly any blessing either of persons or things, but more commonly applied to formal blessings, such as are pronounced by the priest or minister at the close of religious services. In the Roman Catholic Church the term is more often applied to a popular form of devotion to the Blessed Sacrament The details of this rite differ considerably in different places and in different circumstances, since it is informal in character and spirit, but the essential act is blessing the people with the Host. *See* also CONSECRATION.

BENEDICTUS, the song of thanksgiving of Zacharias on the occasion of the birth of his son, John the Baptist (Luke i, 68–79), so called from the opening word of the Latin version. The hymn has been used in Christian worship since at least the 9th century, being sung liturgically at Lauds in the Roman Catholic Church and from this usage adopted into the Anglican Order of Morning Prayer.

The name is also given to a part of the Roman Catholic Mass service beginning *Benedictus qui venit* ("Blessed be he who comes [in the name of the Lord]"; Matt. xxi, 9), following the Sanctus.

BENEDICTUS ABBAS (d. 1194), abbot of Peterborough, first makes his appearance in 1174 as the chancellor of Richard, the successor of Thomas Becket as archbishop of Canterbury. In 1175 Benedictus became prior of Holy Trinity, Canterbury; in 1177 he received from Henry II the abbacy of Peterborough, which he held until his death. Benedictus wrote two works, one dealing with the martyrdom and one with the miracles of Becket. Fragments of the former work have come down in the compilation known as the *Quadrilogus,* which is printed in the fourth volume of J. C. Robertson's *Materials for the Hzstory of Thomas Becket;* the work on the miracles is extant in its entirety, and is printed in the second volume of the same collection. Benedictus used to be regarded as the author of an important chronicle, the *Gesta Henrici regis secundi,* but in fact he merely caused the first section of this work to be transcribed for the Peterborough library. It is only through the force of custom that it is still occasionally cited under the name of Benedictus.

See W. Stubbs, *Gesta regis Henrici secundi Benedicti abbatis* (1867) and particularly the preface to the first volume.

(H. W. C. D.; F. M.P.)

BENEFACTOR, a province in the western part of the Dominican Republic. Area 1,375 sq mi. Pop (1960) 148,206. Its wide upland valley of San Juan, watered by the Rio Yaque del Sur, is bounded by the Cordillera Central to the north and the Sierra de Neiba to the south. It is a leading producer of peanuts, irrigated rice and corn. Lumbering is also significant. It was created in 1938 from the western part of Azua province and reduced in size by the formation of San Rafael (Elías Piña) province on the Haitian border in 1942. In 1961 its name was changed to that of its capital, San Juan de la Maguana (municipal pop. [1960] 16,654), which was founded in 1777. (D R. D.)

BENEFICE, from the Latin *beneficium* ("a kindness," "a benefit"), came into use in the 8th century in the kingdom of the Franks as a term for a particular kind of land tenure. A Frankish sovereign or lord, the seigneur, leased an estate to a free man on easy terms in *beneficium* ("for the benefit of the tenant") and this came to be called a *beneficium,* a benefice. The lease normally came to an end on the death of the seigneur or of the tenant, though holders of benefices often succeeded in turning them into hereditary holdings. If the lease was reduced to writing there were two documents, one from the tenant called a *precaria,* one from the seigneur called a *praestaria.* As an ordinary form of land tenure, the benefice was eventually superseded by the fief or fee (*q.v.*).

Although benefice was dying out by the 12th century as a term for a feudal land tenure, it retained an important place in the law of the Roman Catholic Church and the Church of England. In the early days of the church its endowments in each city were centralized under the administration of the bishop; from them he paid the stipends of the clergy, but there was no endowment attached to a particular ecclesiastical office. Early village churches were founded largely by bishops, who committed the care of each church to a priest (or constituted him the priest of the village church). Each village church had its own endowments, administered by the priest under the supervision of the bishop and from them were paid his own stipend and the stipends of the other clergy serving the church, but there was no particular endowment specially set apart for the payment of the priest. By the 8th century churches were being founded in villages by the seigneurs, usually laymen, who were allowed to appoint the priest. Parish churches thus fell into two groups, the earlier type founded and controlled by bishops, the later type under the control of the lay seigneur. Both bishops and lay seigneurs began to treat each church and its endowments as property to be leased like any other part of their estates, and appointed the priest by leasing to him as a piece of property the church and its endowment in return for carrying out the spiritual duties.

Various forms of lease were adopted, some involving the priest in a heavy rent and labour services, some like the *livello,* popular in Italy, giving the priest wide and lucrative rights over the property of the church. Among the leases adopted by bishops and lay seigneurs was the lease *in beneficium.* Sometimes the church was leased to a layman who paid a priest to carry out the spiritual duties. In this case. part of the endowment was set aside to be leased by him to a priest as a benefice and called a *beneficium,* or *presbyteratus* or *fevum presbyteri* ("the priest's fief"). The priest held the church for life, unless a term of years was specifically mentioned in the lease; and in return he paid a token rent to the seigneur (though he had to pay a heavy fee at the outset for the grant of the lease), kept the church and its farm buildings in repair and its lands in cultivation and conducted the church services. Benefice terminology was not used in England before the Norman Conquest. In Anglo-Saxon England the priest held his church for life, paying the seigneur or thane a rent of twopence an acre for the glebe.

In the 12th century benefice came to mean an ecclesiastical estate, consisting largely of tithe, glebe and offerings, which was permanently attached to an ecclesiastical office and had to be leased to the holder of the office for the time being. The procedure was made to conform to the ideals of Gregory VII (1073–85) and his school, one tenet of which was that a lay seigneur could not grant an ecclesiastical office directly to a priest or receive any

rent or payment for it. The lay seigneur of the church therefore became the patron, owning not the church itself but its advowson or patronage; he chose the priest but could not lease him the church or receive any rent for it. The church had to be leased or granted to the priest by the bishop.

The procedure consisted of three stages. First. the patron presented the priest of his choice to the bishop. Second.-the bishop admitted and instituted the priest to the church and cure of souls (he had only a very limited power of refusing the patron's nominee); in the middle ages the bishop accompanied the institution by an investiture with a ring and in the post-Tridentine period in Europe with a biretta. Where the bishop was patron. there was of course no presentation and the institution was called a collation. Third. on behalf of the bishop. the archdeacon inducted the priest into the benefice or invested him with it by placing his hand on the door key of the church. and the priest rang the bell to show he now had full possession of the benefice. This procedure has remained in use in the Church of England. Once inducted the priest holds the church for life or until he resigns and his resignation is accepted by the bishop. Otherwise he is only bound to vacate the benefice if he is deprived of it in a court of law or if he is instituted to another benefice with a cure of souls. in which case he automatically vacates the first benefice unless he has,a dispensation to hold two or more benefices in plurality. In the middle ages a dispensation to hold benefices in plurality had to be obtained from the pope. but in the Church of England after the Reformation the dispensing authority became the archbishop of Canterbury.

The procedure in the Church of England for giving a benefice to a priest and the terms on which he holds it have been modified in two respects. The bishop has wider powers of refusing the patron's nominee and, in a vacancy, the parochial church council has the right to be consulted before an appointment is made. The circumstances under which a priest can be removed from his benefice have been enlarged: a priest must vacate his benefice if he is found guilty of conduct unbecoming the character of a clerk in holy orders or of serious, persistent or continuous neglect of duty, or if he is found unable to discharge adequately the duties attaching to his benefice. In the Roman Catholic Church *(see* canon 2117 of the *Codex juris canonici)* the circumstances under which a priest can be removed from his benefice have similarly been enlarged. The benefice system, by making the parish priest dependent on no man's pleasure for his income or continuance in office, gave him an immeasurable status and strength in carrying out his duties. *See* also PARISH; TITHES.

BENEFIT SOCIETY, an association formed to provide its members, or the heirs or dependents of members, with certain benefits such as payments for funeral costs and allowances during illness and for other purposes. Burial societies were among the earliest of such associations in the United States. Benefit societies, usually known as "friendly societies'! *(see* FRIENDLY SOCIETY) in the United Kingdom are, in fact, mutual insurance societies. Their activities range over a wide field, sometimes including social activities that are not necessarily associated with their principal purpose. In the United Kingdom most friendly societies have acquired a legal status as "approved societies" under the National Insurance act. In the United States such societies are governed by the insurance laws of the several states. *See* also FRATERNAL ORGANIZATIONS. (FK. L. K.)

BENE-ISRAEL ("Sons of Israel"), a Jewish community of India, established mainly in the region of Bombay and descended from a band of Jews who, according to their own tradition, fled from persecution across the Indian ocean about the 4th or the 6th century A.D. and were wrecked on islands off the Indian coast. Subsequent to their arrival in India they are said to have abandoned nearly all Jewish custom (except the keeping of the Sabbath and some fasts and festivals, circumcision and the reading of the Shema prayer) until the religious revival under Rahabi c. A.D. 900. A further revival under Divekar (1796) brought them still closer to orthodox practice. Their prayer books are in Marathi. their vernacular. The women wear Hindu dress, the men have adopted European.

See J. H. Lord, *Jews in India and the Far East* (1907); R. E. Enthoven, *The Tribes and Castes of Bombay* (1920).

BENELUX. The so-called Benelux customs union agreement was signed at London on Sept. j, 1944, between the governments of Belgium, the Netherlands and Luxembourg. It was revised by the Hague protocol, March 14, 1947, and came into operation at the beginning of 1948. On July 25, 1921, Belgium and Luxembourg had previously formed an economic union which continued to exist independently.

Benelux was an agreement to abolish tariff duties within the union and to apply a common tariff to imports from other countries. The contracting governments retained their sovereignty and were separately represented abroad. For commodities appearing in the tariffs of the Netherlands and the Belgian-Luxembourg union, the common tariff imposed rates halfway between the Dutch and the higher Belgian duties.

The free list, which had been extensive in the Dutch tariff, was much reduced so that the net effect of the customs union was to raise tariffs against other countries. Within the union, quantitative restrictions such as import licences and quotas, as well as subsidies: remained, and elaborate provisions were adopted to safeguard any damage to national production that might result from their progressive removal. After 1950, in pursuance of trade liberalization under the European Payments union, most of these restrictions were eliminated; but the effect on wages and the mobility of labour and capital was limited, largely as a result of cartel action.

Benelux was once regarded as a promising experiment by which neighbouring countries would form customs unions which might then merge into wider unions. There were negotiations between France and Italy and some discussion of the merging of Benelux and a Franco-Italian union into one body (to be called Fritalux); but following the formation of the European Coal and Steel Community in 1953, interest shifted to wider plans for European integration resulting in the formation of the European Economic Community in 1958. of which Belgium. Luxembourg and the Netherlands were members, togeiher with France, Italy and Germany.

BENES, EDVARD (1884–1948), Czechoslovak statesman who served as foreign minister of his country from 1918 to 1935 and as head of state from 1935 to 1938 and from 1940 to 1948, was born on May 28, 1884, in the village of Kozlany in northwestern Bohemia. He was the tenth and youngest child of a Czech farmer but received a good education. He studied at the universities of Prague, of Paris and of Dijon, where he qualified as a doctor of laws in 1908. After lecturing at the Prague commercial academy from 1909. he began to teach at the Czech university in Prague in 1913.

Meanwhile Benes had come under the influence of T. G. Masaryk *(q.v.)*, whose Realist party he joined; thereafter he tried always to serve Masaryk's conception of constitutional democracy. After the outbreak of World War I he was eager to follow Masaryk's lead in liberating the Czechs from Austrian rule and was high in Masaryk's confidence. In the autumn of 1915 he joined Masaryk in Switzerland, where they began their efforts to mobilize world opinion against the Habsburg regime. Masaryk then went to London. but Benes returned to Paris with the Slovak leader, Milan Stefanik. These men formed a Czechoslovak foreign committee, which in Jan. 1916 became the Czechoslovak National council, with Masaryk as president and Benes as secretary-general. The council gradually developed into the provisional government of emergent Czechoslovakia; on Oct. 14, 1918, Benes notified the Allied powers of the establishment of this interim regime with himself as minister of foreign affairs. By the end of the year

the first Czechoslovak republic was launched. and in 1919 Benes led the Czechoslovak delegation to the peace conference in Paris. *(See* CZECHOSLOVAKIA: *History.)*

Benes remained at the head of the Czechoslovak foreign office for 17 years; during one of these. 1921–22, he was also prime minister. From 1920 onward he led the Czechoslovak delegation to the new League of Nations, in which he played an important part. He was indeed one of the architects of the Geneva protocol drawn up in 1924. according to which the gap in the League covenant was to be filled and arbitration betaeen its members made compulsory. As the representative of a newly created state, he looked to the new international organization for the preservation of the *status quo.* Within the framework of the League he initiated the triple alliance between Czechoslovakia, Rumania and Yugoslavia which became known as the little entente (*q.v.*).

In 1918 French opinion was divided on the future of the former Habsburg lands, and Benes would have wished to be at least as closely linked with London as with Paris. The British. however, fought shy of continental entanglements and opposed the Geneva protocol, leaving him little choice but to lean on France. From the beginning he was unpopular in the new state of Poland. There was an old feud between the Poles and the Czechs, for the latter preferred the Russians. In July 1920, when Poland faced a Soviet invasion, the Czechs blocked war material sent from France to the aid of Poland and took advantage of the situation in order to acquire the lion's share of the disputed territory of Tesin (Cieszyn). It would have been difficult for any Czech foreign minister to have been more conciliatory to the Poles, but Benes was held personally responsible in Warsaw. When Hitler came to power and Germany left the League of Nations in 1933 it was natural for that organization to look more favourably on the U.S.S.R. Thus in 1934, soon after Benes had established diplomatic relations with Moscow in June, the U.S.S.R. was admitted into the League. The propaganda which now poured from Nazi Germany depicted Benes as a Communist agent who oppressed the German minority in Czechoslovakia.

On Dec. 18. 1935. Benes was elected president of the republic in succession to Masaryk, who had retired and who died in Sept. 1937. Thus it became easier to focus hostile attacks on Benes, who was left in isolation to face the crisis of 1938. When it became clear in September of that year that the Czechoslovaks would have to fight Germany by themselves if they resisted Hitler's demands for the cession of the frontier districts which were mainly German-speaking, Benes bore the whole responsibility for the decision to give way. On Oct. 5, 1938, he resigned the presidency and went into exile.

After the outbreak of World War II Benes established a Czechoslovak national committee and military unit in France, but after the collapse of that country he had to begin again in Great Britain. He resumed the presidency of a provisional government in London on July 23, 1940, but it was not until July 18, 1941, that he was fully recognized as head of state by the British government. In spite of friction in London with his old rival, the Slovak Stefan Osusky, and with the Sudeten German Socialist Wenzel Jaksch, he was full of optimism during the war. On July 18, 1941, recognition had also come from the U.S.S.R. Above all things he hoped that the old link between Czechs and Russians would enable him to ride the crest of the wave of pro-Soviet feeling which swept over the western world after the battle of Stalingrad. On Dec. 11, 1943, he arrived in Ploscow and on Dec. 12 signed a treaty of alliance with the U.S.S.R. From then onward he regarded himself as a special link between the U.S.S.R. and the west, although he felt obliged to support Moscow against the west over Poland.

On March 17, 1945, Benes visited Moscow a second time on his way to Kosice in Slovakia, where he set up the temporary headquarters of the restored Czechoslovak government on April 3. On May 16 he was welcomed hack enthusiastically by the population of Prague. Soviet armies had liberated Czechoslovakia from the Germans, and Benes and his supporters were glad to have escaped the fate of the Polish and Yugoslav governments in exile; he seemed not to have realized that Stalin had no intention of giving him a free hand to rule the second republic democratically. He mas only 61 but his health was impoverished, and in 1947 he suffered two strokes from which he only partially recovered. On Feb. 25. 1948. his Communist prime minister. Klement Gottwald. demanded from him that he should accept a Communist-dominated cabinet. All the Communist organizations in the country were mobilized to enforce the demand, and Benes was again obliged to make a fateful surrender: having refused to sign the new constitution. he resigned the presidency on June 7. After the death of his lifelong friend, Jan Masaryk (*q.v.*), in March, it is no exaggeration to say that he'died of a broken heart at his home at Sezimovo Usti on Sept. 3, 1948. He wrote *My War Memoirs* (Eng. trans.. 1928) and left unfinished his *Memoirs: From Munich to New War and New Victory* (Eng. trans.. 1954).

BENÉT, STEPHEN VINCENT (1808–1943), U.S. poet, novelist and writer of short stories, was best known for *John Brown's Body,* a long narrative poem on the Civil War. He was born in Bethlehem, Pa., July 22, 1898, into a military family with literary inclinations, and was reared in army posts. His father read poetry aloud to Stephen, an older brother, William Rose, and a sister, Laura. All of them became writers. Inspired by his father's and grandfather's campaign records, Stephen became an avid reader of military historv as well as of Alexandre Dumas, Howard Pyle and William Morris. He began writing at an early age and published his first book at 17. Civilian government service during World War I interrupted his education at Yale University. He received his A.M. degree, after the war, submitting his third volume of poems instead of a thesis.

After publishing the much-admired *Ballad of William Sycamore 1790–1880* (1923), three novels and a number of short stories, he returned to France, with his wife, Rosemary Carr Benét. While there on a Guggenheim fellowship he wrote *John Brown's Body* (1928), which was called by the historian, Henry Steele Commager, "not only the best poem about the Civil War, and the best narrative," but also "the best history." The poem, however, has several weaknesses: it lacks unity of style and subject; the diction is often infelicitous; the verse forms are too facile and the characters lack depth. The best parts undoubtedly are the ballads. For this work, Benét received the Pulitzer award for poetry in 1929, and was probably read more widely in the United States than any comparable work. *A Book of Americans* (1933), poems written with his wife, brought many historical characters to life for U.S. school children. Benét's preoccupation with historical themes was also the basis for *Western Star,* an ambitious story of America, first planned in 1934 as possibly five books, but left uncompleted at the time of his death. Book I, complete in itself and finished in 1942, was published posthumously. and won for Benét a second Pulitzer prize. The poem lacks unity and depth; it is all too clear and all too facile.

Benét's models were minor contemporary poems, rather than the great traditional ones. He was at his best in his less ambitious work—in his light or ironic verse ("For City Spring" and "Evening and Morning"); in his ballads ("Captain Kidd," "Thomas Jefferson." "The Mountain Whippoorwill"); and in his New York poems ("Metropolitan Nightmare" and "Notes to Be Left in a Cornerstone"). In all Benét published over 17 volumes of prose and verse. His best-known short story, *The Devil and Daniel Webster* (1937), a humorous treatment of a folklore theme, was the basis for a play, an opera and a motion picture. He died in New York city on March 13, 1943.

His older brother, WILLIAM ROSE BENÉT (1886–1950), poet and critic, was born Feb. 2, 1886, at Fort Hamilton, N.Y., and died in New York city on May 4, 1950. His second wife was the poet, Elinor Wylie, whose *Collected Poems* (1932) he edited after her death. He held various positions as critic and editor, finally that of poetry critic for the *Saturday Review of Literature.* The weaknesses in his criticism result from his inability to be objective. He wrote 12 volumes of verse, one of which, *The Dust Which Is God,* won a Pulitzer prize in 1942, and four volumes of prose.

See Charles Fenton, *Stephen Vincent Benét* (1958), a biography. (J. G. SH.)

BENEVENTO, a city of south central Italy in the region of Campania, capital of the province of the same name and an archiepiscopal see, is situated on a ridge between the Calore river and its tributary the Sabato, 62 km. (38.5 mi.) N.E. of Naples, by road. Pop. (1957 est.) 53.382. The cathedral (founded in the 7th century, enlarged in the 12th and 13th centuries and severely shattered during World War II, but later reconstructed) has magnificent bronze doors and the interior is divided into five aisles by Doric columns. The cloister of S. Sophia is of the 12th century. The Ponte Vanvitelli over the Calore was built by Luigi Vanvitelli. The most important monuments, however, are those from classical days and include Trajan's arch (Porta Aurea) erected in A.D. 114–115, the Roman theatre, and the Ponte Lebroso, a bridge over the Sabato.

Originally an Oscan or Samnite city, Malies, later known as Maleventum or Maluentum, it was supposedly founded by Diomedes, companion of Ulysses. The Romans changed its name to Beneventum (*Bonus* Eventus). With Capua it became an important town on the Appian way and was a base for Roman expansion in south Italy. In 275 B.C., Pyrrhus, king of Epirus, fought his last battle against the Romans at Maleventum. He was defeated by the combined forces of Lucius Cornelius Lentulus and Manius Curius Dentatus. Plutarch, Livy and Horace mention the battle. In the middle ages it passed, after partial destruction by Totila in A.D. 452, from the Lombards to the Byzantines and then to the papacy. On Feb. 26, 1266, Charles of Anjou, brother of "Saint" Louis IX, king of France, there defeated and killed Manfred, king of Naples and Sicily, son of the emperor Frederick II of Swabia. Charles had been appealed to by Pope Clement IV who feared the power of the Swabian rulers. His victory marked the beginning of the predominance of the Angevins in Sicily. Manfred is commemorated in Dante's *Purgatoria* (Canto III). The city remained in papal hands until 1806 when Napoleon granted it to Charles Maurice de Talleyrand-Périgord, with the title of prince. In 1815 it was returned to the papacy, but was united with Italy in 1860. Damaged by earthquakes, it was further devastated by air raids during World War II prior to its capture by Allied forces on Oct. 3, 1943.

The basic economy of the city is agriculture with wheat. grapes. olives and vegetables as the main products. Two characteristic products of Benevento are almond cakes and a liqueur called Strega. Bricks, matches, chocolate and biscuits are produced, as well as agricultural machinery. Benevento was one of the first places in Italy to grow tobacco.

BENEVENTO PROVINCE is entirely inland, situated in the Apennine mountains. Area 796 sq.mi.; pop. (1961) 313,950. After the capital, the main towns are Sant'Agata de Goti and San Bartolomeo in Galdo. The chief rivers are the Volturno and its tributary, the Calore. (M. T. A. N.)

BENEVOLENCE, a term used in a special sense to indicate sums of money, disguised as gifts, which were extorted by various English kings from their subjects without consent of parliament. Edward II and Richard II had obtained funds by resorting to forced loans, a practice which was probably not unusual in earlier times. Edward IV, however. discarded even the pretense of repayment. and in 1473 the word "benevolence" was first used with reference to a royal demand for a gift. Edward was very successful in these efforts. But when Richard III sought to emulate his brother's example protests led to the passing of an act of parliament in 1484 abolishing benevolences as "new and unlawful inventions." In spite of this act Richard demanded a further benevolence in 1485, although he kept technically within the letter of the law by calling it a loan and promising repayment. But it was Henry VII who made the most extensive use of the system. Indeed. in 1495 parliament passed an act making those who had promised gifts legally liable for any unpaid arrears. In 1528 Henry VIII demanded a benevolence, and in 1545 he demanded a "loving contribution" from all who possessed lands worth not less than 40*s*. a year or chattels to the value of £1 j.

The practice was abandoned hy the later Tudors. In 1614, however, some bishops and courtiers offered free gifts to James I and the City answered his request for a loan by saying that it would rather give him £10,000 than lend him £100.000. These offers, which brought in more than £20,000. encouraged James to order the collection of a general benevolence from all persons of ability. and about £40,000 was collected. Four counties had, however, distinguished themselves hy protests against this demand, and some objectors had cited the act of Richard III. Representatives from the four counties were called before the privy council, where Sir Edward Coke defended the action of the king, quoted the Tudor precedents and urged that the act of 1484 was to prevent exactions, not voluntary gifts. In 1615 an attempt to exact a benevolence in Ireland failed, and in 1620 it was decided to demand one ior the defense of the Palatinate. Circular letters were sent out, punishments were inflicted. but many excuses were made, and only about £34,000 was contributed. In 1622 a further attempt was made; as in 1614. judges of assize and others were ordered to press for contributions, wealthy men were called before the privy council and asked to name a sum at which to be rated, and William Fiennes, 1st Viscount Saye and Sele. was imprisoned for six months for protesting. Yet only about £88.000 was raised instead of the £200.000 that had been hoped for. This was the last time benevolences were collected. although they were suggested later in 1622 and again in 1625 and 1633. (R. B. WM.)

BENFEY, THEODOR (1809–1881), German philologist and Sanskrit scholar, was born on Jan. 28, 1809. Benfey's iriterest in philology was awakened by the careful instruction in Hebrew which he received from his father. After studying at Gottingen he spent a year at Munich, where he was greatly impressed by the lectures of Friedrich von Schelling. He later settled as a teacher in Frankfurt am Main. His pursuits were at first chiefly classical, but his attention mas diverted to Sanskrit by an accidental wager that he would learn enough of the language in a few weeks to be able to review a new book on it. This feat he accomplished, and in later years he rivaled it when he learned Russian in order to translate V. P. Vasilev's work on Buddhism. For the time, however, his labours were chiefly in classical and Semitic philology.

Frpm 1839 to 1842 he published the *Lexicon* of *Greek Roots*, which gained him the Volney prize of the Institute of France. His attention from that time was principally given to Sanskrit. He published in 1848 his edition of the *Samaveda;* in 1852–54 his *Manual of Sanskrit,* comprising a grammar and chrestomathy; in 1858 his practical Sanskrit grammar, afterward translated into English; and in 1859 his edition of the *Panchatantra*, with an extensive dissertation on the fables and mythologies of primitive nations. In 1862 he was appointed ordinary professor at Göttingen, after 14 years' service as extraordinary professor. In 1866 he published his great Sanskrit-English dictionary. In 1869 he wrote a history of German philological research, especially oriental, during the 19th century. While engaged on a grammar of Vedic Sanskrit. he died at Gottingen on June 26. 1881.

BENGAL, a region of northeast India and East Pakistan and formerly a province of British India. It now comprises West Bengal (a state of the Republic of India) and East Pakistan (a province of Pakistan). West Bengal includes the remainder of the old province together with the state of Cooch-Behar. which was merged with West Bengal on Jan. 1, 1950; it has an area of 33.928 sq.mi. and at the 1961 census had a population of 34,967,634. East Pakistan consists of the Dacca and Chittagong divisions and parts of the Presidency and Rajshahi divisions of the iormer province, together with the greater part of the Sylhet district of Assam; it has an area of 55.133 sq.mi. and in 1961 the population was 50.844.000 of whom about 77% were Muslims.

The geographical limits of Benga! have varied throughout the centuries. Its boundaries have been altered either as the result of conquest or for admiriistrative reasons. Before the 1947 partition it stretched from the Duars immediately south of Sikkim and Bhutan to the Sundarbans and the mouth of the Ganges. It was bounded on the west by Bihar and on the east by Assam and that part of Burma which lay to the east of the Chittagong coastal tract. It included the marshy, submontane tarai (*q.v.*), known as the Duars, and the Ganges-Brahmaputra doab, or region be-

tween the two rivers, together with the slightly elevated semi-laterite region known as the Barind. The most distinctive feature of the area is its network of rivers, the Ganges and Brahmaputra, with their affluents and distributaries.

History. — The name Bengal or Bangala is derived from the ancient deltaic kingdom of Vanga or Banga. References to it occur in early Sanskrit literature but it played no conspicuous part in the legendary warfare depicted in the Mahabharata. Its early history is obscure until the 3rd century B.C. when it formed part of the extensive Maurya empire inherited by Asoka. With the decline of Maurya power anarchy once more supervened. In the 4th century A.D. it was absorbed into the Gupta empire of Samudragupta, to whom tribute was paid by the frontier kingdoms of Samatata (the delta of the Brahmaputra), Kamarupa (Assam) and Nepal. The extent of Harsha's empire (A.D. 606–647) is controversial, but it apparently embraced Bengal, including the deltaic region of Samatata. From the death of Harsha to the rise of Pala power in the second half of the 8th century little is known of Bengal except that its anarchical condition was aggravated by repeated invasions. The Palas had great difficulty in maintaining their position in Bengal against attacks by the powerful Gurjara-Prathiharas of Kanauj and the Rashtrakutas of the Deccan. The Chinese pilgrims, Fa-Hsien in the 5th century and Hsüan Tsang in the 7th century, found the Buddhist religion prevailing in Bengal, but already engaged in a fierce struggle with Hinduism, which ended about the 9th or 10th century in the general establishment of the latter faith. The Pala dynasty ruled over Bengal for more than three centuries and is justly renowned for its cultural achievements. Its rulers were Buddhists but were tolerant of Hinduism. In the 12th century the Palas were overthrown by the Senas who were champions of Vaishnavism.

Muslim and *Mogul* Rule. — Between 1199 and 1202 Bihar and Bengal were overrun by Muslim invaders under an able general named Mohammed Bakhtiyar. Odantapuri, the capital of Bihar, was captured and the Buddhist monks in its monastery massacred. The advance into Bengal met with no resistance. Gaur, or Lakhnauti, was made the capital of the newly conquered territories. From the beginning of the 13th century to Robert Clive's conquest of the province in 1757, Bengal remained under Muslim rule, at times under governors acknowledging the suzerainty of the Delhi sultans, but chiefly under independent rulers. It formed part of the extensive empire of Mohammed Tughluq, but the decline of Tughluq power enabled its rulers to proclaim their independence in 1341. They continued to assert a precarious independence until 1540, from which date until the conquest of the province by the Mogul emperor, Akbar, in 1576 it remained under Afghan (Pathan) rulers. Mogul rule in Bengal saw the emergence of new forces which deeply affected the development of the Bengali people. It synchronized with the growth of European enterprise, especially the trading activities of the Portuguese. It was also a period when Bengal felt the effect of various religious movements: the neo-Vaishnava movement which laid great emphasis on the Bhakti (devotion) cult; the Vaishnava Sahajiya movement with its strong Yogic-Tantric bias; and the erotic Shakta-Tantric cult (see SAKTISM).

The British in *Bengal*.—With the decline of Mogul power in the first half of the 18th century the provincial governors of the empire began to assume an independent attitude. In 1740 Sarfaraz Khan. the viceroy of the three provinces of Bengal, Bihar and Orissa, was overthrown by Ali Vardi Khan, a subordinate official in charge of the administration of Bihar. From this usurpation can be traced the rise of the independent dynasty of the *nawab-nazims* of Bengal, with whom Clive came into contact. Ali Vardi Khan had no sooner gained control of Bengal than he was called upon to defend his recent acquisitions against Maratha incursions. In addition to continuous raiding there were five separate invasions between 1742 and 1751. He was finally forced to come to terms and pay the Maratha demands for chauth which amounted to one-fourth of the standard land revenue assessment. His successor, the nawab Siraj ud-daula. in 1756 attacked and captured the English settlement at Calcutta, incarcerating a number of Englishmen in the notorious Black Hole. Clive easily recaptured Calcutta and forced Siraj ud-daula to subscribe to a treaty confirming all the privileges which the English had formerly enjoyed. His continued recalcitrancy and intrigues with the French led to war which ended with Clive's victory at Plassey in 1757, as a result of which the British became the de *facto* rulers of Bengal. Clive's policy was to govern Bengal through puppet nawabs. His successor, Henry Vansittart, deposed Clive's nominee, Mir Jafar, replacing him by Mir Kasim, who attempted to assert his independence and reverse the decision of Plassey. After the cold-blooded massacre of 150 Englishmen at Patna in 1763, Mir Kasim was defeated and fled the province. This was followed by the restoration of the more pliant Mir Jafar. A final attempt by the titular Mogul emperor, Shah Alam, and the ruler of Oudh, Shuja ud-Daulah, to overthrow the British power in Bengal was frustrated by Hector Munro's victory at Buxar in 1764. Thenceforward the British were the unchallenged rulers of the province.

In 1765 Shah Alam, the defeated Mogul emperor, in return for an annual tribute of 26 lakhs of rupees (£325,000) granted to the East India company the *diwani* of Bengal, Bihar and Orissa — that is, the right to collect and administer the revenues of this area. By the Regulating act of 1773 Warren Hastings, the governor of Bengal, became the first governor general of Bengal, which was declared to be the supreme government with powers of superintendence over the other two presidencies of Madras and Bombay. Warren Hastings' term of office was a period of consolidation after conquest and of experiment in the spheres of judicial and revenue administration. Under Lord Cornwallis in 1793, by what is known as the Permanent Settlement of Bengal, the government's land revenue demand was fixed in perpetuity and the existing landholders and revenue collectors, the *zamindars*, were transformed into landowners. His failure to protect the ryots and undertenants was rectified by the Bengal Tenancy acts of 1859, 1885, 1928, 1938 and 1941.

Partition. — In 1854 the governor general was relieved of the

direct administration of Bengal, which was placed under a lieutenant governor. Thenceforward the government of India became entirely distinct from that of Bengal. In 1874 Assam was transferred from the charge of the lieutenant governor and placed under a separate chief commissioner. It was felt in 1905 that Bengal had become too unwieldy a charge for a single administration and, in spite of violent Hindu protests, it was partitioned into two provinces, (1) Western Bengal, Bihar and Orissa and (2) Eastern Bengal and Assam, each under a lieutenant governor. In 1912, because of continued opposition to partition, Bengal was placed under a governor, Bihar and Orissa under a lieutenant governor and Assam once more under a chief commissioner. At the same time Delhi became the capital of India in place of Calcutta. Under the Government of India act, 1935, Bengal was constituted an autonomous province in 1937. This was the situation until the Indian subcontinent was partitioned into the two dominions of Pakistan and India after the British withdrawal in 1947. Boundary disputes arising out of the Radcliffe award of Aug. 1947 were settled by the report of the Bagge tribunal in Feb. 1950. In Feb. 1952 a proposal to make Urdu the national language of Pakistan produced serious rioting in East Bengal.

BENGAL, BAY OF, part of the Indian ocean north of lat. 10° N., between the Indian peninsula on the west and the Arakan coasts of Burma and the continuation southward of the Arakan Yoma mountains in the Andaman Islands on the east. The bay is roughly triangular in shape, the blunted northern apex coinciding with the delta of the Ganges-Brahmaputra. The vast volumes of silt and mud brought down by these rivers result in a very shallow sea; it is 100 or 150 mi. from the shore before a depth of 600 ft. (100 fathoms) is reached in the north. Similarly, on the west the Mahanadi, Godavari and Krishna (formerly Kistna) have built up considerable deltas extended seaward by shallow water. The Arakan coast, on the other hand, is a Pacific type of coast with fringing islands. The main part of the bay, however, reaches a maximum depth of 13,920 ft. (2,320 fathoms) and has no islands. The numerous large rivers result in reduced salinity of surface waters on the margins of the bay. The western coast has no natural harbours but artificial protection has been provided at Madras and Vishakhapatnam. Surface movements of the waters change direction with the season, the northeast monsoon giving them a clockwise circulation, the southwest monsoon a counterclockwise movement. Severe storms occur at the change of monsoon, particularly in the southern areas in October. (L. D. S.)

BENGALI LANGUAGE. Bengali, Bihari, Oriya and Assamese comprise the eastern group of the Indo-Aryan languages (*q.v.*) which have been identified as immediate descendants of the Māgadhī Prakrit (*see* PRAKRIT LANGUAGES) of south Bihar. Bengali is spoken in the area comprising the Indian state of West Bengal and East Pakistan by more than 70,000,000 persons. The land of "Bangala" is mentioned a number of times in the accounts of European travelers (Marco Polo's being one of the first) between the 13th and 17th centuries A.D. The English word "Bengal" is a variation of this, and the term "Bengali" is derived from it. Bengalis refer to their language as "Bāṅglā" or "Bāṅgālā" and write it in a script derived from an early form of the Nagari character of northern India.

A significant dialectal difference in Bengali is that between the literary speech (*Sādhu-Bhāṣā*) and the colloquial (*Colit-Bhāṣā*), the latter being based on the dialect of Calcutta and the districts along the Hugli river. *Colit-Bhāṣā,* with its contracted forms and colloquialisms, is spoken by all educated Bengalis, as contrasted with *Sādhu-Bhāṣā,* whose highly Sanskritized vocabulary and numerous archaic or pseudo-archaic grammatical forms render it unintelligible to the uneducated who knows the colloquial. When a colloquial or *tadbhava* word occurs in literature, it appears as its corresponding *tatsama* or Sanskrit loanword, although the *tadbhava* is read.

Phonetics.—Standard Colloquial Bengali, the speech of the educated classes of Calcutta, has these sounds: *Vowels—ā i e ē æ u ŏ ō,* and their nasalized counterparts, *ã̄ ĩ ẽ ẽ̄ æ̃ ũ õ̆ ȭ.* Diphthongs consist of combinations of any one of the vowels with any one of the other vowels, *e.g., ŏi ŏu āē ōē iō ui,* etc., with the exception of *e* and *æ* which do not occur as second members. *Consonants—k g c j ṭ ḍ ṛ t d p b* and their aspirated counterparts, *kh gh ch jh ṭh ḍh ṛh th dh ph bh* (*ph* has a variant *f,* and *bh, v*), *n* (with positional variants *ṇ ñ*) *ñ, m r l h ś s* (with positional variant *ṣ*). "Long" or "doubled" consonants, indicated by writing the consonant twice, are pronounced by arranging the pertinent vocal organs for making the single sound and holding the closure longer than for the single sound. With aspirated plosives (*ph, bh, th,* etc.) and affricates (*ch, jh*) only the stop element is lengthened, *e.g., pph, tth, cch,* etc. In compound words and in certain phrase-groups, when plosives of the same class, such as gutturals (*k, g*), palatals (*c, j*), dentals (*t, d*) and others, are in contact, the first consonant is assimilated to the second. When the first is an aspirate it loses the aspiration in the process.

In isolated words, stress falls on the initial syllable. Word stress is subsidiary to sentence stress. Sentence stress usually falls on the initial syllable of the first significant word of a phrase. Each of the phrases comprising a sentence has approximately the same time interval, resulting in a rhythm which is especially marked in recitation or reading.

Declension.—There is no special system of declension for masculine, feminine or neuter. Sex is indicated either by terms such as "male" or "female," or by noun pairs, as in English "bull" and "cow," "stallion" and "mare." The noun has two numbers, singular and plural. The usual plural suffixes are *-rā -ērā* (nominative) and *-dēr -ēdēr* (oblique) for rational beings and *-gulā, -gulī* for both animate and inanimate nouns. Plurality can also be indicated by words meaning "all, group, collection." Case suffixes are attached to the nominative forms. Usually, these are employed with specific postpositions. Postpositions are also used with the oblique forms.

The adjective does not change for gender, number or case.

Of the three personal pronouns, the second person has three forms, "common," "inferior" and "honorific," and the third has two forms, "common" and "honorific." The three pronouns of the third person also serve as demonstrative pronouns. The personal pronouns, together with the relative, interrogative, indefinite and reflexive pronouns, have plural and oblique forms to which are added case suffixes.

Conjugation.—The Bengali verb does not distinguish between singular and plural. The same set of personal endings serves both functions. The second person ending has three forms, corresponding to those of the pronoun ("common," "inferior" and "honorific"), and the third person two ("common" and "honorific"). Bengali verbal bases fall into two groups: (1) simple bases or roots to which the personal endings are attached directly; and (2) complex bases, comprising verbal roots which undergo suffixation before the endings are attached. The first is exemplified by the simple present tense; the second by the bases of the causative, and the past, future and conditional (including the past habitual) tenses. The suffix of the past tense base is *-l-*, that of the future *-b-*, and of the last two *-t-*. Compound tenses (the "present" and "past progressive" and the "present" and "past perfect"), are fashioned with the appropriate forms of the auxiliary verb *āch-* "be."

Colloquial Bengali differs most from the literary dialect in the

conjugation of the verb. A prominent feature of the colloquial Bengali verb is the operation of vowel alternation in the root through the influence of a following vowel.

BENGALI LITERATURE. The earliest work in Bengali literature — that is, literature in the Bengali language (*q.v.*)—is a pre-12th-century collection of lyrics entitled *Caryacaryaviniscaya* contained in a manuscript discovered in Nepal in 1907 by Harprasad Shastri. The poems reflect the beliefs and practices of the Sahajiya sect. The 12th century was an age of poetic activity, but the language used was Sanskrit, not Bengali. The principal poets were Jayadeva, who composed Gitagovinda, a sequence of lyrics on the mythological Radha-Krishna theme, and Umapati Dhar, of whose work little has survived. The Muslim invasion in 1199 dispersed the poets, and there is no evidence of further activity until the mid-14th century. Bengali literature is thereafter divisible into medieval (1360–1800) and modern (after 1800).

The Medieval Period.—Medieval Bengali literature consists entirely of verse composed to be sung and transmitted orally. It falls mainly into three streams: mangalkavya, narrative poems based on stories connected with popular religious cults; *mahakavya,* epic poems on the Ramayana and Mahabharata themes; and Vaishnava lyrics (padavali) on the Radha-Krishna theme (see VISHNU; KRISHNA).

Mangalkavya Poems.—These poems narrate the campaigns waged by various deities to establish their worship on earth. The stories and characters differ but the general pattern is similar: the deity descends to earth and appoints an agent for the new cult, who after much conflict with religious antagonists ultimately succeeds, and the ending is happy for all. Many deities are represented, including principally: Manasa, a goddess indigenous to Bengal, who is mistress of all snakes; Candi and Kālī, wives of Siva; Dharmathakur, a non-Aryan deity. The human characters are mostly of low caste, which suggests that they lived originally in a pre-Brahmanical era. The literary interest of the mangalkavya lies in the character and suffering of the human participants, the deity being little more than a deus ex *machina* who keeps the action moving. The principal mangalkavya poets are: for Manasa: Vijay Gupta (d. c. 1494), Vipradas (d. c. 1495), Vamsivadan (16th century), Ksemananda Ketakadas (d. c. 1641). Ramjivan Vidyabhushan (d. c. 1703), Jivankrishna Maitra (d. c. 1744); for Candi: Manik Datta (15th century), Madhavacarya (d. c. 1579), Mukundaram Kavikankan (d. c. 1594), Dvijaharinam (17th century) Janardan (17th century); for Kālī: Sridhar (d. *c.* 1533), Krishnaramdas (end 17th century), Bharatcandra Ray (d. c. 1760), Ramprasad Sen, the famous composer of Sakta lyrics (latter 18th century); for Dharmathakur: Rupram (late 17th century), Ramdas, Sitaramdas (both 17th century).

Mahakavya *Poems.*—Krittivas Ojha's Ramayana (late 14th century), is the earliest great Mahakavya composed in Bengali. It is not a translation of the Sanskrit epic but an original work on the same theme, and for the Bengali it alone is the Ramayana. It is alive today and is still sung at Ram festivals. In it the hero, Ram, is a Bengali, and his wife Sita is the ideal of Bengali wifehood. The landscape and social conditions are those of Bengal. The versions of the Mahabharata, the greatest of which is that of Kashiramdas, also mirror the life of contemporary Bengal. The principal poets are: on the Ramayana epic: Krittivas Ojha (see above), Kavicandra (18th century); on the Mahabharata epic: Kavindra (d. 1525), Kashiramdas (d. 1602), Krishananda Vasu (17th century), Kavicandra (18th century).

Vaishnava Literature (*Padavali*).—The presentation of the Radha-Krishna *lila* (sacred play), initiated by Jayadeva, was continued in the 15th century by Baru Candidas in Shrikrishnakirtan, a lyric sequence in 13 cantos. In this work, as in Jayadeva's, the emphasis is on the human rather than the religious aspects of the *lila*. In the early 16th century, the teaching of Sricaitanya (d. 1533) changed the character of the padavali, by converting human love songs into fervent religious hymns, though the substance was unchanged and the sensuous imagery of human passion was retained. Sricaitanya was deified by his disciples, and the fervour he created found expression in prolific literary activity, which continued into the 18th century. It became an accepted convention to preface groups of Radha-Krishna hymns with others to Caitanya. These were known as gauracandrika. The language of most of the padavali was not Bengali but Brajbuli, an artificial literary language of uncertain origin, though its linguistic affinities are to Maithili and Bengali.

The greatest of the *padkartas* or *mahajans,* as the Vaishnava poets were called, are: Locandas, Jnandas, who wrote in both Bengali and Brajbuli, Balaramdas, Govindadas and a poet or poets named Candidas. They all belong to the 16th or early 17th century.

Muslim Poets.—The school of 17th-century Muslim Bengali poets in Arakan stands apart from the main streams of literature: their works are secular and their subjects were drawn from other sources. The earliest. Daulat Kaji, wrote Sati Mayanamati and Lorcandrani between 1622 and 1638. Both were left unfinished. The pre-eminent poet of this school was Alaol. His works are Padmavati (*c.* 1648), a version of a poem of the same name by the Hindi poet Jaysi, Saiyad *Muluk, Baduijjamal* and *Hapta* Paikar. The last three, which were written between 1660 and 1669, are based on Perso-Arabian stories. Alaol also completed the unfinished poems of Daulat Kaji.

The Modern Period.—Prose.—The literary use of prose was begun in Calcutta in 1800 by the missionary, William Carey, and his pandits, Ram Ram Basu and Mrityunjay Bidyalankar. After translating the Bible, Carey organized the production of prose texts for use in Fort William college and schools. Ram Ram Basu's Pratapadityacarit (1801) was the first original prose work by a Bengali. The pioneers of prose worked their apprenticeship in meeting the needs of the classroom. The second phase was that of the newspaper, inaugurated by John Marshman in 1818 with the publication of Samacar *Darpan.* Other papers followed: *Sambad* Kaumudi (1821), by Ram Mohan Ray, who had already published some prose theological studies, and Samacar Candrika (1822), by Bhabanicaran Bandyopadhay. More than 30 papers were issued within the next ten years, including Isvarcandra Gupta's Sambad Prabhakar, which became the training ground for many important writers. Among later newspapers were *Tattvabodhini* Patrzka (1843), by Debendranath Thakur and Akshay Kumar Dutt (Datta), and Banga Darshan (1872) by Bankimcandra Cattopadhyay (see CHATTERJI, BANKIM CHANDRA). Prose reached full literary status with Akshay Kumar Dutt (1820–69) and, more especially, with Isvarcandra Bidyasagar (1820–91), who is regarded as the father of Bengali prose.

The Novel.—The novel as a literary form emerged in 1858 with *Alaler* Gharer Dulal by Pyaricad Mitra. It is a social satire, as also is *Hutom* Pecar *Naksa* by Kaliprasanna Simha (1862). *Aitihasik Upanyas* (1862), by Bhudeb Mukhopadhyay, was the first historical novel. In 1865 Bankim Chandra Chatterji burst upon Bengal with Durgesnandini, and others in close succession. A little later came Rabindranath Tagore (*q.v.*). With these two the Bengali novel reached maturity. Outstanding among subsequent writers are Saratcandra Cattopadhyay and Bibhutibhushan Bandyopadhyay. The latter's moving portrayal of village life in *Pather* Panchali (1917) is known outside India as the basis for a distinguished film of the same title, made in Bengal in the 1950s. But Saratcandra comes nearest to the heart of the Bengali reader. His novels may have structural weaknesses, but his characters are live and convincing. "He writes as we speak," said one contemporary reader. The colloquial language (calti bhasa), well handled by Rabindranath, has in Saratcandra and Bibhutibhushan become firmly established as a literary medium.

The Drama.—The Bengali theatre as a regular institution dates from 1872, when the national theatre was founded by Giriscandra Ghosh (1844–1911). The first original Bengali play, *Kulinkulsarvasva,* was written by Ramnarayan Tarkaratna in 1854. Within the decade Michael Madhu Sudan Dutt (*q.v.*) and Dinabandhu Mitra wrote a number of plays, but they were not of notable qual-

ity, and their production was dependent on patronage. The national theatre was a professional theatre, dependent on popular support, and in it women were employed as actresses for the first time. Giriscandra Ghosh, the genius behind this enterprise, was, as well as being producer and actor, a playwright of no mean talent, a poet and musician. He wrote no fewer than 80 plays. In them he combined the techniques of European drama with those of the indigenous drama, the *yatra*. After Ghosh came Dvijendralal Ray (1863–1913), a writer of popular but mediocre historical plays, and Rabindranath.

Poetry. — *Early* 19th-century poetry was medieval in form and content, except that in the poems of Isvarcandra Gupta *(see* above) can be felt the stirrings of patriotic sentiment. The modern phase began in the 6th decade, under the influence of English poetry. Its principal features were: metrical innovations based on western models; adoption of new, often contemporary, subjects; and a tendency to hero-worship and patriotic enthusiasm. The pioneers in metrical innovation were Madhu Sudan Dutt, who introduced blank verse, modeled on Milton, and Rangalal Bandyopadhyay (1826–77), who experimented with new lyric stanzas. Biharilal Cakrabarti (1835–94) trod a new path in his descriptions of natural scenery, reaching his highest power in *Saradamangal* (1876). The compositions of Hemcandra Bandyopadhyay (1838–1903) embrace dramatic, narrative and lyric poetry. He drew upon Sanskrit authors, Shakespeare, Dante and Madhu Sudan. His metrical range includes medieval metres, blank verse after Madhu Sudan, and various new lyrical forms. His principal works are two volumes of lyrics (1870 and 1905); *Britrasamhar* (1877), an epic poem; a translation of *Romeo and Juliet;* and *Chayamaya* (1905). Hemcandra is well known for his patriotic poems, but like others he suffers from comparison with his great contemporary Rabindranath.

See J. C. Ghosh, *Bengali Literature (1948)*; *Sukumar* Sen, *History of Bengali Literature (1960).* (T. W. CL.)

BENGASI (BANGHAZI), chief seaport and capital of the province of Cyrenaica (Barca), Libya, and joint capital, with Tripoli, of the country, lies southwest of the site of the ancient Euhesperides or Hesperides-Berenice. Situated 600 mi. E. of Tripoli by road, Bengasi covers about a mile of the coast line, facing west on a narrow strip of land between the Gulf of Sidra (Khalij Surt) and a salt marsh, and extends about ½ mi. toward the flat rocky hinterland. There are sandy beaches nearby. Pop. (1954) 69,718.

Founded by the Greeks of Cyrenaica under the name of Hesperides, the town received from Ptolemy III the additional name of Berenice in honour of his wife. The ruins of the ancient town, which became the chief place in the province after the 3rd century A.D.. are now nearly buried in the sand. There are numerous rock-cut tombs of the Ptolemaic and Roman period, when there mas a considerable Jewish colony. No traces exist of the buildings attributed to Justinian, who is said to hace fortified it. In World War II Bengasi suffered considerably and after changing hands five times was finally captured by the British 8th army in Nov. 1942. The federal government moved there from Tripoli in Oct. 1957.

Bengasi, still bearing marks of war damage in the early 1960s, is nevertheless an attractive town overlooking the harbour, with its promenade dominated by modern buildings, including the Roman Catholic cathedral and the imposing Berenice hotel. The National University of Libya was opened in 1955 with a faculty of arts and education to which a faculty of commerce was added in 1957. There is a golf course and a public park with a small zoo.

In a predominantly pastoral and agricultural district, Bengasi's industries mainly supply local needs, but exports include hides and skins, wool, sponges and live sheep. A good east-west coast road runs through the town and short railways operate in the area. There is a steamship service with Italy. Benina airport, 10 mi. outside the town, is an important commercial airport. *See* also CYRENAICA. (P. W. I.; M. F. J.)

BENGEL, JOHANN ALBRECHT (1687–1752), German Lutheran pastor and theologian who produced the first critical edition of the Greek New Testament, mas born at Winnenden, Württemberg, on June 24, 1687. After studying at the University of Tübingen he taught at the evangelical Klosterschule, Denkendorf (1713–1741), and then became general superintendent at Herbrechtingen (1741) and Alpirsbach (1749). He died at Stuttgart on Nov. 2, 1752.

A firm believer in the importance of a personal understanding and application to life of the Bible by the individual Christian, he was dissatisfied with the immense array of variant readings in John Mill's edition of the Greek New Testament (1707j, which seemed to shake the reliability of the text. He therefore determined himself to edit the text on objective critical principles and thus have a secure basis for its exegesis. In his edition (1743), besides altering the *textus receptus* in certain places, he puts at the foot of each page those variants arranged according to their value which he thinks worth consideration, discusses each of them in an appendix and adds a treatise on the whole problem of variant readings. He concludes that the mere number of manuscripts supporting any one reading is of no value in itself, for the manuscripts must be grouped into families before the worth of each as a witness to the text can be determined. The first step in grouping the manuscripts is to determine which variant can be explained as derived from which other variant; a guiding principle is that the difficult reading is to be preferred to the easy one *(proclivi scriptioni praestat ardua),* the famous rule best known in the wording *difficilior lectio potior.* Bengel thus opened the way to a really methodical handling not only of the New Testament but of other texts as well. But he regarded his edition of the New Testament merely as the preparation for his *Gnomon novi testamenti* (1742; Eng. trans. 1857–58), a commentary in which he gives a careful word for word explanation of the Greek text in an unusually concise and penetrating way.

See K. Hermann, *J. A. Bengel (193'1).* (W. G. KÜ.)

BENGHAZI: *see* BENGASI.

BENGUELA, a city and district of Angola, west Africa. The city was founded in 1617 around St. Philip fortress and was the fulcrum of Portuguese expansion in Africa. It continued to grow (pop. [1955 est.] 15,399 including 4,875 Europeans) in spite of the competition of the neighbouring Lobito, one of the finest ports of the west African coast. Benguela is politically, commercially and industrially the co-ordinating centre for the inland activities. The most important buildings are the Government hall and the luxurious Mombaka hotel (1958). There is a lyceum and an industrial school. The city is linked with Lobito by an asphalt road and by other roads with Sá da Bandeira, Nova Lisboa, Silva Porto and Luanda; and by rail with the Republic of the Congo and the Rhodesias.

BENGUELA DISTRICT had a population in 1550 of 323,933, of whom 12,213 were Europeans and 2,606 mixed. It includes the four *concelhos* ("counties") of Benguela, Lobito. Ganda and Balombo. The area of the district is 15,042 sq.mi. The chief towns are Benguela, Lobito, Catumbela, Norton de Matos and Mariano Machado. The principal products are sugar cane, oil-producing seeds, coffee, cotton, sisal, maize, broad beans, many kinds of vegetables and fruit, and timber. At Ganda is a coffee experimental station, and stockraising is assisted by a veterinary station. Industries include cement, sisal and oil processing, and metal works. A hydroelectric power station is at Biópio on the Catumbela river. (A. A. G. P.)

BEN-GURION, DAVID (1886–), one of the founders of the state of Israel and its first prime minister, was born at Plonsk in Poland on Oct. 16, 1886. Devoted from boyhood to Zionism and to socialism, he went to Palestine in 1906 as a labourer and set out to form a Labour party and also a body of guards for the defense of Jewish agricultural settlements there. Soon after the outbreak of World War I he was expelled from Palestine by the Turks and went to New York, where he married and where he organized a Zionist Labour party. He joined the Jewish legion, which was raised there in 1918. to be part of the British forces in Palestine. From 1918 he lived in Tel Aviv and was head of the Labour party (Mapai), which became the most powerful political and economic force. He also formed the General Federation of Jewish Labour (Histadruth). In the Zionist organization he carried on a struggle with Chaim Weizmann for supreme power, and

the frustration of Jewish hopes by the British government's policy from 1938 strengthened his hold on the young generation in Palestine. Convinced that the Jews must have a state. he organized the Haganah as a fighting force.

It was Ben-Gurion who, on May 14, 1948, at Tel Aviv, read the declaration of Israel's independence. In the new state he became prime minister as well as minister of defense, continuously retaining these two offices except for a period from Dec. 1953 till summer 1955. After each general election he had to form a coalition government, but Mapai was always the core, and Ben-Gurion was always the strong man of the state. His main aim was to bring to Israel all the Jews who were willing to come; and the "ingathering of the exiles" brought nearly 1,000,000 immigrants in the first decade. He attacked the "Anglo-Saxon Zionists" because only a few were prepared to move their homes to Israel. His role in the Suez conflict of 1956, when he mobilized Israel's forces and sent them into Sinai, strengthened his authority; and his visits in 1960 and 1961 to the United States, Great Britain and France marked his standing as a statesman. m those years his authority in Israel was impaired by an internal conflict over the secretary of the Histadruth. He was, however, prime minister of a new coalition government in 1961. *See* also ISRAEL: *History.*

(NO. B.)

BENI (EL BENI), a department in the lowlands of northeastern Bolivia, was established in 1842 during the administration of Gen. José Ballivián. It is bounded northwest by the department of Pando, northeast by Brazil, south by the departments of Santa Cruz and Cochabamba and west by La Paz. Population (1959 est.) 135,518; area 82,457 sq mi. Trinidad, the capital (pop. [1959 est.], 12,542), founded in 1556 by Tristán de Tejada and Juan de Salinas, is about 6 mi. from the Mamoré river. Partly forested. Beni is largely a plains region subject to widespread flooding from February to June. The Mamoré and Beni rivers leading to northern Bolivia and Brazil and their tributaries are the main channels of communication and transport. The Jesuits established *reducciones* or mission settlements in this region in the 17th and 18th centuries. They introduced cattle and horses ahich multiplied to extraordinary numbers on the Llanos de Mojos. and are still a major source of wealth. The collection of rubber, quinine and Brazil nuts are important forest industries. A wide range of agricultural products including rice, sugar cane, bananas, coffee,cacao, manioc. cotton and corn are grown in the area. Inadequate communication facilities, geographical isolation and underpopulation have impeded the successful development of this great trontier region. (J. L. TR.)

BENI 'AMER: *see* BEJA.

BÉNI MELLAL, a small town and capital of a province of the same name. of central Morocco, 121 mi. N.E. of Marrakesh on the road to Fès, lies at 2,034 ft. above sea level on the foothills of the Middle Atlas. Pop. (1960) 28,933. At the entrance to the town is the Rasba Bel Kush, built in the 17th century and restored in the 19th century. This little agricultural centre gained its importance from the development of the Tadla plain, achieved mainly by the construction of the barrage of Bin el Ouidane on the Wadi el Abid, nhich was opened in 1955.

Béni Mellal province (pop. [1960] 474.001) was formerly a dry plateau frequented only by shepherd tribes. The Tadla was transformed by irrigation. which, at full stretch, covers about 1.500 sq.mi. Though the peasants have retained the ownership of their land, cultivation is regulated by a government office. Experiments have been made in growing new crops, especially cotton, which has been successful. (A. AM.)

BENIN, the name of a city of the Western region of Nigeria, Africa, and of an old west African kingdom. The name was formerly applied to the whole Guinea coast from the Volta to the Rio del Rey and included the Slave Coast, the delta of the Niger and some country to the east. The part of the sea which washes the Slave Coast is still called the Bight of Benin.

Benin city lies on the Benin river. north of the swamps and creeks of the Niger delta in the dense tropical forest of the coastal plain. 260 ft. above sea level. Pop. (1960 est) 61,745. It is the administrative centre of the midwest area of the Western region. The old walled town, which had occupied this site for centuries, was burned down in 1897 (see *History* below). Traces of the old mall and moat remain, but the new town is a close-packed pattern of houses and streets converging on the *oba's* ("king's") palace and the government offices. The palace is of historical interest and a juju ceremonial house, containing the *oba's* ceremonial robes of coral beads, still stands in the compound. A small museum houses items of historic value which survived the fire. In the main square is a statue of Emotan, a lady said to have offeredherself for sacrifice to restore the prestige of her husband, the *oba.* Benin has long been known for its brasswork, some of which is said to date from the 13th century, and for its woodcarvings. Though the ancient artistry has been lost, traditional designs are still produced in both these crafts.

Benin has no railway but stands on the main highway from Lagos (323 mi.) via Ibadan to the east. A direct road from Lagos has reduced the distance to about 180 mi. The town's own port has been constructed at Koko on the Benin river. Benin is also a principal centre in Nigeria's internal airways network. The timber and rubber industries of western Nigeria centre on Benin, and rubber development includes improved collecting facilities and processing factories.

History.—Benin city was the capital of one of the most highly organized states of west Africa. The period of its greatest expansion appears to have been between the 14th and 17th centuries. Lagos was founded by a Benin army and continued to pay tribute to the *oba* of Benin until about the end of the 19th century. He ruled over Yoruba, Ibo, Itsekiri and Ijo (Ijaw) as well as the Edo-speaking peoples. The *oba* was reputed to be descended from Oduduwa, the founder of the Yoruba peoples, though the Binis, or Edos, a Negro people inhabiting Benin city and the surrounding area (see EDO), have always considered themselves to be a race apart; they are sharply differentiated linguistically from the Yoruba. Ibo and other neighbours, and are further distinguished by cultural and social characteristics. Akenzua II, who was the reigning *oba* in the 1950s, was the 35th king of the dynasty, of which the 15th was reigning about 1472 when Benin was first visited by a European, the Portuguese João Affonso d'Aveiro. Other Portuguese traders and missionaries followed. Dutch traders replaced the Portuguese for a time, and the first Englishman to visit Benin coast was Thomas Wyndham in 1553. Apart from ivory, palm oil and tailed pepper, the state profited much from the slave trade. In 1668 Olfert Dapper described the city as large and prosperous, and reported the *oba* as able to raise 20,000 armed men in a day and 100.000 if necessary. With the abolition of the slave trade its fortunes declined.

The oba was the supreme political, judicial, economic and spiritual head of his people. He and his ancestors were the object of state cults, which were the occasion of much of the human sacrifice that earned Benin the title of "the city of blood." It was, however, only in the 19th century that this title came into use; early travelers had reported the people of Benin as gentle and welcoming to strangers. The practice of human sacrifice was stamped out only after the burning of the city by the British in 1897, though in the 20th century it survived in the annual (non-human) sacrifices to the *oba's* head; *i.e.,* to his divinity as the reincarnation of his ancestors. On his well-being the health and prosperity of the nation is believed to depend. In 1885 the coast was placed under British protection and attempts were made to persuade the *oba* to enter into trade relations and to put a stop to human sacrifices. A treaty made in 1892 was not observed by the *oba,* and in Jan. 1897 an unarmed mission which set out for Benin nas massacred. A punitive expedition the following month captured and partly burned the city, which was found to be reeking of human sacrifices. The *oba,* Overami, was deported, but on his death in 1914 his son was installed as Eweka II; his son in turn became *oba* in 1933 as Akenzua II. By mid-20th century the *oba's* authority was restricted to the Benin division.

Benin city was described by early travelers as organized in two halves. "palace" and "town," and subdivided into about 50 wards. each under its own chiefs and elders, and affiliated to one of three palace societies. Each ward was inhabited by members

of a particular craft or function. Something of this organization has survived. *See* also NIGERIA: *History.*

BENI RIVER, a river of Bolivia, 600 mi. long, formed by numerous confluents rising in the northern sector of the Cordillera Real near La Pax. The Beni flows east and northeast through the densely forested and plains country until it joins the Madre de Dios at Riberalta. It is navigable from Rurrenabaque for several hundred miles as far as the Esperanza rapids near its junction with the Mamoré. The rapids are 330 yd. long with a declivity of 20 ft.; the Beni there is nearly 1.000 yds. wide and 18 ft. deep. From Riberalta, after passing the rapids. the Beni joins the Mamoré at the town of Villa Bella and the two rivers then flow northward as the Madeira, constituting the frontier with Brazil until uniting with the Abuna. Seasonal variation of the water level of the Beni renders navigation uncertain. Only during the season of high water is steam navigation reliable. Generally. steamboats run freely on the Beni (and the Madre de Dios) from December to May. (J. L. TR.)

BENI SUEF: *see* BANI SUWAYF.

BENITOITE, a titanium mineral discovered in 1907 near the headwaters of the San Benito river, San Benito county, Calif., in veins with natrolite in green schist. Benitoite may be colourless or blue, the colour varying sometimes in different parts, and passing to a deep sapphire blue. The blue variety is cut as a gem stone and oiten resembles blue spinel. though its comparative softness distinguishes it from spinel and sapphire. It is a titanosilicate of barium ($BaTiSi_3O_9$), crystallizing in the trigonal system, with a hardness of 6.5 and specific gravity of 3.65.

BENJAMIN, a tribe of Israel that traced its pedigree back to Jacob and Rachel, hence closely allied, possibly subordinate, to the Joseph tribes. *See* TWELVE TRIBES OF ISRAEL.

BENJAMIN OF TUDELA (fl. 1159–1173), rabbi and traveler who between 1159 and 1173 traveled to the western borders of China from Saragossa. His *Itinerary* throws light on the position of Jews in the 12th century. The *Itinerary* was translated from the Hebrew into Latin by Arias Montanus in 1575. The best English translation (with critical Hebrew text) is by M. N. Adler, *The Itinerary of Benjamin of Tudela* (1907). (E. M. J. C.)

BENJAMIN, JUDAH PHILIP (1811–1884), Anglo-L.S. lawyer, secretary of state of the Confederate States of America during the American Civil War. was born a British subject at St. Thomas in the West Indies on Aug. 11, 1811. About 1813 his parents moved to Wilmington, N.C.. and subsequently the family lived in Charleston, S.C. After some time spent at Yale college. Benjamin studied law in New Orleans, being admitted to the bar in 1832. In 1834 he and Thomas Slidell published a digest of decisions of the territorial and supreme court of Louisiana that for many years was the standard work on Louisiana law. Benjamin's practice was extremely successful in the field of commercial and insurance law, and he was one of the leaders of the U.S. bar. Pres. Millard Fillmore offered him a justiceship on the supreme court. which he declined. In 1852 he mas elected a Cnited States senator for Louisiana. and he quickly became a leader of the extremist southern faction in the pre-Civil War congressional debates. He withdrew from the senate in 1861 to join the government of the Confederacy, first as attorney general, then as secretary of war and finally as secretary of state (1862–65). After Xppomattox he escaped from the coast of Florida and reached England as an exile.

At age 55 Benjamin was taken as a pupil into the chambers of Charles Pollock, son of Sir Frederick Pollock *(see* POLLOCK, family), lord chief baron of the exchequer, and through the influence of English judges who knew of his abilities he was called to the bar in June 1866. He quickly became one of the leaders of the English bar, becoming a queen's counsel in 1872. His treatise. *Law of Sale of Personal Pi-operty,* first published in 1868, was the principal textbook on its subject both in England and the United States for many years. Following his death, May 6. 1884, the *Times* of London declared that Benjamin's was "one of the most remarkable of modern careers," for "he carved out for himself by his own unaided exertions not one, but three . . . histories of great and well-earned distinction."

See Pierce Butler, *Judah* P. *Benjamin* (1907); Robert Douthat Meade, *Judah* P. *Benjamin* (1943). (A. DM.)

BENLOWES, EDWARD (1602–1676), English poet of the metaphysical school. was born on July 12, 1602, at Finchingfield, Essex, where he inherited large estates. He was educated at St. John's college, Cambridge, and Lincoln's Inn. Though his family was Catholic, he early became a vehement Protestant. During 1627–29 he made the grand tour, and then settled down to a life of religious meditation and the cultivation of the arts. He used his wealth to patronize poets, artists and musicians. He commissioned engravings to illustrate his own and his friends' poems and had his own rolling press, worked by a Dutch printer whom he had brought back from the Continent as his personal servant. Among works which he sponsored were Phineas Fletcher's *The Purple Island* (1633) and Francis Quarles's *Emblems* (1635). During the 1640s he gave himself to the composition of his long poem, *Theophila* (printed 1652), which describes the progress of the sou1 through the successive stages of humiliation, zeal and contemplation to a mystical communion with God. It has some fine rhapsodic passages but is noted for its extravagant conceits. His other extant poems, in Latin and English, are mostly short.

A decline in Benlowes' fortunes began with the Civil War. He suffered severe parliamentary taxation, and after taking part in the royalist rising in Essex in 1648 he was heavily fined. To clear off his debts and to provide a dowry of £6.000 for his niece Philippa he sold his estates in 1655. The costs of prolonged litigation completed his ruin. He spent his last years in Oxford! reading in the Bodleian library and still occasionally writing poetry, and died there in destitution, on Dec. 18, 1676.

Theophila and two shorter poems, of which *Tlze Summary of Wisdom* (1657) is a *réchauffé* of passages from *Theophila,* are included in G. Saintsbury's *Minor Poets of the Caroline Period* (1905), vol. I.

See H. Jenkins, *Edward Benlowes* (1952). (HD. J.)

BENN, SIR ERNEST JOHN PICKSTONE, 2ND BARONET (1875–1954). English publisher and author, one of the chief advocates of individual enterprise in an age when leading economists preached in support of collectivism and state planning, was born at Hackney, Middlesex, on June 25, 1875, the eldest son of Sir John Williams Benn. His father devoted himself to politics as a Liberal member of parliament and an original member and early chairman of the London County council. He left the management of his publishing business largely to his capable son, who thus found himself in charge almost before attaining his majority. Young Benn soon acquired the *Hardware Trade Journal* to add to his father's journal, the *Cabinet Maker.* His' experiences selling advertisement space to manufacturers, coupled with his work in World War I at the ministries of munitions and reconstruction, served to form in his mind the views he subsequently expressed so forcefully in contributions to the press and in books. *The Confessions of a Capitalist, Account Rendered* and *The State the Enemy* were his best-known books.

Benn's publishing activities continued to grow, and spread from trade journals to books. He was a pioneer of paperbacks with the Sixpenny Poets and Sixpenny Library, two best-selling popular education series. His public work included the presidency of several national trade charities, and the foundation of the Boys Hostels association. He died at Oxted, Surrey on Jan. 17. 1954. (ED. G. B.)

BENNET, JOHN (c. 1575–?), English composer, chiefly of madrigals. Scarcely anything is known of Bennet's life, but the dedication of his *Madrigalls to Foure Voyces* (1599) suggests that he may have come from the border of Lancashire and Cheshire. Since the title page also describes this collection as "his first works" it may be presumed that he was born c. 1575. He contributed a madrigal, the well-known "All creatures now are merry minded," to Thomas Morley's *The Triumphes of Oriana* (1601). and five four-part settings of traditional tunes to

the undated psalter printed by William Barley; since Barley was one of those to whom Morley had assigned his patent to print music and Morley also contributed to this psalter, he and Bennet probably knew one another. This is also suggested by the style of Bennet's madrigals, which is light but highly finished in Morley's Italianate manner.

Bennet's music was also valued by the composer and compiler Thomas Ravenscroft, who reprinted two of the psalm-settings in his psalter of **1621,** and also included six new compositions by him in his *Briefe Discourse* **(1614).** Two of these, as well ,as Bennet's **1599** collection and his single Oriana madrigal, are included in vol. xxiii of E. H. Fellowes's *The English Madrigal School* **(1922).** (J. J. N.)

BENNETT, (ENOCH) ARNOLD (1867–1931), English novelist, dramatist and journalist, whose best work describes life in "the Potteries." where he lived as a boy, was born at Hanley, Staffordshire, on May 27, **1867.** The son of a solicitor. he left school at **16** and entered his father's office but in **1888** left the Potteries for London where, having published several stories and articles, in **1893** he became assistant editor and, in **1896,** editor, of the magazine *Woman.* His first novel, *A Man From the North,* not autobiographical but closely related to his personal experiences, was published in **1898.** Thenceforward until 1930 he wrote continuously, sometimes publishing more than **300,000** words a year, becoming comparable in common reputation with Bernard Shaw and H. G. Wells, a popular sage expressing opinions on almost every sort of question, and the highest-paid book reviewer of the day. From 1902 to 1913 he lived mainly in France, marrying in 1907 Marguerite Soulié, from whom he was legally separated 14 years later. In the last years of his life he lived with Dorothy Cheston, an actress, who bore him a daughter. "Of his last ten years one's final impression is of a man bound down under the tyranny of things, perpetually tired, often ill, striving despite his enormous success to make both ends meet." (Walter Allen, *Arnold Bennett,* Arthur Barker Ltd., **1948.)** This was the period of Bennett's yacht and luxury flat, of his hobnobbing with the rich and famous, of his theatrical ventures and his weekly two columns in the *Evening Standard.* Yet to see his career as that of the simple provincial corrupted by success is inadequate. He always defied facile pigeonholing, and he maintained an unsentimental integrity to the end of his life. He died in London on March **27,** 1931.

Arnold Bennett's novels are very unequal in value and it is hard to trace any consistent development in them. Throughout his literary career crude, trivial and frankly commercial writings jostle with books showing a sincere effort to portray truth. *Anna of the Five Towns* (1902), *The Old Wives' Tale* (1908), *Clayhanger* (1910) and *Riceyman Steps* (1923) are generally considered the finest of his novels; none of his plays has real distinction, despite the success of *Milestones* (1912), written with Edward Knoblock, and *The Great Adventure* (1913), a dramatization of his *Buried Alive* **(1908).** Much has been made of Bennett's debt to the French novel, especially to the naturalists: Zola in particular. Certainly his concern with presentation ("An artist must have a passion for technique, a deep love of form") owes something to the French, and his attempt to achieve objectivity reflects the aims of naturalism; yet such a novel as *Anne of the Five Towns* seems to be closer in manner to the realism of Balzac and Turgenev. In *Anna* and, more ambitiously, in his masterpiece *The Old Wives' Tale* and in the *Clayhanger* books, Bennett portrays with unequaled knowledge and mature compassion the life, especially the middle-class life, of the Potteries, the "five towns" of north Staffordshire. He is at once close to his subject matter, and detached, objective, critical in his handling of it. When he is closest to it, as in the opening section of *The Old Wives' Tale,* his touch is Dickensian, although in less secure moments he can be facetious. When he stands back a little, as in the moving close of *Anna* or in the entire conception of *Riceyman Steps* (the only one of his major novels not set in the five towns), his objectivity is tinged with a compassionate and unforced irony. The unresolved contradiction in his own life—between the provincial boy and the boulevardier, the socialist who is yet absorbed in maintaining a luxurious way of living, the conscientious artist who became the grand panjandrum of middle-brow culture—is, in his best moments, resolved in this blend of the objective and the ironical. But the contradiction impregnates his novels, like his life, with sadness. Too tough a writer to capitulate to easy sentimentality, his sense of the impossibility of reconciling ideals with reality gives his best work truth and dignity but also leads to a certain lack of confident vitality. Perhaps the keyword of his career, as man and artist, is, with all its ambiguity, the word realism.

The Journals of Arnold Bennett, 1896–1928 were edited by N. Flower in three volumes (1932–33).

BENNETT, CHARLES EDWIN (1858–1921), U.S. classical scholar, whose *Lutin Grammar* **(1895)** was the first successful attempt in the U.S. to adopt the method of the brief, scholarly German school grammar, was born April **6, 1858,** in Providence, R.I. He graduated from Brown university in **1878,** and also studied at Harvard and in Germany. After teaching in secondary schools in Florida, New York and Nebraska, he became professor of Latin at the University of Wisconsin in **1889,** of classical philology at Brown university in **1891** and of Latin at Cornell university in 1892.

His syntactical studies are based on a statistical examination of Latin texts, and are marked by a fresh system of nomenclature. Of interest are his advocacy of quantitative reading of Latin verse, and his *Critique of Some Recent Subjunctive Theories* in *Cornell Studies in Classical Philology,* of which he was editor. His later publications include *Syntax of Early Latin* (1910–14); and *New Latin Composition* **(1912).** He died May **2, 1921,** at Ithaca, N.Y.

BENNETT, JAMES GORDON (1795–1872), U.S. journalist, founder and editor of the *New York Herald,* who greatly influenced journalism in the United States, was born at Newmills, near Keith, Banffshire, Scot., in 1795. He was educated for the Roman Catholic priesthood in a seminary at Aberdeen, but in the spring of **1819** he emigrated to America. After earning a meagre living as teacher, proofreader and translator in Halifax, N.S., .Boston, New York and Charleston, S.C., he settled in New York, where he projected a school, gave lectures on political economy and did subordinate work for the journals. During the next ten years he was employed on various papers, was the Washington, D.C.. correspondent of the *New York Enquirer* and associate editor of the *Courier and Enquirer,* his articles attracting much attention. He founded the short-lived *Globe* in New York in **1832,** and in 1833–34 was the chief editor and one of the proprietors of the *Pennsylvanian* at Philadelphia.

Starting with a capital of $500, he published on May **6, 1835,** the first number of a four-page penny paper bearing the title of *New York* Herald and issuing from a cellar. The proprietor and editor also played the part of salesman. In his initial issue he outlined his policy: "We shall support no party—be the agent of no faction or coterie, and care nothing for any election, or any candidate from president down to constable"; and to this he consistently adhered. By his industry and sagacity, and by considering it the function of a newspaper, "not to instruct, but to startle," he made the paper a great commercial success. He devoted attention particularly to the gathering of news and was the first to introduce many of the methods of the modern U.S. reporter. He published on June **13,** 1835, the first Wall street financial article to appear in any U.S. newspaper; printed a vivid and detailed account of the great fire of Dec. **1835** in New York; was the first, in **1838,** to establish European correspondents; was the first, in **1846,** to obtain the report in full by telegraph of a long political speech; maintained during the Civil War a staff of 63 war correspondents; was a leader in the use of illustrations; introduced a society department; and with the Helm Jewett case was the first in U.S. journalism to publish an account of a love-nest murder. Bennett continued to edit the *Herald* almost till his death on June 1, **1872.** *(See* also NEWSPAPER: *The Penny Press.)*

His son, JAMES GORDON BENNETT (1841–1918), born May 10, 1841, and educated abroad and by private tutors, shared his father's burdens after 1866 and succeeded his father in the control of the *Herald*. He founded the *Evening Telegram*, established a daily edition of the *Herald* in London and later in Paris, financed Henry M. Stanley on his mission to find David Livingstone in central Africa, fitted out the "Jeannette" Polar expedition, and in 1883 organized (with John W. Mackay) the Commercial Cable company. An enthusiastic sportsman, he established trophies for international yacht and motor races. On May 14, 1918, he died in France, from where he had long directed the policies of the *Herald*.

Emery (eds.), *Highlights in the History of the American Press* (1954). Biographical information also may be found in D. C. Seitz, *The James Gordon Bennetts* (1928); on the lather in Oliver Carlson, *The Man Who Made News: James Gordon Bennett* (1942), and on the son in A. S. Crockett, *When James Gordon Bennett Was Caliph of Bagdad* (1926).

BENNETT, RICHARD BEDFORD BENNETT, VISCOUNT (1870–1947), Canadian statesman and prime minister; who was strongly nationalist in economics and largely responsible for the Ottawa economic conference in 1932 which resulted in a series of bilateral trade agreements between various commonwealth states. Born at Hopewell, N.B., July 3, 1870, he was graduated from Dalhousie university, Halifax, and in 1893 was admitted to the bar. In 1897 he migrated westward, serving in the legislative assemblies of the Northwest Territories and of Alberta.

In 1911 he entered the house of commons as member for Calgary, Alta. In 1916 he was director-general of national service and in 1921 minister of justice. In 1927 he became leader of the Conservative party, and in 1930 he was returned to office as prime minister. In Oct. 1935 he was heavily defeated by the Liberals led by Mackenzie King.

Bennett was created a viscount in 1941, a title which became extinct when he died unmarried, on June 27, 1947, at Mickleham, Surrey, Eng. (W. R. GR.)

BENNETT, SIR WILLIAM STERNDALE (1816–1875), English pianist, conductor and composer, a notable figure in the musical life of his time. Born at Sheffield, April 13, 1816, he became a chorister at King's college, Cambridge, and in 1826 entered the Royal Academy of Music where he studied composition under William Crotch and Cipriani Potter. While there he wrote several symphonies and piano concertos. In 1833 his first piano concerto greatly impressed Mendelssohn, who became a close friend.

In 1836 he played his third piano concerto and conducted his overture *The Naiads* at the Gewandhaus concerts in Leipzig where he was enthusiastically received by Schumann.

In 1842 he was appointed one of the directors of the Philharmonic society in London and in 1849 he founded the London Bach society, at which, in 1854, he gave the first performance in England of Bach's *St. Matthew Passion*, which began the movement for the performance of Bach's choral music in England.

He was appointed conductor of the Philharmonic society in 1856 and in the same year became professor of music at Cambridge. In 1866 he became principal of the Royal Academy of Music. He was knighted in 1871. He died in London on Feb. 1, 1875.

Bennett's work, consisting chiefly of concertos and solo pieces for the piano, enjoyed a wide popularity in England and Germany, and his cantata *The May Queen*, written, like so many of his works, for a festival (Leeds, 1858), and the quartet "God Is a Spirit," from the oratorio *The Woman of Samaria* (1867), are still sung by village and church choirs.

See J. R. S. Bennett, *The Life of W. S. Bennett* (1907).

BEN NEVIS, the highest mountain in the British Isles, is in Inverness-shire, Scot. It is 4,406 ft. above sea level. 4½ mi. E.S.E. of Fort William, the meridian of 5° W. passing through it. From Banavie on the Caledonian canal, it shows two great masses and though bulky is much less striking than many other Highland hills. Its summit is a plateau of about 100 ac. with a slight slope to the south and a sheer fall to the northeast of more than 1,500 ft. Snow lies in some corries all the year round. The rocks of its lower half are mainly porphyritic granites intruded into Highland schists and traversed in places by intrusive dikes. The summit, in contrast: consists of volcanic rocks some 2,000 ft. in depth, resting unconformably on the Highland schists: cauldron subsidence has been invoked to explain this feature. Its circumference at the base is about 24 mi. Ben Nevis is really the highest point of a dissected mountain block flanked on the west and south by the glen and water of Nevis, on the east by the river and glen of Treig, and on the north by the river and glen of Spean. A small hotel on the summit has long been closed and is in ruins, as is the meteorological observatory maintained there from 1881 to 1905 and afterward closed for lack of funds. A bridle road up the mountain, which leaves Glen Nevis at Achintee and has a gradient nowhere exceeding 1 in 5, was made for the use of workers at the observatory. (A. T. A. L.)

BENNIGSEN, LEVIN AUGUST (Russian LEONTI LEONTIEVICH), COUNT VON (1745–1826), Russian general prominent in the Napoleonic Wars, was born of a Hanoverian family in Brunswick on Feb. 10, 1745, and served in the Hanoverian army until 1764. In 1773 he entered the Russian service as a field officer. He fought against the Turks in 1774 and in 1778 and became colonel in 1787. He distinguished himself repeatedly in the Polish War of 1793–94 and in the Persian War of 1796. The part played by Bennigsen in the actual assassination of the emperor Paul I is not fully known, but he took a most active share in the formation and conduct of the conspiracy. The emperor Alexander I made him governor general of Lithuania in 1801 and a general of cavalry in 1802. In 1806 he was in command of one of the Russian armies operating against Napoleon and fought the battle of Pultusk. In the sanguinary but indecisive battle of Eylau (Feb. 8, 1807) he could claim to have inflicted the first reverse suffered by Napoleon, but six months later he met with crushing defeat in the battle of Friedland (June 14), the direct consequence of which was the treaty of Tilsit. He retired for some years, but in the campaign of 1812 he commanded the Russian centre at Borodino and defeated Joachim Murat at Tarutino. Because of a quarrel with M. I. Kutuzov, however, he was compelled to retire. After Kutuzov's death he was recalled and placed at the head of an army. Bennigsen led one of the columns that made the decisive attack on the last day of the battle of Leipzig (Oct. 16–19, 1813). On the same evening he was made a count by Alexander I and he afterward commanded the forces operating against L. N. Davout in northern Germany. He retired from active service in 1818 and settled on his Hanoverian estate of Banteln near Hildesheim. He died in Hanover on Dec. 3, 1826.

See FRIEDLAND; NAPOLEONIC CAMPAIGNS. (I. GY.)

BENNIGSEN, RUDOLF VON (1824–1902), for 30 years president of the German National Liberal party, was born at Liineburg on July 10, 1824, the son of a major general in the Hanoverian army. After studying law, he entered the Hanoverian civil service in 1846 but resigned in 1856 on his election to the Hanoverian second chamber, in which he became the leader of the Liberal opposition. In 1859 together with Johann von Miquel, he founded the Nationalverein, becoming its president. The Nationalverein's aims were German unity under Prussian leadership and an all-German parliament. Bennigsen vainly tried to keep Hanover neutral in the Seven Weeks' War, but with Prussia's annexation of Hanover after the war he entered the diet of the North German confederation and the Prussian chamber of deputies, whose president he was from 1873 to 1879. When the Nationalverein was dissolved (1867), Bennigsen helped to found the National Liberal party which worked for German unity and a liberal constitutional development. He took part in the negotiations at Versailles in Dec. 1870 between the North German confederation and the states of southern Germany. Bismarck's attempt to bring him into the Prussian ministry in

1877 failed because the emperor William I disliked him and partly because Bennigsen insisted that two of his party colleagues be also appointed. Despite earlier co-operation, relations between Bismarck and the National Liberals became strained, especially when the party rejected Bismarck's entire protectionist policy in 1879. The parliamentary power of the National Liberals was however shattered when a right-wing protectionist group split away in 1879 and the radicals, of the so-called *Sezession,* in 1880. Bennigsen retired from politics in 1883, but returned in 1887 to enter the *Kartellreichstag,* in which the Conservatives combined with the National Liberals to pass the Septennat bill (for a seven-year army grant). William II appointed Bennigsen president of the province of Hanover in 1888. He resigned from this post and retired from public life in 1897. He died at Bennigsen, in Hanover, on Aug. 7, 1902.

BIBLIOGRAPHY.—There are selections from Bennigsen's letters ed. by H. Oncken, *Deutsche Revue,* 31 (1906–07) and 33 (1908) and an edition of his speeches by W. Schultze and F. Thimme, 2 vol. (1911–22). *See* further H. Oncken, *R. von Bennigsen,* 2 vol. (1910); D. Sandberger, "Die Minister-Kandidatur Bennigsens," *Historische Studien,* vol. 187 (1929); E. Eyck, *Bismarck and the German Empire,* 3 vol. (1941–44).

BENNINGTON, a township including the three villages of Old Bennington, Bennington and North Bennington, in the southwest corner of Vermont, U.S., between the Taconics and Green mountains; the seat of Bennington county. It was chartered in 1749, settled in 1761 and named for Benning Wentworth, the governor of New Hampshire who issued the grant. The settlers were led by Samuel Robinson, who had camped in the valley on the Walloomsac river on his return from the French and Indian War. The group immediately organized the First Congregational Church and, within the year. their first town meeting government in a form (with slight modification) still in existence. The settlers' first difficulties were with the absentee landlords of New York, who claimed rights to Bennington lands, but through successful resistance at the Breakenridge farm in North Bennington, the independence of Vermonters was soon established. These vigorous and independent settlers were already experienced fighters when, as Green Mountain Boys under the leadership of Ethan Allen and Seth Warner, they organized in Aug. 1777 to resist Gen. John Burgoyne and his Loyalists and Hessians on their march to capture the Bennington stores of arms and supplies. The patriots set forth from the Catamount tavern under Cen. John Stark and defeated the British at the battle of Bennington Aug. 16. 1777, a battle which was a turning point in the American Revolution.

During the 19th century the town grew into a textile, pottery, wood products and paper centre. The inhabitants are mostly of English, Irish and French-Canadian extraction and engaged in manufacturing (furniture, textiles, batteries, lithography, transistors), agriculture (dairy products, apples, maple sugar, chickens and Vermont turkeys) or in tourist and service trades. Nearby ski areas (Bromley mountain and Mt. Snow), as well as deer hunting and trout fishing! attract many visitors, as does the spectacular fall foliage of maples and silver birches.

Extant colonial buildings include the Parson Dewey, Governor Tichenor and Governor Robinson houses, the Old First church and the Walloomsac inn. in continuous service since 1763.

The Historical museum contains the oldest stars and stripes flag in existence, fine collections of old Bennington pottery, early American furniture, glass, household wares and genealogical materials. A 304-it.-high obelisk commemorates the battle of Bennington.

Bennington College for Women (founded 1932), enrolling almost 350 students annually, is known for its individually planned programs in the humanities and the sciences and for its winter nonresident term, when all students leave their campus studies for related practical work.

For comparative population figures *see* table in VERMONT: *Population.* (C. O. Fo.)

BENNO, SAINT (d. *c.* 1106), bishop of Meissen, Ger., was a canon attached to the imperial collegiate church of Goslar when, in 1066, he was made bishop of Meissen. In the troubles between empire and papacy that followed, Benno took part against the emperor.

In 1085 he was deposed by the synod of Mainz, but after the death of Pope Gregory VII he submitted and on the recommendation of the imperialist pope Clement III was restored to his see, which he held until his death. His canonization (1523) drew from Martin Luther a violent brochure titled "Against the New Idol and the Old Devil About To Be Set Up at Meissen." Benno's feast day is June 16.

See H. Thurston and D. Attwater (eds.), *Butler's Lives of the Saints,* vol. ii (1956).

BENOIT, PETER LÉONARD LÉOPOLD (1834–1901), Belgian composer who established a Flemish school of choral music. Born on Aug. 17, 1834, at Harelbeke, near Courtrai, he entered the Brussels conservatory in 1851 and studied composition there under F. J. Fétis. He won the Grand Prix de Rome in 1857 and in 1858 traveled throughout Germany. After visiting Paris, where he was conductor at the Théâtre des Bouffes-Parisiens, he returned to Belgium and in 1864 produced at Antwerp a sacred tetralogy, consisting of a Christmas cantata, a Mass, a *Te Deum* and a Requiem. Two years later his oratorio *Lucifer* was given in Brussels.

Under the influence of poets Hendrik Conscience (*q.v.*) and Emanuel Hiel, Benoit became interested in the Flemish national movement and in 1867 founded at Antwerp and became director of the Flemish School of Music. which in 1898 became the Royal Flemish conservatory. He also wrote works reflecting Flemish national ideals. chief of which was his *Rubens-Cantate* (1877), evoking historical scenes at Antwerp. Other of his choral works were inspired by the scenery of his country.

Benoit's conception of a Flemish musical art was democratic, and most of his works were intended to be sung by the people. Though he played an important part in popularizing choral music in Flanders, few of his works were successful abroad. He died at Antwerp on March 8, 1901.

See C. van den Borren, *Peter Benoit* (1942); *A.* Corbet, *Peter Benoit* (1944).

BENOÎT DE SAINTE MAURE (from Ste. Maure, an ancient town in Touraine), 12th-century author of the Old French *Roman de Troie.* This poem, in 30,000 lines, in octosyllabic couplets, is based on late Hellenistic romances, *De excidio Troiae historia,* by Dares Phrygius (*q.v.*) and *Ephemeris belli Troiani* by Dictys Cretensis (*q.v.*), which purport to be eye-witness accounts of the events described by Homer. The main plot is a travesty of the Iliad: Hector slays Patroclus at the outset and is himself slain by Achilles in the course of a battle. A year later, Achilles falls in love with a Trojan princess, Polyxena, and retires to his tent until he is shamed into fighting by the successes of the Greeks; however, he is killed in an ambush while trying to visit Polyxena. Much is said of the amours of Briseida, the daughter of a renegade Trojan priest Calchas (herein lies the germ of Chaucer's *Troilus and Criseyde).* The Amazons come to the aid of the Trojans, but Troy falls because of the treasonable negotiations of Aeneas and Antenor. A prelude to the main story tells of Jason and the Argonauts and an earlier sack of Troy; in an epilogue are the stories of Orestes, Andromache and Ulysses. The whole is an immense baroque tapestry of Greek lore and fable. Benoît was superseded in the later middle ages by an imitator, Guido delle Colonne, who wrote the Latin *Historia destructionis Troiae* (1287), the source of many English "Troy-books." *(See* TROY AND TROAD: *Medieval Legend.)*

It is possible to identify this poet with another Benoît (Beneeit) who flourished at the court of Henry II and wrote a verse history covering the same ground as the *Roman de Rou* of Wace (*q.v.*); but there are weighty arguments against the identification *(see* L. Constans, *Roman de Troie,* vol. vi, pp. 165–181). The relation of *Troie* to the other romances on Greco-Latin themes has led to much debate; it is now agreed that the romances *Troie* and *Éneas* are indebted to that of *Thèbes.*

BENONI, a town of the Transvaal, Republic of South Africa, lies 20 mi. E. of Johannesburg at 5,600 ft. above sea level, covering two sides of a valley which borders four lakes. Pop. (1960) 135,467. Planned in 1903 by a mining leader, Sir George Farrar, as a gold mining town, it has developed into a modern industrial centre. At the north and northeast are European suburbs, the commercial area is in the centre and the industrial section to the south. To the east, beyond a strip of land for industrial development, is the large modern township of Daveyton for Africans. The main street is Prince's avenue, resembling a south European boulevard and bordered with palms and ornamental trees, on which stand the town hall, amid gardens, and office buildings, banks and shops. There are schools of all grades, commercial and technical colleges and a Carnegie library. Sports grounds and swimming baths are of international standard; Willowmoore Park stadium is the headquarters of the Eastern Transvaal Football association and caters for association and rugby football, hockey, cricket and other sports.

Electric trains run to Johannesburg; motor roads link the town with all parts of the Transvaal, and Jan Smuts airport is nearby. Benoni is part of the workshop of the republic; industrial exports include heavy-duty batteries, welding electrodes and engineering machinery.

BENSBERG, a town of Germany which after partition of the nation following World War II is in the Land (state) of North Rhine-Westphalia, Federal Republic of Germany. Pop. (1959 est.) 28,445. It is an administrative and shopping centre, but is chiefly a "dormitory" town; atomic reactors are manufactured and there is a leather industry. There is a baroque *Schloss* ("castle"; 1706–13) that belonged to duke John William of the house of Berg, and the ruins of an old *Schloss* (1250) that had belonged to the counts of the same family. There is a local museum and a Roman Catholic academy. Communications (train, streetcar and bus) are mainly with Cologne, 9 mi. distant. (HA. C.)

BENSERADE, ISAAC DE (1612 or 1613–1691), French poet remembered for his sonnet on "Job," for his libretti and for his rondeaux. His family (whose name he originally spelled Bensserrade) may have been Protestant when he was born, but he is known to have been baptized as a Catholic on Nov. 5. 1613. He began visiting the Hôtel de Rambouillet in Paris in 1634, but seems not to have been much esteemed there. After writing some tragedies (1634 ff.), he turned chiefly to polite and amorous verse, of which there are about 100 examples by him in collections published between 1640 and 1660. In the "Sonnets controversy" (1649) his sonnet on "Job" was upheld by the Jobelins against Vincent Voiture's sonnet to "Uranie," upheld by the Uranistes, to whom victory was eventually adjudged. From 1651 onward he wrote numerous libretti for court ballets, notable for witty allusions to current topics. Elected to the Académie Française in 1674, he was unjustly blamed for turning Ovid's *Metamorphoses* into rondeaux when in fact he had simply composed the 224 rondeaux printed as tailpieces to the splendid illustrations to Ovid published by Sébastien Le Clerc and François Chauveau (1676). He died in Paris on Oct. 20, 1691.

See C. I. Silin, *Benserade and His Ballets de Cour* (1940); *A.* Adam, *Histoire de la litttrature française au XVIIe siècle,* vol. i and iii (1948–52). (AE. A.)

BENSLEY, ROBERT (*c.* 1738–*c.* 1817), English actor praised by Charles Lamb in the Essays *of Elia,* played important parts at the Drury Lane, Covent Garden and Haymarket theatres from 1765 to 1796. His most successful role was that of Malvolio in Twelfth *Night.*

BENSON, EDWARD WHITE (1829–1896), archbishop of Canterbury, mas born on July 14, 1829, at Birmingham. His father, a Yorkshireman and a manufacturing chemist, died in 1842, leaving his family impoverished. Educated at King Edward's school, Birmingham—where he was greatly influenced by the headmaster, James Prince Lee, whom he revered all his life—Benson went in 1848 to Trinity college, Cambridge, joining his intimate friends J. B. Lightfoot and B. F. Westcott (*qq.v.*), both pupils of Prince Lee. The close friendship and common spiritual ideals of these three great scholars (Benson won the senior Chancellor's medal in 1852 and became fellow of Trinity in 1853) richly benefited the Anglican church in the late 19th century.

From 1852 to 1858 Benson was an assistant master at Rugby and in 1859, the year in which he married his cousin Mary Sidgwick, he was appointed on the recommendation of Frederick Temple (then headmaster of Rugby) to the headmastership of the newly founded Wellington college. With astonishing creative power and forcefulness of personality, Benson succeeded in converting a poorly endowed institution for army officers' orphans into a great school. At Wellington, Benson began his study of Cyprian and also took the deepest interest in the building of the school chapel, the mosaics, carvings and windows of which testify to the important part he played in the revived interest in ecclesiastical symbolism and patristic studies.

In 1873 Benson became chancellor of Lincoln. He founded a theological college, conducted a successful mission and established night schools and university extension lectures. In Dec. 1876 Disraeli offered him the newly created see of Truro, and he was consecrated on April 25, 1877. Nonconformity was firmly entrenched there, but by brilliant diocesan organization and frequent pastoral tours and not least by winning the hearts of the Cornish people by his deep interest in their history and traditions, Benson virtually re-established the Anglican church in Cornwall. Truro cathedral is his most fitting monument, the realization of his dearest wish that the cathedral should be the active spiritual centre of a diocese.

In Dec. 1882 Benson accepted Gladstone's offer of the archbishopric of Canterbury on the death of Archbishop Archibald Campbell Tait (in part a recognition of his careful avoidance of party conflict), and was enthroned on March 29, 1883. He was by nature sanguine, believing that faith and unremitting industry could move mountains, and although he suffered occasional lapses into black depression (as when his eldest son, Martin, died in 1878) he fought relentlessly for what he believed to be right. He attended the house of lords regularly, pressing for the reform of church patronage (realized in the Benefices act, 1898) and for the Clergy Discipline act, 1892. In 1886 he created the House of Laymen, a consultative body to convocation. Benson firmly believed in the essential alliance of clergy and laity in defense of the establishment, launching the Central Church Committee for Church Defence and Instructiori in 1893 and successfully organizing resistance to attempts to disestablish the Welsh church. He earned the unqualified praise of Dean R. W. Church and Bishop Westcott, among many others, for his masterly judgment in the bishop of Lincoln's case (1888–90), when against the advice of many friends he heard the charges, alleging unauthorized ritualism, brought by the Church association against Edward King, bishop of Lincoln. The bishop claimed that the archbishop sitting alone had no jurisdiction over his provincials, but this objection was overruled by the privy council. In his judgment, Benson revealed the depth of his learning on ecclesiastical antiquity and liturgy, ignoring previous rulings of the privy council and producing a lucid definition of liturgical practices sanctioned by usage. The Lincoln judgment (*q.v.*) contributed greatly to the ending of one of the most unedifying chapters of 19th-century church history, and was generally accepted by both high church and evangelical parties within the church.

Greater still was his work in encouraging missions and friendly relations with churches not in direct communion with Canterbury. He opened negotiations with the Russian church, re-established the Anglican bishopric in Jerusalem, achieved a peaceful settlement of the unhappy schism in Natal (see COLENSO, JOHN WILLIAM) and founded a mission to the decayed Assyrian church (see NESTORIANS). On the other hand, Benson was suspicious of the negotiations between Leo XIII, the Abbé Portal and Lord Halifax on the question of Roman recognition of Anglican orders.

Benson combined a restless vitality with meticulous love of detail. In bearing, he was dignified and impressive. On Oct. 11. 1896, after an exhausting and successful tour of Ireland, he died from heart failure while staying with the Gladstones, during morning service at Hawarden parish church. His two main literary works were published posthumously: *Cyprian* (1897) and *The Apocalypse* (1900).

See his *Life by A. C.* Benson (1899); *A.* B. Donaldson, *The Bishopric of Truro* (1902); D. *H.* Newsome, *A History of Wellington College, 1859–1959* (1959).

Archbishop Benson's second son, ARTHUR CHRISTOPHER BENSON (1862–1925), teacher and writer, was born at Wellington on April 24, 1862. Educated at Eton and King's college, Cambridge, he was an assistant master at Eton (1885–1903), fellow of Magdalene college, Cambridge (1904), and master of Magdalene (1915–25). During his mastership, Magdalene expanded considerably. He was a kind and generous host and a liberal benefactor. He died on July 17, 1925, at Cambridge. He wrote prolifically, mainly collections of essays and biographical studies, written in a distinctive gentle and wistful style. His essays include *The Upton Letters* (1905), *From a College Window* (1906) and *The Leaves of the Tree* (1911). He also wrote the life of his father (1899) and of his brother Hugh (1915), and edited *The Correspondence of Queen Victoria* 1837–1861 (1907) (with Lord Esher). He wrote the words of the anthem "Land of Hope and Glory."

See E. H. Ryle (ed.) *Arthur Christopher Benson,* (1925).

Archbishop Benson's third son, EDWARD FREDERIC BENSON (1867–1940), born at Wellington on July 24, 1867, and educated at Marlborough and King's college, Cambridge, was also a prolific writer. His main works were *Dodo* (1893), *As We Were* (1930) and *Final Edition* (1940). He died on Feb. 29, 1940.

Archbishop Benson's fourth son, ROBERT HUGH BENSON (1871–1914), became a Roman Catholic writer and apologist. Born at Wellington on Nov. 18, 1871, and educated at Eton and Trinity college, Cambridge, he was ordained in Anglican orders but became a Roman priest (1903) after five years in the Community of the Resurrection at Mirfield. From 1911 he was a papal chamberlain. He was impulsive and full of enthusiasms, an artist and craftsman. He died in Manchester on Oct. 17, 1914. His main works were *The Light Invisible* (1903), *By What Authority* (1904) and *The Papers of a Parish* (1907).

See his *Life* by C. C. Martindale (1916); A. C. Benson, *Hugh* (1915). (D. H. N.)

BENSON, SIR FRANK (ROBERT) (1858–1939), English actor-manager, was born at Alresford, Hampshire, on Nov. 4, 1858. While at New college he produced the first Oxford Greek play, *Agamemnon.* In 1882 he made his first professional appearance at the Lyceum theatre, London, under Henry Irving, playing the role of Paris in *Romeo and Juliet.* The next year he went into managership with a company of his own, taken over from Walter Bentley. In 1886 he married Gertrude Constance Featherstonhaugh (1860–1946), who acted in his company and continued to play leading parts with him. Besides appearing in London he toured regularly in Shakespeare, and went to Canada (1913) and South Africa (1921). His finest parts were Hamlet, Coriolanus, Richard II, Lear and Petruchio. By his organization of a regular touring company, and by his foundation of a dramatic school of acting in 1901, Benson exercised an important influence on the contemporary stage. From the first he devoted himself largely to the production of Shakespeare's plays. After 1888 he organized 26 of the annual Stratford-on-Avon Shakespearean festivals. He was knighted in 1916 in Drury Lane theatre. Benson died in London on Dec. 31, 1939.

See Benson's *My Memoirs* (1930).

BENSON, FRANK WESTON (1862–1951), U.S. painter and etcher, best known for his pictures of women and children and outdoor subjects, was born in Salem, Mass., March 24, 1862. He was a pupil of G. R. C. Boulanger and, of Jules Lefebvre in Paris; won a silver medal at the Paris exhibition (1900); the Potter Palmer medal and prize, Chicago (1910); Logan prize. Chicago Society, of Etchers (1918); William A. Clark prize and Corcoran gold medal (1919); and became a member of the Ten American Painters, and of the National Academy of Design. New York city. In addition to his reputation as a painter, he achieved success with his etchings and wash drawings of wild fowl. He was one of the decorators of the Library of Congress, Washington, D.C. Benson died at Salem on Nov. 14, 1951.

BENT, CHARLES (1799–1847). U.S. pioneer and trader whose name is associated with Bent's fort, a famous trading post built (1828–32) with his brother William on the Arkansas river near the present La Junta, Colo. He was born Nov. 11, 1799, at Charleston. Va. (now W. Va.). The family moved to St. Louis, Mo., in 1806 and Charles soon became interested in the fur trade. He eventually became one of the best-known traders in the west and in 1846 was appointed civil governor of New Mexico. He was killed at Taos on Jan. 19, 1847, during a Mexican and Pueblo Indian uprising against the U.S.

WILLIAM BENT (1809–1869), who is considered Colorado's first permanent white resident, managed the trading post for a number of years with two younger brothers. From an early age he participated in trapping expeditions of Charles and another trader, Ceran St. Vrain, in the Arkansas valley.

SILAS BENT (1820–1887), another brother, was an oceanographer and U.S. naval officer. He served under Commodore Matthew C. Perry on his expedition to Japan, 1852–54.

See Allen H. Bent, *The Bent Family in America* (1900).

BENT, JAMES THEODORE (1852–1897), English explorer and archaeologist, was born near Leeds, Yorkshire, on March 30, 1852. He was educated at Repton school and graduated in 1875 from Wadham college, Oxford. His travels among the Aegean Islands are described in *The Cyclades; or Life Among the Insular Greeks* (1885). In 1890 he traveled in southern Turkey in the Roman province of Cilicia, investigating the visible ruins of ancient cities, and published descriptions, plans and ancient inscriptions of these and other earlier explorations in Asia Minor in the *Journal of Hellenic Studies.* Bent led three expeditions to parts of Africa. He spent a year examining the great Zimbabwe ruins in South Africa, which he described in *The Ruined Cities of Mashonaland* (1892) (*see* ZIMBABWE). His book *The Sacred City of the Ethiopians* (1893) was the result of exploring Eretria and northern Abyssinia, where he visited Aksum and described Sabaean monuments and copied inscriptions. In 1895–96 he discovered an ancient gold mine in the Sudan. Bent also led five expeditions to Arabia. On Bahrein Island in 1889 he was only able to excavate two meagre tombs. In 1893–94 his expedition mapped part of the unexplored Hadhramaut area in southern Arabia, and in 1895 he visited Muscat and explored the Dhofar coast, making maps and briefly describing ancient cities in the area. One of these, Al Beleid, yielded, upon recent excavation, nothing definitely earlier than 1750. Evidence of ancient occupation has been found, however, near the site he rightly identified as Abyssapolis, the ancient frankincense and myrrh port. While in south Arabia again in 1896–97 Bent contracted malaria and died in London on May 5, 1897. Mrs. Bent, his constant companion and photographer of the expeditions, published their last travels in *Southern Arabia, Soudan and Sakotra* (1900). Bent's descriptions of contemporary life, as well as his accounts of ancient ruins in Africa and Arabia, are still valuable, but certain of his theories, such as the Zimbabwe being of Semitic origin or Bahrein being the original home of the Phoenicians, have been found untenable. (J. C. Ru.)

BENT GRASS, the common name for species of *Agrostis,* a large and widely distributed genus of the grass family. A few species are much used in pastures, especially redtop (*A. alba*), and in lawns, particularly certain of the stoloniferous species such as *A. palustris,* the creeping bent with its several strains known as Cocoos, Coos Bay, Metropolitan, Seaside. Seashore and Washington bent grasses that are used for lawns, golf greens and lawn bowling greens. Colonial bent (*A. tenuis*) is also widely used for the same purpose. *See* also GRASSES; LAWNS, CARE OF. (J. M. BL.)

BENTHAM, GEORGE (1800–1884), English botanist and plant cataloguer outstanding as a systematist, was born at Stoke

near Portsmouth on Sept. 22, 1800. His father, Sir Samuel Bentham (1757–1831), the only brother of Jeremy Bentham (*q.v.*), was a naval architect in the service of the empress Catherine II of Russia. The Bentham family spent much time on the continent, and after 1813 settled at Montpellier, France. There George read A. P. de Candolle's edition of J. B. Lamarck's *Flore française* and was much impressed with its analytical tables. He began forthwith to collect the materials for his first botanical work. *Catalogue des plantes indigènes des Pyrénées et du Bas Languedoc* (1826). From 1826–32 he acted as secretary to his uncle, Jeremy Bentham. and studied for the bar at Lincoln's Inn.

In 1854 he found the maintenance of a herbarium and library too great a tax on his means. He therefore offered them to the government on the understanding that they should form the foundation of such necessary aids to research in the Royal Botanic gardens at Kew. In 1858 his *Handbook of the British Flora* was published, and was reprinted several times (7th ed.. 1924). The 5th and 6th editions were prepared by J. D. (later Sir Joseph) Hooker, and "Bentham and Hooker" remained one of the standard floras for students. The government, in 1857. sanctioned a scheme for the preparation of a series of floras of British colonies and possessions. Bentham began with the *Flora Hongkongensis* in 1861. This was followed by the *Flora Australiensis,* in seven volumes (1863–78). His greatest work was the *Genera Plantarum,* 3 vol. (1862–83) in collaboration with Sir Joseph Hooker. He seemed at last only to live for the completion of this monumental work. He died in London on Sept. 10, 1884.

During the period 1826–32, he wrote the *Outline of a New System of Logic, With a Critical Examination of Dr. Whateley's Elements of Logic* (1827) and a number of articles on various legal subjects. In his *Outline* the principle of the qualification of the predicate was explicitly stated for the first time.

BENTHAM, JEREMY (1748–1832), English utilitarian philosopher, economist and theoretical jurist, one of the principal influences on the reforming thought of the 19th century, both in his own country and abroad, was born on Feb. 15, 1748, in Red Lion street, Houndsditch, London, the son of an attorney. At the age of three the child is said to have read eagerly such works as Paul de Rapin's *History* and to have begun the study of Latin. Much of his childhood was spent happily at his two grandmothers' country houses. At Westminster school he obtained a reputation for Greek and Latin verse writing. In 1760 he went to Queen's college, Oxford, where his most important acquisition seems to have been a thorough acquaintance with Robert Sanderson's *Logic.* He took his degree in 1763 and, in November, entered Lincoln's Inn and took his seat as a student in the king's bench, where he listened with rapture to the judgments of Lord Mansfield. In Dec. 1763 he managed also to hear Blackstone's lectures at Oxford, but says that he immediately detected the fallacies which underlay the rounded periods of the future judge *(see* BLACKSTONE, SIR WILLIAM). He spent his time in making chemical experiments and in speculating upon legal abuses rather than in reading lawbooks. On being called to the bar he "found a cause or two at nurse for him, which he did his best to put to death," to the bitter disappointment of his father, who had confidently looked forward to seeing him become lord chancellor.

Bentham's first book, the *Fragment on Government,* appeared in 1776. The subtitle, "an Examination of what is delivered on the subject of Government in the Introduction to Sir William Blackstone's Commentaries," indicates the nature of the work. Bentham found the "grand and fundamental" fault of the *Commentaries* to be Blackstone's "antipathy to reform." Bentham's book, written in a clear and concise style different from that of his later works, may be said to mark the beginning of philosophic radicalism. It is also a very good essay on sovereignty. Lord Shelburne (afterward 1st marquess of Lansdowne) read the book and called upon its author in 1781 in his chambers at Lincoln's Inn. Afterward Bentham was a frequent guest at Bowood. where he met Miss Caroline Fox (daughter of the 2nd Lord Holland), to whom he later made a proposal of marriage. At this period Bentham's mind was much occupied with the work which was published by Étienne Dumont in French as *Théorie des peines et des récompenses,* 2 vol., in 1811, but which eventually appeared as *The Rationale of Reward* (1825) and *The Rationale of Punishment* (1830). In 1785 Bentham started. by way of Italy and Constantinople, on a visit to his brother. Samuel Bentham, a naval engineer in the Russian service; and it was in Russia that he wrote his *Defence of Usury* (published 1787). This, his first essay in economics, cast in the form of a series of letters from Russia, shows him as a disciple of Adam Smith, but one who insisted on the extreme logical application of Smith's principles. He argued that every man was the best judge of his own advantage, that it was desirable from the public point of view that he should seek it without hindrance and that there was no reason for limiting the application of this doctrine in the matter of lending money at interest. His later works on political economy followed the *laissez-faire* principle. though with modifications. In the *Manual of Political Economy* (partial Fr. ed. by Dumont in the *Bibliothèque britannique,* 1798; Eng. text in vol. iii of Bentham's *Works)* he gives a list of uhat the state should and what it should not do, the second list being much longer than the first.

Disappointed, after his return to England in 1788, in the hope of making a political career. he settled down to discovering the principles of legislation. The great work on which he had been engaged for many years, *An Introduction to the Principles of Morels and Legislation,* was published in 1789. In this book he defines the principle of utility as "that property in any object whereby it tends to produce pleasure, good or happiness, or to prevent the happening of mischief, pain, evil or unhappiness to the party whose interest is considered." Mankind, he said, was governed by two sovereign motives, pain and pleasure; and the principle of utility recognized this subjection. The object of all legislation must be the "greatest happiness of the greatest number." He deduced from the principle of utility that. since all punishment involves pain and is therefore evil, it ought only to be admitted "so far as it promises to exclude some greater evil." *(See* UTILITARIANISM.)

The fame of the *Principles* spread widely and rapidly. Bentham was made a French citizen in 1792; and his advice was respectfully received in most of the states of Europe and America, with many of the leading men of which he maintained an active correspondence; one of the most curious of these exchanges was with Mohammed Ali. In 1817 he became a bencher of Lincoln's Inn. It was his ambition to be allowed to prepare a code of laws for his own or some foreign country. The codification of law was one of his chief preoccupations, but he seems to have underestimated both the intrinsic difficulties of the task and the need for diversity of institutions adapted to the tradition and civilization of different countries. Bentham however must be reckoned among the pioneers of prison reform. It is true that the particular scheme that he worked out was bizarre and spoiled by the elaborate detail which he loved. "Morals reformed, health preserved, industry invigorated, instruction diffused" and other similar desiderata would, he thought, be the result if his scheme for a model prison, the "Panopticon," were to be adopted; and for many years he tried to induce the government to adopt it. His endeavours, however, came to nothing *(see* PRISON) ; and though he received £23,000 in compensation in 1813, he lost all faith in the reforming zeal of politicians and officials.

In 1823 he helped to found the *Westminster Review* (1824 ff.) to spread the principles of philosophic radicalism. Bentham had been brought up a Tory, but his experience over the "Panopticon" scheme served to make a democrat of him. As far back as 1809 he had written a tract, *A Catechism of Parliamentary Reform,* which advocated annual elections, equal electoral districts, a wide suffrage and the secret ballot, but it was not published until 1817. He drafted a series of resolutions on reform, based on this tract, which were moved in the house of commons in 1818. A volume of his *Constitutional Code,* which he did not live to complete, was published in 1830.

Bentham died in Queen's Square place on June 6, 1832, in his 85th year. In accordance with his directions. his body was dissected in the presence of his friends. The skeleton was then reconstructed, supplied with a wax head to replace the original

(which had been mummified), dressed in Bentham's own clothes and set upright in a glass-fronted case. Both this effigy and the head are preserved in University college, London.

Bentham's life was a happy one. He gathered around him a group of congenial friends and pupils, such as James and John Stuart Mill. John and Sarah Austin and John Bowring, with whom he could discuss the problems upon which he was engaged and by whom several of his books were practically rewritten from the mass of rough though orderly memoranda which the master had himself prepared. Thus the *Rationale of Judicial Evidence,* 5 vol. (1827), was written out by J. S. Mill, and the *Book of Fallacies* (1824) by Peregrine Bingham. The services of Etienne Dumont in recasting as well as translating the works of Bentham were still more important. It is often difficult to distinguish what part of the work is Bentham's and what is due to his assistants. (X.)

Bentham was much less a philosopher than a critic of law and of judicial and political institutions. Unfortunately, he was not aware of his limitations. He tried to define what he thought were the basic concepts of ethics; and he also elaborated a method for calculating amounts of happiness, the "felicific calculus." Most of his definitions are oversimple or ambiguous or both together, and his calculus, as even his warmest admirers have admitted, cannot be used. It is in principle absurd and not just impractical, for not even an omniscient God could make the calculations imagined by Bentham. It is doubtful whether happiness can be defined in terms of pleasure and the absence of pain. As a moralist and psychologist. Bentham is crude and inadequate; his arguments, though sometimes elaborate, rest too often on ambiguous premises. He had a passion for making definitions and but little talent for the exact analysis of abstract ideas. He seems to have believed both that man is completely selfish and that everyone ought to promote the greatest happiness, no matter whose. Not even the formula of which he made so much, "the greatest happiness of the greatest number," has a definite meaning. The opening chapters of *An Introduction to the Principles of Morals and Legislation,* in which Bentham seeks to explain the ideas fundamental to his philosophy, are remarkably confused. Fortunately, they are more confused than confusing. They spring from simple fallacies easily detected. It must be said in Bentham's favour that he tried to be clear and precise; he did not hide the poverty of his arguments in a fog of rhetoric. He was maladroit but no mystifier.

As a critic of institutions Bentham was admirable. In his *Rationale of Judicial Evidence* he describes the methods that a court should use to get at the truth as quickly as possible; and in the *Essay on Political Tactics* (partial Eng. text, 1791; full text in *Works,* vol. ii) he describes what he considers the most effective forms of debate for a legislative assembly—an account largely based on the procedure of the house of commons. In these works and in others Bentham is concerned to discover what makes for efficiency. Though he defines efficiency in terms of happiness, his reader need not do so; or, if he does, he need not think of happiness as Bentham did. Bentham's assumptions about what makes for happiness are often quite ordinary and sensible; the reader can accept them and still insist that happiness is not to be defined in terms of pleasure and is not to be measured. Whatever is excellent, ingenious and original in Bentham—and there is a great deal of it—need not depend on the "felicific calculus" and "the greatest happiness of the greatest number."

BENTHOS, a Greek word meaning "depth of the sea" and hence used in biology to denote all the sedentary, crawling and burrowing bottom-dwelling organisms of the sea, representing most of the plant and animal phyla, ranging from the lighted, water-soaked beach to the darkened, greatest depths. The term is used in contradistinction to the drifting plankton (*q.v.*) and actively swimming nekton. *See* MARINE BIOLOGY.

BENTINCK, LORD WILLIAM GEORGE FREDERICK CAVENDISH, better known as LORD GEORGE BENTINCK (1802–1848), British politician, who became leader of the protectionist opponents of Sir Robert Peel, was the second surviving son of the 4th duke of Portland by Henrietta, sister of Lady Canning, and was born on Feb. 27, 1802. He served in the army for several years. and entered parliament in 1828 for King's Lynn, which he represented for 20 years. A celebrated sportsman, he was the last member of the house of commons to wear a pink hunting coat there; and he exercised great authority at race meetings. Until within three years of his death he was little known out of the sporting world.

He belonged originally to the moderate Whig party, and voted in favour of Catholic emancipation, as also for the Reform bill, though he opposed some of its principal details. Soon after, however, he joined the ranks of the opposition, with whom he sided up to 1846. When, in that year, Sir Robert Peel openly declared in favour of free trade, the advocates of the corn laws, then without a respectable leader, discovered that Lord George Bentinck was the only man of position and family round whom the several sections of the opposition could be brought to rally. He soon gave convincing evidence of powers so formidable that the protectionist party under his leadership was at once stiffened into real importance. Toward Peel, in particular, his hostility was uncompromising. Believing that that statesman and his colleagues had, as he put it, "hounded to the death his illustrious relative," George Canning, he combined with his political opposition a degree of personal animosity that gave additional force to his invective.

He abandoned his connection with the turf, disposed of his magnificent string of race horses (including the next Derby winner) and devoted his whole energies to the laborious duties of a parliamentary leader. Apart from the question of the corn laws, however, his politics were decidedly independent. In opposition to the rest of his party, for instance, and to please his chief adviser Disraeli, he supported the bill for removing Jewish disabilities. The result was that in Dec. 1847 he resigned the protectionist leadership, though he still remained active in politics. But his positive abilities as a constructive statesman were not to be tested, for he died suddenly at Welbeck, Sept. 21, 1848. Disraeli published a biography of Lord George Bentinck in 1852.

(M. R. D. F.)

BENTINCK, LORD WILLIAM HENRY CAVENDISH- (1774–1839), British soldier and administrator, whose many radical innovations when governor general (1827–35) made him one of the founders of modern India, was born on Sept. 14, 1774, the second son of the 3rd duke of Portland. An ardent Whig, like his father, Lord William was much influenced by Jeremy Bentham and James Mill; though he found reading irksome he was intelligent and industrious, with a flair for action. By many he was considered impetuous, but age ripened his judgment without diminishing his ardour to make possible the achievements of his governor generalship.

Entering the army in 1791, he was present at Marengo and served in the Peninsular War, commanding a division under the duke of Wellington who disapproved of him and thought him headstrong. He was appointed governor of Madras in 1803 at the age of 29, but the Vellore mutiny (1806), for which he was held responsible, led to his recall, along with the commander in chief in 1807. Bentinck deeply resented this action as unjust and never rested until he had achieved reparation. In 1811 he went

to Sicily as British envoy to the court of Naples and became the virtual governor of the island. In a brief intervention in Genoa in 1814 he embarrassed the British government by reviving the former republican constitution of 1797 on his own initiative. His recall in 1815 marked the Tory government's loss of confidence in him and he remained unemployed for 12 years.

After an unsuccessful attempt in 1823 he was appointed governor general of Bengal during George Canning's brief premiership in 1827. Age had brought discretion and his rule amply belied the misgivings caused by his earlier activities. His task was eased by the new approach, with which he sympathized, then developing toward the government of India. After a difficult two years when Wellington was prime minister and the young Lord Ellenborough was trying to replace Bentinck, he found himself supported by the reform ministry of Lord Grey (1830–34) as well as by the directors of the British East India company. In these circumstances he was able to carry through a series of measures which introduced a new era into Indian government.

Bentinck's most pressing business was to economize. The first Burmese War had strained the company's finances and it was urgently necessary to restore them before the approaching parliamentary discussion of the renewal of the company's charter. By economies and good management he turned an annual deficit of £1,000,000 into a surplus of £1,500,000. The economies included, on the company's direct orders, the abolition of double batta, an allowance for field service paid to troops in the Bengal presidency. This measure, which Bentinck privately denounced, was bitterly resented and won him lasting unpopularity in military circles. The fruit of all this work was the renewal of the company's government by the Charter act of 1833 whereby he became the first governor general of India.

Bentinck next dealt with judicial and revenue reform. In the judicial department he admitted Indians to two grades of judgeships. This was the first stage in the admission of Indians to important branches of the government. Land and revenue administration was still confused. Bentinck set out on a great northern tour (1830–33) which resulted in launching of the revenue settlement of R. M. Bird, which became a model for the north.

But Bentinck's greatest work was social and intellectual reform. In effect he introduced the west to India, not only in its personnel but in its institutions and spirit. He prohibited suttee, the Hindu custom of burning of widows on the funeral pyres of their husbands, and suppressed thuggee, the practice of ritual murder by robber gangs. With T. B. Macaulay's support he made English the language of government business and the higher courts instead of Persian. Government-aided education was to be on western lines and the medium of instruction English. These measures had profound effects. Other reforms included the abolition of internal transit duties and of flogging in the army and the introduction of experiments in tea cultivation, steam transport and coal and iron production.

In foreign policy Bentinck was cautious, and in his relations with the Indian states he followed the traditional policy of nonintervention. By ignoring the internal condition of Indian states when there was time for improvement the British were forced eventually to take drastic action, and Bentinck himself had to take over the administration of Mysore in 1831. Bentinck retired in 1835, refused a peerage and entered the house of commons. He died in Paris on June 17. 1839.

BENTIVOGLIO, an Italian family dominant in the city of Bologna during the second half of the 15th century. A native family, long prominent in the politics of the city, their first premature attempt to rule occurred in 1401, when Giovanni I Bentivoglio was proclaimed lord; but in the following year he was defeated in war with the Visconti, overthrown and murdered. Next. in 1420, Anton Galeazzo Bentivoglio seized power, but was compelled to yield Bologna on terms to its papal overlord. Despite these reverses and the active opposition of other ambitious families, notably the Ghisilieri and Canetoli, the Bentivoglio succeeded by the middle of the century in establishing a popular and secure pre-eminence in the city, under the leadership first of Annibale (1443–45) and then of Sante (1446–62) and Giovanni II (1462–1506). This domestic ascendancy they helped to strengthen by wisely calculated alliances with greater powers, which brought them added wealth, land and titles. At home they recognized papal supremacy and had it defined in a concordat (1447) that remained in force until the 18th century. They also chose, like the Medici of Florence, to govern anonymously as "first citizens" of a small ruling group, with a decisive share of public offices and a part of the public revenues. The Bentivoglio maintained a lavish court frequented by many artists and writers and did much to beautify Bologna. But the licentiousness of Giovanni II and his sons and the violence with which they put down disaffected families, the Malvezzi in 1488 and the Marescotti in 1501, in time destroyed their popularity. So, when they were driven from Bologna in 1506 by Pope Julius II and his French allies, all subsequent attempts to return were frustrated.

See G Gozzadini, *Memorie per la vita di Giovanni II Bentivoglio* (1839) ; C. M. Ady, *The Bentivoglio of Bologna* (1937). (P. J. J.)

BENTIVOGLIO, GUIDO (1579–1644), Italian cardinal, diplomat and historian, was born at Ferrara on Oct. 4, 1579. After studying law at Padua, he became one of Pope Clement VIII's privy chamberlains. Pope Paul V sent him as nuncio to Flanders (1607–15) and to France (1616–21) and created him cardinal (Jan. 1621). On the death of Pope Urban VIII, whose close friend he had been, Bentivoglio was one of the ten cardinals counted as eligible for the papacy, but he died suddenly on Sept. 7, 1644, eight days before the end of the conclave. His *Relazioni* in *tempo delle sue nunziature* (1629; partial Eng trans by Henry, earl of Monmouth. *Historical Relations of the United Provinces and Flanders,* 1652) his *Della guerra di Fiandra* (1632–39; Eng. trans. by Monmouth, *The Compleat History of the Warrs oj Flanders,* 1654) and his diplomatic letters to the papal secretariat of state (ed. by L. De Steffani, *La Nunziatura di Francia del cardinale Guido Bentivoglio,* 3 vol , 1863–70, and by R. Belvederi, *Guido Bentivoglio diplomatico,* 1947–) give precise and objective accounts of affairs in the countries that he visited

Bentivoglio's *Opere storichr* were edited with a life by L. Barotti (1806–07), and his *Memorie e lettere* were edited by C. Panigada (1934)

BENTLEY, RICHARD (1662–1742), one of the greatest figures in the history of classical scholarship, was born on Jan. 27. 1662, at Oulton. near Wakefield, Yorkshire. He was educated at Wakefield grammar school and St. John's college, Cambridge. In 1683, after a year as master of Spalding school, he became tutor to the second son of Edward Stillingfleet, dean of St. Paul's. and in 1689 accompanied his pupil to Oxford. There he made the acquaintance of John Mill, who asked him to look through the proof sheets of the Oxford edition of the chronicler John Malalas. The request gave rise to Bentley's *Epistula ad Millium* (1691), a short treatise in uhich his skill in textual emendation and his knonledge of ancient metre were strikingly displayed.

Bentley had taken deacon's orders in 1690. In 1692, and again in 1694. he was appointed Boyle lecturer. In the first series of lectures (the second was not published) he argued against atheism, using the theories of Isaac Newton to prove the existence of an intelligent creator. In 1694 he became keeper of the royal library and fellow of the Royal society.

Bentley contributed a collection of the fragments of Callimachus to J G. Graevius's edition (1697), and in 1699 appeared his *Dissertation upon the Epistles* of *Phalaris.* This arose from the controversy on the relative merits of the ancients and the moderns. A laudatory reference to Phalaris in Sir William Temple's *Essay on Ancient and Modern Learning* gave rise to an edition of the epistles by Charles Boyle of Christ Church, Oxford. As a result of a request from William Wotton, a champion of the moderns. Bentley attacked the genuineness of the epistles in an essay contributed to Wotton's *Reflections on Ancient and Modern Learning* (1697). Boyle and his Oxford friends combined to produce a reply. which in turn resulted in a much enlarged *Disser-*

tntion by Bentley. in which he brought all his learning and critical powers to bear in proof of the spuriousness of the epistles.

In 1700 Bentley was chosen master of Trinity college, Cambridge. His tenure of the office was marked by friction and litigation. He inaugurated reforms in usages and discipline. made improvements in the buildings and encouraged learning both in the college and in the university. But his domineering temper and his contempt for the feelings and rights of the fellows drove them in 1710, after ineffectual resistance within the college. to appeal to the general visitor of the college, the bishop of Ely. Only the bishop's death in 1714 prevented Bentley's ejection from the mastership. In the course of the long-drawn-out quarrel Bentley was deprived of his degrees by the university in 1718, but these were restored to him in 1724. In 1733 he was again brought to trial before the bishop of Ely and was sentenced to deprivation of the mastership, but the college statutes required the sentence to be executed by the vice-master, who refused to act. From a feud which lasted about 30 years Bentley emerged victorious. In addition to his mastership he held the regius professorship of divinity from 1717.

At Trinity college he continued his classical studies. He published a critical appendix to John Davies's edition of Cicero's *Tusculan Disputations* (1709) and contributed notes on two plays of Aristophanes to Ludolf Küster's edition of 1710; in the same year appeared his emendations of the fragments of Menander and Philemon. His edition of Horace, written in haste at a critical period of the quarrel at Trinity and published in 1711, shows his ingenuity and argumentative powers, but few of the many emendations proposed in it became accepted. In his edition of Terence, published in 1726, together with the fables of Aesop and the *Scntentiae* of Publilius Syrus, he threw new light on Terentian metre. In old age (1739) he published an edition of Manilius in which, along with characteristic faults. he displayed his brilliant gifts in emending and interpreting a difficult author. He left notes on other classical authors. such as Nicander, Plautus. Lucretius and Lucan. which were published after his death. Though in his later years he concerned himself mainly with Latin authors, he planned an edition of Hotner which, though never brought to fruition, had an important result in that he discovered the significance for the text of the lost letter *digamma*.

Another project which was never carried out was an edition of the New Testament. *Proposals* for which were issued in 1720. In these he explained his inteniion of publishing a text based on the oldest Greek and Latin manuscripts, and restoring "the true exemplar of Origen, which was the standard to the most learned of the Fathers, at the time of the Council of Nice and two centuries after," He had previously (1713), in his *Remarks* on Anthony Collins's *Discourse* of *Free Thinking*, defended the critical study of the Bible and denied that the existence of textual variants weakened its authority. Some of Bentley's New Testament material was published by A. A. Ellis in *Bentleii Critica Sacra* (1862).

In 1732 he made an unfortunate excursion into English criticism in his edition of *Paradise Lost*. In this he put forward numerous unjustified emendations. assuming that Milton employed both an amanuensis and an editor, who were responsible for the clerical errors, alterations and interpolations which Bentley professed to detect.

He had married in 1701 Joanna, daughter of Sir John Bernard. She died in 1740, leaving a son and two daughters. Bentley himself died at Cambridge on July 14, 1742.

As one of the great figures of classical scholarship Bentley combined wide learning with critical acuteness. Gifted with a powerful and logical mind, he was able to do much to restore the ancient texts and to point the way to new developments in scholarship. At the same time his masterful temperament, his self-confidence and his impatience led him to misuse his gifts. He was at his best when dealing with a badly corrupted text, less happy with an author like Horace whose text is well preserved. In textual criticism his work was followed up by the English Greek scholars of the 18th and early 19th centuries; in his dissertation on Phalaris he pointed the way to the historical and literary criticism of the 19th century.

The Works of Richard Bentley were edited by **A.** Dyce in 3 vol. (1836–38, incomplete) and *The Correspondence* was edited by C. Wordsworth in 2 vol. (1842).

BENTON, THOMAS HART (1782–1858): U.S. political leader and writer, was born March 14, 1782, near Hillsborough, N.C. His father, a successful lawyer, planter, slaveholder and land speculator, died when Thomas was eight. Thomas was deeply affected by his mother's grief and by her charge that he, the eldest son. must assume his father's place. In Jan. 1799, Benton entered the University of North Carolina, Chapel Hill. Finding himself poor compared to his tidewater patrician roommates, he stole money from them, and was publicly disgraced and expelled. These early traumatic events? together with Roman ideals of achievement prompted by early reading in his father's library. produced in Benton strong drives of ambition. At the age of 30 he proclaimed his determination of "doing something worthy of being written," or "writing something worthy of being done." Despite his strong ambition, he also developed inward gentleness and personal charm.

After 1801, when his family moved to a near-wilderness tract south of Nashville, Tenn., Benton was subject to western influences. Admitted to the bar in 1806, he learned the problems of western farmers from circuit riding and land-title cases. Absorbing the Jeifersonian political premises of the region, he entered public controversy in 1808 with vigorous newspaper articles demanding state court reform in the interest of "farming men." and pressed his plan with substantial success in the state senate the next year. An ardent patriot in the War of 1812. he was a colonel of volunteers under Andrew Jackson! but never realized his dreams of military glory. In 1815 he resumed law practice in the frontier village of St. Louis, where his vast energy and strong intellect quickly brought him eminence.

Tall, handsome, with a massive head thrust forward on muscular shoulders as if to express his resolute drives, edgy sense of honour, and courage, Benton engaged in typical western quarrels. One was a disorderly shooting affray at Nashville (1813) in which he and his brother Jesse nearly killed Andrew Jackson, the original aggressor; another, a pair of formal duels at St. Louis (1817) with a fellow lawyer, Charles Lucas, the challenger, who died in a return engagement Benton demanded. But Benton also made warm friends, and the chastening effect of Lucas's death moderated his pugnacity. In 1821 Benton married Elizabeth McDowell of Cherry Grove, near Lexington. Va., who also brought out his gentle. sympathetic side, as did their four daughters, one of whom (Jessie Ann) married the explorer John Charles Frémont. Two sons died in their youth.

As editor of the *St. Louis Enquirer* in 1818–1820, Benton struck a keynote for his ensuing career. He wrote slashing, well-informed, comprehensive articles in the style that later marked his political speeches. "It is time," he proclaimed, "that western men had some share in the destinies of this Republic." He attacked the national administration for "surrendering" American rights in Texas and the Pacific northwest, which he envisioned as a farming community and as a base for "Asiatic commerce." He proposed western development through federal roads and canals, and protection to the fur trade; urged a "gold and silver" currency to replace unsound bank note issues; and demanded statehood for the Missouri territory without restriction on slavery. Such a mixture of agrarian. commercial and slaveholding appeals brought Benton to the national senate in 1821. In Washington he was influenced by the purist-Jeffersonians John Taylor, Nathaniel Macon and John Randolph. He moved from paying political debts to Missouri's fur-trading, mining, and commercial groups. and from early support of Henry Clay's "American System" of protective tariffs and federal roads and canals for capitalist. development, to agrarian. popular-democratic views. Building a new power base in Missouri among small-farmers and

small-traders, he fought repeatedly in 1824 and after for distribution of public lands to settlers at reduced prices or as homestead "donations," and for popular presidential elections. In 1825 he turned to Jackson (with whom he had become reconciled) as his choice for president.

Seeing burgeoning enterprise and bank-credit speculation in conflict with Arcadia, Benton marshalled radical Democrats against the Bank of the United States. He initiated the legislative battle (1831); fought Clay, Daniel Webster, and powerful Whig and established-business opposition to sustain Jackson's veto of recharter (1832); and supported Jackson's removal of government funds from the bank (1833). He also opposed conservative Democrats who sought to extend state banks and their unstable note issues—"I did not join in putting down the Bank of the United States to put up a wilderness of local banks. . . . I did not strike Caesar to make Anthony master of Rome." To serve "the farmer, the artisan, the market man, the day laborer," Benton sponsored coinage acts (1834) to promote "hard money" currency in place of bank note credit; urged gradual suppression of bank notes under twenty dollars; prompted Jackson's specie order (1836) requiring gold or silver in payment for public lands; and worked with Pres. Martin Van Buren for a federal "Independent Treasury" (1840) to perform the public functions of the national bank. Like most Jacksonians, he favoured tariff reduction and opposed federal expenditures for local internal improvements. As an unflagging advocate of agrarian principles and a hard-money crusader, Benton won immense popularity and the sobriquet "Old Bullion." He was frequently proposed for president but never sought the office.

Through the 1830s, Benton, a small slaveholder himself, was generally pro-southern and proslavery, though he rejected John C. Calhoun's doctrine (1832) of state nullification of federal law. When national expansion in the 1840s brought a southern demand for slavery extension, however, Benton regarded it as "aggression" and as a menace to his freeholder's Arcadia and to the union. He opposed immediate annexation of slaveholding Texas and warned against "unjust" war with Mexico (1844), but supported war when it came (1846–48) and acquisition of Mexican territory to the Pacific. He urged American occupation of the Pacific northwest, working with Pres. James K. Polk for a compromise boundary at 49° north latitude instead of the extreme claim of 54° 40'. Maintaining that the new territories were free soil by nature and by Mexican law, Benton opposed as unnecessary the slavery-restrictionist Wilmot proviso, along with Calhoun's slavery-extension resolutions of 1847, as "two halves of a pair of shears" to sever the nation. He pressed for admission of California as a free state, and supported the Whig president, Zachary Taylor. against Clay's Compromise of 1850, which he considered an excessive concession to the south. Such unyielding stands, eventuating in opposition to slavery as an institution, lost Benton the pre-eminent party leadership he had previously enjoyed, and brought his defeat for re-election in slaveholding Missouri in 1851, after a senatorial tenure of 30 years. Elected to the house of representatives, he attacked the Kansas-Nebraska bill (1854) as "a bulging attempt to smuggle slavery into the Territory." Unlike many other antislavery Democrats, he rejected the new Republican party and opposed his own son-in-law, John C. Frémont, as the Republican presidential nominee in 1856. He was, however, sharply critical of proslavery domination in the Democratic administrations of Pierce and Buchanan.

His writings combined political and literary interests. His imposing memoir-history of his senate decades, *Thirty Years View* (2 vol., 1854, 1856), was eloquent with agrarian and Jacksonian-democratic faith, opposition to slavery extension, and concern for the imperiled union. Despite the agony of a fatal cancer, he produced a learned, polemical *Examination* (1858) of the supreme court's Dred Scott decision that congress had no power to prohibit slavery in the territories. His 16-volume *Abridgment* of *the Debates of Congress* through 1850 is still useful. After a long illness, Benton died in Washington, April 10, 1858. and was buried at St. Louis next to his wife, who had died three years before.

BENTON, THOMAS HART (1889–), U.S. painter, the most articulate and controversial of the proponents of native American art known as the Regionalists (Benton, Grant Wood and John Steuart Curry). Born on April 15, 1889, as Neosho, Mo., of a family long distinguished in Missouri politics, Benton was educated at the Art Institute of Chicago (1906–07) and the Académie Julien, Paris (1908–11). Though active in his early years (1906) as a cartoonist for the *Joplin* (Missouri) *American*, he began his career as a professional artist in New York in 1912, served as a draftsman in the U.S. navy during World War I, taught at the Art Students league and then (1935) settled permanently in Kansas City, Mo. where he taught at the Kansas City Art institute until 1941.

Benton's position as an artist was determined not only by his own strong creative temperament, but by the genuinely patriotic character of his midwestern family background, his Paris experience, and the critical period of social and political upheaval of the depression and war years. His was a passion for the historic roots of the rich and varied character of his country, which he learned so well through extensive travel and study.

The record of his development is best seen in the murals for the University of Kansas City (early 1920s), the New School for Social Research (1931) and the Whitney Museum of American Art (1932) in New York city, the Indiana state building for the Chicago World's Fair (1933), the Missouri state capitol in Jefferson City (1935), the Harzfeld store in Kansas City (1946), the Power Authority of New York at Massena and Niagara Falls (1959), and the Truman library in Independence, Mo. (1959). In 1933 he was awarded the gold medal of the Architectural League of New York for his work in mural painting. Like his murals, Benton's easel paintings have caused considerable controversy, but eventually have been acquired by the major museums and collections throughout the nation. His ideas, experiences and controversies are recorded in his autobiographical *An Artist in America* (1937, revised edition 1951) as well as in numerous articles, particularly in the *University of Kansas City Review*.

See Thomas Craven, *Thomas Hart Benton* (1939). (L. E. S.)

BENTON, WILLIAM (1900–), U.S. businessman, educator and statesman, from 1943 publisher of *Encyclopedia Britannica*, was born on April 1, 1900, in Minneapolis, Minn., and moved as a boy with his widowed mother to Montana, where he led a pioneer life on one of the last tracts of homestead land in the United States. After a year at Carleton college, he went to Yale university, from which he graduated in 1921. In a break with family tradition. he entered the advertising business, instead of education or the ministry. With Chester Bowles he founded the agency of Benton and Bowles in 1929, and by 1935, in spite of the economic depression, had made it one of the six largest firms of its kind in the world. His imagination and boldness appeared in everything he did in advertising. Many of the techniques now traditional in that business, particularly in broadcasting, originated with him. Some of them have had such an effect on American culture that he has more than once apologized for thinking of them.

At 35 Benton sold his interest in the agency and in 1937 went to The University of Chicago to become vice-president of the university, where Robert M. Hutchins, a Yale classmate, was president. There he took leadership in making The University of Chicago Round Table the most distinguished forum in the country. He interested himself in the development of sound motion pictures for higher education. He was one of the young administrative officers who gave the university unparalleled vitality at that epoch in its history. While an officer of the university in 1942, he helped organize, with Paul G. Hoffman, the committee for economic development. As founding vice-chairman of its board of trustees and of its research committee, he helped develop its program of scholarly research that made it one of the most influential groups of businessmen in the country. Also as an officer of the university

he dedicated himself to the task of acquiring *Encyclopædia Britannica* as a gift to the university. and, when the trustees of the university hesitated, he put up his own money to supply the working capital. This decided the issue: the university accepted the gift and committed the management and the common stock to Benton, retaining a preferred stock interest and a royalty contract.

In 1945 Benton resigned from the university to become assistant secretary of state under Pres. Harry S. Truman. He organized the first major U.S. program for peacetime international information and educational exchanges. Thus he began the Voice of America broadcasts, including broadcasting in Russian to the U.S.S.R.. established the United States information offices, and promoted international visits of professors and students. He also organized and led U.S. participation in the United Nations Educational, Scientific and Cultural organization (UNESCO). On behalf of the state department, he sponsored such legislation as the Smith-Mundt act and the Fulbright act establishing international educational exchange programs, and the Foreign Service act of 1946 to improve the organization and administration of the service. He resigned in 1947 and in 1949 accepted an appointment as United States senator from Connecticut. In 1950 he was elected to serve two years of an unexpired term.

In the senate he became a champion of freedom and justice throughout the world, defending the United Nations and fighting for civil liberties and civil rights. At the height of Senator Joseph R. McCarthy's power. Senator Benton led the attack on McCarthyism, with a courage unmatched by that of any other politician of the time. He introduced a resolution calling for McCarthy's expulsion from the senate and McCarthy's conduct in relation to this resolution later led to his censure by the senate.

After leaving the senate, Benton divided his energies between his numerous educational and public interests (he is a trustee of several universities) and the affairs of Encyclopaedia Britannica, Inc. He often combined the two, as when he wrote "The Voice of the Kremlin," the first comprehensive'account of Russian education to appear in America. for the 1956 *Britannica Book of the Year*, and, for the same publication, "The Voice of Latin America," the story of his travels to Latin America with Adlai Stevenson (1961).

These two articles were adapted into books, *This Is the Challenge* (1958) and *The Voice of Latin America* (1961). He has also contributed more than 100 articles to major magazines. Under his direction Encyclopaedia Britannica, Inc., acquired Encyclopaedia Britannica Films in 1943, published *Great Books of The Western World* in 1952 and the Spanish-language *Enciclopedia Barsa* in 1957, and purchased *Compton's Pictured Encyclopedia* in 1960. (Ro. M. H.j

BENTON HARBOR, a city of Berrien county, Mich., U.S., near Lake Michigan at the mouth of the St. Joseph river. Benton Harbor was originally an inland extension of its older neighhour, St. Joseph, but in the period 1860–62, as a result of disagreements with the parent city over bridging the river, the town assumed a separate identity as Bronson's Harbor. In 1869 it was incorporated as the village of Benton Harbor and in 1891 was chartered as a city. Benton Harbor is a marketing and processing centre for peaches, grapes, apples, plums. cherries and berries boasting one of the nation's largest open-air, noncitrus auction fruit markets. The city is an important industrial centre as well. manufacturing automotive parts. record players. construction machinery, castings. pumps, electronic equipment, plastics. printing and paper products and home appliances. In 1903. Benjamin ("King Ben") Franklin Purnell established an Adventist colony of the Israelite House of David at Benton Harbor. For comparative population figures *see* table in MICHIGAN: *Population.* (E. O. E.)

BENTONITE is a rock composed of clay minerals formed by the alteration of minute glass particles that once composed volcanic ash. The name was derived from the Ft. Benton series of Cretaceous rocks in Wyoming where it was first found. Two types of bentonite are recognized, and the uses of each depend on specific physical properties. Sodium bentonites. like those of Wyoming and South Dakota, adsorb large quantities of water. swell many times their original volume and give permanent suspensions of jell-like masses. These have been used to seal dams, as drilling muds, in portland cements and concrete. in bonding foundry sands, asbestos and mineral wool, in ceramics, in paper manufacture, in emulsions. in insecticides, in soaps. in pharmaceuticals, in paints and for clarifying water, juices and liquors and as a water softener to remove calcium from hard water. Calcium bentonites are nonswelling and break down to a finely granular aggregate that is widely used as an adsorbent clay. (*See* FULLER'S EARTH.)

Bentonite deposits range in age from Ordovician to Tertiary, or from about 400,000,000 to 1,000,000 years. In the United States the principal production has been from South Dakota. Wyoming. Texas, California and Mississippi. Bentonite is found also in Canada, Peru. England, Germany, Italy and New Zealand. and has been reported from Argentina. France. Poland, Russia, Rumania, China, Japan, Mexico and South Africa. The formation of bentonite involves the alteration of volcanic glass to clay minerals and is connected with the instability of volcanic glass that has less than 68% silica; this requires hydration and a loss of alkalies. bases and possibly silica with the preservation of the textures of the original volcanic glass. The minerals of bentonite are chiefly crystalline clay minerals belonging to the montmorillonite group, which are hydrous aluminum silicates containing iron, magnesium and other elements, but a few tiny grains of original volcanic rock minerals may be present. In the montmorillonite group aluminum substitutes for silicon and some iron or magnesium substitutes for aluminum in the crystal structure. The substitution of an element of high valence for one of lower valence leaves the crystal structure or lattice out of balance and this is compensated by interlayer, exchangeable ions, permitting base exchange. The dominant exchangeable bases are sodium and calcium and these give rise to the two types of bentonites previously mentioned. *See* also CLAY AND CLAY MINERALS. (V. T. A.)

BENUE, a river in west Africa, the greatest of the tributaries of the Niger (*q.v.*). It rises in Cameroun at an altitude of about 3.000 ft. and in the first 150 mi. descends more than 2,000 ft., with many falls and rapids. However, the remainder of its course is largely uninterrupted, making it the only major African river so free. During periods of flooding its waters are linked by way of its tributary, the Mayo-Kebbi, through the Tuburi marshes with those of the Logone which flows to Lake Chad (*q.v.*). Capture of this stream by the Benue is a distinct possibility and when fully effected would take about two-fifths of the water supplying Lake Chad. Below the Mayo-Kebbi the Benue is navigable all the year round by boats drawing less then 24 ft. of water and by larger boats for more restricted periods. Power-driven craft towing barges alongside can navigate to Makurdi. Nigeria, from June to November. to Yola from July to early October, and to Garoua, Cameroun, in Aug. and Sept. The journey upstream from the Niger delta to Garoua takes 17 days and the return journey 11 days. In this way a considerable volume of imports (particularly petroleum) reaches the territory and cotton and peanuts are exported from the Chad region. Between Yola and Makurdi the Benue is joined by the Gongola, an important tributary from the north which rises on the Jos plateau, Nigeria, and flows northeast and then south for a distance of 300 mi., being navigable for about half its course when in flood. There is a sand bar across the Benue at its confluence with the Niger, giving only 2 ft. of water when the flow is at its minimum. The river fleet moving upstream from the delta is frequently held up at Lokoja. Nigeria, waiting for a sufficient depth of water, and must return at the end of the navigation season before the level of water falls too low. Investigations have been made with a view to improving navigation. Total length of the Benue is 673 mi.

Heinrich Barth (*q.v.*) reached the upper Benue at Yola in 1851 and in 1854 W. B. Baikie (*q.v.*) in the "Pleiad" sailed 400 mi. up the river from its confluence with the Niger. Its basin was explored more thoroughly in 1882–84 by E. R. Flegel (*q.v.*), who reached N'Gaoundéré. Further journeys were made by Maj. Claude Macdonald (1889) and by E. Lenfant (1903), who succeeded in crossing the Tuburi marshes and navigating through to the Logone.

BENZ, CARL (1844–1929), German engineer who designed and built the first commercially successful motor car, was born at Karlsruhe on Nov. 26, 1844. In 1879 he started at Mannheim a small factory for the production of his stationary two-stroke gas engines. After improvements, such as the use of high-tension electric ignition in place of flame ignition, these Benz engines gained a sound reputation at home and abroad. He built his three-wheeled prototype motor car in 1885, and equipped it with a new design of four-stroke gasoline engine, which developed 1½ h.p. at 200 r.p.m. and gave the car a speed of 10 m.p.h. The important model III of 1887–88 was developed from this prototype and four were built and sold commercially. The only remaining example is now in the Science museum, London. Improved models appeared, in particular the 3-h.p. "Comfortable" model, of which 4.000 were produced between 1897 and 1900. Benz died at Ladenburg on April 3, 1929. (C. F. CA.)

BENZALDEHYDE (oil of bitter almonds) was first isolated in 1803 and was the subject of an important investigation by Justus von Liebig (*q.v.*) in 1837. It occurs naturally in the form of the glycoside amygdalin, which is present in bitter almonds, cherries, peaches and the leaves of the cherry laurel and is obtained from this substance by hydrolysis with dilute acids. (See GLYCOSIDES, NATURAL.) It occurs free in bitter almonds, being formed by an enzyme decomposition of amygdalin. It may also be prepared by oxidizing benzyl alcohol (*q.v.*) with concentrated nitric acid; by distilling a mixture of calcium benzoate and calcium formate; by the two Gattermann syntheses (see ALDEHYDE AND KETONES) and by the action of chromium oxychloride on toluene dissolved in carbon bisulfide (A. Étard, 1884). It is the simplest of the aromatic aldehydes, having the formula $C_6H_5.CHO$.

Technically, it is prepared from toluene, by converting it into benzyl chloride, which is then heated with lead nitrate, $C_6H_5CH_2Cl + Pb(NO_3)_2 = 2NO_2 + PbCl.OH + C_6H_5.CHO$, or, by converting it into benzylidene chloride (benzal chloride), which is heated with aqueous calcium hydroxide under pressure:

$$C_6H_5CHCl_2 + Ca(OH)_2 = CaCl_2 + C_6H_5CHO + H_2O$$

The direct oxidation of toluene with various metallic oxides (manganese dioxide, ceric oxide, peroxides of nickel and cobalt) in the presence of acid produces benzaldehyde free from chlorinated derivatives. Benzaldehyde, a colourless liquid smelling of bitter almonds, boils at 179.1° C., is only slightly soluble in water, but is readily volatile in steam. It possesses all the characteristic properties of an aldehyde, being readily oxidized to benzoic acid, reducing solutions of silver salts, forming addition products with hydrogen. hydrocyanic acid and sodium bisulfite, and giving an oxime and a hydrazone. On the other hand, it differs from the aliphatic aldehydes in many respects; it does not form an addition product with ammonia but condenses to hydrobenzamide, $(C_6H_5.CH)_3N_2$; on shaking with alcoholic potassium hydroxide it undergoes simultaneous oxidation and reduction; giving potassium benzoate and benzyl alcohol (S. Cannizzaro, 1881); and on warming with alcoholic potassium cyanide it condenses to benzoin.

During the oxidation of benzaldehyde to benzoic acid when exposed to air it has been observed that as much oxygen is rendered "active" as is used up by the substance undergoing oxidation; thus if benzaldehyde is left for some time in contact with air. water and indigosulfonic acid, just as much oxygen is used up in oxidizing the indigo compound as in oxidizing the aldehyde. A. von Baeyer and V. Villiger (1900) showed that a peracid $C_6H_5.CO.O.OH$, formed as an intermediate product, oxidizes the indigo compound, being itself reduced to benzoic acid. They have showed that this peroxide is soluble in benzaldehyde with production of benzoic acid, and it must be assumed that the oxidation of benzaldehyde proceeds as shown in the equations:

$$C_6H_5.CHO + O_2 = C_6H_5.CO.O.OH$$
$$C_6H_5.CO.O.OH + C_6H_5.CHO = 2C_6H_5.COOH$$

The oxime of benzaldehyde, $(C_6H_5.CH:N.OH)$, formed by the addition of hyclroxplamine to the aldehyde, undergoes isomeric change when hydrogen chloride is passed into its ethereal solution, a second modification being produced. The former (known as the α or *syn*-benzaldoxime) melts at 34°–35° C.; the latter (β or *anti*-benzaldoxime) melts at 130° C. and is slowly transformed into the α form. The difference between the two forms was explained by A. Hantzsch and A. Werner (1890) on the assumption of a different spatial arrangement. (See STEREOCHEMISTRY.) Because of the readiness with which it condenses with various compounds, benzaldehyde is an important synthetic reagent. With aniline it forms benzylidineaniline, $C_6H_5.CH:N.C_6H_5$, and with acetone, benzylidineacetone, $C_6H_5.CH:CH.CO.CH_3$. Heated with anhydrous sodium acetate and acetic anhydride it gives cinnamic acid; with dimethylaniline and anhydrous zinc chloride it forms leuco-malachite green, $C_6H_5.CH[C_6H_4N(CH_3)_2]_2$; and with dimethylaniline and concentrated hydrochloric acid it gives dimethylaminobenzhydrol, $C_6H_5.CH(OH)C_6H_4N(CH_3)_2$. (See DYES.) Its addition compound with hydrocyanic acid gives mandelic acid, $C_6H_5.CH(OH).COOH$, on hydrolysis.

BENZEDRINE: see AMPHETAMINE.

BENZENE, a hydrocarbon, was discovered by Michael Faraday in 1825 when he investigated the nature of an oil found in the receptacles of the compressed illuminating gas made from whale oil. Because of the high ratio of carbon to hydrogen, Faraday called the hydrocarbon "bicarburet of hydrogen." E. M. Péligot and E. Mitscherlich prepared it in 1833 and 1834, respectively, by distilling benzoic acid in the presence of lime. Mitscherlich named it benzin, but J. von Liebig suggested the change to benzol. The form "benzene" was used by A. W. Hofmann, who in 1845 demonstrated the presence of the hydrocarbon in coal tar. "Benzene" is the term used by U.S. and English chemists, while "benzol" (U.S.) and "benzole" (Great Britain) are the common designations for the commercial products which contain the hydrocarbon benzene as the chief constituent.

The commercial recovery of benzene began in 1849 when C. B. Mansfield separated it from the solvent naphtha fraction of coal tar. It was first sold as a fuel for illuminating purposes, as a solvent for rubber, and later as a dye intermediate. Rapid expansion of the dye industry made it necessary to augment the supply by recovering it from coal gas. Since in the process of coking coal at high temperatures more than 90% of the benzene formed is found in the gas and less than 10% in the tar, coke-oven gas became the most important source of benzene. The recovery starts with the removal of the light oil from the gas. This contains, in addition to benzene, the methylated homologues, toluene and xylene, and other organic substances. It represents about one volume per cent of the gas. Removing light oil from gas is usually effected by scrubbing it with a high-boiling oil or by adsorption on activated carbon. It is subsequently freed from the condensing medium by steam stripping. At this stage the product is known as crude light oil. With or without a preliminary fractional distillation it is treated with a small volume of sulfuric acid, followed by water and caustic washes. It is finally subjected to a fractional distillation from which the various grades of benzol are recovered. They are sufficiently pure for most markets but still contain traces of thiophene and nonaromatic hydrocarbons. The former can be removed by a treatment with fuming sulfuric acid, and the latter by crystallization of the benzene.

As late as 1940 the supply of benzene available from the coal carbonization industry was more than sufficient to supply the needs of the chemical industry and most of it was disposed as blending agent in motor fuels. Because of the rapidly expanding production of styrene, used in synthetic rubber and plastics, phenol, also used in plastics, and of the synthetic fibre nylon, a shortage had developed by 1950. At that time the petroleum industry began to augment supplies by the catalytic aromatization of suitable naphtha

fractions. Benzene is also needed for the manufacture of aniline, synthetic detergents, maleic anhydride and insecticides such as DDT, and for solvent purposes.

Benzene, C_6H_6, is a colourless. limpid liquid. having a characteristic odour. It boils at 80.1° C. and solidifies at 5.5° C. At 25° C. its density is 0.874 and its refractive index 1.498. It is very slightly soluble in water, more soluble in alcohol, and completely miscible with ether, acetic acid and carbon disulfide. It is an excellent solvent for rubber, gums, fats and many resins.

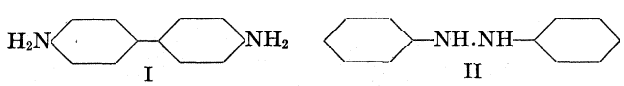
Since benzene is the parent compound of the enormous number of substances belonging to the aromatic or benzenoid series: its structure has been extensively investigated. In 1865 F. A. Kekulé postulated the benzene ring formula which, in spite of deficiencies, has retained its usefulness. It consists of a hexagon in which the carbon atoms form the six corners, alternate pairs of carbon atoms are connected by double bonds and one hydrogen atom is linked to each of the carbon atoms. There are two objections to this formula: (1) benzene does not show the reaction properties associated with the normal double bond; (2) the number of known isomeric disubstituted benzenes is smaller than that predicted by the formula. Kekulé, aware of these failings, postulated an oscillation of the double bond from one side of the carbon atom to the other, thereby giving the benzene ring the symmetry demanded by the known number of disubstituted benzene isomers. By applying the theory of resonance, L. Pauling (1933) gave this hypothesis a more precise interpretation. Applying the concepts of quantum mechanics. he arrived at a hybrid or mesomeric state for the benzene molecule resulting from the resonance of the two structures which Kekulé assumed to he in dynamic equilibrium. This hybrid state gives the carbon-to-carbon bond in the benzene ring a position intermediate between the normal double bond and the single bond, and explains the abnormally low reactivity of benzene. X-ray data support this view: the distance between the carbon atoms of a normal double bond is 1.34 Å; that of a single bond, 1.54; and that of a benzene bond, 1.39.

Benzene reacts with sulfuric acid to give mono-, di- and trisulfonic acids; with nitric acid to give the mono-. di- and trinitro benzenes. When benzene is treated with chlorine or hromine, addition to the benzene molecule with or without suhstitution of hydrogen takes place. In direct sunlight three molecules of chlorine add directly to form hexachlorocyclohexane; in the presence of iron chloride or aluminum chloride, chloro- and dichlorohenzene are formed. Benzene is remarkably resistant to oxidation. By passing benzene vapour and air over vanadium oxide at 450° C. parabenzoquinone and maleic anhydride are formed. Reduction of benzene to cyclohexane takes place in the presence of reduced nickel at 180° C. under elevated hydrogen pressure. Passed through a red-hot tube, benzene vapour yields diphenyl, diphenylbenzenes, acetylene and hydrogen.

See also Index references under "Benzene" in the Index volume. (E. W. V.; X.)

BENZIDINE, an aromatic organic chemical of value in the dyestuff industry. The dyes derived from benzidine are of importance because, unlike other classes of azo dyes, they are "direct" or "substantive" cotton dyes, uniting with cotton fibre without the need of a mordant. They are often called "salt colours" because absorption by the fibre is accelerated by adding inorganic salts such as sodium sulfate.

Preparation. — Benzidine. 4,4′-diaminodiphenyl (see formula I, below)! is easily prepared by reducing nitrobenzene in an alkaline medium to hydrazobenzene (formula II) and treating the latter with a strong acid. In the laboratory, zinc dust or electrolytic reduction is used. For the second stage hydrochloric acid is employed, the benzidine being often precipitated as its sparingly soluble sulfate by adding sodium sulfate to the solution.



I II

The Benzidine Transformation. — The change from II to I shonn above is the simplest case of a molecular rearrangement which takes place in all compounds of the hydrazobenzcnc type. With hydrazobenzene itself there are four products of the rearrangement of which benzidine is formed in the largest amount.

These are all the possible ways in which two units C_6N_5NH- can unite with ortho-para coupling, with the exception of 2,2′-diaminodiphenyl (*o-benzidine*) which would be the product of ortho-ortho coupling. This latter type is, however, formed in the corresponding naphthalene series, often in good yield. A substituent in the para position in the ring, such as $-Cl$, $-CO_2H$, $-SO_3H$, is often ejected in the change, whereas others such as $-OCH_3$ and $-NH_2$ are not displaced, so that the product is the only possible one, the o-semidine.

It is definitely established that the first step in the transformation is not the production of semidine, as was at one time supposed. Moreover, evidence that there is no dissociation of hydrazobenzene into free radicals or ions comes from experiments in which two differently substituted hydrazobenzenes in the same solution give the same benzidines that are produced in the separate rearrangements of each hydrazobenzene. This was confirmed by experiments using radiocarbon as a "tracer." The arrangement is catalyzed by hydrogen ions, in proportion to the square of their concentration.

As the transformation is known to be intramolecular, it must be concluded that the fragments resulting from the rupture of the —NH-NH— linkage in hydrazobenzene are restrained from separating before the *p-p′* (or *p-o′*, etc.) bonds are set up. Mechanisms in terms of classical structures hitherto proposed have not dealt satisfactorily with the stereochemical problems involved.

(T. W. J. T.; D. L. Hk.; X.)

BENZOIC ACID, an organic chemical important as a preservative, antiseptic and the starting point in the manufacture of a large group of chemicals used in medicines, food preservatives, cosmetics, dyes, plastics and insect repellents.

Although benzoic acid is produced synthetically for commercial purposes. it exists widely in plants, including fruits such as cranberries and prunes and in resins such as gum benzoin, from which it obtains its name. Because benzoic acid is found extensively in plants used as foods, the urine of all herbivorous animals, including man, contains hippuric acid. a derivative of benzoic acid.

Benzoic acid, also sometimes called benzenecarboxylic acid or phenylformic acid, has been known for many years, being first described in the second half of the 16th century. It was recognized early for two reasons. It constitutes about 20% of gum benzoin, a common resin! and sublimes below 100° C. For centuries the chief source of benzoic acid was gum benzoin. During the first half of the 19th century the acid was prepared in Germany by the hydrolysis of hippuric acid obtained from the urine of cows and horses. About 1860 it was prepared synthetically for the first tirne from compounds derived from coal tar.

Benzoic acid. whose formula is C_6H_5COOH, and its derivatives played an important part in the development of organic chemistry. Its composition was determined in 1832 by Friedrich Wohler and Justus von Liebig, who showed that in many of its transformations into other chemicals the benzoyl group, C_6H_5CO, remained intact, thus extending to organic chemistry the idea of radicals that had been applied a short time before to inorganic reactions. Eilhardt Mitscherlich in 1833 reported that distillation of benzoic acid with lime gave a hydrocarbon, C_6H_6, which he called benzin but which Liebig changed to benzol, identical with the hydrocarbon isolated by Michael Faraday in 1825 from the products of the thermal decomposition of fats and now known as benzene.

Benzoic acid, the simplest of the carboxylic acids of the aromatic (cyclic) series of organic compounds; is a fairly strong antiseptic and also has diuretic and antipyretic properties that led during the last half of the 19th century to extensive investigation of its use in medicine. However, it is little used in modern therapeutics except in the form of tincture of gum benzoin and in skin salves to treat iungus infections. During the early investigations, however, it was found to bc practically nontoxic, probably because of the ease with which it is detoxified. chiefly in the kidneys, by combination with the amino acid giycine to form hippuric acid, which is eliminated in the urine. 'This detoxification appears to be limited only by tile ability of the liver to protluce giycine, and doses of 10

to 25 g. of sodium benzoate in one day can be tolerated by some persons, although in others large doses may produce nausea. It is considered safe to ingest continuously up to 0.5 g. daily in a concentration of 0.1%.

Because benzoic acid prevents or inhibits the growth of yeasts and molds and in the concentrations used is odourless, tasteless and nontoxic, its most important use is as a food preservative. The free acid is from five to ten times more effective than the sodium salt, but the latter usually is used because its high solubility in water (1 g. in 2 ml.) permits easier mixing. With acidic foods such as fruit juices and condiments, the free acid is liberated and is the effective agent. It also retards rancidity and darkening and is used in oleomargarine, sea foods, pharmaceuticals, cosmetics, soap and adhesives. Although the quantity added is usually only 0.1%, the volume of these products consumed requires a sizable production.

The number of ways in which benzoic acid has been obtained are too numerous to mention. In the commercial process most generally used in the United States and Great Britain after 1930, crude phthalic anhydride and about 5% of a catalyst consisting of equal parts of chromium and sodium phthalates is heated to 220° C. and steam is introduced. The steam hydrolyzes the anhydride to phthalic acid, which decarboxylates to benzoic acid.

$$C_6H_4(CO)_2O + H_2O \rightarrow C_6H_4(COOH)_2$$
$$C_6H_4(COOH)_2 \rightarrow C_6H_5COOH + CO_2$$

In Germany this process competes with (1) vapour phase decarboxylation of phthalic acid over a zinc oxide catalyst at 450°, (2) air oxidation of toluene using a cobalt-manganese catalyst at 190° and (3) oxidation of toluene with aqueous sodium dichromate solution at 250°–300° and regeneration of the dichromate with sodium hydroxide and air at the same temperature.

Some benzoic acid also is produced as a by-product of the production of phthalic anhydride and benzaldehyde. Other processes that have been used commercially are the decarboxylation of sodium acid phthalate in aqueous solution, the oxidation of toluene with nitric acid and the hydrolysis of benzotrichloride from the chlorination of toluene.

Benzoic acid has been obtained with a purity of 99.998% and a melting point of 122.375° ± 0.001" C. Although the boiling point is 250" C., it sublimes below 100° and is readily volatile with steam. In its solid state, benzoic acid exists as white, crystalline needles. Its solubility is only 0.34 g. per 100 g. of water at 25° C., but it is considerably more soluble in most organic liquids. It is a weak acid ($K_A = 6.6 \times 10^{-5}$) although slightly stronger than acetic acid ($K_A = 1.75 \times 10^{-5}$).

The most important derivatives of benzoic acid include the following compounds:

Sodium benzoate, C_6H_5COONa, is prepared by dissolving benzoic acid in an aqueous solution of sodium carbonate until the solution is neutral, then clarifying the solution, evaporating to dryness and grinding the residue.

Benzoyl chloride, C_6H_5COCl, the acid chloride of benzoic acid, can be prepared by the action of phosphorus pentachloride on benzoic acid but is made commercially by the chlorination of benzaldehyde, by the partial hydrolysis of benzotrichloride or by the action of hydrogen chloride on phthalic anhydride in the presence of a decarboxylating catalyst. The last process gives a product free of nucleus-halogenated compounds. Benzoyl chloride is a liquid, b.p. 197° C., has a characteristic odour and is strongly lachrymatory. It is used as a benzoylating agent, especially for the production of benzoic anhydride and benzoyl peroxide.

Benzoic anhydride, $(C_6H_5CO)_2O$, is an odourless solid, m.p. 42° C., b.p. 360° C. It is made by the reaction of acetic anhydride with benzoic acid in the presence of phosphoric acid. or by heating benzoic acid with benzoyl chloride and removing at reduced pressure the hydrogen chloride formed. The anhydride is used for the same purposes as benzoyl chloride but has the advantage that its use does not require equipment resistant to corrosion by hydrogen chloride.

Benzonitrile, C_6H_5CN, b.p. 191° C., is a good solvent for many resins and plastics. It is prepared by fusing sodium benzenesulfonate with sodium cyanide.

Benzyl benzoate, $C_6H_5COOCH_2C_6H_5$, is a liquid, b.p. 324° C., that occurs naturally in Peru and tolu balsams. It has antispasmodic properties and is a chigger repellent. It is also a powerful miticide and is used in the treatment of scabies. During World War II it was used on a large scale to eradicate disease-carrying ticks and mites from South Pacific islands. It can be made by the esterification of benzoic acid with benzyl alcohol but usually is prepared by the catalytic action of a small amount of aluminum ethoxide on benzaldehyde. During World War II it was made also from sodium benzoate and benzyl chloride in the presence of 1% of triethylamine.

Benzoyl peroxide, $(C_6H_5CO)_2O_2$, is a solid that melts at 110° C. It is used extensively as a bleaching agent for edible oils and fats and for flour, because the end product of the reaction, benzoic acid, is harmless and need not be removed. Benzoyl peroxide decomposes into free benzoyloxy radicals which lose carbon dioxide to give free phenyl radicals. Hence benzoyl peroxide is used widely to initiate the polymerization of unsaturated compounds that yield important plastics. It is made by the reaction of benzoyl chloride with an aqueous solution of sodium peroxide or an alkaline solution of hydrogen peroxide.

o-Aminobenzoic acid (anthranilic acid), *o*-$NH_2C_6H_4COOH$, is made by the action of sodium hypochlorite on a solution of sodium phthalamate, prepared from phthalimide. It is used as a dye intermediate and formerly was important for the production of indigo. The methyl ester is used in perfumery and in artificial grape flavours. The menthyl ester is used in sun-screening lotions.

p-Aminobenzoic acid, *p*-$NH_2C_6H_4COOH$, is prepared by the reduction of p-nitrobenzoic acid. It plays an important biological role and makes up part of the molecule of folic acid, which brings about the remission of several forms of anemia. Numerous esters of p-aminobenzoic acid are important local anesthetics. The ethyl ester (anesthesin or benzocaine) and the n-butyl ester (butesin) are valuable surface anesthetics. The hydrochloride of the β-diethylaminoethyl ester (novocaine or procaine) is the most widely accepted chemical for local and spinal anesthesia.

o-Hydroxybenzoic acid (*see* SALICYLIC ACID).

p-Hydroxybenzoic acid, *p*-HOC_6H_4COOH, is more effective than benzoic acid as an antiseptic. Its methyl, ethyl, propyl and butyl esters are used widely in cosmetics and in preparations for treating infections of the skin caused by fungi.

o-Hydroxy-p-aminobenzoic acid (p-aminosalicylic acid, **PAS),** *o*-HO-*p*-$H_2NC_6H_3COOH$, became the most successful of the several substituted benzoic acids found to have tuberculostatic action.

***p*-Nitrobenzoic acid,** $O_2NC_6H_4COOH$, is an intermediate for the preparation of p-aminobenzoic acid and its derivatives. It is made by the oxidation of p-nitrotoluene.

BENZOPHENONE is the simplest ketone in the aromatic series. It is structurally a diphenyl ketone, having the formula $C_6H_5.CO.C_6H_5$. Tetramethyldiamino-benzophenone or Michler's ketone, $CO[C_6H_4N(CH_3)_2]_2$, is of technical importance in the manufacture of synthetic dyes. Benzophenone is a dimorphous substance, existing in two crystalline forms, one melting at 26° C. and the other at 48° C. (T. Zincke, 1871). It boils at 306.1° C. It may be prepared by condensing benzene with benzoyl chloride in the presence of anhydrous aluminum chloride. It is reduced by sodium amalgam to benzhydrol or diphenylcarbinol, $C_6H_5.CH(OH)C_6H_5$; a stronger reducing agent such as hydriodic acid in the presence of amorphous phosphorus converts it into diphenylmethane, $(C_6H_5)_2.CH_2$. With hydroxylamine it forms an oxime, which exists in one form only; if, however, one of the phenyl groups in the oxime be substituted in any way, then two stereoiso-

meric oximes are produced. *See* ALDEHYDES AND KETONES; OXIMES; STEREOCHEMISTRY. (G. W. WD.)

BEN-ZVI, ISAAC (1884–), Israeli statesman, second president of the State of Israel, was born on Dec. 6, 1884, at Poltava, Ukraine. He studied at Kiev university, went to Palestine in 1907 and continued his law studies at the Imperial Ottoman university in Istanbul (1912–14). In 1908 he was one of the founders of Hashomer (the Jewish self-defense organization) and also of the first Hebrew secondary school in Jerusalem. Exiled from Palestine by the Turks in 1915, he went to the United States, where, together with David Ben-Gurion, he established the Hehalutz (Pioneer) movement and the Jewish legion, with which he returned to Palestine after the expulsion of the Turks by the British. One of the founders of the Vaad Leumi (National Council of Palestine Jews) in 1929, he served as its chairman from 1931 to 1944 and later as its president. On May 14, 1948, as a member of the provisional state council, he signed the declaration of independence of Israel. He was elected to the ***knesset*** ("national assembly") in 1949 and in 1951 as a member of the Israeli Labour party (Mapai). On Chaim Weizmann's death Ben-Zvi was nominated as Mapai candidate for the presidency. He was elected by the ***knesset*** on Dec. 8, 1952, and invested two days later. He was re-elected for a second term on Oct. 28, 1957.

BENZYL ALCOHOL (PHENYL CARBINOL) occurs combined with benzoic acid in Peru balsam, with cinnamic acid in tolu balsam, with acetic acid in essential oil of jasmine and also in storax. It is a colourless liquid with a faint aromatic smell, boiling at 206° C. and having the composition $C_6H_5.CH_2OH$. It may be synthetically prepared by the reduction of benzoyl chloride; by the action of nitrous acid on benzylamine; by boiling benzyl chloride with an aqueous solution of potassium carbonate, or by the so-called "Cannizzaro" reaction (1881) in which benzaldehyde is shaken up with potassium hydroxide, one half of the aldehyde being oxidized to benzoic acid, and the other half reduced to the alcohol. On oxidation with nitric acid it is converted into benzaldehyde while chromic acid oxidizes it to benzoic acid. If reduced by hydriodic acid and phosphorus at 140° C. it gives rise to toluene; toluene and benzoic acid result from its distillation with concentrated alcoholic potassium hydroxide.

BEOTHUK, American Indian tribe of hunters and collectors, resident chiefly on the Newfoundland coast where salmon and shellfish could be obtained to eke out the supply of deer. Their skill as canoemen was commented upon by several early writers, but they were equally at home in the woods. The scanty material culture was characterized by the use of wood for household utensils; stone implements were well made; snowshoes were of a peculiar type, and red ochre was extensively employed for painting the body, a habit which probably gave rise to the term "Red" Indian. The Beothuk were gradually forced into the interior of the island by European fishermen and settlers; reduced in numbers, their doom was sealed when, in the 18th century, Micmac hunters, equipped with firearms, began to swarm over from the mainland. A few survivors may have escaped to Labrador, but the last known Beothuk died in 1829.

See J. P. Howley, The Beothucks or Red Indians (1915).

BEOWULF, the finest and most considerable heroic poem in Old English, has survived in a single manuscript, which, to judge by the handwriting of its two scribes, must have been written *c.* 1000. It is in a volume of the Cottonian collection, now in the British museum, London, known as Vitellius A XV. It first aroused scholarly interest in 1705, when Humphrey Wanley described and quoted from it in his catalogue of manuscripts, but in 1731 it was damaged by fire, and has since deteriorated. However, two copies were completed by 1787 for the Icelander Grimur Jonsson Thorkelin; the first, Thorkelin A, by a professional copyist, and the second, Thorkelin B, by Thorkelin himself. These two transcripts are indispensable to modern scholars since much of the manuscript which has now vanished was then visible. Thorkelin's transcript was the basis of the first printed edition (1815). The name of the hero, Beowulf, whose exploits and character provide the connecting theme of the work, is accepted as the title of the poem, which in the manuscript is untitled.

Content of the Poem.—A summary of the events in the poem gives some impression of its scope though nothing of the total effect, which is gained by the superb harmonizing of the theme with the poetic method.

The royal house of Denmark, once renowned for its power through the northern world, is now shamed by the attacks of an anthropomorphous monster, Grendel, who nightly carries off men from King Hroðgar's great hall Heorot, until no Danish warrior dare remain there after dark. Beowulf, a young noble of the Geatas (a people who lived in southern Sweden) sails to Denmark with 14 companions to offer his help. He is welcomed by King Hroðgar (Hrothgar) who, after a banquet where the hero's character and achievements are explored, entrusts the hall to his charge. Grendel comes, and devours one of Beowulf's companions, but in a tremendous battle Beowulf, unarmed, mortally wounds the monster by tearing off his arm.

The next day all is rejoicing in Heorot, and Beowulf is feted and honoured with gifts, but that same night, when Beowulf and his Geatas sleep elsewhere, Grendel's death is avenged by his mother, who carries off from the hall one of Hroðgar's most eminent retainers. Beowulf offers to seek her out in her home at the bottom of a lonely mere in the hills. Fully armed the hero dives into the mere and the monster drags him into her home where Grendel lies dead. Beowulf is nearly worsted when his sword fails against her, but he is saved by noticing a giant sword hanging on the wall with which he manages to kill her. The hilt of this sword and Grendel's head he takes as trophies back to Heorot.

Enriched with honour and princely gifts Beowulf sails home and tells the story of his exploits to his uncle King Hygelac who rewards him with lands and an honoured position in his kingdom. Beowulf serves the king and his son Heardred until Heardred is killed in battle against the Swedes. Then by popular consent Beowulf becomes king and reigns wisely, maintaining peace and justice for 50 years. The events of his reign are quickly passed over but the poet describes his last battle in detail.

A dragon, roused by a theft from the treasure it has guarded for 300 years, ravages the land and to save his people Beowulf goes out to kill it. This fight is much slower than the two of Beowulf's youth. Memories of the hero's past achievements and speeches which sum up the experiences of his life give the prelude to the fight a dreamlike quality, but when the dragon is eventually roused its appearance is so terrible that the aged king's 11 followers flee and leave him to struggle, mortally wounded, in the dragon's grip. Only his young kinsman Wiglaf comes to his aid and together they kill the monster. Before Beowulf dies, Wiglaf shows him part of the treasure that he has won for his people. However, Wiglaf, who succeeds to the kingship, and also conducts Beowulf's magnificent funeral, decrees that the people shall not benefit from the ill-fated treasure and prophesies disaster for the Geatish nation who so failed their king.

Beowulf is cremated and his ashes, with the dragon's treasure, are buried in a great mound. The poem ends with the Geatish warriors' lament for their king: "the kindest and gentlest of men, the most considerate to his people, and most eager for glory."

Nature of the Poem.—We do not know whether a historical Beowulf ever existed, but if he did his deeds were certainly not those of the hero of the poem. As critics have shown, exploits such as the tearing off of the monster's arm and the underwater fight can be paralleled in ancient stories as far apart as Ireland and Mexico. Nevertheless his story gains in effect by being set in a historical background of 6th-century Scandinavia, peopled by figures that we, like the original audience, know to have existed. The Old English audiences liked their stories to be "adorned with truth" and the detailed reminiscences in ***Beowulf*** of the wars between the Swedes and the Geatas, the ancient rivalries of the Danes and the Heaðobards, and of Hygelac's ill-fated attack on the Rhineland, satisfied this desire.

References to such wars and to characters from traditional heroic stories, the retrospective allusions to Beowulf's achievements, and the long speeches which take up 1,300 lines, have been considered irrelevant hindrances to the advance of the story by

critics who have attempted to apply classical standards of narrative structure to the poem. The main story, also, has not escaped stricture both because of the seemingly imperfect balance of the three combats and because the hero is shown solely as a monster killer. However, on the whole modern critics have tended to applaud the poet's achievement. The poem's division into two narrative blocks (the second beginning with Beowulf's recapitulation of his exploits in Denmark) could be explained by the exigencies of oral delivery, but artistically the balance between the combats of the hero's youth and age, with their skilfully differentiated tone and subtle narrative links, justifies itself.

The evidence of English place names testifies to the reality of Beowulf's monsters to the Anglo-Saxon audience, and archaeology provides some evidence that the man-against-beast combat was a well-known theme in pagan Germanic times. However, in tracing the descent of the Grendel tribe from Cain, the poet gives the struggle a further dimension: Grendel and his mother are not entirely symbolic, but like the dragon—otherwise a different type of antagonist, as befits the slayer of the hero—they are irredeemably destructive and malignant to mankind.

Against the poem's background of feuds, divided loyalties and self-seeking ambition Beowulf's "noble, disinterested deeds for the good of the human race" (D. Whitelock, *The Audience of Beowulf,* Oxford University Press, 1951) shine the more brightly, although he is neither a symbol nor a superman but a human being whose achievements are necessarily incomplete.

The formal technique of the *Beowulf* poet largely conforms to traditional Germanic practice. The metrical unit is that of all Old English poetry, a line divided into two halves of equal weight linked by alliteration. The five basic stress patterns can be emphasized by the alliteration and coincide with the stress in sense. Much of the vocabulary of *Beowulf* must have had a long poetic descent, but the poetic diction as a whole is richer in both quantity and quality than that of other Old English poems. This is shown most clearly in the stylistic devices of contrast and variation, and these are used even in the total narrative structure of the poem where the hero's character and achievements are built up in a series of contrasting references, and apparent identities in the human situation are shown to cover subtle and often ironically dramatic differences, as in the way Hroðgar and Beowulf face the troubles that beset them in their old age. One of the most polished examples of subsidiary narrative variation is seen in the account of Grendel's approach to Heorot (li. 705–27): here by repetition and variation the poet conveys not only the monster's menacing advance and his state of mind but gives an increasingly clear impression of him, from the first introduction as a *sceadugenga* ("walker in the shadows"), to the more substantial fiend whose eyes shine fearsomely in the darkness as he finally bursts into the hall.

It is in the creation of compounds like *"sceadugenga,"* known only in *Beowulf,* that the poet is most original and characteristic. Such appellations, which highlight one aspect of the subject's being, he uses most freely to achieve particularly solemn and elevated effects. for example in the account of Scyld's ship burial (li. 47–52):

> Þa gyt hie him asetton segen g(yl) denne
> heah ofer heaiod, leton holm beran,
> geafon on garsecg; him was geomor seia,
> murnende mod. Men ne cunnon
> secgan to soðe, seleradende,
> hæleð under heofenum, hwa þæm hlæste onfeng.

(Then last they set a golden banner high over his head, let the sea carry him off, gare him to the stormy ocean; they were sad at heart, oppressed in spirit. No man can truly say, neither the retainers in the hall nor the heroes under the heavens, who received that cargo.)

Here the sharp picture of the golden banner is followed by the repetition of Scyld's committal to the sea varied in two traditional terms, but the sea plays an active, then a passive role, and this is mirrored in the stress patterns. The variation in diction and metre to express the feelings of the grieving followers, and the qualification of men into two traditional groups, are typical examples of the poet's effective marriage of style and content.

Dating of the Poem.—When exactly the poem as we know it first came into being and where, is still impossible to decide. It seems clear that the work, with its lengthy descriptions of fighting and armour, political events, court life and the social and moral problems of the layman, was intended for the entertainment of a secular audience. However Christianity has so deeply penetrated the language, metaphor and thought of the poem that we must assume an audience with some tradition of Christianity and most probably Christian poetry behind it. The poet naturally presupposes also a wide knowledge of traditional heroic stories but he penetrates below the surface of such stories and their conventional situations, sympathetically considering the sufferings of innocent participants, the impermanence of success and happiness, and the courage of the heroes who had to live without. the consolation of Christianity. We do not know if the author of *Beowulf* was the first to provide this sort of treatment of the traditional past since the poem is unique of its type, but it is normally assumed today that such poetry could hardly have evolved before the 8th century. At that time, however, the courts of several of the English kingdoms could have provided a sympathetic audience, although there are features in the language of the poem that point to an Anglian origin.

It has sometimes been assumed that archaeological evidence can date the poem more exactly by providing dated parallels for the material conditions of aristocratic life the poet describes. Unfortunately the evidence is still incomplete. Most of the illustrative material comes from grave goods buried in the pagan manner with the dead, and as this custom had ceased by the end of the 7th century the material conditions of the 8th century are little known. It is impossible therefore to know how far the poet modernized his story and how far he drew on traditional descriptions from earlier heroic poetry. It seems likely that certain descriptions, for example of the battle equipment of the heroes of the past, became appropriate by long usage but it must also be remembered that such equipment was much prized by the earliest English and handed down as heirlooms. A poet with a historical sense could describe such heirlooms accurately when, like the author of *Beowulf,* he specifically mentions that a certain piece was ancient.

The rich 7th-century ship burial discovered in 1939 at Sutton Hoo, Suffolk, with its wealth of imported silverware, its weapons and armour adorned with gold and jewels, has shown that the *Beowulf* poet's descriptions of the equipment and lavish burials of kings was neither exaggerated nor dependent on pre-English traditions. Moreover Sutton Hoo, showing as it does close links with Swedish art and customs, helps to explain why traditional stories from Scandinavia should have been current among the English.

There is a curious mixture of heathen and Christian elements in the burial *(see* R. L. S. Bruce-Mitford, "The Sutton Hoo Ship Burial," in *Proceedings of the Suffolk Institute of Archaeology,* vol. xxv, pt. 1, 1949) and there was no trace at Sutton Hoo (or in *Beowulf)* of the human or animal sacrifices which were a feature of fully pagan burial rites. It is not certain however whether the poet only knew traditions of such transitional-type funerals or whether he edited fully heathen accounts for himself.

Sutton Hoo does not tell us the date of *Beowulf,* but does at least provide the closest parallels yet known for conditions described in the poem. Like ise, the excavation of the first Anglo-Saxon royal buildings, at Yeavering in Northumberland, is an eloquent illustration of how the great wooden halls such as Heorot must have appeared to the original audience. Archaeological evidence can considerably enrich a study of the poem. It provides proof of the tastes, the external splendour, the delight in craftsmanship, of a society for which *Beowulf* is otherwise our solitary witness.

BÉRAIN, JEAN, THE ELDER (1637–1711), French draftsman, designer, painter and engraver of ornament, was called the oracle of taste of his time in all matters of decoration. He was born on Oct. 28, 1637, at Saint Mihiel. In 1674 he was appointed designer to King Louis XIV, in succession to Henri Gissey, whose pupil he is believed to have been. After the death of Charles Le Brun he was commissioned to compose and supervise the whole of the exterior decoration of the king's ships. Although possessed of no great originality, he was skilful in adapting the work of his predecessors. He designed costumes and decorations for opera, court festivals and public solemnities. His work inspired the ornamentation of rooms and furniture, and exercised enormous influence all over Europe. His numerous designs were for the most part engraved under his own superintendence; a collection of them was published in Paris in 1711. He died in Paris on Jan. 24, 1711.

His son, JEAN BÉRAIN the Younger (1678–1726), best known as an engraver, was his father's pupil, and exercised the same official functions after his death. CLAUDE BÉRAIN, brother of the elder Jean, was still living in 1726. He was engraver to the king, and executed a good number of plates of ornament and arabesque of various kinds.

BÉRANGER, PIERRE JEAN DE (1780–1857), French song writer of much wit who became immensely popular in the early 19th century, was born in Paris, Aug. 19, 1780. Neglected by his father, he spent most of his youth working in an inn and sleeping in a garret, but found his true vocation when he first visited Le Rocher de Cancale, a tavern frequented by song writers. Thanks to Lucien Bonaparte, Napoleon's brother, who secured him a small pension, he was made a clerk at the university, composing in his spare time sentimental, ribald and satirical verses such as "Le Roi d'Yvetot" (c. 1813), a song about a king as easygoing and pleasure-loving as Napoleon was ambitious and despotic, which made him famous before he had published anything. After the fall of the empire (1815) and the restoration of the Bourbon kings he pleased his public by glorifying the era of Napoleon and the deeds of the emperor's veteran troops (as in "Le Vieux Drapeau") and by ridiculing the monarchy and the reactionary clergy. Collections of his work (1821 and 1828) earned him spells of imprisonment, first for three and then for nine months. His fame was increased by this persecution and he used it during the revolution of 1830 to further the cause of the bourgeois king Louis Philippe. A plain man and a liberal, he was praised by writers (Chateaubriand, Alphonse de Lamartine, Félicité de Lamennais and Jules Michelet, *qq.v.*) and politicians like Thiers who tried to cash in on his popularity. He affected modesty, saying that he owed his reputation only to the old tunes to which he set his lyrics. He acquired publicity by pretending to run away from it. After the revolution of 1848 he was elected a deputy but resigned because he said making parliamentary speeches was not his business and thereafter apparently lived in retirement with Judith Frère, who had been his companion for many years, though he would still reappear and catch the public eye on favourable occasions. He died in Paris, July 16, 1857, and Napoleon III, seizing an opportunity to make propaganda for himself, ordered a magnificent funeral in his honour. A poet and humorist, who had played an important part in politics, he had conducted his life with great skill.

His poems appeared in England and the United States in many translations, of which W. Young's *Songs of Bdranger* (1878) was probably the best known. Charles Dickens once said to Ernest Legouvé, the dramatist, "Do you know which French writer is most popular with our enlightened working-class? Béranger."

BERAR, a tract of rich cotton country in eastern Maharashtra, India, extends for about 200 mi. from west to east along the line of the Purna river. It lies 700–1,600 ft. above sea level and is bounded north by the Gawilgarh hills and south by the Ajanta and Satmala ranges. In India's political history the name was given to a province of varying extent, but from the mid-19th to mid-20th century it comprehended specifically the districts of Akola, Amravati, Buldana and Yeotmal (*qq.v.*). In the 1950s "Berar" tended in local popular usage to be replaced by the ancient name "Vidarbha" although this refers to a larger area also embracing the Nagpur plain and other territory to the east.

After the incursions of Muslim armies at the end of the 13th century A.D. Berar or Birar emerged as a distinct political entity; subsequently it was in turn a part of several Muslim kingdoms until, on the breakup of the Mogul empire it fell to the nizam of Hyderabad (*q.v.*). In 1853 it was assigned to the British. A perpetual lease was negotiated in 1902 and the Berar "Assigned Districts" attached as a division to the Central Provinces. When the commissioner's divisions of the newly created province of Madhya Pradesh (*q.v.*) were abolished in 1948 Berar lost its administrative significance.

BERAT, a town of southern Albania on the Osum-Seman river and capital of the district of the same name. The population in 1955 was 14,374, of whom nearly seven-eighths were Muslims and the rest Orthodox. The town is situated on steep hills, through which the Osum has cut its way, and the picturesque, white, terraced houses are crowned by the ruined old citadel. There are several mosques and many old churches. The surrounding valley is fertile. About 7½ mi. to the north is the productive oil field of Stalin (Kuçove), near which is a large modern airfield. To the east towers Tomorr (7,929 ft.), the highest peak in southern Albania.

Berat has a long and romantic history as a strategic point between Illyria and Epirus, and as the scene of many battles. Once probably the ancient Greek Antipatria, it became the Byzantine Pulcheriopolis; rebuilt in the 13th century by Michael Comnenus, despot of Epirus, it was renamed Beligrad (corrupted to Berat) in the 14th century by Stephen Dushan's Serbs and refortified by Ali Pasha in the 19th century. The Turkish bridge was built in 1780. (D. R. O.-H.)

BERBER, a word of uncertain origin designating the indigenous Caucasoid peoples of north Africa who call themselves, in most cases, some variant of the word *imazighen.*

Language.—First recorded as tribal names in Old Kingdom Egyptian inscriptions, Berber languages are spoken by over 10,000,000 persons discontinuously distributed from the Siwa oasis, Egypt, to the Atlantic and from the Niger river to the Mediterranean. Berber is related to ancient Egyptian, Semitic, the Cushitic languages of the eastern Horn of Africa, and, as classified by the linguist J. H. Greenberg, to languages spoken by Negroes near Lake Chad. It is divided into Masmuda, Senhaja, and Zenata and subdivided into regional languages and local dialects. Sex and number are expressed in Berber by both prefixes and suffixes: *e.g.*, Rifian *afunes* = "bull"; *ifunesen* = "bulls"; *thafunesth* = "cow"; *tifunesen* = "cows." Lexically it contains a few possibly Caucaso-Mediterranean, more Latin, and many Arabic roots, while French and Spanish words were incorporated into several Berber vocabularies. The Tuaregs, nomadic Berbers of the Sahara, write love poems in Tifinaq, an ancient Berber alphabet, but otherwise, literate Berbers write both Arabic and Berber in Arabic script. Many also learn French, Spanish, or both.

History.—Well into Roman times many Berbers were still Neolithic farmers, using polished stone cutting tools. From this epoch may have been transmitted widespread traditions of an invasion of Berber ancestors from the western Sahara, replacing

earlier peoples, and a prehistoric war between the Ghomara (Masmuda) and the Senhaja, won by the latter. Greeks and Phoenicians established trading posts at strategic coastal points, and the Phoenicians founded Carthage, destroyed by the Romans, who then colonized Tunisia, eastern Algeria, and western Morocco so effectively that many of the indigenous Berbers became Latin-speaking Christians, like St. Augustine. Meanwhile, Jenish colonists had penetrated the interior, trading widely and introducing metalworking. From them are descended the Berber-speaking mountain Jews. After the first Arab invasion, in the 7th century A.D., Christianity was replaced by Islam and Latin by Arabic in the Romanized areas, while Berbers elsewhere were evangelized by Muslim missionaries, and cities such as Fez and Kairuan were founded. In the 12th century a second wave of Arabs invaded north Africa. These were Bedouin, who turned the orchards and gardens of the coastal plains into grazing lands. Since then Arabs and Berbers mixed extensively and in some tribes exchanged languages. Although most Berbers live in mountains, others share the plains and deserts with Arabs and Europeans. More than half the Muslims of Morocco speak Berber; the ratio diminishes eastward through Algeria and Tunisia to Libya, and on to Siwa, Egypt.

Subgroups. — The principal Berber-speaking peoples in Morocco are the Rifis (*q.v.*) of the eastern Mediterranean coast, Beraber of the Middle Atlas, Shluh of the Great Atlas and Sous valley, and the Zenata of the eastern plains; in Algeria, the Kabyles of the Djurdjura mountains, the Shawiya of the Aurès mountains, numerous oasis populations such as the Mzabites of Ghardai'a, and the Tuareg of the open Sahara; in Tunisia, the Jerbans (Djerba islanders); in Libya, the villagers of Jabal Nefusa; and in Egypt, the Siwans. Although not racially identical all are more or less Mediterranean with variable stature, slender to medium build, Caucasoid facial features and hair, form! and, in most tribes, brunet pigmentation. Stocky builds and blondism are most frequent among mountain tribes, particularly Rifis, and Negroid features among members of scheduled castes—blacksmiths, butchers, well diggers, market attendants and musicians.

Material Culture.—Although most Berbers are sedentary farmers, some tribes cultivate the lowlands in winter and graze their flocks in mountain meadows in summer, while others are year-round pastoral nomads dependent for vegetable foodstuffs on serfs and slaves dwelling in desert plateaus and oases. There are also Berber cities, like Taroudant and Ghardai'a. In Arab and European cities of north Africa certain Berber groups monopolize the corner-grocery trade: Soussis in Morocco, Mzabites in Algeria and Jerbans in Tunisia.

The sedentary agricultural Berbers grow wheat and barley in open fields and irrigated terraces and fruits and vegetables near the river bottoms. Steep slopes, cultivated with the hoe, are covered with vineyards and patches of beans and rye. Fruits and nuts are dried for export and winter consumption, and olive oil, their principal cooking fat, is extracted in communal mills and presses. Women grind grain at home in rotary hand mills, or take it to a communal turbine water mill. Berbers raise much livestock: cattle, sheep, goats, asses, horses, mules and camels, as well as dogs, cats and poultry, the proportions depending on the terrain and climate. Oxen are used for plowing, asses and mules for drawing water, turning machinery, and carrying pack loads; camels for draught and riding; and horses for riding. The first wheeled vehicle commonly used by Berbers in modern times was the automobile.

Most home industries, like pottery making and weaving, are women's work, while full-time crafts are performed by Jews and Negroes outside the Berber social structure. Considered immune in tribal wars, the craftsmen are able to keep up a constant flow of vitally needed products to all tribes and villages, even those under siege. Some blacksmiths are established in villages, while others make the rounds of weekly markets, so ingeniously spaced and scheduled that a villager may walk from home to a market and back every day of the week except Friday, the Muslim sabbath. In the markets are imported hardware and machine-loomed textiles, candles, matches, tea and sugar, and local foods and manufactured products. Professional butchers, who are sometimes blacksmiths as well, work in a secluded section near the livestock market. Outcaste criers shout announcements, and professional weighers facilitate sales. In a special house or under a tree sit the tribal notables, who run the market, exchange information and drink mint tea.

Berber housing varies with climate, degree of mobility and building materials. The sedentary farmers build stone houses with gabled or flat roofs, depending on rainfall. Most houses are single storied and set around a court. The seasonally nomadic tribes erect multistoried castles of pounded earth for defense and storage, and live in black goathair tents when at pasture. Oasis dwellers and urbanites construct large masonry buildings, and the Tuareg live in leather tents.

Social and Political Structure. — Aside from language, Berbers differ from Arabs in four easily recognized ways. (1) Whereas Arabs govern their conduct by the *shariya* or written religious law, Berbers follow their own ancient *kanuns* or oral traditionals, at least as-different from the *shariya* as the Napoleonic code is from English law. (2) Whereas Arabs prefer marriage between the children of two brothers, Berbers forbid it and favour the union between cross cousins—a mother's brother's daughter and a father's sister's son. (3) The position of women is higher among Berbers. They go unveiled, meet guests, sell their own products in the market and keep the money, help arrange betrothals and manage the details of weddings. Many are also literate. (4) Arab government tends to be personal and authoritarian, while Berber government usually is more communal or representative. The simplest Berber political structure, found in independent villages in Algeria and the Great Atlas, is the *jama'a (djemaa)*, a meeting of all reputable grown men in the village square. Such villages are divided into rival moieties that give the meeting structure and provide links with other villages having the same moieties. Among the Rifis a complex representative system evolved, permitting the growth of a nation in time of stress and falling apart when the pressure subsides. Among part-time nomads the need for organization and policing during migration necessitates the election of an annual summer chief, who assigns places in the procession over the steep mountain passes and allots pastures. Among fully nomadic Berbers a constant need of structure gave rise to a permanent chieftainship with a council. Among them the class system is a complex arrangement by which nobles of a warrior caste protect both camel-breeding serfs and agricultural slaves, while guiding, protecting or raiding caravans.

Religious Structure. — All Berber groups harbour one or more ritual castes, said to be descendants of the Prophet or of saints who go about as fearlessly as the blacksmiths at the other end of the scale, immune to harm because of their holiness. They negotiate truces, educate the young and cure the sick by faith healing; they are buried in shrines, often beside great rocks or trees, where their powers are sought out as cures for sterility or special categories of diseases.

Except for Mzabites and Jerbans, who are Khawarij (Kharejites), most Berbers consider themselves Sunnis, usually of the Malikite rite. With notable exceptions as in the Middle Atlas region, circumcision, prayers and fasts are faithfully observed. Sufi brotherhoods in which members of local chapters attain a state of ecstasy through the performance of formal dancing, breathing and chanting rhythms, are popular with some Berbers but frowned upon by others. Certain groups celebrate a very secret annual rituai in which the most sacred Muslim beliefs and practices are ridiculed.

BERBERA, a port of the Somali republic and capital (until 1941) of the former British Somaliland protectorate, Africa, lies on the Gulf of Aden. It has a stable population of about 7,500, most of whom are Somali of the Habar Awal clan, and is the headquarters of Berbera district. A local government council was instituted in 1953. A good water supply comes by pipeline from hot springs, which are of some antiquity, at Dubar to the south. With improved port facilities trade, mainly with Aden, has increased since World War II.

The coast around Berbera was known in classical times and to the early Arab geographers, the first of whom to give a brief description of the town was Ibn Sa'id (d. 1286). The original site of the town was probably a little to the east; and Berbera was one of the Muslim settlements in the medieval state of Adal. It was sacked by the Portuguese in 1518 and in the 17th century became a dependency of the sharifs of Mokha. In 1875 Berbera was occupied by the Egyptians, and when they withdrew at the time of the Mahdist rebellion in the Sudan it was occupied by Britain in 1885.

Travelers in the 19th century generally described the town as a poverty-stricken collection of huts with a population in the hot months of about 7,500. From October to March, however, during the northeast monsoon, when nomadic stockbreeders came down to the coast and the port was open to vessels from Arabia, the Persian gulf and India, bringing dates, cloth, rice, metals, etc., to be traded for slaves, livestock, ghee, hides and skins, and gums, the population swelled to as many as 40,000. (I. M. L.)

BERBICE, a river of British Guiana, South America. It rises in the Kanuku mountains and flows 370 mi. through dense forest to the coastal plain. It enters the Atlantic at New Amsterdam, where its flow is obstructed by shallows. Its basin is restricted by the proximity of its larger neighbours, the Essequibo and Courantyne rivers, and its only tributary of consequence is the Canje creek. It is navigable 100 mi. inland by small vessels; there are many rapids higher up.

The Dutch colony of Berbice was settled in 1627 and separated from Surinam in 1732. It joined Demerara and Essequibo in 1831 to form British Guiana. The county, or region, of Berbice has no modern political significance. (G. LN.)

BERCEO, GONZALO DE (*c.* 1195–c. 1268), the earliest known Castilian poet, was born at Berceo, in what is now the province of Logroiio. Records show that in 1220 he was a deacon and in 1237 a secular priest attached to the Benedictine monastery of San Millán de la Cogolla. He was still alive in 1264. His poetical works on devotional subjects include *Milagros de Nuestra Señora, Loores de Nuestra Senora, Vida de Santo Domingo de Silos, El Sacrificio de la Misa* and *Vida de Santa Oria.* He belonged to a school of erudite poetry known as the *mester de clerecia* and used the *cuaderna via,* which consisted of single-rhyme quatrains, each line having 14 syllables. His *Milagros* probably came from the same source as the *Miracles de la Sainte Vierge* of his French contemporary Gautier de Coincy. Berceo is faithful to his sources, both scriptural and medieval, but adds details, full of charm and life, which sometimes allude to his own mood and surroundings. His poems were discovered in the 18th century and were praised by later Spanish authors including Rubén Dario and Antonio Machado.

BIBLIOGRAPHY.—There is a complete critical edition by A. G. Solalinde (1922) and of separate works by J. D. Fitz-Gerald (1904) and C. Carroll Marden (1928 and 1929). *See* also R. Becker, *Gonzalo de Berceos Milagros und ihre Grundlagen* (1910); G. Cirot, "L'Expression dans Gonzalo de Berceo," in *Revista de Filología Española* (1922); *T.* C. Goode, *Gonzalo de Berceo; El Sacrificio de la Misa, a Study of Its Symbolism and Its Sources* (1933). (JÚ. M.)

BERCEUSE, the French word for "lullaby," is used in music as the title of a character piece, usually for piano. As a title the *berceuse* does not imply a set musical form. The most famous example is the *Berceuse,* Op. 57, by Chopin, which takes the form of lacy figurations played by the right hand against a sequence of chords continuously repeated in the bass. Other *berceuses* are by Benjamin Godard, from the opera *Jocelyn;* Liszt, originally entitled *Träumerei;* Saint-Saens, for piano duet; and Ravel, for violin and piano.

BERCHEM (BERGHEM), **NICOLAES** (CLAES) **PIETERSZ** (1620–1683), Dutch painter and etcher, whose works were in great demand among his contemporaries, was born at Haarlem. He received instruction from his father (Pieter Claesz van Haarlem) and from the painters Jan van Goyen, Jan Baptist Weenix, Jan Wils and Pieter de Grebber. He studied in Italy, and most of his numerous landscapes are southern landscapes in bright sunshine. His finest pictures are at the Amsterdam museum and at the Hermitage, Leningrad. There are examples in London, Vienna, Berlin and elsewhere.

Berchem died on Feb. 18, 1683, in Amsterdam.

BERCHEM, a southern suburb of Antwerp, Belg., is one of the seven satellite communes, which, since the beginning of the 20th century, witnessed considerable development in the outskirts of the old maritime city. Pop. (1955 est.) 46,834. Most of the commune was inside the second ring of fortifications around Antwerp, but now that these have been abandoned Berchem is expanding into the country beyond. Most of the working inhabitants are employed in the port of Antwerp, in nearby photographic and shipbuilding industries and in a telephone manufacturing plant. (R. M. AN.)

BERCHTA (PERCHTA), a minor Teutonic goddess known from beliefs and customs in south Germany. She leads a band of spirits combining beneficent and evil qualities, and is concerned particularly with spinning and plowing. Her day, celebrated by the offering of meals, coincides with the Christian feast of the Epiphany (Jan. 6). (K. C. K.)

BERCHTESGADEN, a town and resort area in southeastern Bavaria, Germany, surrounded on three sides by Austrian territory, lies in a deep valley on the northern side of the Alps on a small stream, the Berchtesgadener Ache, 145 km. (90 mi.) E.S.E. of Munich but only about 12 mi. S. of Salzburg, Aus. Pop. (1959 est.) 4,739. The Marktplatz is the centre of the little town and close by is the Stiftskirche (church) with two spires, on the site of a 12th-century basilica. The castle, originally the home of the provosts of Berchtesgaden and later the summer residence of the kings of Bavaria, now houses a museum. At Obersalzberg, 500 m. (1,640 ft.) above the town, were the chalets of Hitler (the Berghof), Goring, Bormann and other Nazi leaders, with air raid shelters, barracks and various installations. These were destroyed in an Allied air attack in April 1945. In 1952 the ruins were leveled to the ground and trees planted on the site. A paved road winds up the mountain to a tunnel entrance leading to an elevator (the tunnel and shaft cut in solid rock) up to a glass-walled tea house on the very top of the mountain, once Hitler's private retreat, the "Eagle's Nest."

The main industry of Berchtesgaden is the tourist trade. There is mountain climbing and skiing and the neighbourhood is scenic. Salt mines, which can be visited, form one of the oldest and most important industries; others include wood carving, brewing, the manufacture of stockings and buttons, the painting of china and agriculture.

Berchtesgaden grew up around the community of Augustinian monks called Chorherrenstift, which was founded about 1111 by Count Berengar I of Sulzbach. The opening of the salt mines began many centuries of bitter rivalry with Salzburg and Hallein. From 1300 Berchtesgaden was ruled by provosts and in 1491 the emperor Maximilian I gave the provost Ulrich Pernauer the title of *Reichsfürst* ("Prince of the Reich"). For a short time in 1704, during the War of the Spanish Succession, the town was occupied by Austrian troops and in 1803 it was annexed to Austria. In 1809–10 it was directly ruled by the French. From 1810 to 1918 it was part of the Bavarian kingdom; then it was part of Germany. Entered by Allied forces in World War II on May 5, 1945, it was a major resort and recreation area during the occupation. It became part of the Federal Republic of Germany in 1949.

BERCHTOLD, LEOPOLD, GRAF (1863–1942), Austro-Hungarian foreign minister whose ultimatum to Serbia led to the outbreak of World War I, was born in Vienna on April 18, 1863. A wealthy landowner in Bohemia and Moravia, he became one of the richest men in Austria by his marriage to Ferdinandine von Nagy Karolyi in 1893. Having entered the diplomatic service

(1893), he was sent to Paris in 1894 and to London in 1899. In 1906 he was made ambassador at St. Petersburg, where his charm, elegance and discretion won him many important connections. On Feb. 19, 1912, after the death of A. Aehrenthal, he was appointed foreign minister: against his will. Berchtold's standing with Russia had already been compromised by Aehrenthal's agreement with A. P. Izvolski, the Russian foreign minister, concerning the annexation of Bosnia-Hercegovina, later denounced by Izvolski. As foreign minister, Berchtold soon fell under the influence of Conrad von Hotzendorf, chief of the general staff, and his period in office saw a succession of ominous mistakes. In 1912 he hindered Italy's attempts to strengthen the Triple alliance. At the beginning of the first Balkan War he damaged Austria's prestige by an unrealistic attempt to maintain the *status quo,* and after the war his influence prevented Serbia from gaining a corridor to the sea and forced the Montenegrins to withdraw from Shkoder (Scutari) in favour of the new state of Albania. His unsuccessful intervention on Bulgaria's behalf brought about closer relations between Rumania and Russia. Berchtold's vacillating policy converted the old tensions between Austria and Serbia into hatred and further led to the anonymously sponsored propaganda campaign, which led to the murder of the archduke Francis Ferdinand at Sarajevo on June 28, 1914. Urged by Conrad von Hotzendorf, Berchtold was determined on war with Serbia and, on July 21, 1914, decided on an ultimatum whose text should ensure its rejection. Germany was informed but not Italy, since Berchtold feared that Italy would inform Russia and thus hasten its mobilization. At the same time he calmed the fears of the emperor concerning Russia's reaction and misled the general staff with a similar optimism. When Italy demanded territorial concessions in return for neutrality, Berchtold resigned, on Jan. 13, 1915, and accepted high office at court. He died at Peresznye castle, near Csepreg in Hungary, on Nov. 21, 1942.

With an unenviable heritage as foreign minister, Berchtold cannot be entirely blamed for the disastrous outcome of his period in office, but his unpublished memoirs nevertheless reveal a frightening superficiality. Uncertain, even when not mistaken, he let others persuade him into following unrealistic policies.

BERDICHEV, a town of Zhitomir *oblast* (province) of the Ukrainian Soviet Socialist Republic, U.S.S.R., is a railway junction on the Zhitomir-Vinnitsa and Rovno-Kazatin lines. The town suffered heavily in World War II and its population in 1959 of 53.000 was still below the 1939 level of 62,000 when more than half its population was Jewish. Founded in 1482, Berdichev was Polish from 1569 to the partition of 1793. Up to the Russian Revolution it was an important trading centre for the right-bank Ukraine. Its importance is industrial, with two engineering works. a woolen mill, a sugar refinery and a tannery. (R. A. F.)

BERDYAEV, NIKOLAI ALEKSANDROVICH (1874–1948), Russian religious thinker, one of the foremost representatives of "Christian existentialism." was born in Kiev in 1874. He was attracted early by Marxism. although he was critical of its materialist doctrine, for which he originally desired to substitute an idealism derived from Kant, Fichte and, especially. the neo-Kantians. In 1899 he was sentenced to three years' exile in northern Russia on a political charge. Released, he visited Germany and then took up residence in St. Petersburg (1904), where he participated in the widespread religious and cultural revival taking place in Russia at that time.

After another visit to western Europe in 1907, he went to live in Moscow, where he made his most important contribution to the revival. He became a loyal if rather nonconformist member of the Orthodox Church. Brought to trial in 1914 because of an article attacking the Holy Synod, he escaped sentence when the case was dropped on the outbreak of the Russian Revolution. He was later appointed professor of philosophy at Moscow university, but had trouble with the police and eventually, in 1922, was expelled from the U.S.S.R.. together with a number of other Russian intellectuals. After a period in Berlin, he established a religious-philosophical academy in Paris in 1924. He died at his home in the Parisian suburb of Clamart on March 23, 1948.

In manner Berdyaev was more of a prophet than a systematic philosopher, even though he expressed his prophecies in books devoted to the traditional problems of philosophy. Besides a considerable philosophical gift of an intuitive kind and a genuine sensitivity to the moods of his time, he had a controversial zest, evidence of which is provided in his contributions to his periodical *Put'* ("The Way"; Paris, 1925 ff.). Truth, in Berdyaev's view, was not attained by means of knowledge mirroring objects, but through penetration of our environment by a creative act. It is "a light which breaks through from the transcendent world of spirit" into the beclouded, "objectified" world, where everything is outside everything else. The greatness of man is his share in this world of spirit and his divine capacity to create; his tragedy, collective and individual, resides in the "objectification," debasement and eventual loss of the creative impulse. As the gulf between creative ideas and their embodiment widens, regeneration begins again from within man. Berdyaev believed that "the contradictions of modern history" portend such a time of new "divine-human creation." The writers and thinkers whom Berdyaev acknowledged as his masters are Jakob Boehme, Maine de Biran, Kant, Franz von Baader, Nietzsche, Dostoevski and V. S. Soloviev.

In the context of Russian cultural developments Berdyaev aspired to a synthesis of Westernism and Slavophilism. He never completely repudiated his Marxist antecedents. although his socialism and his critique of capitalism were qualified by a conviction that on a certain level the difference between them is insignificant and that socialism can be "the greatest *bourgeois* triumph." Here as elsewhere he was mainly concerned with the defense of the human person against bondage to things. to "fictitious economic and political values." to abstractions and to the fatalism of history. In regard to Soviet Russia he had a divided mind. He condemned "the crimes and violence of the Soviet order"; yet, unlike most of his compatriots in emigration, he not only did not consider the Communist regime to be an alien occupation. but claimed to detect the undertones of true messianism in post-revolutionary Russia.

The most important works by Berdyaev in English translation are *Freedom and the Spirit* (1935), *The Destiny of Man* (1937), *The Origin of Russian Communism* (1938), *Dream and Reality: an Essay in Autobiography* (1950) and *The Beginning and the End* (1952).

BEREA, a town of Madison county. Ky., U.S., in the foothills of the Cumberland mountains, 125 mi. S. of Cincinnati, O. The town grew around Berea college. which was founded in 1855 to promote "the spiritual and material welfare of the mountain region of the South." The college is nondenominational. No tuition is charged, and preference in admission is based on residence in the southern mountain territory, financial need, scholastic ability and character.

All students participate in the educational work program through such adjuncts as the library and laboratories, and such college industries as a bakery. weaving and woodcraft shops, the college press and college hotel. (E. S. PE.)

BERENGAR OF FRIULI (d. 924), king of Italy from 888 and emperor from 915, was the second son of Eberhard, margrave of Friuli, and Gisela, daughter of the emperor Louis I the Pious. After the fall of the emperor Charles III the Fat, Berengar was elected king of Italy (at Pavia, 888) and founded that line of princes of the 9th–11th centuries who in popular Italian histories are ranked quite incorrectly as national kings. Berengar acknowledged the overlordship of the East Frankish king Arnulf (*q.v.*),

as his own position in Italy was contested by Guy of Spoleto (d. 894). Early in 889, however, he was defeated by Guy and had to withdraw to northeastern Italy. In 896 he agreed on a partition of Italy with Lambert, Guy's son and successor; and with the death of Lambert (898) Berengar was recognized throughout the kingdom. In 899 he suffered a defeat on the Brenta river in battle against the invading Magyars. In 900 Louis of Provence *(see* LOUIS III the Blind), invited by the Italian nobles, contested Berengar's position in Italy. Driven out in 902, Louis made a renewed attack against Pavia and Verona in 905 but was captured and blinded by Berengar. Nevertheless Berengar's authority, even after his coronation as emperor by Pope John X in 915, remained weak. The Italian magnates called in Rudolf II of Burgundy against Berengar in 922, and at Fiorenzuola (near Piacenza) Berengar, despite an alliance with the Magyars, was defeated (923). He was murdered by one of his own men at Verona on April 7,924.

BERENGAR (BERENGER or BERENGARIUS) OF TOURS *(c.* 999–1088), medieval theologian, a participant, on the losing side, in the great struggle between theologians affirming the symbolic presence of Christ in the Eucharist and those supporting the doctrine of conversion (transubstantiation), was born at Tours, in France, and educated in the famous school of Fulbert of Chartres. Later, as director of the cathedral school of his native city, he taught with such success as to attract pupils from all parts of France, and powerfully contributed to the diffusion of interest in the study of logic and metaphysics, and to the introduction of the dialectic development of theology. The earliest of his writings of which record remains is an *Exhortatory Discourse* to the hermits of his district, written at their own request and for their spiritual edification. It shows a clear discernment of the dangers of the ascetic life, and a deep insight into the significance of the Augustinian doctrine of grace.

Sometime before 1040 Berengar was made archdeacon of Angers. It was shortly after this that rumours began to spread of his heretical views regarding the sacrament of the Eucharist. Transubstantiation, he held, was contrary to reason, unwarranted by Scripture, and inconsistent with the teaching of men like Ambrose, Jerome and Augustine. He did not conceal this conviction from his scholars and friends, and through them the report spread widely that he denied the common doctrine respecting the Eucharist. His old school companion, Adelmann, archdeacon of Libge, wrote to him letters of expostulation in 1046 and 1048; and Bishop Hugo of Langres wrote (about 1049) a refutation of the views Berengar had expressed to him in conversation. Berengar was not affected by their exhortations. Hearing that Lanfranc, the most celebrated theologian of his day, strongly approved the doctrine of Paschasius Radbertus — who in 844, in the first systematic treatise as the Eucharist, had asserted that the bread and wine are changed into the body and blood of Christ that was born of Mary — he wrote to him a letter expressing his surprise and urging him to reconsider the question. Lanfranc, who was then in Rome (1050), brought the letter to the notice of Leo IX with the result that Berengar was excommunicated and ordered to appear before the council of Vercelli, which was to be held later in the year. Before it assembled he was cast into prison. At the council of Tours (1054) he found a protector in the papal legate, the famous Hildebrand, who, satisfied with the fact that Berengar did not deny the real presence of Christ in the sacramental elements, succeeded in persuading the assembly to be content with a general confession from him that the bread and wine, after consecration, were truly the body and blood of the Lord, without requiring him to define how. At the council of Rome (1059) Berengar signed a formula of faith defining the real presence in an extremely realistic manner; but on returning to France he continued to attack the doctrine of transubstantiation, apparently without objection from either his civil or ecclesiastical superiors. Finally, Hildebrand, now Pope Gregory VII, summoned him to Rome, and, in the council of 1078, tried once more to obtain a declaration of his orthodoxy by means of a confession of faith drawn up in general terms; but in the council of the following'year Berengar was forced to acknowledge a change of the bread into the body of Christ that was born of the Virgin Mary, and that the change was not merely by sign and virtue of the sacrament but in the own nature and truth of substance. He was kindly dismissed by the pope not long after, with a letter recommending him to the protection of the bishops of Tours and Angers, and another pronouncing anathema on all who should do him any injury or call him a heretic. Berengar again recalled his confession but, at the council of Bordeaux (1080), made a final retraction. He passed the rest of his life in retirement and prayer on the island of St. Côme, near Tours, where he died in 1088. He left behind him a number of followers.

The position of Berengar in the Eucharist controversy rested on his theory that dialectic was *par excellence* the instrument for discovering truth, a theory that concerned the whole question of the relation between faith and reason and that meant that reason was to be the criterion in matters of faith. His objections to transubstantiation were chiefly metaphysical. Accidents, he argued, cannot exist without their substance, even by the power of God, and therefore, if the accidents of bread are present on the altar, their substance, and not that of the body of Christ, will be there. Besides, if Christ is present, and bread alone is seen, there is deception, for Christ, who is God, represents himself other than he actually is. Again, if Christ is in heaven, as the Scriptures say, he cannot be on earth or on many altars, since nobody can be in different places at the same time. Moreover, we know that the body of Christ after the resurrection became incorruptible; therefore, it cannot be broken with the teeth or daily recreated. This reasoning Berengar supports by the Bible and the church fathers.

He seems, however, to have admitted the real presence in the Eucharist, for he allowed that after the consecration the elements undergo a *conversio*, not inasmuch as they lose the *esse* that they have, but in the sense of acquiring something else, that something being the real and invisible body of Christ, which constitutes the *res sacramenti*.

The position of Berengar was not entirely new, for in the 9th century, Ratramnus, a monk of Corbie, had rejected the substantial change in the elements as affirmed by Radbertus, and Eriugena had regarded the Eucharist as merely a memorial. As far as the church was concerned, the debates with Berengar led to a clearer exposition of the nature of the change in the sacrament, and an enrichment of the terminology applicable to Eucharistic dogma.

See A. J. Macdonald, *Berengar and the Reform of Sacramental Doctrine* (1930); *D.* Stone, *A History* of *the Doctrine of the Holy Eucharist*, vol. i, pp. 244–259 (1909).

BERENGARIO DA CARPI, JACOPO (1470–1530), Italian physician and anatomist who first described the valves of the heart, was born in Carpi, near Modena. He made other original contributions in his studies and careful descriptions of the sphenoid sinuses, vermiform appendix, uterus, brain and other organs.

Besides being a professor at Bologna (1502–22), he was a successful medical practitioner and became well-known for his treatment of syphilis with mercurial ointment. Berengario da Carpi was praised by Gabriel Fallopius (1523–62) for his contributions to the science of anatomy. He was one of the first, however, to break with tradition by illustrating medical works with drawings from nature instead of schematic drawings and arbitrary features. His works, which were illustrated with artistic drawings, include *lsgogae breves perlucidae et uberrimae in anatomiam corporis humani ad suorum scholasticorum preces editae, cum aliquot fuguris anatomicis* (1514); *De fractura calvarae s. cranii* (1518); and *Commentaria . . . super antomia Mundini* (1521).

He died in Ferrara in 1530.

BÉRENGER, ALPHONSE MARIE (1785–1866), French magistrate and parliamentarian, distinguished for his role in the reform of law and of legal procedure, was born at Valence on May 31, 1785. Appointed judge in Grenoble in 1808, he had a successful career in the magistracy during the first empire. Having

been representative for Drôme during the Hundred Days, he retired to private life at the second Restoration. In 1818 he published his famous work *De la justice criminelle en France,* attacking the special courts of the Restoration and demanding the institution of trial by jury. Returning to politics, he was elected deputy for Valence in 1827 and kept this mandate for 12 years. After the July revolution of 1830 he was a member of the parliamentary commission for the trial of Charles X's ministers and secured the decision that the death penalty should not be imposed. As a member of the court of cassation from 1831, he took part in all juridical discussions, notably in the revision of the criminal code and in securing for juries the right to find extenuating circumstances in crimes. Appointed peer of France in 1839, he gave up all political activities nine years later, though he remained as counselor and then as president of one of the chambers of the court of cassation until 1860. He served as president of the high court of Bourges, judging political trials during the second republic. In his most important work, *De la répression pe'nale, comparaison du système pknitentiaire en France et en Angleterre* (1853), he defended his humanitarian principles in the administration of justice. He died in Paris on March 9, 1866. (JE. V.)

BERENGUER, DÁMASO (1873–1953), Spanish general, was prime minister for most of the short interval between the end of Primo de Rivera's dictatorship and the establishment of the second republic. He was born in Cuba on Aug. 4. 1873, entered the army in 1889, and fought in Cuba and north Africa, where his services secured his promotion to general in 1909. As minister of war (1918) he was so successful that in 1919 he was put in charge of the high commission in Morocco. There his capture of Xauen in 1920 gained him the title conde de Xauen, but he was involved in the Anual disaster (1921) and was court-martialed and placed on the reserve list (June 1924). Less than a month later he was amnestied and in 1926 Alfonso XIII appointed him head of his military household. The king nominated Berenguer to succeed Primo de Rivera on Jan. 28, 1930, his intention being that the new government should prepare for a return to constitutional rule on the one hand, while safeguarding the interests of the monarchy on the other. These aims quickly proved incompatible; the country became increasingly politically unstable and a military rising took place at Jaca in Dec. 1930. Berenguer resigned on Feb. 14, 1931. After being minister of war in the short-lived government of his successor, Admiral J. B. Aznar, he was imprisoned during most of the existence of the second republic. In 1946 he published a defense of his administration: *Crisis del reinado de Alfonso XIII. De la Dictadura a la República.* He died in Madrid on May 19, 1953.

BERENICE (BERNICE), the Macedonian form of the Greek *Pherenice* ("bearer of victory"), the name (1) of several princesses of the Ptolemaic house *(see* PTOLEMIES) and (2) of two Jewish princesses of the Idumean dynasty.

Ptolemies.—Four of the Ptolemaic princesses of the name deserve mention.

BERENICE (fl. late 4th century B.C.), possibly a relation of Antipater (*q.v.*), went to Egypt about 321 B.C. as a lady-in-waiting to Antipater's daughter Eurydice, the bride of Ptolemy I, son of Lagus, who later made himself king in Egypt. Supplanting Eurydice, she married Ptolemy in 316 and bore him a daughter, Arsinoe (*q.v.*), and a son, Ptolemy II Philadelphus, who obtained the succession over the heads of Eurydice's children. By an earlier marriage she was the mother of Magas, king of Cyrene.

BERENICE (d. 246 B.C.), daughter of Ptolemy II Philadelphus and Arsinoe I, was married *c.* 252 B.C., in furtherance of a political agreement, to the Seleucid king Antiochus II Theos, who repudiated his former wife Laodice and her descendants in favour of the new queen. In the civil war that broke out within the Seleucid realm after the deaths of Antiochus II and Ptolemy II she and her infant son were put to death by Laodice's party (246) before Ptolemy III could come to their assistance.

BERENICE (d. 221 B.C.), daughter of Magas of Cyrene and so a granddaughter of the first Berenice *(see* above), brought Cyrene back to its alliance with Egypt by marrying Ptolemy III (247). When her husband undertook an expedition to Syria to rescue his sister (the second Berenice, above), his consort dedicated a lock of her hair in a temple of Aphrodite for his safe return. The hair having disappeared from its place, the astronomer Conon of Samos explained that it had been placed among the stars, and the name Coma Berenices ("hair of Berenice") was then given to the constellation still known by this name. The leading poet of the day, Callimachus of Cyrene, wrote a poem on this subject, which was translated into Latin two centuries later by Catullus. On the accession of her son Ptolemy IV, Berenice was poisoned on the orders of the courtier Sosibius, presumably with the king's connivance (221).

BERENICE (d. 55 B.C.) was the eldest daughter of Ptolemy Auletes and the elder sister of the famous Cleopatra. In 58 B.C. the people of Alexandria recognized her as queen during her father's absence in Rome. In 56 she married Archelaus, a Cappadocian prince, and the two ruled as sovereigns until the following year, when a Roman army under the proconsul of Syria, Aulus Gabinius, restored her father to the throne. Berenice was thereupon put to death by her father.

Idumeans.—BERENICE (fl. late 1st century B.C.), the daughter of Herod I's sister Salome, was married first (*c.* 17 B.C.) to her cousin Aristobulus, the son of Herod and Mariamne. She bore him three sons, Herod of Chalcis, Herod Agrippa I (*q.v.*) and Aristobulus, and two daughters, Herodias and Mariamne. She later married Theudion, brother of Herod I's wife Doris.

BERENICE (*c.* A.D. 28–after A.D. 79) was the eldest daughter of Herod Agrippa I. After the death of her second husband, Herod of Chalcis, in 48 she lived for several years—save for an interval of short-lived marriage with Polemo of Cilicia—in the house of her brother Herod Agrippa II (*q.v.*). Scandal spoke of an incestuous relationship. They were seen frequently together in public; *e.g.,* at Caesarea Palestinae, when they greeted the new procurator of Judaea, Porcius Festus. On that occasion she sat on the tribunal before which St. Paul appeared (*c.* 60). In 66 Berenice and her brother tried in vain to check the impending Jewish rebellion; during the rebellion they remained loyal to Rome. In 69, on her own initiative, Berenice pledged the support of her brother's kingdom to the Roman emperor Vespasian. Although she was about 12 years his senior, Titus, Vespasian's elder son, fell deeply in love with her, and she became his mistress. In 75 she visited Rome with her brother. It was believed that Titus wished to marry her, but public anger at the prospect became so strong that he sent her out of Italy. (R. H. SI.)

BERENSON, BERNARD (1865–1959), U.S. art critic, whose writings, particularly those on Italian renaissance art, are at once popular and authoritative, was born in Vilna, Lithuania, on June 26, 1865. He was raised in Boston, Mass., and was educated at Harvard university, graduating in 1887. His first book, *The Venetian Painters of the Renaissance,* was published in 1894. A discriminating eye, an exceptional memory, perceptive intelligence and humanistic learning were brought to focus in his writings in a lucid, concise style. For a time he was an adviser to Lord Duveen and his opinion was often sought in the purchase of paintings. Many masterpieces now in U.S. museums were bought upon his recommendation. Although he retained his U.S. citizenship, he was a resident of Italy during most of his life. He passed World War II in sequestration in Tuscany, and his diary of this period, *Rumor and Reflection* was published in 1952. He died on Oct. 6, 1959, at his villa, I Tatti, at Settignano, near Florence. He bequeathed the villa, with its distinguished art collection and magnificent library (his proudest creation) to Harvard university, and it is administered as a Center for Italian Renaissance Culture. Among his major works are *Aesthetics and History, Drawings of the Florentine Painters* and the monumental *The Italian Painters of the Renaissance.*

See W. Mostyn-Owen, *Bibliografia di Bernard Berenson (1955).*

BERESFORD, CHARLES WILLIAM DE LA POER BERESFORD, 1ST BARON (1846–1919), British admiral, who was one of the best known sailors and most popular figures of his time, was born at Philipstown, King's county, on Feb. 10, 1846, the second son of the 4th marquess of Waterford.

Lord Charles, as he was generally known, entered the navy

in 1859 and had a distinguished career, his commands including the royal yacht "Osborne." At the bombardment of Alexandria (1882) he took the gunboat "Condor" close inshore, silenced the guns of Ft. Marabout, then landed to restore order in the town. For this service he was promoted captain. Two years later he commanded the naval brigade in Lord Wolseley's expedition for the relief of Khartoum, taking part in the battles of Abu Klea and Metemma. Promoted to flag rank in 1897, he commanded the Channel squadron (1903–05), Mediterranean fleet (1905–07) and Channel fleet (1907–09), becoming a full admiral in 1906. He retired in 1909.

His political career as a member of parliament ran parallel with his naval career, and while on half pay he devoted himself to arousing public interest in the development of sea power. He was Conservative M.P. for Waterford (1874–89), East Marylebone (1885–89), York (1897–1900), Woolwich (1902–03), and finally for Portsmouth (1910–16), then went to the house of lords as Baron Beresford, of Metemmeh and Curraghmore (Jan. 1916). He was made 4th sea lord in 1886, but resigned in Jan. 1888 as a protest against the government's naval program which he thought was inadequate. His criticisms however enlisted a large measure of public support for the Naval Defence act of 1889.

While commander in chief of the principal fleets, he was often in disagreement with the reforms and autocratic methods of Sir John Fisher (afterward Lord Fisher), the 1st sea lord, and as soon as he hauled down his flag attacked the whole policy of the admiralty in a letter to the prime minister who put it before a cabinet committee. Its report mainly supported the admiralty, but some of Beresford's recommendations were implemented later, notably the introduction of a naval general staff. The broad view he took of naval problems is apparent in his book *The Betrayal* (1912) and his *Memories* (1914).

Beresford died suddenly on a visit to Scotland on Sept. 6, 1919, and his peerage became extinct. (W. S. CH.)

BERESFORD, JOHN (1738–1805), Irish statesman, who was a leader of the party which wanted to preserve the political monopoly of the Protestant aristocracy in Ireland, was born in Dublin on March 14,1738, son of Sir Marcus Beresford (afterward earl of Tyrone) and of Catherine, Baroness de la Poer in her own right. John Beresford was educated at Trinity college, Dublin, studied law as a preparation for a political career and entered the Irish parliament in 1761 as member for Waterford, remaining its representative throughout his career. He was made a privy councilor in 1768. and was appointed a commissioner of revenue in 1770, becoming first commissioner in 1780. He had considerable administrative ability and introduced useful reforms in the machinery of taxation. He was also the author of several architectural improvements in Dublin including the new custom house by James Gandon. He was made a member of the English privy council in 1786. Beresford had become the head of one of the powerful Irish political groups. He controlled a vast patronage, and used it to increase his family influence, until the Beresford connection gained a dominant position in Irish politics. Beresford himself was even once described as "king of Ireland." He was a supporter of William Pitt, favouring Pitt's proposed commercial treaty of 1784; it mas over this issue that he first came into conflict with Henry Grattan and the reformers, because they thought the propositions did not go far enough in giving Ireland commercial independence.

The English government was inclined to a policy of concession, hoping in particular that by extending political liberties to Roman Catholics, they would widen and strengthen the aristocratic support of their government in Ireland. Beresford used his considerable influence to resist reform, in order to preserve the power of his class of Protestant landowners. Earl Fitzwilliam was appointed viceroy in 1795 and, determined to carry out a policy of conciliation, dismissed Beresford from office, although his pay was continued and all the office holders in his family retained their positions. Fitzwilliam thought he had Pitt's support for his action, but Beresford's influence was so great that he was instrumental in securing Fitzwilliam's recall (March 1795), and was reinstated under Earl Camden (*q.v.*), Fitzwilliam's successor. A policy of repression was begun which had Beresford's full approval. He also approved Pitt's proposal for union, and was closely involved in planning the details of the fiscal and financial relations between England and Ireland. After the Act of Union he continued to represent Waterford in the imperial parliament, and remained in office until 1802. He died near Londonderry on Nov. 5, 1805. *See* IRELAND: *History.*

See W. Beresford (ed.), Correspondence of the Right Hon. John Beresford (1854).

BERESFORD, WILLIAM CARR BERESFORD, VISCOUNT (1768–1854), British general and Portuguese marshal, who served in the French Revolution and the Napoleonic Wars and won his greatest distinction in the Peninsular War (*q.v.*). He was born on Oct. 2, 1768, and entered the army in 1785, distinguishing himself at Toulon (1793) and commanding the 88th Connaught rangers from 1795. He served under Sir David Baird in the expeditions to Egypt (1801) and to the Cape of Good Hope (1806), and Baird allowed him to sail from South Africa on Sir Home Popham's squadron as brigadier general commanding 1,200 troops in an unauthorized raid on the Spanish colonial city of Buenos Aires (Spain at that time being an ally of France). Beresford captured the town easily, but local forces compelled him to capitulate after hard fighting on Aug. 12, 1806, and imprisoned him for six months. He escaped and at the end of 1807 was sent to occupy and govern Madeira in the name of the king of Portugal. On recall to the British army in Portugal, he was commandant at Lisbon, but marched with Sir John Moore to Spain and was conspicuous at Corunna. In Feb. 1809 Sir Arthur Wellesley (later duke of Wellington) chose Beresford for the reorganization of the Portuguese army, in which he was given the rank of marshal. In the spring of 1811 Gen. R. Hill's illness obliged Wellington to give Beresford, as next in seniority, the command of his detached corps in southern Portugal and Estremadura. Beresford moved to invest Badajoz, met the French relieving army at La Albuera (May 16) and won a victory costly to both sides. He resumed command of the Portuguese, was at the siege of Badajoz and was wounded at Salamanca. For the rest of the war he was a corps commander. In 1814 he was created Baron Beresford of Albuera and Cappoquin. He remained in Portuguese service until the dismissal of the British officers in 1819. In 1823 he was created a viscount. In Wellington's first cabinet in 1828 he was master general of the ordnance. He retired in 1830, lived at Bedgebury, Kent, and died on Jan. 8, 1854. (I. D. E.)

BEREZINA, a tributary of the Dnieper in the Belorussian Soviet Socialist Republic, U.S.S.R., rises near the town of Dokshitsy and flows in a fairly constant south-southeasterly direction to its outfall a few miles above Rechitsa. It is 365 mi. long. Its drainage basin, covering 9,471 sq.mi., is largely level swamp, through which the Berezina and its tributaries, notably the Svisloch, slowly meander. The average discharge is 4,662 cu.ft. per second. The Berezina canal (built 1798–1805), which once linked the river to the Ulla, a headstream of the Western Dvina, has been abandoned. The Berezina itself is navigable only for small craft and rafts of timber. The major towns on the river are Bobruisk and Borisov (*qq.v.*). Near the latter Napoleon forced a crossing of the river, with heavy casualties, during his retreat from Moscow in 1812. (R. A. F.)

BEREZNIKI, a town of Perm *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., lies opposite Usolye (with which it was temporarily incorporated 1932–40) on the left bank of the upper Kama river, above its confluence with the Yayva. From a pre-revolutionary mining settlement Berezniki has grown rapidly to a town of 106,000 inhabitants (1959), on the basis of its large chemical industry. The town lies in the Solikamsk-Berezniki salt and potassium mining area and there is a potassium mine in the town. Nitrate fertilizers, nitric and sulfuric acids, paint and aniline dyes and medicines are produced. There are also soda and magnesium works. Berezniki is linked by rail to Solikamsk and Chusovoi and by road to Perm. (R. A. F.)

BERG, ALBAN (1885–1935), Austrian composer best-known for his opera *Wozzeck,* was born in Vienna, Feb. 9, 1885. A pupil of Arnold Schonberg (1904–10), he continued his associa-

tion with him, and with his fellow pupil, Anton Webern, in the revolutionary "second Viennese school." His works are significant in relating the more radical aspects of Schönberg's methods of composition to tradition: he transmuted Schonberg's "atonal" style of free dissonance into a more conventional harmonic idiom. Later, after 1925, he demonstrated the potentialities of the 12-note technique as an expansion of traditional methods. Berg's musical idiom is less abstruse than that of Schonberg and Webern, and, as his music is also deeply expressive and intensely human, possessing powerful dramatic and lyrical qualities, it is pre-eminently his art that has given validity to the work of the Viennese school.

Berg worked slowly, but, though his compositions are few, each is of great significance. His first opera, *Wozzeck* (1917–21; Berlin, Dec. 14, 1925), is a powerful expressionist work. remarkable for its imposition of highly organized classical forms on the dramatic structure without impeding its flow. His Lyric Suite for string quartet (1925–26) was his first work to use the 12-note technique, but he dealt with the new medium so successfully that it remains one of the most intensely emotional chamber works of the century. His unfinished second opera Lulu (Zurich, 1937) and the expressive violin concerto (1935) revealed the great possibilities in the association of the 12-note technique with traditional harmonic and melodic elements, and decisively demonstrated the true classical lineage of 12-note music. Other compositions include the *Fünf Orchesterlieder,* Opus 4 (1911–12); Drei *Orchesterstücke,* Opus 6 (1913–14); the *Kammerkonzert* (1923–25); and Der *Wein,* for soprano and orchestra (1929).

Berg seldom left Vienna. A sufferer from asthma. he lived humbly, mainly by teaching composition. He died, of blood-poisoning, in Vienna, Dec. 24. 1935. (R. S. BR.)

BERG, former duchy of the German empire, on the right bank of the Rhine, now in the administrative districts of Dusseldorf and Cologne, Germany. In the mid-11th century the counts of Berg administered the imperial abbey of Werden, but by 1133, when the family founded the Cistercian abbey of Altenberg at their ancestral seat they had acquired comital rights and lands east of Cologne and in western and southern Westphalia. In 1161 the family lands were divided between the senior line of Berg and the junior line of Altena (later Mark). The Berg line, which had provided the see of Cologne with three archbishops and had been closely allied to the Hohenstaufen emperors, died out with the murder of Engelbert, archbishop of Cologne, in 1225, the title passing by marriage to the house of Limburg. Adolf V, who in 1283 surrendered his claims to Limburg to John of Brabant, began in 1288 to develop Dusseldorf, later the capital of Berg, as a port. In 1348 Berg passed to Gerhard VI (d. 1360), of the house of Julich, who had married Margaret, heiress to Berg and also to Ravensberg. In 1380 Gerhard's son William received the ducal title and in 1423 the duke Adolf inherited Jülich and Gelders. In 1511 Julich-Berg passed by marriage to the dukes of Cleves-Mark. In 1609 the succession fell vacant (see JÜLICH) and a European crisis ensued, but in 1610 the duchies passed to the counts palatine of Neuburg. Berg, famous for iron manufacture, then developed an important textile industry. In 1806 Napoleon created an enlarged grand duchy of Berg for his brother-in-law Joachim Murat, but in 1815 the congress of Vienna granted Berg to Prussia. (H. W. D.)

BERGAMASCA (BERGOMASK), a lusty 16th-century dance depicting the reputedly awkward manners of the natives of Bergamo in northern Italy. It never became a court dance but had some popularity as an instrumental composition, built on a ground base, in lively 2/2 time. The pastoral bergamasque of 19th-century France bears no likeness to the true bergamasca. Claude Debussy's Suite *Bergamasque* and Gabriel Fauré's *Masques* et *Bergamasques* were inspired by Verlaine's poem, *Clair* de *Lune.* (L. HT.)

BERGAMO, a city of northern Italy in the region of Lombardy and capital of Bergamo province, is situated on the southern fringe of the Alpine foothills between the valleys of the Brembo and Serio, 30 mi. N.E. of Milan by road. Pop. (1937 est.) 111,050 (commune). The old part of the city (Città Alta), on a hill (1,201 ft.), was fortified by the Venetians in the 15th century and retains a medieval atmosphere. The cathedral was rebuilt in 1483 and 1689; the facade dates from 1886. Beside it is the Romanesque church of Santa Maria Maggiore (1137–1355) with a baroque interior. The neighbouring Renaissance Cappella Colleoni by Giovanni Antonio Amadeo has a 14th-century facade with sculptures in polychrome and fine tombs and ceiling frescos by Giovanni Battista Tiepolo. Opposite the cathedral is the baptistery (1340, rebuilt 1898) and nearby is the Gothic Palazzo della Ragione or del Broletto, which with the 16-century Palazzo dello Scamozzi (containing a library) and a museum, surround the Piazza Vecchia, the old town's centre, where there is a memorial to Torquato Tasso, the poet, whose family lived in Bergamo. Other features include the Risorgimento museum in the Rocca (the ruins of a 14th-century castle), a park with a fine panorama, the citadel (1300) with a museum of geology and natural history, and the Donizetti museum where the musician Gaetano Donizetti (*q.v.*) was born. The lower city (Città Piana) has been the town centre since the 19th century and has a fine collection of paintings in the Palazzo dell'Accadémia Carrara. The two halves of the town are linked by a funicular. Bergamo imports the basic materials for the manufacture of textiles and woolen goods, cement, mechanical and electrical products and metal tubes.

Known as Bergomum to the Romans, the city was the centre of the Orobi tribe. It became a Roman city and after destruction by Attila was rebuilt and later became the capital of a Lombard dukedom. From 1264 it was ruled by the Visconti (*q.v.*) but passed to Venice in 1428, under which it remained until 1797. Dominated by the French from that year until 1815 and included in the Cisalpine republic, it became Austrian after the fall of Napoleon and part of the Italian kingdom in 1859. During World War II it was freed by the Allies and Italian partisans at the end of April 1945.

BERGAMOT, OIL OF: see ESSENTIAL OIL; PERFUMES.

BERGDAMA, a Negro people (pop. about 30,000) inhabiting the mountainous regions of central South-West Africa. They speak a click language considered to be a dialect of Hottentot, but racially they are more like Negroes of Central and West Africa. Their origin has been the subject of much speculation, and they seem to be most closely related to the Koroka and Kwisi peoples living in Mossâmedes district of southwestern Angola. When first discovered many of the Bergdama were serfs of the Hottentots and Herero. Knowing the arts of forging iron and of making pottery, they provided iron implements and ornaments for their masters, and also served them as herdsmen.

Bergdama in the aboriginal state subsisted on wild foods, and some groups also kept goats. They were scattered in small exogamous patrilineal extended family bands, each inhabiting a relatively temporary circle of grass-covered huts enclosed by a thornbush fence. A holy fire burned in the centre of each village. The band chief, advised by his elder male kinsmen, controlled the group, and he was also its ritual leader and fire keeper. There was no larger scale political or military organization, and clan organization was lacking.

Bergdama religion included the concept of a supreme being responsible for rain and the annual renewal of plant life. but lacked a creation myth. There was belief in life after death and that sickness and death were caused by the deity or by the souls of departed men who required food. Many Bergdama have adopted Christianity. See HOTTENTOT.

See H. Vedder, *Die Bergdama* (1923); *H.* Vedder, "The Berg Damara," in The *Native Tribes of South West Africa* (1928); H. Vedder, *South West Africa in Early Times,* trans. and ed. by C. G. Hall (1938); C. Estermann, *Etnografia do Sudoeste de Angola,* v. i (1956). (G. D. G.)

RERGEN, a city and seaport in western Norway, forming a separate county (fylke). Pop. (1959) 115,378; area 14 sq.mi. Picturesquely situated on the broad Byfjord, partly on a promontory between the inner harbour (Vaagen) and the Puddefjord, it is bounded landward by the Store Lungegaard inlet, and rises from the harbour in an amphitheatre of gaily painted houses. Since World War II there has been great expansion and many buildings, mostly domestic but also some industrial, have been erected in

the northern and southern sections of the town.

There are many interesting buildings: the church of St. Mary. the oldest building in Bergen, dating from the 12th century; the cathedral, rebuilt in the 13th century; the Bergenhus fortress guarding the harbour; the adjoining Haakon's Hall palace (Haakonshallen, 1261); and the restored Rosenkrantz tower. A university was inaugurated in 1948 and the town contains the Norwegian School of Economics and Business Administration. The most important museums are the Hanseatic, and the Historical, Botanical, Geological and Zoological museums attached to the university; there are also the Vestlandske museum of Applied Art and the Maritime and Fisheries museums. The art gallery contains a representative collection of European art and the valuable Rasmus Meyer collection of Norwegian paintings and interiors. A picturesque open-air museum, Old Bergen (Gamle Bergen), is situated a short distance along the fjord. On the outskirts of the town inland is the old stave church at Fantoft, and a few miles beyond is the medieval pilgrims' church at Fana, finely restored and reopened by King Haakon VII in 1953. Also of interest are the ruins of the Cistercian monastery nearby at Lyse, founded in 1146 by monks from the mother house at Fountains abbey in England. Edvard Grieg is probably the best known of Bergen's native sons. Others are Ole Bull, the violinist; J. C. Dahl, the landscape painter; and Ludvig Holberg, the dramatist.

As a port, Bergen ranks second only to Oslo and maintains regular shipping connections with Newcastle, Rotterdam, Hamburg, Antwerp and New York. The principal industries are shipbuilding. machinery, electrical equipment. office machinery, ship repairing and fitting, textiles, cod-liver oil refineries. foodstuffs, gold and silverwork, rope and fishing tackle. The chief exports are fish products and base metals.

Arterial roads connect the town with national highways and an airport at Flesland for international traffic. The railway to Oslo, opened in 1909, is both an engineering and a scenic triumph.

The settlement (formerly Bjorgvin), founded by King Olaf III *c.* 1070, grew rapidly and figured prominently in the medieval civil wars, being the seat of the court up to 1300. The Hanseatic league merchants established *(c.* 1350) in Bergen their most active northern "Kontor"; some of their 17th-century buildings have survived, notably the museum now housing Hanseatic relics. Disastrous fires occurred in 1702, 1855 and 1916, and since then the central part of the town has been reconstructed, with broad open spaces to guard against further fires. During the German invasion of 1940 and the five years of occupation, Bergen suffered severely from bombing and other disasters. (B. Lo.)

BERGEN OP ZOOM, a town of North Brabant province. Neth., lies on both sides of the small Zoom river, near its confluence with the East Scheldt, 62 km. (38.5 mi.) N.E. of Flushing by rail. Pop. (1957 est.) 33,855 (mun.).

It was taken by the Normans in 880. In the 13th century Count Gerhard of Wesemael surrounded it with walls and one of the gates (1300) has been preserved. In the 15th century it prospered greatly owing to the free fairs where much business was done in cloth, wool, linen and madder. These fairs were visited by English and Scottish merchants who enjoyed special privileges. In 1576 the town joined the United Netherlands and was fortified: it successfully resisted the Spaniards on several occasions, the last being in 1622. In the 18th century the fortifications were strengthened! the work being completed in 1740. In 1747 the town was taken by the French. Restored at the end of the war, it was again taken by the French in 1795 and successfully held by them against the English, who tried to drive them out in 1814. During World War II the Germans captured the town in 1940 but it was liberated by a Canadian army division in 1944.

The lordship of Bergen op Zoom dates from 1287 by separation from the lordship of Breda (*q.v.*). It was a hereditary fief of the duchy of Brabant (*q.v.*). Toward the end of the 15th century one of the lords built a small palace, the "Markiezenhof," which is preserved. In 1533 Bergen op Zoom was raised to a margraviate by Charles V and was held by various families until in 1742 it passed to the royal house of Bavaria, by whom it was renounced in favour of the Batavian republic in 1801.

The town has an important metal industry (factories for manufacturing hearths and stoves), engineering works, confectioneries and biscuit factories, as well as one of the largest distilleries in Europe. (C. SL.)

BERGHAUS, HEINRICH (1797–1884), German geographer, cartographer and writer! best known as author of a world famous physical atlas, was born at Cleves on May 3, 1797. In 1816 he obtained an appointment in the trigonometrical survey oi the Prussian war ministry. From 1821 to 1855 (from 1824 as professor) he taught applied geometry, cartographic drawing and machine building at the Berlin Bauakademie. He moved to Potsdam in 1836, where, in 1839, he founded a school for cartography and geography which continued until 1848 and where his most outstanding pupils were his nephew, Hermann Berghaus (1828–90), his foster son, August Petermann, and Henry Lange. He died at Stettin on Feb. 17, 1884.

His most important works are his cartographic contributions, notably the *Physikalischer Atlas* (1838–48, 1849–52, 1886–92). This was inspired by Alexander von Humboldt (*q.v.*) to illustrate his *Kosmos;* English edition by Alex Keith Johnston (with H. Lange). His written works include *Allgemeine Länder und Völkerkunde,* 6 vol. (1837–44); *Grundriss der Geographie* j parts (1840–43); *Die Volker des Erdballs . . .* (1847, etc.) and *Briefwechsel mit Alexander von Humboldt, 1825–58* (1863). Commissioned by B. H. Hodgson of Darjeeling he wrote a geography textbook for Hindu schools. It is uncertain if it was published.

See also H. Beck, "Heinrich Berghaus und Alexander von Humboldt" *Petermanns Geogr. Mitt.,* 100 (1956). (K. A. S.)

BERGISCH GLADBACH, a town of Germany which after partition of the nation following World War II became the capital of the Rheinisch-Bergisch *Kreis* (county) in the *Land* (state) of North Rhine-Wesphalia, formerly a part of the Prussian Rhineland (*q.v.*), Federal Republic of Germany. It is a resort city of woods and gardens in the hills to the east of the lower Rhine valley lying between 210 and 755 ft. high, 15 km. (9 mi.) E.N.E. of Cologne. Pop. (1959 est.) 39,942. There are a 12th-century Romanesque church in the Paffrath district, the once moated Blegge castle (18th century), the Zweifelsstrunden castle (17th century), the 16th-century headquarters of the Order of St. John in Herrenstrunden and a museum of fossils. The chief industry is papermaking but there is also manufacture of light and heavy machinery and electrical equipment, iron smelting, wool-spinning and the production of glass fibre and pharmaceutical products. Bergisch Gladbach attained the status of a city in 1856. In World War II it was captured by the Allies in April 1945. (WI. O.)

BERGIUS, FRIEDRICH (1884–1949), German chemist and Nobel prize winner, was born Oct. 11, 1884, at Goldschmieden near Breslau. He studied at the universities of Breslau, Leipzig and Berlin and at the technical schools in Karlsruhe and Hanover. Later he founded a private technical research laboratory in Hanover and studied the influence of high pressure on chemical actions. This is described in his book *The Use of High Pressure in Chemical Actions* (1913). These studies led to his work on the conversion of coal into liquid products. Through the action of hydrogen under high pressure and at high temperature, he succeeded in converting a high percentage of coal dust directly into oil, without first obtaining intermediate products. Bergius was awarded the Nobel prize for chemistry, 1931, with Carl Bosch. He died March 30, 1949, in Buenos Aires, Arg.

BERGMAN, BO HJALMAR (1869–), Swedish lyrical poet, whose early work, with its simple rhythms and clear-cut style, contrasted strongly with the rich romanticism of the 1890s, was born in Stockholm on Oct. 6, 1869. His first collection of poems. *Narionetterna* (1903), expresses a *fin de siècle* pessimism and disillusionment. Bergman became reconciled to life, however, and during an age of war and political unrest he wrote as the champion of reason, humanity and truth. Other collections include *Elden* (1917), *Livets ogon* (1922), *Trots allt* (1931), *Gamla gudar* (1939) and *Riket* (1944). He also wrote novels and short stories. (L. G. G. T.)

BERGMAN, HJALMAR FREDRIK ELGÉRUS (1883–1931), Swedish novelist: dramatist and short-story writer, one of

the outstanding figures in Swedish literature of his generation, was born at Örebro on Nov. 19, 1883. The son of a wealthy banker, he was brought up in conventional middle-class ease, and no notice was taken of his extreme sensibility and imaginative powers. In his early teens his father, who had hitherto despised him, became aware of his precocious talents, and the shy, awkward, but observant boy became the object of an overpowering and domineering afiection. At this period he accompanied his father on business trips in Bergslagen, the mining district outside Örebro, which was to form the background of many of his books. To these various factors in his early life can be traced much of his later development.

During 1900–01 Bergman studied at Uppsala university, under the eminent philosopher Hans Larsson, with whom he was to maintain permanent contact. He read much philosophy, which, with psychology and aesthetics, was to remain an abiding interest. From 1901 to 1908 he traveled in Europe, especially in Italy: Florence became his favourite city. Delicate nerves and the threat of blindness made his life difficult. In 1908 he married Stina, the daughter of the actor-producer August Lindberg, and she became his defense against the world. They settled first in Lindesberg, then for a time in Rome. For the rest of his life, except during World War I, Bergman led a restless and curiously isolated existence between Sweden and other parts of Europe.

His first play, *Maria, Jesu moder* (1905), owes much to the literary ideas of the 1890s, but shows an original approach to the psychology of Christ and the Virgin Mary. Other plays from this apprentice stage of his career reveal the influence of Ibsen. Bergman preferred the drama to any other medium, and if he had not been so discouraged by his experience of the Swedish theatre, would have written more plays. Turning to the writing of fiction, however, he applied to it his dramatic gifts and technique, and so achieved work of great individuality. In 1910 came his first popular success *Hans Nåds testamente* ("His Grace's Will"), set in Bergslagen, in which the eccentric Baron Roger and his valet Vickberg figure in richly comic scenes. Characteristically, however, as in later works, beneath the humour there are undertones of tragedy. In the same year he published a collection of short stories *Amourer,* mostly set in Italy, in which he displayed his mastery of this medium and his subtle understanding of the irrational as a decisive factor in human behaviour. Bergman went on to produce a series of novels and long short-stories, starting with *Vi Bookar, Krokar och Rothar* (1912) and ending with *En dods memoarer* (1918). These were mainly concerned with Bergslagen, from early times to the present day, and with the fortunes and complicated feuds of certain' families and characters which constantly recur. His amazing memory and powers of observation enabled Bergman to create out of his own experiences, and out of oral traditions, a grotesque, fantastic, sombre and yet moving world which was peculiarly his own, despite its real-life setting. His work was appreciated by a small but discriminating public, but his experimental *Marionettspel* (1917; "Marionette Plays") was a failure, and his father's death in 1915 had made him increasingly dependent on his pen for a livelihood. With *Markurells i Wadköping* (1919; Eng. trans. by E. Classen, *God's Orchid,* 1924) he at last captured the wider public. This vigorous comic novel, the action of which takes place—with numerous recapitulations—within 24 hours, is the story of the grotesque innkeeper Markurell, who through his financial machinations has got most of the inhabitants of the town of Wadköping in his power, but, for love of his adopted son Johan, whose real father proves to be his chief enemy, shows mercy. Although the novel is written ironically, there are tragic implications.

Bergman followed this with other successes, including *Farmor och Vdr Herre* (1921; Eng. trans. by C. Napier, *Thy Rod and Thy Staff,* 1937) and *Chefen Fru Ingeborg* (1924; Eng. trans, by E. Sprigge and C. Napier, *The Head of the Firm,* 1936). His play *Swedenhielms* (1925) is among the few living Swedish comedies and his dramatization of *Markurells* also remained popular. He also wrote radio and film scripts, and in 1923–24 visited Hollywood: he detested it. He died in Berlin, on Jan. 1, 1931.

His later novels, of which *Clownen Jac* (1930) was the last, tend to diffuseness and unnecessary twists of plot, but on the whole Bergman remained a remarkable stylist. Fundamentally a pessimist. he felt for all the weaknesses of man understanding pity irradiated by humour: Bergman's collected writings were edited by J. Edfelt in 30 volumes (1949–58).

BERGMAN, TORBERN OLOF (1735–1784), Swedish chemist and naturalist, who introduced many improvements in methods of chemical analysis and made considerable contributions to mineralogical and geological chemistry and to crystallography. Born at Katrineberg, Vestergotland, on March 20, 1735, he was educated at the University of Uppsala. After taking his degree, he began to teach mathematics and physics at the university, publishing papers on the rainbow, the aurora, the pyroelectric phenomena of tourmaline, etc. In 1767 he became professor of chemistry and mineralogy. He died at Medevi on Lake Vetter on July 8, 1784. Bergman's most important chemical paper is his *Essay of Elective Attractions* (1775), a study of chemical affinity. He also made observations of the transit of Venus in 1761, and published a *Physical Description of the Earth* in 1766.

BERGMANN, ERNST VON (1836–1907), German surgeon of Russian birth, one of the greatest surgeons of his time, was born at Riga on Dec. 16, 1836. He was educated at Dorpat, where he was professor of surgery from 1871 to 1878. In the latter year he moved to the University of Würzburg and in 1882 he succeeded B. von Langenbeck at Berlin. In 1886 Bergmann introduced steam sterilization and in 1891 began to use aseptic methods. He also improved the design of operating rooms. His principal contributions are in cranial surgery, on which his work *Die chirurgische Behandlung der Hirnkrankheiten* (1888) is *a* classic. Bergmann died at Wiesbaden on March 25, 1907.

BERGSCHRUND (Ger. *Berg,* "mountain": *Schrund,* "cleft" or "crevice"), a gaping crack in the upper part of a snow field or a glacier, beneath which sapping and erosion commonly produce a semicircular landform called a cirque (*q.v.*).

BERGSON, HENRI (1859–1941), one of the most influential philosophers of his time, was born in Paris, of Irish-Jewish parents, on Oct. 18, 1859. Having been naturalized as a French subject he entered the École Normale Supérieure (where Jean Jaurès was his contemporary) in 1878. After teaching philosophy in the *lycées* of Angers (1881–83) and Clermont-Ferrand (1883–88) and then at the Collhge Rollin and at the Lycée Henry IV in Paris (1889–98), he received an appointment at the École Normale Supérieure, from which he went to the Collège de France as professor of philosophy in 1900. Elected to succeed Émile Ollivier in the Académie Française in 1914, he delayed his reception till 1918, serving on French diplomatic missions to Spain and to the United States during World War I. His connection with international affairs was maintained after the war when he became president of the League of Nations' committee on intellectual co-operation. He was awarded the Nobel prize for literature (1927) in 1928. Bergson died in Paris on Jan. 4, 1941. Before his death an increasing sympathy toward Roman Catholicism had been apparent in Bergson; and the fact that he did not publicly declare himself converted is attributed to a desire not to dissociate himself from the Jews during the period of persecution.

Bergson's Philosophy. — The progressive development of Bergson's thought is reflected in the series of books mhich non him his world-wide reputation. He was not the creator of a great system conceived as a whole in youth and gradually expressed in later life. There is, nevertheless, in his philosophy one outstanding idea which is said to have come to him during a walk at Clermont-Ferrand when he was 25 years old. Whereas, since Plato. philosophy had consisted in eliminating duration, in regarding time as an illusion and finite being and eternity as one, Bergson asked himself whether, on the contrary. the being of which the philosopher took

cognizance by reflection might not be one which endured, might not be time itself. For the phrase of Descartes, *Je suis une chose qui pense* ("I am a thing which thinks"), he substituted *Je suis une chose qui dure* ("I am a thing which continues"); and whereas Spinoza had presented reality *sub specie aeternitatis* ("in its eternal aspect"), Bergson presented it *sub specie durationis* ("in its durational aspect"). As he substituted durational for nontemporal values: so for static values he substituted values of motion and change. This was the Bergsonian revolution, which may be related to the German and English historical and evolutionist philosophies characteristic of the 19th century.

All Bergson's work is thus concerned with duration and movement. He does not proceed by general speculation. Each of his books is a study of one particular question. and this illustrates his second characteristic, originality of method. In his opinion, philosophy, like science, can only progress by disregarding general theories and universal systems so as to concentrate on particular problems, each of which demands its own point of view. The solution of any one of these does not necessarily involve an analogous solution of the others. Bergsonism implies continued striving after a precise adaptation to reality. The aim of each of his works is the elucidation of a detailed problem, though each is also part of a general philosophy. the philosophy of duration and change. For him, the true nature of things is apprehended by intuition; but those who see in Bergsonism nothing but an apotheosis of intuition and of mystical values and a depreciation of intelligence misunderstand his theories.

The *Essai sur les données immédiates de la conscience* (1889; Eng. trans., *Time and Free Will,* 1910), which was Bergson's thesis for the doctorate, constitutes an attempt. primarily, to establish his notion of *durée* (duration) as opposed to what he considered to be the spatialized conception of time employed for scientific and public purposes; and then to proceed toward an original solution of the problem of free will. *Matière et mémoire* (1896; Eng. trans.: *Matter and Memory,* 1911) contains a detailed consideration of the problem of aphasia, leading to a profound study of the means, namely the memory. by which existence is made continuous. In *L'Évolution créatrice* (1907; Eng. trans., *Creative Evolution,* 1911) he studies the whole problem of existence. While Spencer merely supported evolution by evidence derived from fragments of the evolved. Bergson takes as his material the essential motion of the being changing, or rather the being which is itseli both change and movement. This is his most famous and influential work and the one which most fully expresses his ideas as to the secret of the universe.

An important part of Bergson's philosophy is to be found in his minor works, such as the essay *Le Kire* (1900; Eng. trans.. *Laughter,* 1911), his lectures at Oxford entitled *La Perception du changement* (1911) and the volume *Durée et simultanéité* (1922), in which he discusses Einstein's theories. His later publications are the articles collected under the title *L'Énergie spirituelle* (1919); *Les Deux Sources de la morale et de la religion* (1932; Eng. trans.. *The Two Sources of Morality and Religion,* 1935); and *La Pensée et le mouvant* (1934).

Bergson's influence on Marcel Proust makes his philosophy important for 20th-century literature. His lectures at the Collège de France enjoyed great popularity; but it was probably as a master at the Lycée Henri IV that his influence was most felt.

BERHAMPUR, a town in the district of Ganjam (*q.v.*), Orissa. India. 103 mi. S.W. of Cuttack and 9 mi. from the Bay of Bengal. Pop. (1961) 77.147. Berhampur is the headquarters of two administrative subdivisions of Ganjam district. It is the seat of Khallkiote college (1878), a coeducational institution affiliated to Utkal university. There are also a women's college; an engineering school and a teachers' training school. The town is on the Calcutta-Madras national highway and the South-eastern railway main line between Calcutta (Howrah) and Madras It is also a road transport and commodity distribution centre for the hinterland. (MA. M.; N. K. S.)

BERHAMPUR TOWN, headquarters of the district of Murshidabad in West Bengal. India. lies on the east bank of the Bhagirathi river, 117 mi. N. of Calcutta, and is linkrd with the city by rail and a national highway. Pop. (1961) 62.352. A large oxbon lake occurs in the heart of the town. Silk weaving, ivory carving, gold and silverworks, and brass and bell metalworks are the chief industries. The town was founded and fortified in the mid-18th century by the East India company and continued as a cantonment until 1870. The old military barracks still stand on the bank of the Bhagirathi. Near the barracks are the old cemetery with 18th-century historical monuments, and the imposing Krishnath college There are two other colleges, all affiliated to Calcutta university.

Cossimbazar, now merely an industrial suburb of Berhampur, is much older. Its proximity to Murshidabad, then capital of Bengal. attracted European traders in the 17th century. In those days Cossimbazar had a flourishing silk industry, and its products were exported. The English factory founded in 1658 with John Ken as its chief prospered until its capture by Nawab Siraj-ud-daula in 1757. Even after the nawab's defeat at Plassey. Cossimbazar could not fully regain its commercial importance, and it declined early in the 19th century, mainly because of the westward shifting of the Bharirathi river. The palace of the maharaja of Cossimbazar contains fine carved stone pillars. (S. P. C.)

BERIA (BERIYA), **LAVRENTI PAVLOVICH** (1899–1953). Soviet statesman who from 1938 to 1953 played an active part in the persecution of opponents to Stalin's regime, was born on March 29, 1899, at Merkheuli in the Sukhumi district of Georgia. According to his official biography he came of "poor peasant" stock, but he succeeded in obtaining an education at the local high school and at the higher technical college in Baku (1919). He joined the Communist party in 1917 and engaged in revolutionary activity among the workers of Azerbaijan and Georgia and in the armed forces. In 1921 he was drawn into intelligence and counterintelligence work, a profession in which he remained all his life. He was appointed to the political leadership of the Transcaucasian republics in 1931 and was responsible for their integration into the Soviet Union. After the political purges and show trials of the 1930s came to an end, Stalin summoned Beria to Moscow and in Dec. 1938 made him commissar for internal affairs in place of N. I. Yezhov. Beria, who had had Yezhov shot. retained this position and the supervision of the internal security organization longer than any of his predecessors. He was made a deputy prime minister of the U.S.S.R. in Feb. 1941 and was a member of the State Defense committee during World War II. Apart from being responsible for supervising the internal security of the Soviet Union during the war. Beria played an important role in armaments production, for which he was in 1945 made a marshal of the U.S.S.R.

Beria was a member of the central committee of the Communist party from 1934 and of the politburo (later presidium) from 1946. On Stalin's death in March 1953 he became one of the four deputy prime ministers and minister for internal affairs. He was one of the three leaders, with G. M. Malenkov and V. M. Molotov, to pronounce an oration at Stalin's funeral. He did not retain his high position long, for on July 10. 1953, it was announced that he had been divested of all his posts in government and party on account of "criminal anti-party and anti-State activities" and had been arrested. The truth behind the many farfetched accusations made against him appeared to be that he had tried to make his security organization the only instrument of political power, and to establish his own personal dictatorship. His trial did not take place until the end of 1953. and it was announced on Dec. 23 that he and a group of high security officialshad been convicted of high treason and executed that day. (D. FD.)

BERIBERI is a disease caused, in large part, by a specific dietary deficiency of thiamine (vitamin B_1). It occurs most frequently in parts of the world where unbalanced diets are prevalent. The highest incidence has been in Asia where, from the 19th cen-

tury, rice has been highly polished during the milling process. The Asiatic importance of this disease is emphasized by its name, for the term beriberi is derived from the Singhalese word meaning extreme weakness. The history of the recognition, the cause and the cure of beriberi is dramatic and is well-documented in medical literature. In 1897 Christiaan Eijkman, working in the Netherlands Indies, demonstrated that a beriberi-like disease could he produced in chickens by a diet consisting of polished rice. That beriberi in man was also related to the ingestion of white rice was confirmed by British workers in the Malay states. There W. Fletcher in 1907 and Henry Fraser and A. T. Stanton in 1909 showed that in selected groups under close observation beriberi occurred in persons who were eating a polished rice diet whereas those eating parboiled or brown rice did not develop the disease.

In 1911, Casimir Funk demonstrated that beriberi could be cured in pigeons by feeding them a concentrate made from rice polishings. Following this discovery he proposed that this, as well as several other conditions. were due to the ingestion of diets which were deficient in specific factors which he termed "vitamines."

Later the implicated substance was isolated and its chemical structure determined. The official terminology in the *Pharmacopoea Internationalis* became *Thiamini hydrochloridum* with the synonym *Aneurini hydrochloridum.* In common parlance it is often referred to as vitamin B,.

Beriberi has been divided into several types. The infantile form occurs in the first few months of life and is characterized by an acute onset with involvement of the heart and gastrointestinal system. The outcome is fatal unless actively treated with thiamine. It is often associated with active or latent beriberi in the nursing mother. The adult form is usually slow in onset and more chronic in its course. The symptoms are associated with the nervous and cardiovascular systems. In the neuritic or dry type there is symmetrical, ascending neuritis. At first, this causes weakness of the muscles of the legs, which leads to difficulty in walking. Later, there is also involvement of the arms. As the disease progresses, severe pain may be induced by minor stimuli, such as the weight of the sheets upon a bedridden patient. More acute than these manifestations are those connected with cardiac or wet beriberi. Here there is heart failure with the concomitant development of edema; *i.e.,* the collection of fluid in dependent parts — abdomen, thorax, etc. The heart failure may lead to sudden death unless therapy is vigorously instituted and maintained. According to D. T. Rowlands and C. F. Vilter, there are no pathological changes in the myocardium in patients with beriberi heart disease. They believe that there is a reversible biochemical lesion.

The prevention of beriberi is accomplished by eating a well-balanced diet since thiamine is present in most raw and untreated foods. The highest content is found in whole cereals, pork, yeast, peas, beans and other vegetables. Thiamine is affected by excess heat, both intensity and duration of heat causing inactivation. Excess alkali will also lead to a degradation of thiamine. Ordinary cooking, canning, freezing and dehydration of food do not cause an excessive loss of thiamine. Although thiamine is found in almost all of the tissues of the body, it is not stored in great excess. In studies by P. T. McCarthy, L. R. Cerecedo and E. V. Brown in 1954, it was noted that the highest concentrations were found in muscle, testes, kidneys, liver, heart and brain. It was also determined that 64% of thiamine that was injected intramuscularly was excreted in ten days. Because of the relatively rapid excretion and the lack of stored reserves! beriberi may occur fairly soon after a diet deficient in thiamine is begun.

Thiamine is intimately associated with the utilization of carbohydrates. It is essential for the breakdown of pyruvic acid. This being the case, the daily requirement of thiamine is dependent upon the type of diet. If the diet is rich in carbohydrates the requirement will be greater. On the other hand. if the diet contains a large proportion of fat, the requirement will be less.

The treatment of beriberi should not consist only of replacement therapy of thiamine since isolated deficiency is rarely present. Supplements of the other members of the vitamin B complex (*i.e.,* riboflavin, nicotinic acid, etc.) as well as the other vitamins should be given.

BERING, VITUS JONASSEN (1681–1741j, Danish-Russian explorer who pioneered Russian arctic exploration and discovered Bering strait and Alaska. was born at Horsens, Jutland, in 1681. He went to sea, and, after a voyage to the East Indies, made the' acquaintance of the Norwegian-Russian Admiral G. Cruys and joined the fleet of Peter the Great as sublieutenant. In 1724 the tsar appointed him to lead the First Kamchatkan expedition, whose main task was to determine whether Asia and America were connected by land. Having built a ship near the mouth of the Kamchatka river in Siberia, he sailed with a crew of 44 on July 13, 1728. He reached 67° 18′ N. in about 167° W. and decided that the two continents were not joined. Returning, he saw and named the Diomede Islands in the middle of the strait, but did not sight the American coast.

In St. Petersburg Bering's observations were not sufficiently credited and he appealed to the empress Anne for a second expedition. His simple plans were, however, turned into an over-ambitious scheme and a Great Northern expedition of about 600 men, inadequately supported, left St. Petersburg in 1733. The unknown north coast was attacked from the Pechora, Ob, Yenesei and Lena rivers. and the second in command. M. Spangberg, visited Japan and explored the Kurile Islands, but it was not until June 4, 1741, that Bering could put to sea in the "St. Peter" with Alexei Chirikov in the "St. Paul." After fruitlessly carrying out instructions to search for an imaginary Gamaland about 500 mi. south of the nearer Aleutian Islands, he became separated from the "St. Paul." sailed northeast and landed in the Gulf of Alaska on Aug. 20. Worn out with the hardship of the past eight years and anxious to get his ship back to safety he was only able to reconnoitre the southwestern coast of Alaska, the Alaskan peninsula and the Aleutian Islands. Suffering more and more from scurvy he was unable to maintain effective control and the "St. Peter" was allowed to go ashore on Bering Island early in November. There he died on Dec. 19, 1741, of hunger, cold and grief, within 300 mi. of his starting point, Petropavlovsk, which he had founded the year before. After his death the expedition melted away. Its reports contained a tremendous contribution to the geography of the region, but they were not used to full advantage, and Bering's work is not well known.

See P. Lauridsen, *Russian Explorations, 1725–1743: Vitus Bering: the Discoverer of Bering Strait,* trans. by J. E. Olson (1889); F. A. Golder (ed), *Bering's Voyages* (1922, 192*j*).

(G. E. R. D.)

BERING SEA AND STRAIT. These are named after the explorer Vitus Jonassen Bering. Bering sea (Beringovo more) continues the Pacific ocean northward and is demarcated from it by the Aleutian Islands. It is bounded on the east by Alaska, and on the west by the Siberian and Kamchatkan coast. Its area is about 885.000 sq.mi. In the north and east it has numerous islands (St. Lawrence, St. Matthew, Nunivak and the Pribilof group) and is shallow; in the southwest it reaches a depth of 15.659 ft. (2,610 fathoms). The seal fisheries are important. since two of the three known breeding colonies of fur seals are located in this sea, and there is a Soviet whale fishery. The sea connects with the Arctic ocean by Bering strait (Proliv Beringa), at the narrowest part of which East cape (Mys Dezhneva) in Asia approaches within about 56 mi. of Cape Prince of Wales on the shore of the North American mainland, and is there 144 ft. (24 fathoms) deep.

The shallowness prevents any considerable water transport between Pacific and Arctic oceans. North and south of these points the coasts on both sides rapidly diverge. The strait contains two small islands known as the Diomede Islands (*q.v.*). These granite domes, lacking a harbour, lie more than a mile apart; and the international date line, and the boundary line between the possessions of the U.S.S.R. and the United States passes between them. They are inhabited by Eskimos, who call the western island Nunárbook and the eastern Ignalook.

The climate is severe. From November to May the temperature of the air is below 32° F., sometimes well below, and in summer it hardly exceeds 50°. The ice found in this sea is usually of local origin and not derived from the polar basin; it develops mostly on the coasts and in shallow waters. The ice limit usually runs from the eastern Aleutian Islands past St. Paul northward to 60" N. latitude, thence following the coast of Kamchatka southward. The areas of the greatest depths remain ice free. In July, August and September the ice usually retreats north of the Bering strait, because south winds drive a strong current with rather warmer water from the Pacific northward. This current was much used by the whale fishers of the 19th century and was also utilized by polar expeditions, in order to reach the north coast of North America.

Isai Ignatiev went east from the Kolyma river in 1646, and Semen Dezhnev in 1648 followed his route and prolonged it, rounding the East cape and entering the strait. The post of Anadyr was founded on the Anadyr river: and an overland way gradually opened up. At the behest of Peter the Great, Vitus Bering sailed into the strait in 1728 but did not see the Alaskan coast. The propinquity of America was discovered in 1732 by M. S. Grozdev and Ivan Fedorov. Under Bering on his last voyage (1741) was Comdr. Alexei Chirikov of the "St. Paul." who explored the Alaskan coast. Capt. James Cook, working from the south, explored the sea and strait in 1778.

Bering island (Ostrov Beringa). which was the scene of Bering's death in 1741. lies on the southwestern boundary of the sea. off the coast of Kamchatka, being one of the Commander or Komandorski group. belonging to the U.S.S.R. It is 53 mi. long and 25 mi. in extreme breadth; the area is 615 sq.mi. The extreme elevation is about 2,200 ft., and it is treeless. (T. E. ,\.)

BERING SEA ARBITRATION: **see** ALASKA: *History: Diplomacy Involving Alaska.*

BERKELEY, the name of an English family remarkable for its long tenure of the ancient Gloucestershire castle of Berkeley. The family descends from ROBERT FITZHARDING (d. 1171), the reeve of Bristol, to whom in 1153–54 Henry Plantagenet (afterward Henry II) gave the lordship of Berkeley. His successors came to hold extensive lands, notably in the Severn valley and in Somerset, including Redcliffe and Bedminster in the suburbs of Bristol where their interests often clashed violently with those of the growing town. They were also patrons and benefactors of St. Augustine's abbey at Bristol (now the cathedral), where many of them were buried.

The lords of Berkeley had played a prominent part in the campaigns and political upheavals of the 12th and 13th centuries. THOMAS (1245–1321) fought at the battles of Falkirk (1298) and Bannockburn (1314). His son MAURICE (c. 1271–1326) joined (1321–22) the earls of Lancaster and March against Edward II. forfeited his estates and died in prison. His son THOMAS (d. 1361), who married a daughter of Roger Mortimer, earl of March, was the scarcely impartial jailer of the deposed Edward II, and was certainly implicated in his prisoner's murder at Berkeley castle in 1327. His son MAURICE (1330–68) distinguished himself at the battle of Poitiers (1356), where he received wounds said to have caused his premature death.

The death of his son THOMAS without male issue in 1417 began the longest lawsuit in English history. The title of his nephew and heir male, JAMES BERKELEY (c. 1394–1463), to the family inheritance was contested by Thomas' daughter, ELIZABETH, wife of the powerful Richard Beauchamp, earl of Warwick, and by her descendants. Their claim was pressed forward within and without the courts, and occasionally flared into open violence: the Berkeleys fought a pitched battle in 1470 at Nibley green (Gloucestershire) with Elizabeth's great-grandson, Viscount Lisle. who was defeated and killed. This engagement is usually claimed as the last private battle on English soil. James's son, the childless WILLIAM, LORD BERKELEY (1426–92), whom the family chronicler called "the Wast all.!' brought further disaster to the family fortunes. Created successively a viscount (1481), earl of Nottingham (1483) and Earl Marshal (1486), his ill-judged social ambition led him to settle almost all his lands on Henry VII and his male heirs in return for the title of marquess of Berkeley. Not until Edward VI died without issue in 1553 could the Berkeleys recover their ancestral possessions. They still had to contend with Elizabeth Berkeley's descendants, whose claims passed from the Greys to the Dudleys and finally to the crown. Queen Elizabeth I pushed her title in the courts, and the Berkeleys again lost almost all their lands. A final settlement was reached in 1609, almost two centuries after the dispute had begun, and an impoverished family was left in peace.

The Berkeleys achieved an earldom in 1679. FREDERICK AUGUSTUS (1745–1810), 5th earl, disinherited his legitimate heirs by Mary Cole in favour of the children born before their marriage: the house of lords, in a famous case (1811), refused to accept the plea that he had contracted an earlier marriage with her. Berkeley castle belonged to the illegitimate branch of the family, the Lords FitzHardinge, until 1916. when it returned to the earls of Berkeley. descended from a brother of the 5th earl. The earldom became extinct in 1942, but the castle remained the home of a member of the Berkeley family. Among the many cadet branches of the family are the Berkeleys of Stratton, who held extensive properties in London's West End and gave their name to Berkeley square and Stratton street in Mayfair.

BERKELEY, GEORGE (1685–1753). Anglican bishop active in various fields but remembered chiefly as a philosopher. was born of English stock in or near Kilkenny, in Ireland, on March 12. 1685. He began his studies at Kilkenny school, with William Congreve as a contemporary and Jonathan Swift as a predecessor. He entered Trinity college. Dublin. in 1700, became a fellow of that college in 1707, lectured from time to time on Greek. Hebrew and divinity and retained his fellowship, despite long absences between 1713 and 1721, until 1724, when he was appointed dean of Derry. The absences were spent in two tours on the continent (1713–14 and 1716–20) and in sojourns in London, where he frequented the court and moved in the circles of Swift, Joseph Addison, Richard Steele and Alexander Pope. Instead of settling at Derry he returned for a few years in London. gathering high support for his project of a college in Bermuda for the education of young colonists and Indians of the American mainland. The project had to be dropped. but not before he had spent three years (1729–31) in Newport, R.I., giving much encouragement to higher education in the colonies: he is still honoured at Yale and Harvard, and Berkeley. Calif., was named after him. His appointment to the see of Cloyne (near Cork) came in Jan. 1734. Thenceforward he devoted himself to his pastoral duties and to public promotion of the economic and spiritual betterment of Ireland. In 1744 he started the European vogue of tar water as a general medicine. Eight years later he retired to Oxford, where he died after only a few months, on Jan. 14, 1753.

His published works are distinguished by their literary quality and their range. In the handling oi the English language he has few equals. The most patent features of his style are precision, economy and a seemingly inevitable grace, with here and there salty satire and teasing wit; the roots of it are a natural logicality, a rare purity of sentiment and a deep philanthropy. There is a perfect philosophical style in the early sections of his *Treatise Concerning the Principles of Human Knowledge* (1710) and almost perfect philosophical dialogue in *Three Dialogues Between Hylas and Philonous* (1713). *Alciphron* (1732), seven dialogues

in defense of morality and religion. shows all the qualities of his pen. from weight to wit. In more leisured days some of the best English men of letters savoured the curious beauty of his late scientific and philosophical meditation, *Siris* (1744). *The Querist* (1735–37) is a troop of epigrams, some of them mordant, on the economic plight of Ireland, all directed by prescient insight into principle and by detailed knowledge of relevant fact. The range of his competence is further illustrated by *The Analyst* (1734), in which he initiated what proved to be a useful criticism of Isaac Newton's differential calculus. These are his chief works, along with *An Essay Towards a New Theory of Vision* (1 jog), a brilliant piece of pure psychology, on the perception of space, the conclusions of which have been widely accepted.

Berkeley's philosophy, little appreciated in his own day, came into prominence chiefly through the criticism of it in Thomas Reid's *Inquiry into the Human Mind* (1764). Kant noticed it, S. T. Coleridge admired it, J. S. Mill felt much of it to be congenial, and after A. C. Fraser's edition of Berkeley's *Works* (1871) it became a regular subject of discussion in British universities. Interest in it declined in the 1930s with the emergence in England of a school of philosophers who banished metaphysics and had little interest in the history of thought; but Berkeley's title to continuing fame is likely to be secure, both because the course of British philosophy cannot be understood without him and because there is genius in the radically simple way in which he handled his problems.

"Esse is *percipi"* ("to be is to be perceived") is his most famous dictum and doctrine; that is, that the very existence of the immediate objects of sensation consists in their being perceived. Put concretely. colour means something seen. sound something heard. shape something seen or touched, and motion a seen or touched or otherwise felt sequence of something spatial. Therefore, to think of any of these as existing prior to, or at any time independent of, mind, is an elementary logical error. What is meant by the corporeal is always and entirely the sensory: a rock, for instance, is a shape, resistance, colour, etc. The whole corporeal world, then. can exist only as a set of objects of consciousness, as a system of ideas. So much Berkeley says unmistakably. There is some ground. therefore, for the usual designation of his philosophy as subjective idealism: the supposedly external and bodily world is nonexistent, there being nothing but minds and their internal sensations. This interpretation, however, clashes with Berkeley's often repeated avowal that he was trying to justify our natural belief that we have direct knowledge of a really corporeal world. One of the main points of his criticism of the Cartesians (especially N. Malebranche) and of Locke was that they had logically undermined that belief and had thus opened the door to subjectivism or scepticism. His antisceptical intention requires an objectivist interpretation, and his texts support one. He has not said that what he perceives by sense exists only because he perceives it and as a part of his own mind. That the mode of existence of sensory objects consists in being perceived is for him a necessary proposition. the predicate following from the very nature of such objects: shape, colour, etc., imply being perceived. *"Esse* is *percipi"* is thus a statement of a logical analysis, the entirely general proposition that the sensory as such is dependent on mind as such, the mode of dependence being that of an object to a subject. Again, that the sensory is the corporeal and that the corporeal is not mental are for him logical statements, analyses of the meaning of the terms. It is when Berkeley asks on what mind or minds the objects which we actually perceive depend that he leaves logic for experience. His explicit answer is that they are not dependent on our minds since they are obviously given to us. Further, they constitute an orderly system, as is shown by common and scientific observation. Then comes Berkeley's bold and original metaphysical leap: the only way of fitting the empirical fact of an independent corporeal universe to the logical truth that the *esse* of the corporeal is *percipi* is to postulate a cosmic mind. of which that universe is the constant object. Sensory fact is only evidenced by our perceiving; it is constituted by God's. The existence of God is thus required to explain the objectivity of the corporeal world; and the explanation saves its corporeality too, as that world, though bound to God's mind, is not taken up into His mental nature —it remains at the distance of being an object. In perceiving, Berkeley says against Malebranche, we are not looking into God's mind; we are simply being aware of certain things of which He is aware.

Berkeley's other characteristic doctrines are closely connected with that novel attitude and argument. Three may be noted. First, there is the denial of matter. He is not denying the corporeal world: he affirms this as real and as having in it all that we perceive. He is taking the term "matter" in two special meanings then current in philosophical circles. One of them followed from the prevailing assumption that the objects of sense are subjective, parts of the sensing mind. "Matter" then meant their counterpart, the corporeal as the reality existing outside of the mind. Having rejected the assumption, Berkeley has no need of the counterpart. The objects of sense are themselves the corporeal. not mental copies of it, so that to posit a second corporeal world behind them is gratuitous; and it is mischievous as well, for to suppose the perceivable world to be subjective and to posit an unperceivable world as the real one is to fall into scepticism, for it is then impossible in principle to compare the former with the latter. The other use of the term "matter" was Locke's: it meant what Locke called "a something I know not what" which he postulated as underlying the sensible properties of a thing, in order to account for their constant togetherness (*see* SUBSTANCE). Berkeley retorts, negatively, that an *x* to which no content from sense or reason can ever be given can explain nothing, and, positively, that on the *esse-percipi* principle the togetherness is accounted for by God's awareness and will.

Secondly, there is the denial of corporeal causality. All that we perceive, Berkeley declares, is that one quality or event uniformly attends another. and no amount of rational inspection of either can show us why. He is not alone in this contention: Locke had said much the same before him, and Hume said exactly the same thing after him. What neither of these went on to say, as Berkeley did, is that causal power belongs only to minds.

Thirdly, there is the denial of abstract general ideas. Berkeley restricted the term "idea" to sensory objects. That these, whether sensed or imagined, are in fact always particular, was an accepted commonplace. Berkeley's new point was that the particularity is essential, that the sensory means something particular and therefore that when the particularity is thought away what is left is not an abstract idea but nothing at all. A general "idea," then, is both a logical and a psychological impossibility. This does not make general names meaningless: each stands for all the particular members of a class, and the object which at any moment it may bring before the mind is any one of those indifferently. In brief, a general name is general in meaning only in its scope of reference; there is no correspondent general "idea."

No thinker's philosophy is simply, as the above summary is, a system of propositions, though he must try to make it so. To be properly understood it has to be seen in its historical and biographical setting. With Berkeley that setting is large. He was confronting not only Locke but also Hobbes and the Cartesians, and not only the philosophers but also the new mathematical physicists; and he was combating as well the rather pretentious chatter of the "free-thinkers" in the coffeehouses. As for his motives, it must be enough here to say that he had on the one hand an irresistible itch to clarify thinking and to reduce and simplify theory and on the other hand an urgent practicality that made him search for a philosophy in which a pure religion and an altruistic morality would be reasonably grounded.

BERKELEY, MILES JOSEPH (1803–1889), the foremost British mycologist and plant pathologist of his period, was born at Biggin hall, Northamptonshire on April 1, 1803, and educated at Rugby and Christ's college, Cambridge. Ordained in 1826, he was first incumbent of Apethorpe, becoming vicar of Sibbertoft, near Market Harborough, in 1868.

Approximately 6,000 species of fungi were credited to him, but his *Introduction to Cryptogamic Botany* (1857), his *Gleanings of British Algae* (1833), and his papers on "Vegetable Pathology" in the *Gardener's Chronicle* (from 1854 onward) show a broad grasp of the whole domain of physiology and morphology as understood in those days. He was largely instrumental in demolishing the wild claims made by Ernst von Hallier on the metamorphosis of fungi. In his pioneer investigations on potato murrain (late blight), Berkeley showed that the fungus, *Phytophthora infestans,* was the cause of the disease, not its result, and is consequently regarded as the father of plant pathology. He also studied grape mildew, to which he gave the name *Oidium Tuckeri,* and the pathogenic fungi of wheat rust, hop mildew, and various diseases of cabbage, pears, coffee, onions, tomatoes, etc., with important results bearing on the life history of these pests. Berkeley was the founder of British mycology, and his most important work on that subject is contained in the account of native British fungi in Sir W. Hooker's *British Flora* (1836), in his *Introduction to Cryptogamic Botany* (1857), and in his *Outlines of British Fungology* (1860). He revised the Latin of Bentham and Hooker's *Genera Plantarum.* Berkeley's herbarium at Kew, which contains over 9,000 specimens, and is enriched by numerous notes and sketches, forms one of the most important type series in the world. He died at Sibbertoft on July 30, 1889.

A list of his publications will be found in the *Catalogue of Scientific Papers* of the Royal society, and sketches of his life in *Proc. Roy, soc.,* vol. xlvii (1890); *Ann. Bot.,* vol. iii (1889), vol. xi (1897).

BERKELEY, SIR WILLIAM (1606–1677), colonial governor of Virginia. was the youngest son of Sir Maurice Berkeley and the brother of John, first Lord Berkeley of Stratton, one of the Carolina and New Jersey proprietors. Soon after his graduation from Oxford (B. A., 1624: M.A., 1629). he was given a seat in the privy chamber and served in the colonial office as a commissioner of Canadian affairs. He wrote a play. *The Lost Lady,* for the London stage in 1637, was knighted by Charles I in 1639 and was appointed governor of Virginia in 1641.

Berkeley's governorship of Virginia was almost continuous from this date until his death except during the period of the English Commonwealth. 1652–59. His first years as governor were very successful. Berkeley experimented with crop diversification, encouraged manufacturing, promoted expansion and coped successfully with both Indian and Dutch hostilities. His loyalty to the crown during the Great Rebellion led him to declare Virginia an asylum for Charles II and his friends. This loyalty also resulted in his forced retirement from the governorship until the Restoration (1660).

Berkeley's second period as governor was marred by Indian attacks on the frontier, economic depression, crop failures and high taxes. His irascibility and ineptitude in dealing with the frustrations of his people and the ambitions of his impetuous and demagogic cousin by marriage, Nathaniel Bacon (*q.v.*), resulted in a rebellion in 1676. He was recalled by Charles II to give an account of this tragedy but died on July 9, 1677, soon after his arrival in England and before he had an opportunity to report to the king,

BERKELEY, a market town in Gloucestershire, Eng., 16 mi. S.S.W. of Gloucester by road, in the fertile Vale of Berkeley. Pop. (1961) 1,116. In the reign of Edward I Berkeley was constituted a borough and governed by a mayor and aldermen, but the corporation mas dissolved in 1885. The moated castle is an excellent example of a medieval fortress and is still inhabited by the Berkeley family. The manor was granted (1153) by Henry II to Robert FitzHardinge, and building was begun on the strong castle keep. Robert's son Maurice married Alice Berkeley and later took that name. The deposed Edward II was imprisoned and brutally murdered in the castle (13'27). The buildings around the inner court, including a hall 61 ft. long, are mostly 14th century. Parliamentary forces breached the west wall of the castle in 1645. It still contains many interesting portraits and relics and is open to the public at certain times. With the death of the last earl of Berkeley in 1942 the title lapsed.

Berkeley was the birthplace and home of Edward Jenner (1749–1823). who introduced vaccination against smallpox. In 1957 work was begun on a nuclear power station on the river Severn. Kearby is Sharpness, with docks, at the end of the Gloucester and Berkeley ship canal, which was opened in 1827. (B. C. F.)

BERKELEY, a city of California, U.S., on the east side of San Francisco bay in the northern part of Alameda county, directly opposite the Golden Gate bridge. The area is approximately rectangular, with 9.58 sq.mi. of land and 8 sq.mi. of water. From sea level the elevation rises to 1,500 ft. The city adjoins Oakland and Emeryville to the south and Albany and El Cerrito to the north.

The Spanish pioneers of San Francisco called the region the *Contra Costa* or "opposite shore." It was explored by Capt. Pedro Fages and Father Juan Crespi in 1772, but remained unsettled, except by Indians, until 1820, when the land now included in the cities of Berkeley, Albany, Emeryville, Oakland, Piedmont and Alameda was given in grant to Sgt. Luis Peralta by the Spanish governor of California. Twenty years later Peralta divided his grant, called Rancho San Antonio, among his four sons. Domingo Peralta was given the part which later became Berkeley but, like many another California ranchero, lost ownership of his land soon after California became a part of the United States.

In 1858 the College of California, which had been incorporated three years earlier with temporary quarters in Oakland, selected a site at the foot of the hills for a permanent campus which was dedicated in 1860. In 1866 the trustees chose the name of Berkeley for the projected college town, to commemorate Bishop George Berkeley (*q.v.*).

The trustees of the College of California donated their institution to the University of California upon its incorporation in 1868 but classes continued to be held in Oakland until 1873 when the first buildings were completed on the Berkeley site. As the university grew, it attracted other institutions to the city, including 6 divinity schools, the state's schools for the deaf and blind (founded 1866) and several private educational institutions.

While the eastern part of the city was becoming a major centre of learning. West Berkeley, originally called Ocean View, began to develop light manufacturing. It shared in the industrial development of San Francisco bay, enjoying the same advantages of transportation, climate and scenic beauty.

The city was incorporated in 1878, adopted its first charter in 1895 and the present charter in 1909. After 1923 it has operated under the council-manager form of municipal government. Public cultural and recreational facilities are many: the Berkeley Public library, Community Theatre, Municipal Rose garden, public parks, a municipal yacht harbour and fishing pier, and an aquatic park are maintained by the city, and Tilden park, one of a series of regional parks jointly supported by all the east bay communities, adjoins Berkeley on its eastern border.

The climate of Berkeley is temperate: summers are cool; winters are mild. A rainy season, characterized by intermittent storms, lasts from late November through February; little rain falls during the rest of the year.

A quiet village of little more than 5,000 inhabitants in 1890, Berkeley grew rapidly thereafter and numbered more than 40,000 inhabitants by 1910. In 1960 Berkeley's population was 111,268. (For comparative population figures see table in CALIFORNIA:

Population.) Most of the city's residents lived in single-family homes. Berkeley has become a favourite residential area for many who work in the neighbouring business centres of San Francisco and Oakland (G. P. Hd.)

BERKELIUM. The synthetic element berkelium has the chemical symbol Bk and the atomic number 97. It occupies a position in the periodic system of the elements as the eighth member of a rare-earth like transition series, the actinide series, which includes the heaviest known elements and in which an inner electronic shell (the 5f shell) is being filled. For a discussion of its discovery, see TRANSURANIUM ELEMENTS.

The tracer method of investigation has been used to study the chemical properties of berkelium. Berkelium (as Bk^{249} which has a half life of 290 days) nas isolated in neighable amounts for the first time by S. G. Thompson and B. B. Cunningham in 1958. This isotope can be prepared by the intense neutron bombardment of Cm^{244} (see CURIUM) as the result of the capture of successive neutrons in a sequence of reactions forming first Cm^{245}, then Cm^{246}, Cm^{247}, Cm^{248} and Cm^{249}. The Cm^{249} decays with the emission of a negative beta particle to form Bk^{249}. There appears to be no completely logical way of assigning an atomic weight for this element, which has only relatively short-lived isotopes, but the mass number 249 (more precisely, 249.08 on the chemical scale) might be used since this species can be produced in weighable amounts, isotopically pure.

Isotopes of Berkelium

Isotope	Half life	Type* and energy of radiation (Mev)
Bk^{243}	4.5 hr.	EC α (~0.1%): 6.72 (30%) 6.55 (53%) 6.20 (17%)
Bk^{244}	4.4 hr.	EC α (6×10^{-3}%) 6.67 (100%)
Bk^{245}	4.95 days	EC α (~0.1%): 6.33 (33%) 6.17 (41%) 5.89 (26%)
Bk^{246}	1.9 days	EC
Bk^{247}	~10^4 yr.	α 5.30 (5%) 5.51 (58%) 5.67 (37%)
Bk^{248}	16 hr.	β^- (70%) 0.65 EC (30%)
Bk^{249}	290 days	β^-0.1 α (~10^{-3}%): 5.40
Bk^{250}	3.13 hr.	β^- 0.9, 1.9

*EC = electron capture; a = alpha particle; β^- = negative beta particle.

The tracer chemical studies have demonstrated that berkelium exists in aqueous solution in two oxidation states, the (III) and the (IV) states. and the ionic species presumably correspond to Bk^{+3} and Bk^{+4}. The oxidation potential for the berkelium (III) —berkelium (IV) couple is about —1.6 v. on the scale nhere that for the hydrogen-hydrogen ion couple is taken as zero.

The solubility properties of berkelium in its two oxidation states are entirely analogous to those of the actinide and lanthanide elements in the corresponding oxidation states. Thus in the tripositive state such compounds as the fluoride and the oxalate are insoluble in acid solution, and the tetrapositive state exhibits such insoluble compounds as the iodate and phosphate in acid solution. The nitrate, sulfate, halides. perchlorate and sulfide of both oxidation states apparently are soluble.

Much of the chemical information which has been obtained for berkelium has been concerned with its ion exchange and elution behaviour uith columns packed with ion exchange resins.

An interesting aspect of the chemistry of tripositive berkelium is its solution behaviour following adsorption on a column packed with the ion-exchange resin Dowex-50. There is a remarkable similarity in the relative rates of elution of the lanthanide quadrad, europium-gadolinium-terbium-dysprosium, and the actinide quadrad, americium-curium-berkelium-californium. The remarkable similarity between these two groups of elements indicates the same kind of change in ionic size (and consequently, rate of elution) on filling in the 4f and jf electrons. The break in change of radius which is encountered after the half-filling of the 4f shell and which results in the large separation of terbium from gadolinium occurs again at the half-filling of the jf shell and results in the large separation of berkelium from curium.

Berkelium is best separated in the tripositive form from the other tripositive actinide elements by the above described, ion-exchange, adsorption-elution method; from the tripositive rare-earth elements it is best separated by the additional use of elution with concentrated hydrochloric acid in which the actinide elements form complex ions under conditions where the lanthanides do so to a much smaller extent. Separation from tripositive actinides and lanthanides may also be effected by making use of the tetrapositive state of berkelium.

BERKHAMSTED, an urban district of Hertfordshire, Eng., 28 mi. N.W. of London by road, lies in the wooded Bulbourne valley which runs through the Chiltern hills. Pop. (1961) 13.048. The town is mainly residential and has a church dating from the 13th century and many old houses and schools, the largest of which. Berkhamsted school, was founded in 1541. Through the Bulbourne valley run the Grand Union canal, the London-Northampton railway line and the London-Warwick road. Veterinary remedies, sheep dips, clothing and office furniture are made and there are timber mills. Berkhamsted was important in Saxon times and it was there that the Saxon nobles offered the English crown to William of Normandy in 1066. A moated castle was built by Robert, half-brother of William I, and its later residents included Thomas Becket. Edward III and the Black Prince. In 1216 the castle was besieged by the dauphin of France. After 1496, when it was last occupied, the castle fell into ruin and in 1930 was thoroughly excavated and is now preserved. William Cowper was born in Berkhamsted rectory. The Foundling hospital was transferred from London to Berkhamsted in 1935 and renamed the Thomas Coram school, but the premises are now occupied by Ashlyns county secondary and grammar school. Ashridge house, since 1929 the Bonar Law college for citizenship. is 3 mi. north. Ashridge estate (5.6 sq.mi.) is owned by the National Trust, and Berkhamsted common (part of the estate until 1928). which dates from Anglo-Saxon times. was the scene of a fantastic escapade in 1866 when a special midnight train from London secretly unloaded, nearby, more than 100 workmen who set about before dawn dismantling an iron fence which had been erected around parts of the common. This vigorous action of the Commons Preservation society mas later upheld by law.

BERKSHIRE, a southern county of England, is bounded on the north by Oxfordshire and Buckinghamshire, on the east by Surrey, on the south by Hampshire and on the west by Wiltshire. The area of the geographical county is 725.0 sq mi.

Physical Features. — The county is a somewhat haphazard cross section of the Jurassic and Cretaceous scarplands of southern England and sections of the main structural elements are represented from south to north in the pattern which follows. The Tertiary sands and clays in the axial trough of the Thames-Kennet Tertiary basin (the axis running roughly along the southern boundary of the county) are found in the south and east. stretching from the Surrey boundary almost to Newbury. To the north, the Berkshire downs are a part of the principal chalk syncline (trough) of south-eastern England and form a section of the line of hills stretching from the Marlborough downs across to the eastern end of the Chiltern hills. In the downland area. south and east of a line from Compton to Hungerford, deposits of clay with flints occur and are often recognizable by the fact that they support islands of mixed woodland in the midst of agricultural land. Beneath the steep northern slopes of the downs lies the fertile Vale of the White Horse. comprising Gault and Kimmeridge clays, separated from the chalk by a band of Upper Greensand at the base of the escarpment. Between the vale and the Thames lies an elevated ridge of Corallian beds running from Faringdon eastward to the Cumnor and Wytham hills, overlooking the city of Oxford. North of this ridge lies the Oxford clay of the Upper Thames valley.

The most significant physical features of Berkshire are the

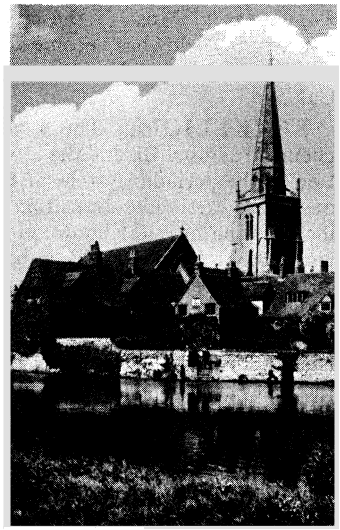
valleys of the Thames and its tributaries, the Ock, Pang, Kennet and Loddon, and of the Lambourn and the Enborne flowing into the Kennet, and the Blackwater flowing into the Loddon. Between them they form natural lines of communication, unifying an otherwise heterogeneous administrative area. The Thames forms the northern boundary of the county, while the Enborne marks a considerable part of the southern boundary before turning northward to join the Kennet near Aldermaston. The Enborne rises in an outcrop of the Hampshire chalk downs and the highest point in Berkshire and indeed of the chalklands of southern England, Inkpen Beacon (975 ft.), is a part of this outcrop. The Kennet, the principal tributary, joins the Thames at Reading. The Kennet valley stretching westward from Newbury almost joins with the Vale of Pewsey in Wiltshire near Savernake and the two form an east-west lowland route of great historical importance. The valley of the Lambourn, which joins the Kennet at Newbury, forms a line of approach to the heart of the downland and to the Vale of the White Horse. The Goring gap, where the Thames breaks through between the Berkshire downs and the Chilterns, provides a means of access from Reading northwestward to northern Berkshire, Oxford and the Midlands. To the east of Reading, where a border of hills flanking the Thames rises to its highest in the Cookham area, the land is flat, crossed by the Loddon, and rises to a sandy plateau of heath and woodland in the extreme southeast.

The former administrative divisions of Berkshire—Hill, Vale and Forest—coincide with the main recognizable physical divisions. The face of the county is as varied as the geological structure would suggest. The Tertiary sands and clays of eastern and southern Berkshire produce soils which are not particularly suitable for cultivation, but support extensive areas of heath and wooded common in Windsor forest. The continuation of these soils along the Kennet valley accounts for similar expanses of heath and wooded common west of Reading at Burghfield, Bucklebury. Padworth, Greenham and Crookham. The Kennet itself, the main drainage channel of the chalk uplands of Berkshire and Hampshire, follows a meandering course and is flanked by flat, marshy lands. The Vale of the White Horse, with its flat, cultivated lands, affords a contrast with the downs with their bare, grassy slopes.

History.—Natural features and lines of communication have combined to exert a great influence on the county's development from prehistoric times. The distribution of the remains of prehistoric man, more especially from Neolithic times, clearly demonstrates that the Berkshire downs were the centre of first settlement and the point from which later settlement radiated. Running like a spinal column along the downs, the ancient Ridgeway formed part of the network of ancient roads radiating from Salisbury plain with convenient routes to lower, more fertile ground and to waterways. Once they had left the height of the downs, men could travel the Lambourn and Ock valleys, the White Horse vale and the Kennet valley till they reached the Thames and the forest and lowland. Such evidence as has been found suggests little settlement of the damper forestland of eastern Berkshire or the river valleys before the Iron Age, although archaeological finds in the bed of the Thames, point to its use as a highway from Neolithic times. The principal fortifications of prehistoric Berkshire, notably Uffington castle, and Letcombe castle or Sagsbury, are all on downland sites, and the lower parts of the downs are dotted with lesser fortification works and barrows.

From the Iron Age onward, the evidence of the spread of settlement from downland to lowland becomes more plentiful and by the time of the Belgic habitation of Silchester, just over the Hampshire border, the spread is clearly marked. Roman evidence is distributed fairly evenly throughout the county, which was well served by roads radiating from Silchester. The immediate vicinity of the Thames itself began to be inhabited and the first seeds of future urban development can be seen dotted along the river. There was, however, no major Romano-British settlement in the county, although there is evidence that at Sutton Courtenay, for example, was a Romano-British village taken over by the Saxons.

Of the effects of Saxon settlement little is known, but the county became a buffer frontier province of the kingdom of Wessex and it ff t t of all such buffers tl g the n ding warfare which crossed and re-ossed its frontiers. In 779 Offa annexed th ounty t his kingdom of Mercia and it was t until some time between 840 and 850 th Wessex regained what was to be the native y of Alfred the Great, who was born at Wantage cu 848. I those u ttl l times, the first r ona tery t Abingdon perished under the sword and the Danes from Mercia en at Reading. It was on Berkshire soil that Aethelred and Alfred won tl vict over the Danes t t battle of Ashdown in 871, within a t ti of Alfred's l g compelled t buy peace from the Danes. As late as 1006 Danish raids were laying waste the fortifications of Wallingford. In 1086 the imane of later Berkshire is barely discernible. Of the towns. Wallingford was predominant; Old Windsor was next in importance; Abingdon was but a cluster of dwellings around the abbey gates; Newbury, Maidenhead and Wokingham were hardly entities; Reading was slowly gaining stature; and William the Conqueror's castle at Windsor was still under construction. Lambourn and Faringdon occupied a more important position than now. The predominance of royal and monastic landholding is clearly marked, the former remaining an actuality until the 19th century, the latter disappearing at the time of the Dissolution. By the late 13th century the pattern had changed and Berkshire as it is now known was clearly emerging. Wallingford was declining. Reading rapidly advancing in importance. The bridge at Maidenhead had encouraged the development of a town at the riverside, and the advent of the wool and cloth trades had fostered Newbury's growth. Sheep, wool and cloth became the staple industries of the county. The new bridge at Abingdon, rebuilt in 1416, forced on the growth of the town and hastened Wallingford's decline.



E. W. TATTERSALL

TOWER AND SPIRE OF ST. HELEN'S CHURCH OVERLOOKING THE THAMES, ABINGDON; 14TH CENTURY

A speculative land market, resulting from the Dissolution, coupled with the slow decay of the wool and cloth trades, brought on by the rise of "new draperies" elsewhere, characterize Berkshire in the 16th century. The "skittish lands" of Berkshire, as Thomas Fuller calls them, from which few great estates were carved and in which few great families took root, were born in this century. The cloth trade never recovered and by the late 17th century had died away. Agriculture remained the sole industry of note until the mid-19th century. Jethro Tull conducted many of his experiments on Berkshire soils and "Farmer" George III tried out his new Flemish and Norfolk husbandry in Windsor Great park.

The Civil War brought armies to Berkshire, which had heard few martial blasts since the clash of Stephen's and Matilda's forces in the mid-12th century, and at Newbury in 1643 and 1644 royalist and parliamentarian joined battle. The county was split between king in the west and parliament in the east. Personalities connected with the county illustrate the political and social cleavage: William Laud and Henry Marten, prelate and regicide, John Wildman and William Penn, plotter and Quaker.

With the changes in communication in the 18th century, the tempo of Berkshire life quickened. The stagecoaches made their way to Bath and Bristol along the new turnpike road begun in 1746, and improvements to navigation along the Kennet and Thames set a greater flow of products on their way to wider markets from the agricultural lands of the county. With the coming of the railways, Berkshire was served by the main Great Western line to Bristol in the 1840s, by the line to Hungerford and Devizes, which siphoned off the Kennet traffic, and by the lines from London to Oxford and the Midlands and the feeder line from Didcot to Newbury and Southampton in the 1880s.

The 19th century saw Reading rise to primacy among Berkshire's towns at the expense of Abingdon, which had succeeded Wallingford as county town. Reading became the commercial and industrial centre of the county with its threefold supports of biscuits, beer and seeds. The railways, which could have meant much to Berkshire's towns. unfortunately passed by those which might have benefited most — Abingdon, Wallingford, Wantage and Faringdon — and only served to enhance the status of Reading.

Until the end of World War II. Berkshire remained an agrarian county changing little in character. After 1945, however, it became increasingly more industrial as a result of the influx of nuclear research establishments and light industry.

Windsor castle is the most noted building in the county. The 15th-century Ockwell manor near Bray: the 14th-century tithe barn at Great Coxwell and the 14th-century painted ceiling in St. Helen's church. Xbingdon, are some of the notable late medieval antiquities. The Norman church at Avington and the 12th-century church at Uffington represent earlier Berkshire. The later buildings are Ufton court; Bisham abbey; Christ's hospital. Abingdon; Shaw house and St. Bartholomew's hospital, Newbury. Abingdon, Radley, Wellington and Bradfield colleges are boy's public schools, and the Royal Military academy is at Sandhurst (*q.v.*).

Population and Administration. — Thegeographical county had a population of 503,357 in 1961 of whom 119,870 lived in the county borough of Reading. now the county town, and 383,487 in the administrative county. The other principal towns within the county, all of which are municipal boroughs, with their population, are Abingdon (14.283). Maidenhead (35,374), Newbury (20,386), Wallingford (4.829) (*qq.v.*), Wokingham (11,400) and New Windsor (27,126). The population of the cbunty grew rapidly after 1945 and in the early 1960s was increasing at the rate of 3% a year. Between 1951 and 1961, the total percentage increase was 24.9%.

The county, excluding the boroughs, is divided into 1 urban and 11 rural districts comprising 176 civil parishes. There is a court of quarter sessions for the county, divided into 12 petty sessional divisions, and Abingdon, Newbury, New Windsor and Reading have separate commissions of the peace and courts of quarter sessions. The assizes, on the Oxford circuit, are held at Reading. One new town has been established under the Ken- Towns act, 1946. at Bracknell (*q.v.*), the designated area forming a separate civil parish. Five members represent the county in parliament, one each irom the constituencies of Abingdon, Newbury, Windsor and Wokingham and one from the parliamentary borough of Reading.

Ecclesiastically, the geographical county is virtually coterminous with the archdeaconry of Berkshire and since 1836 has been in the diocese of Oxford to which it was transferred from the diocese of Salisbury. The archdeaconry comprises Berkshire less the parishes of Wytham and North and South Hinksey, but including Benson. Warborough and Crowmarsh Gifford in Oxfordshire. The archdeacon of Berkshire is suffragan bishop of Reading. Berkshire forms part of the Roman Catholic diocese of Portsmouth in the Westminster province.

The Economy. — Farming, for centuries the county's staple industry, is declining in importance, though it is still the most widespread industry in the county. In the early 1960s more than 150.000 ac. were under crop or fallow and about 107,000 ac. were under permanent grass. Barley is the principal grain crop, followed by wheat and oats. Potatoes and cabbage and kale for fodder are grown in quantity. Dairy, pig and poultry farming are extensively practised, but sheep farming is declining. The chief fruit growing areas are apple and cherry orchards in the White Horse vale and on the northern slope of the downs. The eastern part of the county is well wooded, mainly by oaks and conifers. Approximately 45,000 ac. are occupied by woodland.

Horticulturally. the county is noted for its seed warehouses and testing grounds in the immediate vicinity of Reading. There are agricultural or horticultural research stations at Shinfield, Warfield and Compton, while Reading university (chartered in 1926) is a centre of agricultural education and research.

Industry. — After 1935 the supremacy of farming in Berkshire was overcome by the rapid influx of industry. Farming provided work for less than 6% of an employed population of about 170,000. Before World War II the manufacture of agricultural implements and machinery coupled with a certain amount of light industry were the only industrial enterprises in the county. The location within the county of two nuclear research centres — the Atomic Energy Research establishment at Harwell and the Atomic Weapons Research establishment at Aldermaston — and the influx of a variety of light industries to the Reading and. particularly, the Bracknell areas have noticeably influenced the industrial aspect of the county and afiected both the size and character of its population. The automobile industry has offshoots at Abingdon, while paper and board are manufactured at Colthrop.

Communications. — There were 1,612 mi. of roads in 1960, the two principal ones being part of the Great West road — the main trunk road to Bristol and the west — and a section of the trunk road from Winchester to Birmingham and beyond, both of which bisect the county. The projected London to south Wales motorway will cross Berkshire also. The Western Region railway lines to the west and the midlands cross the county. and the Southern Region services to Guildford. London. Basingstoke and the south coast commence at Reading, which is an important rail centre.

BERKSHIRES, the highlands of western Massachusetts, are a part of the Appalachian system, and a continuation of the Green mountains of Vermont. The Berkshire country is among the most beautiful regions in the United States. It is a rolling highland dominated by long, wooded ridges, remarkably even-topped in general elevation (about 1.500 ft.), and intersected and broken by deep valleys. The chief streams are the Deerfield and Westfield in the east and the Hoosac and Housatonic in the west. About a score of the summits are over 2,000 ft. above sea level, and of these the highest are Greylock. or Saddleback (3,491 ft.) and Mt. Williams (2,951 ft.), in the extreme northwest corner of the state. Because of its numerous lakes, the district is often called the Lake Region of America, partly from the comparableness of its scenic beauties with the English lake country. The Berkshires. home of the Berkshire Symphonic festivals at Tanglewood, have been, for many years, a favourite holiday resort.

BERLAGE, HENDRIK PETRUS (1856–1934), Dutch architect and urban designer, was born in Amsterdam, Neth., on Feb. 21, 1856. He received his technical training in Amsterdam and Ziirich and eventually settled in The Hague. By the 1890s Berlage had attacked the eclectic practices of the traditional architecture of the period. His most famous and influential building was the Amsterdam stock exchange (1898–1903). His rediscovery of the beauty of the naked wall and the flat surface was a revelation to the younger generation. After a visit to the United States in 1911, Berlage became a strong advocate of Frank Lloyd Wright. In his master plans for south Amsterdam in 1902 and 1915 he opened the era of large-scale urban design. He died on Aug. 12, 1934, at The Hague. (S. GN.)

BERLICHINGEN, GÖTZ (or GOTTFRIED) **VON** (1481–1562), called "Gotz of the Iron Hand," a Franconian knight born the youngest of five sons at the castle of Jagsthausen in Württemberg. Famous as the hero of Goethe's play *Gotz von Berlichingen* and often affectionately regarded and romanticized as a sort of bluff, fearless German Robin Hood, Gotz belonged to the class of imperial knights fast.becoming anachronistic as medieval conditions mere superseded by the new modern Europe taking shape, and he spent his life in a manner typical of this class in a succession of feuds. battles and campaigns, in which the warrior of popular legend becomes something bordering on a wellborn highway robber. His iron hand was a substitute for the hand, whether left or right is uncertain, shot away in 1504 while Gotz was assisting Albert IV, duke of Bavaria, at the siege of Landshut. An

iron hand claiming, possibly correctly, to be the original one is still exhibited at Jagsthausen. Perhaps the most remarkable thing about Gotz' life is that he survived in a turbulent and violent era to live to a ripe old age and tell all about it in his *Autobiography,* the main source of our knowledge of him and, for all its inaccuracies, an entertaining account of a life covering a very eventful period of German history.

Gotz pursued his feuds, mainly for booty and ransom, against other nobles and against towns and cities, and took part in the many wars that marked the times, beginning with campaigns in Burgundy, Lorraine, Brabant and Switzerland under Frederick IV, margrave of Brandenburg-Ansbach, and the emperor Maximilian I in 1497 and 1498, and ending with the wars against the Turks in Hungary in 1542 and the campaign of Charles V against the French in 1544. He was twice put under the ban of the empire and twice taken prisoner; sometimes he had to pay ransoms to obtain his freedom, at other times he extracted money himself, as in 1516, when he held Graf Philipp von Waldeck to ransom and used the 8,900 ducats to pay for the castle of Hornberg, where he eventually died on July 23, 1562.

Gotz played an active role in the Peasants' War of 1525. To cover himself he made it appear that he had been compelled by the rebels to take part in the uprising, and in fact led a section of them in the Odenwald district. For his part in the rebellion he was acquitted by the imperial chamber (Oct. 17, 1526), but seized by the Swabian league in 1528, when a promise of safe conduct was broken. and kept prisoner at Augsburg until 1530. At some period in his life Gotz became a Protestant, though he gives no details of this. He married twice and left three daughters and seven sons.

Weimann, Gotz *von Berlichingen* (1930). Gotz' *Autobiography,* first published by Pistorius at Nürnberg in 1731, was well edited by H. S. M. Stuart in 1956. (D. G. D.)

BERLIN, IRVING (original name, ISRAEL BALIN) (1888–), U.S. composer who played a leading part in the evolution of the popular song from the early ragtime to jazz (*q.v.*). Born at Temoyun, Kirgizia, Russia, May 11, 1888, he went to the United States in 1893, where his early years were spent in great poverty. In 1904 he worked as a singing waiter in Chinatown and Bowery cabarets of New York city. In 1911 he became a pioneer of ragtime with "Alexander's Ragtime Band" (originally "Alexander and his Clarinet") and "Everybody's Doin' It." In 1914 he wrote his first musical comedy, *Watch Your Step,* and in 1919 started a firm for the publication of his music. Thereafter he wrote scores for numerous musical comedies from *Music Box Revue* (first edition, 1921) to *Annie Get Your Gun* (1946). His gift for simple, fresh melody won him immense popularity. Among his best-known songs are "Always," "All Alone," "Remember," "White Christmas," "Oh, How I Hate to Get Up in the Morning" and "God Bless America." He wrote his first film score, *The Cocoanuts,* in 1929. In 1945 he won the medal for merit for his musical comedy, *This is the Army,* which had been played to U.S. troops in many parts of the world and had earned large sums for war charities.

See D. Ewen, *The Story of Irving Berlin* (1950).

BERLIN, capital of the German *Reich* from 1871 to 1945, in former Prussia, 165 mi. S.E. of Hamburg. The city is divided into two municipalities; east Berlin, the capital of the German Democratic Republic, and west Berlin, a *Land* (state) and a city of the Federal Republic of Germany, although not a constituent part of the Federal Republic. The 20 districts of greater Berlin together cover 342 sq.mi. The city lies in a flat sandy plain, 110 ft. above sea level, on both banks of the Spree, which intersects it from southeast to northeast. The highest natural point in the immediate neighbourhood is the Kreuzberg (216 ft.), a hill in the southern district of Schoneberg. A rather higher point than the Kreuzberg was built up in the Grunewald after 1945 out of countless tons of rubble from bombed buildings.

Berlin lies at the centre of a great system of canals, begun in the 17th century. The routes of these canals were marked out by nature, for the passing away of the great ice sheets of the Pleistocene epoch left on the northern European plain, lines of low hills formed of terminal moraines running east to west. The rivers follow the troughs between the moraines until they break through to the north at weak spots in the successive lines. It is these east and west courses that were organized into the canal system which emphasized the focal position of Berlin. By these canals, by roads and later by railways Berlin gathered traffic to itself and became a power which was to dominate the northern plain.

So great a change was made in the city's existence by World War II and the divisions of the postwar period that the history and even the appearance of the city must be seen in two parts—the years before and after the collapse of the third *Reich.*

BEFORE WORLD WAR II

Rise of the City.—Berlin is a comparatively young town by European standards. When the Saxon north mark, or border region, was founded in the 12th century by Albert the Bear, after successful wars against the indigenous Slavs, it comprised at first only a little land on the east bank of the Elbe. It was only gradually that Albert's successors penetrated farther into the districts of the upper Havel and the Spree, and only at the beginning of the 13th century that the first towns, Berlin and Kolln, were founded in these districts. The choice of this particular site for the foundation of the two towns probably resulted from the wish to safeguard the important crossing of the Spree.

Berlin grew up south of the Spree, Kolln north of it, on the island formed by the two arms of the river. The first mention of Berlin in the records that have been preserved occurs in 1230; Kolln appears to be a little older. The charter and administration of the two towns were at first totally separate, even though they had a common civil government and common courts of justice from 1307 onward. Only in 1709 were they completely amalgamated.

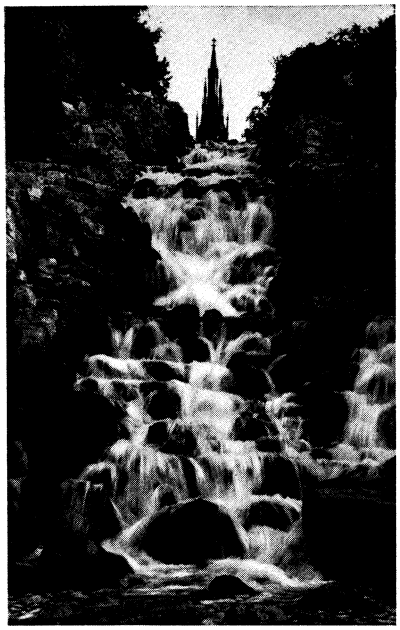
It was soon found that the situation of the two new towns was advantageous for commerce to the east and northeast and they quickly became prosperous. Their military importance became secondary when the frontiers of the mark were extended farther to the north and east. Their rapid commercial growth brought an increasing need to enter into closer and permanent relations with the other commercial cities of northern Germany, which were growing up rapidly. They joined the great Hanseatic league (*q.v.*), which was formed in the latter half of the 13th century. They were soon among the leading cities of the mark of Brandenburg and were thus involved in the many internal struggles which arose between princes, nobles and cities after the Ascanian family, the descendents of Albert the Bear, became extinct in the 14th century.

The cities of Berlin and Kölln, however, long remained almost wholly independent, their connection with the Hanseatic league putting them in a strong position, even toward their own sovereign prince. In 1391 they received complete judicial authority within their walls.

Conditions changed only after 1415, when the Hohenzollerns had permanently established their rule in the mark. Frederick II (1440–70) aimed at incorporating the large cities more closely into his territory. He subdued Berlin and Kolln, although not without a sharp struggle, and deprived the cities of part of their old privileges, in particular of the right of concluding independent alliances with other towns. He built a fortress in Kolln on the site later occupied by the royal palace and his successor made this spot his principal seat. From the end of the 15th century Berlin-Kolln was the permanent residence of the Hohenzollerns and the capital of the electorate of Brandenburg.

In 1654 the united population of the two towns was only about 10,000. At that time they played a comparatively subordinate part in the history of the electorate and could not challenge any comparison with the wealth and repute of the great old commercial cities of Germany, such as Niirnberg, Augsburg, Strasbourg, Frankfurt am Main or Cologne. They suffered severely, moreover, from sackings and forced levies during the Thirty Years' War.

It was only with the growing power of the electors of Branden-



Viktoria falls cascading over the Kreuzberg, highest natural point in Berlin, district of Schöneberg. The spire of the cathedral can be seen in the background

burg from the 17th century onward that the extent and importance of their place of residence began to grow. Frederick William the Great Elector (1640–88) married a Dutch princess and during his reign Brandenburg became a Protestant refuge and a field for Dutch energy. Canals were built and the name of the Friedrich Wilhelm canal from the Oder to the Spree commemorates an achievement of this time.

Frederick William laid out extensive fortifications and founded three small towns, Friedrichwerder, Dorotheenstadt and Friedrichstadt, which soon amalgamated with Berlin and Kolln. Huguenots, refugees from the French persecutions, settled there and brought into the city elements whose influence on commerce and industry was considerable. At the end of the 17th century there were more than 5,000 French Huguenots out of a total population of about 25,000.

Frederick William's successor, Frederick I, the first king in Prussia, amalgamated the towns into a single municipality, the city of Berlin, and, in the new palace built by Andreas Schliiter (pulled down after World War 11), gave it the first nonecclesiastical building of any architectural importance. Almost adjoining this Frederick built the arsenal, laid out the plans on which this quarter of the modern town developed and erected a beautiful monument to his father (by Schliiter). He encouraged education by founding the Academy of Sciences (Akademie der Wissenschaften).

Under the two kings who succeeded him the city expanded in all directions. Frederick William I had the old fortifications razed, thus making further expansion possible. Frederick the Great adorned the city with a number of new buildings, among which the opera deserves chief mention. He also turned the Tiergarten into a large park. The population, which had numbered about 70,000 at his accession, had risen by the end of the 18th century to 172,000. Even the temporary occupation of the town by the Austrians and the Russians during the Seven Years' War (1756–1763) was unable to check its development.

19th-Century Prosperity. — Berlin passed through a difficult period at the beginning of the 19th century; it was occupied by the French after the battle of Jena (1806) and the king was obliged to transfer his seat temporarily to Konigsberg. After the fall of Napoleon and the restoration and enlargement of the state of Prussia, however, Berlin became the capital of the second largest German state, the centre of a European world power. As Prussia's influence over the development of Germany grew in the following decades, so did Berlin rise higher and higher above the other German towns.

The foundation of the Friedrich Wilhelm university in 1809 and the erection of the Altes museum, designed by K. F. Schinkel (1822–30), gave the town new intellectual centres. The university was founded when Prussia lost the University of Halle to Napoleon's newly created kingdom of Westphalia. Wilhelm von Humboldt, J. G. Fichte, J. A. W. Neander, Georg Hegel, Barthold Niebuhr and others began to make its fame and they were followed by such men as Franz Bopp, Friedrich Schelling and the brothers Grimm.

In 1870 Berlin was practically bounded on the south by the Landwehr canal, but it afterward extended far beyond. An idea of the rapid growth of the city since 1800 may be gathered from the population statistics. In 1816 the population was 197,717; in 1871, 826,341; in 1905, 2,040,148; in 1933, 4,242,501; and in 1939, 4,332,242. Part of this phenomenal rise was the result of extension of boundaries. The boundaries of the city itself remained the same from 1860 to 1920, although in 1912 an association was formed of the city and its suburbs (the towns of Charlottenburg, Schoneberg, Neukolln, Wilmersdorf and Lichtenberg, and the administrative circles of Teltow and Niederbarnim) and the whole was called greater Berlin. The objects of this association were to institute a common control of streets and the elevated railway and of building plans, to co-ordinate police regulations and to acquire tracts of forest and land for building. It soon became manifest that further co-ordination was needed.

In 1920 a new municipality of Berlin was formed, embracing all the suburbs in a single administration. The law that brought this into effect left large powers of local self-government to the individual communes.

Communications. — Of decisive importance for the development of Berlin was the construction of the German railway system, which began about the middle of the 19th century. Berlin became the centre of this great network, no fewer than 12 lines concentrating upon it. Internal communication was provided for by the *Ringbahn,* ("circular railway"), which was opened in 1871, and by a system connecting the main-line terminals. The through traffic from east to west was carried by the *Stadtbahn* ("city railway"), which connected with the *Ringbahn.* This line ran through the heart of the city. The north and south tube, begun before 1914, was opened in 1923. Later it was connected with a subway system running east and west beneath Unter den Linden and extending far into the suburbs.

The canals have already been mentioned. The Landwehr canal, leaving the Spree near the Schlesische Tor and rejoining it at Charlottenburg, was designed to relieve the congestion of the water traffic in the heart of Berlin. It was superseded in 1906 by the Teltow canal to the south, which leaves the Spree above Berlin at Kopenick and enters the Havel at Teltow. In 1914 a ship canal to Stettin was begun and in Sept. 1923 a new harbour, called the West harbour, was opened; there 68 large ships from the Elbe could be loaded simultaneously.

Industry and Commerce. — Machinery factories which were established in the first half of the 19th century were the starting point of Berlin's great industrial prosperity. By 1939 it had become the greatest industrial and commercial city on the continent of Europe and the sixth largest city in the world. The old wool industry had become much expanded and included such products as shawls, carpets and hosiery.

The city excelled in the working of iron and steel and cloth and in the by-products of these. Among the chief manufactures were locomotives, sewing machines, bicycles, chronometers, electrical equipment and appliances, bronze, chemicals and china. It had extensive breweries. Berlin was also the centre and chief market for wheat, rye and other cereals which reached it by water from eastern Germany, from Poland, Austria and the U.S.S.R. It was a large publishing centre, even rivaling Leipzig.

Appearance of the City. — The oldest part of Berlin, the city and Alt-Kolln, built along the arms of the Spree, was, together with that portion of the town lying immediately west, the centre of business activity. The west end and the southwest were the residential quarters; the northwest was largely occupied by academic, scientific and military institutions; the north was the seat of machinery works; the northeast of the woolen manufactures; the east and southeast of the dyeing, furniture and metal industries; and the south of railway works.

The social and official life of the capital centred upon Unter den Linden, running from the former royal palace to the Brandenburger Tor. This street, one of the finest and most spacious in Europe, nearly a mile in length, its double avenue divided by a promenade planted with linden trees (cut down in Hitler's day), presented Berlin life in all its aspects. South of Unter den Linden lies the Friedrichstadt, with its parallel lines of straight streets — the official quarter of the capital — which extends to the busy Leipziger Strasse, running from the Potsdamer Platz to the Donhoff Platz. This street and Unter den Linden are crossed at right angles by the Friedrich Strasse, two miles long, and formed the chief shopping centres.

The establishment of the imperial government in Berlin naturally brought with it the erection of a large number of public buildings and the great prosperity of the country from 1870 to 1914, as well as the enhanced national feeling, enabled them to be built on a fine scale.

The former royal palace was a huge quadrangular building with four courts. In 1921 the Schloss museum of pottery, silver and furniture was opened in this palace. After 1919, much of the former palace was used for government offices. The state-supported opera and theatre were of old standing.

A sport field and great concrete stadium seating 100,000 spectators was built in west Berlin for the Olympic games of 1936,

DIVISION OF BERLIN. AS IT WAS INSTITUTED IN JUNE 1945

with a powerful radio transmitting station nearby.

On the east, north and west the city was surrounded at a distance of about five miles from its centre by a thick belt of pine woods, the Jungfernheide, the Spandauer forest and the Grunewald, the last-named stretching away in a southwesterly direction as far as Potsdam and fringing the beautiful chain of Havel lakes. After the opening of the circular railway in 1871 these districts were developed and a "villa colony" was built at the edge of the Grunewald between the station Westend and the Spandauer Bock. From these beginnings, mainly because of the expansion of the important suburb of Charlottenburg, resulted a complete transformation of the eastern part of the Grunewald into a picturesque villa suburb connected by the Kurfurstendamm with the city. The former fishing villages on the shores of the lakes, notably the Wannsee, became a residential area. (E. BRA.; S. B. F.)

WORLD WAR II AND AFTER

The Devastation. — On the outbreak of World War II Hermann Goring, chief of the *Luftwaffe,* publicly stated that not an enemy bomb would fall on Berlin. The Royal Air Force, however, made more than 30 air raids on the city in 1940 alone. The attacks grew in intensity, especially during the last two years of hostilities when, with the participation of U.S. aircraft, the city suffered a succession of 1,000-bomber raids and, apart from some of the outlying residential districts, was extensively damaged. From the first British air raid on Aug. 25, 1940, until April 20, 1945, the city was blasted with more than 75,000 tons of explosives and incendiary bombs. The devastation was increased by Soviet artillery which in the culminating battle of the last ten days of April concentrated about 40,000 tons of shells on the city.

Berlin was captured by Soviet forces on May 1, 1945. The last military aircraft to leave Berlin took off from the lower part of the "east-west axis," a broad highway continuing the Unter den Linden from the Brandenburger Tor through the Tiergarten and out to the *Reichsautobahn.* The site of Hitler's chancery, where he died by his own hand the day before the city was captured, was later cleared by the Russians, who included most of the red marble in their massive war memorial at Treptow. The pleasantly wooded Tiergarten, raked by bombs and shellfire, had been cleared at the height of the food shortage to make way for vegetable plots; but after the war most of it was landscaped and replanted. Most public buildings had been brought down or badly gutted during the war, though many of Berlin's fine art collections had been moved from the museums to places of safety. The *Reichstag* was reduced to a gaunt wreck and when troops of the western Allies took over their sectors ten weeks after the Soviet entry it was difficult to identify many ministries, embassies and once-handsome office buildings in the Unter den Linden. The cathedral, erected in 1893, was badly holed, as was the old schloss, the ruins of which were cleared away by the east Berlin authorities. The former palace of the crown prince, which had been used as an art gallery, and the state opera house, were restored. The schools did not escape and for years after the war classes were working in three shifts a day for want of accommodation. The city's theatres were hard hit, though by 1959 eight theatres were functioning in the east sector and nine in the western sectors, including the newly built Schiller theatre.

Berlin suffered more than any other part of Germany after the end of World War II. It was under four-power control but cut off from natural markets in the west by political disagreements and in the east by Soviet disinterest in the future of the city. By 1948 it was completely divided into the Soviet sector on the one hand and the three western sectors on the other.

East Berlin became virtually part of the Soviet zone and by the late 1950s almost no vestige of four-power administration remained.

In 1939 Berlin had a population of 4,332,242. By 1950 it had dropped to 3,336,026 and there was only a small rise after that time. In 1959 west Berlin had an estimated 2,207,984 and east Berlin 1,082,349 inhabitants. The birth rate fell from 17.2 per thousand in 1941 to 10.5 in 1950, with a low point of 8.6 in 1944. The death rate rose from 13.2 in 1938 to 55.5 in 1945, but was down to 12.9 in 1950. Infant mortality figures are similar, illustrating the special horror of 1945.

The Political Difficulties. — Berlin came under four-power (originally three-power) control soon after the end of the war and as a result of the proposal of the European Advisory commission in 1944 which was confirmed by the Yalta and Potsdam agreements. An Allied *Kommandantura* of four military commandants was created to administer the city but was increasingly paralyzed by the differing German policies of the four occupying powers. In Berlin, as in the rest of Germany, the principal difference was in economic policy. The Russians rigorously dismantled west Berlin industries before handing over two-thirds of Berlin to the three western powers; in their own sector they encouraged rising industrial production but took a large proportion of it as reparations.

Berlin stands about 100 mi. inside the boundary of the German Democratic Republic. Its communications with the west were poor and for a long time consisted only of the road and rail line to the west German town of Helmstedt, and of defined air corridors and waterways. An Allied military train ran from Helmstedt and members of the three former occupying western powers had special use of the Berlin-Helmstedt *Autobahn.* West Berlin continued to receive most of its foodstuffs and essential raw materials from the west.

Political developments accentuated the differences between the two parts of the city. In 1946 the Social Democratic and Communist parties in the Soviet zone were fused into the Socialist Unity party (*Sozialistische Einheitspartei Deutschlands;* S.E.D.) which was soundly beaten in the 1946 all-Berlin city elections. The S.E.D. polled 20% of the electorate; the Social Democrats *(Sozialdemokratische Partei Deutschlands;* S.P.D.) secured 49%. They appointed the first chief burgomaster, Otto Ostrowski. In June 1948 the Soviet commandant proclaimed the division of Berlin by dissolving the *Kommandantura.* As a result the east Berliners appointed their own burgomaster, Fritz Ebert, son of the first president of the Weimar republic. Ernst Reuter became chief burgomaster of west Berlin at the head of a preponderantly Social Democratic coalition, which was gradually given complete powers by the western commandants. The 1948 city elections gave his party 65% of the electorate. The percentages for the C.D.U. (*Christlich Demokratische Union)* and the Free Democratic party *(Freie Demokratische Partei; F.D.P.)* were 19%, and 16%. In 1950 the balance in west Berlin moved in favour of the two latter parties whose percentages of the total vote moved up to 24% and 23%. Ernst Reuter, by far the most famous Berliner of the postwar era, died in Sept. 1953. At the 1954 elections the C.D.U.'s vote rose to 30% but that of the Free Democrats dropped to under 13%. The S.P.D. once again appointed the chief burgomaster, Otto Suhr. The 1958 elections gave the S.P.D. 52.6% of a record 93% poll of the 1,760,000 voters. Willy Brandt, who succeeded

Otto Suhr when the latter died in 1957, remained chief burgomaster.

The division of Berlin (western sectors 481 sq.km. [186 sq.mi.], east Berlin 403 sq.km. [156 sq.mi.]) became more absolute as time passed. West Berlin became the greatest focus for refugees from the German Democratic Republic, with an average of 7,000 a month arriving in the late 1950s. In Aug. 1960 about 16,000 arrived. A wall was built and the border sealed by the east Germans in 1961.

The government of the Democratic Republic sits in Pankow, east Berlin; both the west German *Bundestag* and *Bundesrat* (upper chamber) have held meetings in west Berlin and the federal president was re-elected there for his second term in July 1954. In July 1959 a new federal president, Heinrich Liibke, was elected in Berlin. The division of Berlin was accentuated by the rising of July 1953, which began in the eastern part of the city and spread to the whole of the Democratic Republic. For the first time since 1945 Red army troops and tanks moved into the middle of Berlin, shooting a number of German citizens and restoring order. The western commandants made formal protests.

The Berlin Blockade.— A blockade was imposed by the Soviet authorities in June 1948, in an attempt to force the western powers to abandon their rights in the city. The blockade began after several Soviet protests against steps taken in western Germany toward self-government and coincided with the introduction in west Berlin of the new Deutschemark, which the Russians regarded as a threat to the east German currency. The blockade was placed on all land and water communications between Berlin and the west. The western powers countered with the air lift and in spite of crippling shortages of fuel and electric power the life of west Berlin was maintained for 11 months. During this period a total of 1.583.686 tons of foodstuffs and other vital supplies was flown into west Berlin by U.S. and British aircraft which used three west Berlin airfields and the waters of the Havel river as landing grounds. An industrial air lift was organized in the opposite direction for west Berlin's greatly reduced exports.

The people of west Berlin remained loyal to west Germany and only about 4% of them at any time accepted the eastern bribe of better food rations which they drew, during the blockade, in the Soviet sector of the city.

The blockade ended on May 12, 1949, after the air lift had cost $170,000,000. (The air lift was actually continued until Sept. 1949.) This was partly due to the countermeasures imposed by the western powers on east German communications, but even more to the embargo placed on strategic goods previously exported to the countries of the eastern bloc. Attempts by the security council of the United Nations to bring the blockade to an end failed.

The Soviet and east German authorities never entirely relaxed their grip on west Berlin's communications. There was interference with the Berlin railways in 1949, the imposition of a tiresome system of bills of lading for goods shipments from Berlin in 1951 and the cutting of telephone connections between east and west Berlin in the same year. Rail and road traffic between Berlin and the west was frequently held up over short periods and dislocated. In 1952 the east Germans completed their rail and canal bypasses around west Berlin.

Reconstruction.— After the end of the blockade west Berlin made remarkable strides along the road to comparative prosperity. In mid-1949 industrial production was still only 19% of the 1936 figure. By 1954 it had risen to 70% and by 1959 to 132%. For years west Berlin suffered from a lack of capital and from the removal of factories and head offices of banks and other commercial enterprises. In 1950 unemployment was still around 300,000; in Sept. 1959 it reached the lowest postwar figure, 36,000. This was achieved in spite of the continuing influx of east German refugees. One reason was the increase in investment, which increased sixfold between 1950 and 1960. Another was the steady help, amounting to an average of 650,000.000 DM. a year, given by the Federal Republic, and reaching over 1,000,000,000 DM. in 1960.

In the early 1950s Berlin was still a ruined city, although after the blockade it became Allied policy to make west Berlin a "western shopwindow" for the east. The effects of this policy were at first more apparent than real. First to recover their former prosperity in west Berlin were shops, restaurants, places of entertainment and particularly the large network of bars and night clubs for which the city has always been famous. While west Berlin was recapturing a great deal of glitter, east Berlin remained bleak and forlorn, and its main décor was the flags and bunting draped on whole houses and ruins alike and the monster pictures and placards of the leaders of communism.

West Berlin gradually regained its position as the artistic centre of Germany; and its festivals of music and drama and many of its exhibitions compared favourably with prewar days. In 1948 the Free University of Berlin was founded in the western sector, with the help of a big grant from the Ford foundation, because the old Humboldt university, formerly the University of Berlin, is in the eastern sector. But both the western powers and the west Berlin authorities realized that the major effort in the recovery of the city had to be made in two fields, the rebuilding of the city and the development of its industries. Total rebuilding was estimated at 12,000,000,000 DM. and allocations had averaged 700,000,000 DM. a year from 1953 to 1956. In 1957 the "Hansa" district of the British sector of Berlin was rebuilt as a model homes exhibition. Blocks of flats were designed by outstanding European architects. Extensive plans were made for the rebuilding of the central parts of the city and for the laying out of parks and recreation grounds and increasing sums of money were channeled into the electrical, light metal and clothing industries which are west Berlin's main sources of livelihood.

BERLIN: *see* CARRIAGE.

BERLIN, CONGRESS OF (1878). By the treaty of San Stefano (*q.v.*) of March 3, 1878, which terminated the Russo-Turkish War of 1877, Russia compelled Turkey to agree to the creation of a large Bulgarian state, the so-called "Great Bulgaria," in accordance with the policy of the Asiatic department of the Russian foreign office. A large unwieldy Bulgaria would necessarily have looked to Russia for support. This solution, however, was unacceptable to Austria-Hungary because the formation of large Slav states in the Balkans would serve to attract the Slavs of the southern regions of the Habsburg empire. thus threatening its integrity. Lord Beaconsfield's Conservative government in Great Britain likewise objected to any solution which might detract from the authority of the Ottoman sultans. Before the signing of the treaty, the German chancellor, Prince von Bismarck, on Feb. 19, 1878, had proposed a congress in which Germany would have the role of "honest broker" reconciling the various powers, for which reason the congress was held in Berlin.

On May 29, 1878, Lord Salisbury, the British foreign secretary, came to an agreement with the Russian government through its ambassador in London, Count P. A. Shuvalov, by which Russia abandoned the "Great Bulgaria" policy. Austria and Great Britain by their convention of June 6, 1878, agreed to work together at the congress for the creation of an autonomous Bulgarian state which was not to extend south or southwest of the Balkan range. Thus before the congress of Berlin met the "Small Bulgaria" solution had been accepted in principle.

The congress assembled in Berlin on June 13 under Bismarck's presidency. The principal plenipotentiaries were Lord Beaconsfield and Lord Salisbury for Great Britain, Count Gyula Andrássy for Austria-Hungary, Prince A. M. Gorchakov and Count Shuvalov for Russia, and Alexandros Karatheodori (Carathkodory) Pasha, a Phanariot Greek, for Turkey. France was represented by the foreign minister, W. H. Waddington, and Italy by Luigi Corti, who played only a small part in the working of the congress. In view of his poor health and failing memory Gorchakov left the effective negotiating in Shuvalov's hands, while on the British side Beacons-

field's lack of familiarity with Balkan problems meant that Salisbury was the more important British representative. Andrássy tended to allow the British to take the initiative in resisting the Russians. The Russian experts' closer acquaintance with the Balkan terrain permitted Russia, within the limitations imposed by the understanding with Great Britain, to achieve certain minor successes.

The provisions of the treaty signed on July 13, 1878, may be divided into four main groups:

1. Bulgaria.—The congress constructed a "Small Bulgaria" north of the Balkan range including the towns of Varna and Sofia, which was to be an autonomous and tributary principality under Turkish suzerainty, but ruled by an elected Christian prince. South of the Balkan range a province of Eastern Rumelia was formed, to enjoy administrative autonomy under the sultan's direct military and political authority, but with a Christian governor general. The purpose of this was to satisfy the demands of the Bulgarian population, but at the same time to give Turkey an adequate defense line in the Balkan mountains. This latter aim was, however, to some extent modified by the grant to Bulgaria of the sanjak as well as the town of Sofia.

2. Bosnia-Hercegovina and Montenegro.—Bosnia-Hercegovina was placed under the occupation and administration of Austria-Hungary, but technically remained part of the Ottoman empire. Montenegro was given some extension of territory including access to the Adriatic at Bar (Antivari), but this extension was much less than that accorded by the treaty of San Stefano. Austria-Hungary also obtained the right in case of need to garrison the sanjak of Novibazar (Novi Pazar), which divided Montenegro from Serbia, and to maintain lines of communication there. Thus Andrássy obtained the main aims of Austro-Hungarian policy. The Slavs of Bosnia-Hercegovina could be kept under control by Austrian troops without at the same time their being citizens of Austria-Hungary, while the right to intervene in the sanjak of Novibazar placed Austria-Hungary in a position to prevent a union of Serbia and Montenegro.

3. Rumania, Serbia, Greece and the Danube.—Rumania and Serbia obtained recognition of their independence together with some territorial changes, Rumania receiving part of the Dobruja as compensation for the retrocession of southern Bessarabia to Russia, and Serbia receiving extension including the towns of Nis, Pirot and Vranje. Greece obtained the prqvision that Crete should be governed in accordance with the organic statute of 1868. Provision was made for the international supervision of navigation on the Danube.

4. Asia Minor.—Turkey ceded to Russia the territories of Ardahan, Kars and Batum, subject to the condition that Batum should be a free port. Turkey undertook to institute reforms in areas inhabited by Armenians and to observe religious toleration throughout the Ottoman dominions.

While Austria-Hungary made real gains and Great Britain was reasonably content, the treaty of Berlin did not solve the Eastern question (q v.). The Christian populations subject to Turkey remained discontented—a situation which the chronic disorder of the Ottoman administration did nothing to improve.

BIBLIOGRAPHY.—For the text of the treaty see E. Hertslet, History of *Europe* by Treaty, vol. iv, p. 2759 (1891). See also W. N. Medlicott, The *Congress* of Berlin and After (1938); B. H. Sumner, Russia *and* the Balkans, 1870–1880 (1937). (R. F. LE.)

BERLIN-STETTIN CANAL is a canal system consisting of three parts: the Havel river below Spandau, the lower Oder to Stettin (Szczecin, Pol.) and the interconnecting Oder-Havel canal. The last, from below Oranienburg on the Havel to Hohensaaten on the Oder, also named the Hohenzollern canal, built in 1914, is 56 km. (35 mi.) long. The whole stretch of this waterway is available for 750-ton barges, but although it was the principal water-outlet for Berlin before World War II, its postwar traffic has been greatly reduced. (R. E. DI.)

BERLIOZ, (LOUIS) HECTOR (1803–1869), French composer, critic and conductor, a many-sided genius whose contributions to 19th-century music only began to be fully understood some 50 years after his death. He was born on Dec. 11, 1803, in the village of La Côte-Saint-André 35 mi. N.W. of Grenoble in the French Alps. France was at war, the schools were disrupted and Berlioz received his education from his father, an enlightened and cultured physician, who gave him his first lessons in music as well as in Latin. But, like many great composers, Berlioz received in his early years little formal training in music. He worked out for himself the elements of harmony and by his 12th year was composing for local chamber music groups. With help from performers he learned to play the flute and the guitar, becoming a virtuoso on the latter instrument.

In 1821 his father sent him to Paris to study medicine, and for a year he followed his courses faithfully enough to obtain his first degree in science. But he took every opportunity to go to the Opéra, where he studied the works of Gluck, score in hand. His vocation was so clear in his mind that he contrived to become accepted as a pupil of Jean François Lesueur, professor of composition at the Conservatoire de Musique. This led to disagreements with his family that embittered nearly eight years of his life. He persevered, took the obligatory courses at the Conservatoire, notably Anton Reicha's in counterpoint, and in 1830 won the Prix de Rome, having received second prize in an earlier competition. These successes pacified his family but were, in a sense, incidental to his career, for in the same year he had finished and obtained a performance of his first great score, which is also a seminal work in 19th-century music, the Symphonie *Fantastique*.

It was in some respects unfortunate that instead of being able to follow up this success Berlioz was required, under the terms of his prize, to spend three years abroad, two of them in Italy. During his long Paris apprenticeship he had experienced the "revelation" of two modern musicians, Beethoven and Weber, and of two great poets, Shakespeare and Goethe. He had meanwhile fallen in love, at a distance, with Harriet Smithson, a Shakespearian actress who had taken Paris by storm; he on the rebound, had become engaged to a brilliant and beautiful pianist, Camille Moke, later Mme Pleyel. In leaving Paris, Berlioz was not only leaving a flirtatious fiancée and the artistic environment that had stimulated his powers; he was also leaving the opportunity to demonstrate what modern French music should be. The public was content with the "Paris school," dating back to the 1780s and 1790s, and there is evidence that all Europe (including the Vienna of Beethoven and Schubert) accepted the productions of Grétry, Méhul, Cherubini and their followers as leading the musical world.

Berlioz wanted to bring forward the work of Weber and Beethoven (including the last quartets) and add contributions of his own. He also preached, for the sake of dramatic expression in music, a return to an older master, Gluck. These three musicians were all in some sense dramatists, and to Berlioz music must first and foremost be dramatically expressive. This doctrine he had begun to expound in his first musical reviews, as early as 1823, and, because of the sharpness and strength of his early vision, it remained the artistic creed of his mature years. When one understands its intellectual and intuitive basis, one understands also the reasons for his dynamic career. What may look like self-seeking—the unceasing effort to have his music played—was in fact the dedication of his tremendous energies to a cause, often at the expense of his own creative work. The result of his many journeys to Germany, Belgium, England, Russia and Austria-Hungary was that he taught the leading orchestras of Europe a new style, and through them a new idiom to the young composers and critics who flocked wherever he went.

But before these "campaigns" began, Berlioz had his time of reflection in Italy. He has told in his *Mémoires* (1870) how bored he was, and unproductive, after the rich output of the Paris years, which had brought forth an oratorio, numerous cantatas, two dozen songs, a mass, part of an opera, two overtures, a fantasia on Shakespeare's Tempest, and eight scenes from Goethe's Faust, as well as the *Symphonie Fantastique*. However, even in Italy, Berlioz filled notebooks, met Glinka, made a lifelong friend of Mendelssohn and tramped the hills with his guitar over his shoulder, playing for the peasants and *banditti* whose meals he shared. The impressions gathered in Italy remained a source of

both musical and dramatic inspiration to his last works, *Les Troyens* and *Bkatrice et Bénédict*.

Meanwhile, his love affairnot prospering and his impatience with life at the Villa Medici in Rome becoming acute, he returned to France after 18 months, thus forfeiting part of his prize.

Back in Paris, he set about conquering it anew. He put together a collection of earlier pieces in a form then fashionable, the monodrama, or recitation by one actor interspersed with musical scenes. Since the *Symphonie Fantastique* had ended with the death of the protagonist, Berlioz called his new work *Le Retour à la Vie* (later *Lélio,* after the hero's name). First performed in 1832, this concoction, which contains three or four delightful pieces, enjoyed great success, and Berlioz had reason to think himself launched again.

A series of accidents brought him in touch with the actress Harriet Smithson, still beautiful but in financial straits, and. his mental and artistic attachment to her reviving, he married her on Oct. 3, 1833. The marriage did not last, though for some years the couple led a peaceful existence at Montmartre in the house that Maurice Utrillo later never tired of painting. Among the visitors there were the young poets and musicians of the romantic movement, including Alfred de Vigny and Chopin. It was there that Berlioz's only child, Louis, was born and also where he composed his great Requiem, the *Grande Messe des Morts* (1837), the symphonies *Harold en Italie* (1834, inspired by Byron's *Childe Harold)* and *Roméo et Juliette* (1839), and the opera *Benvenuto Cellini* (Paris. 1838).

It was after the *premikre* of *Harold en Italie* that Berlioz had the astonishing experience of seeing the world-famous violin virtuoso Paganini fall at his feet and declare that he was a genius destined to carry on the new musical tradition initiated by Beethoven. The next day Berlioz received 20,000 francs with a letter from Paganini repeating this judgment. He used the money to free himself from journalistic drudgery and to compose the choral symphony, *Roméo et Juliette,* dedicated to Paganini.

But in Paris it was always expected that a composer, regardless of his bent, should be tested at the Opéra. Berlioz's friends intrigued to procure the assignment of a libretto. An adaptation of Benvenuto Cellini's autobiography was secured, and Berlioz finished his score in a short time. But the intrigue now passed to the other side, which saw to it that the production of *Benvenuto Cellini* at the Opéra failed. From this blow the work itself and the composer's reputation in France never recovered during his lifetime. The score, still little known in the early 1960s, is a masterpiece, and the attribution of the failure to the libretto shows ignorance of the qualities of both the libretto and the music.

The Requiem of 1837 had been a government commission for a military and ceremonial occasion designed to encourage the Rome laureate. and the request to compose the *Symphonie funèbre et triomphale* for military band, chorus and strings for the tenth anniversary of the July Revolution (1840) was intended as a partial solace for the defeat of *Benvenuto Cellini.* A few years before, Berlioz's literary gifts had won him the post of music critic for the leading Paris newspaper, the *Journal des Débats,* and his employers wielded political influence. Once again there were intrigues, but the score was ready for the inauguration of the Bastille column. Unfortunately the music was drowned by the assembled drum corps, a disaster that Berlioz repaired by giving the work the following month at a concert hall. This was the score that Wagner, then seeking fame and fortune in Paris, admired so wholeheartedly.

Berlioz was able to put Wagner in the way of some musical journalism, and thus began a fitful connection of 30 years between the two men whose influence on modern music still resembles a battle of ideals: Berlioz aiming at the creation of drama in and through music alone; Wagner at a marriage of symphony with opera. Though they met again in London in 1855 and found each other congenial, their philosophical differences generally kept them apart, as did also Wagner's habitual duplicity.

After 1840 Berlioz's life consisted of a series of tours across Europe. The last was an exhausting series of concerts in St. Petersburg and Moscow in 1867, when he was desperately ill. But it had the effect of introducing the Russian "Five," notably Mussorgsky, to his style through his manuscript scores and his conducting. For Berlioz was the first of the virtuoso conductors, having made himself such in order to supply the deficiencies of men who were unable to direct the new music according to the new canon: play what is written. Moreover the rhythmical difficulties of his scores and the unfamiliar curve of his melodies disconcerted many. The orchestras themselves had to be taught a new precision, vigour and ensemble, and this was Berlioz's handiwork.

On orchestration itself (and, even more important, on instrumentation) Berlioz produced the leading treatise, *Grand Traitk d' Instrumentation et d'orchestration modernes* (1844). Being much more than a technical handbook, it served later generations as an introduction to the aesthetic expressiveness in music. As Albert Schweitzer has shown, its principle is as applicable to Bach as to Berlioz, and it is in no way governed by considerations of so-called "program music."

Among Berlioz's dramatic works two became internationally known: the *Damnation de Faust* (1846) and *L'Enfance du Christ* (1854). Two others began to emerge from neglect after World War I: the massive two-part drama *Les Troyens* (composed 1855–58; part II produced in Paris, 1863; entire, in Carlsruhe, 1890) based on Virgil's story of Dido and Aeneas, and the short, witty comedy *Be'atrice* et *Bénédict* written between 1860 and 1862 and based on Shakespeare's *Much Ado About Nothing.* For all these Berlioz wrote his own librettos. He also wrote a *Te Deum* (1849; performed 1855), which is a fitting counterpart to the Requiem, and between 1843 and 1856 he orchestrated his songs, including the song cycle *Nuits d'été.* Among his best-known overtures are *Le Roi Lear* (performed 1833); *Le Carnaval romain* (1844) based on material from *Benvenuto Cellini,* and *Le Corsaire* (1855).

Berlioz's last years were marked by fame abroad and vulgar hostility at home. In his private life he was incapacitated by illness and saddened by many deaths. His first wife, from whom he was separated but to whom he still felt a deep attachment, died in 1854; his second wife, Marie Recio. who had been his companion for many years and whom he had married when he became a widower. died suddenly in 1862. Finally, his son, who was a sea captain and on whom he concentrated the affection of his declining years, died of yellow fever in Havana at the age of 33, two years before Berlioz's own death in Paris on March 8, 1869.

Characteristics of Berlioz's Music.—The outstanding characteristics of Berlioz's music—its dramatic expressiveness and variety—account for the feeling of attraction or repulsion that it produces in the listener. Its variety also means that devotees of one work may dislike others, as one finds lovers of Shakespeare who detest *Othello.* But Berlioz also presents a particular difficulty of musicianship in being closer to the true sources of music than to its German, Italian or French conventions; his melody is abundant and extended, and disconcerting to the lover of four-bar phrases; his harmony may be obvious or subtle, but it is always functional and frequently depends on elements of timbre; his modulations can be harsh and may even seem harsher than they would in another composer, because he uses his effects sparingly and achieves much by small means and adroit contrasts. This is also true of his orchestration, generally light and transparent, never pasty. As Shaw said: "Call no conductor sensitive in the highest degree to musical impressions until you have heard him in Berlioz and Mozart."

Estimates of Berlioz's **Art.**—César Franck once said that Berlioz's whole output is made up of masterpieces. He meant by this that each of the composer's dozen great works was the realization of a conception distinct from all the others, rather than successive effortsto attain perfection in the last or best of the series. Franck's judgment is borne out by the fact that, unlike many composers, Berlioz almost never repeats himself. Rather, he creates a fresh style for each of his subjects, with the result that familiarity with one is no guaranty of ready access to another. Nothing could be less alike than the *Symphonie funèbre et triomphale* and *Roméo et Julliette,* or than the *Requiem* and *L'Enfance du Christ.* To be sure, Berlioz's harmonic system seems the same throughout, partly because it deviates so noticeably from common expectation, partly because its nuances have scarcely begun to be appreciated. Again, his melody and free counterpoint everywhere carry his

mark—the sinewy originality and dynamic equilibrium of the former, the ingeniously careless independence of the latter—but out of similar elements Berlioz makes a radically different atmosphere for each of his dramas, and within them for each of his dramatis personae. Only a repeated hearing of any given work discloses all the power and art that it contains. This does not mean that these works are without flaw; it does mean that they are unique creations, to be taken for what they have to give, which no other composer provides.

In the creation of drama and atmosphere Berlioz excels in scenes of melancholy, introspection, love—gentle or passionate—the contemplation of nature, and the tumult of crowds. His intention throughout is to combine truth with musical sensations, be they powerful, or (to quote Shaw again): "wonderful in their tenuity and delicacy, unearthly, unexpected, unaccountable."

Much might be added or quoted that would show the extent to which Berlioz's music still needs careful and dispassionate study. In 1935 Donald Tovey, who had not before heard *Les Troyens,* declared that it is "one of the most gigantic and convincing masterpieces of music drama." And he went on: "You never know where you are with Berlioz." What is certain is that books that date from the 19th century or echo its views, with or without a bias toward Wagner or Debussy, will mislead the student and possibly close the ears of the listener. It is easy to represent Berlioz as merely a craftsman in tone colour who helped develop the resources of the orchestra. The cause that has begun to change both the hostile and the bewildered views is the repeated performance of the major works. Before 1945 the Berlioz repertoire in the western world was limited to the *Symphonie Fantastique* and a few brief extracts. The great works. done once, and usually with insufficient preparation, produced little effect and confirmed the wisdom of letting them lie. The advent of long-playing records radically altered the situation. Audiences can now judge the interpretations that they are increasingly being given, so that with respect to Berlioz they are approaching the state in which they hear the other classical composers. Still wanting is an intensive study of the musical and aesthetic elements in Berlioz's work as a whole—a study based on the original scores and one that should lead to a scholarly edition of the works, the so-called German edition being untrustworthy for either study or performance.

When Berlioz is truly known in both the scholar's and the listener's way it will be time to attempt a final assessment of his art.

BERMEJO, BARTOLOMÉ (BARTOLOMÉ DE CÁRDENAS) (fl. 1474–1495), Spanish painter of Córdoban origin, a cultivator of the Flemish style. was trained, apparently, in the circle of Dierick Bouts, though little is known of his early activity. It is certain that between 1474 and 1477 he worked in Aragon, where he left disciples, and between 1486 and 1495 in Catalonia. where he collaborated with J. Huguet, the principal master of that school.

Among his main works are the "Santo Domingo de Silos" (Prado, Madrid), a monumental figure seated on a rich gilt throne, and the "San Miguel With Donor" (Ludlow collection) from Tous, Valencia. The latter is signed "Bartolomeus Rubeus"—the latinized form of his name—and its background is of the gold so much to the taste of the region. In another masterpiece. the "Pietà" with the portrait of Canon Luis Desplá (Barcelona cathedral), completed in 1480 and probably the most important Spanish painting of the 15th century, he omitted the gold and painted as background a beautiful landscape very much in the Eyckian manner. Other works are "Virgin with Donor" (Acqui cathedral, Italy). "Adoration of the Kings" (Capilla Real. Granadn) "Santa Enpracia" (Gardner collection, Boston) and "Santo Domingo de Silos" (Art Institute, Chicago). (DI. A.)

BERMONDSEY, a metropolitan and parliamentary borough of London, Eng., is bounded north and east by the Thames, southeast by Deptford, southwest by Camberwell, and west by Southwark. Pop. (1961) 51,815. The site was anciently marshland and the name, which appears in Domesday Book, suggests an island (*ey*) of firm ground held by one Beornmund. Bermondsey was favoured by the Norman kings as a place of residence, and there was a palace there, perhaps from pre-Norman times. In the 7th century some monks were sent from Peterborough to found a monastery in Bermondsey. A Cluniac monastery was founded by William Rufus about 1082, and Bermondsey Cross became a frequent place of pilgrimage. The foundation mas erected into an abbey in 1399 and pulled down in the 16th century when a mansion was built. Abbey street and Grange road recall the site. St. Olave's and St. Saviour's Grammar school (1562) is in the Horsleydown district.

The parish of Rotherhithe, once Redriff, in the northeast has long been associated with a seafaring population, and the extensive Surrey Commercial docks are there. St. Mary's parish church (rebuilt 1714–15) has registers recording the burial of Christopher Jones (March 5, 1621), who was master and part owner of the "Mayflower." The burial in 1638 of John Moore, also part owner, and the baptism in 1575 of John Clarke, who was probably the master's mate and pilot, are also recorded. Clarke married at St. Mary's (1610); Clarke's island in Plymouth bay, Mass., is named after him. Rotherhithe appraisers condemned the "Mayflower" in 1624 and at Rotherhithe the ship was probably broken up. A road tunnel ($1\frac{1}{4}$ mi.) to Whitechapel on the opposite shore of the river was opened in 1908. The neighbouring Thames tunnel to Wapping was the joint work of Sir Marc Isambard Brunel and his son Isambard Kingdom Brunel, and opened in 1843; it is now part of the Metropolitan line.

Bermondsey is a highly industrialized area, dealing mainly with the distribution, manufacture and storage of foods, railway, riverside, dock and wharf works, locomotive repairs and timber. The borough is noted for its tanneries and leather works: exemplified by the National Leatherseller's college and museum of leathercraft in Tower Bridge road. Southwark park. in the centre, is 63 ac. in extent. Since 1950 Bermondsey has sent one member to parliament.

BERMUDA GRASS. (*Cynodon dactylon),* a native of the Mediterranean region, is perhaps the most important pasture grass in the southern and southwestern United States and is also much used on lawns and golf greens. On moist fertile soils it may become sufficiently tall to be cut for hay. It is a low growing perennial grass, with creeping rhizomes and stolons, and slender digitate spikes borne at the ends of the stems. Propagation is by seeds and by the rhizomes and stolons, and: because of the latter method, it often becomes a troublesome weed in cultivated ground. *See* also LAWNS, CARE OF; GRASSES. (J. M. BL.)

BERMUDA RIG (also known as the MARCONI or JIB-HEADED RIG), the lofty! triangular fore-and-aft mainsail of modern racing and cruising yachts. Its prototype is generally held to be the "shoulder-of-mutton" rig used in ships' boats and other small naval vessels, and it was first seen in about 1808 on the small craft of the Bermudas.

In its original form it consisted of a tall mast, raking well aft, and a loose-footed sail with a sprit to hold it out instead of a boom. As developed for use in yachts the mast was lengthened considerably, being well stayed with spreaders for strength. and the foot of the sail shortened. This was to give a long "leading edge" to the sail, the ratio of height (or hoist) to foot being as high as 2.5 to 1 on small yachts, although 2 to 1 or 1.5 to 1 is more common in yachts over 50 ft. long. The rig is very efficient in working to windward, there being no gaff to sag away to leeward and so spill the wind out of the sail. In its modified form the rig did not come into general use on yachts outside the Bermudas until after 1918, but between World Wars I and II its advantages in efficiency and ease of handling became widely appreciated, and by the 1950s it had been adopted throughout the world in the majority of auxiliary yachts as well as racing yachts and dinghies.

See also YACHTING.

BERMUDAS, a British colony consisting of a group of islands in the western North Atlantic, about 570 mi. E.S.E. of Cape Hatteras, N.C. The group comprises about 300 islands, islets and rocks clustered in a chain shaped like a fishhook, with an over-all length of about 22 mi. and an area of 20.59 sq.mi. Only about 20 of the islands are inhabited. Great Bermuda or the "mainland" is the largest (about 14 mi. long) and contains the capital, Hamilton (*q.v.*). It is linked by bridge and causeway to six other islands: St. George's and St. David's to the east, and Somerset, Watford, Boaz and Ireland to the west. This chain partially encloses four large expanses of sea—St. George's harbour, Castle harbour, Harrington sound, and Great sound—in which most of the remaining small islands are situated.

Geology and Relief.—The Bermudas form one of the northernmost groups of coral islands in the world and consist principally of wind-blown calcareous deposits capping a submerged and beveled volcanic cone which rises over 10,000 ft. from the floor of the Atlantic. The deposits are thought to derive from an extensive shelf, now submerged, which surrounds the islands and was probably dry land during Pleistocene phases of lowered sea level. Relief is generally low. with hills rising to a maximum height of about 260 ft., and there is no surface water. The soil consists of thin red-brown clay and loam, often mixed with white coral sand.

Climate.—Mild and fairly humid conditions are experienced. The average temperature for January is 62.6° F. and for July 78.4°, with recorded extremes of 94° and 39°. Rainfall is evenly distributed throughout the year and averages 58 in. It is the only source of fresh water, and is collected from the roof tops of almost all buildings and stored in tanks.

Vegetation and Animal Life.—When first discovered the islands were thickly wooded. The commonest tree was (and still is) a species of juniper known as Bermuda cedar, but it has suffered a severe infestation of juniper scale disease and dead trees disfigure large areas. Replanting began in 1952. Many plants have been introduced, deliberately or accidentally, and some of them, such as prickly pear cactus, have spread widely. Due to their remote oceanic position the Bermudas have no native mammals, only one native reptile—a lizard—and seven species of native land birds; but several animals, such as frogs, rats and mice, have been introduced, and many land birds migrate to the islands. Among the sea birds is the Bermuda petrel (*Pterodrama cahow*). Before 1951, when it was rediscovered, this bird had been supposed extinct for over 300 years. The surrounding waters are rich in fish and lobsters and in 1960 attempts were made to develop both a local fishihg industry and game fishing as a sport for visiting tourists.

History.—Mystery surrounds the discovery and naming of the islands. The Spanish navigator and historian Fernandez de Oviedo sailed close to them in 1515; they were then already known as the Bermudas and he ascribed their discovery to his countryman, Juan de Bermudez. Other ships visited them in the 16th century, and they were accidentally settled by the British in 1609 when the ship "Sea Venture" under Sir George Somers, taking colonists to the Virginia plantations, was wrecked off the Bermudas. Somers' narrative of the wreck was one of the sources used by Shakespeare in 1611 for The Tempest, which mentions "the still-vexed Bermoothes." In May 1610, the castaways reached Virginia and in 1612 the Bermudas were included in the third charter of the Virginia company, 60 settlers then being sent out. The Bermudas have been a British possession ever since, remaining under company rule until 1684 when they reverted to the crown. In the 18th century they became a British naval base and from 1797 had a garrison. During the 1950s the naval dockyard was closed and the troops withdrawn. In 1941 the United States was granted a 99-year lease of sites for naval and air bases.

Population.—The Bermudas were uninhabited when first discovered. Following British settlement Negro slaves were imported, as later were Portuguese labourers from Madeira and the Azores. By 1881 the total population numbered about 14,000, but by 1960 it had increased to 42,640 so that the average density was over 2,000 per sq.mi. About 60% of the population is Negro.

BY COURTESY OF BERMUDA NEWS BUREAU

GOVERNMENT HOUSE, HAMILTON, GREAT BERMUDA

The population of Hamilton was 2,763 and of the former capital, St. George, 1,335. If the growth of population continued at the rate reached at the beginning of the 1960s, it would produce acute overcrowding and emigration would become increasingly necessary.

Administration.—The colony has representative but not responsible government. Executive government is conducted by a governor, appointed by the crown, who is advised by an executive council of seven members. Legislative authority rests in the governor, in a legislative council of 11 members and in a representative house of assembly of 36 members, 4 of whom are elected by each of the nine parishes for a term of five years. There is adult suffrage for men and women, subject to a property qualification. Primary education, from 7 to 13 years of age, is compulsory and free, and there are a number of secondary schools.

The Economy.—The economy depends primarily on tourism, but in the past agriculture and the building and repairing of ships sustained the colony. With the increase of population and housing the land available for cultivation has greatly diminished. In 1956 only about 2,000 ac. remained available, of which about one-half was devoted to pasture, supporting mainly dairy cattle; about one-third to vegetables, principally potatoes, carrots and tomatoes; and the remainder to fruits, flowers and bulbs (chiefly bananas, citrus fruits and Easter lilies). The islands' main sources of employment are the tourist and ship-repairing industries and the installations of the United States forces. Attempts to attract light industries have resulted in the establishment of factories making pharmaceutical products and concentrated essences which, in 1958, provided the two most valuable exports. Lily flowers and bulbs are the only important agricultural exports; foodstuffs from the United States are the main imports. The railway was discontinued in 1948.

Motor vehicles, which were prohibited until 1946 and are now limited in size and power, provide transport on the 128 mi. of public roads, and ferries ply across the Great sound. External communications are maintained by numerous shipping and air lines which use the harbour at Hamilton and Kindley Field airport on St. David's Island. In 1959 more than 109,000 tourists visited the Bermudas, 88% of whom arrived by air.

BERN (BERNE), a Swiss canton and its capital city, which is also the capital of the Swiss confederation.

The City.—Bern stands mainly in a narrow loop of the Aare river, 1,800 ft. above sea level. Six road bridges connect old Bern with the newer residential area; a seventh bridge was being built in 1960. The population in 1960 was 163,172, of whom the majority were German-speaking. In the 1950 census there were 118,823 Protestants, 24,384 Roman Catholics and 792 Jews.

The existence of the ancient castle of Nydegg at the eastern end of the peninsula, guarding the passage over the Aare, probably

led Berchtold V, duke of Zahringen, to found Bern in 1191 as a military post on the frontier between the German-speaking Alamannians and the French-speaking Burgundians. The walls protecting the town were three times moved westward—in 1256, 1346 and 1622. After the extinction of the Zahringen dynasty (1218) Bern became a free imperial city, and gradually extended its power by acquiring surrounding territory, establishing its position over its rivals by the victories of Dornbiihl (1298) and Laupen (1339) and becoming an independent state that in 1353 entered the Swiss confederation, founded in 1291. It soon took the lead within the confederation. In 1528 it was the scene of a disputation between Catholics and reformers that led to its acceptance and subsequent championship of reformed doctrines. In the 18th century the town governed 52 territories, the Bernese patricians thus being extremely powerful. Attempts to break down this monopoly failed in 1723 and 1749, but the whole system was swept away by the French in 1798, and though partially revived in 1815, ended in 1831 *(see* SWITZERLAND: *History).* In 1848 Bern became the political capital of the Swiss confederation.

Bern preserves more of its medieval appearance than any other town in Switzerland. The Gothic *Münster* (cathedral) dominates the city; begun in 1421, the spire was not finished until 1893. The city hall dates from 1406 and was restored in 1942. West of the central Nydegg bridge stretch a number of picturesque old streets lined with flower-decked houses and arcades in which are excellent shops. At the main crossroads is the famous *Zeitglockenturm* (clock tower) with a 16th-century clock and puppets (a crowing cock, bears, etc.) that revolve at the hour. This and the *Käfigturm* (prison tower) at the other end of the *Marktgasse* are the two remaining towers of the old walls. Some of the sites of outlying fortifications have been converted into promenades: one of the most famous is the *Schänzli* (little fortress) terrace just across the river, with magnificent views of the Alps, and a restaurant and casino. The federal houses of parliament, of which the oldest part dates from 1852–57, occupy a commanding position on a bluff 130 ft. above the river, also with fine Alpine views from the terrace. The buildings also house the administrative and executive offices; nearby are the headquarters of the national bank. The city and university library contains more than 800,000 volumes, including many manuscripts and rare printed books. The Swiss national library is also in Bern and houses more than 1,000,000 volumes. There are historical, natural history, art, rifle and Alpine museums. The university was founded in 1834 and incorporates the theological school (founded 1528). Bern has several exceptionally well-equipped and well-run hospitals.

The bear (Old High German *bero),* the town's heraldic device which appears on the first known seal (1224) and from which the town is said to take its name, is a favourite decorative motif. The famous bear pit, where bears have been kept since 1513, is just across the Nydegg bridge. There is a nature reserve and deer park along the river at Elfenau.

As well as being the seat of the Swiss parliament and administration, Bern has become headquarters of the international postal, telegraph, railway and copyright unions. It has flourishing industries, notably chocolate-making, engine-building, instrument-making and the manufacture of textiles and chemical and pharmaceutical products. It is also a market for local agricultural produce. It is an important railway junction and has an airport at Belpmoos, 4 mi. S.E. of the city, with a regular summer service that links Bern with Zurich's international airport.

The Canton.—Bern canton extends from beyond the Jura to the snow-clad ranges over against the canton of Valais. The second largest canton, it covers 2,659 sq.mi., of which more than 100 sq.mi. are occupied by glaciers. Pop. (1960) 889,523. It is mainly watered by the Aare (*q.v.*) river, with its affluents, the Saane (left) and the Emme (right); the Aare forms the two lakes of Brienz and Thun. Three divisions are usually distinguished: (1) the Oberland (highlands), which includes the snowy Alps culminating in the Finsteraarhorn, 14,022 ft., and the Jungfrau, 13,642 ft., as well as the famous summer resorts of Interlaken, Thun (*qq.v.*) and Meiringen, and the summer and winter resorts of Grindelwald, Mürren, Kandersteg (*qq.v.*) and Gstaad. (2) The Mittelland (midlands), comprising the valley of the Aare below Thun, that of the Emme, the outliers of the high Alps, the open country around the town of Bern and the Seeland (lakeland) around Lake Biel; (3) the Jura, extending from Biel across the Jura to Porrentruy, in the extreme northwest of Switzerland. The Oberland, Mittelland and Seeland form the "old" canton, the Jura having been acquired only in 1815 and differing from the rest of the canton in being French-speaking and predominantly (54%) Roman Catholic. The population, mainly German-speaking Protestants, numbered 869,000 in 1959, the second highest of any Swiss canton. Besides Bern, other important towns are Biel (*q.v.*), Burgdorf, Delémont, Porrentruy, Thun and Langenthal. The canton is divided into 30 administrative districts and contains 492 communes. The existing constitution dates from 1893, but in 1906 the direct popular election of the executive (*Regierungsrat)* of nine members (hitherto named by the legislature) was introduced. The legislature or *Grosse Rat* is elected for four years (like the executive). The obligatory referendum obtains in the case of all laws, and of decrees relating to an expenditure of over 1,000,000 Fr., while 12,000 citizens have the right of initiative in the case of legislative projects, and 15,000 may demand the revision of the cantonal constitution. The two members sent by the canton to the federal *Standerat* (council of states) are elected by the *Grosse Rat,* while the 33 members sent, on the basis of the census of 1950, to the federal *Nationalrat* (national council), are chosen by a popular vote.

In the Alpine portions of the canton the tourist trade both in summer and winter, agriculture, cattle-breeding, cheese-making (Emmental) and the operation of hydroelectric power stations are the important means of living; other occupations are wood carving (at Brienz) and pottery making at Heimberg near Thun. The Mittelland is both agricultural and industrial; vine culture is carried on in the Seeland (around Lake Biel). Watch-making is the principal industry of the Jura; horse-breeding and engineering works are also important.

The canton of Bern is composed of the various districts acquired by the town of Bern. The more important, with dates of acquisition, are the following: Laupen (1324); Hasli and Meiringen (1334); Thun and Burgdorf (1384); Unterseen and the upper Simme valley (1386); Frutigen (1400); lower Simme valley (1439–49); Interlaken, with Grindelwald, Lauterbrunnen and Brienz (1528); Saanen or Gessenay (1555); Köniz (1729), and the Bernese Jura with Biel. But certain regions previously won were lost in 1798: Aargau (1415); Aigle and Grandson (1475); Vaud (1536); and the Pays d'Enhaut (1555). From 1803 to 1814 the canton of Bern was one of the six "directorial" cantons of the confederation. Its position on the frontier between the German- and French-speaking parts of Switzerland has permitted, and still permits, Bern to exercise an important unifying influence.

BERNADETTE, SAINT, OF LOURDES (MARIE BERNARDE SOUBIROUS) (1844–1879), French peasant girl whose visions led to the foundation of the shrine of Lourdes (*q.v.*), was born at Lourdes on Jan. 7, 1844. The eldest of nine children, she was brought up in extreme poverty. Though very backward at school, she had good practical ability and a lively, simple and lovable character; and she shared her parents' religious piety.

At the age of 14 she had a series of visions of the Blessed Virgin Mary, who revealed her identity with the words "I am the Immaculate Conception." Bernadette steadfastly defended the genuineness of these visions despite strong opposition from her parents, the local clergy and civil authorities, and faithfully transmitted the heavenly visitor's messages. She returned to school

and everyday life with unspoiled simplicity; but to escape public attention she later became a boarder in the local school run by the Sisters of Charity of Nevers. In 1866 she begged for, and was reluctantly granted, admission into this congregation of nuns, and passed her remaining 12 years in the mother house at Nevers in prayer and seclusion, happy and loved for her kindliness, holiness and wit, despite almost constant sickness and pain.

She died in agony on April 16, 1879, willingly accepting her great sufferings in faithful fulfillment of her "Lady's" request for penance. She was canonized in 1933. Her feast day is Feb. 18 in France; elsewhere it is celebrated on April 16.

BERNADOTTE, JEAN: *see* CHARLES *XIV.*

BERNADOTTE AF WISBORG, FOLKE, COUNT (1895–1948), Swedish army officer and humanitarian, was born at Stockholm, on Jan. 2, 1895, the son of Prince Oscar August and nephew of King Gustavus V. An official of the Boy Scout movement and the Red Cross organization, he was appointed mediator between the Arabs and Jews in Palestine by the United Nations security council in May 1948. Following a number of threats against his life, he was assassinated in Jerusalem by Jewish extremists on Sept. 17. 1948. *See* ISRAEL; UNITED NATIONS.

BERNANOS, GEORGES (1888–1948), French novelist and polemical writer, whose first novel, *Sous le soleil de Satan* (1926; Eng. trans., 1940, 1946), established him as one of the most original and independent Catholic writers of his time, was born in Paris on Feb. 20, 1888. He began life as a royalist journalist and later worked as an inspector for an insurance company. Like his predecessor Léon Bloy, Bernanos was a visionary for whom the supernatural world was never far away. He was also a man of humor and humanity, who abhorred materialism and any compromise with evil. His vehement sincerity inspired his political pamphlets *La Grande Peur des bien-pensants* (1931) and *Les Grands Cimetières sous la lune* (1938; Eng. trans., *A Diary of My Times,* 1938), the latter a fierce attack on fascist excesses during the Spanish civil war and on the church dignitaries who supported them.

In controversy his views were sometimes inconsistent or oversimplified. As a novelist he made his theme the struggle between the forces of good and evil for the soul of man, a conflict particularly exemplified in his studies of the priesthood. His characters represent far extremes of human behaviour, ranging from saintliness to utter depravity: they are powerfully imagined and realistically drawn, but at times come too close to melodrama.

In 1936 Bernanos published his masterpiece, *Journal d'un curé de campagne* (Eng. trans., *The Diary of a Country Priest,* 1937), a story of a young priest's war against sin despite mortal illness, much apparent failure and almost unending frustration. Other notable works were *La Joie* (1929; Eng. trans., 1946), *Nouvelle Histoire de Mouchette* (1937) and *Monsieur Ouine* (written, 1931–40; published in Rio de Janeiro in 1943, in Paris 1946; Eng. trans., *The Open Mind,* 1945). Over this last novel critical opinion was much divided.

Political events troubled Bernanos increasingly. In July 1938 he went into self-imposed exile with his wife and six children and began an unsuccessful farming career in Brazil. He felt acutely what he regarded as the moral degradation of the Munich agreement (*Scandale de la vérité,* 1939). This pamphlet contained a violent denunciation of Charles Maurras (*q.v.*), leader of the *Action française* group, with whose policies Bernanos had found himself increasingly at variance from 1919 onward. In June 1940 he gave his support to Gen. Charles de Gaulle. His broadcast messages and his *Lettre aux Anglais* (1942; Eng. trans., *Plea for Liberty,* 1944) influenced his compatriots during World War II. A return to France in 1945 brought disillusionment.

Shortly before his death at Neuilly-sur-Seine on July 5, 1948, Bernanos completed the dialogues for a film scenario. This was a moving account of the attitude of 16 nuns martyred during the French Revolution, based on the story, *Die Letzte am Schafott,* by Gertrud von le Fort. In 1949 it was made into a play by Marcelle Tassencourt and Albert Béguin under the title *Dialogues des Carmélites* (Eng. trans., *The Fearless Heart,* 1952) and performed in 1952. An opera by Francis Poulenc, based on this work, was first performed in Milan in 1957. Béguin also edited *Georges Bernanos: Essais et témoignages inédits* (1949) and *Bernanos par lui-même* (1954; Eng. trans. of both, *Last Essays,* 1955).

BERNARD, SAINT (1090–1153), abbot of Clairvaux, mystic and reformer, was born either at Fontaines, Burgundy, the family seat near Dijon, or at Chbtillon-sur-Seine, where his family, members of the Burgundian nobility, also had a residence. A centuries-old tradition favours Fontaines. Timid and retiring, Bernard was marked out early by his parents for an ecclesiastical career and was accordingly sent, as soon as he was old enough, to be educated by the canons who served the church of St. Vorles at Chbtillon. There he became a literary genius of sorts (especially, one contemporary suggestion has it, in the composition of ribald verses) and more timid than ever. His studies would not seem to have progressed beyond the medieval trivium of grammar-rhetoric-dialectic, if indeed they progressed that far.

When he was 17 the death of his mother, Aleth, who earlier had been the chief influence upon his life, set in motion his long "conversion," as he called it. Eventually, becoming "conscious that my weak character needed a strong medicine," he considered joining a Benedictine monastery of an especially strict religious observance that had been founded recently at nearby Citeaux. But to his own natural repugnance for a life of such austerity there were added the persistent inducements of his friends to a life of pleasure and the urgings, no less persistent, of his relatives to a life of further study and ecclesiastical preferment. After four years of this, when he was at the very point of saying good-by before setting out for Germany and more studies, he abruptly resolved upon Citeaux. The opposition of his relatives and friends he overcame by simply persuading them, about 30 in number, to join Citeaux along with him. This astonishing ability of the shy, dedicated Bernard suddenly to transform intransigent opponents into enthusiastic followers remained with him almost to his dying day. After a period of six months in which he conducted, for them and for himself, a prefatory trial of the monastic mode of existence in his father's house at Châtillon, the strange and varied group presented itself at Citeaux. It included married men who, to follow Bernard, had foresworn their wives and their children; churchmen who, under the same powerful suasion, had abandoned their profitable benefices. And it embraced, it would seem, all his available relatives, two uncles, two cousins and four of his five brothers (the fifth, too young at the time, later also donned the Cistercian habit, as did his father, Tescelin). Small wonder that, as a contemporary chronicle attests, "mothers hid their sons and wives their husbands" from Bernard in those days. He was then 22 years old.

The period of his novitiate, April 1112 to June 1115, was one of extraordinary, self-imposed penances which in large part induced the ill-health which was to plague Bernard the rest of his days. In 1115 the abbot, Stephen Harding, put him at the head of 12 monks whom he sent to found an abbey at Clairvaux in Champagne. There, to the fatigues which the pioneering condition of the new foundation imposed upon his already debilitated physical condition, was added an acute psychic distress: Bernard found himself split between his aspirations for a solitary life, wholly given over to contemplation, and the duty of directing his fellow monks. At first he sought to heal the lesion by adjusting his religious duty to his private preference and drove his monks along the road he followed himself. Gradually, however, he acquired an attitude of greater patience and reserve, which, if it did not resolve his difficulty, made it possible for him to live with it and for others to live with him. It was a self-adjustment that stood him in good stead in his career as "the conscience of all Europe," which now opened before him.

It was within the monastic system itself that his influence was initially exercised. The Cistercian experiment (*see* CISTERCIANS), which upon his arrival at Citeaux seemed close to failing, took on

a new and vigorous life under his influence and grew rapidly into a far-flung order; before his death there were 338 monasteries with several hundred monks in each. But even more important than this numerical expansion was the development in depth which he effected by his writings chiefly sermons or treatises, such as *The Steps of Humility*, which were elaborations of original sermons. He, who had been so rigid, took as his constant theme liberty of spirit. the cherished. hard-won insight which is so luminously presented in his *Grace and Free Will,* and which dictated his response to Hugh of St. Victor ("Letter 77"): freedom of opinion in all matters not determined by faith. His unvarying centre of reference is Christ. whom he views with predilection as the Word. Indeed so marked is this orientation in the writings of Bernard that he has been credited. unjustifiably, with having originated Christocentrism in spirituality.

It is with even less warrant that Bernard has been termed the Marian doctor. Upon the salutary mediation of the Virgin hlary he expressed himself with more vigour, but with less exactitude, than had any previous monastic author. Texts in which he preaches on Mary justify neither by their number. their extent, their theological solidity nor their doctrinal originality the traditional appellation accorded him.

In all his preaching and writing Bernard had constant recourse to the Scriptures. His manner of doing so was of a singular effectiveness not only upon his intended auditors or readers but also upon the formation of an entire subsequent tradition of monastic theology. for he made no pretense at exegesis. His purpose, he declared, was "to penetrate hearts rather than to explain words." Apropos of the Bible, with the aid of the Bible, it was his own thought that he expressed. The perpetual relevancy of the aords of Scripture consists in this. each reader can use them as expressive of his enthusiasm or as bespeaking his own experience. Only by exception, when engaged in strictly dogmatic matters, does Bernard approach the scriptural text with an attempt at objectivity.

From the earliest years, his influence. quite against his will, began to extend beyond the confines of monasticism, and with increasing frequency he was drawn out of his solitude to act as peacemaker, reformer, judge. He took part in important ecclesiastical discussions, was adviser to papal legates and in 1128 was secretary of the Council of Troyes. But, aside from the eulogy which the council asked him to compose in praise of the Knights Templars as an aid to recruitment, and the initial draft of a rule of life for such military orders which he wrote at that time. his work was comparatively circumscribed and local With the election of two contenders to the papacy in 1130, however, he was drann fully into the public eye and for almost a quarter of a century all Europe became his parish

At the Council of Étampes, convoked by Louis VI of France to aid him in finding out whether it was Innocent II or Anacletus II who was the legitimate successor of Honorius II, Bernard began with the postulate (derived from Yves de Chartres) that such a problem is to be resolved. first and foremost, in terms of the personalities involved: the one who is the better man is the lawful pope. There was no doubt in his own mind who of the two in this instance was the better man. Anacletus had been a monk of that earlier community at Cluny which Bernard despised even more than he did the existing one; Anacletus was of Jewish origin and, as Bernard was to write later, "it would be an insult to Christ if the offspring of a Jew occupied the throne of Peter"; Anacletus was not the friend of Bernard's friend, Haimeric, who had engineered the election of Innocent. There was no doubt in the king's mind either when Bernard had finished and the council pronounced for Innocent. With the pronouncement Bernard assumed the task of convincing Europe. Unceasing correspondence, travel and deployment of his oratorical skills soon won over France. Germany and England. It was largely due to his own efforts that he was able to say of Innocent before long: *Pulsus urbe, ab orbe suscipitur,* "From Rome expelled, by the world he is accepted." But then, not uncharacteristically, he went on to use the felicitous and memorable formula as an argument in favour of the validity of Innocent's election By 1133 he was in a position to negotiate successfully with the emperor and the cities of Italy and so enter Rome with Innocent and see him precariously installed at the Lateran.

Then followed the years. crowded with politics. which forced from him the cry: "I have become a sort of modern chimera, neither a cleric nor a layman." All his political activities were marked by the same singleness of purpose and ambiguity of method that characterized his handling of the Anacletus incident: they differed merely in a heightened intenseness of activity. No one not actually pope. with the possible exception of Athanasius (*q.v.*), ever determined the policy and fortunes of the church so markedly as did Bernard in the last two decades of his life. Having confirmed one pope. in his *On Consideration* he undertook the instruction of another, Eugenius III. It was Bernard who put down the revolutions at Milan. in Lorraine, at Bamber, and brought the new antipope, Gregory (Victor IV), to his knees in repentance at Rome. He decided the agenda for councils. He desposed princes and replaced bishops. He fought Cluny, the greatest monastic federation the west had ever seen, and Peter Xbelard (*q.v.*), the most incisive mind the new dialectic had produced *(see* MYSTICISM: *Antidialectical).* In 1145 he sent Christendom on its second crusade. And all the while he was drawing to his abbey at Clairvaux and sending abroad throughout Europe a powerful elite that included a pope, cardinals. bishops and saints.

Historical opinion is not at one in its assessment of these turbulent decades and of the man who was at their centre. Most scholars, like the majority of his own contemporaries, have been inclined simply to bow before the manifest goodness and disinterestedness of Bernard and to inquire no further. Others have gone on to consider the highly specialized character of that disinterestedness. To all that fell within the perspective of Bernard's ideal of reform, he gave himself without a thought to his own reputation, physical discomfort or danger. To all who seemed to agree with him in that ideal he turned an astonishingly credulous ear. The upshot was an unhappy ability to believe—and precipitately to noise abroad—the very worst about ideals dissimilar to his own and about people other than his friends. And yet, it has also been felt, his sustained campaigns of personal vilification against Anacletus, the Cluniacs, Girard of Angoulème, Abelard, William of Tork and others, which served to distort the historical record of those years, can distort as well the figure of Bernard if divorced from the picture of him provided by his *Sermons on the Canticle of Canticles* of those same years: the timid. pain-racked saint, seated in the quiet eye of the continental hurricane he raised, speaking to his monks of the love of God. No chimera, St. Bernard was and remains a mystery.

He died at Clairvaux, Aug. 20, 1153, and was canonized in 1174. His feast day is Aug. 20. He was named a doctor of the church in 1830.

Most of St. Bernard's authentic works are to be found in J. P. Migne, *Patrologia Latina,* clxxxii–clxxxiii. English versions are found in G. Lewis, *St. Bernard On Consideration* (1908); E. G. Gardiner, *The Book of St. Bernard on the Love of God* (1915); a priest of Mount Meleray, *Works,* six volumes (1920–25); W. Williams. *Grace and Free Will* (1920), Of *Conversion* (1938); G. B. Burch, *The Steps of Humility* (1940); B. S. James, *Letters* (1953).

BIBLIOGRAPHY.—Four ancient lives are provided in J. P. Migne (ed.), *Patrologia Latina,* clxxxv, 225–550. Of the *Vita prima* (225–466), the chief source of information for the biographer, only hk. i (by William of St. Thierry), ii (by Arnold Bonneval), iii–v (by Geoffrey of Auxerre) were checked and approved by the bishops and abbots gathered at Clairvaux in 1155. The chronology of St. Bernard has been established by E. Vacandard in his *Vie de S. Bernard* (1895), the standard biography. Doctrine is emphasized in A. J. Luddy, *Life and Teachings oj St. Bernard* (1907); political activity in W. Williams, *St. Bernard of Clairvaux* (1935); and his personality in B. S. James, *Saint Bernard of Clairvaux* (1958). *See* also Etienne Gilson, *The Mystical Theology* of *St. Bernard* (Eng. trans., 1940). (E. O'B.)

BERNARD OF CHARTRES (d. *c.* 1130), French scholastic philosopher, described by John of Salisbury as *perfectissimus inter Platonicos nostri saeculi* ("the most consummate Platonist of our age"), was a distinguished member of the school of Chartres, being head of this school from 1114 to 1119 and chancellor of the cathedral of Chartres from 1119 to 1124. Bernard was deeply interested in the classics and was an extreme realist in the Platonic tradition. He divided being into three categories: (1) the supreme

and eternal reality, God; (2) matter created by God out of nothing; and (3) ideas, the eternal exemplars in the Divine Mind through which the individuals of the finite world are ever present to God. John of Salisbury, whose *Metalogicus* is the source of information on Bernard's teaching, states that Bernard tried to reconcile Plato and Aristotle. Gilbert de la Porrée (who succeeded him as head of the school) and William of Conches were his pupils.

BERNARD, CHARLES DE (PIERRE MARIE CHARLES BERNARD DU GRAIL DE LA VILLETTE) (1804–1850), French writer whose novels and short stories present vivid and amusing pictures of Parisian and provincial society during the reign of Louis-Philippe, was born in Besançon, Feb. 24. 1804. He studied law, became a journalist and, encouraged by his friend Balzac, settled in Paris and wrote stories for Legitimist newspapers. *Le Noeud Gordien* (1838) and *L'Écueil* (1842) contain his best *nouvelles;* his novels include *Gerfaut* (1838). *Les Ailes d'Icare* (1840) and *Un Homme sérieux* (1843). In *French Poets and Novelists* (1878) Henry James describes Bernard as "a second-rate genius." but one with "the lightness, the ease, the gaiety, the urbanity, the good taste, the good spirits, the discretion . . . that have traditionally marked the French character." He died at Neuilly, March 6, 1850.

BIBLIOGRAPHY.—Bernard's *Oeuvres*, 10 vol. (1854–55); *see* Thackeray's *Paris Sketch-Book* (1840); *G.* Saintsbury, "C. de Bernard," *Fortnightly Review*, no. cxxxviii (1878); J. S. van der Wal, *C. de Bernard* (1940).

BERNARD, CLAUDE (1813–1878), French physiologist, one of the greatest of the great 19th-century physiologists and teachers. was born on July 12, 1813, in the village of Saint-Julien near Villefranche. He received his early education in the Jesuit school of that town, and then proceeded to the college at Lyons, which, however, he soon left to become assistant in a druggist's shop. His leisure hours were devoted to the composition of a vaudeville comedy, *La Rose du Rhône;* and the success it achieved moved him to attempt a prose drama in five acts, *Arthur de Bretagne*. At the age of 21 he went to Paris, armed with this play and an introduction to Saint-Marc Girardin, but the critic urged him to take up the study of medicine, and in due course he became interne at the Hôtel-Dieu. He worked under the great physiologist François Magendie (*q.v.*), who was physician to the hospital, became his deputy in 1848 and in 1855 succeeded him as full professor. Some time previously he had been chosen the first occupant of the newly instituted chair of physiology at the Sorbonne. There no laboratory was provided for his use, but Louis Napoleon, after an interview with him in 1864, remedied the deficiency, at the same time building a laboratory at the natural history museum in the Jardin des Plantes, and establishing a professorship, which Bernard left the Sorbonne to accept in 1868—the year in which he was admitted a member of the institute. He died in Paris on Feb. 10, 1878, and was accorded a public funeral—an honour never before bestowed by France on a man of science.

Claude Bernard's first important work was on the functions of the pancreas gland, the juice of which he proved to be of great significance in the process of digestion. A second investigation (perhaps his most famous) was on the glycogenic function of the liver; in the course of this he was led to the conclusion, which threw light on the causation of diabetes, that the liver, in addition to secreting bile, is the seat of an "internal secretion," by which it prepares sugar at the expense of the elements of the blood passing through it. A third research resulted in the discovery of the vasomotor system. While engaged, about 1851, in examining the effects produced in the temperature of various parts of the body by section of the nerve or nerves belonging to them. he noticed that division of the cervical sympathetic gave rise to more active circulation and more forcible pulsation of the arteries in certain parts of the head, and a few months afterward he observed that electrical excitation of the upper portion of the divided nerve had the contrary effect. In this way he established the existence of vasomotor nerves—both vasodilator and vasoconstrictor. The study of the physiological action of poisons was also a favourite one with him, his attention being devoted in particular to curare and carbon monoxide gas.

The full exposition of his views, and even the statement of some of the original facts. can be found only in the 17 volumes of Bernard's published lectures. He also published *Introduction a la médecine expdrimentale* (1865) and *Physiologie générale* (1872).

An English *Life of Bernard*, by Sir Michael Foster, was published in London in 1899. A more extensive one was published in 1938 by J. M. D. Olmsted.

BERNARD, JACQUES (1658–1718), French ,Protestant minister and publicist, chiefly important for his continuation of influential periodicals begun by Jean le Clerc and Pierre Bayle (*qq.v.*). Born at Nyons, Dauphiné, Sept. 1, 1658, and educated in Geneva: he became a pastor at Ventesol in 1679. In 1685 he fled to Geneva. and thence to Holland, where he continued his ministry and also opened a school. He became an associate professor at Leyden in 1705, and full professor of philosophy in 1712. He died on April 27, 1718.

In 1691 Jean le Clerc, who was Bernard's cousin, asked him to edit some volumes of his *Bibliothèque universelle et historique*, and in 1699 he succeeded Bayle as editor of the *Nouvelles de la république des lettres*. He himself began another similar work. *Lettres historiques*, which was published by him from 1692 to 1698. and continued by others. He also wrote a short history of Europe (1686–88), a *Recueil de traités de paix . . . 536–1700* (1700), and works on Christian faith and practice. His style is laborious, but shows the vigour of a zealous preacher and propagandist.

BERNARD, JEAN JACQUES (1888–), French playwright, the chief representative of the "school of silence," or, more exactly, "the drama of the unexpressed!" exemplified particularly by *Martine* (1922), in which the spoken dialogue does not express the characters' real attitudes. He was born at Enghien, July 30, 1888, the son of the dramatist Tristan Bernard, and began writing plays before World War I. Unconscious jealousy forms the theme of two somewhat static dramas, *Le Feu qui reprend mal* (1921) and *Le Printemps des autres* (1924). In *L'Ame en peine* (1926) Bernard turned to mysticism: two characters who never meet feel a strange disquiet whenever they are in the same vicinity. *A la Recherche des coeurs* (1931) and *Jeanne de Pantin* (1933) show a partial return to traditional methods. Bernard's nondramatic writings include *Le Camp de la mort lente* (1944; Eng. trans., *The Camp* of *Slow Death*, 1945), a description of the German concentration camp at Compiègne in which he was interned as a Jew, and *Mon Ami le théâtre* (1958). A translation by J. L. Frith of five of Bernard's plays appeared under the title *The Sulky Fire* (1939).

See P. Blanchart, *Jean-Jacques Bernard* (1928); Map Daniels, *The French Drama of the Unspoken* (1953). (D. Ks.)

BERNARD, TRISTAN (real name PAUL) (1866–1947), French playwright and novelist, whose work is characterized by mocking humour and acute observation. was born at Besançon on Sept. 7, 1866. His plays range from one-act comedies like Le *Fardeau de la liberté* (1897) and *L'Anglais tel qu'on le parle* (1899) to full-length comedies of character, intrigue or manners, such as *Monsieur Codomat* (1907), *Le Cordon bleu* (1920) and *Jules, Juliette et Julien* (1929). The title of the comedy *La Volonté de l'homme* (1917, "The Will of Man") indicates his favourite theme, while *Triplepatte* (1905), written in collaboration with André Godfernaux, offers a representative incarnation of his favourite hero. Among his novels were *Les Mémoires d'un jeune homme rangé* (1899) and *La Féerie bourgeoise* (1924).

He died in Paris on Dec. 7, 1947.

See P. Blanchart, *Tristan Bernard: son oeuvre* (1932); Jean Jacques Bernard, *Mon Père Tristan Bernard* (1955). (D. Ks.)

BERNARDIN DE SAINT-PIERRE, JACQUES HENRI (1737–1814), French man of letters, author of *Paul et Virginie*, was a friend of Jean Jacques Rousseau (*q.v.*) and a precursor of romanticism. Born at Le Havre. Jan. 19, 1737, he was devoted in his childhood to the reading of travel tales, particularly *Robinson Crusoe*. He visited Martinique at the age of 12. Completing his education on his return to France, at Rouen, Caen and Paris (where he spent two years), he embarked on a military

career which took him to Germany, Malta, Holland and Russia. In 1768 he received an engineering appointment in Mauritius, where he had several sentimental adventures. In 1771 he returned to France and lived for some years in poverty. His description of Mauritius, *Voyage à l'fle de France,* two volumes (1773), opened his literary career. Meanwhile he had made the acquaintance of many writers of the day, most notably of Rousseau, whose close friend and disciple he became. This friendship did much to mold Bernardin's outlook. as is particularly evident in his *Études de la nature,* three volumes (1784), in which he combines a teleological discussion of the affinities between man and nature with highly poetic descriptions of natural beauty. To the third edition of the *Études* (1788) was appended *Paul et Virginie,* a novel and his most celebrated work, in which he realizes most successfully the declared aim of uniting to the beauty of nature in the tropics the moral beauty of a small society. In 1790 he published another exotic tale, *La Chaumière indienne.* He was twice married: in 1793 to Félicité Didot, who brought a substantial dowry, and after her death in 1800 to Désirée Pelleporc, then only 20, who survived him. He died at Éragny (Seine-et-Oise), Jan. 21. 1814.

See M. Souriau, *Bernardin de Saint-Pierre d'après ses manuscrits* (1905). Previous studies contain many inaccuracies and are to be treated with great reserve. (R T S)

BERNARDINO, SAINT, OF SIENA (1380–1444), Italian Franciscan theologian and preacher of great eloquence, was born at Massa Marittima on Sept. 8, 1380, of a noble family. Orphaned early, he completed his education and then served the sick in the hospitals of Siena, where he contracted and nearly died of plague In 1402 he entered the strict branch of the Franciscan order (the Observant) and with St. John of Capistrano (*q.v.*) became one of its chief promoters *(see* FRANCISCANS). Bernardino became a priest in 1404, but did not begin his preaching tours through Italy until 1417. Appalled by the breakdown in morals, the lawlessness and the civil strife which resulted from the Great Schism of the West, he strove to restore morals by inculcating a deep love of Jesus Christ, personalizing it through devotion to the name of Jesus. Lawlessness was to be curbed by insisting on the prestige of the papacy and of legitimate rulers. He took part in the Council of Florence in 1439, furthering the union of the Greek Church with the Roman. The centre of his movement was a small chapel in Rome, Il Gesù, later given to St. Ignatius of Loyola. Bernardino died at Aquila on May 20, 1444, and was canonized in 1450. His feast day is May 20.

Bernardino's *Opera omnia* were published in five volumes in 1950–56.

See Paul Thureau-Dangin, *The Life of St. Bernardino of Siena,* Eng. trans. by G. von Hügel (1909). (A. S. TR.)

BERNAUER, AGNES (d. 1435), daughter of an Augsburg baker, was secretly married about 1432 to Albert (1401–60), son of Ernest, duke of Bavaria-Munich. Ignorant of the marriage, Ernest urged his son to marry and reproached him with his connection with Agnes. Albert then declared she was his lawful wife; and subsequently, during his absence, she was seized by order of Duke Ernest and condemned to death for witchcraft. On Oct. 12, 1435, she was drowned in the Danube near Straubing. This story lived long in the memory of the people, and has afforded material for several dramas. Adolf Bottger, Christian Friedrich Hebbel and Otto Ludwig have each written a play entitled *Agnes Bernauer*

BERNBURG, a town in the district of Halle, in former Saxony-Anhalt *(see* ANHALT), Germany, lies on the Saale river about 50 km. (31 mi.) S. of Magdeburg by road. Pop. (1959 est.) 44,464 The castle, probably built in the 10th century. was later converted into a Renaissance-style château. It was the residence of the dukes when the town was the capital of the duchy of Anhalt-Bernburg. The *Autobahn* from Magdeburg to Halle passes the town. Bernburg produces salt, soda, paper, agricultural machinery and pharmaceutical products (serums). First mentioned in 961, it was important in the middle ages as it lay on an ancient trade route. Bernburg consisted of two almost completely separate and independent communities both of which acquired civic rights in 1278, extended in 1311 and 1366 on the pattern of the civic rights of Magdeburg (*q.v.*). The hill settlement (now called Bergstadt) was raised to the status of a town in 1457. The hill and valley towns have been united since 1825 and in 1871 Waldaus was incorporated in Bernburg. The town is built over salt and shell-lime deposits which began to be exploited commercially in the 19th century. In World War II Bernburg was captured by U.S forces in April 1945. Since it was in the zone of Russian occupation, the U.S. forces withdrew in July 1945, and Bernburg was included in the German Democratic Republic. (Ho. M.)

BERNE: *see* BERN.

BERNERS, JOHN BOURCHIER, 2ND BARON *(c.* 1469–1533), English translator of Jean Froissart's *Chronicle,* was born probably at Tharfield, Hertfordshire. He succeeded to his grandfather's title in 1474 and was knighted in 1477. He early began his active political and military career, and in 1484, having been involved in a premature attempt to make Henry Richmond (later Henry VII) king, was forced to flee to Brittany. He helped to suppress the 1497 Cornish rebellion in favour of the pretender Perkin Warbeck, and continued his military services to the Tudor dynasty during the French and Scottish campaigns of 1513.

Berners was also involved in the tortuous diplomacy supporting Henry VIII's alternative alliances with France and Spain. He acted as chamberlain to princess Mary on her marriage to Louis XII in 1514, and was present at the Field of Cloth of Gold. In 1518 he inaugurated conversations in Madrid which led ultimately to a Spanish treaty. His appointment in 1520 as deputy of Calais represented not advancement but an attempt to provide a stable income and terminate the loans he had been receiving from the crown since 1511. He held the post with an interval from 1526 to 1531 until his death on March 15, 1533.

His greatest work is the translation of Froissart's *Chronicle* (first printed in two volumes, 1523 and 1525), in which the style matches Froissart's own in its fresh and energetic simplicity. Berners' achievement in this respect approaches Sir Thomas Malory's in catching at the last moment for English prose the virtues of the best medieval narrative. With descriptive force and vivid dialogue Berners has helped to make permanently English Froissart's feeling for the glamour of medieval chivalry and for both the virtues and vices of medieval men. His *The Boke Huon de Bordeuxe* (1534?), a translation of the delightful French romance, has almost equal virtues, and the added distinction of introducing Oberon, king of the fairies, into English literature. Another translation, *Arthur of Lytell Brytane* (1555?) is duller.

Near the end of his life he translated two of the newly fashionable courtesy books: *The Castell of Love* (1540?) from Diego de San Pedro, and *The Golden Boke of Marcus Aurelius* (1535) from Antonio Guevara. This last was by far the most popular of his works. These two translations, like their originals, are written in the then new antithetical style (euphuism; *q.v.*) later perfected by John Lyly; *The Golden Boke* was one of the several sources of this style in England.

The best edition of Berners' translation of Froissart is by W. P. Ker, six volumes (1901–03), reprinted, eight volumes (1927–28). For Berners' life *see* Sir Sidney Lee's introduction to *Huon of Bordeuxe* (Early English Text society; 1882–87) and J. H. McQill, in the *Times Literary Supplement* (April 17, 1930). (D. S B.)

BERNHARD OF SAXE-WEIMAR (1604–1639), Protestant general during the Thirty Years' War. was born in Weimar on Aug. 16, 1604, the 11th son of the reigning duke. Without hereditary prospects. he tried to win a livelihood and, if possible, a principality in military service. From 1622 he fought under Palatine, Baden and Danish colours against the Roman Catholic and imperial forces and in 1631 joined Gustavus Adolphus, first as a colonel and from April 1632 as a general. After the battle of Breitenfeld he undertook successful raids into southern and western Germany. On the king's death in the battle of Liitzen (1632), Bernhard assumed command and decided the Swedish victory. Together with the Swedish general G. K Horn he invaded south Germany, acquired the duchy of Franconia (chiefly the bishoprics of Bamberg and Würzburg) as a Swedish fief (June 1633) and crowned his successes by the conquest of Regensburg (Nov. 1633), which contributed largely to Wallenstein's downfall In 1634, however, he

suffered severe reverses, largely because of his incessant, quarrels with Axel Oxenstierna and Horn who advocated a defensive warfare. the loss of Regensburg (July) and his and Horn's crushing defeat of Nördlingen (*q.v.*) at the hands of Ferdinand III and Matthias Gallas (September), for which Bernhard bears the main responsihility and which cost him his duchy of Franconia. By the treaty of St. Germain-en-Laye (Oct. 1635) Bernhard entered French service. and Richelieu promised him the duchy of Alsace as reward. A series of victories in Lorraine and the upper Khine valley against the imperial general Gallas and the Bavarian general Johann von Werth (whom he took prisoner, March 1638) culminated in the capture of Rheinfelden. Freiburg and (Nov. 1638) the key fortress of Breisach. thereby decisively breaking the Habsburg stranglehold on France. On the eve of a fresh campaign he suddenly died, probably of smallpox, at Neuenburg (between Breisach and Basel) on July 18, 1639. His conquests and his army were taken over by France.

See G. Droysen, *Bernhard von Weimar,* 2 vol. (1885); A. M. R. A. de Noailles, *Bernhard de Saxe-Weimar* (1908). (S. H. S.)

BERNHARDI, FRIEDRICH VON (1849–1930). German general and military writer whose work provoked much anti-German feeling in the years just before World War **I,** was born in St. Petersburg, Russia, on Nov. 22, 1849, his father being in the Prussian diplomatic service. He entered the Prussian army just before the Franco-German War (1870–71). From 1891 to 1894 he was German military attach6 in Bern, Switz., after which he joined the military history department in Berlin. In 1907–08 he was given command of the VII army corps and the rank of general of cavalry, but in 1909 he retired to become a military writer, and it was in this field that he became best known.

Bernhardi held the view that a European war was inevitable and that Germany must either conquer or go under. Consequently he advocated the policy of German armament up to the limit of the country's manhood and financial resources. This theory was explained in detail in his book *Deutschland und der nachste Krieg* (1912), which was translated into English and widely read in the English-speaking world, where it caused a great sensation and was responsible for the widespread belief in Germany's aggressive intentions. The German army officer Erich Ludendorff went so far as to suggest that its publication in English was a deliberate piece of British anti-German propaganda and declared that it would have been better if the book had never been written.

On the outbreak of war in 1914 Bernhardi emerged from retirement and served on the eastern front. In 1918 he was transferred to the western front and played a prominent part in the battle of Armentières.

Bernhardi appears to have been a very efficient officer, but one who shunned publicity. As an officer he was practically unknown among the public. but highly regarded in German military circles (Ludendorff described him as a born soldier inspired with an ardent love for his country). The most important of his later writings on military subjects was *Deutschlands Heldenkampf 1914–1918* (1921). Bernhardi died at Kunersdorf near Hirschberg in Silesia, on July 11, 1930. (C. N. B.)

BERNHARDT, SARAH (HENRIETTE ROSINE BERNARD) (1844–1923), French actress. was born in Paris in 1844; the exact date of her birth has been a subject of much controversy. She was baptized May 21, 1856. and brought up in a convent. At the age of 16 she entered the Conservatoire and after two years of studies made her debut at the Comédie Française on Aug. 11, 1862, in the title role of Racine's *Iphigénie en Aulide.* She attracted the attention of the most formidable critic. Francisque Sarcey, but after a few months she broke with the famous theatre. For a while she held an engagement at the Gymnase and subsequently appeared in an operetta at the Porte St. Martin. Early in Dec. 1866 she joined the Odéon, where she remained until July 1872. She had her first resounding success as the page Zanetto in François Coppée's *Le Passant* (1869). From that time she steadily increased her reputation. especially after her return to the Comédie Française in 1872, when she was given such parts as Racine's *Andromaque* (1873) and *Phèdre* (1874) as well as Doña Sol in Victor Hugo's *Hernani* (1877) and Queen Maria in his *Ruy Blas* (1879).

Mlle. Bernhardt appeared at the Gaiety theatre in London during the summer of 1879, discovering there that she could be successful on foreign soil, though Henry James refused to succumb to the charms of her picturesque artistic personality, calling her an "advertising genius" and "too American not to succeed in America." In 1880 she resigned from the Comédie and began a series of world tours that led her to England, Belgium, Denmark. the United States and Canada. At last she was the star in a company she had assembled. For her United States tour she included Dumas' *La Dame nux camélias* in her repertory. in which *Adrienne Lecouvreur* ranked second in popularity. She appeared in New York for the first time on Nov. 8, 1880, with a grandiose reception for which ingenious advertising had paved the way. She was to make eight more tours in the United States.

After conquering Russian audiences, Mlle. Bernhardt returned to Paris, where Sardou provided her with three parts that were to be her greatest successes: the title roles of *Fédora* (1882), *Théodora* (1884) and *La Toscn* (1887). The costume changed. but the victorious personality of the actress remained the same. In 1886 she performed in South America and in 1891 embarked on a world tour that led her across the Cnited States to Australia and Africa and brought her large financial profits. She assumed the management of the Théâtre de la Renaissance in 1893 but relinquished the house six years later because she associated it with bad luck. She then opened the Théâtre Sarah Bernhardt. where she acted her first *Hamlet;* she had played Musset's Florentine Hamlet in *Lorenznccio* and was to create still another "Hamlet," the duc de Reichstadt in Rostand's *L'Aiglon* (1900).

In 1905 Mlle. Bernhardt injured her knee in an accident, and ten years later her right leg had to be amputated; nevertheless, she toured America again in 1917. In 1922 she created her last part in Verneuil's *Régine Armand.* She died in Paris on March 26, 1923.

Mlle. Bernhardt had some talent as a sculptor, and she wrote a few dramatic trifles. In 1907 she published her memoirs, *Ma double vie.*

BERNI, FRANCESCO (1498–1535), Italian poet famous for his burlesque poems, was born in Lamporecchio (Tuscany) in 1498 and spent his early years in Florence. He went to Rome in the service of Cardinal da Bibbiena and of Bibbiena's nephew, Angelo Dovizi, then to Verona as secretary to the bishop, Giammatteo Ghiberti, and finally returned to Florence where he died, on May 26, 1535. Despite his ridicule of literary convention and of slavish imitation of Petrarch, he was himself essentially a "literary" writer and used his native language in a masterly way. His free version (*rifacimento*) in pure Tuscan of Boiardo's *Orlando Innamorato* is evidence of his literary ability. Two rustic farces in Tuscan dialect (*Catrina* and *Mogliazzo*) show his love for colourful words and lively expressions. The same characteristics are shown in his burlesque poems (sonnets and *capitoli,* or satires) most of which deal with trivial or obscene subjects; others, such as the sonnets against the popes Hadrian VI and Clement VII, are merely violent invectives. The best are those in which paradoxical exaggeration is developed for its own sake, such as the sonnet on the mule of Galeazzo Florimonte and the one on the beard of Domenico D'Ancona. Thanks to Berni, the old Italian tradition of burlesque and satirical poetry reached the dignity of a literary genre, called after him the *bernesco.*

BIBLIOGRAPHY.—His *Poesie e prose* mere ed. by E. Chiorboli (1934) and the *Orlando Innamorato rifatto* by S. Ferrari (1911); *see* also A. Sorrentino, *Francesco Berni, poeta della scapigliatura del Rinascimento* (1933). (G. A.)

BERNICIA, the northern of the two Anglo-Saxon kingdoms which were united in the kingdom of Northumbria (*q.v.*). It stretched northward from the river Tyne, ultimately reaching the Firth of Forth and beyond the Solway firth. It had a royal residence at Bamburgh and another at Yeavering, where excavation has revealed an impressive complex of buildings and a great wooden

structure like an amphitheatre. The first recorded king is Ida, whose accession is dated 547. His grandson Aethelfrith (*q.v.*), reigning from 593 to 616, united Bernicia and Deira (*q.v.*), and his successor, Edwin of Deira, ruled both kingdoms. These split apart on his death in 632, but from the accession of Aethelfrith's son Oswald in 633 kings of Bernicia ruled Deira also.

See Bede, *Historia Ecclesiastica,* bk. i, ch. 34, bk. ii, ch. 14, bk. iii, ch. 1–4, 6, 12, 16, bk. v, ch. 24; Nennius, *Historia Brittonum,* ed. by T. Mommsen (1894), ch. 63. (D. Wk.)

BERNINI, GIOVANNI LORENZO (1598–1680), Italian architect and sculptor, in whose works are found many of the greatest realizations of the tendencies of baroque art, was born at Naples on Dec. 7, 1598. After studying sculpture with his father, Bernini found a patron in Maffeo Barberini, later Pope Urban VIII, whose palace he designed. In statues such as the "David" (1623) or the "Apollo and Daphne" (1622–24) in the Borghese gallery, Rome, the beginning of the baroque manner can be seen. Its full development came in the Cornaro chapel in Santa Maria della Vittoria at Rome, where indirect theatrical lighting illuminates Bernini's sculpture of the "Ecstasy of St. Theresa" (1645–52). By amazing control of the techniques of carving Bernini was able to convey in marble the difference in the textures of flesh, silk, feathers and even clouds. Baroque interest in colour was dramatically presented with varicoloured marbles and gilded bronze in his tomb of Pope Urban VIII (1628–47) in St. Peter's at Rome. Among Bernini's works one of the finest was a bust of Louis XIV of France (1665) at Versailles in which the proud, dominating personality was magnificently expressed. The wonderful water displays of the outdoor fountains at Rome owe much to Bernini, who designed the fountain of the Triton (completed 1637) in the Piazza Barberini and the fountain of the Four Rivers (1648–51) in the Piazza Navona.

As an architect of St. Peter's in Rome Bernini added the great altar canopy (1624–33) over the tomb of St. Peter and the bronze chair of St. Peter (1657–66) dominating the west end of the church, but his finest architectural creation was the tremendous square in front of St. Peter's in which the arms of the colonnade seem to come out to embrace all visitors. Bernini's fame as an artist was so great that in 1665 he was invited by Louis XIV of France to come to Paris to design the palace of the Louvre, but nothing came of his architectural design. Other examples of his architecture are Sant'Andrea al Quirinale (1658–65) and the Palazzo Montecitorio (1650–55) in Rome and churches at Castel Gandolfo (1658–61) and Ariccia (1662–64). He died at Rome on Nov. 28, 1680.

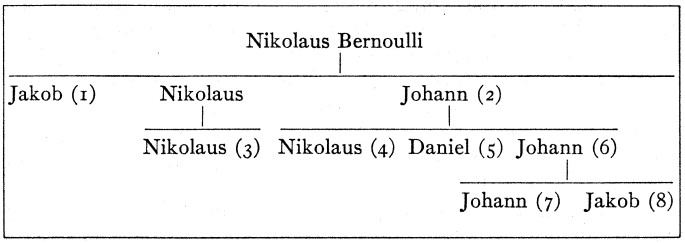
See R. Pane, *Bernini architetto* (1953); Rudolf Wittkower, *Gian Lorenzo Bernini, the Sculptor of the Roman Baroque* (1955) and *Art and Architecture in Italy, 1600 to 1750* (1958). (D. R. Cn.)

BERNIS, FRANÇOIS JOACHIM DE PIERRE DE (1715–1794), French statesman and cardinal who played an important part in the diplomatic revolution of 1756–57, in the suppression of the Society of Jesus by the papacy in 1773, and in the unsuccessful negotiations in 1790–91 between the French government and Pius VI for the recognition of the Constituent Assembly's ecclesiastical reforms. Born of aristocratic parentage, on May 22, 1715, at St. Marcel d'Ardèche, Bernis was trained for the church and did not become prominent in French politics until 1745, when he became a member of the entourage of Madame Le Normant, later known as Madame de Pompadour. Diplomatic experience acquired as ambassador to Venice between 1752 and 1755 and the favour of Madame de Pompadour caused his nomination as confidential and secret intermediary to discuss with the Austrian ambassador in Paris, G. A. von Starhemberg, Austria's proposals for a French alliance (Aug. 1755). Strongly supported by Louis XV himself, these negotiations led to the first, defensive, treaty of Versailles between France and Austria (May 1, 1756) and then to the second, offensive, treaty of Versailles (May 1, 1757). This alliance with France's old enemy and the abandonment of the former alliance with Prussia formed the diplomatic prelude to the Seven Years' War. Bernis held office as French foreign minister from June 27, 1757, until Dec. 1758, when his fall was precipitated by French military reverses, by his desire to reform the financial system and by the hostility of Madame de Pompadour. He became a cardinal in 1758 and archbishop of Albi in 1764. Though he used his influence with Pope Clement XIV to promote the suppression of the Jesuits, he exercised a moderating influence on French policy and did not approve of the drastic pressure exerted on the papacy by Charles III of Spain. Between 1769 and 1794 he acted as French ambassador to Rome. Hostile to the ecclesiastical reforms of the Revolution, which affected his status and income as a prelate, he was in touch with the French *émigré* princes and played an ambiguous part in helping to crystallize papal opposition to the Civil Constitution of the Clergy. He died at Rome on Nov. 3, 1794. There is an edition of his *Mémoires et lettres* by F. Masson, two volumes (1878).

See F. Masson, *Le Cardinal de Bernis depuis son ministère* (1884); Sir Marcus Cheke, *The Cardinal de Bernis* (1958). (A. Gn.)

BERNOULLI or Bernouilli, the name of a Swiss family of famous scientists and mathematicians, who made their home in Basel, Switz. In the following family tree the most distinguished mathematicians are indicated by numbers.



(1) Jakob (Jacques) Bernoulli (1654–1705) studied theology upon the insistence of his father. After six years of travel he returned to Basel, refused a church appointment and began lecturing on experimental physics. In 1687 he became professor of mathematics at the university; later he served as its rector. His first papers concern astronomy, particularly the motion of comets. Later he wrote on infinite series and their summation; the Bernoulli numbers are named for him. Upon the discovery of the infinitesimal calculus, Bernoulli entered into a correspondence with Leibniz and made important applications of the new theory. In his study of the isoperimetric problem he introduced the first principles of the calculus of variation. He examined many special curves, among them the lemniscate and the logarithmic spiral, using polar co-ordinates for the first time. He determined the catenary, the curve of a hanging chain and the isochrone, the curve along which a body falls with uniform vertical velocity. His *Ars Conjectandi* (published posthumously, 1713) was one of the pioneer works in the theory of probability (*see* also Bernoulli Numbers; Probability). His works were published as *Opera Jacobi Bernoullii,* 2 vol. (1744).

(2) Johann (Jean) Bernoulli (1667–1748), Jakob's younger brother, studied medicine and obtained his doctor's degree in Basel in 1694, with a thesis on muscular contraction. Like his brother, he became fascinated by the new mathematical calculus, which he applied to the determination of length and area of curves, to differential equations and to mechanical problems—for instance, the determination of the tautochrone curve, important in clock construction. This pendulum curve, which is a cycloid, is characterized by the property that the time of fall of a particle to the lowest point is independent of the amplitude. Marquis de l'Hôpital wrote the first text on calculus, *Analyse des infiniment petits* (1696), largely on the basis of lectures and letters from Johann Bernoulli; in return, the latter received a considerable pension from the marquis. The two Bernoulli brothers worked partly on the same problems; this gave rise to jealousy and even violent public feuds. Most bitter was the dispute over the brachystochrone problem, *i.e.,* the determination of the curve of most rapid descent of a particle under the influence of gravity; this curve is also a cycloid. In 1695, under the recommendation of Huygens, Johann was appointed professor at Groningen, Holland; after the death of

his brother he became his successor in Basel. During his last years he worked mainly on the principles of mechanics.

See *Opera Johannis Bernoullii,* 4 vol. (1742); and J. O. Fleckenstein, Johann *und* Jakob Bernoulli (*Kurze Mathematikerbiographien,* Heft 6, 1949). His correspondence with Leibniz appeased in 1745.

(3) NIKOLAUS (NICOLAUS) BERNOULLI (1687–1759), a nephew and pupil of Jakob and Johann, first studied law, then was professor of mathematics in Padua (1716–19). His works dealt with infinite series and probability. He returned to Basel to become professor of logic (1722), and of jurisprudence (1731j.

Johann Bernoulli had three sons who were mathematicians:

(4) NIKOLAUS BERNOULLI (1695–1726), eldest son of Johann, studied law and became professor in this subject in Bern at the age of 27. In order to devote his time to his real fancy, mathematics, he accepted a position at the Russian academy, but died shortly after his arrival in St. Petersburg.

(5) DAXIEL BERNOULLI (1700–1782), was the most distinguished of Johann's sons. He received his doctorate in medicine with a thesis on the action of the lungs. He spent seven years (1726–33) as mathematician at the Russian academy. Upon his return to Basel he was successively professor of botany, anatomy and natural philosophy. The prize of the French Academy was awarded him no less than ten times. His most important work is the *Hydrodynamica* (1738) dealing with the theory of statics and motion of fluids, with practical applications; *e.g.,* the propulsion of ships. Later he studied probability and its applications to statistics.

(6) JOHANN BERNOULLI (1710–1790), brother of Nikolaus and Daniel. was professor of rhetoric from 1738 until he became his father's successor to the chair of mathematics (1743). He received the prizes of the French Academy on three occasions. Among his numerous children may be mentioned:

(7) JOHANN BERNOULLI (1744–1807), doctor of law and later director for the observatory in Berlin.

(8) JAKOB BERNOULLI (1759–1789), who first studied law and then became professor of mathematics at the Russian academy. His works are related to those of his uncle and teacher. Daniel.

The first volume of the correspondence of the mathematicians Bernoulli, Der *Briefwechsel von* Johann Bernoulli, was published in 1955.

See also Eric *T.* Bell, *Men of Mathematics* (1937). (O. **OE.**)

BERNOULLI NUMBERS (BERNOULLIAN NUMBERS), an important sequence of rational numbers occurring in many branches of mathematics. first introduced by Jakob Bernoulli (*q.v.*) in a posthumous work Ars *Conjectandi* (1713). The nth Bernoulli number is usually denoted by the symbol B_n and the first few Bernoulli numbers are as follows: $B_0 = 1$, $B_1 = -\frac{1}{2}$, $B_2 = \frac{1}{6}$, $B_3 = 0$, $B_4 = -\frac{1}{30}$, $B_5 = 0$, $B_6 = \frac{1}{42}$, $B_7 = 0$, $B_8 = -\frac{1}{30}$, $B_9 = 0$, $B_{10} = \frac{5}{66}$.

The Bernoulli numbers of odd order: aside from B_1, are zero, while the Bernoulli numbers of even order, aside from B,, alternate in sign. For this reason some authors label the Bernoulli numbers somewhat differently, omitting $B_0, B_1, B_3, B_5, \ldots$ from consideration and writing B_k for the absolute value of B_{2k}.

Several simple definitions of Bernoulli numbers can be given. Each represents a different field of application and suggests generalizations in different directions. Historically the first of these, as given by Bernoulli himself, is

$$1^k + 2^k + 3^k + \cdots + (N-1)^k = \frac{1}{k+1}\left\{B_0 N^{k+1} + B_1\binom{k+1}{1}N^k + \cdots + B_k\binom{k+1}{k}N\right\} \quad (1)$$

$$\text{where } \binom{n}{m} = \frac{n!}{m!(n-m)!}$$

(If n is a positive whole number, the symbol n! denotes the product of the positive whole numbers from 1 up to n inclusive.)

A more common definition is the following symbolic one

$$B_n = (B+1)^n \quad (2)$$

where, after expanding the binomial, the exponents of B are degraded to subscripts; in this definition $n > 1$. Thus, for example, for $n = 4$

$$B_4 = (B+1)^4 = B^4 + 4B_3 + 6B_2 + 4B_1 + B_0$$

This does not determine B_4 but expresses B_3 in terms of earlier B's. This is the simplest of a host of recursion formulas which have been proposed for the calculation of the B's. Most of these may be derived from the general formula

$$f(x+B+1) - f(x+B) = f'(x)$$

where $f(x)$ is any polynomial or formal poner series. $f'(x)$ its derivative and nhere the above convention about powers of B holds. Any recursion formula expressing B,, in terms of previous B's may be used to express B_n as a determinant

Another common definition of B_n is by means of one of the generating functions

$$\frac{x}{e^x - 1} = \sum_{n=0}^{\infty}\frac{B_n x^n}{n!}, \quad x\cot x = \sum_{n=0}^{\infty}\frac{(-1)^n B_{2n}(2x)^{2n}}{(2n)!} \quad (3)$$

Another definition of B_n, this time as a direct formula, is

$$B_{2n} = \frac{2(-1)^{n-1}(2n)!}{(2\pi)^{2n}}\left(1 + \frac{1}{2^{2n}} + \frac{1}{3^{2n}} + \frac{1}{4^{2n}} + \cdots\right) \quad (4)$$

This striking result is due to Euler who thus made (in 1748) an independent discovery of Bernoulli numbers. It was used by S E. Serebrennikov in computing B_{184}. It also shows that although the early Bernoulli numbers are comparatively small, the numbers $|B_{2n}|$ tend to infinity with more than exponential rapidity. In fact for n large $|B_{2n}| = 4n^{2n}(\pi e)^{-2n}\sqrt{\pi n}$ (approximately).

Bernoulli Polynomials — Each of the above definitions of B_n is easily extended to an important polynomial of degree n usually denoted by $B_n(x)$ and introduced originally by Bernoulli. These definitions are, in order:

$$1^k + 2^k + 3^k + \ldots + (N-1)^k = \{B_{k+1}(N) - B_{k+1}(0)\}/(k+1) \quad (1')$$

$$(B+x)^n = B_n(x) \quad (2')$$

$$xe^{xt}/(e^x - 1) = \sum_{n=0}^{\infty} B_n(t)\, x^n/n! \quad (3')$$

$$B_n(x) = -2n!\sum_{m=1}^{\infty}(2\pi m)^{-n}\cos(2\pi m x - \tfrac{1}{2}\pi n) \quad (0 < x < 1) \quad (4')$$

An independent definition of $B_n(x)$ may be given by the relations:

$$B_0(x) = 1,\ B_n'(x) = nB_{n-1}(x) \text{ if } n > 0$$

$$\int_0^1 B_n(x)dx = \begin{cases} 1 \text{ if } n = 0 \\ 0 \text{ if } n > 0 \end{cases}$$

This gives in fact still another useful approach to Bernoulli numbers which may be defined now as $B_n = B_n(0)$. The first Bernoulli polynomials are:

$$B_0(x) = 1,\ B_1(x) = x - \tfrac{1}{2},\ B_2(x) = x^2 - x - \tfrac{1}{6}$$
$$B_3(x) = x^3 - \tfrac{3}{2}x^2 + \tfrac{1}{2}x,\ B_4(x) = x^4 - 2x^3 + x^2 - \tfrac{1}{30}$$

These polynomials $B_n(x)$ are possessed of a number of interesting and useful properties such as

$$B_n(x+1) - B_n(x), = nx^{n-1}$$
$$B_n(1-x) = (-1)^n B_n(x)$$

$$B_n(kx) = k^{n-1}\sum_{r=0}^{k-1} B_n\left(x + \frac{r}{k}\right)$$

If the function $f(x)$ can be expressed in a series of Bernoulli polynomials:

$$f(x) = \frac{C_0 B_0(x)}{0!} + \frac{C_1 B_1(x)}{1!} + \frac{C_2 B_2(x)}{2!} + \cdots$$

then the general coefficient C, is given by $\int_0^1 f^{(n)}(x)dx$. This statement is equivalent to the celebrated Euler-Maclaurin summa-

tion formula. *(See* CALCULUS OF DIFFERENCES.)

Arithmetical Properties of B_n.—These are the subject of numerous interesting but often difficult investigations. Some of these properties are still imperfectly understood. Perhaps the most famous number-theoretic property of B_n is the Von Staudt-Clausen theorem to the effect that

$$B_{2n} = A_n - \frac{1}{p_1} - \frac{1}{p_2} - \cdots - \frac{1}{p_k}$$

where A_n is an integer and $p_1, p_2, \ldots, p_k$ are those primes which exceed by 1 a divisor of 2n. For example

$$B_{12} = -\frac{691}{2730} = 1 - \frac{1}{2} - \frac{1}{3} - \frac{1}{5} - \frac{1}{7} - \frac{1}{13}$$

This striking theorem has many applications.

Bernoulli numbers occur in many problems in number theory, the most famous of which is Fermat's last theorem (*q.v.*). A theorem of E. E. Kummer states that if p is an odd prime not dividing the numerators of $B_2, B_4, \ldots, B_{p-3}$, then $x^p + y^p = z^p$ cannot be solved in positive integers x, y, z. Much of the 20th century work on Bernoulli numbers has been connected with Fermat's last theorem.

Tables of Bernoulli Numbers.—Many engineering handbooks, collected mathematical tables, and textbooks on infinite series have short tables of the first dozen Bernoulli numbers. These are sufficient for routine applications of these numbers. More extensive tables are needed for number theory work or for calculations of extreme accuracy. In spite of the great number of formulas proposed for calculating B_n only a few actual calculations have been made. These may be given the tabular description:

Name	Range of n in B_{2n}	Date
J. Bernoulli	1–5	1712
L. Euler	1–15	1781
Dr. Rothe	1–31	1840
J. C. Adams	1–62	1877
S. E. Serebrennikov	1–92	1905, 1907
D. H. Lehmer	91–110	1936

J. W. L. Glaisher has given a 10-place table of the common logarithms of B_{2n} for $n \leqq 250$ together with their natural values to nine significant figures. This table, which was computed from (4), has been reprinted by H. T. Davis who gives also values of $B_n(x) - B_n$ for $2 \leqq n \leqq 8$ and for $0 \leqq x \leqq 1$ at intervals of .01 to ten decimals.

BIBLIOGRAPHY.—H. T. Davis, *Tables of the Higher Mathematical Functions,* vol. 2 (1935), contains extensive tabular and bibliographical material on Bernoulli numbers. *See* also N. (D. H. LR.; P. T. B.)

BERNSTEIN, EDUARD (1850–1932), German Social Democratic propagandist, political theorist and historian, was born in Berlin on Jan. 6, 1850, of a lower-middle-class Jewish family, his father being an engine driver. Going to work in a bank at the age of 16, Bernstein was encouraged to pursue his early interest in politics by his uncle Aaron Bernstein. In 1872 Bernstein joined the Social Democratic party (founded at Eisenach in 1869), and in 1878, shortly before the promulgation of the anti-Socialist emergency laws, he became secretary to the Socialist philanthropist Karl Hochberg, in Switzerland. From 1881 to 1890 he was the senior editor of the *Sozialdemokrat* (the organ of the party during the period of the anti-Socialist legislation), which he published in Ziirich until 1888 and from then on in London.

Like many other Social Democrats, Bernstein was strongly influenced by the writings of the Berlin professor Eugen Duhring until Friedrich Engels' *Anti-Dühring* (1878) converted him to Marxism. During the '80s, together with his friend Karl Kautsky, he devoted his writings to the spreading of Marxist doctrines among German Social Democrats. His long exile in London (1888–1901) brought him into contact with the young Labour movement there and with the Fabian society. Meanwhile he enjoyed a close personal friendship with Engels until the latter's death in 1895.

Even Engels, in his introduction to a new edition of Marx's *Klassenkämpfe in Frankreich,* showed himself aware that new methods might be needed in the Socialist struggle under changed political and economic conditions, and such considerations formed the starting point of Bernstein's argument in the series of articles which he published, under the title "Probleme des Sozialismus," in the paper *Die Neue Zeit* from 1896 on (reprinted in 1901 under the title *Zur Geschichte und Theorie des Sozialismus*). These articles tended to the conclusion that Marxism could and should be revised, and Bernstein's divergence from Marxist orthodoxy became more pronounced with the publication of *Die Voraussetzungen des Sozialismus und die Aufgaben der Sozialdemokratie* (1899; Eng. trans., *Evolutionary Socialism,* 1909). According to Bernstein, Marx's theory of impoverishment and his thesis that the capitalist economy would, because of its intrinsic contradictions, inevitably collapse, had not been borne out by events. He therefore called on the Social Democrats to free themselves from stale revolutionary phraseology and to acknowledge themselves as a party of reform—"which in these days they in fact are." The consequences that he drew from the evident discrepancy between theory and practice let loose within the party disputes which raged for more than a decade.

Returned from exile. Bernstein was elected as member of the *Reichstag* for Breslau in 1902. He held this seat for four years and was again a member between 1912 and 1918 and between 1920 and 1928. Although reckoned as a leading member of his party's right wing, he joined the Independent Social Democratic party during World War I as a protest against the majority party's support of the war. He returned to the majority party, however, when revolution broke out in Germany. His strength of character, his warm humanity and his intellectual abilities, discernible in his many autobiographical writings, make Bernstein one of the most attractive personalities in his party's history. By nature he was inclined to the life of a scholar rather than to that of party leader and agitator. He died in Berlin on Dec. 18, 1932.

See P. Gay, *The Dilemma of Democratic Socialism* (1952).

(E. MA.)

BERNSTEIN, HENRY LEON GUSTAVE CHARLES (1876–1953), French playwright, who dominated the "boulevard" drama for nearly half a century, was born in Paris, Jan. 20, 1876. Beginning with quick-moving, violent dramas such as *La Rafale* (1905) and *Samson* (1907), he passed on, with Le *Secret* (1913), to a more psychological type of play stressing subconscious motivation. The influence of both Freud and Pirandello is obvious in *La Galerie des glaces* (1924) and other plays written in the 1920s, which also reflect the spiritual unrest of the times. Experimenting with dramatic form, Bernstein copied the technique of the film in *Mélo* (1929) and that of the novel in *Le Voyage* (1937). During 1900–50 he wrote 28 plays. He died in Paris, Nov. 27, 1953.

See Pierre Bathille, *Henry Bernstein* (1932). (D. Ks.)

BERNSTEIN, LEONARD (1918–), U.S. conductor and composer, whose brilliant accomplishments in both serious and popular music made him one of the most spectacular figures on the American scene. was born Aug. 25, 1918, in Lawrence, Mass. He studied composition under Walter Piston at Harvard university and, later, the piano with Isabelle Vengerova and conducting with Fritz Reiner at the Curtis Institute of Music, Philadelwhia. He perfected his conducting technique under Koussevitzky at the Berkshire Music Center at Tanglewood, Mass., in the summers of 1940 and 1941.

In 1943 Bernstein was appointed assistant conductor of the New York Philharmonic; his first signal success came on Nov. 14, 1943, when he was summoned unexpectedly to substitute for Bruno Walter, who was indisposed. His technical self-assurance under difficult circumstances and his interpretive excellence made an im-

mediate impression and marked the beginning of a brilliant career. He subsequently conducted the New York City Center orchestra (1945–47) and appeared as guest conductor in the United States, in Europe and in Israel. In 1958 Bernstein became permanent conductor of the New York Philharmonic, sometimes. as piano soloist, conducting from the keyboard. With this orchestra he made several international tours. in South and Central America (1958), in Europe, including the USSR (1959), and in Japan (1961). His popularity increased through his appearances on television in special programs not only as conductor and pianist but also as commentator and all-round entertainer.

Bernstein's spectacular success as conductor has somewhat obscured his position as a serious composer of norks in which he made a skilful use of diverse element5 ranging from Jewish liturgical themes, as in the *Jeremiah Symphony* (1942), to jazz rhythms, as in the *Age of Anxiety* (after W. H. Auden) for piano and orchestra (1949). He also wrote the score for the ballet *Fancy Free* (1944) and several musical comedies for Broadway, of which *West Side Story* (1957) became enormously popular. He published a collection of lectures, *The Joy of Music* (1959).

See D. Ewen, *Leonard Bernstein* (1960); J. Briggs, *Leonard Bernstein* (1961). (N. Sy.)

BERNSTORFF, ANDREAS PETER, Count vos (1735–1797), Danish statesman who maintained Denmark's neutrality during the last quarter of the 18th century, was born in Hanover on Aug. 28, 1735. His uncle, J. H. E. Bernstorff, sent him to German and Swiss universities, enabled him to travel in Italy, France, England and Holland and, in 1758, introduced him into the Danish foreign office. In 1767 Bernstorff was created count but was dismissed with his uncle in 1770 by order of Count Johann Struensee. the royal favourite under Christian VII of Denmark. After the fall of Struensee, Bernstorff returned to office as foreign minister and the director of the German chancery for Holstein-Gottorp, in 1773. His first officialact was to conclude his uncle's negotiations with Russia over Holstein-Gottorp *(see* Bernstorff, Johann Hartwig Ernst), by the signing of the exchange treaty with the grand duke Paul on June 1, 1773. There followed the treaty of alliance between Denmark and Russia of Aug. 12, 1773, which was partly defensive and partly aimed against Gustavus III of Sweden, and was a further continuation of his uncle's policy whose anti-Swedish nature Bernstorfi maintained for a time.

During the American Revolution Bernstorff inclined toward England despite the irritation in Denmark-Norway over Great Britain's assertion of her right to search for "contraband of war." In 1779 he favoured the triple alliance between Great Britain, Russia, and Denmark-Norway proposed by England to compel the Bourbon powers to accept peace terms, but this policy was unyieldingly opposed by the court which favoured the Russian chancellor Nikita Panin's proposal for an armed league of all the neutral powers to protect neutral shipping. This proposal was similar to one made by Bernstorff himself in Sept. 1778, but as now presented by Russia he rightly regarded it as directed exclusively against England. He acceded to it unwillingly (July 9, 1750) but had previously, on July 4, come to an agreement with England on what constituted "contraband of war"; on Nov. 13, however, Bernstorff was obliged to resign, it is thought by Frederick, the hereditary prince, who feared the Russian reaction to the agreement. Bernstorff retired to his Mecklenburg estates but was recalled to office in April 1784 after the fall of O. H. Guldberg. From then until his death, Bernstorff was the foreign minister in a moderate liberal government and beside his diplomatic activities did much for the liberation of the serfs. Moreover, he introduced in his own estates improvements which anticipated the agricultural reforms' of the next generation.

Meanwhile, as Bernstorff had predicted, the Russian neutrality project had resulted in a breach between Great Britain and Russia. During the Russo-Swedish War of 1788. Bernstorff took care that the assistance rendered to Russia under treaty obligations should be as trifling as possible, to avoid offending Great Britain and Prussia. On the outbreak of the French Revolution, Bernstorfi condemned on principle any interference in the domestic affairs of France, believing that Denmark's safest policy was to keep clear of every anti-French coalition. His neutrality treaty with Sweden (March 7, 1794), for protecting the merchant shipping of the two countries by combined squadrons, was valuable both commercially and politically. Bernstorff's great faculties appeared, indeed. to mature and increase with age. and his death on June 21, 1797, was regarded in Denmark as a national calamity.

See A. Friis, *A. P. Bernstorff og Ove Hoegh Guldberg* (1899), *Bernstorfferne og Danmark,* 2 vol. (1903–19); *Bernstorffske Papirer,* 3 vol. (1904–13). (F. Sk.)

BERNSTORFF, CHRISTIAN GÜNTHER, Count von (1769–1835), Danish and Prussian diplomat and an architect of the German customs union *(Zollverein).* The son of Count A. P. von Bernstorff, he was born in Copenhagen on April 3, 1769. He began his career in 1787 as an attaché to the Danish representative at the opening of the Swedish diet and by 1791 had become minister plenipotentiary at Stockholm. Ambassador at Stockholm from 1794 to May 1797, he was summoned to Copenhagen to act as substitute for his sick father on whose death (June 21) he succeeded as foreign minister, becoming a privy councilor in 1803.

In 1801 at the battle of Copenhagen and again in 1807 with the bombardment of the city and the capture of the Danish fleet, Denmark suffered from England's retaliatory measures against the second Armed Neutrality, and in May 1810 Bernstorff retired. In 1812 he was appointed Danish ambassador at Vienna and, probably in agreement with Metternich, strove to obtain favourable peace conditions for Denmark. He was present at the signature of the first peace of Paris (May 1814) and represented Denmark at the congress of Vienna where as a member for the commission on German affairs he was in part responsible for a further confusion of German and Danish interests in Schleswig and Holstein. In 1816 he was appointed Danish ambassador to Berlin and in 1818 at the invitation of Prince Mardenberg he entered the Prussian service.

Bernstorff attended the congress at Aix-la-Chapelle (Oct. 1818) as a Prussian diplomat and returned to Berlin as foreign minister. By nature opposed to the principles of the French Revolution, Bernstorff was initiated as a Prussian minister by the reactionary J. P. F. Ancillon. He is accused of having subordinated the interests of Prussia to the European policy of Metternich and the "Holy Alliance." But although he supported the Carlsbad decrees (1819), the Vienna Final act and Metternich's policy at the congresses of Laibach (Ljubljana, Yugos.), Troppau (Opava, Czech.) and Verona, he was also one of the founders of the *Zollverein* which became the basis of Prussian hegemony in Germany. He supported Russia's war against Turkey over the Greek question in 1828 and in the crisis of 1830 he did much to confine the troubles in Poland and Belgium to those countries. He resigned his ministry to Ancillon for reasons of health in 1832 and died at Berlin on March 28, 1835.

Bibliography.—H. von Treitschke, *Deutsche Geschichte,* Eng. trans. vol. iii, iv and v (1917–19); C. Ringhoffer, *Ein Dezennium preussischer Orientpolitik, 1821–30* (1897); Axel Linvald, *Kronprins Frederik og hans Regering 1797–1807* (1923); *Neue Deutsche Biographie,* vol. i (1955). (F. Sk.)

BERNSTORFF, JOHANN HARTWIG ERNST, Count von (1712–1772), Danish foreign minister and his country's leading statesman between 1751 and 1770, was born at Hanover on May 13, 1712, of an ancient Mecklenburg family. His father was chamberlain to the elector of Hanover but in 1733 Bernstorff was introduced into the Danish service by his relations C. A. and C. L. Plessen, ministers under Christian VI of Denmark, and served first as Danish envoy to the Saxon court. He remained in Germany until 1744 when he became ambassador in Paris. In 1751 he became foreign minister and for the next 19 years his opinion was decisive in the council of state of Denmark.

Bernstorff preserved Denmark's neutrality during the Seven Years' War despite treaty obligations to Prussia and the suspicions of England and Sweden, and on May 4, 1758, concluded a treaty with France whereby in return for Denmark's securing Hamburg, Liibeck and Gottorp from invasion for the duration of the war, France and later Austria agreed to support Denmark in its negotiations with Russia over Holstein. However, with the accession of Tsar Peter III and his declaration of war against Den-

mark in Jan. 1762, Denmark's allies deserted and Bernstorff was obliged to send a well-equipped Danish army into Mecklenburg. Peter III's overthrow in June 1762 removed the Russian threat and in March 1765 the empress Catherine II and the Danish king, Frederick V, came to a provisional agreement over the Holstein estates. Bernstorff achieved the ratification of a treaty in April 1767, when Catherine renounced her claims on Gottorp and undertook to persuade her son, the grand duke Paul, on his coming of age, to cede Gottorp in exchange for Oldenburg and Delmenhorst. For his part in the treaty, Bernstorff was created a count. As the reign of Christian VII (1766–1808) progressed Bernstorff's position became precarious. His last act was the treaty with Russia of Dec. 13, 1769, which stated that any change in the Swedish constitution would be regarded by Denmark and Russia as a *causus* belli against Sweden. On Sept. 15, 1770, Bernstorff was dismissed by order of Count Johann Struensee, the royal favourite, and retired to his Holstein estates, where he died on Feb. 18, 1772.

BEROSSUS (BEL-USUR?) (4th–3rd century B.C.), a Chaldean priest of Bel in Babylon, who wrote in Greek a work in three books describing the history and culture of Babylonia. This work has perished, but it was much used by later Greek compilers whose versions in turn were quoted by Eusebius, Abydenus, Josephus and others. Berossus is said to have migrated late in life to the island of Cos. where he founded a school of astronomy.

In his first book Berossus described the land of Babylonia, the bringing thither of civilization by the monster Oannes and other divinities coming out of the sea, and the story of the creation according to the native legend, which led to an account of Chaldean astrology. The second and third books contained the chronology and history of Babylonia and of later Assyria, beginning with the "ten kings before the Flood," then the story of the Flood itself, followed by the restoration of kingship with a long line of kings "after the Flood," then "five dynasties," and finally the late age of history under the Assyrians, the last Babylonian kingdom, and the Persians. Much of Berossus' account has been confirmed with the recovery of original literature in the cuneiform tablets. His scheme of chronology and history, though imperfectly preserved in quotations, has been elaborately investigated by modern scholars.

Lehmann-Haupt "Berossos" in *Reallexikon der Assyriologie* (1933). (C. J. G.)

BERRUGUETE, ALONSO (c. 1486–1561), Spanish sculptor, painter and architect, perhaps the most considerable artist of the Spanish Renaissance, was the son of the painter Pedro Berruguete. Alonso was born in Paredes de Nava about 1486. His paintings, if they are indeed correctly ascribed to him, were Italianate and Mannerist in style, and as an architect he was apparently merely the author of decorative retables and ornamental doorways. As a sculptor he was an able and indeed a favourite pupil of Michelangelo. He was a skilful wood carver. In his rather rich all-over delicate ornamentation he worked truly in the Spanish Plateresque style. In his figures he is a typical Mannerist. The retable of S. Benito in Valladolid is his first important work (1520) after his apprenticeship in Italy. Fragments from this altarpiece are now in the Museum of Valladolid. The carvings on the upper range of stalls (1539 ff.) in the Cathedral of Toledo are another good example of Berruguete's work and somewhat more moderated and classical in feeling. His last important commission and perhaps his masterpiece was the tomb of Cardinal Tavera in the Hospital de Afuera at Toledo. The recumbent figure alone, however, appears to be by his hand (1554–61). Berruguete died in Toledo at the end of Sept. 1561.

Alonso's father, PEDRO BERRUGUETE (fl. 1483–1503/4), was court painter to Ferdinand and Isabella. His major works were executed at Avila and Toledo.

See Ricardo de Orueta, *Berruguete y su obra* (1917). (A. K. McC.)

BERRY, the name of a family that acquired important properties in the newspaper and publishing business in England and large industrial interests in south Wales. There were three brothers, HENRY SEYMOUR BERRY (1877–1928), who was raised to the peerage as Lord Buckland; WILLIAM EWERT BERRY (1879–1954), created baronet in 1921 and Viscount Camrose in 1941; and JAMES GOMER BERRY (1883–), created baronet in 1928 and Viscount Kemsley in 1945. Lord Buckland, an industrial magnate. was chairman of Guest, Keen and Nettlefolds. William Ewert Berry founded the Advertising *World* in 1901, and thereafter he and James Gomer Berry worked together in acquiring large and important newspaper and publishing interests. Their holdings, which they divided in 1937, included the Sunday Times, Daily Telegraph, Financial *Times, Daily* Graphic, Kelly's directories, Cassell and Co., Ltd. (book publishers), the Amalgamated press and many provincial newspapers. Lord Kemsley became chairman of Allied Newspapers (the *Sunday Times* and the provincial groups), whose name was changed in 1943 to Kemsley Newspapers. In 1959 he retired and Kemsley Newspapers became Thomson Allied Newspapers. Ltd. (H. J. SG.)

BERRY, CHARLES FERDINAND DE BOURBON, DUC DE (1778–1820), a prince of the royal house of France, was born at Versailles on Jan. 24, 1778, the younger son of the comte d'Artois (afterward Charles X of France). Taken abroad by his father at the outbreak of the Revolution in 1789, he served in the prince de Condé's army from 1792 to 1797 and went with Condé to Russia, where the tsar Paul gave him a cavalry regiment. From 1801 to 1814, however, he lived in England. There he began a liaison with an Englishwoman, Emma (Amy) Brown, by whom he had two daughters (afterward baronne de Charette and comtesse de Faucigny-Lucinge). While much has been written on the question whether he married her or not, a judgment by the court of appeal at Chambéry (July 1. 1952) gives very cogent grounds for a negative answer. Returning to France in 1815. Berry retired to Ghent during the Hundred Days, but returned again to Paris at the second Restoration. On June 17, 1816, he was married to Caroline of the Two Sicilies (see below). On Feb. 13, 1820, as he was leaving the Paris opéra, he was mortally wounded by a saddler, Louis Pierre Louvel. He died next day. His and Caroline's daughter Louise (1819–64) later became duchess and regent of Parma. His posthumous son is known to history as the comte de Chambord (*q.v.*).

CAROLINE (Maria Carolina Ferdinanda Luisa; 1798–1870), duchesse de Berry from 1816, was born on Nov. 5, 1798, the eldest daughter of Francis I of the Two Sicilies. She followed Charles X into exile from France in 1830, but was determined to recover the throne for her son, then knonn as the duc de Bordeaux. From England she went to Italy, and she landed in France near Marseilles in April 1832. Receiving no support there, she made her way toward the loyal regions of Vendée and Brittany. Her followers were defeated, and after remaining concealed for five months in a house in Nantes she was betrayed and imprisoned at Blaye. There she gave birth to a daughter, allegedly the child of a secret marriage with an Italian count, Ettore Lucchesi-Palli (1806–64). Announcement of this marriage deprived the duchess of the sympathies of her supporters, and the French government released her in June 1833. She set sail for Sicily and, joining Lucchesi-Palli, lived in retirement until her death, at Brunsee, in Austria, on April 16, 1870.

BERRY, JEAN DE FRANCE, DUC DE (1340–1416), French prince distinguished for his political role in France in the middle period of the Hundred Years' War (*q.v.*), for his wealth and power as a territorial magnate, for his building and for his patronage of the arts, was born at Vincennes on Nov. 30, 1340, the third son of John II the Good, king of France, and Bonne of Luxembourg. Created count of Poitiers and of Macon in 1356, he was made king's lieutenant for Languedoc, Auvergne, Périgord and Poitou in 1358, during his father's captivity in England, thus

gaining control of one-third of France despite the opposition of the dauphin. In 1360 Berry and Auvergne were raised to the rank of duchies and granted to him in appanage by his father. When his brother had succeeded to the throne as Charles V, Berry exploited the resources of his lands for the defense of the kingdom, but taxed them so oppressively that after Charles's death riots broke out in the towns of Languedoc and the peasants there revolted (rising of the Tuchins, 1381–84). As a member of the regency council for the young Charles VI, Berry advocated peace with England. He negotiated with the duke of Lancaster (John of Gaunt), solicited papal mediation and caused the planned attack on England to be postponed. When conflict developed between his brother Louis, duc d'Orléans, and John the Fearless, duke of Burgundy, Berry shifted between them and. as captain general of Paris. arranged a precarious reconciliation (1405). Sole master of the government after the assassination of Louis and John's temporary withdrawal (Nov. 1407), Berry tried at first to keep on good terms with the Burgundians. but as his influence waned he changed over to the Armagnac side (April 1410). After being besieged in Bourges by the Burgundians in 1412, he resumed his role of mediator (peace of Auxerre, 1412; of Pontoise, 1413). (See FRANCE: History.)

Berry lived sumptuously and when he died, in Paris, on June 15, 1416, there was no money to pay for his funeral. He had spent fortunes on the treasures that remain as his monument—paintings. tapestries, jewelry and illuminated manuscripts. His book of hours, the *Très* riches *heures* in the Chantilly museum, is an excellent pictorial record of his magnificent residences.

By Jeanne of Armagnac (d. 1387), whom he had married in 1360. Berry had three sons and two daughters, one of whom, Bonne, was married first to Amadeus VII of Savoy, then to Bernard VII of Armagnac, who gave his name to the Orléans party. Berry's second marriage (1389) was to Jeanne de Boulogne, whose father he had despoiled.

Bred in the bitterness after the battle of Crécy and dying in the mourning that followed that of Agincourt, Berry lived in a period of great public misfortunes. Rapacious and sensuous, an oppressor of his subjects and thirsty for power at the expense of the crown, he was often lacking in courage and in sense of duty, but deserves credit at least for his unremitting efforts to restore peace and for his enlightened protection of the arts and artists.

(1901–31); J. d'Avout, La *Querelle* des Armagnacs et des *Bourguignons* (1943); A. de Champeaux and P. Gauchery, Les Travaux d'art *exécutés* pour Jean de France, *duc* de Berry (1894). (J. D'A.)

BERRY (BERRI), an old province of France, absorbed in 1790 into the *départements* of Cher (corresponding roughly to Haut-Berry), Indre (Bas-Berry) and to a lesser extent adjoining *départements*. Under the Romans the territory of the Bituriges Cubi (see **BITURIGES**) was incorporated in Aquitania, with Bourges (*q.v.*) as the capital of the province. The county passed to the Visigoths in 475, then to the Franks about 507. The first count of Berry, Chunibert (d. 763), was created by Waifer, duke of Aquitaine, from whom the country was wrested by Pepin the Short. Pepin made it his residence and left it to his son Carloman, on whose death it fell to his brother Charlemagne. The chief authority in Berry eventually passed to the viscounts of Bourges who, while recognizing the royal suzerainty, preserved a certain independence until 1101, when the viscount Odo Arpin de Dun sold his fief to the crown. Other powerful feudatories, however, regarded themselves primarily as vassals of Aquitaine, so that when Aquitaine passed to Henry II of England the possession of Berry became a matter of dispute between the French and English kings until 1200, when Berry reverted by treaty with John of England to Philip II Augustus of France and the various fiefs of Berry were given as a dowry to John's niece, Blanche of Castile, on her marriage with Philip's son Louis (afterward Louis VIII). Philip Augustus established an effective control over the administration of the province by the appointment of a royal *bailli*. John II made it a duchy for his third son (see BERRY. JEAN DE FRANCE, DUC DE) in 1360. Thenceforward it was held as an appanage of the French crown, usually by a member of the royal family closely related to the king. In 1601, on the death of Henry III's widow, Louise of Lorraine, the country was finally reabsorbed into the royal domain. The title duc de Berry was subsequently granted to Louis XIV's grandson Charles (1686–1714) and to Louis XVI's nephew Charles Ferdinand (1778–1820).

See Marcel Marion, *Histoire* du *Berry* et *du Bourbonnais* (1933).

BERRYER, PIERRE ANTOINE (1790–1868), French advocate and parliamentarian who won distinction both for his championship of legitimism and for his defense of the freedom of the press, was born in Paris on Jan. 4, 1790. Called to the bar in 1811, he was associated with his father, Pierre Nicolas Berryer, and with André Dupin in the defense at the trial of Marshal Michel Ney and alone defended Gen. Pierre Cambronne (1816), securing his acquittal. On many occasions he acted on behalf of those accused of infringing the press laws of the Restoration: in 1826 he successfully defended F. R. de Lamennais against a charge of atheism. A staunch royalist and a devout Roman Catholic, Berryer was in Jan. 1830 elected to parliament, where he displayed his great gifts as an orator. After the July revolution he was the only legitimist representative to he re-elected. In 1832 he tried to dissuade the duchesse de Berry from her attempt to raise a revolt in southern France. Arrested as an accomplice, he was brought to trial, but was acquitted. He then made a memorable speech in defense of Chateaubriand's conduct in the same affair. In 1840 he defended Louis Napoleon aiter the failure of the Boulogne conspiracy. After the revolution of 1848 he was a member of the constituent assembly, where he continued to fight for the legitimist cause. He strongly opposed the coup *d'état* of Dec. 2, 1851, which put a stop to his parliamentary career for 12 years. He continued, however, to practise at the bar. In 1855 he was elected to the Académie Française. In 1863 he entered the corps *législatif* as an opposition member, still faithful to his royalist principles. He died at Augerville, Loiret, on Nov. 29, 1868.

See C. de Lacombe, Vie de Berryer, 3 vol. (1894–95); P. Jacomet, *Berryer* au prdtoire (1938).

BERSAGLIERI, literally targeteers or marksmen, from *bersaglio*, "a target"; historically, the selected light infantry of the Italian army. Founded by Charles Albert in the old kingdom of Sardinia (Piedmont) under the inspiration of Alessandro Ferrero della Marmora in 1836, they played a worthy role in the campaigns of 1848 and 1849. By the Crimean War the corps was increased to ten battalions, and in the subsequent wars of the Risorgimento these troops distinguished themselves. Great emphasis was placed on their rigorous physical training and by 1914 they were famous not only for their beautiful plumed hats but also as some of the most rapid marchers in the world. After World War I the Bersaglieri were converted into cyclist units; after World War II they were mechanized and their function became that of armoured infantry. (H. M. SM.)

BERSERKER, in Scandinavian mythology, the name of the 12 sons of Berserk, grandson of the eight-handed Starkadder and Alfhilde (from the "sark" or shirt of bearskin worn by them). Berserk was famed for the reckless fury with which he fought, always going into battle without armour. In Old Norse the term "berserker" was later applied to the bodyguards of several of the Scandinavian heroes.

BERT, PAUL (1833–1886), French physiologist and politician who conducted important pioneer research into the effects of air pressure on humans, was born Oct. 17, 1833, at Auxerre, Yonne. He was appointed professor of physiology at Bordeaux in 1366 and at the Sorbonne in 1869. In 1878 he published La *Pression barométrique,* which has remained a classical work on the physiological effects of air pressure both above and below normal. This book was translated into English in 1943 and served as an important fundamental background for aviation medicine during World War II. Some of his earlier investigations were devoted to the grafting of animal tissues.

He was more distinguished as a scientist than as a politician or administrator. After being elected deputy from Yonne in 1872 he displayed leanings far to the left and anticlerical. In 1881–82 he was minister of education and welfare in Gambetta's short-

lived cabinet. In 1886 he was appointed governor-general in Annam and Tongking (Tonkin) and died of dysentery at Hanoi on Nov. 11 of that year.

See AVIATION MEDICINE. (E. B. BY.)

BERTANI, AGOSTINO (1812–1886), Italian patriot and social reformer, was born in Milan on Oct. 19, 1812. He took part in the March insurrection in Milan in 1848 and in the defense of Rome in 1849, when he organized the republicans' ambulance service. In Genoa, where he was working with Mazzini, he distinguished himself during the cholera epidemic of 1854. In the Austro-Sardinian War of 1859 he was a surgeon in Garibaldi's corps. In 1860 he was one of the organizers, with Garibaldi, of the March of the Thousand, but he disapproved of the annexation of the Two Sicilies before the occupation of Rome. On entering Naples (Sept. 1860), Garibaldi made Bertani his secretary-general, in which capacity he reorganized the police and planned the suppression of the religious orders and the sanitary reconstruction of the city. After the battle of Aspromonte (1862) he treated Garibaldi's wounds. In the war against Austria (1866), he organized the medical service for Garibaldi's 40,000, and in 1867 he fought at Mentana, although he disapproved of the march on Rome *(see* ITALY: *History).* Bertani had entered the Italian parliament in 1861 and became the leader of the extreme left in the chamber. In 1866 he founded *La Riforma,* a journal advocating social reforms. When the left took office in 1876, Bertani remained in opposition, disliking the *trasformismo* of Agostino Depretis. He died in Rome on April 10. 1886.

See Leopoldo Marchetti, *Bertani* (1948). (N. S. J.)

BERTAUT, JEAN (1552–1611), French poet, notable as a writer of polished light verse, was born probably at Donnay in 1552. As a young man he became tutor to the children of a noble family and accompanied his pupils to court. There he began to write poetry which shows the influence of both Ronsard and Philippe Desportes. He composed love lyrics and poems celebrating the events of court life, turning in his later work to religious themes. His *Recueil des oeuvres poétiques* was published in 1601, and *Recueil de quelques vers amoureux* appeared in the following year. Bertaut held various official positions including those of councilor of the parliament of Grenoble, almoner to the queen and abbot of Aunay. In 1606 he was appointed bishop of Séez in Normandy, where he died on June 8, 1611.

See G. Grente, *Jean Bertaut* (1903).

BERTHELOT, PHILIPPE JOSEPH LOUIS (1866–1934), French diplomat, son of the great chemist Pierre Eugene Marcelin Berthelot (*q.v.*), was born on Oct. 9, 1866, at Sèvres. He began his career in the diplomatic service in 1889 and went into the ministry of foreign affairs in 1904. He became assistant director in its politiçal and commercial department in 1913 and played an important part in the negotiations immediately preceding the outbreak of World War I. During that war he served as liaison officer between the Allied staffs. In 1919 he was promoted to he head of the political department of the ministry of foreign affairs. The next year he became its secretary-general, with the rank of ambassador. In 1921 he resigned, being accused of using his influence improperly in connection with the affairs of the Industrial Bank of China, of which his brother mas a director. Reappointed secretary-general by Edouard Herriot in 1925, he accompanied Aristide Briand to Locarno and to London and conducted negotiations with G. V. Chicherin for resuming Franco-Russian relations. From then until 1932 he virtually controlled the internal organization of the ministry, following a policy which he described as that of "close union with England and of *rapprochement* with Germany." He died on Nov. 22, 1934.

BERTHELOT, PIERRE EUGÈNE MARCELIN (1827–1907), one of France's most distinguished chemists of the 19th century, who made significant contributions in organic chemistry and thermochemistry. He also held a number of important political posts. Berthelot was born at Paris on Oct. 27, 1827. In 1851 he became a member of the staff of the Collège de France as assistant to A. J. Balard, his former teacher. He made a reputation by his doctoral thesis, *Sur les combinaisons de la glyckrine avec les acides,* which described a series of researches in continuation and amplification of M. E. Chevreul's classical work. In 1859 he was appointed professor of organic chemistry at the École Supérieure de Pharmacie, and in 1865 he accepted the new chair of organic chemistry, which was specially created for his benefit at the Collège de France. He became a member of the Academy of Medicine in 1863 and ten years afterward entered the Academy of Sciences, of which he became secretary in 1889 in succession to Louis Pasteur. He was appointed inspector-general of higher education in 1876, and after his election as life senator in 1881 he continued to take an active interest in educational questions, especially as affected by compulsory military service. In René Goblet's ministry of 1886–87 he was minister of public instruction, and in Léon Bourgeois's cabinet of 1895–96 he held the portfolio for foreign affairs. Berthelot died on March 18, 1907, at Paris.

He vigorously opposed the belief then generally accepted that the formation of organic substances requires the intervention of vital activity. His investigations on the synthesis of organic compounds were published in numerous papers and books, including *Chimie organique fondée sur la synthèse* (1860) and *Les Carbures d'hydrogdne* (1901). Again he held that chemical phenomena are not governed by any peculiar laws special to themselves but are explicable in terms of the genera1 laws of mechanics that are in operation throughout the universe; he developed this view, with the aid of thousands of experiments, in *Mécanique chimique* (1878) and *Thernzochimie* (1897). Berthelot invented the terms "exothermic" and "endothermic." He investigated explosives, and on the theoretical side arrived at the results published in his work *Sur la force de la poudre et des matikres explosives* (1872). On the practical side he was able to render important services to his country as president of the scientific defense committee during the siege of Paris in 1870–71 and subsequently as chief of the French explosives committee.

In 1883 he founded a botanical-chemical experiment station at Meudon, where he carried out many studies. He rediscovered the action of micro-organisms in the fixation of nitrogen in soils.

Berthelot's other works include: *Les Origines de l'alchimie* (1885); *Introduction à l'étude de la chimie des anciens et du moyen âge* (1889); translations of various old Greek, Syriac and Arabic treatises on alchemy and chemistry *(Collection des anciens alclzimistes grecs,* 1887–88, and *La Chimie au moyen age,* 1893); *Chimie animale* (1899); *Science et philosophie* (1886); *La Révolution chimique, Lavoisier* (1890); *Science et morale* (1897), and numerous articles in *La Grande Encyclopédie,* which he helped to establish. (R. E. O.; X.)

BERTHIER, LOUIS ALEXANDRE, PRINCE DE WAGRAM (1753–1815), French soldier, the first of Napoleon's marshals, chief of staff in the Grande Armée and sovereign prince of Neuchâtel, was born Nov. 20, 1753, at Versailles, the son of the court works surveyor, who was ennobled in 1756. Entering the army in 1770, he served during the American Revolution. In the French Revolution, being thoroughly trained as a survey and staff officer, he was chief of staff in one short-lived command after another in 1791–92, but was dismissed in Aug. 1792 because of his association with La Fayette. Requisitioned against the royalists in western France in March 1793, he was removed as a noble after four months' hard and dangerous service. He reappeared, however, as general of division and chief of staff in the army of the Alps and of Italy, first under F. C. Kellermann (1795), then under Napoleon Bonaparte (1796–97). A short, stout man who worked and rode untiringly and remembered what he was told, he was the perfect assistant to Napoleon. Commanding in Italy, he had to occupy Rome in Feb. 1798, but was with his chief again in Egypt.

Minister of war after the *coup d'état* of 18 Brumaire, commander in chief (with the first consul at his side) at the battle of Marengo, minister of war again (until 1807), Berthier was made marshal in 1804. In the Grande Armée from 1805 he was major-général (chief of staff) with a staff of six generals and eight colonels. This staff, executive rather than advisory, was the machinery of Napoleon's armies, and Berthier's fame rests on it. He said that he himself was "nothing," only the man who signed

the orders; but other marshals, especially when reprimanded, did not regard him as so impersonal, and the increase in the powers of the staff did not reduce friction between him and them. In 1806 Napoleon made him sovereign prince of Neuchâtel, declaring him to be "the man who has served me longest and has never failed me." In 1808 he married the duchess Marie, of the Bavarian Zweibrücken line. In 1809 he was given the French title of prince de Wagram.

Berthier seldom played a distinguishing role in Napoleon's battles. In 1809 he was for a week alone in command on the Danube while the Austrians developed their offensive, and he could not alter the prescribed dispositions even when the emperor's first plan was being falsified by events. It is hard to say what his influence was: reprimands and angry scenes became more .frequent. and in Russia in 1812 he was more often silent. Yet at the end of the retreat from Russia and after Napoleon had gone he struggled devotedly to keep some kind of order in the army. After Napoleon's abdication he submitted to Louis XVIII and, as captain of his guards, escorted him out of France when Napoleon returned He then joined his wife in Bavaria and they were at Bamberg when on June 1, 1815. Berthier fell from a window and died, while Russian cavalry were passing through the town. There were stories of suicide or murder; the accident was probably due to illness.

See NAPOLEONIC CAMPAIGNS.

See V. B. Derrécagaix, *Le Maréchal Berthier,* 2 vol. (1904–05); S. J. Watson, *By Command of the Emperor* (1957). (I. D. E.)

BERTHOLD VON HENNEBERG (1442–1504), elector and archbishop of Mainz, son of George, count of Henneberg, was made archbishop of Mainz in 1484. He was an enemy of clerical abuses and a careful administrator of his diocese. As archbishop he began to play a leading role in the empire and in 1486 was very active in securing the election of Maximilian I as Roman king Under the emperor Frederick III he had brought the question of administrative reform before the diet, and after Frederick's death (1493), when he became imperial chancellor, he led the party which pressed the need for reform upon hlaximilian at the diet of Worms in 1495. He continued the struggle and gained a temporary victory when the diet of Augsburg in 1500 established a council of regency (Reiclzsregiment). But while Berthold aimed at reform on the basis of an aristocratic council, Maximilian was intent upon re-establishing royal authority. In 1502 Maximilian dissolved the Reiclzsregiment, and Berthold's attempts to persuade the electors to form a union to uphold the reforms of 1495 and 1500 were of no effect. Berthold died on Dec. 21, 1504. His ideas for an ordered and united Germany were visionary but his methods conservative, and it was his tragedy to live in an age when the idea of a strong monarchy was everywhere triumphing.

See J. Weiss, *Berthold von Henneberg, Erzbischof von Mainz* (1889); E. Ziehen, *Mzttelrhein und Reich im Zeitalter der Reichs-reform 1356–1504,* 2 vol. (1934–37). (A. LH.)

BERTHOLET, ALFRED (1868–1951), Swiss Protestant Old Testament scholar, who also wrote on the phenomenology of religion, was born on Nov. 9, 1868, in Basel, Switz. After serving as pastor of the German-Dutch church at Leghorn (Livorno) for 18 months he took his doctorate in Basel (1895) where he became Privatdocent (1896) and then professor (1899). Later he was made professor in Tiibingen (1913), Gottingen (1914) and Berlin (1928–39). He died at bliinsterlingen on Aug. 24, 1951.

Bertholet's uork was dominated by a delight in the individual facets of religious experience, historical interests taking second place. This is already evident in his doctoral thesis, Die *Stellung* der *Israeliten* und der Juden *zu* den *Fremden* (1896) and in his Kulturgeschiclzte *Israels* (1919; Eng. trans. 1926). In spite of this, or perhaps because of it, his Apokryphen und *Pseudepigraphen* (1906) was an important contribution to Jewish literary history. and the second volume of *Biblische* Theologie (1911), conceived as a history of Old Testament religion, broke new ground. His works on the history of religion, such as *Dynamismus und Personalismus* in der *Seelenauffassung* (1930). Gotterspaltung und Gottervereinigung (1933) and Das Geschlecht der *Gottheit* (1934), also are marked by immense care in the collection of material and by the skill with which problems are laid bare and solutions to them offered.

See L. Rost in *Theologische Literaturzeitung,* vol. *77* (1952); A. Staehelin (ed.), *Professoren der Universität Basel* (1960). (H. P. RU.)

BERTHOLLET, CLAUDE LOUIS (1748–1822), French chemist, was notable for being the first to claim that chemical reactions depend in part upon the masses of the reacting substances, thus coming close to formulating the law of mass action. However, he incorrectly concluded that elements unite in all proportions and published analyses to this effect. A controversy with Joseph Louis Proust over these claims led to the establishment of the law of definite proportions.

Berthollet was born at Talloires, near Annecy, Savoy, on Dec. 9, 1748. In early life he became associated with Antoine Lavoisier in the reform of chemical nomenclature. He disagreed with Lavoisier's idea that oxygen was an essential element in all acids: although he considered himself of the school of Lavoisier. His principal service to industry was the introduction of chlorine as a bleaching agent. He regarded chlorine not as an element but as oxygenated muriatic (hydrochloric) acid. In practical researches undertaken during the Napoleonic wars he determined how to obtain iron from ore and convert it into steel. His preparation of potassium chlorate did not provide the substitute for imported saltpetre for use in gunpowder that he intended but did make possible coloured fireworks (*q.v.*).

His career was varied and distinguished. Educated in medicine at Turin, he became physician in the household of the duc d'Orléans and spent much of his time in chemical research. During the French Revolution he served on many scientific committees, and in 1792 he became a commissioner of the national mint. In 1794 he was appointed commissioner of agriculture and professor at the polytechnic and normal schools. In 179j he was active in reorganizing the academy as the Institut National; the following year he and Gaspard Monge were chosen chieis of a commission sent to Italy to select the choicest specimens of ancient and modern art for the national galleries of Paris. He instructed Napoleon in chemistry and accompanied him on his expedition to Egypt in 1798. There he joined with scientific associates in forming the Institute of Egypt modeled on the Institut National, and first presented his ideas on the laws of chemical affinity later published in his book Essai de Statique *Chimie.*

On the fall of the Directory he became a senator and a grand officer of the Légion d'Honneur; under the empire he became a count. After the Restoration he took his seat as a peer. Ultimately he retired to Arcueil where he maintained a laboratory and sponsored meetings of distinguished scientists, whose discussions were published between 1807 and 1817 as the *Mémoires* de la *société d'Arcueil.* Berthollet died on Nov. 6, 1822, and was buried at Arcueil, where a statue was later erected.

Berthollet was forward looking; his disputes with Lavoisier and with Proust had a clarifying effect upon chemical theory that has earned him a prominent place in chemical history.

BERTILLON, ALPHONSE (1853–1914), French anthropometrist, who invented the system of criminal identification known as Bertillonage described in his La *Photographie judiciaire* (1890), was born on April 23. 1853, in Paris. His system involved recording of bodily measurements and photographs. and was used in France and many other countries until superseded by the introduction of fingerprinting (see INVESTIGATION, CRIMINAL: Identification). He was appointed in 1854 to report on the handwriting evidence in the Dreyfus case, and was a witness for the prosecution before the court of appeal on Jan. 18, 1899. He died on Feb. 13, 1914, in Paris.

See R. W. McClaughay, *The Bertillon System of Identification* (1906).

Lor-IS ADOLPHE BERTILLON (1821–1883), a statistician and the father of Alphonse, was born on April 1, 1821, in Paris. A doctor

by profession. he was one of the founders of the school of anthropology of Paris and was appointed professor of demography there in 1876; he also was director of the statistical office of Paris. His principal work was *Démographie figurée de la France* (18'74). He died on Feb. 28, 1883, at Neuilly.

JACQUES BERTILLON (1851–1922). brother of Alphonse and a statistician, was born on Xov. 11, 1851, in Paris. He was principal of the office of statistics, and in 1885 the director of the "Annales de Démographie." He wrote *La Statistique humaine en France* (1880). He died on July 7. 1922.

BERTOLD VON REGENSBURG (*c.* 1220–1272), Franciscan preacher, was a native of Regensburg (Ratisbon). From about 1250 onward his fame as a preacher spread over all Germany, for the earnestness and straightforward eloquence with which he insisted that true repentance came from the heart, that pious pilgrimages and absolution mere mere outward symbols, appealed to all classes. He died in Regensburg in Dec. 1272.

His German sermons, which reflect the life of the people, form the chief monuments of Middle High German prose; his Latin ones are written in a clear and direct style. The former were edited by F. Pfeiffer and J. Strobl (2 vol., 1862–80, reprinted 1906) and also esist in a modern German version by F. Göbel (4th ed., 1906); the latter were edited by G. Jakob (1880).

BERTRAND, HENRI GRATPEN, COMTE (1773–1844), French military engineer, the friend and confidant of Napoleon I and his most faithful companion in exile, was born at Châteauroux on March 28, 1773. He entered the army in 1792 as an engineer. After service in Italy (1797), where he first met Napoleon Bonaparte. he n-as sent on the expedition to Egypt, where he was wounded at the battle of Abukir and directed the fortification of Alexsndria. being promoted brigadier general in 1800. Appointed aide-de-camp to Napoleon in 1804, he distinguished himself during the Austrian campaign. Promoted general of division in 1807, he was created *comte* in 1808. The bridges that he constructed for the French crossing of the Danube at Wagram in 1809 were described by Napoleon as the finest work since the Romans. Appointed grand marshal of the palace in 1813, he subsequently accompanied Napoleon to Elba and to St. Helena, where he shared his captivity for six years. The secret diary that he kept during this period. with its frank account of Napoleon's character and life in exile, is an invaluable document. After Napoleon's death in 1821 Bertrand returned to France, where the death sentence that had been passed on him *in absentia* in 1816 was annulled. He was elected deputy for Châteauroux in 1831. In 1840 he accompanied the prince de Joinville to St. Helena to bring Napoleon's body back to France. He died at Chdteauroux on Jan. 31, 1844. In 1847 his remains were transferred to the crypt of the Invalides in Paris. His diary was deciphered and annotated by P. Fleuriot de Langle and published by him as *Cahiers de Sainte-Hélène,* 1816–21, three volumes (1949–59; Eng. trans. of vol. iii by F. Hume, *Napoleon at St. Nelena,* 1952).

See J. de Vasson, *Le Grand Maréchal de Ste. Hélène* (1935).

(P. F. DE L.)

BERTRAND, JACQUES LOUIS NAPOLEON (ALOYSIUS) (1807–1841), French writer, whose *Gaspard de la nuit,* dealing with medieval Dijon! introduced the prose-poem into French literature and inspired the Symbolists. Born in Ceva, Piedmont, on April 20, 1807, he is associated with Dijon, where his family lived after 1815 and where he was educated. It was as a member of the Société d'Études that he collected the historical material on Burgundy used in his early poems (*Volupté*) and in *Gaspard de la nuit.* In 1828 he became manager of the local paper. *Le Provincial,* and his contributions to it were favourably noticed by Charles Nodier, Victor Hugo and C. A. Sainte-Beuve. This enabled him to go to Paris, where he is heard of at the *salon* of Joseph Delorme. Sainte-Beuve, to whom he showed some of his prose-poems, encouraged him, but, unable to find congenial employment, he returned to Dijon, where he wrote for *Le Spectateur* until its suspension under the ordonnances of Charles X. After the revolution of 1830 he edited the revolutionary *Le Patriote de la Côte d'or,* until 1833 when, finding that his political activities made it impossible to remain, he returned to Paris. He struggled against poverty and ill-health, trying to live by casual journalism. In 1836 he sold *Gaspard de la nuit,* but taste was returning to classical inspiration and the publisher lost interest in it. When it was obvious that Bertrand had not long to live, his close friends—the sculptor David D'Angers and Sainte-Beuve—attempted to get it published, but he died of tuberculosis, aggravated by starvation, on April 29, 1841, and it did not appear until 1842. It aroused little interest but at the end of the century, during the Symbolist movement. it came into its own. Its admirers included Mallarmé, Ravel, whose pianoforte suite, *Gaspard de la nuit,* was inspired by it, and Baudelaire. Bertrand described his prose-poems as *"fantaisies à la manière de Rembrandt et de Callot,"* saying that he had tried to create a new form of poetry in rhythmic and picturesque prose. Many of them reach a high standard of artistry and originality, and Baudelaire, in the preface to his own prose-poems, *Spleen de Paris,* declared that he had wished to attempt for modern Paris what Bertrand had achieved for medieval Dijon.

See C. Sprietsma, *Louis Bertrand dit Aloysius Bertrand* (1926).

(E. ST.)

BERTRAND, LOUIS MARIE EMILE (1866–1941), French writer of novels and travel books mostly about North Africa. was born at Spincourt, Meuse, March 20, 1866. Educated at the École Normale Supérieure, he taught classics, spending nine years in Algiers. In 1926 he became a member of the Académie Française. His books express his preference for the Christian and Latin rather than the Muslim and Arab traditions of North Africa: through studying Spanish and North African religious history he regained his lost Catholic faith. His novels include *Le Sang des races* (1899), a study of the French pioneers in Algeria; other works are *Le Livre de la Méditerranée* (1911), *Saint Augustin* (1913). *Les Villes d' or* (1921), *Les Martyrs Africains* (1930), *Histoire d' Espagne* (1932, Eng. trans. 1934, 1952) and *Le Livre de consolation* (1933). He died at Cap d' Antibes, Dec. 6, 1941.

See Maurice Ricord, *Louis Bertrand l' Africain* (1947).

BERTRAND, MARCEL ALEXANDRE (1847–1907), French geologist who pioneered in the study of rock structures resulting from deformation of the earth's crust, was horn in Paris on July 2, 1847. He was educated at the École Polytechnique and École Nationale Supdrieure des Mines, where he became instructor and professor. During summers he carried on field work for the French geological survey. Several seasons in the Jura mountains made Bertrand familiar with relatively uniform symmetrical folds. Transferred to Provence, he proved the existence of overturned folds and thrust faults, modified by later compression which produced thrusts of great extent, often called sheets or nappes. In the cool basin of northern France he traced equally great thrust faults of post-Carboniferous age. His publications on these structures established modern tectonic research, especially in regions such as the Alps (*q.v.*).

In 1896 Bertrand wrote the preface to the French edition of Eduard Suess's *Das Antlitz der Erde* and became a member of the Acaddmie des Sciences. Despite the significance of his work he produced few papers and no long ones; his chief influence was exercised through students. He died in Paris on Feb. 13, 1907.

(M. A. F.; C. L. FE.)

BÉRULLE, PIERRE DE (1575–1629), French cardinal and statesman, founder of the Oratory in France and one of the most important figures in French spiritual life in the 17th century, was born at Cérilly near Troyes on Feb. 4, 1575. He studied theology at the Collège de Clermont and at the Sorbonne. Prompted by his cousin Madame Acarie (Barbe Avrillot), the mystic whose house was the centre of the Catholic revival in France and who introduced him to the Carthusian Richard Beaucousin, to the Capuchin Benedict Canfield and to François de Sales, he went to Spain in 1604 and thence, after difficult negotiations, brought back the seven nuns who were to establish the Order of the Discalced Carmelites in France. Bérulle then became the official visitor of their monasteries, 30 of which had been founded by the time of his death. His main purpose, however, was to reform the clergy, and his greatest achievement was the foundation of the

Oratory (1611). This congregation of priests, who were bound only by an annual engagement, played an important part in the foundation of new seminaries. in the improvement of preaching, in the promotion of theological studies and also in education.

Bérulle always took a great interest in political affairs. At first his relations with Richelieu were excellent, but very soon he found himself in opposition to Richelieu's anti-Spanish policy and appears to have tried to prevent his being promoted cardinal in 1622. For some time, however, no rupture occurred between them. In 1624 Richelieu sent him to Rome to obtain the papal dispensation for the marriage of the French princess Henrietta Maria to the future Charles I of England; and in 1625 Bérulle accompanied the young queen to England. Returning to France, he kept up a correspondence with Henrietta Maria, encouraging her to be intransigent on religious matters—advice that was not in accordance with Richelieu's policy. His negotiations with the Spaniards about the Valtellina (*q.v.*) led to the treaty of Monzón (1626), which Richelieu was later to deprecate in his *Mémoires*. Richelieu presumably disapproved of Bérulle's elevation to the cardinalate (1627), but they still worked together during the operations against the Protestants in La Rochelle (1627–28). The definite breach came at the end of 1628. Bérulle was then the principal adviser of the queen mother, Marie de Médicis, and a leader of the extreme Catholic party whose policy was to destroy Protestantism throughout Europe, whereas Richelieu was ready to support the German Protestants in order to humble the Habsburgs. Bérulle was thus completely out of favour at the time of his death, which took place suddenly, while he was saying mass, on Oct. 2, 1629.

Bérulle's political activity came to nothing. In the revival of Catholicism, however, he had played an essential role. His Oratory served as a model for those new congregations of priests which characterize the religious history of 17th-century France—the Lazarists of St. Vincent de Paul, the Sulpicians of J. J. Olier and the Eudists of St. John Eudes. He also exercised a decisive influence on the religious development of the abbé de St. Cyran (see DUVERGIER DE HAURANNE, JEAN) and so, through him, on Port Royal (*q.v.*). Largely inspired by Plato, by the pseudo-Dionysius Areopagiticus and by the Florentine Platonists of the Renaissance, Bérulle represents that type of Augustinian piety of which Jansenism constitutes only one aspect. He stands at the head of the "French school" of spiritual thought.

Editions of his works appeared in 1644 (republished 1960), 1657 and 1665; there is also one by J. P. Migne (1856). (JE. DA.)

BERVIC, CHARLES CLÉMENT (1756–1822), French engraver, known for the brilliance and softness he achieved and for his striving for exactness and regularity, was born in Paris, on May 23, 1756. His family name was Balvay, but he preferred to use Bervic, his father's surname. He studied with Jean Baptiste le Prince and Jean Georges Wille. A full-length portrait of Louis XVI in coronation robes, after a painting by Antoine Callet, established his reputation. The Order of the Reunion was given him in 1813 and the Legion of Honour in 1819. So slowly did he work that in his lifetime he produced only about 15 plates. He died in Paris on March 23, 1822. (H. Es.)

BERWALD, FRANZ ADOLF (1796–1868), the most important Swedish composer of the 19th century. Born at Stockholm on July 23, 1796, of a renowned family of musicians, he studied the violin with his father and composition with J. B. E. Du Puy. After writing numerous concertos, orchestral and chamber works between 1818 and 1828, he lived in Berlin (1829–41) and Vienna (1842) where, as in Sweden, his music was received with respect rather than enthusiasm. His work includes five symphonies (1820–45), the opera *Estrella* de *Soria* (Stockholm, 1862, revived 1946) and many choral and chamber works. Harmonically resourceful and original in construction, Berwald's music has a northern character, the severity of which is often relieved by a light and capricious sense of rhythm. He died at Stockholm on April 3, 1868.

See R. Layton, ***Franz Berwald*** (1959).

BERWICK, JAMES FITZJAMES, DUKE OF (1670–1734), marshal of France, was born at Moulins, in Bourbonnais, on Aug. 21, 1670, the son of Arabella Churchill (sister of John Churchill, the future duke of Marlborough) by James, duke of York (later King James II of England). He was educated in France and gained some experience of war in the Holy Roman emperor's service against the Turks in Hungary. In England he was created duke of Berwick in 1687 and was made colonel of two regiments and governor of Portsmouth. After the battle of the Boyne (1690) he commanded the Jacobites for a time in southern Ireland, in ineffective opposition to his uncle Marlborough. Returning to France, Berwick organized the remnants of eight Irish infantry regiments for the French army and was in 1693 made a French lieutenant general. The Irish were a notable element in all his commands, and both his marriages (with Honora Sarsfield in 1695 and with Anne Bulkeley in 1700) linked him with the Irish Jacobite officers. In the battle of Neerwinden (1693) he was taken prisoner by another of his uncles, Gen. Charles Churchill. Released by exchange, he went secretly to England in 1695, but then turned definitely to France. In 1701–03, early in the War of the Spanish Succession (*q.v.*), he was with the marshal de Boufflers on the Rhine and Meuse and before Antwerp, facing Marlborough, with whom he maintained a secret correspondence.

In 1704 Berwick was sent by Louis XIV to be captain general in the Spanish army, but in spite of some successes on the Portuguese frontier he was soon recalled as the Spaniards preferred the marshal de Tessé (René de Froullay). He then commanded against the insurgent Camisards in Languedoc until he was required instead to capture Nice. For this service he was made marshal of France (Feb. 1706) and sent back to Spain. While King Philip V and Tessé were being worsted before Barcelona, Berwick retreated from Portugal to Burgos, where gradually all available Spanish and French troops passed under his orders. He recovered Madrid and had cleared a large area to the southeast before the earl of Galway attacked him with a much smaller force of Portuguese, English and Dutch. In the ensuing battle of Almansa (April 25, 1707), Berwick won a victory which confirmed King Philip on his throne and gave Berwick a European reputation. He was rewarded with the Spanish duchies of Liria and Xerica and with the government of a French province, the Limousin.

In France, however, Louis XIV would give Berwick only secondary commands and assigned him first to Dauphiné, then to the Rhine. In 1708 Berwick brought 27,000 men from the Rhine to support the duc de Vendôme in Flanders; but he would not serve under Vendôme and had his share in the disunion of counsel which enabled Marlborough to capture Lille. In 1710 he was created duc de FitzJames by Louis XIV. From 1710 to 1713, apart from intervals of service in northern France, he was in Dauphiné, where his scientific system of defending the Alpine passes was successful. In 1714 all troops in the south were sent with him into Catalonia to end the war in Spain. The storming of Barcelona (Sept. 11) was a triumph for him and for the Irish regiments.

Berwick was given charge of the French demonstrations across the Spanish frontier in 1718. Governor of Strasbourg from 1730, he received the command on the Rhine when the War of the Polish Succession broke out (1733). He was besieging Philippsburg when he was killed by a cannon shot on June 12, 1734. His *Mémoires,* with a supplement by L. J. Hooke, were published by his son, the marshal duc de FitzJames (1778; Eng. trans. 1779).

See Sir Charles Petrie, ***The Marshal Duke of Berwick (1933).*** (I. D. E.)

BERWICKSHIRE, a border county of southeastern Scotland, is bounded on the north by East Lothian, west by Midlothian, south by Roxburghshire, southeast along the Tweed by Northumberland and northeast by the North sea. Area 457 sq.mi.

Physical Features.—Lammermuir, the northern third of the county, consists of plateaus of 1,400–1,600 ft. in the north; above which residual heights swell gently (*e.g.,* Meikle Says Law [1,750 ft.]), and plateaus of about 700–900 ft. in the south and stretching east through Coldingham moor to the great sea cliffs around St. Abb's head. These plateaus are planed across slaty Silurian shales and grits, folded and metamorphosed in the Caledonian orogenesis, and in places across Old Red Sandstone sedi-

mentaries and igneous intrusions; there are also some felsites of Carboniferous age (Dirrington Laws, 1,191 ft. and 1.309 ft.). Rainfall is moderate and averages 35–40 in. annually. The vegetation is of heather and bent grass moorland (sheep runs, with grouse-shooting) upon poor acid soils, with rushes, cotton grass and sphagnum moss on damper flats, often over peat. There are occasional shelter belts of Scots pine on the moors, mixed woodland on steep slopes and some conifer plantations. Brawling trout streams like the Whiteadder, the haunt of water ousel and wagtail, wind between steep bluffs across flat moors of melt-water gravels, leaving curving haughs (meadows) clad in fescue and heather. The western tenth of Berwickshire is the widest of these valleys, Lauderdale, where the Leader and its tributaries have carved out a broad swathe of lowland.

The southern, lowland two-thirds of the county is the Merse (March or borderland, possibly marshland). This consists of glacially plastered low plateaus at about 200 ft. and 500 ft. cut across Old Red Sandstone and also Lower Carboniferous sandstones and shales, above which stand a few volcanic hills of basalt or trachyte. The Merse was transformed by glacial deposition of groundmoraine drumlins (from the main southern upland glacier), aligned west–east to affect road and field patterns and settlement sites, and forming the basis of well-drained soils of good mineral content; while between the hummocks are innumerable ill-drained hollows and some considerable stretches of lowland peats. Meltwater deposits give occasional stretches of light sands and gravels. The mean annual rainfall is about 25–30 in.; the spring may be cool with dry easterly winds, but harvests are often sunny and early; locally there are severe winter frosts. Apart from some still unreclaimed birch, heather and mosses, this is a farming landscape varied by parks and woodlands, including beech. The fauna include fox. (A. T. A. L.)

History. — There are Roman marching camps at Channelkirk and at Belchester near Coldstream, while on Cockburnlaw near Duns is one of the few brochs in southern Scotland, known as Woden's or Edin's Hall. Many early British camps can be found in the north of the county (St. Abb's head, Duns law, Cockburnlaw). During the Saxon period the area formed part of Northumbria and in the 6th and 7th centuries Christianity was introduced by the saints Modan, Aidan, Oswald and Cuthbert. The Danes landed in 886 and destroyed the nunnery at Coldingham which had been founded by Ebba, daughter of King Aethelfrith, after whom St. Abb's head was named, and in 1098 King Edgar founded a Benedictine priory on the site. This became one of the wealthiest in Scotland and James III annexed its revenues for his personal gain, thus hastening the revolt of the nobles (1488). Burned by the earl of Hertford (1545) and blown up by Cromwell (1650), part of the chancel was repaired and is still used as the parish church. Dryburgh abbey, in the southwest, founded in 1150 for a colony of Premonstratensians, was at the height of its importance in 1296 when these canons swore fealty to Edward I, but it was burned and pillaged by Edward II in 1322 and finally ruined by Hertford in 1545. The church is a sandstone ruin retaining a rose window which measures 100 ft. by 30 ft. One of the few pre-Reformation churches still standing in its entirety is at Ladykirk, having been built by James IV in gratitude for his rescue from drowning in the river Tweed. In Lamberton church in 1502 was signed the contract for the marriage of James IV and Margaret Tudor.

In 1018, after the battle of Carham, the area was annexed to Scotland. At Birgham, near Coldstream, in 1188 William the Lion and the nobles and clergy refused the request of the bishop of Durham, made on behalf of Henry II, for funds for a new crusade against the sultan Saladin. There in 1289 a committee of estates consented to the marriage between Margaret, the maid of Norway, virtual heir to the Scottish throne, and Prince Edward of England; and there the following year was signed the treaty of Birgham, assuring Scotland's independence. In 1296 Edward I crossed the Tweed at Coldstream prior to the siege of Berwick, which, after years of border warfare, was finally ceded to England in 1482. Coldstream (*q.v.*) became the headquarters of the army in Scotland and it was there that General Monck's regiment of foot was organized and renamed his majesty's Coldstream regiment of footguards.

Besides ecclesiastical remains, Rhymer's tower near Earlston, the reputed abode of Thomas the Rhymer, and Greenknowe tower near Gordon are of great architectural value. The remains of Fast castle on the coast were the original "Wolf's Crag" of Sir Walter Scott's Bride *of Lammermoor*. Hume castle, near Greenlaw, scene of many battles, was once the seat of the earls of Home; while important examples of the work of William and Robert Adam are the houses of Mellerstain, near Eden Water and Paxton, west of Berwick-upon-Tweed. (W. R. EL.)

Population and Administration. — The population of Berwickshire in 1961 was 22,441, compared with 30,824 in 1901. There are four small burghs: Duns (*q.v.*), the county town (1,838), Eyemouth (2,160), Coldstream (1,227) and Lauder (597). A feature of the Merse are the "ferme towns" of up to a dozen cottages attached to a single farm. With East Lothian, the county returns one member to parliament. Berwickshire forms a sheriffdom with Roxburghshire and Selkirkshire. (A. H. C. S.)

Industries and Communications. — Farming dominates the economy. The Lammermuir heather grazings are occupied by extensive sheep farms, where Scotch Black-face ewes produce purebred lambs or Gray-faces by Border Leicester tups. Farm income is mainly from lambs and calves sold for fattening and breeding on better land, and from wool. Livestock-rearing farms cover most of the Lammermuir foothills and upper Lauderdale, their income being principally from half-bred (Border Leicester with Cheviot) lambs and beef calves, both sent widely over Scotland and England, and wool. A little cash cropping — oats, barley and potatoes — is possible.

Climate and soil in the Merse favour diversified farming. Barley, oats, wheat, potatoes and a little sugar beet are cash crops produced on a rotational basis. The farms, mostly large, carry big flocks of half-bred ewes replenished annually by young sheep from higher ground. Crossbred lambs sired by Down rams are bred and fattened on grass or roots, and additional purchased lambs are often fattened on roots. Traditionally, purchased bullocks are fattened on grass and in courts, but now beef cattle are often bred on the farms.

Large numbers of animals are sold at St. Boswells and Hawick in Roxburghshire and at Reston in Berwickshire. Sales of grain and other business are conducted at the weekly markets in Berwick and Edinburgh.

The forestry commission has established forests in Lauderdale and north of Duns. The Tweed salmon fisheries are famous and the lesser rivers of the Merse are esteemed by anglers. Eyemouth, Burnmouth and Cove are engaged in sea fisheries; haddock, herring, lobsters and crabs are chiefly taken. There is quarrying of the intrusive igneous rocks found in limited areas. Earlston produces woolen cloths and has a large sawmill, while at Cumledge (on Whiteadder Water) and Chirnside blankets and paper, respectively, are manufactured.

The Great North road (A1) passes through Berwick. The only railway services for passengers are to two or three stations on the main Berwick-Edinburgh line, though goods can be sent to Duns from Reston and to Greenlaw from St. Boswells. (W. A. Bu.)

BIBLIOGRAPHY.—A. A. Carr, *A History of Coldingham Priory (1857)*; C. Rogers, *Chartulary of the Cistercian Priory of Coldstream (1879)*; Land Utilisation Survey of Britain, *The Land of Britain*, pt. *14, Berwickshire*, by P. C. Waite (1941); G. Chalmers, *Caledonia* (1824).

BERWICK-UPON-TWEED, a municipal borough and seaport of Northumberland, Eng., lies at the mouth of the Tweed about 337 mi. N.W. of London by road. Pop. (1961) 12,166. Both the east coast railway route from London to Scotland and the Great North road cross the border at the northern boundary of the borough. With long stretches of soft sands and fine country, the town attracts visitors from both north and south of the border.

In certain proclamations Berwick is still mentioned individually, after Wales, a custom dating from the time when the fluctuations of border warfare led it to be regarded as part of neither England nor Scotland. It was made a free town in 1551 and in 1836 was redeclared by act of parliament to be a county of itself. The

liberties of the borough, commonly called Berwick bounds, include the townships of Spittal and Tweedmouth, on the soutli bank of the river. Berwick was at first represented in the court of the four royal burghs and in 1326 in Robert Bruce's parliament. After being occupied by the English it remained unrepresented until it was retaken by the Scots, when it sent two members to the parliament in Edinburgh from 1476 until 1479. In 1482 the burgesses were allowed to send two members to the English parliament and were represented there until 1885, when the town was merged in the parliamentary division of Northumberland that bears its name.

Very little is known of the history of Berwick before the Norman Conquest. It was not until the Tweed became the boundary between England and Scotland in the 12th century that Berwick, as the chief border town, became important. After changing hands 13 times it was finally surrendered to England in 1482. After Edward I had conquered Berwick in 1302 he gave the burgesses a charter by which the town was made a free borough with a guild merchant, having two markets every week and a fair. James I granted the incorporation charter in 1604, but on his accession to the throne Berwick rapidly lost its importance as a bastion against the Scots. It is one of the few towns still surrounded by a complete set of ramparts. The original walls, built by Edward I, were rebuilt by Elizabeth I. The bell tower, from which alarms were given when border raiders were observed, is in iair condition. Adjoining the walls, between the windmill and the brass bastions, are the oldest occupied barracks (1719) in England. There are scanty remains of the Norman castle, which fell into disrepair after the union of England and Scotland and was despoiled when the railway station was built. Berwick has the only parish church (1648–52) built and completed during the Commonwealth. Three bridges connect the town with the south bank of the Tweed: the oldest, of 15 arches, was opened in 1624. In 1928 it was supplemented by the much larger and wider Royal Tweed bridge. The Royal Border bridge, a quarter of a mile up the river. was built by Robert Stephenson in 1847–50 and is a striking railway viaduct 126 ft. high with 28 arches.

The reach of the river from the old bridge to the mouth forms the harbour. The principal export is grain; imports are oil and timber. Fairs are held annually at the beginning of March and the end of May. Industries include a small shipyard, engineering, sawmills and joinery works, salmon fishing (for which the town has been noted from very early times), fertilizer factories? and tweed and hosiery mills. The weekly grain and livestock markets are important.

BERWYN, a city of Cook county, Ill., U.S., about 7 mi. W.S.W. of Chicago's loop on the Chicago Sanitary and Ship canal. Primarily a residential suburb, Berwyn also manufactures electrical equipment, machine tools, leather and tobacco products. Founded in 1890, Berwyn was incorporated as a village in 1891 and as a city in 1908. Pop. (1960) 54,224. For comparative population figures see table in ILLINOIS: Population.

BERYL, the commercial source of beryllium. is a mineral species of considerable interest because certain varieties have long been used as gem stones. Beryl, which is harder than quartz and will scratch glass, is commonly pale green, but it may be deep green, blue, yellow, brown, colourless or pink. Special names are given to the coloured gem varieties. Emerald (*q.v.*) is deep green, coloured by a small amount of chromium: aquamarine (*q.v.*) is pale blue-green; morganite is pink, probably coloured by cesium; golden beryl is yellow. The colour of many beryls used as gems has been induced by heat treatment. Greenish-yellow beryls turn to clear green at about 275° C.; green beryl turns blue between 300° C. and 400° C.; but the emerald does not change colour on heating.

Beryl occurs as an accessory mineral in many granitic rocks and associated pegmatite dikes and also is found in gneisses and mica schist. The usual occurrence of the gem varieties other than emerald is in cavities in pegmatites. The commonest gem beryl, aquamarine. has been found in Brazil, the chief source. and in Siberia and Madagascar: in the United States it has been found in Maine, New Hampshire. Connecticut, North Carolina and Colorado. Golden beryl is found in Maine, Connecticut and North Carolina. and also in Brazil, Siberia and Ceylon. Rose-coloured beryl comes chiefly from California and Madagascar. Emeralds are found in a mica schist in the Ural mountains east of Sverdlovsk, U.S.S.R., but the most important locality is at Muso. 65 mi. N.W. of Bogotá, Colombia. There emeralds of gem quality, found in veins in a dark bituminous limestone, have been mined almost continually since the middle of the 16th century.

Common beryl of nongem quality is found in many pegmatites, but usually in small disseminated crystals. However, crystals weighing many tons have been found. At Albany, Me.. a single tapering crystal was found in 1949 that measured 27 ft. 7 in. in length with an average diameter of more than 2 ft.; from it approximately 1 j tons of beryl were extracted. A crystal 7 ft. in diameter but of unknown length was found in a pegmatite in the Black hills of South Dakota.

Before 1925 beryl was of commercial interest only as a gem stone. Thereafter many important uses were found for beryllium, and common beryl has been widely sought as the ore of this rare element. No large deposits have been found, and much of the production is a by-product in the mining of feldspar and mica. Although the amount of beryl mined fluctuates from year to year. there was a rather steady increase after 1930. Brazil became the major producer. Other producers are Southern Rhodesia, the Union of South Africa. South-West Africa and the United States. The United States consumes more than 90% of the total production. mostly in the manufacture of beryllium copper alloys. (For other important uses *see* BERYLLIUM.)

Composition and Characters. — Beryl is essentially a beryllium aluminum silicate, $Be_3Al_2Si_6O_{18}$; but alkalis (sodium, potassium, lithium and cesium) may be present up to 7%. Small amounts of other elements give rise to the colour varieties. Beryl crystallizes in the dihexagonal-dipyramidal class of the hexagonal system (*see* CRYSTALLOGRAPHY) with crystals characteristically long six-sided prisms terminated by the basal plane. Pyramidal faces are present on some crystals. An imperfect cleavage is parallel to the base. The specific gravity is about 2.7 and the hardness 7.j to 8.

Synthesis. — Because of the high value of the emerald, attempts were long made to manufacture it synthetically. These efforts finally met with success shortly before World War II when a German patent was issued to cover its synthesis. Beginning in 1946 emeralds of fine quality were manufactured in the United States by a secret process, probably in a water solution at elevated temperature and pressure. The crystals thus grown appeared very similar to those found in nature and rivaled natural stones in colour and beauty. A synthetic emerald observed under ultraviolet light fluoresces a deep red; the natural stones do not fluoresce. See also GEM. (C. S. H.)

M. Myers, *Nonmetallic Minerals,* 2nd ed., pp. 102–104 (1951); Arthur Montgomery. "The Harding Pegmatite, Remarkable Storehouse of Massive White Beryl," *Mining World* (July, 1951).

BERYLLIUM is a light, metallic element, some of its properties resembling those of magnesium, aluminum or zinc. It has assumed importance in the field of atomic energy. (See *Uses,* below.)

In this article various aspects of beryllium are treated under the following sections and subsections:

I. HISTORY

Beryllia (beryllium oxide) was first isolated in 1797 by L. N Vauquelin from beryl, a silicate of beryllium and aluminum from which came the name beryllium. (The alternate name, glucinum, reluctantly adopted by Vauquelin, was suggested by the editors of *Annales* de *Chimie*, publishers of Vauquelin's article, because of the pronounced sweetish taste of its salts.) Vauquelin's discovery of beryllium was aided by its having both basic and acidic properties; beryllium hydroxide precipitates from its boiling alkaline solution while aluminum hydroxide does not The latter element was thought at that time to be the only metal in beryl.

BY COURTESY OF SMITHSONIAN INSTITUTION
GOLDEN BERYL WITH MUSCOVITE WEIGHING 1.800 G. FOUND IN THE MINAS GERAIS REGION OF BRAZIL

Friedrich Wöhler and A. A. B. Bussy, working independently. first isolated the element as an impure powder by the reduction of its chloride with potassium in 1828. In 1897 Paul Lebeau prepared alloys of copper, chromium, molybdenum and tungsten mith as high as 10% of beryllium by reducing in an electric arc finely divided beryllium oxide intimately mixed with carbon and the other metal. In 1898 he obtained a finely divided beryllium powder by electrolyzing sodium beryllium fluoride in a nickel crucible at low red heat. In 1921 A Stock and Hans Goldschmidt directly produced compact beryllium by electrolysis of mixtures of barium fluoride with beryllium fluorides at temperatures above the melting point of the metal.

II. OCCURRENCE

Beryllium is estimated to occur in earth's igneous rocks to the extent of 0.0006%, thus having slightly more abundance than arsenic but only one-seventh that of tin. Unfortunately. these rocks usually contain too little beryllium for the existence of its specific minerals and it therefore enters the structure of other minerals. without accompanying significant concentration.

Of 28 minerals in which beryllium is an essential constituent and 27 minerals in which beryllium is a minor accessory constituent only one, beryl, has been found in sufficient quantity to constitute a commercial ore. Beryl, a primary mineral, is widely distributed and most commonly found in granitic igneous rocks known as pegmatite (*q.v.*). These are dikelike bodies of rocks characterized by the relatively large crystal size attained by the component minerals. (Single crystals of beryl weighing 35 tons have been noted.) Pegmatites are formed in enclosing rock by the solidification and precipitation of minerals carried in emanations from deep-seated granitic magmas. Such deposition takes place at great depth. Pegmatites observable at the earth's surface have been exposed by erosional processes which, active over a great period of geologic time, have removed the original overlying rock cover. Although traces of beryl occur in many pegmatites, only in a relatively few are the amounts sufficient to be significant for production, even when aided by the presence of by-product minerals.

In the best beryl-producing pegmatites, 1 part beryl is generally associated with so–roo parts of feldspar and quartz, together with lesser amounts of minor minerals, among which are tantalum, lithium, uranium: rare-earth minerals and mica. Large. low-grade deposits of beryl occur as disseminations (about 0.2%–0.4%) in granite, and in certain types of quartz veins in granite where beryl is associated with tungsten (wolframite) ore. For composition, appearance, occurrences, etc.. see BERYL.

TABLE I.—Some of the Minerals of Beryllium

Mineral	Formula	Per cent BeO
Phenacite	Be_2SiO_4	
Chrysoberyl	$BeAl_2O_4$	45
Beryllonite	$NaBePO_4$	19
Beryl	$Be_3Al_2Si_6O_{18}$	14
Helvite	$(Be.Fe\ Mn)\ Si_3O_{12}S$	10

Mining of pegmatite minerals is usually done by open-pit or quarry methods although in some large, rich pegmatites underground mining methods are used. Because of its diffuse occurrence in the pegmatites. the mining of beryl remained expensive, for no really satisfactory deposit was known.

Spectrographic testing of mine tailings, industrial wastes, core drillings and natural concentrates has been recommended for discovering new sources of this element. A chemical spot test suitable for field use in testing individual minerals for beryllium is described based on the dye principle, *p*-nitrobenzene-azoorcinal.

III. INDUSTRIAL PRODUCTION

Industrially. beryllium hydroxide is extracted from beryl ore by two different methods. In one of these methods beryl ore is fused at 1,500°–1,600° C. and then quenched with water (without changing composition) to produce a reactive glass or frit. This material is heat-treated to increase its reactivity, ground to a fine powder, mixed and heated with a small excess of concentrated sulfuric acid, leached with water and from the resulting solution of beryllium and aluminum sulfates, the bulk of aluminum is separated as crystallized ammonium alum. The remaining aluminum content is eliminated as sodium aluminate in subsequent operations. Following the alum crystallization, chelating compounds are added to the mother liquor so as to hold undesirable impurities, such as iron, etc., in the solution. Excess sodium hydroxide is then added to convert the aluminum and beryllium to aluminate and beryllate respectively, both of which are quite soluble in cold alkaline solution but different in the respect that the beryllate decomposes on boiling to precipitate beryllium hydroxide, whereas the aluminate is unaffected. The beryllium hydroxide is separated by filtration and if required is ignited to oxide. One plant in the United States uses this method industrially.

In the second of these methods, finely ground beryl ore is mixed with sodium fluosilicate, sodium fluoride or sodium carbonate and heated to 750° C. At this temperature, sodium beryllium fluoride (Na_2BeF_4) is formed. This compound is water soluble and leached out with water to form a dilute solution. Beryllium hydroxide is precipitated from this solution with sodium hydroxide, separated by filtration and, if required, ignited to oxide. One plant in the United States, one in England and one in France use this method industrially.

The reduction of beryllium fluoride by means of magnesium (see *Extraction in the Laboratory*, below) is employed for industrial production of pure metal by two plants in the Cnited States. One plant in England and one in France convert beryllium oxide to anhydrous beryllium chloride which is electrolyzed in the presence of sodium chloride to produce pure beryllium in flake form. Generally a nickel pot serves as the cathode and a graphite electrode as the anode. The temperature maintained is well below the melting point of beryllium (730° C at the start, increased to 820° C at the finish). The remaining melt is poured or siphoned off, and the beryllium flake left cemented to the cathode walls is freed with large quantities of ice water and dried at low temperature to prevent oxidation.

By far the largest use of metallic beryllium has been in beryllium copper, although the utilization of pure beryllium is increasing rapidly. For this purpose a master alloy of 4% beryllium in copper is produced by a modification of Lebeau's arc furnace process described above. Copper chips, beryllium oxide and carbon are mixed together in a ball mill and charged into a three-phase graphite-lined arc furnace constricted toward the top and protected from the atmosphere The furnace temperature is maintained at 1,900°–2,000° C ; when the content has progressively accumulated to a sufficient extent, it is poured into a normalizing furnace where carbide and dross contained in the melt are rejected as the melt stands slightly above solidification. The carbide and dross in the form of thick metal are skimmed off for reuse in the arc furnace, and the remaining clean metal poured into pigs. A typical analysis is: Be 4%, Fe o 10%, Si 0.1%, Al 0.06%, Cu substantially to balance.

IV. USES

Beryllium is the only stable light metal with a relatively high melting point. These properties, coupled with its excellent electrical conductivity. high heat absorption, good mechanical properties at elevated temperature, oxidation resistance and very high modulus of elasticity, make it of interest for structural and thermal applications, as well as for nuclear reactors. The principal use in the past has been as X-ray windows for transmission of rays and to filter out electrons. Beryllium transmits 17 times as well as aluminum and is particularly useful when longer and more easily absorbed X-rays are present. For principal uses of inorganic compounds see *Inorganic Compounds,* below.

1. Structural Parts. — Beryllium is machined to very close tolerances into gyroscopes, accelerometers and computer parts for inertial guidance instruments as well as other types of missile hardware. The combination of properties is also of interest for the development of rolled, forged, extruded and machined products for missile. aircraft and space-vehicle structures. The combination of high heat conductivity and specific heat coupled with high-temperature mechanical properties are utilized in heavy-duty brake drums and in other applications where the use of beryllium as a heat sink is important.

2. Nuclear **Applications.**—Nuclear applications are primarily for machined parts as moderators and reflectors in compact high-flux nuclear reactors and test reactors. Beryllium has been used in the Materials Testing reactor, Engineering Testing reactor, and certain mobile reactors: such as the Submarine Intermediate reactor, in the United States, and for other test reactors built in Europe. In high-temperature gas-cooled reactors, especially where natural uranium or slightly enriched uranium is desired as fuel, considerable experimental work has been done particularly in Europe on using beryllium as a canning material for fuel elements. Beryllium is used as a neutron source mixed with radium or with deuterons in the cyclotron or with neutrons in nuclear reactors for neutron generation. *(See* also *Physical Properties,* below.)

3. Alloys.—Alloying with aluminum confers some ductility but at the loss of high melting point and electrical conductivity. Ternary beryllium-aluminum alloys containing 25% of beryllium were developed with tensile strengths as high as 89,000 lb. per square inch (p.s.i.) but, because they are difficult to fabricate, were not applied successfully for pistons for airplane engines where their use was indicated.

The industrial application of beryllium as a low percentage component of alloys wherein it produces precipitation hardening far exceeds all others. The most important alloys are those with copper as the main constituent. but the effect is used also in nickel- and iron-base alloys. This action of beryllium as a powerful precipitation hardener is probably rather general, the amount employed ranging from 0.1% to perhaps 3%. The hardening action is frequently modulated by adding 0.3%–2.5% of a third component such as iron. nickel. cobalt or chromium. In such applications the alloys are first heated to temperatures approaching their melting points and quickly cooled as by quenching in water. They are then in a soft ductile condition, capable of withstanding cold working. When. after cold shaping, it is desired to harden the alloys. they are reheated to lower temperatures ranging from 2jo° to 500° C. This reheating not only causes metallic beryllides to precipitate within the metal but also reaches temperatures high enough to relieve internal strains and thus place the metal in the best possible condition to develop maximum elastic limit, endurance limit and tensile strength. Maximum hardnesses ranging from 350 Brinell in 2% beryllium copper to more than 600 Brinell in 2% beryllium nickel can be obtained. One per cent of beryllium added to stainless steel is capable of producing precipitation-hardened springs said to hold their temper at red heat.

Beryllium copper alloys are used where spring qualities are required in combination with corrosion resistance. The soft ductile state of the quenched alloys permits cold-drawing and -forming operations which may then be followed by low-temperature heat hardening to maximum strengths and elasticity. In this respect beryllium copper alloys possess an important advantage over ordinary bronzes whose final hardness is produced in foundry or mill. The unusual hardness of beryllium copper has resulted in its use for tools where sparking might be dangerous, as in powder factories. Beryllium contributes nothing to the reduction of sparking but merely strengthens the copper which is of low-sparking characteristic.

hletallic beryllium has the additional property, useful in oxidizable alloys up to about 825° C., of forming powerful self-generating protective surface films. even when present in the alloy in small quantities ranging from 0.001% to 0.20%. The effect is particularly marked in magnesium where only 0.005% reduces inflammability to an extraordinary degree, although associated with some grain coarsening. This protective effect is not limited to minimizing inflammability but extends even in nonflammable alloys to the preservation from loss of easily oxidizable alloy components such as magnesium. A corollary of this protective action is the clean, bright surface frequently found on castings containing beryllium. In certain silver alloys, beryllium has the effect of reducing tarnishing.

Related to its use as a protective film-forming component is the use of beryllium as a deoxidant to promote fluidity and soundness in castings whose main constituent ranges from copper to aluminum and magnesium.

4. Fabrication. — Cnlike most metals, beryllium is not usually fabricated by foundry techniques, inasmuch as casting has a strong tendency to produce very coarse grains with associated brittleness and low tensile strength; *i.e.,* 19,000 p.s.i. In the cast form it is also difficult to machine. When encased in strong steel jackets for hot working. cast beryllium may be extruded. forged and rolled. but the strength of these products is only about one-half of what is achieved using beryllium powder billets.

The primary method of fabrication for commercially pure beryllium is through various powder-metallurgical processes, of which hot pressing is employed the most. Conventional cold pressing and sintering. and sintering the powder as a slip without pressure are also used. Hot pressings up to 2,000 lb. have been made without substantial porosity by pressing beryllium at about 1,050° C. *in vacuo.* Such compacts may contain from 0.6% to 2% beryllium oxide. depending on the particle size and exposure to oxidizing influences. The beryllium oxide serves to act as a barrier at grain boundaries to help the retention of fine grains el-en at elevated temperatures. Because of the random packing of the powder and the limited grain growth, the sintered compacts produced are substantially nondirectional and may exhibit ultimate strengths up to 50,000 p.s.i. with elongations up to 3%.

Either low-density sintered metal, powder compacts, cold-pressed and sintered. or hot-pressed billets can serve as material for further working into sheet, extrusions or forgings. Hot pressings also are machined into various thermal, nuclear or mechanical products. Unlike cast beryllium. it can be readily machined to extremely high tolerances.

Methods have been developed for rolling. extruding, forging, welding by arc and resistance methods. brazing, soldering and surface finishing by electroplating and chemical treatment. Working of beryllium is carried out from 400° to 700° C. without protection inasmuch as little oxidation takes place at these temperatures. Hot working at 1,000°–1,100° C. is carried out under the protection of a steel jacket.

In the fabrication of beryllium. precautions must be taken to avoid scratching or notching, as it is quite notch sensitive. In annealing, care must be taken not to overheat. especially after working, inasmuch as the tendency to grow grains is greater after the oxide barriers have been broken by hot or warm working, and poor mechanical properties result with increased grain size (see *Physical Properties,* below). Beryllium should not be fabricated or worked below 400° C., as it is quite brittle at low temperatures. Above 850° C. it has a tendency to become hot short (brittle when worked) and it should be worked very carefully or under protection of a steel sheath at elevated temperatures.

V. PHYSICAL AND CHEMICAL PROPERTIES

Beryllium has the symbol Be, valence +2, atomic number 4 and atomic weight 9013. The only stable isotope has a mass num-

ber of 9. There are no other naturally occurring isotopes, but isotopes of mass numbers 6, 7, 8, 10 and 11, all peculiarly radioactive, have been artificially produced. Beryllium has an electron arrangement as follows: $1s^2$, $2s^2$.

1. Extraction in **the** Laboratory.— For the laboratory extraction of beryllium oxide (for precautions see *Toxicology,* below) beryl is fused with its own weight of potassium hydroxide at low red heat in a nickel crucible. The fused mass is then just covered with water, concentrated sulfuric acid added to slight excess and the resulting mass heated with accompanying pulverization until fumes of sulfuric acid appear and the whole is a fine white powder. This residue is extracted with hot water and evaporated to separate out as much alum as possible in the cold. The iron is then oxidized and the solution is neutralized with ammonia and saturated with sodium bicarbonate. After about 24 hours. during which time the solution is warmed and stirred, most of the beryllium hydroxide dissolves and may be filtered off from the insoluble aluminum and iron hydroxides. Upon dilution and boiling. basic beryllium carbonate precipitates and may be ignited to beryllium oxide.

For producing the metal in the laboratory, beryllium oxide is dissolved in aqueous ammonium bifluoride to form ammonium beryllium fluoride. This salt is then crystallized out and heated under a hood to bright redness in a protected graphite, platinum or nickel crucible to drive off the ammonium fluoride. The residual melted beryllium fluoride is then poured into a graphite mold or allowed to solidify in the crucible.

The laboratory reduction of the fluoride to beryllium is carried out in a graphite crucible about 2 in. in diameter and 6 in. in length placed under a strong-draft hood and inside a high-frequency, insulated furnace coil. The crucible may be covered and heated empty to about 900° C. A small amount of beryllium fluoride is introduced into the crucible to coat its bottom and sides by means of the vapour. Ten grams of pure magnesium metal are introduced; and, just as the metal comes to the melting point. it is covered with 30 g. of solid beryllium fluoride and heated for five minutes or until the reaction has been completed. This operation may he repeated until the crucible is three-quarters full. The reduced beryllium will be distributed throughout the semiliquid melt as a fine powder. The introduction of beryllium fluoride in solid form prevents the reaction from proceeding violently, and its 50% excess lowers the slag melting point to about 1,100° C. To cause the beryllium powder to coalesce, the temperature of the melt is raised to about 1,350° C. and maintained for one hour. After cooling, the coherent beryllium may be removed from the top of the melt.

This method may be modified for the direct production of beryllium copper or other beryllium alloys by introducing the other element of the desired beryllium alloy with the magnesium. The latter will then be replaced in the alloy by beryllium, which it reduces. This reaction proceeds without violence because of the dilution of the magnesium.

2. Physical Properties.— Some general physical properties of beryllium are indicated in Table II. The peculiar nuclear behaviour of stable beryllium (atomic weight 9.013) and its artificially produced isotopes (mass numbers 6, 7, 8, 10 and 11) deserves some special comment. Naturally occurring Be^9 is stable and has a small capture cross section for thermal neutrons. It emits neutrons under proton, neutron, deuteron, alpha-particle and gamma-ray bombardment.

Because of the small mass of its nucleus and its low affinity for slow neutrons it is more efficient than graphite for slowing down neutrons in atomic energy devices and, in addition, has little tendency to absorb them. *(See* also **NEUTRON:** *Neutron Production.)*

Be^{10} has a long half life of about 2,700,000 years. Its now established radioactivity escaped observation for some time. The short-lived isotope Be^8 is unstable and, when produced in nuclear reactions, splits into two alpha particles in less than 10^{-15} sec. In the case of Be^7, gamma radiation has been observed and is thought to be associated with the capture by the nucleus of one of its orbital electrons. It is possible that chemical combination may affect its radioactivity. For example, in the oxide, the interaction of the Is and 2s electrons of beryllium may be strong enough to alter the position of the 1s electrons and thus produce a slight change in the observed radioactivity.

TABLE II.—*Physical Properties of Beryllium*

Colour	Steel gray
Taste	Sweetish
Solubility	Soluble in acids and strong bases with evolution of H_2
Density, grams per millilitre (X-ray)	1.8445
Melting point	1,285° C.

Magnetic mass susceptibility, c.g.s. electromagnetic units, 20° C.	1.0×10^{-6}

Table II.—*Physical Properties of Beryllium*

The mechanical properties of beryllium depend largely on its structure, which is that of a close-packed hexagonal crystal having a high degree of anisotropy (directionality). At room temperature, beryllium has a fracture stress in the basal plane lower than slip stresses, essentially failing in this plane even though it has substantial elongation in the prismatic planes of all degrees of purity (up to about 2% nonberyllium additives).

However, at elevated temperature, about 200°–300° C., a brittle-ductile transition takes place wherein metal having a tensile elongation of 0.5%–3% at room temperature develops from 25% to 50% at 400°–450° C. Beyond this temperature, failure takes place principally at grain boundaries, with the metal becoming hot short at about 850° C. Dispersed-phase alloys containing beryllium oxide or intermetallics of other metals can substantially increase mechanical properties, especially strength, at the higher temperatures.

The properties of beryllium, therefore, depend upon the grain size, purity content and directionality. For instance, in working along preferential planes, such as by extrusion, substantial elongation can be obtained in the direction of extrusion at room temperature. By cross rolling, uniaxial ductility in the plane of the sheet can be obtained. However, unless working can take place in all directions, at least one plane of brittleness remains,

†Room temperature.

giving unfavourable properties under biaxial loading and notch sensitivity nith triaxial stresses.

Some tensile properties are shown in Table III. The compression properties are similar to these and shear strengths are somewhat lower. However, the shear properties for beryllium are excellent compared with other metals. The poorest values are in tension although its tensile modulus, 42,000,000 p.s.i., is one of the highest of all elements.

3. Chemical Properties. — The position of beryllium at the head of group II in the periodic chart indicates a valence of two. In chemical properties it resembles both magnesium, which is number 2 of its own group, and aluminum, which is number 2 of the next succeeding group. As would he expected. beryllium is less basic than magnesium but more basic than aluminum. This is particularly evident upon attempting to dissolve samples of these three light metals in concentrated sodium or potassium hydroxide solutions. Aluminum readily forms the aluminate with evolution of hydrogen; the formation of the beryllate proceeds more slowly and requires greater concentration of the hydroxide but may be carried to completion; magnesium is not attacked at all.

Like aluminum, beryllium forms a protective skin of oxide and to this ones its stability in air up to red heat. It is attacked by most acids. but its aqueous solutions show a great tendency to hydrolyze and with few exceptions form sticky basic masses upon evaporation in an effort to crystallize. Beryllium hydroxide is readily dissolved in large amounts by solutions of its salts such as the sulfate. nitrate, chloride, etc. Consequently, a surprisingly large amount of ammonium hydroxide must be added to beryllium solutions before the resulting beryllium hydroxide precipitate becomes permanent.

The halogens and their hydroacids react directly with beryllium when heated with it. At temperatures of 1,200° C. or above, beryllium metal reacts slowly with nitrogen and carbon to form the nitride and carbide. With sulfur it reacts slowly if at all.

The inorganic compounds of beryllium are mostly colourless.

4. Inorganic Compounds.-Beryllium oxide, BeO. melting point 2 530° C.. density 3.009, is refractory and difficult to reduce. It is prepared as a fluffy white powder which serves as a base for most beryllium compounds. It has tno uses in the lighting industry. namely, in Welsbach mantles where it exists in a small percentage in the luminous mixture of oxides and in certain fluorescent lamps as beryllium zinc silicate, the active "phosphor" which produces an ivory-coloured bank of light. It may be fused and ground to form into crucibles for high-temperature applications requiring chemical inertness, strength, resistance to thermal shock and high thermal conductivity (about ten times that of alumina). Reports show successful service at temperatures as high as 2,000° C. and a plurality of melts. It retains its electrical insulation well at high temperatures and so is uniquely adapted to certain melting operations, especially those above the temperature limits for alumina.

High density beryllium oxide ware has one of the best combinations of thermal, electrical and nuclear properties found in ceramic oxides.

It can be used in high-temperature nuclear devices, operating above the melting point of beryllium, for the same applications as the metal. These bodies are produced by hot pressing. extrusion and firing, as well as dust pressing and firing. Other uses are found in electronics such as low-loss dielectrics and wave-guide windows as well as a component in high-modulus structural glass fibres.

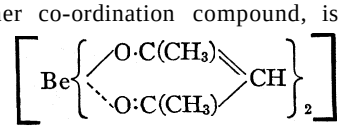
Beryllium carbide, Be_2C, density 2.44, decomposes at temperatures above 2,100° C. and is slowly attacked by water vapour even at room temperatures. But both beryllium carbide and oxide are of much potential value for high-temperature moderators in nuclear-power equipment where the oxygen or carbon atoms add to the action of beryllium.

Beryllium chloride, $BeCl_2$, is formed by passing dry hydrogen chloride over the heated metal. It is prepared by the action of the phosphorus chlorides, sulfur chloride or preferably carbon tetrachloride on beryllia at 700°–800° C. (C. Matignon and M. Piettre). It is a white, crystalline, hygroscopic solid melting at about 400° C. and is soluble in water with formation of hydrochloric acid.

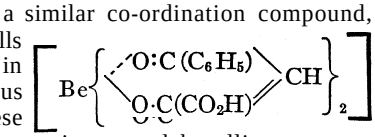
Beryllium fluoride remains as a glassy transparent mass on heating the double fluoride of beryllium and ammonium, and is less hygroscopic than beryllium chloride. The beryllium halides cannot be crystallized from aqueous solutions, nor can they conduct electricity in the pure molten state.

5. Organic Compounds. — Basic beryllium acetate, $(CH_3.CO_2)_6Be_4O$, produced by dissolving beryllium hydroxide or basic carbonate in acetic acid, is insoluble as such in water but soluble in such organic solvents as glacial acetic acid. chloroform, ether and alcohol. From these solutions the compound separates in well-defined crystals belonging to the cubic system. These crystals have a definite melting point and can be distilled unchanged under normal or reduced pressure. When subjected to X-ray examination, the component parts of the basic acetate molecule are found to be arranged as follows: the lone oxygen atom is placed centrally, the four beryllium atoms occupy the four vertices of a regular tetrahedron and the six acetate groups span symmetrically the six sides of this regular solid. Homologues, $(R.CO_2)_6Be_4O$, have also been prepared and examined (G. T. Morgan and W. T. Astbury, 1926), namely the propionate, n- and iso-butyrates, and privalate (trimethylacetate). These derivatives are also readily soluble in organic mediums.

Beryllium acetylacetone, another co-ordination compound, is also insoluble in water but soluble in organic solvents; it melts and distills without decomposition. In this substance beryllium is in fourfold association with two ring-forming radicals (chelate groups).



Beryllium benzoylpyruvate, a similar co-ordination compound, has been shown by W. H. Mills and R. A Gotts (1926) to exist in two optically active forms, thus establishing the fact that these arrangements of four associating units around beryllium are not uniplanar but tetrahedral. (See STEREOCHEMISTRY.)



In the foregoing co-ordination compounds, beryllium is not combined directly with carbon but only indirectly through oxygen. True organometallic derivatives have, however, been obtained in which the metal is attached directly to one or two organic radicals. Earlier workers (A. Cahours, 1860, and V. Lavroff, 1884) indicated the probable existence of such beryllium compounds, and Gilman and Schulze (1927), by using anhydrous beryllium chloride with the appropriate Grignard reagent, definitely identified beryllium dimethyl as a snow-white solid subliming at 200° C., and beryllium diethyl as a colourless liquid, melting point 12° C., boiling point 110° C./15 mm., both being spontaneously inflammable in air. These observers also obtained beryllium di-n-butyl and the corresponding diphenyl together with compounds of the type R.Be X, where R is an alkyl or aryl group and X is bromine or iodine. (*See* ORGANOMETALLIC COMPOUNDS.)

6. Toxicology. — Soluble compounds of beryllium in the form of solutions, dry dusts. vapours or fumes can produce dermatitis varying in intensity of response with the individual. When brought into contact with the mucous membranes through inhalation or otherwise, these same dusts, mists or fumes may affect them and the respiratory tract, producing acute effects not unlike those of phosgene and sometimes having consequences as serious though slower in progress. The halides of beryllium appear to be more virulent than the sulfates.

A delayed pulmonary effect attracted attention after World War II, particularly among workers in the fluorescent lamp industry employing beryllium zinc silicate. Xumerous lawsuits followed and resulted in the abandonment, a few years later. of the general use of beryllium zinc silicate. However, increasing knowledge as to what constitutes. in most instances, harmful exposure, together with increased experience in controlling atmospheric pollution, demonstrated that all beryllium processing can be adequately controlled and that some processing steps, particularly those not involving the production of finely divided berylliurn or beryllium

compounds, could apparently be carried out without the need for controls of the kind observed with respect to most of the processing.

7. Analysis. — For primary determination of beryllium the method employed is the weighing of beryllium oxide from the precipitated hydroxide or from the ignition of such salts as the sulfate, nitrate or carbonate. To obtain the hydroxide in a pure form it is ordinarily precipitated with ammonia after other special separations have been completed. The most important of these is the hydroxyquinoline separation with careful hydrogen-ion control. This separates out aluminum and numerous heavy metal ions. For quicker determination in control laboratories, field use, etc., a reliable colorimetric method employing *p*-nitrobenzeneazoorcinol has been developed. Where accuracy is necessary a photoelectric colorimeter is required.

BERYLLONITE, a rare beryllium mineral, is a phosphate of beryllium and sodium found as highly complex crystals in granite pegmatite veins at Stoneham and Newry, Me., where it is associated with herderite, feldspar. smoky quartz, beryl and columbite. The crystals vary from colourless to white or pale yellowish, and are transparent with a vitreous lustre. Crystallization is orthorhombic and there is a perfect cleavage in one direction. The formula is $NaBePO_4$. Its hardness is 5.5 to 6; specific gravity 2.84. (CL. F.)

BERZELIUS, JÖNS JACOB (1779–1848), Swedish chemist, was one of the founders of modern chemistry. Particularly notable were his determinations of atomic weights; his development of the modern system of chemical symbols; and his isolation of many of the elements for the first time. He was born at Vaversunda Sörgård, near Linkoping, on Aug. 20, 1779, studied chemistry and medicine, and graduated as M.D. in 1802 at Uppsala. Appointed assistant professor of botany and pharmacy at Stockholm in the same year, he became full professor in 1807, and from 1815 to 1832 was professor of chemistry in the Caroline medico-chirurgical institution of that city. The Stockholm Royal Academy of Sciences elected him a member in 1808. and in 1818 he became its perpetual secretary. He was made a baron by Charles XIV in 1835. He died at Stockholm on Aug. 7, 1848. An extensive collection of his apparatus is preserved by the academy at Freskati, near Stockholm.

During the first few years of his scientific career, Berzelius was mainly engaged on questions of physiological chemistry, but about 1807 he began to devote himself to the elucidation of the composition of chemical compounds through study of the law of multiple proportions and the atomic theory. Perceiving the determination of the exact composition to be of fundamental importance, he spent ten years in analyzing about 2,000 simple and compound bodies, and the results he published in 1818 attained a remarkable standard of accuracy, which was still further improved in a second table of combining proportions and atomic weights that appeared in 1826. He used oxygen — in his view the pivot around which the whole of chemistry revolves — as the basis of reference for the atomic weights of other substances, and the data on which he chiefly relied were the proportions of oxygen in oxygen compounds, the doctrines of isomorphism, and Gay-Lussac's law of volumes. When Alessandro Volta's discovery of the electric cell became known, Berzelius, with W. Hisinger (1766–1852), began experiments on the electrolysis of salt solutions, ammonia, sulfuric acid, etc., and later this work led him to his electrochemical theory, a full exposition of which he gave in his memoir on the *Theory of Chemical Proportions and the Chemical Action of Electricity* (1814). This theory was founded on the supposition that the atoms of the elements are electrically polarized, the positive charge predominating in some and the negative in others, and from it followed his dualistic hypothesis. according to which compounds are made up of two electrically different components.

At first this hypothesis was confined to inorganic chemistry. but later he extended it to organic compounds which he saw might similarly be regarded as containing a group or groups of atoms — a compound radical — in place of simple elements. Although his conception of the nature of compound radicals did not long retain general favour — indeed, he himself changed it more than once — he is entitled to rank as one of the chief founders of the radical theory. He continued and extended the efforts of Antoine Lavoisier and his associates to establish a convenient system of chemical nomenclature. By using the initial letters of the Latin (occasionally Greek) names of the elements as symbols for them, and adding a small numeral subscript to show the number of atoms of each present in a compound, he introduced the present system of chemical formulation (*see* CHEMISTRY). Each symbol had a definite weight and volume connotation. He effected improvements in analytical methods and the technique of the blowpipe (*Über die Anwendung des Lothrohrs,* 1820). He is often referred to as the father of gravimetric analysis; he introduced the use of rubber tubing, the water bath, desiccator, wash bottle, filter paper, etc. He classified minerals on a chemical basis and carried out many individual researches such as those on tellurium, selenium, silicon, thorium, titanium, zirconium and molybdenum, most of which he isolated for the first time. He invented the term catalysis and did considerable work in this field. Berzelius was interested in and wrote on geology.

Apart from his original memoirs, of which he published more than 250, mostly in Swedish in the *Transactions* of the Stockholm academy, he published a *Lehrbuch der Chemie,* which went through five editions (first, 1803–18; fifth, 1843–48) and was translated into the principal European languages. A critical annual report on the progress of physics and chemistry, the *Jahresbericht* (1821–48), was prepared by him at the instance of the Stockholm academy. For many years he was the leading figure in the chemical world.

BERZSENYI, DÁNIEL (1776–1836), Hungarian poet born in Egyházashetye on May 7, 1776, was a country squire who spent his life far from any town, unconnected for many years — the really productive ones — with any literary circle. He wrote for himself, and his literary activity was discovered by chance. Ferenc Kazinczy, a leading figure in Hungarian letters, took an interest in the works of the solitary poet and through his efforts Berzsenyi's poems became known and his fame established well before the publication of his first, and only, volume of poetry (1813). In 1817 Ferenc Kolcsey, another great poet of the period, passed an unduly severe judgment on Berzsenyi's work. The poet, deeply hurt, withdrew, and thereafter wrote a few essays in defense of his ideas, but virtually ceased to write poetry. This was a loss to Hungarian literature which Kölcsey himself — in a most moving funeral oration on Berzsenyi — deplored bitterly.

Berzsenyi was imbued with the spirit of the classics. The influence of Latin poetry, that of Horace in particular, can be noticed not only in the form of his poems, most of which were written in classical metres, but also in his vocabulary, his choice of subjects and his philosophy. His many allusions to antiquity often seem burdensome to the modern reader but the grandeur of his thought and the concise vigour of his expression are moving His love of his country and his attachment to the ideals dictated by an uncompromising moral rectitude inspired some splendid odes. One of these. *Magyarokhoz* ("To the Hungarians") castigates bitterly the decadence of his compatriots. Some of his tender, restrained elegies and his *Fohász* ("Prayer") are among the

purest gems of Hungarian poetry. Berzsenyi died at Nikla on Feb. 24, 1836. (Ds. Sr.)

BES, the Egyptian god of recreation, represented as a dwarf with large head, goggle eyes, protruding tongue, shaggy beard, bowlegs, bushy tail (sometimes clearly part of a skin girdle) and usually a large crown of feathers on his head. A Beslike mask was found among remains of the 12th dynasty. In the temple of the queen Hatshepsut at Deir el-Bahri (*c.* 1500 B.C.), he is figured along with the hippopotamus goddess as present at the queen's birth. His figure is that of a grotesque mountebank, intended to inspire joy or drive away pain and sorrow, his hideousness being perhaps supposed actually to scare away the evil spirits. In his joyous aspect Bes plays the harp or flute, dances, etc. He is figured on mirrors, ointment vases and other articles of the toilet. Amulets and ornaments in the form of the figure or mask of Bes are common after the New Kingdom; he is often associated with children and with childbirth and is figured in the "birth houses" devoted to the cult of the child god. Perhaps his earliest-known appearance in large-size temple sculptures is that at Jebel Barkal, Nubia, dating from the beginning of the 7th century B.C. As the protector of children and others he is the enemy of noxious beasts, such as lions, crocodiles, serpents and scorpions. Large wooden figures of Bes are generally found to contain the remains of a human fetus. In the first centuries of the Christian era an oracle of Besas was consulted at Xbydos, and prescriptions exist for consulting him in dreams. Bes may be of non-Egyptian origin, African. Arabian or even Babylonian; he is often named "coming from the Divine Land" (*i.e.,* the east or Arabia), or "Lord of Puoni" (Punt; *i* e., the African coast of the Red sea), and his effigy is found on Greek coins of Arabia. Contrary to the usual rule, he is commonly represented in Egyptian sculptures and paintings full faced instead of in profile. (F. Ll. G.; X.)

BESANÇON, a city in the Franche-Comté region of eastern France. capital of the *département* of Doubs, is 122 km. (76 mi.) E. of Dijon on the main railway line from Basel to Lyons. Pop. (1954) 61.139. It lies on the Doubs river which almost surrounds the city proper, and beyond the river are the hills of the western Jura. The limestone plateau of the Jura, with its open stretches and salt springs. was a centre of population in the Hallstatt period (Early Iron Age) and the site of the present city was soon recognized as of strategic importance. As Vesontio it was the chief town of the Sequani (*q.v.*), and in 58 B.C. was occupied by Julius Caesar. Marcus Aurelius raised it to the rank of a *colonia.* The neck of the peninsula formed by the encircling river rises to 1,205 ft., and on it stood the Roman castrum, replaced in the 17th century by a citadel. Forts crowned the surrounding heights. Other Roman remains include a triumphal arch (the Porte Noire, partly rebuilt in 1820) decorated with bas-reliefs, thought to have been built in commemoration of the victories of Marcus Aurelius in 167, and the remains of a theatre or amphitheatre. of an aqueduct and of a bridge which now forms part of a modern bridge. During succeeding centuries the city was several times destroyed and rebuilt. The archbishopric dates from the end of the 2nd century. and the archbishops gradually acquired considerable temporal power. In 1184 Frederick Barharossa made Besançon a free imperial city. During the 14th century it fell to the dukes of Burgundy. from whom it passed to the emperor Maximilian I. through his marriage with Mary of Burgundy. Under the Austro-Spanish domination it became very prosperous. and superseded Dôle as the real capital of Franche-Comté (*q.v.*). During the 17th century it was several times attacked by the French, to whom it was ceded by the treaty of Nijmegen in 1678. It was then fortified by Sebastien le Prestre de Vauban (*q.v.*). Until 1789 it was the seat of a parliament. It was invested and bombarded by the Austrians in 1814 and was important during the Franco-German War (1870–71). It was damaged in World War II.

The river is bordered by fine quays and by the shady promenades which are a feature of the city. The cathedral of St. Jean, founded in the 4th century and often reconstructed since, resembles the churches of the Rhine basin and also Nevers cathedral in having apses at both ends. The main parts date from the 11th, 12th and 13th centuries, the eastern apse and the tower being 18th-century work, as is the archbishop's palace which adjoins the cathedral. In the latter are a number of medieval and modern works of art. The Palais Granvelle, which was built from 1534 to 1540 by Nicolas Perrenot de Granvella, chancellor to Charles V, centres on an arcaded courtyard in the heart of the town and is occupied by Besançon's learned societies. The *hôtel de ville* (town hall). like much of the town, dates from the 16th century. The law court preserves a Renaissance façade and an 18th-century audience hall. A 15th-century round tower and the 16th-century Porte Rivotte are relics of fortifications. The seat of a university (founded 1422 in Dôle and moved to Besançon in 1691), the city acquired collections of pictures, antiquities and specimens of natural history. On the right bank of the river (to the north) are populous industrial suburbs, including the spa of Besançon-la-Mouillère. Watch- and clock-making were introduced from the district of Neuchâtel, Switz., in the 18th century and the artificial silk industry also grew. Besançon is at the crossroad of the routes running between Paris and Switzerland and from Alsace to the Canal du Midi.

BESANT, ANNIE (née Wood) (1847–1933), British social reformer, sometime Fabian socialist, theosophist and Indian independence leader, was born in London on Oct. 1, 1847, daughter of William Wood. She was educated privately and in 1867 married Frank Besant (d. 1917), an Anglican clergyman from whom, after she had passed from Anglicanism through theism to atheism, she was separated legally in 1873 She became closely associated with Charles Bradlaugh (*q.v.*) as a Freethought writer, lecturer and officer in the National Secular society, an editor of the *National Reformer* and a helper in his notable campaign to gain his seat in parliament, denied to him because of his atheism. She became the first prominent woman in England to accept Neo-Malthusianism and advocate birth control; with Bradlaugh she was prosecuted by the government for obscenity in a legal *cause célèbre* arising from their publication of Charles Knowlton's *The Fruits of Philosophy: or, The Private Companion of Young Married People,* and her children mere taken from her (*see* also Knowlton, Charles'). Through the instrumentality of Bernard Shaw. with whom she mas intimate for several years, she was converted from radicalism to Fabian socialism in 1885: for some time she devoted her magazine, *Our Corner,* largely to this cause: and wrote one of the famed *Fabian Essays* in 1889. She eventually joined the more Marxist Social Democratic federation.

Then suddenly, at the height of her fame and influence as a leading materialist. reformer, strike leader, union organizer and member of the London school board, Mrs. Besant underwent another of her remarkable changes in orientation and was converted to theosophy (*q.v.*) through the reading of Madame H. P. Blavatsky's *The Secret Doctrine* in 1889. On Madame Blavatsky's death in 1891 Mrs. Besant became the most prominent member of the Theosophical society. and in 1907, in spite of many sensations and scandals, none of which tainted her personally. was elected international president of the society, an office which she held to her death. Her genius as a propagandist and organizer brought this mystical and occult society an influence for many years far out of proportion to its actual size.

An inveterate world traveler; Mrs. Besant went to India for the first time in 1893. When she discovered that in most of her previous reincarnations she had been an Indian (as well as Hypatia and Giordano Bruno), she adopted Hinduism as her basic religion, and thereafter played a major role in reviving the Indians' damaged pride in their ancient traditions, history and culture. Vitally interested in education also. she founded the Central Hindu college at Benares. Just before World War I she entered into Indian politics, and through her influential Madras newspaper, *New India,* threw herself headlong into the home rule movement, the first league of which she started. Because of her refusal to cease her agitation during the war, she was interned in 1917. On her release she was elected president of the Indian National congress in recognition of her services. Her influence began to

deteriorate, however, when she aligned herself against the extreme nationalists and when she rejected the methods of passive resistance and civil disobedience advocated by her former admirers Motilal and Jawaharlal Nehru and by Gandhi, because she believed that these methods paradoxically resulted in violence and bloodshed. Mrs. Besant's old age was rendered more unhappy by the defection of J. Krishnamurti, a young Hindu whom she had helped to "discover" in 1909; after a sensational guardianship trial in Madras, he had been offered to the world as the world teacher and the vehicle of the new Messiah, but by 1929 he renounced the claim of messiahship and went off on his own spiritual course, after dissolving the Order of the Star in the East which Mrs. Besant and others had developed for him.

She died at Adyar, Madras, on Sept. 20, 1933, confident that she would soon be reincarnated and return to the mission which had been assigned her by the occult hierarchy.

See A. Besant. *Autobiography* (1885, 1893); Gertrude M. Williams, *The Passionate Pilgrim* (1931); A. H. Nethercot, The *Strange Lives of Annie Besant* (1960). (A. H. N.)

BESANT, SIR WALTER (1836-I~OI), English novelist and philanthropist, whose best work describes life in London's East End, was born at Portsmouth on Aug. 14, 1836. He studied at King's college. London. and Christ's college, Cambridge, and. after teaching in Mauritius, became secretary to the Palestine Exploration fund (1868). In 1871 he began a literary collaboration with James Rice, editor of *Once a Week,* which lasted until Rice's death (1882). Besant's account of this partnership, which produced 14 romantic. improbable and verbose novels, prefaces the 1887 edition of the first, *Ready-Money Mortiboy* (1872).

In 1882 Besant published his first independent novel, All *Sorts and Conditions of Men,* based on impressions of the East London slums. which he saw as joyless rather than vicious. Its "Palace of Delights" became a reality when the People's palace was founded in Mile End road in 1887. Besant co-operated in its establishment. The *Children of Gibeon* (1886) also described slum life. Besant wrote 32 novels after Rice's death, including *Dorothy Forster* (1884) and *Amorel of Lyonesse* (1890). His biogrsphies include *Rabelais* (1879), and he also wrote critical and topographical studies, the chief of which. his *Survey of London,* 10 vol. (1902–12) was never finished. He helped to found the Society of Authors in 1884 and edited its journal until his death at Hampstead on June 9, 1901. He was knighted in 1895.

The Autobiography of *Sir Walter Besant,* edited by S. S. Sprigge, was published in 1902.

See G. Godwin, *Queen Mary College* (1939); F. W. Boege, "Sir Walter Besant," in *19th Century Fiction,* vol. 10 (1955). (P. M. Y.)

BESNARD, (PAUL) ALBERT (1849–1934), French painter and etcher, whose works reveal an adherence to French academic tradition mingled with contemporary influences, especially English, was born in Paris on June 2, 1849. He was a pupil of J. Brémond and, at the École des Beaux-Arts, of A. Cabanel. Bremond had been a pupil of Ingres, as had Besnard's father, and Albert Besnard's earlier works, such as "Procession des Seigneurs de Vauhallan," display a romanticized classicism derived from Ingres. Besnard was in Rome. 1874–78, and in England. 1881–83, where meetings with Xlphonse Legros and Anders Zorn turned his attention to etching. He seems to have originated the technique of suggesting form by coarse crosshatching while omitting any enclosing line, a practice adopted by Zorn in his later plates. "Le Remords" (oil) and "Le Viol" (etching) show how Besnard was affected by English Pre-Raphaelitism, while Constable's landscapes and the portraits of Vandyke and Sargent also clearly impressed him ("Portrait de Theatre: Mme. Rejane"). After 1883 Besnard came under the influence of Impressionism; but he overpassed Impressionism's informal. snapshot character and presently his style again became tighter, more linear and decorative. He made many impressive portraits in oils, etching and pastels, and executed frescoes in the Ecole de Pharmacie and the Nouvelle Sorbonne, neobaroque cupolas for the Théâtre Français and the Petit Palais, and 12 almost surrealist allegories of the Cross for the hospital chapel at Berck. Pas-de-Calnis. Besnard was director of the French Academy in Rome, 1913–21, in succession to Carolus Duran, and of the École des Beaux-Arts, Paris. after 1922. He died in Paris on Dec. 4, 1934.

BESSARABIA, a region of eastern Europe, 17,151 sq.mi. in area, bounded on the west by the Prut river, which separates it from Bukovina and from Moldavia proper; on the north and on the east by the Dniester river, which separates it from the Ukraine; on the southeast by the Black sea; and on the south by the Kiliya (Chilia) arm of the Danube delta, which separates it from northern Dobruja. In the 1940s the Moldavian Soviet Socialist Republic was formed out of the greater part of Bessarabia, with the addition of a strip of territory east of the Dniester, but the extreme north of Bessarabia (*i.e.,* the district of Khotin) and the whole coastal plain from the Danube to the Dniester were attached to the Ukrainian Soviet Socialist Republic.

The soil in the northeast is Ukrainian black earth; in the centre there are low hills, dissected by tributaries of the Prut and of the Dniester, formerly thickly afforested with hardwoods; the southern steppe, known as the Budzhak, with a light soil, merges into salt marshes and lagoons (limans). Bessarabia is a favoured region for agricultural production, chiefly cereals, fruit and wine. Because of exploitation in the 19th century little of the land is under forest, and soil erosion has proceeded far in many districts. Animal husbandry was formerly extensive in the steppe region; the limans are rich fishing grounds. There are some stone quarries and lignite deposits; clay is worked. The chief town is Kishinev (Chişinău), centrally situated on the small Byk river. Other towns are Khotin (Hotin), Soroki (Soroca), Bendery (Bender, Tighina) and Belgorod-Dnestrovski (called Akkerman under Turkey and Cetatea Albă under Rumania) on the Dniester; Beltsy (Bălti) and Orgeyev (Orheiu) in the north. on the Reut; and Kiliya (Chilia), Izmail (Ismailj and Reni on the Danube.

History.—The early history of Bessarabia (Basarabia) is obscure. Greek colonies on the Black sea coast of what is now Moldavia date from the 7th century B.C.; in the 2nd century A.D. the territory probably formed part of the kingdom of Dacia. conquered by Trajan. The Slavs began to appear in the 6th century, but settlement was interrupted by successive invasions of nomads from the east, the last being that of the Mongols in the 13th century.

Moldavia.—The Genoese, founding fortified commercial outposts on the Dniester in the 14th century, paved the way for contact with western civilization, but Bessarabia's history did not take shape until the end of that century with the rise of the principalities of Moldavia and Walachia, which soon expanded to include the territory *(see* RUMANIA: *History).* The southern area, which fell originally into the Walachian sphere, probably took its name from the Basarab dynasty. The whole province became part of Moldavia in the 15th century, but was soon exposed to the Turkish onslaught; the key points of Akkerman and Chilia were captured in 1484 and this was ratified by treaty (1503, 1513). The southern part of Bessarabia was again detached and organized by the Turks into two sanjaks of the Ottoman empire.

Russia entered the scene with the rise of Peter the Great, and Moldavian princes more than once sought Russian support against Turkey. Russia, in its drive toward the mouths of the Danube? occupied Moldavia five times between 1711 and 1812 and finally secured the cession of Bessarabia proper, with half of Moldavia, by the Porte in the treaty of ,Bucharest of the latter year. The name of Bessarabia was then extended to the whole area.

The Russian Administration, 1812–1917.—In 1829 in the treaty of Xdrianople, Russia pushed the frontier south to include the Danube delta. After the Crimean War the treaty of Paris in 1856 restored Danubian Bessarabia (at that time divided into three districts, namely Izmail, Kagul, and Bolgrad) to Moldavia; but in 1878, despite Rumania's having fought on the Russian side against Turkey, the treaty of Berlin assigned these three districts once more to Russia, giving Rumania the inadequate compensation of Dobruja (*q.v.*).

The Russian administration was at first liberal. Autonomy

was granted in 1818 and remained in force until 1828; a Moldavian boyar was made governor and a Moldavian archbishop installed. Nevertheless many Moldavian peasants fled across the Prut fearing the introduction of serfdom. The introduction of the zemstvo system in 1869 provided a measure of local autonomy, but a policy of russification in both civil and ecclesiastical administration was thereafter pursued, with little effect on the largely illiterate peasantry. The founding of the kingdom of Rumania (1881) formed a centre of attraction for Moldavian nationalism, but no lively movement developed in Bessarahia until after the Russian revolution of 1905. Its strength was drawn, not from the boyars (largely russified), but from schoolteachers and parish priests. Bessarabia achieved some prosperity under Russian rule, the empire forming a good market for its agricultural produce, which was dispatched by river or by the railway system built to link the country with the north-south main line to Odessa. Kishinev was a relatively flourishing town, though its large Jewish population suffered severely in the pogrom of 1903.

World War I *and the Russian Revolution.* — *In* World War I the Central Powers tempted Rumania to their side with offers to restore Bessarabia; but the scales were tipped in favour of the entente by counteroffers of Transylvania and Bukovina, as well as by the francopbile sentiment of the Rumanian people, so that by 1916 Rumania was fighting as Russia's ally. The revolutionary and nationalist ferment in the Russian empire spread quickly to Bessarabia, which proclaimed support for A. F. Kerenski in March 1917. In April a National Moldavian committee demanded autonomy, land reform and the use of the Rumanian language; similar rights were claimed for the Moldavians, about 400,000 in number, settled east of the Dniester. A move toward complete independence was encouraged by events in the Ukraine, and in Nov. 1917 a council known as *sfatul ţărei* was set up on the model of the Kiev rada. It had originally 84 Moldavian deputies and 36 from the minorities chosen by military and professional organizations and a peasants' congress. On Dec. 2, 1917, the *sfat* proclaimed Bessarabia an autonomous constituent republic of the Federation of Russian Republics. Disorders caused by the revolutionary Russian soldiery led the *sfat* to appeal to the entente's representatives and to the Rumanian government at Iagi for military help, whereupon the Bolsheviks occupied Kishinev on Jan. 5, 1918. They were driven out by a Rumanian division on Jan. 13; and on Jan. 24 the *sfat,* again following Kiev, proclaimed Bessarabia an independent Moldavian republic, renouncing all ties with Soviet Russia. Realizing the economic impossibility of isolation and alarmed by the pretensions of the German-sponsored Ukrainian government, the *sfat* voted for conditional union with Rumania on March 27, 1918. With the defeat of the Central Powers and the creation of greater Rumania, reservations were abandoned and unconditional union voted at the final session of the *sfat* on Dec. 9, 1918. The union of Bessarabia with Rumania was recognized by the Paris treaty of Oct. 28, 1920, signed by Great Britain, France, Italy and Japan. Great Britain ratified this treaty in 1922 and France in 1924; Italy delayed ratification until 1927; and Japan never ratified it. The U.S.S.R. never recognized Rumania's right to the province. The frontier along the Dniester was closed; but the railway bridge at Tighina was opened in 1936, two years after the resumption of diplomatic relations.

The Rumanian Administration, 1918–40. — The Rumanian government immediately put through a drastic land reform, initiated by *sfatul ţărei,* whereby the maximum holding allowed was 100 ha. Despite this, the province languished economically. The uncertainty caused by the continued pretensions of the U.S.S.R. hindered development; Rumania had little need of Bessarabia's fruit, corn and wine; roads were inadequate; the railway system was geared to that of Russia; and the closing of the Dniester and the loss of the natural outlet, Odessa, had a disastrous effect. The province was put under a centralized regime, at times military in character; in 1938 King Carol attempted to break up the historic unity by dividing it among newly created regions. Some tardy concessions to the minorities were made in 1939.

World War II. — After the German-Soviet pact of hug. 1939, the U.S.S.R. revived claims to Bessarabia; and the collapse of the western front in 1940 precipitated action On June 27 a Soviet ultimatum to Rumania demanded the cession of Bessarabia and of northern Bukovina as "compensation for Rumanian misrule in Bessarabia." The Rumanian government had to submit, and Russian troops marched in (June 28). On July 11 the districts of central Bessarabia inhabited predominantly by Moldavians were joined to part of the Moldavian Autonomous Soviet Socialist Republic across the Dniester (an autonomous republic of the Ukraine set up in 1924) to form. in August, a Moldavian Soviet Socialist Republic, with Kishinev as capital. The Khotin district in the north was incorporated in the Ukrainian Soviet Socialist Republic as were the southern districts of Cetatea Albă and Izmail Further land was expropriated. and collectivization launched. Many Moldavians left, some Jews entered and the whole German population was removed to western Poland under an agreement between Germany and the U.S.S.R. In July 1941 Rumania, having entered the war as Germany's ally against the U.S.S.R., reoccupied Bessarabia, and by Dec. 1942 it was fully governed as Rumanian territory, though a formal decree of annexation was postponed until the end of hostilities. Some Moldavian peasants from Transnistria, the newly organized Rumanian province between the Dniester and the Bug, were settled on the farms of departed Germans, and many Jews were killed or deported.

Reincorporation in the U.S.S.R. — The Russians reoccupied Bessarabia in the course of 1944, and by the peace treaty of Feb. 1947 (ratified in September), Rumania had once more to yield Bessarabia and northern Bukovina to the Soviet Union. The Soviet territorial arrangements of Aug. 1940 were restored; the Communist system was introduced; and Bessarabia lost its administrative identity.

Population includes Moldavians, Ukrainians, Armenians, Rumanians, Russians, Jews and Bulgarians. (See also MOLDAVIA.)

Antiquities. — Bessarabia contains much of archaeological interest, notably many mounds and barrows of different early epochs. Remains of earthworks, probably of a wall built by Trajan, can be traced from Leovo on the Prut almost to the junction of the Botna river with the Dniester: and there is another similar line farther south. There are few traces of the old Greek and Roman towns known to have existed except at Belgorod-Dnestrovski (the Tyras of the Greeks). The most striking monuments are the great forts along the Dniester at Khotin. Soroki, Belgorod-Dnestrovski and Bendery, mostly begun by the Genoese. There are some old churches, both monastic and parochial, one of the most interesting being the 15th-century Armenian church at Belgorod-Dnestrovski.

BESSARION, JOHN (afterward BASIL) **(c.** 1400–1472), Byzantine humanist and theologian, and later Roman cardinal, who contributed to the revival of letters in the 15th century, was born at Trebizond. He was educated at Constantinople and took the name of Bessarion on becoming a monk in 1423. He studied under the Neoplatonist Gemistus Pletho and in 1437 was made archbishop of Nicaea by John VIII Palaeologus, whom he accompanied to Italy in order to bring about a union between the Byzantine and western churches, with the object of obtaining help against the Turks. At the councils held in Ferrara and Florence, Bessarion supported union: but this was not accepted by the Byzantine church. Bessarion, however, remained in communion with Rome and gained the favour of Pope Eugenius IV, who made him a cardinal (1439). From that time he resided in Italy, doing much, by his patronage of scholars, by his collection of books and manuscripts and by his writing to spread knowledge of Greek language and learning. In 1463 he received the title of Latin patri-

arch of Constantinople. For five years (1450–55) he was legate at Bologna, and he was engaged on embassies to foreign princes, including Louis XI of France in 1471. He died on Nov. 19, 1472, at Ravenna.

Bessarion was one of the most learned scholars of his time. Besides his translations of Aristotle's *Metaphysics* and Xenophon's *Memorabilia,* his most important work is a treatise against George of Trebizond, a violent Aristotelian, entitled *In calumniatorem Platonis*. Bessarion sought to reconcile the two philosophies. His library, containing a large collection of Greek manuscripts. was presented by him to the senate of Venice, and formed the nucleus of the library of St. Mark.

BESSEL, FRIEDRICH WILHELM (1784–1846), German astronomer and mathematician. made fundamental contributions to accurate positional astronomy, to geodesy and to celestial mechanics. He was born at Minden near Hanover on July 22, 1784. In 1804 he calculated the orbit of Halley's comet from observations of 1607; H. W. M. Olbers secured publication of the results (*Monatliche Correspondenz* x., 1804) and recommended his appointment as assistant to J. H. Schroter at Lilienthal observatory. In 1810 he was appointed professor of astronomy at Konigsberg, East Prussia, directing the observatory from its completion in 1813 until his death. His work there inaugurated the era of accurate positional astronomy. To improve star places, he reduced James Bradley's Greenwich observations, deriving the mean places of 3,222 stars *(Fundamenta astronomiae,* 1818). The uniform system of reduction he established in *Tabulae Regiomontanae* (1830) is still standard. During 1821–33 he observed all stars to the ninth magnitude in zones from declination $-15°$ to $+45°$, increasing the number observed to about 50,000. In 1826 he corrected the seconds pendulum (in a discussion republished by H. Bruns in 1889); during 1831–32 he directed geodetical measurements of meridian arcs in East Prussia; and in 1841 deduced a value 1/299 for the ellipticity of the earth. In 1838 he made the first definite parallax measurement for a fixed star, 0.″31 for 61 Cygni *(Astronomische Nachrichten,* xvi, no. 365–366). In 1844 he inferred from their varying proper motions the binary nature of Sirius and Procyon. Shortly before his death he had begun the study of the irregular motion of Uranus, which problem at the hands'of others later led to the discovery of Neptune. He was first to make effective use of the heliometer, to introduce corrections for personal equation (1823), and to study instrumental errors systematically. He issued a multi-volume series *Astronomische Beobachtungen auf der Sternwarte zu Konigsberg* (1815–44). Of special interest are his *Astronomische Untersuchungen* (1841–42), *Populare Vorlesungen wissenschaftliche Gegenstände* (1848) and the collection *Abhandlungen* (1875–82). His minor papers numbered over 350. He enlarged the resources of pure mathematics by the introduction of what are now termed Bessel functions, making preliminary use of them in 1817 to study Kepler's problem *(Transactions, Berlin Academy,* p. 49 [1816–17]), fully developing them seven years later for application to planetary perturbations (*Transactions, Berlin Academy,* pp. 1–52 [1824]). He died at Konigsberg on March 17, 1846.

BESSEMER, SIR HENRY (1813–1898), English inventor and engineer, who discovered and developed the first process for making inexpensive and plentiful steel, was born at Charlton, near Hitchin, Hertfordshire, on Jan. 19, 1813, the son of a type founder. His engineering education was self-acquired and was applied first to the development of electrotyping, and to the improvement of a typesetting machine. A casual inquiry about the cost of "gold" paint led him to work out and operate in secret a process for the manufacture of "gold" powder which made him a small fortune.

At the time of the Crimean War he designed a rotating artillery shell and, finding the cast-iron cannon of the day too weak for it, set out to discover a stronger material. He hit upon a process (announced in 1856) in which air was blown through molten pig iron to decarburize it, sufficient heat being generated by the reactions to keep the charge hot and liquid. The result was an extremely malleable mild steel. Early success, however, was followed by relative failure as it had not been understood that, in a converter lined with siliceous (acid) refractories, harmful phosphorus was not removed. Bessemer, however, developed his own source of nonphosphoric pig iron and, with some assistance from his Swedish licensee Göran Göransson, brought it to commercial success, and it was widely adopted from 1864 onward. Modification to enable the use of phosphoric pig irons was made by Sidney Gilchrist Thomas, in 1878, by employing magnesian (basic) refractories. By this time the use of the open-hearth process invented by Sir William Siemens was extending. Nevertheless, the Bessemer process, both acid and basic, produced enormous quantities of steel used in bridges, railway construction and shipbuilding. In his later years Bessemer, while still interested in steel, devoted his energies to other matters, such as an only partly successful stabilized cross-channel steamer, a solar furnace and a large telescope. He was made a fellow of the Royal society, was knighted in 1879 and received many other honours. He died at Bessemer Grange, Denmark Hill, London, on March 15, 1898.

BESSEMER, a city of Jefferson county, Ala., U.S., 13 mi. S.W. of the centre of Birmingham, in the heart of the iron, coal and limestone region of the state. It is a part of the Birmingham industrial district and has large iron and steel industries and coal-mining operations, and also manufactures brick, clay pipes, coal-tar derivatives, fertilizer, high explosives, lumber and meat products. Under the influence of Henry F. DeBardeleben, Bessemer was laid out in 1887 and incorporated in 1888. It was named after Sir Henry Bessemer, inventor of a steelmaking process. For comparative population figures *see* table in ALABAMA: *Population.* (H. T. Sh.)

BESSEMER STEEL: *see* CONVERTER STEEL.

BESSEY, CHARLES EDWIN (1845–1915), U.S. botanist, an outstanding teacher and author of a classification of plants, was born near Milton, O., on May 21, 1845, and studied with Asa Gray at Harvard (1872–73 and 1875–76).

At Iowa State Agricultural college (now Iowa State college), Ames, he was professor of botany (1870–84), and was acting president in 1882. At the University of Nebraska, Lincoln, he was professor of botany after 1884, acting chancellor (1888–91, 1899–1900 and 1907) and head dean after 1909.

With the publication of *Botany for High Schools and Colleges* (1880), he introduced morphology to the United States. This book was the first in the series of "Bessey's textbooks," which set a standard for modern work. Bessey also wrote a number of other textbooks and reference works on botany.

BESSIÈRES, JEAN BAPTISTE, DUC D'ISTRIE (1768–1813), French soldier, one of Napoleon's marshals, was born at Prayssac, near Cahors, on Aug. 6, 1768, a surgeon's son. Educated at Cahors college, he joined the army and was for a time in Louis XVI's constitutional guard with Joachim Murat. After service with Jean Lannes in Catalonia, he was in 1796 chosen to command Napoleon's escort of guides in Italy. He fought bravely in Egypt at Aboukir (1798) and, in Italy again, commanded 800 men of the consular guard at Marengo (1800). In 1804, only four years alter becoming general of brigade, he was made a marshal. While Napoleon followed the example of many kings

of France in making his personal friend a marshal, this also marked a decision to develop the imperial guard.

In 1805 Bessières had 9,000 guards. both infantry and cavalry, under his orders and led a famous charge against the Russian guard cavalry at Austerlitz. In 1806 he had 12,000 men. The guard cavalry saved the day at Eylau. but the guard infantry had little fighting. Bessières went to Spain in 1808 to gain experience, and his victory at Medina de Rioseco enabled Joseph Bonaparte to reach Madrid. In command of the cavalry corps against Austria in 1809, he led charges to cover the retreat in the battle of Aspern-Essling and to gain time at Wagram, where he was severely wounded. Even so he was very soon sent to end the British Walcheren expedition in Flanders. In 1809 also he was created duc d'Istrie. Sent back to Spain to hold the north, he had 50.000 men under his orders in 1811, yet when he joined André Masséna for the battle of Fuentes de Oñoro he brought only a few cavalry; he could not concentrate a field force. In 1812 he led the guard cavalry to Russia and lost them there almost without fighting. Few cavalry were ready for his command in the new army in Germany in 1813. On May 1 of that year he was riding out on reconnaissance near Liitzen and was killed by a chance shot. His loss was a real sorrow to Napoleon, one of whose few intimate friends he had been—a calm, steady man never spoiled by his success.

See A. Bessières, *Le Mardchal Bessières* (1952). (I. D. E.)

BEST, CHARLES HERBERT (1899–), professor of physiology at the University of Toronto and the first, along with Frederick G. Banting, to extract insulin from the pancreatic gland. Born at West Pembroke, Me., on Feb. 27, 1899, he received his higher education in Canada. During World War I he enlisted in the Canadian army, thereby acquiring Canadian citizenship. After service overseas he resumed his studies at the University of Toronto.

In May 1921, while still an undergraduate, he became a laboratory assistant to Banting, who had come to the university to test his idea that insulin, a hormone secreted by certain cells within the pancreas, would cure diabetes. After several months, Banting and Best proved that insulin was present in the pancreas and that extracts made from pancreases of healthy dogs would control diabetes in dogs that had been made diabetic by surgical removal of this gland. Insulin also proved effective on humans, and at long last an effective treatment for diabetes was available.

A department of medical research was created at the university in 1923 in honor of Banting and Best. Best, who received his medical degree in 1925, became research associate in 1923 and director on July 1, 1941, following the death of Banting. He was appointed professor and head of the department of physiology at the University of Toronto in 1929. (M. C. L.)

BESTIARY, the name of a medieval collection of stories containing pseudoscientific descriptions of animals, plants and stones, etc., which drew parallels between the world of natural history and that of religion, thus giving moral instruction. There was no one standard text for the various stories. They were translated from the Greek Physiologus, whose origin is obscure. The supposed author of the book was "Physiologus" (*i.e.,* "the Naturalist"), who is often mentioned as the source of the descriptions. The Physiologus seems to have originated in Egypt, where animal symbolism in religion was common in about the 2nd century A.D., and to have been early taken over by Christian interpreters who favoured the allegorical and typological exegesis of the Bible. Some of its information can be traced back to Aristotle. Each description of an animal, plant, etc., and each lesson drawn from it is usually linked to a biblical text; the popularity of such descriptions can be seen from the commentaries by Basil and Ambrose on the hexameron (the six days of creation in Genesis), which have much in common with descriptions found in the Physiologus.

The Greek text of the Physiologus is extant in several versions, dating from the 4th century onward, some being ascribed to church fathers such as Epiphanius and Basil. A Latin version of the Physiologus is first mentioned in the 5th or 6th century as circulating under the name of Ambrose. The application of Christian moralizations to traditional lore was doubtless assisted by the many zoological metaphors found in the Bible—"the lion of the house of Judah," "the deaf adder that stoppeth her ears," etc. In the 12th century especially, bestiaries in Latin prose were greatly expanded and their material classified into sections under beasts, birds, reptiles and fishes, with the addition, in a few manuscripts, of trees and stones.

The Physiologus, or "Bestiary" as it was later called, was a popular book in the middle ages, both Byzantine and western, being translated into oriental as well as into modern European languages. Anglo-Saxon poems in the Exeter Book on the panther, the whale and a bird which may be the partridge show that the Physiologus was known in England before the Korman conquest. In the 11th century a certain Thetbaldus wrote a text in Latin verse which was the main source of the unique Middle English metrical version in the 13th-century manuscript Arundel 292 (in the British museum, London). The Bestiary was illustrated not only in the manuscripts but also in carvings and frescoes. It fell into disfavour after the realization that it was not based on true natural science.

BESTUZHEV-RYUMIN, ALEKSEI PETROVICH, COUNT (1693–1766), grand chancellor of Russia, notable for his conduct of foreign affairs under the empress Elizabeth, was born in Moscow on June 1 (new style; May 22, old style), 1693, the younger brother of Mikhail Petrovich Bestuzhev-Ryumin (*q.v.*), with whom he was educated in Copenhagen and Berlin. He served his apprenticeship to diplomacy at the congress of Utrecht (1712) under Prince B. I. Kurakin and in the service of the elector of Hanover, whom he followed to London when he became George I of England. After a short service at the court of Anna, duchess of Courland, he was sent to Copenhagen in 1721 as a Russian minister. The death of Peter the Great in 1725 prevented his advancement, and it was only in 1740, at 47 years of age, that he was recalled to Russia by E. J. Biron (*q.v.*). After Biron's fall, he was for a short time imprisoned at Schliisselburg.

His chance came in 1741 with the accession of the empress Elizabeth, who appointed him vice-chancellor. For the next 16 years, during a period of exceptional difficulty, he controlled the foreigd policy of Russia. In the War of the Austrian Succession, which had just broken out, France and Prussia were on one side, Austria and Great Britain on the other. Bestuzhev rightly recognized that the interests of France and Russia in Turkey, Poland and Sweden were diametrically opposed; that Russia could never hope to be safe from French influence in these countries; and that Prussia, under Frederick the Great, was also a danger. His basic policy, therefore, was to bring about a quadruple alliance between Russia, Austria, Great Britain and Saxony to counterpoise the Franco-Prussian league. The empress, however, was adverse to an alliance with Great Britain and Austria, whose representatives had striven to prevent her accession; and many of her personal friends, in the pay of France and Prussia, took part in conspiracies to overthrow Bestuzhev. Nevertheless Bestuzhev, aided by his brother Mikhail, carried out his policy. In Dec. 1742 a defensive alliance was concluded between Great Britain and Russia. Bestuzhev had previously rejected the French proposals to mediate between Russia and Sweden on the basis of a territorial

surrender by Russia, and he conducted the war against Sweden so vigorously that at the peace congress of Åbo (Jan.–Aug. 1743) he could insist on the cession of the whole of Finland to Russia. The French party. however, contrived to get better terms for Sweden by appealing to the empress's fondness for the house of Holstein. The Swedes accepted Adolphus Frederick, duke of Holstein, as their future king and, in return, received back most of the duchy of Finland.

Bestuzhev could not prevent the signing of a Russo-Prussian defensive alliance (March 1743), but he deprived it of all significance by excluding the proposed guarantee of Frederick the Great's Silesian conquests. Moreover, through Bestuzhev's efforts, the credit of Frederick (whom he regarded as more dangerous than France) at the Russian court fell steadily, and the vice-chancellor prepared the way for an alliance with Austria by acceding (Nov. 1, 1743) to the treaty of Breslau. A bogus conspiracy, however, started by the Holstein faction, aided by France and Prussia, who persuaded Elizabeth that the Austrian ambassador was intriguing to put Ivan VI back on the throne, alienated the empress from Austria; and Bestuzhev's ruin was regarded as certain when, in 1743, the French ambassador, J. J. Trotti, marquis de La Chétardie, arrived to reinforce his other enemies. Though Bestuzhev found a friend in M. I. Vorontsov, the empress's confidant, his position remained delicate, especially when the betrothal between the grand duke Peter and Sophia of Anhalt-Zerbst (afterward Catherine II) was carried through against his will, and Elizabeth of Holstein, the bride's mother, arrived in the Prussian interest to spy upon him. Frederick of Prussia, conscious of the instability of his French ally, was now anxious to contract an alliance with Russia and so was eager to see Bestuzhev overthrown. Bestuzhev, however, convinced the empress that La Chétardie was an intriguer. In June 1744 La Chétardie was expelled from Russia; in July Bestuzhev was made grand chancellor; and before the end of the year Elizabeth of Holstein was also expelled.

Bestuzhev's offer to attack Prussia if Great Britain would guarantee subsidies was rejected by the British in 1745. Then he turned to Austria and on May 22, 1746, an alliance was concluded between the two powers against Prussia. Alliances were also concluded with Denmark (1746) and with Turkey (1747), and a closer agreement was reached with Great Britain by the treaty of St. Petersburg (Dec. 9, 1747).

Bestuzhev's triumph coincided with the peace congress of Aix-la-Chapelle (1748), which ended the War of the Austrian Succession. Subsequently the diplomatic revolution changed the alignment of the European powers: Prussia broke with France and made a rapprochement with Great Britain; France and Prussia's enemies allied themselves. Bestuzhev's political prejudices at first prevented him from properly recognizing this change. His anglomania also misled him. His enemies, this time headed by his brother Mikhail and the vice-chancellor, Vorontsov, quickly took advantage of his mistakes. The Anglo-Prussian alliance of Jan. 1756 made nonsense of a subsidy treaty that Bestuzhev had made with Great Britain in Sept. 1755 (ratified, against the empress's wishes, on Feb. 1, 1756) and justified the arguments of his enemies that Great Britain was impossible, while his hatred of France prevented him from adopting the only alternative. To prevent underground intrigues he secured the erection of a council of ministers and at its first session, in March 1756, an alliance with Austria, France and Poland against Prussia was proposed, though Bestuzhev opposed any composition with France. Elizabeth maintained that the conclusion of the Anglo-Prussian treaty nullified Russian engagements with Great Britain. Bestuzhev tried to support his failing credit by a secret alliance with the grand duchess Catherine, whom he hoped after Elizabeth's death to make regent for her son, passing over Peter, from whom Bestuzhev expected nothing good either for himself or for Russia. These machinations later helped Bestuzhev's enemies ruin him. Meanwhile his anti-Prussian policy was being completed over his head and on Dec. 31, 1756, Russia acceded to the Franco-Austrian coalition of May 1756 against Prussia in spite of Bestuzhev's aversion for any alliance with France. The pretext for ousting him definitely presented itself when, after defeating the Prussians at Gross-Jagerndorf (Aug. 1757), his friend the Russian commander in chief S. F. Apraksin refrained from active operations. Accused of having launched a plot, Bestuzhev was arrested (Feb. 1758) and condemned to death, which was commuted to banishment to his estate at Goretovo (April 1759). Immediately after her accession (1762) Catherine II recalled him and made him a field marshal. He was also publicly exonerated, but he took no leading part in affairs. He died on April 21 (N.S., April 10, O.S.), 1766. (R. N. B.; Lo. L.)

BESTUZHEV-RYUMIN, MIKHAIL PETROVICH, COUNT (1688–1760), Russian diplomat, the elder brother of the great Aleksei Petrovich Bestuzhev-Ryumin (*q.v.*), was the son of the empress Anna's early favourite, Count Petr Mikhailovich Bestuzhev. Sent abroad with his brother in 1708, he was attached to the Russian embassy in Copenhagen. After having served in the Turkish campaign of 1711, he was for some years employed by Peter the Great in various capacities. In March 1720 he was appointed resident in London, at a time when the British court was greatly inflamed against Peter, who was regarded as a dangerous rival in the Baltic. Bestuzhev protested sharply against the lately formed Anglo-Swedish alliance and in November was forced to leave the country within eight days. On the conclusion of the peace of Nystad between Russia and Sweden in 1721, he was sent as ambassador to Stockholm, where in 1724 he managed to conclude a 12-year defensive alliance. He was successively transferred to Warsaw (1726) and to Berlin (1730), but returned to Stockholm in 1732 and succeeded in renewing the Swedish-Russian alliance for an additional 12 years.

In 1739, however, Bestuzhev's work was wrecked through the advice that he had himself given to the Russian government concerning the Swedish agent Malkolm Sinclair, whose mission to Istanbul was supposed to be hostile to Russia and who was murdered at Griinberg, in Silesia, on his journey home (June 28). The news of the murder aroused a storm of public indignation against Bestuzhev, who nevertheless tried to stick to his post. After the outbreak of the Swedish-Russian War (1741) Bestuzhev was transferred first to Hamburg and subsequently to Hanover, where he endeavoured to conclude an alliance between Great Britain and Russia. On his return to Russia in 1743, he was made grand marshal and married Anna Gavrilovna Yaguzhinskaya, a widow. A few months later, however, his wife was implicated in a political intrigue that Bestuzhev's enemies, including the marquis de La Chétardie (J. J. Trotti), the French ambassador, had hoped would ruin both brothers. Although his wife was publicly whipped, had her tongue cut out and was banished to Siberia, Bestuzhev was able to resume his diplomatic career. He served in Berlin (1743), in Warsaw (1744) and in Vienna (1748). His last mission was to Versailles, where he arrived in 1757, shortly after Russia's adhesion to the Franco-Austrian coalition against Prussia. Bestuzhev died in Paris on March 8 (new style; Feb. 26, old style), 1760. (Lo. L.)

BETA RAYS, a term applied to streams of electrons (see ELECTRON) from whatever source (see CATHODE RAYS; ELECTRICITY, CONDUCTION OF: Conduction in Gases; RADIOACTIVITY, NATURAL: Radiations Prom Radioactive Substances and Properties of β Rays). Since the discovery of the positron or positive electron, the term "beta emitter," *i.e.*, emitter of beta rays, is used for substances that emit, or methods that produce, streams of either negative or positive electrons. See NUCLEUS: Description and History and Constituents of the Nucleus; RADIATION (RAYS): Alpha and Beta Rays; see also Index references under "Beta Rays" in the Index volume. (H. B. LM.)

BETATRON: see ACCELERATORS, PARTICLE: Betatrons.

BETELGEUSE, α Orionis, a bright supergiant star in the constellation Orion. It is yellowish-red, and is thus easily distinguished from the other important stars in the constellation, which are white. Betelgeuse is an irregular variable, sometimes above and sometimes below the first magnitude. It was the first star whose apparent diameter was measured, in 1920, by Michelson's stellar interferometer. (See INTERFEROMETER.) The approximate distance of Betelgeuse from the sun is about 500 light years. It is of spectral type M, its spectrum showing the char-

acteristics of titanium oxide. *See* SPECTROSCOPY, ASTRONOMICAL; STAR.

BETEL NUT. The name betel is applied to two different plants which in the east are very closely associated in the purposes to which they are applied. The betel nut is the fruit of the areca or betel palm (*Areca* catechu) and the betel leaf is the produce of the betel pepper or pan (Piper betle), a plant allied to that which yields black pepper.

The areca palm is a native of Malaya and is extensively cultivated in the south of India, Ceylon, Thailand, the Malay archipelago and the Philippines. It is a graceful tree with a straight. slender, unbranched stem reaching 40 or 50 ft. in height and about $1\frac{1}{2}$ ft. in circumference, and bearing a crown of six to nine very large spreading pinnate fronds. The fruit is about the size of a small hen's egg, and within its fibrous rind is the seed or so-called nut, the albumen of which is hard, and has a mottled gray and brown appearance. The chief purpose for which betel nuts are cultivated and collected is for chewing, their use in this form being so widespread among oriental nations that it has been estimated that one-tenth of the world population indulges in betel chewing.

For chewing, the fruits are annually gathered between the months of August and November, before they are quite ripe, and deprived of their husks. They are prepared by boiling in water, cutting up into slices and drying in the sun, by which treatment the slices assume a dark brown or black colour. In chewing, a small piece is wrapped in a leaf of the betel pepper, with a pellet of shell lime or chunam; in some cases a little cardamom, tumeric or other aromatic is added. Chewing of the material causes a copious flow of brick-red saliva, which may temporarily dye the mouth. lips and gums an orange-brown colour. Contrary to general belief, the teeth of habitual chewers are not blackened by the betel juice, though chewers often artificially stain the teeth a black colour. Betel nuts are used as a source of inferior catechu (*q.v*); its chief alkaloid is arecoline, to which anthelmintic properties are attributed. The drug finds some use in veterinary medicine as an anthelmintic.

BETHANY (Arabic AL 'AYZARIYAH; Hebrew BEIT HANIYA), a small village $1\frac{3}{4}$ mi. from Jerusalem in Jordan, set among fruit trees on the eastern foot of the Mount of Olives along the Jericho highway. Pop. (1959 est.) 2,909. It figures prominently in the Gospels as the home of Lazarus and his sisters Mary and Martha, as the home of Simon the leper (Matt. xxvi, 6; Mark xiv, 3), and as the lodging place of Jesus during Holy Week. An ancient tower marks the site of a convent of Benedictine nuns, founded by Queen Millicent in 1147 and abandoned when Saladin took Jerusalem in 1187. A church was shown at this spot in the 4th century. Underneath is a vault opening on to a tomb chamber claimed to be that of Lazarus The original entrance was through the church, but when the church was converted to a mosque in the 16th century a separate entrance was excavated. The so-called house of Mary and Martha is about 30 yd. east of the tower (J. S. I.)

BETHEL ("house of God"), an ancient city of Palestine, 11 mi. N. of Jerusalem. Lying 2,900 ft. above sea level on the watershed of the Judaean hill country, the site is occupied by the modern village of Beitin (in the Jerusalem district of Jordan). Bethel (originally called Luz) was a place of importance in Old Testament times. It is frequently associated with Abraham and Jacob. Archaeological evidence suggests that Bethel may have been the actual scene of the events described in the Old Testament as having taken place at Ai (*q.v.*) during Joshua's campaign against Canaan. During the period of the Judges (*c.* 13th–11th centuries B.C.). Bethel was destroyed several times. The ark of the covenant (Judg. xx, 27) was there at one time, and Samuel visited the city regularly in his judging circuit (I Sam. vii. 16). After the division of Israel, Jeroboam I (10th century B.C.) made Bethel the northern kingdom's chief sanctuary. Bethel was the centre for the prophetic ministry of Amos. The city apparently escaped destruction by the Assyrians at the time of the fall of Samaria (722 or 721 B.C.), but was occupied by Josiah of Judah (reigned c. 640–609 B.C.). Bethel was one of the strong places of Judah fortified by Bacchides (I Macc. ix, 50). The New Testament does not mention Bethel, although the city was flourishing at that time. It reached its population climax in the Byzantine period. The site had no military advantages, but there are many nearby springs, so that cisterns were not needed until New Testament times. The site has been excavated in part, work being done jointly by the American School of Oriental Research and the Pittsburgh-Xenia Theological seminary in 1934, 1954, 1957 and 1960. (E. D. GR.)

BETHEL, a borough of Allegheny county, Pa., U.S., 6 mi. S. of Pittsburgh. For many years a coal mining community, Bethel later became one of the fastest growing residential communities in Allegheny county; many of its residents are employed in nearby Pittsburgh. Bethel's industrial products include plastics, soft-water tanks and concrete septic tanks.

Bethel township, named after the pioneer Presbyterian Church of Western Pennsylvania (1779), was organized in 1886 and incorporated as a borough in 1950. For comparative population figures see table in PENNSYLVANIA: Population. (M. R. Wo.)

BÉTHENCOURT, JEAN DE (*c.* 1360–1422), Norman-French explorer, renowned as the conqueror of the Canary Islands. He set out for the Canaries from La Rochelle on May 1, 1402, in a joint expedition with Gadifer de la Salle (*q.v.*). Soon after their arrival (June), BCthencourt, by agreement with Gadifer, departed for Spain to seek help. He returned after about 18 months, with the title of king, bestowed upon him by Henry III of Castile, and with a bull from the antipope Benedict XIII recognizing the conquest. BCthencourt's title caused a quarrel with Gadifer, who had meanwhile explored and taken possession of the islands. The associates sought the arbitration of the king of Castile; he decided in BCthencourt's favour and Gadifer returned to France. Béthencourt then profited from Gadifer's work to undertake, with Norman peasants. the first colonization of the Canaries. He entrusted the kingdom to his nephew, Maciot de BCthencourt, and returned to France in 1406. He died in his castle at Grainville in 1422. See also CANARY ISLANDS.

BIBLIOGRAPHY.—A contemporary account of the expedition up to 1404 by Gadifer's chaplain, Pierre Boutier. was discovered in 1889 (British Museum, Egerton manuscript 2709; ed. by P. Margry, *La Conquête et les conquérants des îles Canaries,* 1896). In *1482,* however, the manuscript, together with an anonymous account (now lost) of events after 1404, had been used by BCthencourt's nephew, Jean V de BCthencourt, in writing a false account of the expedition, entirely favourable to his uncle. A truncated version of this false account was published by P. Bergeron, *Histoire de la première descouverte et conquête des Canaries* (1630), and the manuscript that Bergeron had used, of which there are complete versions by R. H. Major, *The Canarian* (Eng. trans. 1872), and by G. Gravier, *Le Canarien* (1874), was until 1889 believed to he Pierre Boutier's original account. Discoveries of still further alterations made to Boutier's manuscript by Jean Leverrier, BCthencourt's chaplain, are disclosed in E. Serra Rafols and A. Cioranescu, *Le Canarien. Crónicas francesas de la conquista de Canarias,* vol. i (1959).

BETHESDA, an urban district 5 mi. S.E. of Bangor by road, Caernarvonshire. Wales. Pop. (1961) 4,151. Area 1.4 sq.mi. The district stands at the entrance to the famous Nant Ffrancon pass and is a gateway to the Snowdonia national park surrounded by an amphitheatre of mountain peaks of 2,500 ft. and over. It is a centre for fresh-water fishing and mountain climbing and there is a mountaineering instructional centre at Ogwen, at the head of the Nant Ffrancon pass. Developed after 1850, Bethesda was named after a Congregational church in the main street. It is reached by bus from Bangor, railway facilities being confined to freight. The majority of the inhabitants are employed at the slate quarries. There are also small factories producing cellulose, enamels and metal goods. (E. H. Ow.)

BETHESDA–CHEVY CHASE, a suburban area adjoining Washington, D.C., to the northwest in Montgomery county, Md. Not an incorporated entity but a group of communities, the area before 1949 was governed by county commissioners appointed by Maryland's governor; thereafter it came under the jurisdiction of a newly chartered, popularly elected seven-man county council. The Washington Suburban Sanitary commission and the Maryland-National Capital Park and Planning commission, created in 1918 and 1927 respectively, also exercise some

authority. Each neighbourhood maintains a volunteer fire department, supports its own civic association and, through representation in the county-wide civic federation. has a voice in formulating public policy. The first of these neighbourhoods arose in the 1890s when a Washington real estate syndicate acquired farm lands along the District of Columbia's northwest line and sponsored the founding of the Chevy Chase country club. Bethesda, farther west, remained largely rural until Washington's metropolitan growth in the mid-1930s gradually inspired residential developments. By 1960 the area, solidly built up, had a population of about 82,000.

Government installations accounted for much of that expansion. In 1935 the U.S. public health service located the National Cancer institute in Bethesda; in 1937 it erected an administration building there and later added other units to what became the National Institutes of Health. The U.S. navy opened a large research hospital nearby in 1942. After World War II the program at the National institutes was widened further. By 1960 it included basic research in microbiology, neurology, heart ailments. mental health and several other special fields. Bethesda thus became the foremost centre of medical research in the United States.

(C. McL. G.)

BETHLEHEM (Hebrew BEIT LÉHEM, Arabic BAYT LAHM, "house of bread"), a town in Jordan regarded by Christendom as the birthplace of Jesus Christ, is situated 5 mi. S. of Jerusalem on an eastern spur of the Judaean watershed at an altitude of 2.500 ft., overlooking the wilderness of Judaea. (There is a village of the same name in Galilee, 7 mi. N. of Nazareth.)

Modern Town.— Bethlehem had an estimated population in 1959 of 23.559, the majority Christian, the minority Muslim. It is a well-built town, the market of a country district rich in olive groves and vineyards as well as flocks. Apart from husbandry, its people specialize in the manufacture and sale of religious mementos made from olivewood, mother-of-pearl or "Dead sea stone." Various Christian missions maintain schools and charitable institutions that help give the town its marked Christian character.

History.— Called in Hebrew either Bethlehem. Ephrath or Bethlehem Ephrathah, it is known from early in the 2nd millennium B.C. through the story of Rachel's death. her traditional tomb lying about ½ mi. to the north (Gen. xxxv. 19). During the period of the Judges. late in the 2nd millennium. it was the residence of Boaz (Booz) and Ruth. and hence the ancestral home of Jesse and his son David. who as leader of the Bethlehemites overcame the Philistines and became king of Israel and Judah (Ruth; I Sam. xvi ff.). Already fortified. it seems (II Sam. xxiii, 14), it was one of the towns garrisoned under Rehoboam, grandson of David (II Chron. xi. 6j. After the Babylonian captivity it was reoccupied about 450 B.C. (Ezra ii, 21). As the birthplace of David it became in late Jewish times the expected birthplace of a new national leader, the Messiah (Mic. v; Matt. ii. 5). According to the Gospel of Luke (ii, 4) because of his descent from David, Joseph came to Bethlehem with Mary for the Roman provincial census and so Jesus came to be born there.

In A.D. 315 Bethlehem was little more than a wilderness. Justinian I rebuilt and fortified the little town and its monasteries (531). The Persians spared it in their invasion (614), and the Arabs in theirs (after 633). The crusaders (*q.v.*) under Godfrey of Bouillon occupied it at the invitation of the inhabitants before attacking Jerusalem (1099); Baldwin I was crowned in the church as king of Jerusalem (Christmas day. 1100); and a Latin bishopric was set up (1110). With the other Christian holy places it passed to the Muslims again in 1187. except for a brief restoration through treaty (1229–44). In 1263 its wall and towers were demolished and the moat filled in by order of the sultan Baybars. Repairs to the church were carried out in 1380 through the Franciscans. through the Greek Orthodox patriarch in 1671, and again in 1842. In 1834 Ibrahim Pasha of Egypt laid waste the Muslim quarter as punishment for insurrection. During World War I the British took the district from the Turks when advancing on Jerusalem (1917). It became part of the Hashemite Kingdom of Jordan after the British mandate for Palestine ended in 1948.

REX PHOTO STUDIO

CHURCH OF THE NATIVITY. BETHLEHEM; BEGUN IN 326 A.D.

The Church of the Nativity.— That the birth of Jesus took place in a cave is a Christian tradition that first became explicit about A.D. 150 in St. Justin's Dialogue with the Jew Trypho and in the Book of James (see M. R. James, The Apocryphal *New Testament*, 1953). Like other Jewish and Christian holy places it was desecrated under the Roman emperor Hadrian and planted as a grove sacred to Adonis. Two centuries later the emperor Constantine the Great. "paying due honours to the cave of the first Theophany." began (in 326) to erect a great church over what is now one of Christianity's principal shrines, the Grotto of the Nativity. It was that cave to which local tradition pointed as the site of the manger according to Palestinian contemporaries, Origen and Eusebius of Caesarea. As excavations by the British administration showed in 1934. Constantine's church was of basilican form with an octagonal sanctuary around a well showing the grotto, one of a series of caves which underlie the church. another being associated with St. Jerome and his translation of the Bible into Latin as the Vulgate. The excavations showed that this church was wholly rebuilt in the 6th century under the emperor Justinian I. its rich but damaged mosaic floor covered over, its stately colonnades reset, and its sanctuary enlarged. It still stands in this form, almost alone of its age, though without the cloistered forecourt which once occupied the present broad parvis or pavement in front. Muslim conquerors of Palestine always respected this church because of Mary's place in the Koran (ch. xix).

The church interior retains something of its decoration dating from the crusades (*q.v.*) of the 12th and 13th centuries. In 1169 Amalric I. the French king of Jerusalem, and Manuel I Comnenus, the Byzantine emperor, dedicated jointly a series of wall mosaics which are known to have ranged from the story of the incarnation in the choir and transepts (as illustrated by scenes from the Gospels) to the descent of Joseph from Jesse in the nave (as represented by a gallery of portraits). Above these was a series of texts, some of which remain. giving the consensus of councils and synods of Christendom on those aspects of Christ's nature. divine as well as human, which the pictures themselves symbolized. On many of the pillars in the nave and aisles are votive paintings of saints honoured likewise in the east or the west. From their subjects. style and mixture of Latin with Greek titles. these paintings must have been added during the crusaders' occupation. Generally they are in the statuesque Byzantine style. But among them is a "Madonna and Child" which at this period is remarkable for its very human treatment. more comparable to the Italian I'rimitives than the stylized eastern icon; its Latin invocation and the costume of the kneeling donors at the foot alike evince its western inspiration. Among the western European nations represented by patron saints are Italy and Spain. Norway and Denmark, and also the Normans of France and Sicily. The Normans are most notably symbolized by St. Catald. an Irish bishop of Tarentum (modern Taranto), in their principality of Otranto (south Italy), hut an Anglo-Norman was bishop there when the mosaics were put up. Beside such western saints are the fathers of eastern asceticism and monasticism, including those particularly associated with the

Judaean wilderness, that region east of Bethlehem now famous for the Dead sea scrolls.

To the north of the church is the modern Franciscan church and convent, built around a cloister of the 12th century, and to the south the Armenian convent. also dating from the 12th century but largely of the 18th century. The clergy of both and of the Greek Orthodox Church serve the sanctuary in turn according to a strict routine which is jealously guarded by each rite.

(C. N. J.)

BETHLEHEM, a city of Pennsylvania, U.S. in Northampton and Lehigh counties, on the Lehigh river, 50 mi. N.W. of Philadelphia. Pop. (1960) city, 75,408; Allentown-Bethlehem-Easton standard metropolitan statistical area (Lehigh. Northampton counties, Pa.; Warren county. N.J.), 492.168. (For comparative population figures see table in PENNSYLVANIA: *Population.*) The city is built on hills on both sides of the river and commands views as far as the Blue mountains, 20 mi. to the north.

Bethlehem is the centre of industrial activity of the Lehigh valley. It is one of the most important U.S. centres of steel production; the area also produces a large amount of the world's cement supply. Other local manufactures include foundry and machine products, metal products. electrical apparatus, oil burners, silk and textiles, clothing, candy, furniture, pumps, paints, plumbing fixtures. paper boxes. chemicals, spark plugs, heating appliances, ornamental iron, millwork, shoes, mattresses, cigars, brick, tar products and many food products.

The first Moravian arrivals to Pennsylvania were unable to agree upon the location of their permanent home. Finally, in Feb. 1741, they decided by lot upon the site at the forks of the Monocacy creek and the Lehigh river. With Henry Antes as agent, William Allen and his wife signed, on April 2, 1741, the deed which conveyed to the Moravian Church its first real estate in Pennsylvania.

Eveq before this date, the Moravians began building their first house, which was completed in March 1741. The building was divided into two sections, the smaller to house the cattle, the larger to serve as a common dwelling and as a place of worship. The Moravians next concentrated their efforts on preparing land for cultivation and on the construction of a large community house.

These first settlers. who lived under a communal system which lasted for several years, came from Bohemia and Moravia in search of religious freedom and to do missionary work among the Indians. On Christmas eve, when they assembled in the log house to observe the vigil of Christmas, Count Nicolaus Zinzendorf, their recently arrived patron, led the worshipers into that portion of the building occupied by the cattle, singing a German Epiphany hymn, which emphasized the little town of Bethlehem. This suggested to them the name of their settlement, Bethlehem.

During the American Revolution Bethlehem was a thoroughfare for troops, and in 1776–77 one of the Moravian buildings was used as a military hospital. For a short time the Sun inn there was the refuge of a part of the continental congress.

The water supply system was one of the first in North America, beginning regular operations June.27, 1755. With the completion of the Lehigh canal in 1829, traffic in coal began and in 1855 the Lehigh Valley railroad began operating trains through Bethlehem. In 1845 the north bank borough of Bethlehem was incorporated and people other than Moravians were allowed to own land. In 1865 South Bethlehem was incorporated and was united with the mother town in 1917. In the same year other boroughs on both sides of the river were incorporated. With the annexation in 1920 of Northampton Heights, the consolidated city encompassed an area of 18.89 sq.mi.

The first steel enterprise at Bethlehem, the Saucona Iron company, was formed April 8, 1857. In 1904 the Bethlehem Steel company was incorporated, and later became the second largest steel producer in the U.S. and the world's largest shipbuilding organization.

Bethlehem has a certain distinction as a music centre. An orchestra of strings, wind and brass was used in the church services before 1750. From 1754 a choir of trombones has played at funerals, and from the belfry of the church has announced festival days and national holidays and the deaths of members of the church. An orchestra and a chorus (first the Collegium Musicum, which gave the first performance in America of Franz Joseph Haydn's *Creation,* and later the Philharmonic society) were in existence almost continuously until 1885.

Choral music was revived a few years later in Bethlehem by the organist J. F. Wolle, and under his direction a national reputation was gained for the rendering of the works of Johann Sebastian Bach. From 1895, except for the period 1906–12, an annual Bach festival has been held in May attracting music lovers from all parts of the world.

The Moravian seminary. the first hoarding school for girls in the 13 colonies. was founded in 1742. Moravian College and Theological seminary was founded in 1807. These institutions merged in 1953–54 under the name of Moravian college, which enrolls more than 750 students annually. Lehigh university, which enrolls more than 3.000 students annually, was established in Bethlehem in 1865. It offers courses in arts and sciences, business administration and engineering at both undergraduate and graduate levels.

(G. D. H.j

BETHLEN, GABRIEL (GÁBOR) (1580–1629), prince of Transylvania and for a brief period king of Hungary, was a memher of a leading Protestant family of northern Hungary which had extensive estates in Transylvania. As a young man he was sent to the court of Prince Sigismund Báthory, whom he accompanied on his campaign of 1600. Subsequently he assisted István Bocskay to obtain the throne of Transylvania (1605) and then supported Bocskay's successor, Gabriel Báthory, from 1608 to 1613. Báthory's jealousy of Bethlen's superior ability, however, forced him to take refuge with the Turks. The sultan Ahmed I, as suzerain of the principality, proclaimed Bethlen prince of Transylvania and provided him with an army. On the murder of Báthory, the diet of Kolozsvár (Cluj) confirmed the sultan's choice (Oct. 13, 1613), and Bethlen was also recognized by the Holy Roman emperor Matthias, the Habsburg king of Hungary, in 1615.

Bethlen had hardly consolidated his power in Transylvania when the Thirty Years' War broke out, presenting him with the opportunity to enter the war in defense of the Hungarian constitution and freedom of religion. While Matthias' successor Ferdinand II was occupied with the Bohemian revolt in 1618, Bethlen led his troops into northern Hungary and, supported by the population, occupied most of upper Hungary and captured Pozsony (Czech. Bratislava; Ger. Pressburg), where he seized the crown of St. Stephen. Ferdinand, anxious to settle the Hungarian problem, entered into negotiations with Bethlen. When the negotiations collapsed because Ferdinand would not agree to including Bethlen's ally Frederick, king of Bohemia, in the treaty, the diet at Besztercebanya elected Bethlen king of Hungary (Aug. 20, 1620). He accepted the title, but refused to be crowned because he knew that a Protestant king would never be accepted by the Catholic nobility. Thereupon the war was renewed and continued until the defeat of the Bohemians at the battle of the White Mountain (1620) gave a new turn to the events. Bethlen saw the futility of continuing the war and on Dec. 31, 1621, concluded peace with Ferdinand at Kikolsburg (Mikulov). In the treaty Bethlen renounced the royal title and returned the crown of St. Stephen; Ferdinand II in return reaffirmed the treaty of Vienna (1606), which had guaranteed liberty of worship to the Protestants, and promised to summon the national diet within six months. Bethlen secured for himself the title of prince of the Holy Roman empire and seven counties in northeastern Hungary, together with the fortresses of Tokaj. Munkács (Mukačevo) and Ecsed. Even so, he considered the treaty only an armistice and secretly planned the expulsion of Ferdinand from Hungary, the occupation of Bo-

hemia and the restoration of his friend Frederick to the Bohemian throne.

After securing Turkish support and receiving the invitation of the German Protestant princes to join their anti-Catholic and anti-Habsburg alliance, Bethlen re-entered the war against Ferdinand in 1623. Though he won military successes in Bohemia, the defeat of the Protestant forces in Germany convinced him that he could not carry on the war against Ferdinand alone. He therefore concluded the treaty of Vienna in 1624, which essentially reaffirmed the provisions of Nikolsburg. Bethlen then turned to planning an eastern European alliance in order to attack the Turkish empire, to liberate and reunite Hungary and to expel the Turks from Europe. To carry out this plan he hoped to marry one of Ferdinand's daughters and to form an alliance with the emperor, but in Vienna his sincerity was doubted and his overtures were rejected. Thereupon he married Catherine, sister of the elector George William of Brandenburg, and joined the German Protestant princes once more; the overwhelming victories of the Catholic and imperial forces, however, obliged him to come to terms with Ferdinand again (treaty of Pozsony, 1626). Although the terms of the new treaty were set by Ferdinand, its main provisions reaffirmed the treaty of Vienna of 1624.

Thereafter, Bethlen was involved in negotiations with some Polish nobles. who offered him the crown of Poland for his help against the emperor. He also reached agreement with Gustavus Adolphus of Sweden, who invited him to join the Lutheran princes and lend military assistance against Ferdinand, but his rapidly declining health prevented Bethlen from further action. He died on Nov. 15, 1629, at Gyula-Fehérvár (Alba Iulia) in Transylvania.

Bethlen is considered the greatest Hungarian of his time. His extensive correspondence with the rulers and leaders of Europe reveals an original thinker. Although an ardent Calvinist, he was free of prejudice and even helped the Jesuit Gyorgy Káldy to translate the Scriptures into Hungarian. (T. K.)

BETHLEN, ISTVÁN, COUNT (1874–1947?), Hungarian statesman, prime minister of his country from 1921 to 1931. was born at Gérnyeszeg (Cornești) in Transylvania on Oct. 8, 1874, of a family belonging to the inner circle of the Transylvanian aristocracy. He entered the Hungarian parliament in 1901, first as a Liberal, but soon joined the national opposition. He was a leading figure of the counterrevolutionary emigration during Béla Kun's Communist regime, on the fall of which he returned to Hungary and re-entered parliament. His aim from the first was to establish an impregnable Conservative political regime. and he put the finishing touches to this on becoming prime minister on April 14, 1921. The "Bethlen system" was essentially one of government through a single party, itself entirely subservient to its leader, an opposition being allowed to voice its views (to which some heed was paid). but never to gain control. Bethlen's domestic policy was one of authoritarian, but not totalitarian, conservatism, which did not deny necessary concessions to changing conditions, but limited them to the minimum. In foreign policy, his ultimate aim was reversal of the treaty of Trianon, but he saw this to be impracticable until Hungary had regained internal strength and made the right friends abroad. Accordingly, while evading commitments which would tie his hands, he eschewed "policies of adventure" (this involved him in repressing right-wing extremism, which was also repugnant to his spirit), contracted no dangerous alliances (his treaty of friendship with Italy, of April 1927, was essentially defensive) and devoted himself to a long-term operation of consolidation and reconstruction. He negotiated Hungary's admission to the League of Nations, obtained a reconstruction loan and facilitated the influx of private capital from abroad. Under his guidance Hungary really achieved a large measure of internal pacification and economic recovery, but this was shattered by the world economic depression which set in in 1929. Bethlen resigned on Aug. 19, 1931. He hoped to return to officelater, but opportunity never recurred. Although still regarded as their leader by all forces antagonistic to the new right-wing radicalism, he could do no more than play the oracle. He went into hiding on the German occupation of Hungary (March 1944) and evaded the Germans, but was taken by the Russians in 1945 to Moscow, where he was reported to have died in 1947.

Bethlen was undoubtedly a politician of extreme sagacity and a statesman of European format and vision. His gifts were regarded with awe by most of his countrymen. The Hungary of the 1920s, for good or for ill, was largely his handiwork.

See C. A. *Macartney, October 15th: a History of Modern Hungary, 1929–1945 (1956).* (C. A. M.)

BETHMANN HOLLWEG, THEOBALD VON (1856–1921), the German imperial chancellor before and during World War I, was born on Nov. 29, 1856, at Hohenfinow, in Brandenburg, of a family of Frankfurt bankers which acquired wealth and repute in the 19th century. Belonging to the "aristocracy of officials," Bethmann received a good humanistic education at Schulpforta, studied law at Strassburg, Leipzig and Berlin, and entered the civil service. Moderately conservative, he became Oberprasident ("senior president") in Potsdam (1896) and *Regierungspräsident* ("president of the administration") in Bromberg (1899). He was appointed Prussian minister of the interior in March 1905 and state secretary in the imperial office of the interior in June 1907. An advocate of a cautious conservative approach to reform, he was chosen to succeed Prince von Bülow as imperial chancellor in July 1909. as he seemed suited to collaborate with the coalition of conservatives and centre which was to remain in power until 1914, both in the Reich and in Prussia.

Bethmann Hollweg was the first chancellor to be appointed from the merely administrative grade. He was a true bureaucrat without strong ambition for political power and typified his class in his conscientiousness, in his efforts to maintain the existing state of affairs (even where he tried to introduce necessary reforms), in his conviction of superiority (which the emperor William II termed "schoolmasterish") and in his avoidance of violent controversy. These characteristics persistently detracted from the undisputed sincerity of his intentions, and from 1909 to 1914 he was unable to resolve the internal political and social tensions of the empire. A conservative servant of the monarchy and a supporter of the traditional authoritarian state. he did not think of abandoning the dualism of *Reich* and Prussia or of introducing parliamentarianism into the Reich. In Prussia he sought, cautiously and inadequately, to undertake the reform of the three-class electoral laws, but yielded, in 1906 and again in 1909, to the strong resistance of the conservatives. The enactment of further social legislation in the *Reich* was held up by fear of the decisive step of giving equal political rights to the workers and of social democracy. Though in 1911 he granted universal suffrage with equal electoral rights and a secret ballot in Xlsace-Lorraine as well as limited internal autonomy, he remained powerless against the military influences which, through the Saverne (Zabern) affair of Nov. 1913 (see ALSACE-LORRAINE), destroyed every effect of this measure. This affair also gave rise to a vote of no confidence in the *Reichstag* against the chancellor, who himself felt "unequal to the situation." He believed, however, that he must remain in office to prevent worse things from happening—as he was to do, with some justification, after the outbreak of World War I.

Even the greatest success of Bethmann's home policy, the bill introduced in April 1913 for increasing the strength of the army, did not fully achieve its aim, namely that of reducing anxiety about Germany's international situation. Sharing the conviction that Germany was menaced by the formation of the entente between France and Great Britain, he had tried to reduce tension by diplomatic means through the Potsdam agreement with Russia (1910) and through more sustained overtures to Great Britain, which however in the end proved equally fruitless. Powerless against the emperor and Adm. Alfred von Tirpitz, he was unable, either in 1909 or on the occasion of Lord Haldane's visit in 1912, to obtain a renunciation or any essential modification of the naval program; nor could he persuade the British to diminish their obligations to the entente to any acceptable degree.

Personally without any desire for war, Bethmann in fact opened the July crisis of 1914 with the disastrous blank check to Austria-Hungary for measures against Serbia. His belated admonitions for peace to Vienna could not undo the effect of this. Once the race to mobilization had started, he capitulated helplessly to the

military experts, the rightness of whose opinions he did not venture to question, either then or after World War I had broken out. This capitulation accelerated the subordination of politics to strategy — the catastrophic consequences of which he sought to combat during the mar.

It is no longer possible to maintain the view that Bethmann in World War I simply worked for a negotiated peace. without any idea of German annexations. He made more concessions to the nationalism of public opinion and to the demands of the military than mas once supposed. Admittedly, it remains in doubt how far he may merely have yielded to superior pressure (particularly from 1916) in the hope that the force of events would expose the unreality of claims with which he identified himself against his will. This applies not only to the extension of German territorial claims, but also to the proclamation of the kingdom of Poland in Nov. 1916. It is nevertheless certain that he would personally have welcomed a peace based on the *status quo* as adequate, even though he could not point the way to it. He toughly resisted the advocates of unlimited U-boat warfare, as he fully recognized that the entry of the United States into the war would be decisive. It is all the more characteristic that he remained in office even after the fatal rejection of his point of view on Jan. 9, 1917.

Bethmann Hollweg also recognized the necessity of radical internal reforms, though up to the Russian Revolution of 1917 he wanted to postpone them until the end of the war. When, however. he seriously took up the struggle for electoral reform in Prussia (with the Easter message of April 7, 1917), his position not only in relation to the military high command, which was striving for dictatorship, and the Prussian conservatives but also in relation to the parties of the centre and the left became so precarious that he mas unable to maintain his policy. He fell from power in the debates on the Peace resolution (July 1917). because despite the sincerity of his intentions he no longer enjoyed solid support from any quarter.

A man of missed opportunities. Bethmann's figure is none the less historically memorable and tragic because though he understood more and more fully the disastrous turn of German history, he was unable successfully to oppose it, tied as he was to tradition and to the existing state of affairs. Bethmann Hollweg died at Hohenfinow on Jan. 1, 1921. His memoirs of World War I were published as *Betrachtungen zum Weltkriege,* 2 pt. (1919–22). with Eng. trans. of pt. i, *Reflections on the World War* (1920)

BETHNAL GREEN, a metropolitan borough (1900) of east London. Eng , is bounded north by Hackney, east by Poplar. south by Stepney and north and west by Shoreditch. Pop. (1961) 47,018. Area 1 2 sq.mi.

Persistent in legend. play and verse, the "blind beggar of Bethnal Green" pictured on the borough seal is supposed to have been Henry, son of Simon de Montfort (*q.v.*). According to history Henry was killed at the battle of Evesham (1263) but the legend has it that. wounded and blind. he was rescued from the battlefield by a baron's daughter who married him. Disguised as a beggar he lived at Bethnal Green with his wife and their daughter "pretty Bessee." Her beauty attracted many suitors, supposedly far above her social standing, but at her wedding her father revealed his identity and established her true position. There is a 14th-century reference to the agricultural district of Blithehale ("happy corner"). Several fine residences there included Bethnall house where Pepys' diary was lodged during the Great Fire of London (1666) and Bishop's hall. a residence of the bishops of London for centuries. The district. formerly one of the Tower Hamlets and once noted for its silk-weaving. is now a working-class area of blocks of flats and small houses. In 1740 the population was about 15,000; by 1847 it was 82,000.

The Bethnal Green museum (1872) is a branch of the Victoria and Albert museum, Kensington. The Regent's canal crosses the borough and there are about 100 ac. of open spaces, including 70 of Victoria park. In World War II the mother parish church. St. Matthew's (1746, rebuilt 1861), was destroyed; a temporary church was completed within its walls in 1952 and a full restoration in 1960–61. The chief industries are furniture making, tailoring and brewing. Weekday and Sunday markets, selling a wide variety of goods including pets and flowers, are a feature of the borough.

BÉTHUNE, the name of a great French family descended from the seigneurs de Béthune (in Picardy), who were *avoués* (*advocati*) of the great abbey of St. Vaast at Arras from the 11th century. By the end of the *ancien régime* its members had held the titles of ducs de Sully, de Charost. d'Orval and d'Ancenis; marquis de Rosny, de Courville and de Chabris; comte de Selles; and princes de Boisbelle and de Henrichemont. The most illustrious member of the family was Maximilien, baron de Rosny and afterward duc de Sully (*q.v.*), minister of Henry IV.

Maximilien's brother Philippe (1561–1649), comte de Selles and comte de Charost, was ambassador to Scotland, Rome, Savoy and Germany. His son Hippolyte (1603–65), comte de Selles and marquis de Chabris, bequeathed to Louis XIV a magnificent collection of historical documents and works of art. Louis de Béthune (1605–81), another son of Philippe, was created duc de Charost in 1651. The last duc de Charost was Armand Joseph (1738–1800), in the fifth generation from Louis. After serving in the army during the Seven Years' War, he retired to his estates and distinguished himself as a philanthropist and economist, trying to improve the lot of his peasants by abolishing feudal dues and introducing reforms in agriculture. Louis XV said of him, "Look at this man, his appearance is insignificant, but he has put new life into three of my provinces." His only son, Armand Louis (1770–94), marquis de Charost; was guillotined during the French Revolution.

BETHUNE, MARY McLEOD (1875–1955), U.S. educator, was born at Mayesville, S.C., on July 10, 1875. Her parents had been slaves before the American Civil War. She graduated from Scotia seminary (later Barber-Scotia college) at Concord, N.C., in 1893. and attended the Moody Bible institute in Chicago.

In 1904 she opened an institute for girls at Daytona Beach, Fla., which was merged in 1923 with Cookman institute for men. Jacksonville. Fla., to form Bethune-Cookman college at Daytona Beach. She served as president of the college until she retired in 1942 and again from 1946 to 1947.

She was director of the Division of Negro Affairs of the National Youth administration, 1936–44, and during World War II assisted the secretary of war in selecting officer candidates for the women's army auxiliary corps. She was also an observer for the U.S. state department at the founding conference of the United Nations in San Francisco. Calif. (1945). A vice-president of the National Association for the Advancement of Colored People, she received various awards for her public service. She died at Daytona Beach on May 18, 1935.

BETROTHAL. Betrothal was anciently a formal ceremony which in most cases preceded the actual marriage service, usually by a period of some weeks, but the marriage might be delayed for years. The canon law distinguished two types of betrothal: (1) *sponsalia de praesenti;* (2) *sponsalia de futuro.* The first was a true though irregular marriage and was abolished by the Council of Trent as inimical to morality. The second was a promise to marry at a future date.

The church never determined the form of the ceremony, but demanded that it should be entered into freely and at a legal age. The church further declared that females between the ages of 7 and 12, and males between 7 and 14, could be betrothed, but not married. The ill-defined laws as to betrothals tended to encourage abuses. especially in the rural districts. Betrothal consisted of the "interchange of rings — the kiss — the joining of hands, to which is to be added the testimony of witnesses." In France the presence of a priest was essential, and it was customary elsewhere for the couple to get their parish priest to witness their promise. Among the peasantry the place of rings was taken by a coin which was broken between the pair, each taking a part. But almost any

gift sufficed. Sometimes the bride-elect received a bent or crooked sixpence. At the conclusion of the ceremony it was usual for the couple to pledge each other in a cup of wine. Gifts given at betrothal could be recovered by the parties if the marriage did not take place.

The church jealously watched over the fulfillment of such contracts and punished their violation. Betrothal, validly contracted, could be dissolved either by mutual consent or by the failure to fulfill one of the conditions of the contract. But there the church stepped in to override such law as existed by decreeing that whoever, after betrothal, refused to marry *in facie ecclesiae* was liable to excommunication. In England the law was settled by an act of 1753, which enacted that an aggrieved party could obtain redress only by an action at common law for breach of promise of marriage. Among the ancient Jews betrothal was formal and as binding as marriage *(see* MARRIAGE). Formal betrothal still retains much of its former importance on the European continent. *See* also BRIDE.

(1898). *See* also R. *H.* Lowie, *Social Organization* (1948).

BETTER BUSINESS BUREAUS, organizations formed in the United States and Canada to protect both business and the community from unfair, misleading or fraudulent advertising and selling practices. Early in the 20th century it became clear to advertising men that fraudulent practices in advertising tended to bring advertising in general into public disfavour. They established a National Vigilance committee to police their own industry, and local communities also formed such associations.

The local organizations became known as Better Business bureaus. and co-ordinated their functions through the National Association of Better Business Bureaus, with the bureau in New York city assuming direct responsibility for problems concerned with national advertising. Though the original purpose of the organization was confined to fraudulent practices in advertising, the association later investigated misleading advertising and questionable selling practices. Better Business bureaus distribute educational literature and reports to alert the public as to methods of deceit and fraud. investigate business practices and take other action to protect the public. They promote the slogan, "Before you invest — investigate."

BETTERMENT denotes an improvement upon real property which enhances its value more than mere repairs, particularly the increased value resulting from causes for which a tenant or the public, but not the owner, is responsible. Thus, when real property acquires additional value because of some public improvement such as widening or paving a street, statutes may require that any owner of the property who derives direct pecuniary benefit from the public improvement contribute a fair proportion of the total cost through a "special assessment" imposed on the property. In the United States, statutes often provide that a bona fide occupant and claimant of real estate who in good faith makes lasting improvements, should the true owner recover it, has a lien upon the real estate and may obtain reimbursement from the owner to the extent that the improvements have increased the value of the property. (RT. K.)

BETTERTON, THOMAS *(c.* 1635–1710), leading English actor of the Restoration period and author of several adaptations which were popular in their day. He made his debut in 1660 at the Cockpit in Drury lane and in the following year was hired by Sir William Davenant for the Duke's company, which played successively at the Lincoln's Inn Fields theatre and at Dorset Garden. After the collapse of the rival King's Men, the two companies merged (1682). and the joint companies, with Betterton as the artistic leader, played at Drury Lane until 1695 when Betterton and the older players revolted against Christopher Rich, the spokesman for the patentees.

Betterton led the secession of the players who moved into Lincoln's Inn Fields theatre and later into the new Haymnrket. Betterton died on April 28, 1710, survived by his widow, the former Mary Saunderson (d. 1712), an actress who had made her mark in Shakespearean parts.

Betterton's range of characters was extremely wide. He created about 130 new roles, aside from the leading parts which he played in the older dramas: Hamlet, Nacbeth. Henry VIII, Mercutio, King Lear, Othello. Brutus and Hotspur.

Contemporary observers agree that Betterton used restraint in his acting. Colley Cibber, in his *Apology,* credited him with preserving a medium "between mouthing and meaning too little," and quoted the actor as having said "that there were many mays of deceiving an Audience into a loud one; but to keep them husht and quiet, nas an Applause which only Truth and Merit could arrive at." Yet Betterton could turn on the full trumpet notes when occasion called for them, as in Nathaniel Lee's *Alexander,* where the "Flights of the false Sublime" had to be drowned in music by the perfect elocutionist.

BETTI, ENRICO (1823–1892), Italian mathematician, one of the founders of the later Italian school, who counted among his pupils U. Dini. L. Bianchi and V. Volterra, was born near Pistoia on Oct. 21, 1823. He studied at Pisa university where. at the age of 34. he obtained a chair which he held until his death.

The first phase of his research was concerned with algebra and elliptic functions; in particular he extended and clarified the work of E. Galois on the theory of equations, furnishing proofs of results which had hitherto remained mere enunciations. Betti was the first to resolve integral (entire) functions of a complex variable into their primary factors, an achievement with which he is seldom credited. His later work was decisively affected by the arrival of G. F. B. Riemann at Pisa in 1863. Riemann awakened his interest in mathematical physics, in particular potential theory and elasticity; in the latter field he produced fundamental work. Kiemann likewise inspired the pioneer memoir (1871) on topology, which remained neglected for 30 years; here there first appear the celebrated Betti numbers of a manifold. Betti died on Aug. 11. 1892. (L. R.)

BETTI, UGO (1892–1953), the foremost Italian playwright, after Pirandello, of the first half of the 20th c'entury, was born at Camerino, Marche, on Feb. 4, 1892, and educated for the law. After army service in World War I, during which he was for a time a prisoner of war, he rose to a judgeship in Rome (1930) and was later appointed librarian at the ministry of justice (1944). He died in Rome on June 9, 1953.

Betti's first publication was a book of poems. *Il Re pensieroso* (1922), followed by more poems in *Canzonette—La Morte* (1932) and *Uomo e donna* (1937). He also wrote some books of short stories (1928. 1933). From *La Padrona* (1927) to *L'Aiuola bruciata* (1953) he wrote 27 plays, of which 24 were produced in his lifetime. The most important of these were *Frana allo scalo Nord* (1936), about a landslide that caused the death of some workmen and the subsequent inquiry; *Il Vento notturno* (1945); *Ispezione* (1947); *Corruzione al palazzo di giustizia* (1949), also about a judicial inquiry; *Lotta fino all'alba* (1949); *Delitto all'isola delle capre* (1950), outstanding as a treatment of passionate love and pitiless revenge; *Il Giocatore* (1951); and *La Regina e gli insorti* (1951). Chiefly concerned with problems of human responsibility and guilt, moral freedom and expiation, Betti is inclined to propose a solution in terms of Christian forgiveness and mercy. Abstract moralization, however, sometimes mars the effect of his genuinely dramatic inventiveness.

BETTING: *see* GAMBLING AND *BETTING.*

BETTY, WILLIAM HENRY WEST (1791–1874), English boy actor, known as "the young Roscius," was born on Sept. 13, 1791, at Shrewsbury, Eng. He first appeared on the stage at Belfast before he was 12 in an English version of Voltaire's *Zaire.* He afterward played with success in Dublin, Glasgow and Edinburgh. In 1804 when he first appeared at Covent Garden, London, troops

had to be called out to preserve order, so great was the crush to obtain admittance. At Drury Lane he played for the unprecedented salary of over 75 guineas a night. George III presented him to the queen, and William Pitt on one occasion adjourned the house of commons that members might be in time for his performance as Hamlet. In 1808 he made his final appearance as a boy actor, and entered Christ's college, Cambridge. He reappeared some years later, but the public would have none of him. He died in London on Aug. 24, 1874.

BETUL, town and district in Madhya Pradesh, India. The town is 103 mi. S.S.E. of Bhopal. the state capital. Pop. (1951) 15,563. It is the seat of a pre-university arts college affiliated to Saugar university, and is on the main central railway, Delhi-Nagpur, 65 mi. S. of Itarsi by rail, the junction of the Allahahad-Bornbay line.

BETUL DISTRICT (3,884 sq.mi.; pop. [1961] 560,356) is on the elevated tract which divides the Narbada valley on the north from the Berar plain on the south. The northern part of the district is well wooded and resembles parkland, but the population is sparse and the cultivation poor. The central tract has the best soil in the Machna and Sampna valleys. It is well cultivated and studded with villages.

In the south lies a rolling plateau of basaltic formation forming the watershed of the Tapti (*q.v.*), Karhan, hlachna and Wardha rivers. The richer soils produce wheat, pulses and some sugar cane, irrigated from wells; the poorer, oilseeds and small millets. The poorer tracts in the north are mainly inhabited by aboriginal tribes, Gonds and Korkus, but the fertile areas in the centre and south of the district are occupied by Hindu immigrants.

The climate is comparatively temperate. Forests produce bamboos, teak and other timber. Agriculture and forestry provide the population's chief employment and there are no major industries.

Twenty-five miles southeast of Betul is the town of Multai, sacred to some religious adherents because it contains a tank or pool reputed to be the source of the Tapti.

The district passed by conquest from Gond chieftains to the Marathas in 1743 and came under British rule in 1818.

(D. G. NA.)

BETULACEAE (or CORYLACEAE), the birch family, includes six genera and over 100 species of deciduous trees and shrubs, found predominantly in the northern hemisphere (less than 30 species occur in the United States). The simple, serrate leaves are alternate. Male and female flowers are borne on the same plant: the former are grouped in long, drooping catkins, whereas the latter are borne in short catkins or clusters. The fruit is usually a small samara. Many species of birch (*Betula*), alder (*Alnus*), hazelnut (*Corylus*), hornbeam (*Carpinus*) and hop hornbeam (Ostrya) are widely cultivated. Birchwood is used for lumber and the manufacture of high-grade charcoal, the bark is peeled for canoe making or for writing paper, and the twigs furnish oil of betula (similar to wintergreen). Hazelnuts are edible. The Betulaceae are also known from fossils dating from the Upper Cretaceous period (about 70,000,000 years ago).

See also ALDER; BIRCH; FILBERT; HAZEL; etc. (T. K. J.)

BETWA (anc. VETRAVATI, "containing canes"), an unnavigable river of India, rises about 2,000 ft. above sea level in the Vindhya hills about 25 mi. S.S.E. of Bhopal, Madhya Pradesh. After a 360-mi. northeasterly course it enters the Jumna 500 ft. above sea level 7 mi. E. of Hamirpur, Uttar Pradesh. Nearly one-half its course is run over the Deccan lava plateau of Malwa (*q.v.*) before it breaks into the gneissic upland of Bundelkhand (*q.v.*) through a gap in the sandstone scarp 20 mi. S.W. of Lalitpur. The Betwa's main tributaries, on its right bank, are the Jamni, which flows into it 23 mi. S. of Jhansi. and the Dhasan, which joins it 15 mi. S. of Orai. A 60-ft. weir and a reservoir on the Betwa at Parichha, 17 mi. S.E. of Jhansi, and another weir upstream at Dukwan feed a canal system irrigating more than 200.000 ac.

BETWS-Y-COED, an urban district in the Conway parliamentary division of Caernarvonshire, Wales, at the junction of the counties of Caernarvon and Denbigh. A noted tourist resort; it lies at the head of the Vale of Conway, between its confluence with the valleys of the Llugmy and the Lledr, 24 mi. E.S.E. of Caernarvon and 21 mi. S.E. of Bangor by road. Pop. (1961) 778; Area 7 sq.mi. *Betws,* meaning "beded house," and y coed, "(in) the wood," describe the village's situation among the wooded slopes, rivers. and mountains bordering Snowdonia, which attract many climbers, naturalists and anglers. There are numerous trout streams and the Conway abounds in salmon. From David Cox onward artists have added to the reputation of Betws. The seldom used old parish church of St. Michael contains an effigy in armour of Gryifyd ap Dafydd Goch, of the princely house of Llewelyn. West of the village is the winter residence of Rhys Gethin, a 15th-century Welsh knight who campaigned against the English.

The stone Bridge of the Cauldron (Pont-y-Pair), sometimes attributed to Inigo Jones: is separated by rapids and falls from Fir Tree Island. Waterloo bridge, built in 1815 to commemorate the battle, was one of the first iron bridges to be built. To the north of this, past the narrow wooded gorge called Fairy glen, are the Conway and Machno falls. The Swallow falls are 2 mi. W. along the Llugwy. Betws is connected by rail with Chester. Slate: from which the local cottages are tiled, is quarried in the neighbourhood. Most of the male population is employed in forestry.

BEUEL, a town of Germany which after partition of the nation following World War II was in the Land (state) of North Rhine-Westphalia, Federal Republic of Germany. It lies on the east bank of the Rhine opposite Bonn and is on the railway from Cologne to Frankfurt. Pop. (1959 est.) 31,447. It was formerly a small town! but has grown rapidly since the construction of the bridge over the Rhine in 1896–98 (destroyed in World War II and replaced in 1949). The church of Schwarz-Rheindorf, originally consecrated in 1151 and restored in 1902–04, is one of the most notable Romanesque buildings in Germany, not only for the peculiarity of its two-storied construction but also for the wealth of its 12th-century mural decoration. The town has textile, chemical, wood and paper industries.

BEUST, FRIEDRICH FERDINAND, GRAF VON (1809–1886), Saxon and later Austrian statesman and chief author of the Austro-Hungarian compromise of 1867, mas born in Dresden on Jan. 13, 1809. Entering the Saxon diplomatic service in 1830, Beust became resident minister in London (1846) and ambassador in Berlin (1848). In 1849 he became the Saxon foreign minister. I-Iaving called in Prussian troops to suppress the popular risings of May, he negotiated the alliance of Saxony, Prussia and Hanover (*Dreikönigsbündnis*) later the same month. In 1850, however, he supported Austrian attempts to dissolve the Prussian union. As minister of the interior from 1853 he promoted the rapid economic development of Saxony. In 1863 Beust again supported Austria in its plans for federal constitutional reform and in 1863 he advocated the union of the middle German states.

In the Austro-Prussian War of 1866 Beust allied Saxony with Austria, but after the defeat of Koniggratz (Sadowa) he left the country and, at the invitation of the emperor Francis Joseph, became foreign minister of Austria. In Feb. 1867 Beust succeeded Graf Richard Belcredi as first minister, becoming the imperial chancellor of Austria-Hungary. His aim was the humiliation of Prussia which he hoped would result from the growing tension between Prussia and France.

Between Oct. and Dec. 1867, Beust concluded the compromise between Austria and Hungary, whereby he not only surrendered the Slav populations in Hungary to Magyar rule but also gave the Hungarians a considerable say in Austrian foreign affairs. In the western half of the empire Beust's attempts to establish German ascendancy only embittered the Czechs.

Beust was forced to resign as foreign minister on Oct. 16, 1871. After being Austrian ambassador first in London and then in Paris (1878), he retired in 1882 and died at Schloss Altenberg near Vienna on Oct. 24, 1886. An English edition of his memoirs, *Memoirs* of *Friedrich Ferdinand Count* von Beust, was published in 1887. In foreign affairs Beust was a statesman of the first rank, but as a foreigner he was ill-equipped to master the racial problems of Austria-Hungary and was hardly aware of the fatal errors of his Slav policy.

BEVAN, ANEURIN (1897–1960), British statesman, the most controversial figure in British politics in the first decade after World War II, is chiefly remembered as the architect of the national health service and for his subsequent leadership of the "Bevanite" group within the Labour party. Born at Tredegar, Monmouthshire, on Nov. 15, 1897, the son of a coal miner, he entered mining himself in 1910 but had to leave the mines after a few years because of eye disease. He became an active trade unionist and, after two years at the Central Labour college and a short apprenticeship in local politics, was elected to the house of commons in 1929 as Labour member for Ebbw Vale. In 1934 he married another Socialist, Jennie Lee, who had also first been elected to parliament in 1929. Initially active in parliament on mining affairs. Bevan's later association with Sir Stafford Cripps's British united front movement led to his expulsion from the Labour party in March 1939. He was readmitted in Dec. 1939 and was an active critic of the government throughout World War II.

As minister of health in C. R. Attlee's postwar Labour governments, Bevan was responsible for housing and for formulating and introducing the national health service. The health service, which brought him into conflict with the medical profession, remained of great personal concern to Bevan even after he had moved to the ministry of labour in Jan. 1951. and the cabinet's agreement to authorize charges for certain of the health service facilities was one of the reasons for his resignation from the government in April that year. For the next few years Bevan was the centre of considerable controversy within the Labour party. He gained great support for his point of view from the constituency parties and involuntarily gave his name to the party's left-wing "Bevanite" group, whose opinions were expressed in the London weekly *Tribune*, of which Bevan himself had been editor from 1940 to 1945. In successive years, 1954 and 1955, he unsuccessfully contested Hugh Gaitskell's election as Labour party treasurer and. after Attlee's resignation in Dec. 1955, he was also defeated by Gaitskell in the election of party leader. Thereafter Bevan accepted official Labour party policy, losing the support of many of his former followers on the party's left wing. He was made Labour spokesman first on colonial affairs and, later, on foreign policy. His speeches became more statesmanlike and he himself mellower. After the general election in 1959. he was elected deputy leader of the party, but soon afterward he became fatally ill. He died at Chesham, Buckinghamshire, on July 6, 1960.

A fighter and a man of political principle and courage, Bevan was a colourful public personality and a scintillating and spontaneous debater. Although he could at times be so rude to his political opponents that he once evoked from Winston Churchill the rebuke that he was a "merchant of discourtesy," he was nevertheless possessed of great personal charm, wit and brilliance. Bevan's autobiography, *In Place of Fear*, was published in 1952.

(E. A. J. D.)

BEVERIDGE. ALBERT JEREMIAH (1862–1927), U.S. senator, orator and scholar, was born in Highland county, O., on Oct. 6, 1862. He graduated from De Pauw university, and in 1887 began the practice of law in Indianapolis. By 1898 he had built a reputation as a lawyer and had attracted attention as an orator in Republican campaigns. He was elected to the U.S. senate in 1899. After a tour of the far east, Beveridge took office and was a stalwart partisan. He toured Russia and Manchuria in 1901 and afterward published a book, *The Russian Advance* (1903). As a senator from 1899 to 1911, Beveridge supported President Theodore Roosevelt in his efforts to regulate trusts. He drafted the federal meat inspection bill and battled for a child labour act. During the Taft administration he joined the insurgents and was keynote speaker at the Progressive party convention (1912). Beveridge was nominated for governor of Indiana but was defeated. He was the Progressive party candidate for senator in 1914, but failed of election and became disillusioned with the collapse of the Progressive party. After visiting the warring countries of Europe in 1914, he published his book *What Is Buck of the War* (1915), which was later denounced as pro-German. He opposed U.S. participation in the League of Nations. In 1922 he won the Republican nomination for senator, but again lost. Between campaigns he worked on his biography of John Marshall. When published in four volumes (1916–19) it was widely acclaimed as an outstanding work. He died in Indianapolis, April 27, 1927, while working on a biography of Abraham Lincoln, two volumes of which were published posthumously.

See Claude G. Bowers, *Beveridge and the Progressive Era* (1932).

(H. F. TT.)

BEVERIDGE, WILLIAM HENRY BEVERIDGE, 1ST BARON, OF TUGGAL (1879–), British economist and academic administrator who profoundly influenced British social services through his report on *Social Insurance and Allied Services* (1942), known as the Beveridge report. Beveridge was born at Rangpur, India, on March 5, 1879. After a brilliant career at Oxford, at the age of 24 he was appointed subwarden of Toynbee hall, a London settlement house! where his lifelong interest in the causes and cure of unemployment began. *Unemployment: a Problem of Industry* (1909) revealed the extent to which this was due to the organization of industries. He produced a revised version of his views in *Full Employment in a Free Society* (1944), strongly influenced by Keynesian economics.

Beveridge was director of labour exchanges (1909–16) and permanent secretary of the ministry of food (1919). In 1919 he became director of the London School of Economics and Political Science and served until 1937 when he was elected master of University college, Oxford. He was prominent in several spheres of public service and served on the Royal Commission on the Coal Industry (1925) and on various committees. Beveridge's crowning achievement came in World War II when, at the invitation of the government, he worked out the blueprints of the new welfare state. (See GREAT BRITAIN: *Setting Up of the Welfare State.*) Knighted in 1919, he was created a baron in 1946.

Beveridge's other works include *Insurance for All* (1924), *British Food Control* (1928), *Planning Under Socialism* (1936), *Pillars of Security* (1943), *The Price of Peace* (1945), *Voluntary Action* (1948), *Power and Influence* (1953), and *A Defence of Free Learning* (1959). (B. TH.)

BEVERLEY, a municipal borough and market town in the East Riding of Yorkshire (of which it is the county town), Eng., lies in the level country east of the Yorkshire wolds, 8 mi. S.N.W. of Hull by road. Pop. (1961) 16,024. Area 3.8 sq.mi. (one-half consisting of common pastures). The town owed its early importance to a religious house founded and dedicated to St. John the Evangelist by John of Beverley (640–721), who became archbishop of York in 705, mas canonized in 1037 and who became the patron saint of Beverley. Destroyed by the Danes in 866, the monastery was refounded and rededicated to St. John of Beverley by King Aethelstan as a college of secular canons, with the right of sanctuary for a mile in every direction from the minster, which still contains the fridstool (sanctuary chair). The college was dissolved in 1547. Beverley minster is a building as large as many cathedrals: the west front and slender towers are pure Perpendicular; the nave is Decorated, as is the magnificent Percy tomb; the transepts are Early English.

The first of many charters was granted to the town in 1129, that of incorporation in 1573 and the last by James II. Beverley, a large market centre, was granted three fairs and holds two weekly markets. The cattle market is held in Norwood and the general market in Saturday Market, where there is a fine market cross (1714). Of the five "bars" through which admission was formerly gained to the town only the North Bar (1409) remains, and in North Bar Within is the parish church of St. Mary, a splendid cruciform building chiefly Decorated and Perpendicular. There is a museum. an art gallery and a technical institute; the grammar school was founded in 721. Saint John Fisher (*q.v.*), the martyr, was born at Beverley.

Beverley lies on the main railway line from Hull to York and from 1344 it has been connected by a canal (the Beck) with the river Hull. 1 mi. W., and then with the Humber. Cloth manufacture, Beverley's chief medieval industry, had, by mid-20th century,

been superseded by shipbuilding (especially deep-sea trawlers), tanning, gelatin and the manufacture of railway and automobile accessories.

BEVERLY, a city of Essex county, Mass., U.S., 18 mi. N. of Boston on the Atlantic ocean. Beverly is a small manufacturing and residential city. (For comparative population figures see table in MASSACHUSETTS: *Population.*) More than half of Beverly's labour force is engaged in manufacturing. Machinery making is the city's largest industry. Leather industries are also important.

Beverly was settled in 1626, incorporated as a separate township in 1668, and as a city in 1894. Beverly was first occupied by settlers from nearby Salem, and the town rapidly became a fishing centre and later an important colonial port. The first ship to become part of the U.S. navy, the "Hannah," was commissioned there in 1775. After the American Revolution, Beverly gained even greater stature in foreign trade, but this was largely lost during the War of 1812.

Pride's Crossing and Beverly Farms are two well-known residential sections of Beverly, where large estates front upon a coast line of rocky headlands and sandy beaches. (G. K. L.)

BEVERLY HILLS, a residential city of Los Angeles county, Calif., U.S., completely surrounded by the city of Los Angeles (*q.v.*). As a city of homes, it is famous throughout the western portion of the United States. Attractive residences form the chief architecture of the city. Industrial development has been greatly restricted, only light industry being permitted; these consist, primarily, of electronics enterprises. The downtown area contains numerous shops, a large number of which sell luxury clothing.

Beverly Hills developed as an urban community entirely in the 20th century. During. Spanish, Mexican and early American times, it was part of a ranch owned by Maria Rita Valdez de Villa. Between 1854 and 1906 the land was used for a variety of agricultural purposes. In 1906 it was acquired by a land and water company for development, and given its present name. At the same time, rigid zoning regulations were established for the development of a residential community.

With only 674 inhabitants, Beverly Hills was incorporated as a city in 1914. The population increased 2500% from 1922 to 1930 with the boom in the motion-picture industrv. For comparative population figures see table in CALIFORNIA: *Population.* (J. M. Wo.)

BEVERWIJK, an industrial town of North Holland province, Neth., to the north of the North Sea canal, is on the eastern fringe of the coastal sand dunes where they level off to the dead-flat landscape of northern Holland. It is north of IJmuiden and 24 km. (15 mi.) W.N.W. by road of Amsterdam. Pop. (1957 est.) 32.544 mun. In the early 1960s the town was being developed from an agricultural centre into a residential and shopping town for the IJmond furnace and steelworks area. Except for its churches and its town hall, Beverwijk has few buildings of historical interest. The community includes Wijk aan Zee, a growing seaside resort with a fine sandy beach. Manufactures include freight cars, chemicals and lubricating oil. Engineering and iron and steel plants are located there. Vegetables, flowers and strawberries are exported. (P. v. D. E.)

BEVIN, ERNEST (1881–1951), British trade unionist and statesman. who was one of the most prominent leaders of the British Labour movement during the first half of the 20th century and is especially remembered for his tenure of the foreign office from 1945 to 1951. was born at Winsford in Somerset on hlarch 7, 1881. Brought up in poverty and orphaned at the age of 8, he left school when he was 11 and began work on a farm. He moved in 1894 to Bristol, where he eventually found regular employment driving a horse and cart on a mineral-water delivery route.

Like many other trade union leaders. Bevin graduated into the Socialist movement from a Nonconformist upbringing. He formed a carters' branch of the Dockers' union in Bristol in 1910 and by the end of World War I had become the union's assistant general secretary (though the post was not actually created for him until May 1920). He stood, unsuccessfully, as Labour candidate for Bristol Central in the general election of 1918. His reputation as the most forceful and able of the younger trade union leaders was made in 1920 by his presentation of the dockers' case for a guaranteed wage before Lord Shaw's court of inquiry (this won him the title "the dockers' K.C.") and by the part he played in organizing the council of action which threatened widespread strikes if the British government intervened in the war between Poland and the U.S.S.R. In 1921 he persuaded the transport unions to amalgamate, and set up the Transport and General Workers' union, of which he became general secretary and which subsequently grew to be the largest trade union in the world.

As the dockers' leader, Bevin was in the thick of the labour troubles which marked the early 1920s in Great Britain. He became a member of the general council of the Trades Union congress (T.C.C.) in 1925 and was responsible for the improvised organization which carried through the general strike of 1926. When the failure of the strike sapped the militant spirit of the trade unions. Bevin took the lead in persuading the T.U.C. not to fall back on routine wage negotiations but to form and express a trade union policy on the major economic issues facing the country. He played a leading part in the Mond-Turner talks between the two sides of industry (1928–29) and in setting up the economic committee of the T.U.C. general council (1929). In the same spirit, he accepted an invitation to serve on the Macmillan Committee on Finance and Industry (1930) and impressed its members, including John Maynard Keynes, by his grasp of economic and financial problems.

Bevin was critical of the second Labour government's failure to adopt radical measures to deal with the mounting unemployment of the depression years and refused to support James Ramsay MacDonald's "national" government formed in 1931. The uncompromising opposition of the T.U.C. led by Bevin and the general secretary Walter Citrine steadied the badly split Labour party and Bevin agreed. under persuasion from Arthur Henderson, to stand for Gateshead at the election of 1931. His defeat did not weaken his conviction of the need for trade unions to draw closer to the Labour party, and as a member of the National Council of Labour he used all his influence in persuading the Labour party to adopt what he considered a more realistic foreign and defense policy in face of the threat from Hitler and Mussolini.

Bevin's approach to international affairs was highly practical and he played a major role in the International Transport Workers' federation and the International Labour office. Among the groups of workers for the improvement of whose conditions of work he fought a series of unremitting battles were the dockers, road transport workers and the seamen, and with his election as chairman of the T.U.C. general council in 1937 his position as the outstanding trade union leader of his generation was widely recognized.

Bevin had refused any suggestions that he should enter parliament after 1931 and was planning to retire at the age of 60. When Winston Churchill formed his coalition government in May 1940, however, he at once called on Bevin to assume responsibility for the mobilization of the nation's manpower as minister of labour and national service. Bevin was found a seat in the house of commons as member of parliament for Central Wandsworth and was soon invited by Churchill to join the inner war cabinet. No minister played a greater part in organizing the country's resources to win the war. Under Bevin's direction, Great Britain most effectively mobilized men and women for the armed forces and war industry.

When C. R. Attlee formed his Labour government in 1945, Bevin was appointed foreign secretary. Establishing relations of confidence with the United States, he gave a strong lead in building up the framework within which western Europe was enabled to maintain its independence and recover its prosperity. The major stages in this policy were. in 1945, the Brussels treaty, the Berlin airlift, the Organization for European Economic Cooperation and, in 1949, the establishment of the North Atlantic Treaty organization, which Bevin regarded as his greatest triumph. Outside Europe, which was then the main theatre of the cold war, and the Atlantic alliance, Bevin was less successful. His efforts to find a new basis

for Great Britain's relations with the middle east countries broke down in face of the Arab-Israeli conflict and involved Bevin in a hitter dispute with the Zionists. In his last year of office, however. he was able to give expression to his plans to help the underdeveloped countries by setting up the Colombo plan for southeast Asia.

Ill-health forced Bevin's resignation on March 9, 1951. He remained in the cabinet as lord privy seal, but he died in London on April 14, 1951.

Bevin mas a man whose massive self-confidence and forceful personality inevitably created strong likes and dislikes. Unembarrassed by his humble origins or his lack of formal education, he was completely himself in any surroundings and rarely failed to impress by his natural intelligence and a power of judgment and foresight which drew on his rich experience of men and affairs. A controversial figure throughout his career, he showed unswerving loyalty to the working class, but won the respect and admiration of his political opponents by his courage and largeness of mind.

See Francis Williams, *Ernest Bevin* (1952); Alan Bullock, *The Life and Times of Ernest Bevin,* vol. i, *Trade Unzon Leader, 1881–1940* (1960). (A. Bk.)

BEWICK, THOMAS (1753–1828), English engraver, credited with the revival of the art of wood engraving in England, was born at Cherryburn, Northumberland, Aug. 12. 1753. His master (later his partner) was Ralph Beilby. an engraver who did much work for the Newcastle silversmiths. Bewick continued engraving on plate even after he had successfully taken up more rewarding kinds of work. but his most remarkable talents were displayed as a wood engraver, especially in little vignettes of an unaffected rusticity, and in his illustrations of birds and animals. He published several illustrated works of a popular character. His *General History of Quadrupeds* appeared in 1790. and while working on this he engraved the large and celebrated block of "The Chillingham Bull." His most famous publication was *History* of *British Birds* (vol. I, *Land Birds,* 1797: vol. II, *Water Birds,* 1804); this ran to many editions. The British museum and the Hancock museum, Newcastle upon Tyne, possess many fine water-colour studies for this work. Among his other works are illustrations for Oliver Goldsmith's *The Traveller* and *The Deserted Village,* Thomas Parnell's *The Hermit* and William Somervile's *The Chase.* Bewick died at Gateshead, Durham, Nov. 8, 1828. *See* Woodcut and Wood Engraving.

Thomson, *Life and Works of Bewick* (1882) and *Water Colour Drawings of Thomas Bewick* (1930); G. Reynolds, *Thomas Bewick: A Résumé of His Life and Work* (1949); S. Roscoe, *Thomas Bewick* (1953). (R. E. W. J.)

BEXHILL, a seaside town and municipal borough (1902) in the Rye parliamentary division of East Sussex, Eng., 43 mi. W. of Hastings, on the English channel. Pop. (1961) 28,926. Area 12.5 sq.mi. The residential and resort area dates from the 1880s, but the old village, built around its Norman and Early English parish church of St. Peter founded in the 8th century, lies ½ mi. inland up on the cliff that rises steeply behind it. Though damaged by air raids in World War II, Bexhill flourishes again; by the De la Warr pavilion (1935) is the centre of the town's social life. It has parks and gardens, a bracing climate, and sand is uncovered at low tide along the whole of the 5 mi. of coast line within the borough. There are many boarding schools in the area.

BEXLEY, NICHOLAS VANSITTART, 1st Baron (1766–1851), English politician, was a friend of Henry Addington, Viscount Sidmouth, to whom he owed his political advancement and especially his appointment as chancellor of the exchequer (1812–23). Born in London on April 29, 1766, the fifth son of Henry Vansittart (1732–70), governor of Bengal from 1760 to 1764, he was educated at Christ Church, Oxford, and was called to the bar in 1791. Pamphlets which he wrote between 1793 and 1795 in defense of the government's financial and war policy brought him to the notice of William Pitt, and in 1796 he was provided with a seat in parliament.

At first a follower of Pitt, Vansittart attached himself to Henry Addington in 1801, when he was appointed joint secretary of the treasury, an office which he held until Addington's resignation in May 1804. When, in Jan. 1805. Addington joined Pitt's last ministry, Vansittart was given the Irish secretaryship, but resigned it in September after Lord Sidmouth (as Addington had become) had retired. In the ministry "of all the talents" (Feb. 1806–March 1807) Vansittart was again secretary of the treasury. He was out of office from 1807 to 1812, loyalty to Sidmouth, to whom no offer was made, causing him to reject Spencer Perceval's invitation to take the chancellorship of the exchequer in Oct. 1809. He held that office, however, under Lord Liverpool, from May 1812 to the beginning of 1823.

His abilities, though perhaps more considerable than he has generally been given credit for, hardly rose above mediocrity. After peace returned in 1815, he made himself increasingly unpopular by refusing to cut down expenditure and taxation to a degree which public opinion demanded, but the government survived its defeat on a vital question of finance in 1816—being compelled to abolish the income tax, the sheet anchor of the budget. His own colleagues recognized his financial incapacity but, as the duke of Wellington once remarked, it was much easier to put a man into the cabinet than to turn him out. It is significant that Sidmouth's resignation of the home department (Dec. 1821) was soon followed by Vansittart's departure from the exchequer. He retained his seat in the cabinet, and was given the chancellorship of the duchy of Lancaster and a peerage. He remained in office under George Canning and Lord Goderich (April 1827–Jan. 1828), but Wellington had no use for him and his official career came to an end in 1828. A devout Tory evangelical, he was opposed to Catholic emancipation, and he voted against the Relief bill in 1829. Three years later he was a die-hard opponent of the Reform bill. Bexley died on Feb. 8, 1851.

See Elie Halévy, *History of the English People in the Nineteenth Century,* Eng. trans. by E. I. Watkin, vol. i and ii, 2nd ed. (1949–52). (A. Al.)

BEXLEY, a municipal borough (1937) in the Bexley parliamentary division of Kent. Eng., 14 mi. E.S.E. of London by road. Pop. (1961) 89,629. Area 7.6 sq.mi. Mentioned as Bixle in the 8th century, Bexley stands north of the river Cray, on the London-Dover road on a part of the ancient Watling street. The parish church of St. Mary is Early English with later additions. Hall place, now belonging to the town, is a stately mainly 16th-century mansion. Bexley is now a residential district with more than 500 ac. of parks and other open spaces, the chief of which is Danson park, covering one-eighth of the borough's area. The population increased fourfold between 1921 and 1961 (89,629)) but there were still very few factories in the 1960s. The historian William Camden was once lord of the manor. There are famous deneholes in the surrounding woods.

At Bexleyheath William Morris lived for five years in the Red house, which he built in 1860.

BEY, the modern Turkish spelling of a title found in various forms *(beg, big, biy,* and the feminine *begam)* among Turkish peoples from the earliest times. It was given to rulers of small tribal groups, to members of ruling families and to important officials. Under the Ottoman empire a bey was the ruler of a province, distinguished by his own flag *(sanjak, liwa),* but only in Tunis after 1705 did the title become hereditary. Later the word depreciated into a general title of respect, added after a personal name and equivalent to "esquire" (or "sir" in conversation). Under the Turkish republic, bey, though surviving in polite conversation, was replaced by *bay* before the name (equivalent to "Mr."). (A. D. A.)

BEYERS, CHRISTIAAN FREDERIK (1869–1914), South African general, prominent during the South African War and a leader of the rebellion in 1914, was born in the Cape Colony on Sept. 23, 1869, and educated at Victoria college (later Stellenbosch university). In 1889 he went to the Transvaal, where he qualified and practised as a lawyer. His military ability earned him rapid promotion during the South African War. In Sept. 1900 he was made a general and commanded the Boer forces in the northern Transvaal. After the conclusion of peace (1902) he entered politics and was elected to the head committee of Louis Botha's

Transvaal party, *Het Volk* ("The People"). in May 1904. Beyers subsequently opposed Botha's policy of conciliating the British as being inimical to Afrikaner national interests. After the election under responsible government in 1907, Botha excluded Beyers from his cabinet and had him elected speaker of the legislative assembly As speaker Beyers, competent and impartial. won the confidence of all, but despite Botha's support in 1910 he failed to become speaker in the first parliament of the Union. Under the defense act of 1912, Beyers became commandant-general of the Union defense force. On the outbreak of war in 1914 he opposed the cabinet's accession to the British request to conquer German South-West Africa. After parliament had endorsed the cabinet's decision, Beyers resigned (Sept. 15, 1914). From this point he drifted reluctantly into armed protest and so became involved in the rebellion. His reputation as a patriot and a religious man brought to his side many Transvaal Boers who believed (erroneously) that Botha and J. C. Smuts had wished to commandeer them to fight in South-West Africa. Folloning abortive negotiations and some skirmishing, his forces were broken up in the Orange Free State and Beyers himself, in trying to escape across the Vaal river, was drowned on Dec. 8, 1914. (N. G. GA.)

BEYLE, MARIE HENRI: *see* STENDHAL.

BEZA, THEODORE (THEODORUS BEZA, THÉODORE DE BÈZE) (1519–1605), French Protestant theologian, heir of John Calvin in Geneva. was born June 24, 1519, at Vézelay, Burgundy, the son of a lawyer and bailiff, Pierre de Bbze, and Marie Bourdelot, of noble family. An uncle, Nicholas, counsellor of the Paris *parlement,* placed him under the learned Melchior Wolmar, who had taught Calvin Greek, at Orléans, then at Bourges. The young Beza studied law in Orléans (1535–39) and thereafter began practice in Paris, where, among fashionable friends, he published *Juvenilia,* containing amorous verses later embarrassing to him. After a severe illness he "renewed a vow to serve God openly in his true church," married Claudine Denosse and in 1548 traveled to Geneva to join Calvin. As Greek professor in Lausanne, he aided Calvin's reform and defended him in the case of the burning of Michael Servetus (*q.v.*) in De *Haereticis* a *civili magistratu puniendis* (1554). In 1559 Beza became rector of the new Geneva academy, a post from which he became after Calvin's death (1564) one of the leading educators, theologians and statesmen of the Reform in Europe.

Like Calvin a devotee of classical studies, but unlike him an Aristotelian in theological method, Beza contributed to the development of Aristotelian structures in the scholastic Reformed theology of the following century. Opposing his former student, Jacobus Arminius, he elaborated supralapsarian predestination; *i* e., that God decreed salvation "before" he decreed man's sin. Numerous influential theological and polemical treatises and philological studies came from his pen. His Greek editions and Latin translations of the New Testament were basic to Protestant students for two centuries, and lay behind both the Geneva and the King James bibles. His sermons and commentaries were widely read in his lifetime, and the famous Codex Bezae (D) was presented by him to Cambridge university *(see* BIBLE. *Text* of *the New Testament).* The writing *De jure magistratum* (1574) defending the right of revolt against tyranny led by inferior magistrates appeared in the wake of the St. Bartholomew's day massacre and became a major political manifesto of Calvinism. Beza died Oct 13. 1605.

BEZANT (BYZANT), a Byzantine gold coin (known also as a solidus) which had a wide circulation throughout Europe up to about 1250. *(See* MONEY, MEDIEVAL.) Bezants were also issued in Flanders and Spain. Silver bezants, in value from one to two shillings, were in circulation in England in the 13th and 14th centuries. In Wycliffe's translation of the Bible he uses the word for a "talent" (*e.g.,* in Luke xv. 8). In heraldry, bezants are represented by gold circles on the shield, and nere introduced by the crusaders. In architecture a bezant is a flat disk used for ornamentation.

BEZBORODKO, ALEKSANDR ANDREEVICH, PRINCE (1747–1799), Russian statesman, foreign minister under the empress Catherine II and grand chancellor of the empire under Paul I, was born at Glukhovo in the Ukraine on March 25 (new style; March 14, old style), 1747, and educated at home and in the clerical academy in Kiev. He accompanied Count P. A. Rumyantsev to the Turkish War in 1768, and was present at the engagements of Larga and Kagul and at the storming of Silistria. Rumyantsev recommended him to Catherine II. and in 1775 she appointed him her secretary of petitions. In 1780 he accompanied her on her journey through Belorussia. On his return from a mission to Copenhagen. he presented to the empress "a memorial on political affairs." which comprised the first plan of a partition of Turkey between Russia and Austria. This document mas transmitted almost word for nord to Vienna as the Russian proposals. He followed this up with "Epitomized Historical Information Concerning Moldavia." For these two state papers he was rewarded with the posts of "plenipotentiary for all negotiations" in the foreign office and postmaster general. From this time he was inseparably associated with Catherine in all important diplomatic affairs, though officially he was the subordinate of the vice-chancellor, Count A. A. Osterman. He nrote dispatches to the Russian ministers abroad, concluded all treaties and performed all the functions of a secretary of state. He identified himself with Catherine's political ideas, even with that of re-establishing the Byzantine empire under her grandson Constantine. In 1786 he was promoted to the senate and it was through him that the empress communicated her will to it. In 1787 he accompanied Catherine on her triumphal progress through the Ukraine in the capacity of minister of foreign affairs. On his return from concluding the peace of Jassy (Iaşi) (1792) he found his post of secretary of petitions occupied by the empress's last favourite. P. A. Zubov. He complained of this to the empress in a private memorial in 1793. Subsequently Catherine reconciled him with Zubov and he resumed the conduct of foreign affairs. It was he who advised her on the engineering of the second and third partitions of Poland.

On Catherine's death, the emperor Paul entrusted Bezborodko with the examination of her private papers and shortly afterward made him a prince of the Russian empire. with a correspondingly splendid appanage. On Osterman's retirement Bezborodko received the highest dignity in the Russian empire — that of imperial chancellor. He was the only Russian minister who retained Paul's favour to the last. During the last two years of Bezborodko's life the control of Russia's diplomacy was entirely in his hands. His program was peace with all the European powers, revolutionary France included. The emperor's growing aversion to this policy induced the old minister to try to "seek safety in moral and physical repose." Paul refused to accept his resignation. Bezborodko died in St. Petersburg on April 17 (N.S.; April 6. O.S.), 1799.

See N. *I.* Grigorovich, *Kantsler Knyaz A. A. Bezborodko v svvazi s sobytiyami ego vremeni* ("The Chancellor Prince A. A. Bezborodko in Connection With the Events of His Time"), 2 vol. (1879–81). (R. N. B.; Lo. L.)

BÉZIERS, a town of southern France, is 76 km. (47 mi.) S.W. of Montpellier and 14½ km. (9 mi.) inland from Valras. the nearest seaside resort. in the *département* of Hérault. Pop. (1954) 58,814. Béziers is the capital of an *arrondissement,* the seat of a subprefect. and has tribunals of first instance. It lies in the great vine-growing district of Languedoc and is one of its chief wine markets. The old, once walled, town occupies a hilly site overlooking the left bank of the Orb river. which is there intersected by the Canal du Midi. or Languedoc canal. Béziers (Besara) was a Roman colony. The early medieval town and cathedral were destroyed with accompanying massacre in 1209 by Simon de Montfort during the crusade against the Albigenses. The walls were rebuilt in 1289, but the town again suffered severely during the wars of the 16th century, and all its fortifications were destroyed in 1632. The Allée Paul Riquet separates the old town (nest) from the modern extension. In its centre is a statue of Riquet, builder of the canal (1666–81), nho nas born in Béziers. At its southern end, before the railway station. is the public garden, the Plateau des Poètes, so called because of its numerous busts of Languedoc poets and writers. The former cathedral church of St. Nazaire, dom-

inating the old town, is a good example of the ecclesiastical fortification common in southern France. The Romanesque church of St. Jacques is also noteworthy, and there are remains of a Roman arena. The main road and railway. as well as the Canal du Midi, cross the Orb at Béziers. Associated with its commercial role in the Languedoc vine-growing country, its industries are alcohol distilling, artificial fertilizers and chemicals for treating the vines.

(AR. E. S.)

BEZIQUE, a game of cards of French origin. Earlier games incorporating similar principles, such as mariage and *brusquembille,* were played in France in the 17th century or before. Bezique suddenly became popular in Paris in 1860 and in London in 1868. A Swedish and German form of bezique, now called pinochle (*q.v.*), became and remained one of the games most widely played in the United States, while several other developments of bezique —rubicon bezique and six-pack or Chinese bezique — grew to equivalent popularity in England and France. The etymology of the term is conjectural but is most often attributed to the Spanish besico, "little kiss," a supposed allusion to the "little marriage" of the spade queen and diamond knave.

The Original Game.—Two players use a 64-card pack consisting of two 32-card packs shuffled together, so that there are duplicates of A, 10, K, Q, J, 9, 8. 7, of each suit, the cards ranking downward in that order. Each player receives eight cards, dealt three, two and three at a time. The next card is turned up to determine the trump suit, and the remainder of the pack is placed face down so as partly to cover the trump card, these cards being the stock. The objects of the game are to win tricks containing aces and tens (brisques), which score 10 each; to win the last trick, which scores 10; and to declare certain combinations, as follows:

Royal marriage (K-Q of trumps)	40
Marriage (any other K-Q in the same suit)	20
Bezique (♤Q and ♢J)	40
Double bezique	500
Sequence (A-10-K-Q-J of trumps)	250
Any four aces	100
Any four kings	80
Any four queens	60
Any four knaves	40

Any seven of trumps counts 10 for dealer if turned as trump; and either player holding a seven of trumps may, upon winning a trick, either exchange it for the trump card or merely declare it, and score 10.

The play.—Each trick consists of a card led by one player and a card played by the other. Nondealer leads first. The card led loses to a higher-ranking card of the same suit or to a trump, but wins otherwise. After each trick, each player draws a card from the top of the stock to restore his hand to eight cards, the winner of the trick drawing first. Until the stock is exhausted, it is not necessary to follow suit; thereafter, a player must follow suit to the card led if he can, and must win the trick if he can.

Declaring.—The winner of each trick, before drawing from the stock, may declare and score any of the combinations listed above. Such cards are placed face up on the table in front of the player, but are available for play as though they were still in his hand. The following rules govern declaring:

No card may be counted twice as part of the same declaration (having declared four queens. one must have four different queens to declare the same combination again). A royal marriage may be declared and then the A-J-10 added for a sequence, but a king or queen once used in a sequence may not thereafter be used in a marriage. One bezique may be declared for 40 and another added later for 500, but if both are declared at once they count only 500. Two combinations may be declared in a turn, but no more than one may be scored; for example, with QQ already on the table, one may put down four kings, scoring 80 and saying "Twenty to score" (for the ♤K-Q), and the 20 may be scored when next that player wins a trick. There may be no declaring when only two cards remain in the stock, or thereafter.

Scores are usually recorded on special bezique markers. but counters or chipr may be used. Declarations are recorded as scored, and brisques are added after play ends. The first player to reach 1,000 points wins the game. Some play that he wins a rubicon (a double game, or the combined points of both players) if his opponent has less than 500.

Rubicon Bezique.—This form of the game had virtually replaced the original game by 1910. Four 32-card packs are used, and each player receives nine cards. No trump is turned; the first marriage declared establishes the trump. If a sequence is declared before a marriage, it establishes the trump. In addition to the declarations listed above, the following are scored:

Back door (sequence, not in trumps)	150
Triple bezique	1,500
Quadruple bezique	4,500

The last trick counts 50 instead of 10. There is no count for the seven of trumps. A player holding carte blanche (no K, Q or J in his original nine cards) scores 50, and continues to do so after each draw until he draws a court card. He must show his hand to score it.

The principal difference between bezique and rubicon bezique is in the scoring of declarations. Cards may be played from a declaration already made and then the declaration restored by adding equivalent cards, whereupon the entire declaration is scored again.

Each deal constitutes a game. The player with the higher score wins the difference in scores plus 500. If the loser has less than 1,000. he is rubiconed and the winner receives the combined scores plus 500, even if the winner's total was also under 1,000. Brisques are not counted unless necessary to prevent a rubicon, but in the event of a rubicon the winner always receives 300 for all the brisques.

Six-pack, or Chinese, **Bezique.**—This is a development of rubicon bezique and largely supplanted that game in England and France. Six 32-card packs are used, and each player receives 12 cards in the deal. The scoring and play are the same as in rubicon bezique, except as follows:

Four aces of trumps score 1,000; four tens of trumps, 900; four kings of trumps, 800; four queens of trumps, 600; four knaves of trumps, 400. Last trick counts 250. Carte blanche counts 250. Brisques do not count at all. and the tricks are not gathered in.

The high scorer in each deal adds 1,000 for game and wins a rubicon if the loser's score is under 3,000.

In some games, the cards forming bezique depend on what suit is trump: then the QQ and ♢J are bezique only when spades are trumps. When diamonds are trumps, bezique is ♢Q and ♤J; hearts. ♡Q and ♧J; clubs, ♧Q and ♡J. The same suit cannot be trump in two successive deals.

Eight-pack **Bezique.**—This is merely an extension of six-pack bezique, eight 32-card packs being used and each player receiving 15 cards. Quintuple bezique counts 9,000. Five aces of trumps count 2,000; five tens of trumps, 1,800; five kings of trumps, 1,600; five queens of trumps. 1,200; five knaves of trumps, 800. The loser is rubiconed if he fails to reach 5,000.

See Albert *H*. Morehead *et al., The New Complete Hoyle* (1956).

BEZRUC, PETR (pseudonym of VLADIMIR VASEK) (1867–1958), one of the finest and most individual Czech poets. was born at Opava, Silesia, Sept. 15, 1867. After studying in Prague he became a postal official in Moravia, retaining his position until 1927. Thereafter he lived in retirement. shunning honours and publicity He died at Kostelec. Moravia, Feb. 17. 1958.

Bezruc's reputation rests on the remarkable series of poems written during 1899–1900 and published in the periodical *Cas* between 1899 and 1903. He never matched this intense outburst of inspiration. The subject of almost all these poems is the people of Czech Silesia whom Bezruc saw as a dying race, doomed to denationalization at the hands of German industrialists and Polish priests. From this local theme he created a poetry of national and indeed, universal validity. In simple, vivid, locally coloured language he portrayed the towns and landscape of Silesia; and the destiny of its people was illuminated in his delineation of a few representative figures who entered into local folklore. The 32

poems of the Silesian issue of *Cas* (1903) had swelled to 88 by the last edition of the collected *Slezske pisne* ("Silesian Songs," 1956). His other poems, though individual in style, are of less lasting significance. (R. Ay.)

BEZZENBERGER, ADALBERT (1851–1922), German philologist and archaeologist, was a specialist in the Baltic area. Born in Cassel. Bezzenberger studied at Munich and Gottingen (Ph.D. in 1874). He taught at Gottingen from 1874 to 1880, and later, as professor of Sanskrit and comparative linguistics. at the University of Konigsberg. In 1877 he founded the journal *Beiträge zur Kunde der indogermanischen Sprachen*, which in 1907 was fused with the *Zeitschrift fur vergleichende Sprachforschung.* He laid the foundations of Baltic philology by re-editing old texts (16th and 17th centuries), in several monographs on Lithuanian, Lettish and Old Prussian, and by numerous articles on Baltic linguistics. His search for the original homeland of the Baltic people led him to archaeological studies, including excavations. in the Baltic area. For 25 years he was the director of the "Prussia" museum in Konigsberg and editor of the proceedings of the *Altertumsgesellschaft Prussia.* (Ad. Sn.)

BHADGAON (Bhatgaon or Bhaktapur), a town of Nepal, lies 8 mi. S.E. of the capital city of Katmandu. Pop. (1954) 32,-118. It is said to have been founded by Raja Ananda Malla in A.D. 865, and for 200 years prior to the Gurkha conquest (1768) was the most important town in the valley. the territories of Bhadgaon kingdom extending widely outside the valley. After the fall of Katmandu and Patan, Bhadgaon surrendered to Prithvi Narayan without a struggle and so escaped much of the plunder and destruction suffered by the other two towns. The old palace in Durbar square is well preserved and has beautiful carved woodwork and a finely worked gilt gateway, one of the finest pieces of work in Nepal, and perhaps in all Asia. Opposite on a stone pillar is the figure. beautifully worked in copper gilt. of King Bhupatindra Malla who built the palace in about A.D. 1700. There are other temples in this square, and a little to the south is another square in which is the Nyatpola, or five-tiered temple, also built by Bhupatindra hlalla. It is raised on a plinth. the steps of which are guarded by a number of mythical figures: the lowest are two fabulous heroes, Jaya Malla and Phatta. said to be stronger than ten men; behind them are two elephants ten times as strong as they; behind these again are two mythical lions or *singhas* ten times as strong again; then come two dragons, and lastly the two goddesses Bhagini and Singhini whose strength is supernatural. On another side of the square is a fine temple to Bhairava, guarded by two copper-gilt *singhas.* About 1 mi. S. of the town, on a wooded ridge, is the temple of Surji Banaik, dedicated to Ganes. On the western outskirts is a large tank, the Sidha Pakhari, built by Raja Partab Malla in 1640–50. (Ri R. P.)

BHAGALPUR, a city and district in Bihar state. India. Surrounded by groves of trees the city stretches along the high right bank of the Ganges for 7 mi. Pop. (1961) 143.994. There are four colleges, all connected with Bihar university. Tej Narayan Jubilee (T.N.J.) college, established in 1887. has fine buildings. Sabour, 4 mi. E. of Bhagalpur, is the seat of Bihar's premier agricultural college. Bhagalpur is on the Sahebganj loop line of the Eastern railway. The city is noted for coloured and artistic fabrics made by local weavers from tussore (tasar) and *eri* silk, and a government silk institute has been established to foster this industry.

Bhagalpur District is bounded on thr north by a line about 10 mi. N. of the Ganges. Area 2,179 sq.mi. Pop. (1961) 1,715.128. The southern third of the district lies in the forested uplands of the Chota Nagpur plateau and the remainder in the alluvial Gangetic plain. The portion of the district lying north of the Ganges is naturally well watered, while that to its south is irrigated by private canals The principal crops are rice, maize, wheat, barley, gram, oilseeds, lac and silk.

The district is served by the Eastern and Northeastern railways, the two systems being linked across the Ganges by steamer service. Rock sculptures of the 6th or 7th century are found at Patharghatta 8 mi. N. of Colgong. (E. Ah.)

BHAGAVAD GITA, forming part of book vi of the Indian epic the Mahabharata. is one of the great religious classics of the world. It is to Hindus what the Sermon on the Mount is to Christians. It is in the form of a dialogue between Arjuna, the hero of the epic, and Krishna, his friend and charioteer, who is believed to be an incarnation of God. The dialogue occurs at the most dramatic moment in the epic. In the fratricidal war between the Pandavas and the Kauravas, when their mighty hosts meet on the baitlefield of Kurukshetra and the historic battle is about to begin, Arjuna is tempted to desert his post of duty when he sees before him all his kinsmen who would have to be slain before victory could be secured. He consequently proposes to retire from the contest and allow himself to be slain by the enemy. Krishna thereupon reprimands him and points out to him the higher way of dispassionately discharging his duty, with faith in God and irrespective of consequences, and at last persuades him to fight. On the field of battle the discourse must obviously have been a brief one. Vyasa, the traditional author of the Mahabharata, writing probably about the 5th century B.C., expanded it a little, and perhaps some additions were made later. The poem, as it stands now, consists of 700 verses! divided into 18 chapters.

The Gita goes far beyond the ethical question with which it starts. There are. indeed. two broad streams of thought in it: a philosophical stream describing what God is, and a religious stream suggesting what man should do to reach Him. The greatness of the scripture lies in the fact that in its description of both the end and the means it gives a synopsis of the religious thought and experience of India through the ages. Being a predominantly theistic work, it often describes the ultimate reality as a personal god. identified with the avatar Krishna (*q.v.*). But it also quite frequently refers to the supreme as the immanent spirit, as the transcendent absolute and. finally, as the state of one's own awakened soul. Similarly, the means to realization is described in various terms—as the way of works (Karma yoga). as the way of love (Bhakti yoga) and as the way of knowledge (Jnana yoga). These are the three well-known paths of the Hindu religious tradition leading to the mystic union with God. In the Gita they are described as the different aspects of a single way of approach.

The immense popularity of the Gita is shown by the numberless commentaries, glossaries and expository books written on it in both ancient and modern times. The earliest commentary that has come down to us is that of the great philosopher Shankara (*q.v.*). The other important commentaries of ancient times are those of Ramanuja, Madhva, Nilakanta, Sridhara and Madhusudana, and the most important commentaries of modern times are those of Balgangadhar Tilak, Aurobindo Ghose, Mahatma Gandhi and Sarvepalli Radhakrishnan. The Gita has been translated into many languages. *See* also Hinduism. (D. S. Sa.)

See Swami Nikhilananda, *The Bhagavad Gita* (1944), and S. Radhakrishnan, *The Bhagavadgita* (1948), both English translations with introductions and notes.

BHAMO, a town and district in Kachin state in the northern part of the Union of Burma. The town was in ancient times the capital of the Shan state of Manmaw. Pop. (1953) 9,817, a large proportion being Chinese and Chinese Shans. About 300 mi. up the Irrawaddy river from Mandalay, and nearly 1.000 mi. by river from the sea, the town is normally the highest point reached by the regular steamer services of the Inland Water Transport board. It is also the nearest point on the river to the Chinese frontier (53 mi.). It stretches for nearly 4 mi. along the Irrawaddy bank in a series of small villages, but the town proper is confined mainly to one high ridge of land running at right angles to the river. Bhamo had long been the terminus of land commerce from China until the building of the Burma road, 1937–39.

Bhamo District lies wholly in the basin of the Irrawaddy. Pop. (1941) 129,302. Area 4,146 sq.mi. On the east of the river is the Shan plateau with its edge running north and south. West of the Irrawaddy there is a series of ranges, enclosing the basins of the Kaukkwe, Mosit, Indaw and other streams down which timber is floated. The hills are inhabited chiefly by Kachins. (L. D. S.)

BHANDARA, a town and district of Maharashtra state, India. The town (pop. [1951] 22,640) is on the Wainganga river 7 mi. from a station on the South Eastern railway and 33 mi. E. of

Nagpur. Cotton cloth and brassware are manufactured there.

BHANDARA DISTRICT with an area of 3.582 sq.mi. and with a population of 1,248.519 (1961) was transferred from Madhya Pradesh to Bombay in 1956 and from Bombay to Maharashtra when the latter state was formed in 1960. It is hilly and well wooded, containing many small lakes and tanks which are used for irrigation. Crops include tobacco, rice, wheat and jowar (millet).

The peoples of Bhandara include the *Ponwans* who are cultivators and Kohlis who are tank constructors and sugar cane growers. There are extensive deposits of high-grade manganese in the northwest of the district producing about 300,000 tons of ore annually; other industries include weaving, which is declining. and cigarette making. The Great Eastern road and the South Eastern railway from Nagpur to Calcutta traverse the district. The chief towns in the interior of the district are Sindia ([1951] 36,686); Pauni, an old walled town and fort (14,389); and Tumsar (18.23'0).

(M. R. P.)

BHANG, an East Indian name for the hemp plant, *Cannabis sativa,* applied specially to the leaves dried and prepared for use as a narcotic drug. See HEMP.

BHARAL (*Pseudois nahura*), the wild blue sheep'of Tibet and'western China, live in bands of 10 to 50 in mountain meadows above 10,000 feet. The ram is characterized by a black band separating the blue-gray back from the white under parts and by smooth, sigmoid horns sweeping backward in a semicircle.

(H. K. B.)

BHARATA NATYAM, a form of Hindu temple dance indigenous to the Madras region in southeastern India. Its very ancient techniques and terminology were written by the sage Bharata in a work (extant in palm-leaf manuscript) titled the *Natya Shastra.* The probable date of this work is the 6th century, B.C. Bharata Natyam was originally performed exclusively by female temple dancers (devadasisj in temple services, marriages and other religious ceremonies, as well as for the entertainment of the rulers. Not until about 1930 was this art brought to the stage for public performances.

A program of Bharata Natyam usually lasts two hours without interruptions and includes a specific list of procedures, all performed by one dancer who does not leave the stage or change costume. The accompanying orchestra (composed of drums, drone and singer) occupies the back of the stage, led by the guru (teacher) of the dancer.

In pure style, Bharata Natyam is classically clear in technique, The feet beat out complicated counter-rhythms; the lower limbs are bent in a characteristic low squat; arms. neck and shoulders are part of the movement. In the pantomime sections, the hands tell the story through conventional gesture-language, while the face expresses the mood. In the pure dance, the hands are restricted to the 11 pure-dance mudras (hand poses). (R. M. Hs.)

BHARATPUR (BHURTPORE), a city and district of Rajasthan, India. The city is on the Western railway, 34 mi. W. of Agra, Uttar Pradesh, and is surrounded by mud ramparts. Pop. (1951) 37,321. The town is noted for its manufacture of chowries, or fly whisks, with handles of sandalwood, ivory and silver and tails also made of strips of ivory or sandalwood as fine as horsehair. The palace of Suraj Mal, founder of the modern noble house of Bharatpur, is at Dig, 21 mi. N.W. of the city.

BHARATPUR DISTRICT (area 3,127 sq.mi.; pop. [1961] 1,150,-849) comprises most of the former princely state of the same name, absorbed into Rajasthan on May 15, 1949. and more than 1,000 sq.mi. of additional territory from neighbouring states. The country is generally level, but detached hills rising to 200 ft. in height occur. especially in the north. These hills contain good building stone and also deposits of iron ore. The Banganga, the only river flowing through the district, enters the Jumna below Agra.

The princely state rose to importance under Suraj Mal, a Jat chieftain, who bore a conspicuous part in the destruction of the Delhi empire. Having built the forts of Dig and Kumbher in 1730, he received in 1756 the title of raja, and subsequently joined the Maratha army with 30.000 troops. In 1803 the East India company concluded a treaty, offensive and defensive, with Bharatpur. In 1804, however, the raja assisted the Marathas against the British. Lord Lake captured the fort of Dig and besieged Bharatpur, but was compelled to raise the siege after four attempts at storming. A treaty, concluded on April 17. 1805. guaranteed the raja's territory, but a dispute as to the right of the succession again led to a war in 1825, and Lord Combermere captured Bharatpur on Jan. 18, 1826. The fortifications were dismantled, the hostile chief deported to Benares (Varanasi) and an infant son of the former raja installed under a treaty favourable to the company. In 1853 the state came under British management during a minority and up to India's attainment of independence in 1947 was controlled through the Eastern Rajputana subagency of the Rajputana states agency. (S. M. T. R.)

BHASKARA (BHASKARACARYA, *i.e.,* Bhaskara the learned) (b. 1114) was almost the last great Hindu mathematician until modern times. His versified *Siddhanta-siromani* (1150) consisted of two mathematical and two astronomical parts. The mathematical parts, which are of great originality, were translated with the work of Brahmagupta (*q.v.*) by H. T. Colebrooke (1817), and those on astronomy, which merely restate clearly the older astronomical views, by L. Wilkinson (1861–62). Bhaskara realized the true nature of division by zero; he anticipated modern theory on the convention of signs (minus by minus makes plus, minus by plus makes minus); he represented unknown quantities by letters; he gave general solutions for quadratic equations reduced to a single type (considering positive roots only as genuine); and solved a few cubic and biquadratic equations and some indeterminate equations of the first and second degree. He also computed elaborate tables of sines, studied regular polygons up to 384 sides, giving $\pi = \frac{7}{2}\frac{5}{2}\frac{4}{0}$ (3.141666 . . .), and anticipated Kepler's method for determining the surface and volume of a sphere.

BHATINDA, a town in the Patiala division of Punjab, India, the headquarters of Bhatinda district, is 173 mi. N.W. of Delhi. Pop. (1951) 34.991. The town has a massive fort, with ramparts 118 ft. high, which was built during the reign of Sher Shah Sur at Delhi (1540–45). It is the seat of Rajindra college, affiliated to Punjab university. Bhatinda is a major junction of the Northern railway (opened in 1897), with main (broad-gauge) lines converging from Delhi, Ferozepur and Patiala, and from Macleodganj over the Pakistan border; and metre-gauge lines from Fazilka, Hissar and Bikaner. The town is chiefly a railway and administrative centre.

BHATINDA DISTRICT is part of the level alluvial plain south of the Sutlej river (*q.v.*). Pop. (1961) 1,056,033, predominantly agricultural. Area 2,253sq.mi. Rainfall is meagre and unreliable: irrigation is from the Sirhind and Bhakra canals running northeast to southwest across the district. Wheat, gram, cotton, millets and sugar cane are the main crops. Local trade centres include Kotkapura and Faridkot, the seat of another Punjab university college. (O. P. B.)

BHATPARA, a city in Twenty-Four Parganas district, West Bengal. India, lies on the east bank of the Hooghly river, 25 mi. N. of Calcutta. It is in the industrial belt that stretches along the Hooghly and that has a population density of 2,100 per sq.mi. In 1961 its population figure was 147,725 according to the census, and thus it had the fourth' largest population in West Bengal, and the largest percentage of industrial workers. Bhatpara and its suburb Jagatdal have one of the five great concentrations of jute mills in the Calcutta area and there are also cotton mills and engineering works. The city was once a famous centre of Sanskrit learning and was notable for its *tols* or free Sanskritic schools.

(D. G. NA.)

BHAVABHUTI, a Brahman of Vidarbha (the part of central India later called Berar), writing in Sanskrit. He passed his literary life chiefly at the court of Yashovarman of Kanauj (about A.D. 700). He was the author of three plays, the first of which, *Mahaviracharita* ("Life of the Great Hero") gives in seven acts the main incidents in the Ramayana, up to the defeat of Ravana and the coronation of Rama. The second, *Malatimadhava,* a do-

mestic drama in ten acts, tells the story of Madhava and Malati, the son and daughter of two ministers of neighbouring kings, who from childhood have been destined for each other, but are for a time threatened with separation by the king's wish to marry Malati to his old and ugly favourite. The play abounds in stirring, though sometimes improbable, incidents. Finally, there is the *Uttara-ramacharita* ("The Later Adventures of Rama"), again in seven acts which continues the story of Rama from his coronation to the banishment of Sita and their final reunion. This play, though containing far less action than the other two, shows Bhavabhuti at the height of his power in characterization and in presenting suspense and climax, leading many to rate him more highly than Kalidasa (*q.v.*), as a dramatic poet. (J. E. B. G.)

BHAVE, VINOBA (1895–), Indian ascetic and founder of the *Bhoodan Yajna* or land-gift movement, was born on Sept. 11, 1895, at Gagode in Baroda, of a Chitpavan Brahman family. He was educated at the Baroda high school, but abandoned his studies and, in 1916, joined M. K. Gandhi's *ashram* ("community"). He wholeheartedly accepted Gandhi's ideas and devoted himself to a life of austerity, concentrating upon ways of improving Indian village life. At Gandhi's behest he committed civil disobedience and was imprisoned on several occasions. He conceived the idea of the land-gift movement in 1951, while touring villages in Telingana (Andhra Pradesh), where Communist disturbances had been prevalent. A landholder offered him some land in response to his appeal on behalf of a group of landless Harijans (untouchables). After that, he walked from village to village, appealing for gifts of land, to be distributed among those who had little or none. He claimed that this was applying to the land problem Gandhi's doctrine of *nhimsa,* or nonviolence. Land reform would be secured by a change of heart and not enforced by government action. Between 1951 and 1956, 4,000,000 ac. were given. While some critics pointed out that less than 1,000,000 ac. had been distributed, Vinoba saw the need for organization and, in 1954, established a special training camp for *Bhoodan* workers at Kanjirapalli (Kerala state). Against the further objection that the fragmentation of land would obstruct any rationalization of agriculture. Vinoba maintained that he preferred the fragmentation of land to the fragmentation of hearts. Later, however, *gramdan* was encouraged; *i.e.,* the pooling by villagers of all their land. after which the village would be reorganized on co-operative lines. By 1957, more than 2,500 villages had been pooled in this way. Vinoba explained his original project and his philosophy of life in a series of articles later collected together in *Bhoodan Yajna* (1953, reprinted 1957).

See R. P Masani, *The Five Gifts* (1957). (KE. A. B.)

BHAVNAGAR, a municipal town and seaport in the district of the same name in Gujarat state, India, is situated on the west coast of the Gulf of Cambay. Pop. (1961) 177.488. It has three colleges and a 'polytechnic institute; the Darbargadh (the old royal palace) and various lakes, parks and temples. It is an important commercial and industrial centre with spinning and weaving mills, steam presses, tile and brick factories, sawmills, ice factories and an iron foundry. It is connected with the main Western railway system and has a good port for small vessels. The town was founded in 1723 by the local ruler Thakur Sahib Bhausinghji.

BHAVNAGAR DISTRICT comprises the former princely state of Bhavnagar whose ruler or thakur was the head of the clan of Gohel Rajputs of Saurashtra who probably settled in the area about 1260 and which was part of the Western India States Agency during the combined Baroda-Western India administration (1944–47) under British paramountcy. Pop. (1961) 1,116,206; area 4,652 sq.mi. After Indian independence in 1947. the state was merged into the new state of Saurashtra, which now forms part of Gujarat state. More than one-half the area consists of regur or black cotton-soil. The chief products are grain, cotton and salt, and manufactures are oil, copper and brass vessels and cloth (M. R. P.)

BHIL, the name applied to more than 2,000,000 varied, partly tribal peoples of western India, a name connotative of banditry and rugged independence.

Bhils are distributed widely in upland areas from Ajmer in Rajasthnn on the north to Thana district in Maharashtra on the south, and eastward as far as Indore in Madhya Pradesh. Some Bhils may have been pushed southeastward by medieval Rajput conquests: rulers ascending the throne of Udaipur formerly had to be anointed by a Bhil with his own blood.

Nearly all Bhils practise agriculture, a few by the slash-and-burn method, most by the plow even on hilltop millet fields. Highland Bhils generally live in scattered. often-shifted houses of open wattle and thatch. They are self-sufficient in many crafts. Bhils follow Rajasthani kinship usages in Rajasthan, Maharashtrian usages in Maharashtra, etc., but with easier marriage and divorce. Most Bhils worship local deities in varied pantheons only slightly touching the practices of higher Hinduism; a few aristocratic segments such as the Bhilala and some plains groups employ Brahman priests; others are converts to Islam.

Bhils now speak Indo-Aryan dialects akin to Gujarati or to other neighbouring languages. A small non-Indo-Aryan residuum in the Bhil vocabulary is neither Munda nor Dravidian but of unknown affinities. Physical evidence and traditions of intermarriage likewise indicate that the Bhils have received many genetic contributions from the higher Hindu castes, whom many Bhils now resemble more closely than they do any more isolated aboriginal peoples.

Bhil regiments were active and loyal in British service through the latter half of the 19th century.

Simcox, *Memoirs of the Khandesh Bhil Corps 1825–1891* (1914). (M. MA.)

BHILSA (ancient. and modern official. VIDISHA), a town and district in Madhya Pradesh, India. The town headquarters of Bhilsa district is on the east bank of the Betwa river (*q.v.*), 33 mi. N.E. of Bhopal. Pop. (1951) 19,184. It is on the Central railway main line from Delhi to Bombay.

Bhilsa was central on the ancient routes between Sovira and Magadha (*q.v.*) and between the Andhra capital Paithan and Sravasti (*see* GONDA). This is reflected in the many Hindu, Buddhist and Jain monuments within 12 mi. radius, including about 60 ruined stupas or Buddhist relic-domes. Bhilsa is identified as Vidisha, seat of the Sunga prince Agnimitra (2nd century B.C.) and the eastern capital of Malwa (*q.v*). Jain scriptures call it Bhadalpur, birthplace of Sitalnath. the Jains' 10th *tirthankara* or patriarch. Outside the archaeological museum in Bhilsa camp stand a colossal stone figure of Kubera, king of the yakshas (a class of Indian deities), and a yakshi statue, both found in the river bed.

Four miles northwest of Bhilsa is Besnagar (Vesnagar), birthplace of Devi. consort of the emperor Asoka (*q.v.*). There stands the monolithic Kham-baba or Heliodorus column (late 2nd–early 1st century B.C.). It was erected in honour of Vasudeva (Vishnu) by Heliodorus, envoy of the Indo-Greek king Antialkidas of Taxila. Two miles further northwest are the nine rock-cut Vaishnavite and Jain sanctuaries of Udayagiri (late 4th century AD.).

BHILSA DISTRICT is drained by the Betwa and its tributaries. The eastern part is traversed from south to north by a branch of the Vindhya range, from which good building sandstone is quarried. The remainder has rich black soils: wheat and tobacco are cultivated. Pop. (1961) 490.200: area 2.839 sq.mi. (D. G. NA.)

BHILWARA, a town and district formerly in the state, and now in the division of Udaipur. Rajasthan, India. The town lies about 80 mi. N.E. of Udaipur city, on the Western railway. It is the headquarters of the district. The population in 1901 was 10.346 and by 1951 it had risen to 29,668. Bhilwara is noted for the excellence and durability of its tinned utensils. which are largely exported, and for cotton ginning and pressing. There was formerly a mint producing coins called Bhilari.

BHILWARA DISTRICT, had a population of 865.835 in 1961, an increase of 513.789 from 1901. The greater part of the district is covered with rocky outcrops and parts of it are hilly and forested, the plains being mostly barren with sparse bush and thorn scrub.

The main marketable products are fuel and charcoal. The nearest markets for the products of the forest areas are Beawar and Ajmer. (S. M. T. R.)

BHIMA, in the epic Hindu mythology, one of the Pandava princes in the Mahabharata, distinguished by his size, strength and voracity.

BHIND, a town and district in Madhya Pradesh, India. The town, the headquarters of the district, lies 48 mi. N.E. of Gwalior. Pop. (1961) 28,193. It is on the road from Gwalior northeastward to Etawah in Uttar Pradesh, and at the terminus of a metre-gauge branch from Gwalior on the Central railway's Delhi-Bombay main line. Locally known as Bhind Bhadwara, it was the chief seat of the Bhadwara branch of the Chauhan Rajput clan until it fell in the 18th century to Sindhia of Gwalior.

The town has an old fort and a lake. Gauri Tal, on which stands the Vyankateshwar temple. There are a few cotton presses and ginning factories.

BHIND DISTRICT is in the Jumna-Chambal badlands and its fertile land is scoured by many ravines. 30–40 ft. deep. and large-scale gully erosion. Pop. (1961) 611,226; area 1,723 sq.mi. The Chambal forms the district's northern border before joining the Jumna; another Jumna tributary, the Sindh, crosses the east of the district. Main crops are wheat, cotton and millets. (S. M. A.)

BHIR (BIR), a town and district in Maharashtra state, India. The town, headquarters of the district, is 67 mi. S.S.E. of Aurangabad. Pop. (1951) 25.636. It is connected with other parts of the state by road, but there is no rail connection. It is noted for leatherwork, especially the type of Indian water bottle known as a chagul. Before the Muslim invasion of the Deccan, Bhir mas a possession of the Chalukyas (see CHALUKYA) and, in the 13th century, of another Hindu dynasty — the Yadavas of Deogiri (now Daulatabadj. It was taken by Mohammed ibn Tughlak, sultan of Delhi, in 1327 during his efforts to reassert authority in the Deccan. The subsequent history of the town is part of that of the Deccan under the Muslim regimes of the Bahmani kings, the sultans of Ahmednagar (*q.v.*), the Moguls and the nizams of Hyderabad (*q.v.*).

BHIR DISTRICT lies between the Godavari river (*q.v.*) and its tributary the Manjra to the south. Pop. (1961) 1,001,105; area 4,261 sq.mi. Its climate is in general temperate with an annual average rainfall of 30 in. The main agricultural products are cotton, linseed, jowar and hajra millets, wheat and pulses. The district was transferred to Bombay state on the dissolution of Hyderabad in 1956 and was included in Maharashtra state on its foundation in 1960. (S. AH.)

BHOPAL, capital city of Madhya Pradesh, India, is in the district of Sehore (*q.v.*), 183 mi. N.W. of Nagpur (Maharashtra). Pop. (1961) 225,460. It is the seat of a postgraduate teachers' college attached to the University of Sagar and a government degree college and a medical school of Agra university. The city, lying 3.000 ft. above sea level, enjoys a temperate climate with an average annual rainfall of 40 in. Bhopal is served only by a secondary road network but is on the main Delhi-Bombay line of the Central railway. Another line runs westward via Sehore and Ujjain to Nagda on the Western railway's Agra-Bombay route. There is an airport west of the city, but no regular service. The main industry is the manufacture of transformers, switchgear, traction motors and other heavy electrical equipment. The factory, established in 1960, has a large training school for apprentice engineers, and also in the city is a division of the National Power Research institute.

BHOPAL STATE, of which the city was the capital, was the second largest Muslim principality of the British-Indian empire. It was founded in 1723 by Dost Mohammed Khan, an Afghan adventurer. In 1778, when Warren Hastings, dispatched Gen. Thomas Goddard's column on its spectacular march across India against the Marathas, Bhopal was the only central Indian power to show itself friendly. When another British expedition arrived under Gen. Sir Barry Close in 1809 the nawab of Bhopal petitioned earnestly but in vain for British protection. In 1817, however, at the outbreak of the Pindari War, a subsidiary treaty was concluded between the then nawab and the British. From 1844 to 1926 the state had female rulers, three of whom, Sultan Jahan and her predecessors, Nawab Sikander and Shah Jahan, were considered enlightened and benevolent.

Bhopal was controlled under British paramountcy through the Central India agency and a local subsidiary administration, the Bhopal agency, which also conducted imperial relations with a number of adjacent petty states and hereditary estates. When India became independent, Bhopal remained a separate province of the new dominion, to which it formally acceded in 1949. But in 1952 the central government removed the last vestiges of the nawab's absolute rule and installed a chief commissioner to govern the state with the assistance of a ministry and elected legislature. In 1956 when, under the States Reorganization Commission act, all the Hindi-speaking areas south of the Vindhyas were united in the enlarged Madhya Pradesh, Bhopal was absorbed into it. At the same time Marathi-speaking Nagpur was transferred to Bombay state (now Maharashtra) and Bhopal city replaced it as capital of Madhya Pradesh. (S. GL.)

BHUBANESWAR (BHUVANESWAR), the capital of Orissa state, eastern India, is in the district of Puri (*q.v.*), 18 mi. S. of the former capital, Cuttack. Pop. (1961) 40,000. It is on the Southeastern railway main line and has an airport served by flights between Calcutta (409 km. [254 mi.] N.E.) and Madras.

Bhubaneswar has two parts: the old city of temples, and, to the north, a planned township built after the state capital was transferred there from Cuttack in 1958. In the latter are the Rajbhavan (residence of the state governor), secretariat, legislative assembly, Orissa state museum and the buildings of Utkal university (founded in Cuttack in 1943) and of the Rural university with their affiliated colleges. At the city centre is the Gandhi Memorial park. In the 1960s a zoological and botanical garden was established.

Bhubaneswar's history can be traced back to the 3rd century B.C. in archaeological remains nearby. These include rocks inscribed with edicts of Asoka (*q.v.*) on Dhauli hill, 5 mi. S., which refer to his viceregal town of Tosali. Known elsewhere as Ekamrakanan the place later became known as Bhubaneswar after Tribhuvaneswar Siva, its presiding deity. From the 7th to the 16th century A.D., under the Soma and Ganga dynasties, many temples were built, of which about 30 survive intact. There may be seen the whole development of Orissan temple architecture, from the small Parasurameswara shrine (c. A.D. 750) to the splendid temples of Lingaraja (c. A.D. 1000) and Raja Rani (c. A.D. 1000) with their soaring towers, rich exterior sculpture and complex of assembly and ritual halls. At Udayagiri hill (6 mi. N.W.) is a group of caves about 2,000 years old. Excavations at Sisupalgarh, 1 mi. E., revealed Kalinganagar, the capital of Kharavela (1st century B.C.).

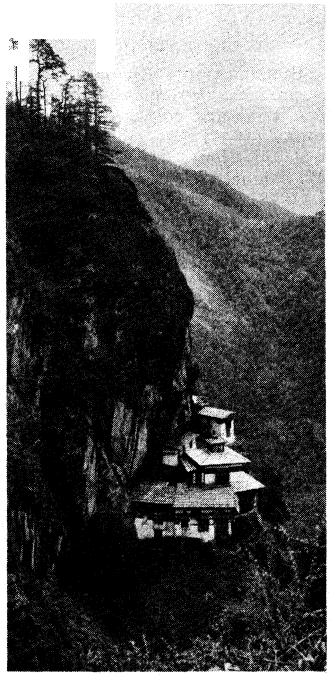
See P. Brown, *Indian Architecture (Buddhist and Hindu Periods)*, pp. 118–124 (1942). (**Ma.** M.; N. K. S.)

BHUTAN (DRUK-YUL), a semi-independent state, lies in the eastern Himalayas between Tibet and India and is a country of great scenic beauty. It is bounded on the west by Sikkim. Rugged mountains and dense forests prevent easy access from the outside world. Even the best road into the country through the Chumbi valley and the Natu La (pass) in Tibet requires several days of difficult travel. The government enforced this isolation as a means of preserving peace, but at the price of maintaining a premedieval existence of the people. By the middle of the 20th century most Bhutanese (*Drukpa* or Thunder people) had never seen a wheel. Then, under pressure of neighbouring countries with strategic interests in Bhutan, a very slow change began and the lack of outside contacts became a hindrance to modernization. The land attracted international attention when part of it was included within China's boundaries on maps printed by the Chinese Communist government in 1958 (see History, below).

Physical Geography. — The country is about 200 mi. long and up to 90 mi. wide, yet it reaches from 24,000-ft. peaks in the north to the low hills and the pass through the Sinchula mountains at Buxa Duar on India's borders. The most northerly tract, running from east to west and about 20 mi. wide, is wild and snowy, offering little but grasslands for herds of yaks. The next tract, about 40 mi. wide and between 3,500 and 10,000 ft. high, is covered with coniferous arid some other trees and contains in its western half most of the population. The most southerly tract, about 30 mi. wide, is the lowest, hottest and most humid. It is covered with

dense. semitropical vegetation with an abundance of big game.

The country is cut up by mountain ranges. running from north to south. of such character that people usually can exist only in the river valleys separating the ranges. The main ranges, from east to west, are the Masong-chung-dong. between the rivers Amo Chu and Wang Chu; the Dokyong La between the Wang Chu and Ma Chu; the Black Mountain range, between the Ma Chu and Manas, and finally the Tawang range. In those valleys which are flat. low and temperate enough. such as Paro, Ha and Punakha, the Bhutanese grow rice, corn (maize), barley, wheat, buckwheat and some other cereals, fruits and vegetables, for their own support and some export to Tibet. All kinds of climate can be found and the estimated rainfall varies up to 300 in. annually in the tropical region to 40–60 in. in the more temperate zones.



THE TIMES, LONDON

TAK TSANG ("TIGER'S LAIR") MONASTERY. 2.000 FT. ABOVE PARO VALLEY. BHUTAN

The People. — The total area of Bhutan is 19,305 sq.mi. with a population (1958 est.) of 650,000. The people live in villages, though there are some towns of a few thousand inhabitants. such as Punakha. the winter capital; Tashi Chho and Paro, the summer capitals; Tongsa; and Ha. In effect, the capital is where the maharaja resides and this is presumed to be Thimbu most of the time. About 65% of the people are Bhutias, of Tibetan stock, speaking a basically Tibetan language They are predominantly Lamaist Buddhists. recognizing the dalai lama as their spiritual leader and supporting a large number of lamas spread across the country in numerous monasteries. In outlook and character these people are Mongolian and oriented more to Tibet than India. They live mostly west of the Black Mountain range. The sparse population east of that range came presumably from the hills to the northeast of Assam. About 20% to 30% of the population are Nepalese, concentrated in the foothills west of the Amo Chu. They are in many ways discriminated against for fear that eventually they might outnumber the Bhutias.

Agriculture is the main occupation of the people, though they are skilled also in handicrafts, mainly wood carving, metalwork and weaving. About 10 to 15 prominent families each own between 100 and 150 ac. of land. Average holdings are 5 to 10 ac. and a 1960 law aims at maximum holdings of 30 ac.

History. — Bhutan's. early history is unknown. It is clear, though, that Bhutan has existed as a political entity for many centuries. Early sagas report constant warring among Bhutan's neighbours and the Bhutanese themselves for control of the country. It is fairly certain that by the 9th century A.D. the Tibetans had driven out the Indians and settled in the country. In 1720 a Chinese imperial army invaded Tibet and established suzerainty there and also over Bhutan. Control over the country changed several times thereafter and its exact territorial extent was not clear. When the British established dominion over Bengal in 1765, Bhutan included parts of Darjeeling and the duar ("door" or pass) of Jalpaiguri. In 1772 the Bhutanese invaded Cooch-Behar and carried off the raja as a prisoner. Warren Hastings, governor of Bengal, responded to an appeal for help and invaded Bhutan. The regent of Tibet, the tashi lama, claiming Bhutan as a dependency, intervened and a peace treaty was signed on April 25, 1774. In that year George Bogle and in 1783 Samuel Turner, British emissaries on their way to Tibet, passed through Bhutan to settle frontier issues and promote trade. They failed. Friction in the border region increased when the British occupied Assam in 1826. To put an end to it, the British, in 1841, took over the duars in the Darrang district of Assam and promised payment of a subsidy of Rs. 1,000 to Bhutan as long as peace prevailed It did not do so for long. In 1863 Sir Ashley Eden went to Bhutan to demand reparations for border raids but instead was forced to sign a treaty, which the British denounced as soon as Sir Ashley escaped from Bhutan. They sent an ultimatum to Bhutan and followed it up with an invasion of the country in 1865. The Bhutanese, finally defeated, signed the treaty of Sinchula on Nov. 11. Bhutan agreed to free all British prisoners; to cede the Athara Duars in the foothills as well as the Assam, Bengal, and Eastern Duars; and to accept British mediation in disputes between Bhutan and the chiefs of Cooch-Behar and Sikkim. In return, Great Britain promised to pay Bhutan an annual subsidy of Rs 25.000, increasing gradually to Rs. 50.000, as long as the treaty would be kept. All this fighting and the treaty negotiations proceeded with disregard of the Chinese or Tibetan governments, thereby weakening their claim to suzerainty. The definitive end of that suzerainty came in 1910 when, over Chinese protests, the Bhutanese government agreed in a treaty to be guided by Great Britain in external affairs in return for an annual subsidy of Rs. 100,000 (increased to Rs 200,000 in 1942) and the British promise of noninterference in Bhutan's internal affairs. This treaty reflected both British security interests and the friendly relntions between the two countries. Bhutan became gradually oriented politically toward India, although much of its trade continued with Tibet

Upon India's independence, a Bhutanese delegation appeared in New Delhi in 1946 to clarify the country's new position. After much discussion, on Aug. 8, 1949, a treaty was signed continuing the British system, but increasing the subsidy to Rs. 500.000 and transferring 32 sq.mi. of land, known as the Dewangiri, in Assam, to Bhutan. As a result. India handles Bhutan's foreign relations, with the exception that Bhutan has an agent in Lhasa. Tibet. This arrangement was of little relevance while both countries agreed that Bhutan should continue its isolation from the world. The situation changed when the Chinese Communist government took over Tibet in 1950 and deployed troops along the Himalayan borders Contacts betneen Indian and Bhutanese officials increased. Since 1958 Chinese Communist maps showed considerable areas of Bhutan as within China. Chinese pressure for direct relations between China and Bhutan began. India urged Bhutan to take measures for its own security and in 1959 promised to come to its aid in case of aggression. To avoid use of the path through Tibet, the two countries began to build roads for direct communication, the first road runs between Phunchholing, on the Indian frontier. and Paro.

Government. — The government of Bhutan has always been autocratic. with no law codes, courts or any of the features of modern public administration. Between the middle of the 17th and the early 20th centuries, the government was divided between a spiritual ruler, the Dharma raja, an incarnation of the Buddha who was usually discovered among the children of the ruling families, and the Deb raja, the temporal ruler, formally elected, but in fact nominated by the *penlop* ("governor") of either the Tongsa or the Paro district (west and east Bhutan), the most powerful among the *penlops.* In 1907, after the Dharma raja had died and the Deb raja withdrawn into a life of contemplation, the then strongest *penlop*, Sir Ugyen Wangchuk of Tongsa, was "elected" by a council of lamas, abbots, councilors and laymen as hereditary maharaja, while the lamas continued to have strong spiritual influence.

The maharaja rules with the assistance of a prime minister, a council of ministers and a national assembly in which each of the ten administrative districts is represented. Every district has a *penlop* or a *dzongpon*, resembling a feudal lord and residing in a fort *(dzong, jong),* the centre of public life, around which the villages are clustered. His functions consist mainly in collecting taxes and maintaining order. He is assisted by a small staff in the *dzong* and a hierarchy of officials, among whom the richest landholders usually can be found. Also at his disposal are the local troops, poorly trained and equipped, but adequate to control the peaceful population.

This medieval system of government underwent a very slow, steady change with the influx of new ideas from neighbouring countries after World War II and especially after the arrival of the Chinese Communists on Bhutan's borders.

The assembly's participation in legislation increased. The government began to plan for the construction of roads, the creation of schools, the building of hospitals and dispensaries, the exploitation of natural resources, the training of a professional army and the centralization of the national administration. The Indian government offered financial and technical aid, but taxes had to be raised nevertheless to realize these measures. Dissatisfaction was spreading among the population, but could not be expressed because the maharaja did not tolerate opposition. Thereupon, the national congress, a party created by the long-dissatisfied Nepalese in Bhutan with headquarters in Siliguri (India) near the Bhutanese border, made itself the spokesman also of these dissatisfied elements and added to its program of abolishing discrimination against the Nepalese, the liberalization of the "autocratic and arbitrary rule" of the maharaja and a demand for the establishment of popular government in Bhutan, but the government made few concessions to these demands.

The government of India is represented by its political officer residing in Gangtok. Sikkim.

BIALIK, HAYYIM NAHMAN (1873–1934), the leading Hebrew poet of modern times, was born in Rady, Volhynia (Ukraine), Jan. 9, 1873. His father died when he was five or six and he was brought up by his grandfather. He suffered under rigorous traditional education and soon left the famous Talmudic academy in Volozhin (now Belorussia), where he wrote his first poem El *ha-Tzippor* ("To the Bird"). Bialik. who, like his fellow writers, wished to transform Jewish national cultural and social life, turned his back on the existence prevailing among eastern European Jewry and in 1891 went to Odessa. then the centre of Jewish modernism. He failed to make a living there and left to work and write in various out-of-the-way places, establishing himself as a "national" poet and leader of Hebrew culture before returning to Odessa (1900). In 1921 he left Soviet Russia for Germany, where Jewish writers had established a short-lived Hebrew centre, then settled in Palestine (1924) and visited the U.S. (1926). In Palestine he devoted himself to scientific matters and public affairs, producing few poems, the most important of which was *Yutmut* ("Orphanhood"), a long poem about his childhood, written shortly before his death. He died in Vienna. July 4, 1934.

Bialik is the classic poet of modern Hebrew. His poetry deals largely with his childhood sufferings and his inner struggle with tradition, most movingly in the long poem *Ha-Matmid* ("The Talmud Student"); his poems in reaction to the Kishinev pogrom (1903), Zionist poetry and poems in the folk-song manner are important. He also wrote in Yiddish, translated some European classics and S. A. Anski's Yiddish play Der *Dybbuk* into Hebrew and wrote stories and essays.

An indefatigable editor and literary organizer, Bialik was active in the ingathering (*Kinnus*) and the presentation to the modern Jew of early and medieval Hebrew literature, assisted by his lifelong associate J. H. Rawnitzki, with whom he founded the publishing firm Devir and edited the *Sefer ha-Aggadah* (1908–10), the most popular collection of midrashic legends. He also edited the poems of Solomon ibn Gabirol (*q.v.*) and began a popular modern commentary on the Mishnah. Bialik's influence upon the formation of Hebrew culture in what is now Israel can hardly be overestimated. His long participation in the Language council's work affected the development of the Hebrew language.

BIBLIOGRAPHY.—Bialik's collected works, complete ed., 5 vol. (1935); poems *(Tushiyyah,* 1902); *Iggerot,* letters (1937–39); *Devarim shebe'alpeh,* talks and conversations, 2 vol. (1935); *Pirke Hayyim,* autobiography (1944).

BIALYSTOK, a town and *wojewodztwo* (province) in northeastern Poland. The town, capital of the *wojewodztwo,* lies in the Podlasie lowlands on the Warsaw-Leningrad railway line. Pop. (1960) 120,800. When the Germans occupied the town during World War II they massacred about 50% of the population, including all the Jews in the ghetto. Bialystok was known as a village in the 14th century. Town rights mere granted it in 1749 as a result of representations made to Klemens Branicki, its owner. From 1795 to 1807 Bialystok belonged to Prussia, but was transferred to Russian rule by the treaty of Tilsit (*q.v.*). It returned to Poland in 1919. In 1939 it was incorporated in the U.S.S.R., occupied by Germany in 1941 and returned to Poland in 1945.

The development of Bialystok has been closely associated with the foundation in 1824 of the textile industry, mainly woolen goods, which increased rapidly in the town and neighbourhood to supply the demand of the Russian market. The Germans destroyed 76% of the industry between 1941–45, but it was rebuilt and extended after the war. The main emphasis was placed on the linen industry. based on the use of local resources. The timber industry was also represented. Two colleges were opened in Bialystok after 1945: the Academy of Medicine and the Higher Evening Technical college.

BIALYSTOK WOJEWODZTWO borders to the north and east on the U.S.S.R. Pop. (1960) 1,089,700. Area 23,148 sq.km. (8,937 sq.mi.). The province contains 12 *powiaty* (districts) of which three (Elk, Goldap and Olecko) were incorporated in Poland after World War II. Most of the region consists of lowlands drained by the Narew, Biebrza and Bug rivers which flow through wide, marshy plains. There are about 500 lakes in the northern, wooded sector, with its varied moraine landscapes. The *wojewodztwo* has mainly poor: sandy soils; the chief industry is agriculture, which produces rye, oats, potatoes and flax. Approximately 45.4% of the area is used as arable land, 21.6% as meadows and pastures and the remainder is forested. The forests, mostly coniferous, include that of Bialowieza (Puszcza Bialowieska) 1,250 sq.km. (483 sq.mi.) in area, the largest wooded region in the central European plain! which provides raw material for the large timber works at Hajnowka. Since 1945, 580 sq.km. (224 sq.mi.) of the forest have belonged to Poland, the remainder to the U.S.S.R. In 1921, 4,716 ha. (18 sq.mi.) of the forest were made into the Bialowieza National park. It contains bison, elk and beaver.

Economically the *wojewodztwo* is one of the most underdeveloped regions in Poland, and is sparsely populated (47 inhabitants per sq.km.). Only 28% of the population is employed in industry (mainly textile and timber) which is concentrated in a few urban centres. The chief towns (pop. 1960) are Bialystok 120,800. Elk 22,000. Lomza 20.000, Suwalki 20,000, Augustow (pop. 1958 est.) 13.300. The *wojewodztwo* is crossed by the railway line from Warsaw to Leningrad. (K. M. WI.)

BIANCHINI, FRANCESCO (1662–1729). Italian astronomer and antiquarian associated with calendar reform: was born of a noble family at Verona on Dec. 13, 1662. After studying at

Padua he proceeded to Rome in 1684. was for a time librarian to. Cardinal Ottoboni (later Pope Alexander VIII) and established an observatory at Albano. He was subsequently. appointed secretary of a committee on calendar reform by Clement XI and in 1703 he published *De kalendario et cyclo Caesaris.* Among his other published works were *Hesperi et Phosphori nova phaenomena* (1729) in which he gave a 24½-day rotation period for Venus; *Astronomicae et geographicae observationes selectae* (1737); and *Opuscula varia* (1754). He also published some papers, including one on G. D. Cassini's method of parallaxes. He died in Rome on March 2, 1729. (CN. A. R.)

BIARRITZ, the world-famous seaside resort, is in the *département* of Basses-Pyrénées, southwest France, with the Landes to the north and the Pyrénées to the south, on the Bay of Biscay about 8 km. (5 mi.) W.S.W. of Bayonne. Pop. (1954) 21.542 (quadrupled at the height of the season). The town is modern with a large number of hotels and has beaches, casinos and a rich sea museum. The varied scenery both on the coast and inland and the all year mild climate attract a great number of tourists. A promenade runs from the sandy Grand Plage, facing northwest, to the Côte des Basques. It passes south of the triple Promontoire de l'Atalaye whose small peninsulas are surrounded by rocky islets. some of them united by. jetties which enclose the Port des Pêcheurs. The folklore and traditions of the Basque inhabitants of the district are picturesque. Biarritz has two stations on the main line from Paris and Bordeaux to Hendaye and Spain, and a branch line from the Biarritz-Négresse station also serves the centre of the town. From the airport of Biarritz-Parme (2 km. [1 mi.] S.E.) there are services to London, Dublin, Gibraltar, Tangier. Casablanca, Paris, Lourdes and Nice. During the battles around Bayonne on Dec. 10–13, 1813, Biarritz was the scene of fighting, but it remained a fishing village until Napoleon III and the empress Eugénie went to stay there 40 years later and made it a fashionable resort. During World War II it was occupied by the Germans from June 1940 to Aug. 1944. (G. Co.)

BIAS (6th century B.C.), one of the Seven Wise Men of ancient Greece. was a citizen of Priene in Ionia. He was prominent in the political affairs of his city in the difficult period ensuing from the overthrow of Lydia by the Persians and is reported to have advised the Greeks of lonia to emigrate *en masse* to Sardinia (Herodotus, i, 170). A few aphorisms traditionally attributed to Bias propound a common-sense ethic. For the aphorisms *see* F. W. A. Mullach (ed.), *Fragmenta philosophorum graecorum,* i (1860); or H. Diels and W. Kranz, *Fragmente der Vorsokratiker,* ii, 7th ed. (1954).

BIBLIOGRAPHY.—F. A. Bohren, *De septem sapientibus* (1867); *T.* Lenschau, *De rebus Prienensium* (1878); and O. Crusius, "Bias," in Pauly-Wissowa, *Real-Encyclopadie der classischen Altertumswissenschaft,* iii (1907).

BIBAUD, MICHEL (1782–1857), the author of French Canada's first volume of poetry and the first substantial history of Canada. was born on Jan. 19, 1782, at Côte des Neiges, near Montreal, of a poor family. Belatedly educated at the Collège Saint-Raphael and Collège de Montréal. he lived modestly as a teacher, journalist, translator and civil servant. Devoting himself to the development of French-Canadian intellectual life, he began by founding a newspaper (*L'Aurore,* 1817). publishing arithmetic textbooks and composing the satiric and didactic verse of his *Epîtres, satires, chansons, epigrammes et autres pièces de vers* (1830). He then launched a series of short-lived literary and scientific magazines (1825–43). for which he wrote most of the articles. These included chapters of his *Histoire du Canada,* vol, i, on the French regime (1837); vol. ii, on the English regime to 1830 (1844); vol. iii, on the controversial period 1830–37 appeared posthumously (1878). Ponderous and unimaginative, Bibaud's history was not well received by his contemporaries because of its pro-English and bureaucratic sympathies. Disillusioned. he published nothing more but carried on research until a paralytic stroke caused his death in Montreal on Aug. 3, 1857.

BIBER, HEINRICH (IGNAZ FRANZ) VON (1644–1704), Bohemian composer, the first notable central European violinist composer. was born at Wartenberg, Bohemia. Aug. 12, 1644. He spent most of his life at the court of the archbishop of Salzburg, rising from a humble position to that of high steward and musical director (from 1676). He traveled widely as a virtuoso. He died at Salzburg. May 3. 1704.

Biber composed mainly for his own instrument. His sonatas for violin and clavier, and his solo sonatas with *continuo,* are of well-defined form and some technical difficulty, showing development of the resources of the violin, especially use of the *scordatura* (abnormal tuning to produce special effects). His most famous works are the five sonatas on the 15 mysteries in the life of Mary. He also composed a few stage works of which only the librettos, and the score of ***Chi*** *la dura la vince* (1687), have survived. (C. P. Co.)

BIBIENA (BIBBIENA), **GALLI DA,** a family of Italian artists of the 17th and 18th centuries. who took their name from the birthplace of their progenitor, Giovanni Maria Galli (1625–65), born at Bibbiena near Florence. He studied painting under Francesco Albani and first laid the foundations of an artistry which was carried on by his descendants, who devoted themselves to scenic work for the theatre.

Employing freely the highly ornate style of the Italian late baroque architecture and sculpture, the various members of the family produced a series of designs which are amazing for their splendour and spacious proportions achieved by intricate perspective. From about 1690 to 1787 eight Bibienas enchanted most of the courts of Europe with dazzling settings for operas, funerals and weddings. The Habsburgs were their most lavish patrons.

FERDINANDO GALLI BIBIENA (1657–1743), born at Bologna, was the son of Giovanni Maria. He studied painting under Carlo Cignani and architecture under Giulio Troili, called Paradosso. On Cignani's recommendation he entered the service of the duke of Parma. His chief work at this period was the villa and garden of Colorno, but he soon established a reputation for scenic designs and worked for the theatre. In 1708 he was called to Barcelona to arrange the decorations in connection with the wedding festivities of the future emperor, Charles VI; when this prince ascended the imperial throne, Ferdinando went to Vienna and was there employed on designs of scenery and decorations for festivities at the court and at the opera. On his return to Bologna in 1717 he was elected a member of the Academia Clementina. In 1731 he built the royal theatre of Mantua, burned in 1781. He produced several books: *L'Architettura civile* (1711), reissued under various titles, and *Varie opere di prospettiva* (1703–08).

FRANCESO GALLI BIBIENA (1659–1739), born at Bologna, was the second son of Giovanni Maria. He studied under Lorenzo Pasinelli and Cignani, worked at Piacenza, Parma and Rome and then became ducal architect at Mantua. After a stay in Genoa and Naples he was called to Vienna, where he built a large theatre. He was architect of the great theatre at Nancy; of the Teatro Filarmonico at Verona, which Milizia calls the finest theatre in Italy; and of the Teatro Alibert in Rome. In 1726 he returned to Bologna and directed the Academia Clementina.

ALESSANDRO GALLI BIBIENA (1687–1769), eldest son of Ferdinand~was born at Parma. In 1719 he became architect and painter at the court of the elector of the Palatinate. Among his works were the right wing of the *Schloss* and the opera house (both burned 1795) and the Jesuit church at Mannheim.

GIUSEPPE GALLI BIBIENA (1696–1757), second son of Ferdinand~was the most distinguished artist of the family. He was born at Parma on Jan. 5, 1696. As a youth he accompanied his father to Barcelona and afterward to Vienna. Staying on, when his father left, he there became the chief organizer of splendid court festivities and functions. He designed catafalques for the funerals of more than 30 nobles and sovereigns, and scenery for plays and dances. In 1722 he worked in Munich and in 1723 in Prague. In 1742 he designed the decorations for the Vienna opera; in 1747 he was employed at the opera in Dresden; in 1748 he designed the interior of the theatre at Bayreuth and in 1750

renovated the Dresden opera, burned 1849. He died in Berlin in 1757. He published his stage sets in three series of engravings: *Alcina* (1716); *Costanza e Fortezza* (1723); *Architetture e prospettive* (1740–44).

ANTONIO GALLI BIBIENA (1700–1774). third son of Ferdinando, was the architect of the Academia Virgiliana at Mantua and of the Teatro Communale at Bologna. He was also employed at the court of Vienna.

CARLO GALLI BIBIENA (1728–1,787). son of Giuseppe, was born in Vienna. This last of the theatrical Bibienas traveled farther than any. He worked in Germany, France and the Netherlands (1746–60); London (1763); Naples (1772), where he published five opera sets; Stockholm (1774); St. Petersburg until 1778; and died in Florence.

As the Bibienas' works in theatrical scenery were not executed in durable material. and as their decorations for court functions were necessarily of a temporary character, little has survived, and their richness and splendour only can be judged from drawings, which have been preserved in great numbers and are found chiefly at Vienna. Munich and Dresden.

See Corrado Ricci, I *Bibiena* (1915); A. Hyatt Mayor, *The Bibiena Family* (1945). (I. A. R.; A. H. MR.)

BIBLE, the sacred writings of Judaism and Christianity and probably the most influential collection of books in human history. Whatever one may think of the Bible's contents, its role in the development of western culture and in the evolution of many eastern cultures makes at least some acquaintance with its literature and history an indispensable mark of the educated man in the English-speaking world.

For the adherents of Christianity and Judaism. of course, the primary function of the Bible is religious. The Bible is the deposit of divine revelation. It tells the story of those events to which the Jewish and Christian communities look as the source of their existence, and it contains the prescriptions and prohibitions by which pious believers seek to regulate their lives. Becoming acquainted with the biblical narrative of these events is thus part of the process by which children or converts acquire a sense of participation in the community. From the Bible are derived the themes and symbols that dominate the formal and personal worship of both Judaism and Christianity — their hymns, their prayers and their liturgies. When Jews and Christians need to find the resources of their faith for a personal crisis, they often turn to the Bible. Its teachings as well as its terminology have tended to dominate the many controversies that have broken out among theologians and religionists throughout Jewish and Christian history. Even the way religious controversialists cite it is a measure of the importance of the Bible in the internal life of both Judaism and Christianity.

Still it would be a mistake to assume that only the formal adherents of Judaism and Christianity are interested in the Bible, or that only religious people read it. Many Jews, long after they may have severed their connection with the religious community, go on reading the Scriptures. The study of the Bible as literature is part of the curriculum in many colleges and universities. Phrases and sentences have passed from it into the common speech of many countries, although their origin often is forgotten in the process; thus the saying that "a house divided against itself must fall" is attributed as often to Abraham Lincoln as to the Gospels. Knowledge of biblical language and history is useful for an understanding of most major works of literature in most western countries. For the understanding of some major works! such as Dante's *Divine Comedy* or Goethe's *Faust* or Milton's *Paradise Lost*, such knowledge is indispensable, as is evident from the writings of critics who have lacked it. Countless individuals and entire nations have learned to read through the Bible, and the translation of the Bible has been the occasion for the creation of many scripts for languages that previously had been only oral. To be sure, many parts of the Bible do not rank very highly as literature; their style is ordinary and their language repetitive. But the literary power of some sections marks them as classics. To many readers who are without biblical faith, the beauty and power of the Bible still make it a source of inspiration and insight.

Such an article as this cannot hope to treat the history and influence of the Bible exhaustively. For in a sense the entire history of Judaism, of Christianity and of western civilization since the 4th century is a series of footnotes upon the Bible. Nor is this article intended to be a catalogue of all the many theories about the Bible that have come both from simple believers and from scholars. Literary study of the biblical books is a necessary element in their interpretation. but it is not the only element. The pertinent literary information about the several books will be found in the articles dealing with them individually, and relatively little of it will be repeated here. On the other hand, this article does not pretend to be either an exposition of the doctrinal themes in biblical religion (or religions) or an analysis of how to interpret the Bible. These expositions and analyses appear in such articles as CHRISTIANITY and JUDAISM and in the articles dealing with the various Christian denominations, churches and theologians.

What this article does seek to do is to acquaint the reader with the three major divisions in the study of the Bible and in this way to introduce him to the Bible itself. The following are the major divisions of this article:

The reader should consult also the individual articles on the books of the Bible and that on INSPIRATION.

I. OUTLINE OF THE BOOKS OF THE BIBLE

The Bible is not a single book but a collection of books (*biblia*, "books"). These books were composed over a period of many centuries (how many is a matter of debate) in three languages—Hebrew, Aramaic and Greek. Their authors include the shepherd and the king, men of considerable learning and men of very little. The Book of Psalms contains some of the most sublime lyric poetry in literature, the Books of Kings some of the most prosaic prose. The Gospel of Mark is matter-of-fact in its accounts; the Epistles to the Colossians and to the Hebrews are almost breathtaking in their speculations. Initially, therefore, the most impressive single feature about the Bible is the great variety of the literature contained between its covers. Beneath this variety there is an underlying unity. But the unity is one of theme and direction, while the variety is one of form and purpose. For that reason an outline of the biblical books probably should be content to summarize them one at a time, leaving the problems of biblical chronology and the harmonization of the various accounts to the special studies of these topics. Such an outline divides itself naturally into the Old and the New Testament.

A. OLD TESTAMENT

At least three-fourths of the Christian Bible is made up of the

Hebrew Scriptures, known since early Christian days as the Old Testament. Its exact scope and content have been the subject of controversy (see Canon *and Text,* below). In its general framework the Old Testament is the account of God's dealings nith Israel as his chosen people. (However, since the "choseness" of Israel is conceived by reference to the ultimate redemption of all mankind, the Hebrew Bible begins with the story of creation, and in the vision of the prophets it projects the prospect of universal reconciliation with God and deliverance from evil.) Although it begins with the story of the creation, the Old Testament is not an attempt at a history of the world, much less of the universe. Whatever references it contains to the created universe and to the world of nations outside Israel is part of its general purpose— to describe the ways of God in his relations with Israel. That purpose dominates the Old Testament.

Traditionally the Jews have divided the Scriptures into three parts: the Pentateuch, the Prophets and the Hagiographa. The Pentateuch, together with the Book of Joshua (hence the name Hexateuch [*q.v.*]) can be seen as the account of how Israel became a nation and of how it possessed the Promised Land. The division usually designated "the Prophets" continues the story of Israel in the Promised Land, describing the establishment and development of the monarchy and presenting the messages of the prophets to the people. The Hagiographa or "Writings" include speculation on the place of evil and death in the scheme of things (Job and Ecclesiastes), the poetical works of the Old Testament and some additional historical books. In the Apocrypha of the Old Testament various types of literature are represented; the purpose of the Apocrypha seems to be to fill in some of the gaps left by the indisputably canonical books and to carry the history of Israel to the 2nd century B.C.

A detailed chronology of Old Testament history appears in the article JEWS and need not be repeated here. The time span covered by the main body of the Old Testament is approximately 1.000 years. According to most archaeologists and historians the Exodus (q v.) took place some time after 1300 B.C. and the return of Ezra shortly before 400 B.C. For the accounts preceding the Exodus very few chronological data are available, and those exceedingly difficult to synchronize with other information from ancient history. At the other end of the story the Books of the Maccabees provide some additional dates for the period between Ezra and the New Testament. But Old Testament history deals largely nith the nine or ten centuries beginning at the Exodus. Some individual events and persons in that history can be synchronized with what is known of ancient history outside the Old Testament; others can be dated with the help of modern archaeological discoveries. Even with all this, however, most assignments of occurrences in the Old Testament to corresponding dates in the Egyptian, Persian, Syrian and Greek calendars are arbitrary and hypothetical. A chronology of the Old Testament, like a historically satisfying biography of Jesus, is impossible on the basis of the materials in the Bible. As in the case of the life of Jesus, this impossibility leads to a fundamental conclusion about these materials: they are intended not primarily as a chronicle but as a testimony of faith. This intention dominates both the form and the content of the Old Testament and is built into the structure of its several parts.

1. Pentateuch. — In the Pentateuch or Torah ("Law") the Bible presents the record of the divine action and legislation underlying its entire subsequent account. With the completion of the events related in the Pentateuch, Israel had finished its captivity in Egypt and its wanderings and was ready to enter the Promised Land. Thus the Pentateuch in a very real sense is the book of Israel's beginnings. For an analysis of the complex literary problems raised by the present form of the books in the Pentateuch, the reader is referred to the article PENTATEUCH and to the articles on its individual books. Genesis is a book about beginnings. It deals first with the beginnings of the universe and of the human race, sketched in the dramatic form of divine commands and actions. There follows the story of man's fall into sin, which is followed in turn by a sequence of events leading up to the deluge. After the deluge comes the second set of beginnings. and it is with these that Genesis is principally concerned. The call of Abraham inaugurates the special covenant of God with him and his descendants, and the remainder of the book is devoted to the history of this covenant as it passes from Abraham to Isaac to Jacob and thus to the tribes of Israel. In the narrative about each of the patriarchs the events of his career are intertwined with reflections that anticipate the later experiences of Israel. A noteworthy feature of these narratives is their continuing emphasis upon the human frailties of the patriarchs, frailties that also anticipate the history of Israel. Running throughout the book is the theme of God's promises to Abraham and, through him, to the covenant people. These promises, in turn, form the ground for the commandments and the warnings of later books. In more than a simple chronological way, therefore, Genesis is the beginning of the Bible. The outline of the Bible and of its message begins with Genesis; without it the remainder of the biblical narrative, Old or New Testament, would not make sense.

Nevertheless, the real beginning and foundation of the Old Testament is contained not in Genesis but in Exodus, which recounts the deliverance from Egypt upon which the covenant relationship between God and Israel is based. The drama of the deliverance opens with an account (or accounts) of the call of Moses to lead Israel out of Egyptian bondage. It continues with the miracles by which God makes known his power and his desire to liberate the people. With the institution of the Passover and the death of the first-born in Egypt the Exodus is inaugurated, and the crossing of the, Red sea accomplishes it. Now the Book of Exodus makes the transition from the story of the Exodus proper to the story of Sinai, which is the second and larger part of the book. The giving of the Law at Sinai is an occasion for the reminder that God has brought Israel up out of Egypt and is now affirming his covenant with the people. Corresponding to the human frailties of the patriarchs is the idolatry of the people in the worship of the golden calf. But God pays heed to the intercession of Moses and renews the covenant they have disrupted. The closing chapters of Exodus describe the enactment of the prescriptions for worship given at Sinai, the establishment of the priesthood and the presentation of the tabernacle. Further prescriptions for worship make up the bulk of the Book of Leviticus. These deal with the various types of sacrifice and the appropriate acts accompanying them, with the ceremonial and moral equipment of the Levitical priesthood, with the meaning of ceremonial purity and with the main outlines of Israel's sacred calendar. Leviticus is thus an extension of the narrative in Exodus; and some sections of it, notably the "laws of holiness," represent an amplification of the legislation in Exodus as well. When taken together, Exodus and Leviticus summarize the establishment of Israel as God's covenant people and the enactment of the cultic and other laws that were to mark its life as a covenant people.

Numbers and Deuteronomy likewise belong together: despite the differences between their literary histories. Numbers picks up the narrative at Sinai, adding the account of the census and some additional legislation. From Sinai it carries Israel through the 40 years of wandering in the wilderness and describes certain events during those years. Finally it brings the tribes to the plains of Moab and prepares the way for the account of the conquest of Canaan, which is told in the Book of Joshua. Like Exodus, Numbers repeatedly describes the ingratitude and disobedience of the people, the wrath of God and his forgiveness. The setting of its concluding chapters on the plains of Moab is also the scene of the discourses of Moses in Deuteronomy. This last book of the Pentateuch is a rehearsal of the events that have brought Israel within sight of the Promised Land. It reminds the people of the prerogative given them by God through the particular covenant he has made with them. On the basis of this covenant Moses is represented as repeating and interpreting the moral, ceremonial and civil laws summarized in the earlier books of the Pentateuch, with the rewards and punishments attached to them. Deuteronomy closes with Moses' farewell to the people, his final charge to them in two long poems and his death. Most scholars, though agreed that Deuteronomy was composed rather late in Israel's history, have come to lay increasing stress upon it as a summation of the Pentateuch and therefore a link between the

Pentateuch and other sections of the Old Testament. Taken together, the books of the Pentateuch set up the plot for the remainder of the Old Testament. Among the Jews, therefore, the Law has held a unique place within biblical literature, a place that was not changed with the adoption of other sacred books.

2. Prophets. — Under this title the Jewish Scriptures include a collection of eight books according to the Jewish reckoning; these are listed separately in Christian Bibles and total 21. The collection contains the books ascribed to the prophets, plus, several historical books that provide their background and setting.

Historical Books. — The historical books, called the "former prophets," are Joshua (Josue), Judges, I and II Samuel and I and II Kings (Roman Catholic versions of the Old Testament follow the Septuagint in numbering the books of Samuel and of Kings as I–IV Kings). Joshua recounts the narrative of how Israel entered, conquered and divided the Promised Land under the leadership of Joshua; it is closely related to the Pentateuch as the fulfillment of its promises and the completion of its story. The Book of Judges forms a transition from the account in Joshua, describing the situation of Israel after it had taken over Palestine but before it had stabilized its political and religious life. That stabilization came through the establishment of the Jewish monarchy, whose development is portrayed in the books of Samuel and Kings. I Samuel begins with the career of Samuel as a prelude to the history of the monarchy. Samuel anoints Saul as the first king of Israel, and the rest of the book is a chronicle of his reign, his successes and his ultimate downfall. It is especially concerned with the struggle between Saul and the young David, who had been selected as his successor. In II Samuel are found the biography and character portrait of David (supplemented and revised in I Chronicles). The book seems to be an official version of his life but by no means an idealized one. I and II Kings trace the decline of the monarchy after David. The glory of Solomon's reign is followed by his partial apostasy, and after his death the nation is split into the two kingdoms of Judah and Israel. The books conclude with the history of Elijah and Elisha, whose prophetic work is apparently one of the grounds for classifying these books with the Prophets; actually, the term may perhaps be best reserved for the "major" and the "minor" prophets.

Major Prophets. — The major prophets are Isaiah (Isaias). Jeremiah (Jeremias) and Ezekiel (Ezechiel). Isaiah is probably the most important among them and one of the most influential books in the entire Bible. Literary study of the book has led most scholars to the conclusion that in its present form Isaiah represents the work of at least two prophets (see ISAIAH). Ch. i–xxxix are a commentary upon the relation between Judah and other nations, notably Assyria. The prophet interprets the invasion of Palestine by the Assyrian armies as a sign of divine judgment, but he also promises that eventually God will bring salvation to his people and through them to all mankind. In ch. xl–lxvi Jerusalem has been sacked, and the people have been dispersed in Babylon. These chapters elaborate upon the promises of the earlier section, representing the salvation as coming through the faithfulness of God's suffering servant rather than through the military or political might of the nation.

Similar themes appear in the prophecies of Jeremiah, but the political distress of Judah dominates them even more completely than it does Isaiah's. Jeremiah is the voice of doom for the kingdom of Judah. He sees the coming of the Babylonians as an indication that God wanted to wipe Judah off the map as he had Israel. But Jeremiah also foresees the coming of a new covenant, written into the hearts of men and thus indestructible. Therefore he summons the people to repent, to acknowledge that their defeat forms part of God's merciful purpose.

Ezekiel, too, interprets Israel's foreign relations in the light of the purposes of God, using visions rather than prophetic discourses as the vehicle for his interpretation. In the first half of the book the prophet warns his nation of their impending doom and calls upon them to acknowledge their sin; in the second half he comforts the people in their affliction and promises the new city and new land that God would create for them.

For all three of the major prophets, therefore, the purpose of God in permitting the dispersion and captivity of his people is a major theme and a basic problem.

Minor Prophets. — The 12 "minor" prophets are thus designated not because they are less important but because their books are so much smaller; in the Jewish Scriptures they form one book. Hosea (Osee) is a vivid denunciation of Israel's apostasy as adultery, illustrated by the infidelity of the prophet's wife. Joel uses a plague of locusts and a drought as the basis of his denunciation and prophecy that God will punish his people but eventually will deliver them. Amos directs his prophecy against the social and economic injustice of his time, coupled as it was with smugness and a trust in the correctness of Israel's worship as a guarantee of its future. Obadiah (Abdias) is a brief vindication of the cause of Israel against the Edomites, who had helped to destroy the kingdom of Judah. Jonah (Jonas) contains more narrative than prophecy and is intended to show that the mercy of God extends not only to the covenant people but to all nations, even to Nineveh. Micah (Micheas) echoes the prophecies of Amos against the notion that worship without social justice would secure the favour of God. Nahum, like Jonah, deals with the city of Nineveh, but with its ruin rather than with its repentance; he interprets its fall as God's punishment for its past sins. Habakkuk (Habacuc) uses the intrusion of marauding bands of Babylonians not to denounce the sins of the people but to consider the providence of God in relation to evil in human history. Zephaniah (Sophonias) views the collapse of Assyria as a sign that the terrible day of divine judgment is imminent. Haggai (Aggeus) is a call for the reconstruction of the Temple in Jerusalem after the Babylonian captivity. Zechariah (Zacharias) is likewise an appeal for the Temple, but it is cast in the form of eight visions of the future. Malachi (Malachias) denounces both the priests and the people for their disobedience to God and for their betrayal of the covenant between God and the nation.

Thus the books of the prophets, both major and minor, form a commentary upon the history of Judah and of Israel. They interpret this history as a sign of God's judgment and of God's mercy, and they call the nation back to repentance and faithfulness. Their role in the total corpus of Old Testament literature is therefore very important (see also PROPHET).

3. Hagiographa.—This division comprises a miscellaneous collection of sacred writings that cannot be classified in either the Pentateuch or the Prophets.

Psalms, Proverbs, Job. — These three books constitute the principal poetic literature of the Old Testament, although there are poetic sections in other books as well. In many respects they represent the high point of the Old Testament as literature.

In the Psalms are found poems and hymns that date from various periods in the history of Israel, assembled for use at public worship in the Temple of Jerusalem. Tradition maintains that it was David who originally gathered them together into a psalter, and that after David additional psalms were included. The Psalms express the devotion of the individual and of the nation in reflection upon the deeds of God.

A different kind of reflection lies behind the Book of Proverbs. Like the Psalms, it has a composite origin in the wise sayings of many wise men in Israel and even in the proverbial wisdom of other peoples. The Book of Proverbs differs from most of the Old Testament in many ways, but the most significant difference is the absence of any reference to the events of Israel's history during or since the covenant of the Exodus, as well as of any allusions to the hope of Israel for the future. Instead, most of the book is concerned with general maxims about life that would seem to apply even apart from the history and the hope of Israel.

The Book of Job, one of the most difficult and most profound pieces of literature in the entire Bible, describes the plight of a good man who has become the victim of a series of disasters. Through the device of conversations between Job and other people the writer lists most of the explanations that men put forward for such a plight, and in each case the conversation shows that the explanation is wrong or at least oversimplified. Eventually God himself intervenes, not to provide an oversimplified solution of his own but to declare that the ways of God are essentially

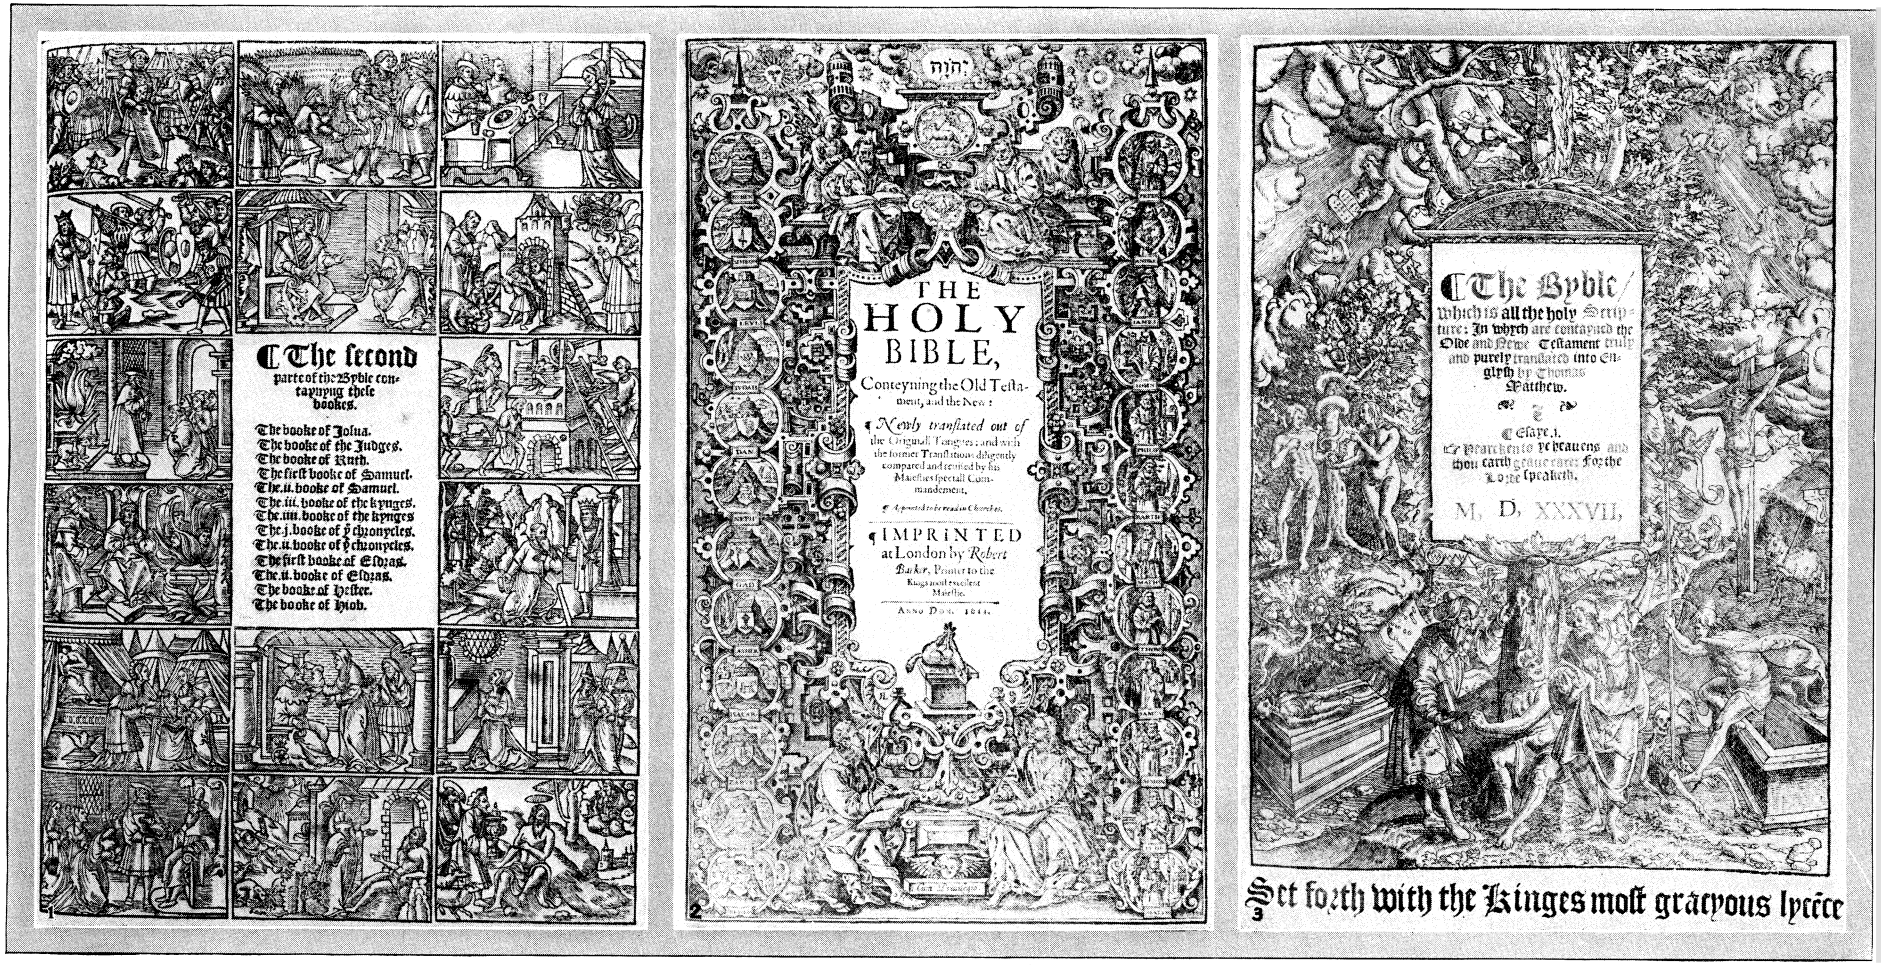
A PAGE FROM THE WYCLIFFE TRANSLATION OF THE BIBLE

A page from Wycliffe's translation of the bible, completed in 1382-1384, taken from a copy made about the latter year. The page contains the gospel of St. Matthew, chapter IV. 3, to chapter V. 11, which is part of the temptation of Jesus, with the Beatitudes



TITLE PAGES FROM EARLY BIBLES OF THE ENGLISH REFORMATION

1. A title page from a part of the Great Bible, of 1539. The decorative border illustrates 16 scenes from Old Testament History
2. Title page of the authorized or King James version of the Holy Bible, of 1611. Illustrations of the twelve tribes of Israel are shown on the left side of the page, and on the right, the twelve Apostles are portrayed. Each illustration bears the name of an Israelite tribe or of an Apostle
3. A title page of New Testament illustrations from the Matthew Bible, of 1537. The illustrations shown trace the plan of God for the salvation of man from the creation of the world to the crucifixion, resurrection and ascension of Christ

BIBLE

7.

And it came to passe, that as the people preassed vpon him to heare the word of God, hee stood by the lake of Genesareth,
2 And saw two ships standing by the lake: but the fishermen were gone out of them, and were washing their nets.
3 And he entred into one of the ships, which was Simons, and prayed him, that hee would thrust out a little from the land: and he sate downe, and taught the people out of the ship.
4 Now when he had left speaking, he sayd vnto Simon, Launch out into the deepe, and let downe your nets for a draught.

8.

My soule magnifieth þ Lorde. And my sprete hath reioysed in God my sauiour. For he hath loked on the lowe degre of hys hande mayden: for lo: now from hence forth shall all generacions call me blessed. Because he þ is myghty, hath done to me greate thinges, & holye is his name. And his mercy is on thẽ that feare him, from generacion to generation. He hath shewed strength with his arme, he hath scattered thẽ that are proude in the ymaginacyon of their herte. He hath putte downe the myghty from their seates, and exalted them of lowe degre. He hath fylled the hongri wt good thynges: and sent awaye the riche emptie. He hath helped hys seruaunt Israel, in remembraunce of his mercye.

11.

Though propheciynges fayle, or tunges ceasse, or knowlege perishe, yet loue falleth neuer awaye. For oure knowlege is vnparfecte, and oure prophecienge is vnparfecte. But whã that which is perfecte, cometh, then shal the vnparfecte be done awaye. When I was a childe, I spake as a childe, I vnderstode as a childe, I ymagined as a childe. But as soone as I was a man, I put awaye childishnes. Now we se thorow a glasse in a darke speakynge, but thẽ shal we se face to face. Now I knowe vnperfectly: but thẽ shal I knowe euẽ as I am knowne. Now abydeth faith, hope, loue, these thre: but the greatest of these is loue.

mysterious and that the only solution is to trust in his hidden purposes.

Megilloth.—A second group in the Hagiographa are the Megilloth or rolls, consisting of the Song of Solomon (Canticle of Canticles), Ruth. Lamentations, Ecclesiastes and Esther. The Song of Solomon, in the opinion of many scholars, is a poem in praise of human love; but by the time it was put into the canon of the Old Testament it was probably being interpreted as an allegory about the love between God and Israel. The Book of Ruth tells the story of a Moabite woman who married an Israelite and became an ancestress or David. Lamentation is a series of acrostics describing the capture of Jerusalem and mourning its fate: it closes with a petition for divine mercy. The Book of Ecclesiastes, like the Book of Job. may well be intended to refute the suggestion that some were drawing from the Proverbs, namely, that the person who obeys the maxims of common-sense morality will prosper on earth; its apparent skepticism stems from the realization that this is not so. The Book of Esther describes the hi-tor?; of King Ahasuerus and Queen Esther as an explanation for the rise of the Jewish festival of Purim. From the Jewish classification of these five books together and from the contents of the books it is evident that the rather "secular" tone of several of them has made their status as Scripture somewhat problematical.

Daniel, Ezra, Nehemiah, Chronicles.—Also included among the Hagiographa are Daniel, Ezra (I Esdras). Nehemiah (II Esdras) and 1 and II Chronicles (I and II Paralipomenon). The Book of Daniel describes the career of Daniel and God's interventions on his behalf. and its second half is a highly symbolic interpretation of world history under the direction of divine providence. The other hooks belong together as apparently the work of one man, usually called the "chronicler." In I and II Chronicles he repeats much of the material from earlier historical books, concentrating upon the history of the kingdom of Judah. I Chronicles is basically a biography of David, which adds further facts to the story as given in Samuel. II Chronicles begins with Solomon and goes through the division of the kingdom to the reign of Zedekiah; here, too, the chronicler had access to materials that supplemented the account in I and II Kings. In the Book of Ezra he describes the return of the Jews from the Babylonian captivity and the reconstruction of the Temple. He includes lists of the families who returned and the texts of the decrees under which they returned. In the Book of Nehemiah, very closely related to Ezra, the reconstruction of the city walls of Jerusalem becomes the basis for a meditation upon the relation between God and his people. This book too contains lists of those who participated in the reconstruction, but much of it concentrates upon the description of Nehemiah and his persistence in performing this assignment.

4. Apocrypha. — Protestants apply this term to those "deuterocanonical" books that appear in the Septuagint translation of the Old Testament into Greek, but not in the Hebrew text, in Roman Catholic but not in Protestant versions of the Scriptures. They include additions to three of the books that appear in the smaller canon: Esther, Jeremiah and Daniel. But they are made up chiefly of seven books: Tobit (Tobias), Judith, the Wisdom of Solomon, Ecclesiasticus, Baruch and I and II Maccabees (I and II Machabees).

The Book of Tobit tells the separate stories of Tobit and of Sarah, each of whom turned to God in prayer after enduring great anguish. With the help of the angel Raphael, Tobit's son Tobias and Sarah are brought together and are married; the book closes with a description of their blessed estate before God. The Kook of Judith is a story of how the beautiful Jewish widow Judith tricked the Assyrian general Holofernes and enabled Israel to resist and defeat its enemy. The Book of Wisdom, like the Book oi Proverbs, contains advice for both rulers and subjects; and like Proverbs, it also establishes the origins of wisdom in God. Ecclesiasticus, too, belongs to the wisdom literature and is sometimes called "the Wisdom of Jesus the Son of Sirach." Baruch is apparently a blending of several elements: confessions of sins, a praise of divine wisdom and a series of poems. The Books of the Maccabees are probably the most important in this entire group, supplying much of the narrative between the Old and the New 'Testament. Both of them relate the struggles of the Jens, under the leadership of the Maccabees, to defend the worship of Israel against the encroachments of pagans like Antiochus Epiphanes. I Maccabees frames its narrative more in historical, II Maccabees more in theological language. Taken together. they are a major source of information about the history of the Jews until a century or so before the time of Jesus.

See also APOCRYPHA, OLD TESTAMENT.

B. New Testament

The New Testament is by far the shorter portion of the Christian Bible, occupying less space than the Psalms plus the major prophets. Through its associations with the spread of Christianity. however, the New Testament has wielded an influence far out of proportion to its modest size. Christians are usually more familiar with the content of the New Testament than they are with that of the Old; and probably more has been written about it, despite its size, than about the Old Testament.

Like the Old Testament, the New Testament is a coilection of books, including a variety of early Christian literature. The four Gospels deal with the life, the person and the teachings of Jesus, as he was remembered by the Christian community. The Book of Acts carries the story of Christianity from the resurrection of Jesus to the end of the career of Paul. The Epistles are letters by various leaders of the early church, chief among them the apostle Paul, applying the message of the church to the sundry needs and problems of early Christian congregations. The Book of Revelation (the Apocalypse) is the only canonical representative of a large genre of apocalyptic literature that appeared in the Christian movement (*see* APOCALYPTIC LITERATURE). Common to all these types of Christian literature is their setting within the communal life of early Christianity. That communal life is presupposed throughout, even in those New Testament passages that do not seem to reflect it. Its worship, its teaching, its use of the Old Testament and its hope for the future are reflected in the language and content of the books in the New Testament, despite the diversity among them.

The setting of the New Testament within the Christian community is one factor that makes a biography of Jesus or a history of the 1st-century church difficult or impossible. (The problems of such biography and history are discussed in the article JESUS CHRIST.) The books of the New Testament were composed not in order to satisfy historical curiosity about the events they recount but to bear witness to a faith in the action of God through those events. A history of the New Testament is made difficult also by the relatively short time span covered by its books when compared with the millennium and more of history described by the Old Testament. There is less historical information in the New Testament than in the Old, and many historical facts about the church in the 1st century therefore must be arrived at by inference from a statement in one of the Gospels or Epistles. For a detailed analysis of the literary problems in the study and interpretation of the books of the New Testament the reader is referred to the individual articles dealing with them, and for the historical and biographical issues they raise he is referred to the article on CHRISTIANITY as well as to the biographical articles on JESUS CHRIST; PAUL, SAINT; PETER, SAINT; etc.

1. Gospels. — What the Pentateuch is to the Old Testament, the Gospels are to the New Testament: the testimony of faith to the basic events by which the believing community has been constituted. For the Pentateuch, these are the events surrounding the Exodus; for the Gospels, they are the events surrounding Jesus Christ. The Gospels also share with the Pentateuch the distinction of being the portion of the Scriptures to which literary critics have devoted the most detailed attention, as the article GOSPEL makes clear. Though they seem to be dependent upon one another for much of their material, the first three Gospels are distinct books, each with its own purpose and structure; and the Fourth Gospel, whatever its origin, is more individual than any of the others. Seen as a composite, these four portraits form

the basis for the rest of the New Testament. Other parts are earlier, some may be theologically more profound. But the Gospels occupy a special place in the outline of the Bible as the presupposition for all subsequent history and instruction.

The Gospel of Matthew begins with the genealogy of Jesus, followed by an account of his birth and infancy. Its narrative of Jesus' public career opens with the story of his baptism and of his temptation in the wilderness. The next major section of the Gospel presents the collection of sayings known as the Sermon on the Mount in the most complete version extant. It is followed by a series of miracles and by the sending of the Twelve. The clash between Jesus and his adversaries, a series of parables and the story of his repudiation at Nazareth prepare the way for the second half of the Gospel. In this Jesus is represented as going up to Jerusalem with his disciples and preparing them for the events of his suffering by warnings and examples. His controversies with his opponents become more intense, and thus the Gospel sets the stage for the account of his suffering and death. This account now follows, containing some details not reported in the other Gospels. The Gospel of St. Matthew concludes with a brief account of some of Jesus' appearances after the resurrection and with his "great commission" to extend the ranks of disciples to all nations. Throughout the Gospel there are many references to the Old Testament, leading many scholars to the conclusion that it was intended for Jews who had become Christian.

The Gospel of Mark is the shortest and (in the opinion of most scholars) the earliest of the four Gospels. It has no data about Jesus' beginnings at all, but plunges in *medias res* with his ministry of miracles and teaching, inaugurated by his baptism at the hands of John the Baptist. The early chapters of St. Mark contain miracles of feeding, healing and power over natural forces, as well as a number of parables. Like Matthew, Mark devotes its middle chapters to preparation for the story of the crucifixion. Jesus is seen as warning his disciples of the impending events, as entering Jerusalem and cleansing its Temple and as predicting the end of the city and of the world. The last chapters of the Gospel contain a narrative of the last days of Jesus, of his capture and execution and of his appearances after the resurrection. In the middle of telling about this last, the text of the Gospel breaks off; at least two attempts were made in the early church to fill out the story. If the emphasis of St. Matthew is upon Jesus as the fulfillment of Old Testament prophecy, the emphasis of St. Mark is less upon this fulfillment than upon Jesus as the worker of mighty deeds.

The Gospel of Luke contains much material that is in neither Matthew nor Mark. It opens with stories about the birth and the early life of Jesus that are unique to it, and to these it adds its own genealogy. The baptism and temptation of Jesus form the prelude to his ministry. This ministry is described first in its Galilean phase, which includes many miracles of healing as well as some instruction, part of which is Luke's shorter version of the Sermon on the Mount. There follows the largest single section of the Gospel, recounting the travels of Jesus through Samaria, Judaea and Peraea. Some of the material in this section appears elsewhere, but much of it is peculiar to Luke, as for example the parable about the prodigal son and that about the Pharisee and the publican. Like Matthew and Mark, Luke prefaces his version of the passion story with an account of Jesus' activities in Jerusalem in the last days. His account of the passion contains some facts that are absent from the other Gospels, and his reports of the appearances of Jesus after the resurrection are particularly detailed. St. Luke seems to have been written for Christians of non-Jewish origin, of whom the unknown Theophilus mentioned in the first chapter was a representative.

The Gospel of John has very little in common with any of the other Gospels. After its famous prologue, dealing with the incarnation of the Word of God, the Gospel narrates the adult life of Jesus around the framework of several Jewish festivals. Thus it is from this Gospel that the supposition of three years, more or less, as the duration of Jesus' ministry is derived. Into the first year St. John seems to put the early miracles of Jesus, the cleansing of the Temple (assigned to the last days of Jesus by the othtr Gospels) and activity in both Judaea and Galilee. As this Gospel seems to reckon the chronology, the second year contains much of the Galilean ministry recounted by the other Gospels. Most of St. John is concerned with the third year, into which it seems to put the majority of its discourses. In addition to details of the passion that appear elsewhere, the Fourth Gospel presents the closing words of Jesus to his disciples in the upper room, including his last prayer to the Father before his suffering. Most of the material in the resurrection accounts of John is also unique to this Gospel. Interpreters are not in agreement about whether the Gospel intends its framework to be chronological or symbolic, but they are agreed in assigning it a distinctive place among the four portraits of Jesus.

2. Acts.—Written as a continuation of the Gospel of Luke, the Acts of the Apostles is also a link between the Gospels and the Epistles. The ascension of Christ and the coming of the Holy Spirit introduce the story of the growth of Christianity. In the early chapters of the book, the dominant figure is Peter, who is the spokesman for the church and the leader of the Twelve. The preaching and the martyrdom of Stephen close this description of the congregation at Jerusalem and provide a transition to the main section of the Acts, the ministry of Paul to the gentiles. A heavenly vision is instrumental in converting Paul, and another convinces Peter that the Gospel is for gentiles as well as Jews. Most of the remaining chapters describe the missionary journeys of Paul and his associates, covering Asia Minor and parts of Europe. The missionary practice on those journeys raises once more the question of applying the Levitical regulations to gentile converts, and a council at Jerusalem has to settle the question. On a subsequent visit to Jerusalem Paul is involved in a riot and appeals to his Roman citizenship. As a result he appears before various Roman officials; and after delays, including a shipwreck, he lands in Rome. Here the book leaves him, and the denouement of the story must be supplied from the Pauline Epistles and from tradition. Neglected though it has sometimes been by students of the Scriptures, the Book of Acts performs for the New Testament the same function that is performed for the Old Testament by its historical books. Without it the reader of the Epistles frequently loses his orientation.

3. Epistles.—By far the largest number of writings in the New Testament are the Epistles, 21 in all. Most of them were composed in response to a specific need in one of the 1st-century Christian congregations, but some of them seem to have been circular letters intended for several congregations. More than half of them are ascribed to Paul, although critics have questioned this ascription in some cases. The state of research on such problems as authorship and date is discussed in the separate articles on each of the Epistles and need not be repeated here.

The Epistle to the Romans has the most complete statement of Paul's teaching contained in any one letter. From the demonstration of the universality of human guilt it moves to the doctrine of justification, exhibited in the faith of Abraham. Next the apostle discusses the new life that comes in justification and his own struggles of faith. Consideration of this leads him to ponder the mystery of Israel and of divine election. The second part of the epistle lists some of the concrete personal and social situations in which the new life is to find expression. I Corinthians describes some of the problems that were afflicting early Christian communities: schism, an overemphasis upon the eloquence of certain preachers, sexual immorality, eating meat offered to idols, discrimination and other disorders at the Lord's Supper, confusion because of the gift of tongues, and denial of the resurrection. II Corinthians, too, considers the problems of the congregation, but not in such detail. It consists largely of a vindication of Paul's apostolic ministry against his detractors and a commendation of the generosity of the Corinthian congregation. Vindication of Paul's apostolic ministry is likewise a major theme of the Epistle to the Galatians, which distinguishes even more sharply than does Romans between the Gospel and the Jewish Law. It is thus a defense oi Christian liberty. The Epistle to the Ephesians also seems to have been occasioned by the problem of Jewish-Christian

relations, but here the theme is the unity of Jew and gentile in the one church of which Christ is the head. The Epistle then applies that unity to the ethical life of Christians, especially to marriage and the family. The Epistle to the Colossians has much in common mith Ephesians, and the literary relationship between them has been a puzzle to New Testament scholars. Like Ephesians, Colossians concentrates its attention upon the church; but it seems to have been evoked by a denial of the church's view of Christ, and therefore the close connection of Christ and the church receives a new emphasis. The Epistle to the Philippians is one of the more personal of Paul's letters. After describing his personal feelings for the church at Philippi, he holds up the humility of Christ as an exemplar for its members and goes on to recount his own faith and experience. On the basis of this he urges them to fulfill their Christian vocation.

The First Epistle to the Thessalonians, like Philippians, has a strongly personal tone. It describes the history of Paul's relationship with the congregation at Thessalonica and then goes on to present the second coming of Christ as a comfort to those who were mourning the death of their fellow-Christians. II Thessalonians seems to have been intended chiefly as a corrective for the impression created by I Thessalonians. Expectation of the second coming had unsettled the congregation, and therefore the writer describes some of the events that had to precede the advent of Christ, especially the rise of the Antichrist; he concludes with an admonition to steadiness and industry.

The Pastoral Epistles (*q.v.*) are written in the form of advice from the apostle to two young associates, Timothy and Titus. Their authorship by Paul is widely questioned by biblical scholars. The First Epistle to Timothy urges Timothy to defend the apostolic faith against false teachers and to conduct his ministry according to the instruction and the example of Paul. II Timothy also counsels him to be steadfast in the conflict with false teachers, and it adds some personal notes about Paul as he faces the prospect of martyrdom. In the Epistle to Philemon Paul pleads the cause of a runaway slave, Onesimus, and asks that he be treated kindly by his master.

The Epistle to the Hebrews is still attributed to Paul by some students of the Bible, but the vast majority of scholars would not maintain that Paul wrote it himself. It is an elaborate argument for Christianity as the successor of Judaism. To support this argument it describes the superiority of Christ to the angelic and human mediators of the old covenant. It is especially concerned to show that he is superior to the priests of the Old Testament, and that his sacrifice is permanent while theirs was temporary. The Epistle concludes with an exhortation to follow the example of the heroes of faith, past and present.

The seven remaining letters in the New Testament often are grouped as the "Catholic Epistles." The Epistle of James seeks to combat the notion that the free grace of God makes good works unnecessary, and it contrasts a false religion of outward Christian profession with the true religion of Christian service. The First Epistle of Peter encourages Christians in the midst of suffering by describing their prerogatives as recipients of God's inheritance, and it urges them to live so blamelessly that, if they do suffer, it will be for their loyalty to Christ and not for any failure in morals. II Peter is much different in character and purpose. It warns its readers against false teachers who have come into the church, describing both their heresies and the horrible fate that awaits them. The Epistle of Jude contains the same warning and probably was used by the author of II Peter. The First Epistle of john also directs itself against the false teachers, but it sets this warning into the context of a discussion about love. Reflection of God's love in human life and a proper confession of Jesus as the Christ are the marks of the true Christian. II John is another admonition to beware of false teachers and to practise Christian charity. III John is a brief letter of recommendation for one Demetrius, addressed to one Gaius.

4. Revelation. — The last book of the Bible, the Revelation to John, or Apocalypse, consists of a series of visions granted to the writer and now communicated by him to several Christian congregations in Asia Minor. In these visions, whose details always have caused consternation to students of the Bible, the seer glimpses the eventual victory of the church over its enemies through the power of Christ, the Lamb of God, but only after a bitter conflict. The victory is to lead to a new heaven and a new earth and to the destruction of the enemies of the church. Written to churches that faced the twin perils of persecution and indifference, these visions were intended to strengthen their hope and their resolution.

II. CANON AND TEXT

From the outline given above it is evident that the Bible is a series of pictures, some of them simple portraits, others more subtle sketches, still others highly abstract symbols. For that reason the determination of what does or does not belong in the Bible is not an easy task, as this section of the article will show. The translation of this variety of language and literature into a new language likewise creates difficulties, some of which will be discussed below, under Translations.

When a Protestant examines a Roman Catholic version of the Bible, he notices the presence of certain books that do not appear in his own Bible. Why should this be so, he may ask, and how did those books get into the Bible? To answer this question is the purpose of studies in the history of the biblical canon. In addition, when almost any reader examines a new translation of the Bible! he discovers that some well-known passages are missing from it. Why should this be so, and on what basis have these passages been excluded? To answer this second question is the purpose of studies in the biblical text. These two questions should be answered together, because they both deal with the problem: What belongs in the Bible and what does not? But since the methods used to answer them are quite different, each question needs to be handled individually. As regards both text and canon, moreover, the study of the Old Testament creates special difficulties, different from those encountered in the study of the New Testament. This discussion will take up these four topics in succession.

A. Canon of the Old Testament

The question as to which books belong in the Old Testament is complicated by the history of the Old Testament in both Judaism and Christianity. Not only is the use of the word "canon" as a designation for an authoritative list of sacred books a rather late phenomenon, even the idea of a fixed and final list came about only after a long evolution.

1. Jewish Canon. — It is not known when and how the earliest collection of sacred writings in Hebrew arose. The incident reported in II Kings xxii clearly presupposes the existence of some such collection; but both the incident and the collection are impossible to date, and some critics believe that the whole story is actually intended to explain the composition of portions of the Pentateuch, including most or all of the Book of Deuteronomy. Evidently, however, the Pentateuch (or at least its first four books) was in process of assembly in Jerusalem before that time.

Division of the Old Testament into the Law, the Prophets and the Hagiographa may reflect stages in the history of the canonization of the Old Testament. Thus the Law (with or without Deuteronomy) may have been the first to be canonized, then the written form of the message of the prophets, then some other writings whose status and scope meanwhile had remained in doubt. On the other hand, some historians of the Old Testament canon are inclined to question this interpretation. It would be possible to speak mith greater authority if the content of the books referred to in the stories of Ezra vii and Nehemiah viii–x as "the Law" were known. A late Jewish tradition maintains that a "Great Synagogue" at the time of Ezra and Nehemiah met to establish the canon of the Bible. Although this tradition has enjoyed wide circulation and credence among both Jews and Christians, most historians tend to doubt its reliability; for it is obvious from other and more reliable sources that the extent of the Old Testament continued to be a problem for Jews and Christians long after Ezra and Nehemiah.

The safest generalization permitted is this: various collections of sacred writings were put together quite early in the history of

Israel, but they did not become a "canon" until much later. How much later, depends upon the interpretation put upon the list of books assembled in the Greek translation of the Old Testament, the Septuagint (see Translations, below). By the time it was completed, this translation included the Law, the Prophets, the Hagiographa and the Old Testament Apocrypha; but it did not list them in that order. The inclusion of the Apocrypha in the Septuagint has caused some scholars to conclude that there were two Jewish canons, a narrower one current in Palestine and a broader one current in the Greek-speaking world. Most scholars, however, have drawn the inference that the Jewish collection of sacred books was still in a fluid state in the 2nd century B.C., that the status of the Apocrypha, as well as that of some books in the Hagiographa. was unclear. This circumstance permitted these books to be included in the Septuagint. But it seems to be an anachronism to speak of any collection in this period as a canon, Palestinian or Alexandrian. For the subsequent history of the Old Testament canon, however, the list of books assembled in the Septuagint was to be of vital importance.

The name canon may properly be applied to the books that seem to have been adopted by the assembly of rabbis at Jamnia about A.D. 90 or 100 under the leadership of Rabbi Akiba. Until then, apparently, the status of the Song of Solomon and of Ecclesiastes remained doubtful, but at Jamnia they were definitely included in the canon. That canon did not include the additions to Esther, Jeremiah and Daniel that are found in the Septuagint; nor did it include Tobit, Judith, Wisdom, Ecclesiasticus, Baruch and the Books of the Maccabees. Formally, then, the Jewish canon of the Scriptures came to include the Pentateuch, the Prophets and the Hagiographa, as it has ever since. In this canon, however, the Pentateuch has held a special place as a "canon within the canon"; the usage in the New Testament suggests that it had some such status by early Christian times and probably much earlier.

Additional light on the process by which the Jewish canon of the Old Testament was formed has come from the discovery of the Dead sea scrolls. The books of the Old Testament included in them suggest that the Pentateuch and the Prophets had been standardized by about the 4th century B.C., together with most of the Hagiographa; but some of the Hagiographa (including apparently Daniel) were still in dispute until the assembly at Jamnia. After the fall of Jerusalem in A.D. 70 and the rise of the Christian movement, the Jewish community felt obliged to fix the limits of its Bible more precisely. So it was that certain books occasionally included were excluded (the Apocrypha) and that others previously challenged were included (some of the Hagiographa).

2. Christian Canon.—The Bible of Jesus and of the early Christians was the Old Testament, but no list of the books it might have included exists. To ascertain its scope it is necessary therefore to scrutinize the Old Testament quotations and references that appear in the New Testament. Such scrutiny has occupied generations of biblical scholars, who have identified references and allusions to most of the books of the Old Testament, though not to all of them. Among the books to which the New Testament refers are several of the deuterocanonical books of the Old Testament, as well as some books, such as Enoch, that do not belong to any canon. Some scholars even have attempted to identify two canons of the Old Testament lying behind the New; they contend that the Old Testament used by the Epistle to the Hebrews was the Septuagint canon, while that used by other portions of the New Testament was the narrower Palestinian canon. These attempts, ho ever, have not proved convincing to the majority of biblical historians. Thus it seems that the study of the Old Testament quotations in the New Testament has led to an ambiguous conclusion regarding the state of the Old Testament "canon" in the 1st century A.D.

That ambiguity makes it understandable that the early Fathers of the Christian Church were unclear about the canon of the Old Testament. Melito of Sardis, who lived during the 2nd century, is said by Eusebius to have inquired among eastern rabbis about the scope of their canon. The catalogue they gave him, as reproduced by Eusebius, corresponds neither to the Hebrew nor to the Greek list of books: it contains the Wisdom of Solomon but it does not contain the Book of Esther. A list given by Origen during the 3rd century includes Esther but puts it at the very end; the catalogue of Athanasius (4th century) omits Esther altogether. For most of the early Christian Fathers the Old Testament meant the Septuagint, since few of them other than Origen knew Hebrew. Although they were aware of the divergence between the canon as accepted by the Jews and the list of books contained in the Septuagint, the examples of Melito, Origen and Athanasius suggest that the status of the disputed books remained in doubt during the first four centuries of the Christian era.

Jerome (c. 347–*c.* 420) was one of the few Christians in those centuries to learn Hebrew. What he learned from Jewish rabbis caused him to distinguish sharply between the canon as approved by the Jews and the catalogue represented in the Septuagint. As he came to prefer the Hebrew text to the Septuagint, so he also assigned primary authority to the Jewish canon and put the deuterocanonical books or Apocrypha into, at best, a secondary position. Jerome's contemporary, Augustine, on the other hand, provides a catalogue of Old Testament writings that includes these books. Throughout the middle ages the status of the deuterocanonical books remained doubtful. Some theologians followed Jerome and excluded them altogether from the Bible in the strict sense; others followed Augustine and accepted them with very little hesitation; still others had reservations about them but used them as Holy Scripture. Contact between Jewish and Christian scholars, which was commoner during the middle ages than is often supposed, served to point out to many Christian theologians the discrepancies between their Old Testament and the Bible of the Jews. But it was not until the period of the Reformation that the issue once more became a matter of concern and of controversy to Christian thinkers.

As part of their insistence that the church return to the Bible, the Protestant Reformers called for the elimination of the deuterocanonical books from the Scriptures. Luther's translation of the Bible included them but put them into a separate section as

Canon* of *the Old Testament

Judaism*	Roman Catholicism and Eastern Orthodoxy	Protestantism
(1) Bereshith	Genesis	Genesis
(2) Shemoth	Exodus	Exodus
(3) Wayiqra	Leviticus	Leviticus
(4) Bemidbar	Numbers	Numbers
(5) Devarim	Deuteronomy	Deuteronomy
(6) Yehoshua	Josue	Joshua
(7) Shofetim	**Judges**	**Judges**
(17) Ruth	**Ruth**	**Ruth**
(8) Shemuel	**I Kings**	I Samuel
	II Kings	II Samuel
(9) Melakhim	**III Kings**	I Kings
	IV Kings	II Kings

(Noncanonical)	I Machabees†	(Apocrypha)
(Noncanonical)	II Machabees†	(Apocrypha)

*Numbers indicate order in Hebrew Bibles.
†Part of the Roman Catholic but not of the Eastern Orthodox canon.

"Apocrypha." which deserved to be read but not to be put on the same level as canonical Scripture. The other Reformers were even more vigorous in their opposition. Believing that the Old Testament canon in use among the Jews of their time was also the Bible of Jesus and of the early Christians, they refused to accept quotations from the Apocrypha as support for Christian teaching. The use of certain passages in the Apocrypha to support prayers for the dead and other Roman Catholic practices arid doctrines only strengthened them in this refusal. During the 19th century Protestants in England went so far as to prohibit the printing of Bibles that included the Apocrypha, even with an explanatory note like the one in Luther's translation. Not until the 20th century did it become possible once more to issue the Apocrypha within the covers of Protestant Bibles, and that only in some few editions.

In antithesis to the position of the Reformers. the Roman Catholic Council of Trent (1545–63) made the larger canon. including the deuterocanonical books, the official list oi books for the church. A century later, in 1672, the Synod of Jerusalem established the Old Testament canon for the Eastern Orthodox churches, accepting four of the books in the Septuagint (Tobit. Judith, Wisdom and Ecclesiasticus) but rejecting Baruch and the Books of the Maccabees.

Ever since the 16th and 17th centuries, therefore. the churches of Christendom have had a clearly defined canon of the Old Testament--or, rather, three canons, one each for Koman Catholicism, Protestantism and Eastern Orthodoxy. 'The canon of Protestantism and that of Judaism are identical, but the order of books is different. The differences among the several canons can best be illustrated by means of a table, in which are given also the names of the Biblical books as they are used in Judaism, Roman Catholicism and Protestantism.

B. Text of the Old Testament

The form in which the Hebrew text of the Old Testament is presented in most manuscripts and printed editions is that of the Masoretic text. the date of which is usually placed somewhere between the 6th and 8th centuries A.D. It is probable that the present text became fixed as early as the 2nd century A.D., but even this earlier date leaves a long interval between the original autographs of the Old Testament writers and the present text. Since the fixing of the Masoretic text the task of preserving and transmitting the sacred hooks has been carried on with the greatest care and fidelity; with the result that the text has undergone practically no change of any real importance; but before that date, owing to various causes, a larger number of corruptions indisputably were introduced into the Hebrew text.

Originally the text consisted only of consonants, since the Hebrew language had an alphabet without vowels. It is also likely that in the earliest texts the words and sentences were not divided. The evolution of the hlasoretic text was an attempt to make up for both these deficiencies. It supplied vowels by adding marks to the consonantal text. and it divided the words and sentences. For many centuries it was believed that these vowel points formed part of the original text; some theologians argued that the points were inspired by the Holy Spirit. But subsequent research has proved beyond doubt that they are younger by almost 1,000 years than the text itself.

On the basis of a variety of evidence it is possible to show that the Masoretic text is not a completely reliable index to the readings of the autographs of the Old Testament. Even a superficial comparison between its readings and the Septuagint translation discloses many passages in which the translators of the Old Testament into Greek ascribed different vowels to the consonantal text or divided the words differently from the way they are now divided in the Hebrew text. In other passages they simply had another text before them. Considering that the Septuagint translation antedates the Masoretes by so long a span, we are forced to admit that the Hebrew text underlying it sometimes comes closer to the original reading of a particular passage than does the Masoretic. Other evidence, too, renders'an uncritical acceptance of Masoretic readings impossible; it is obvious that the text has been tampered with in some places. In determining the text of the Old Testament, the scholar is not faced by the multitude of manuscripts and variants that provide the materials for New Testament textual criticism (*see* below); but fur that very reason the task oi arriving at a reliable text is even more complicated.

What complicates the task is, among other things, the sorry state of the Septuagint text itself. Parts of it are very well attested and may iorm the basis for judgments about the Hebrew, but other parts are so confused textually that in some instances scholars are inclined to posit two or more translations. After all, without a reliable text of the translation, the translation cannot very well be used to emend the text of the original. What is more, a study of the Septuagint also reveals' many passages in which the translators purposely paraphrased the text or changed its meaning when the original was either embarrassing to them or unclear; for example, certain concrete terms in Hebrew are translated into abstract terms in Greek to avoid the charge of anthropomorphism.

Such considerations prompt the textual critics of the Old Testament to be cautious in emending the Masoretic text where it is at variance with the Septuagint. but the critics are by no means agreed about how much weight they should assign to the Masoretic readings and how much to the Septuagint in the various parts of the Old 'Testament. Even so renowned a student of the Old Testament text as Paul Kahle was unable to secure universal acceptance of his textual theories. The Dead sea scrolls have reinforced the reliability of the Masoretic readings in some passages of the Old Testament, while in others they have shon-n a marked similarity to the Hebrew text on which the Septuagint seems to have been based. They make clear the existence of several textual traditions even in Hebrew; they have therefore made important contributions to the textual criticism of the Old Testament, but they have not solved its fundamental problem. Barring a major discovery of manuscript materials. this problem is probably insoluble, and the best that can be achieved is an approximation of the text of the Old Testament.

C. Canon of the New Testament

Christians usually have to think twice to realize that there mas once a time when the Christian Bible did not contain both the Old and the New Testament. New Testament statements such as II Tim, iii, 16, "All scripture is inspired by God," are predicated of what came later to be called the Old Testament; so are many of the references to "Scripture" in the early Fathers. Only gradually did Christians find it necessary to add a second collection of sacred books as the '(New" Testament alongside the Old. In tracing the history of that collection and of its adoption as the canon of the New Testament, we are supplied with a much more detailed set of source materials than we are when we attempt to sketch the evolution of the Old Testament canon. Unfortunately, this does not necessarily mean that the history of the New Testament canon is always clearer than the history of the Old Testament canon, only that it is more amply documented.

1. Canon and Tradition. — Before any books were included in the canon of the New Testament. or even composed, the Christian Church used the Old Testament as its Bible; but it possessed also its tradition of memory about Jesus Christ. This tradition lies behind and is presupposed throughout the New Testament. To it St. Paul could refer in discussing the Eucharist or the resurrection. His Epistles say as little as they do about the life and teachings of Jesus at least partly because the church was already rehearsing these in the forms of its tradition. Its teaching, preaching and worship all reflected this tradition Its very interpretation of the Old Testament appears to have been part of the tradition, as the use of certain Old Testament passages in the New Testament and in early fathers suggests. Awareness of this tradition is necessary for understanding of the processes by which the canon of the New Testament nas evolved, for it helps to explain why certain books were selected as canonical and at least some of the criteria by which the selection was made

Several factors seem to have been responsible for the rise of the New Testament canon, but church historians vary in the amount

of weight they assign to each. One factor certainly was the sheer passage of time. as the church needed to discover whatever resources it could to bind it to its past and to guarantee its continuance in the tradition of the faith; the "memoirs of the apostles" were one such resource. Also responsible for the establishment of the canon was the circulation of writings that bore the names of apostles but did not contain apostolic teaching (as that apostolic teaching was being interpreted by the church). The only way to eliminate these forgeries was to define the limits of the apostolic writings. Such a definition became a crucial necessity when the heretic Marcion (*q.v*) compiled a canon of the New Testament containing his edition of the Epistles of Paul and of the Gospel of Luke, which he regarded as the only genuine Gospel. Although it now appears that Marcion did not cause the church to establish its canon, he did accelerate the process. Another heretical movement that helped to accelerate it was Montanism (q v), whose claim of speaking in the name of the Spirit could be countered only by reference to the authentic speaking of the Spirit in the apostolic witness of the New Testament writings. The task of sifting through the writings of the early church and of identifying this apostolic witness occupied Christians well into the 4th century. Eusebius (*q.v.*) suggested the following division of these writings. (1) some were acknowledged almost universally as part of the New Testament; (2) others were disputed but finally accepted; (3) still others were considered more or less seriously but eventually rejected.

2. Acknowledged Books.—The earliest pieces of Christian literature to be collected seem to have been the letters of Paul, but it could appear that initially at least they did not qualify as "Scripture." From the liturgical usage of the church at Rome it would appear that the Gospels were the first Christian books to be added to the Old Testament as supplementary Scripture, and that this had happened by the middle of the 2nd century. Also from Rome, and also apparently from the 2nd century, comes the oldest extant list of New Testament writings, the so-called Muratorian fragment, so named because it was published by Ludovico Muratori. It was written in Latin and contains the names of the books being read in the church at Rome about A.D. 200. By about that time, as the writings of Irenaeus and Tertullian suggest, both Lyons and Carthage were using the Gospels, the Epistles of Paul and some other Epistles as Scripture. A few years later the works of Origen in Alexandria make it clear that he also was working with a similar though not an identical collection.

From these four places—Rome, Lyons, Carthage and Alexandria—may be compiled a list of books on which they all seem to have been agreed. That list would include the folloning, given in the order now employed in the New Testament: Matthew, Mark, Luke, John, Acts, Romans, I Corinthians, II Corinthians, Galatians, Ephesians, Philippians, Colossians, I Thessalonians, II Thessalonians, I Timothy, II Timothy, Titus, Philemon and I John.

3. Disputed Books.—From these same sources and from several church fathers quoted by Eusebius may be assembled also a list of the books that were disputed on one or another ground. but that eventually were included in the canon of the New Testament. The Epistle to the Hebrews belongs to this category. It seems to have been accepted in the eastern section of the church but disputed in the west, for it does not appear in the Muratorian canon and is also questioned by other writers. The Epistle of James was in doubt among even more writers. Although I Peter is almost universally acknouledged, it is not listed in that category because of its absence from the Muratorian catalogue. II Peter, on the other hand, was questioned by many fathers who accepted I Peter. The Epistle of Jude appears in the Muratorian canon but was rejected elsenhere. II John and III John sometimes were included with I John as one book, but they did not receive the universal support that it did. The Book of Revelation probably was the object of more antagonism than any other of the books eventually canonized. The Montanist movement made apocalyptic literature suspect in the orthodox church, and some writers did not believe that the same man had written the Gospel of John and Revelation.

4. Rejected Books.—An exhaustive list of these appears in the article APOCRYPHA, NEW TESTAMENT.

5. Formation of the Canon.—The writings of Eusebius and of his great contemporary Athanasius make it evident that agreement on the disputed books was approaching by the middle of the 4th century, and that the canon of the New Testament that now appears in our Bibles was gaining general, if not quite universal, acceptance. That canon appears for the first time in the 39th Festal Letter of Athanasius, A.D. 367.

After the Festal Letter other traditions held their own for a time. Thus the school of Antioch in general accepted only three Catholic Epistles—James, I Peter, I John—while one of its most illustrious representatives, Theodore of Mopsuestia, rejected the whole of this section of the canon. The west followed the lead of Athanasius. In 382 a synod was held at Rome under Pope Damasus at nhich the influence of Jerome secured the adoption of a list of books ansnering to that of Athanasius. This was ratified by Pope Gelasius at the end of the 5th century. The same list was confirmed independently for the province of Africa in a series of synods at Hippo Regius in 393 and at Carthage in 397 and 419 under the leadership of Augustine. The second canon of the second Trullan council of 692, the Quinisextum, may be taken to have formally closed the process of the formation of the canon for east and west. Yet Eusebius' distinction between acknowledged books (homologoumena) and disputed books (antilegomena) did not disappear completely from the church. It was revived by Luther in his objections to the Epistle of James, and it formed part of the basis for the modern reconsideration of the canon.

D. TEXT OF THE NEW TESTAMENT

The text of the New Testament probably has received more attention and careful study than any other document in history. ancient or modern. In fact. many of the techniques of textual criticism now applied to literary sources of all kinds were developed originally for the establishment of the text of the New Testament. Textual criticism is important as part of the process by which the church and scholarship seek to determine what belongs in the Bible and what does not. Canonical questions and textual questions are technically distinct, but they often intersect. Thus the question of the "long ending" of Mark's Gospel involves both textual and canonical judgments. Did the last chapter of St. Mark originally end with verse 8, as it now does in the best manuscripts, or with one of the endings attached to it in other manuscripts and in several translations or with a conclusion now lost? On the other hand, when the Gospel became part of the canon, was the "long ending" (verses 9–20) already a part of the accepted text? Usually, however, canonical study determines which books belong in the Bible, while textual study determines which text of each of those books comes closest to being the right one.

1. Evidence.—Textual criticism of the New Testament becomes necessary because of the thousands of variations in the existing manuscripts and versions. Some of these variations, to be sure, are inconsequential, involving three different forms of the name "Jerusalem" or three different renderings of the name "Gerasenes" in Mark v, 1. Other variations, however, affect the meaning of an entire passage or verse If Roman v, 1 reads "We have peace with God," it means one thing; but if it reads "Let us have peace with God," it would seem to mean another thing. When scholars set about to decide which of these two readings should be adopted, they must consult the available textual evidence.

The main source of the evidence and of the variations are the manuscripts of the New Testament, dating from the 2nd to the 10th century or even later. In the process of copying, these manuscripts underwent the revisions that necessitate textual criticism. Some of these revisions were unintentional, as the scribe skipped a word or a line or as he mistook one character for another. Other revisions came from the desire of the scribe to harmonize the text of one Gospel with another or of one Testament with the other, or from his pious wish to "correct" or clarify the text at another point. But now that variations in the text exist, collation of the manuscripts is a difficult task The books listed in the bibliography to this article provide a detailed description of the chief codices of the New Testament, together with plates illustrating the text.

Here are listed only a few of the most important ones, together with their usual symbols.

Codex Sinaiticus (ℵ).—This manuscript (now in the British museum), containing the entire New Testament plus the Epistle of Barnabas and part of the *Shepherd* of *Hermas,* was discovered in 1859 in the monastery of St. Catherine on Mt. Sinai by L. F. K. von Tischendorf (*q.v.*). It was written probably in Egypt, probably during the latter part of the 4th century.

Codex *Alexandrinus (A).*—Presented by Cyril Lucaris to James I of England, this early 5th-century manuscript contains the Greek Bible and I and II Clement. Its history before the 17th century is obscure, but it may have come from Mt. Athos and perhaps was written in Egypt. It is now in the British museum.

Codex *Vaticanus (B).*—Also from the 4th century and probably from Alexandria, this codex contains the entire Greek Bible up to Heb. ix, 14. It is housed in the Vatican library, where it has been at least since 1481; its early history is unknown.

Codex *Ephraemi Syri Rescriptus (C).*—Although this manuscript too is incomplete, its 5th-century origin and the evidence it supplies make it important for the text of certain portions of the New Testament. every book of which except II Thessalonians and II John is represented in it to some extent. It is preserved in the Bibliothèque Nationale, Paris.

Codex Bezae (D).—For the text of the Gospels and the Acts, this manuscript (probably 5th century) in both Greek and Latin is of fundamental significance. It was presented to Cambridge university, where it is still housed. by the Reformed theologian Theodore Beza in 1581. Its history before the 16th century and its place of origin are unknown.

Other Evidence.—In addition to these codices of the New Testament, there are other manuscripts, some of them very ancient. The oldest of these were written on papyrus and have been dated from the 2nd and 3rd centuries. Other less ancient manuscripts have affected certain readings; for the establishment of the text is not simply a matter of giving credence to the oldest available manuscript but a much more complex process.

Nor are the manuscripts of the Greek New Testament. whatever their age; the only source of textual evidence. Versions of the New Testament in other languages sometimes reflect variants in the original text that correct the readings of the Greek manuscripts. Although these versions do not figure so prominently in the study of the text of the New Testament as the Septuagint does in the study of the text of the Old Testament, they must not be ignored in any attempt to establish the text. Especially important textually are the Latin and Syriac versions.

When the textual scholar has examined the manuscripts and the versions, he still has not exhausted the evidence for the New Testament text. The writings of the early Christian fathers often reflect a form of text differing from that in one or another manuscript. In some cases these writings represent the only access to textual traditions that have long since disappeared; and therefore their witness to the text, especially as it corroborates the readings that come from other sources, belongs to the testimony that textual critics must consult before forming their conclusions.

Compilation of Evidence.—Assembling and collating the evidence from all these sources is a task that generations of scholars. have been performing. and the task is not finished yet. Erasmus may be regarded as the father of textual criticism, but it was with the work of Johann Albrecht Bengel that the science moved into its modern phase. Three modern editions of the Greek New Testament are of major importance for their collection of the textual evidence described above: (1) that of Tischendorf (8th ed.. Leipzig, vol. i, 1869; vol. ii, 1872; vol. iii [Prolegomena by C. R. Gregory], 1894); (2) that of B. F. Westcott and F. J. A. Hort (London. 1881–82); and (3) that of H. von Soden (Berlin. 1902–13). Perhaps the most convenient compilations of the evidence are the many editions of the Greek New Testament by Eberhard and Erwin Nestle (Stuttgart, 1898 ff.).

2. Method.—From all the evidence collected in these critical editions, how does a scholar settle upon one reading in preference to all the others? Merely counting the manuscripts pro and con will not decide the question; for they are not all of equal value, and the same manuscript is not of uniform value for various books of the New Testament. The date of a manuscript does not necessarily indicate its relative worth, for a later manuscript may reflect a more trustworthy text. Even grouping the manuscripts by families or by the "quality" of their text is not a satisfactory method. for this "quality" is not constant throughout a manuscript or a group of manuscripts. Selection of the reading that conforms to custom or to some regional tradition is no solution. Each of these methods has some contribution to make, but the only defensible procedure would have to include all of them—and other considerations besides.

The method that most textual critics follow begins with the accumulation and evaluation of the external evidence listed above. This evidence must he assigned relative weight according to the usefulness of a particular manuscript or version or church father for the passage being studied. Once this has been done—and the opinions as to the relative usefulness of these witnesses vary widely—the textual critic also must consider internal evidence. He must examine the context of the passage, the style of the writer, the structure of the sentence and paragraph; these may provide a clue to the proper reading. As he considers the witness of the manuscripts, versions and fathers. he must ask himself which of the variants would most satisfactorily explain the rise of the other variants; the variant that does this deserves consideration as the possible source of the entire textual tradition. When he has exhausted the possibilities supplied by both the external and the internal evidence, the critic must still consider the possibility that no existing text supplies the original reading and that this reading must be arrived at by conjecture. Such conjecture is as hazardous as it is necessary. Some conjectures have been dramatically substantiated by later discoveries; others have received no support.

A good illustration of the problem and of the method is the familiar Gloria *in excelsis* from the Christmas story in Luke ii, 14. Centuries of exposure to the Authorized version have established the text in the minds of many people as: "Glory to God in the highest, and on earth peace, good will to men." That reading has the support of some manuscripts (those usually assigned to Caesarea and to Antioch) of the Syriac text and of some church fathers. Modern editors, however, almost unanimously present the reading that underlies the Revised Standard version: "Glory to God in the highest, and on earth peace among men with whom he is pleased!" This reading is supported by the great codices listed above, as well as by the Latin versions. From this external evidence and from the internal evidence most textual scholars conclude that the reading "men of [God's] good will" is more reliable than the reading "good will to men." But there are still some critics who would prefer the nominative to the genitive. Even from this one instance it is clear how complex the task of the textual critic is and how vital it is to the determination of what the New Testament actually says.

III. TRANSLATIONS

The Bible in whole or in part has been translated into more than 1,000 languages, and into most of these during the 19th and 20th centuries. The mission and expansion of Christianity has brought the Scriptures to new peoples, and in many cases the translation of the Bible provided the occasion for reducing a spoken language to written form. Certain translations, however, have influenced their own cultures and the general course of cultural and religious history so profoundly that they deserve special mention.

A. Greek and Latin

1. Septuagint.—The first translation of the Bible—in fact, one of the first translations of any book to be written down—was the Greek version of the Old Testament from the 3rd and 2nd centuries B.C. Because of the legend that it was composed by 70 or 72 scribes under divine inspiration, the version acquired the name Septuagint (often abbreviated as LXX). Actually, it seems to have been the product of more than a century of work by many hands. First the Pentateuch, then the Prophets, then the Hagiographa (including the Apocrypha) were translated. A translation

of the Old Testament into Greek had become necessary because the large Jewish colony in Alexandria was becoming estranged from the Hebrew and thus from the Jewish faith. To some extent the translators also may have intended the translation as a means of commending Judaism to the Greek-speaking public, but their chief concern appears to have been for the survival of their own religious community.

Careful study of the Septuagint by modern scholars has made it clear that the translation reflects the ambivalence of that community in relation to its gentile environment. Some sections of the Septuagint are so literal in their rendition of the original that any non-Jew would have difficulty understanding them, while others adapt the language and even the thought to the tastes of Greek readers. As was pointed out above, the Septuagint plays a significant role in the textual criticism of the Old Testament, based as it is upon a Hebrew text older than most of those at hand today. The state of its own text, however, is confused and in some sections chaotic. This confusion and the obvious misreading of the Hebrew that is evident in some passages complicate the problem of using the Septuagint as a guide to the Hebrew text, and many scholars have serious reservations about its reliability.

Nevertheless, the influence of the Septuagint upon Jewish and especially upon Christian history has been very extensive. The growing conservatism of Jewish religious leaders after the destruction of Jerusalem in A.D. 70 made the Septuagint unacceptable, especially because it differed in both canon and text from the Hebrew version then being adopted. Among Greek-speaking Jews the Septuagint was partially replaced by the extremely literal translation of Aquila (about A.D. 140). In spite of this Jewish attitude, or perhaps because of it, the Septuagint was the Old Testament for most early Christians. Its collection of books became the Old Testament canon of a large part of Christendom, and upon its text were based many of the most important liturgical and theological discussions of the first Christian centuries. The New Testament itself manifests the influence of the Septuagint, though not uniformly throughout; thus the Epistle to the Hebrews depends upon it far more than does the Gospel of Mark. Most of the church fathers could not read Hebrew, and the Septuagint gave them their sole access to the Hebrew Scriptures.

2. Vulgate.——From the writings of Tertullian and Cyprian it is evident that during the 2nd and 3rd centuries there arose Latin translations of the Bible, one in north African usage and another in Italian usage. Confusion between these two versions and the existence of yet other Latin translations caused Pope Damasus I to commission Jerome as editor of a new and standardized text of the Latin Scriptures. The outcome of this commissioning was the Vulgate, which was the Bible of the Western Church for more than a millennium.

Jerome laboured at this project for more than 20 years, revising and reworking different sections of the Bible. It was completed in about 404. Some parts of his translation differ radically from earlier versions, while others follow the Old Latin text more closely. Three separate and distinct renditions of the Psalms appeared under Jerome's name, the first two based upon the Septuagint and the third translated from the Hebrew. Jerome's Bible did not win immediate support, despite the endorsement of Augustine and other leading churchmen. Once it was adopted, it fell victim to the same difficulties of transmission that have afflicted the Greek text. Indeed, the wide circulation of the older Latin versions made the transmission of the Vulgate even more complex, for snatches of these versions were introduced into Vulgate manuscripts as they were being copied. Throughout the middle ages scholars attempted to purify the text; but when the advent of printing made a standard text necessary, there was none. The Council of Trent adopted the Vulgate as the standard Latin version to be used in the church, and at the same time it ordered the preparation of a new edition. One such, prepared in 1590 and revised in 1592, was called the Clementine Vulgate after Pope Clement VIII. In 1907 Pope Pius X appointed an international commission to work on a new edition of the Vulgate, the first volume of which appeared in 1926.

As the official version of the Bible in the Western Church for so many centuries, the Vulgate has helped to mold the development of many national cultures. Phrases such as Agnus *Dei* or *Gloria* in *excelsis* have passed from it into the liturgy and thus into the language of the western peoples. It shaped the hymnody of Christendom, and its rhythms became the basis for the Gregorian chant. Even the language of the Protestant Reformers is incomprehensible without a knowledge of the Vulgate. Roman Catholic translations of the Bible into modern languages continue to be based upon it. It is probably accurate to say that no other version of the Bible has exerted so broad an influence upon western religion and culture as has the Vulgate.

B. English

Despite the many English translations of the Bible in whole or in part undertaken during the middle ages, it is not until the 16th century that the history of the English Bible as we know it actually begins. The New Testament of William Tyndale, published in 1525–26, was a translation directly from the Greek original rather than from the Vulgate, as its predecessors had been. Tyndale followed this with translations from the Hebrew Old Testament, but he did not finish the entire Bible. The translation of Miles Coverdale, published in 1535, although it included the entire Bible, was based upon other translations rather than upon the Greek and Hebrew texts. Circulation of these and other translations of the Scriptures during the 16th century caused a demand for a version of the Bible that would have the sanction of ecclesiastical authorities behind it. In response to this demand an official commission prepared the so-called Great Bible of 1539, which the leaders of church and state sought to enforce as the only permissible version of the Scriptures. Yet the continuing popularity of other versions made some revisions of the Great Bible seem desirable; these were incorporated into the Bishops' Bible, published in 1568. Even these revisions did not go far enough, and the Bishops' Bible did not succeed in establishing itself among the people or even in the churches. England needed a new translation that would incorporate the best features of earlier versions but recast them.

Such a new translation was provided by the Authorized or King James version of 1611. While the Authorized version has never lacked critics, it has so embedded itself in the religious and literary history of the English-speaking peoples that its secure place has been challenged only by revisions of it, not by replacements for it. Such revisions came in the (British) Revised version of 1881–85, followed by the American Standard version of 1901. This latter was more drastically revised in the Revised Standard version (New Testament 1946, Old Testament 1952, Apocrypha 1957), which was accorded more general acceptance among U.S. Protestants than the American Standard had received. In addition to these official revisions of the Authorized version, private translations of the Bible have continued to appear in English. The 20th century was especially rich in these, many of them attempting to introduce more colloquial forms of expression in place of the formal and sometimes stilted language of the Authorized version. Of these private translations those of R. F. Weymouth, James Moffatt and J. M. Powis Smith-E. J. Goodspeed were perhaps the most noteworthy. In 1947 a commission of scholars from Great Britain began working on a completely new translation; their translation of the New Testament appeared in 1961.

Of the Roman Catholic translations of the Bible into English the most influential was the Reiins-Douai Bible of 1582–1610, more commonly known as the Douai version. In accordance with the decree of the Council of Trent it was based upon the Vulgate. Modern studies have demonstrated many instances of its influence on the Authorized version. The Douai version, too, has required revision from time to time. Roman Catholic scholars in the English-speaking world also have issued modern translations of the Bible, particularly of the New Testament. One prepared by the Confraternity of Christian Doctrine and one produced by Ronald Knox aroused more than ordinary interest.

Translation of the Bible is fraught with special problems, in addition to those present in the translation of any literary classic.

It requires the knowledge of not one but two major languages, Hebrew and Greek. and an awareness of the distinctiveness of Aramaic alongside Hebrew. To render biblical terms appositely into another language, the translator ought to be able to presuppose the presence in that language of the technical terms for the myriad theological, liturgical and mystical concepts throughout the Old and the New Testament. On the other hand, such technical terms cannot appear in a language until it possesses and absorbs a translation of the Scriptures. There is therefore a continuous reciprocity between the history of biblical translation and the history of language. In addition, few books contain the variety of literary forms present within the Bible. If the translator ignores the unique patterns of Hebrew poetry or of Hebrew historiography or prophetic denunciation, he will falsify the meaning of the text. Each portion of the Bible contains special pitfalls for the translator. and the history of biblical translation is filled with the sometimes comic pictures of scholars falling into these pitfalls.

Speaking both for themselves and for all translators of the Bible into all languages, the editors of the *Revised Standard Version of the Holy Bible* (copyrighted by the Division of Christian Education of the National Council of Churches [1946, 1952]) expressed the religious significance of the Bible for all ages of Jewish and Christian believers:

The Bible is more than a historical document to be preserved. And it is more than a classic of English literature to be cherished and admired. It is a record of God's dealing with men, of God's revelation of Himself and His will. It records the life and work of Him in whom the Word of God became flesh and dwelt among men. The Bible carries its full message, not to those who regard it simply as a heritage of the past or praise its literary style, but to those who read it that they may discern and understand God's Word to men. That Word must not be disguised in phrases that are no longer clear, or hidden under words that have changed or lost their meaning. It must stand forth in language that is direct and plain and meaningful to people today. It is our hope and our earnest prayer that this Revised Standard Version of the Bible may be used by God to speak to men in these momentous times, and to help them to understand and believe and obey His Word.

See further BIBLE, TRANSLATIONS OF; see also Index references under "Bible" in the Index volume.

BIBLIOGRAPHY.—Most of the books listed below are intended more for the general reader than for the specialist in biblical literature, history and religion. They contain bibliographies of more specialized works on individual problems of biblical study. Thus the reader of this article can move next to some of the titles listed below, and then, if he wishes, to titles listed in them.

General: Andre Robert, *Guide to the Bible,* 2 vol. (1951–55), is a leading Roman Catholic introduction; others are John E. Steinmueller, *A Companion to Scripture Studies* (1941); John Joseph Laux, *Introduction to the Bible* (1932); Henry Daniel-Rops, *What Is the Bible?* (1958). Books by Protestant scholars include: E. C. Colwell, *The Study of the Bible* (1937); G. Ernest Wright and Reginald H. Fuller, *The Book of the Acts of God* (1957); *The Interpreter's Bible,* ed. by Nolan B. Harmon, 12 vol. (1952 ff.), contains not only introductions to individual books and commentaries upon them but materials on questions of history, canon and text, with bibliographies.

Canon and Text: Robert Gordis, *The Biblical Text in the Making* (1937); Ernst Wiirthwein, *The Text of the Old Testament* (1957); B. J. Roberts, *The Old Testantent Text and Versions* (19.51); S. Zeitlin, *A Historical Study of the Canonization of the Hebrew Scriptures* (1933); M. L. Margolis, *The Hebrew Scriptures in the Making* (1922); Gunnar Ostborn, *Cult and Canon: A Study in the Canonization of the Old Testament* (1950); Alexander Souter, *The Text and Canon of the New Testament,* 2nd ed. (1954); Adolf Harnack, *The Origin of the New Testament and the Most Important Consequences of the New Creation* (1925); E. J. Goodspeed, *The Formation of the New Testament* (1926); Ira Maurice Price, *The Ancestry of Our English Bible,* 2nd rev. ed. by William A. Irwin and Allen P. Wikgren (1949); F. G. Kenyon, *The Text of the Greek Bible* (1937); Léon Vaganay, *An Introduction to the Textual Criticism of the New Testament* (1937).

Translations: Bernhard Pick, *Translations of the Bible* (1913) is a chronological catalogue; H. Wheeler Robinson (ed.), *The Bible in Its Ancient and English Versions* (1940); Hugh Pope, *English Versions of the Bible* (1952); E. J. Goodspeed, *The Making of the English New Testament* (1925); F. G. Kenyon, *Our Bible and the Ancient Manuscripts* (1940); Luther A. Weigle, *The English New Testament From Tyndale to the Revised Standard Version* (1949); *see* also BIBLE, TRANSLATIONS OF: *Bibliography.* (J. J. PN.)

BIBLE, TRANSLATIONS OF. By 1960 parts of the Bible had been translated into 1,151 languages, including the entire Bible in 219 languages. As the earliest versions can be dated back to the 3rd century B.C., the tradition of biblical translation is more than 2.000 years old. About A.D. 1450, the time of the invention of printing, the number of translations was 33; by about 1800 the number had risen to 71. These numbers, however, are of no great significance, for in the middle ages, when illiteracy was widespread, the religious communities could learn the sacred story from sermons and recitations of paraphrases in prose and rhyme, or from frescoes, carvings and paintings in churches and from the *Biblia pauperum* (these last, common in the middle ages, were picture books demonstrating the fulfillment of the Old Testament in the New).

In this article only actual translations of the Bible will be discussed; paraphrases or poetry about biblical subjects are omitted. A short outline of the principles underlying biblical translations from Jerome to Erasmus is followed by a history of English translations and a brief account of translations into other European and into non-European languages.

PRINCIPLES OF BIBLICAL TRANSLATION

It would be possible to discuss all the questions concerning biblical translation from the religious point of view, asking if a rendering of God's Word is possible without detracting from its religious significance. The desirability of making Holy Scripture accessible to the ignorant layman, who might try to interpret the most difficult passages without knowing of the restraint imposed upon the pious by tradition, could be questioned. It might be argued that even the most faithful rendering could create diversities of exegesis that might lead to diversity of religious views and destroy the unity of the religious community. Such questions have played their part in the history of biblical translation. and the conviction that certain versions of the Bible contradicted tradition and were therefore heretical led of necessity to the prohibition of some and the authorization of other translations.

In addition to religious questions, there are questions of a literary character. How should the Bible be translated? Is there a difference between the rendering of a profane work of literature and that of God's Word? St. Jerome, following earlier traditions, asserted that every translation should be according to sense but that the Bible should be rendered word for word to preserve the unfathomable profundity of the sacred text. Augustine maintained that the translator who is not inspired should be "in servitude to the words." This demand for word-for-word rendering contributed to the establishment of the literal translation of the Bible in the middle ages. In modern times this view has frequently been challenged. Ronald Knox, for example, applied to the translation of the Bible Hilaire Belloc's advice: "Transmute boldly: render the sense by the corresponding sense without troubling over the verbal difficulties in your way" (*On Translation,* Clarendon Press, 1931). On this view the translator should change the style of the original into the corresponding mode of expression in his own language, and no difference is made between translating the Bible and rendering a profane book.

Finally it is important to consider the influence of biblical translation on the European languages. The Bible has a distinctive terminology that influenced the vocabularies of all those nations that were converted to Christianity. Moreover, literal renderings transformed the style of the vernacular languages, whose own linguistic structures were consolidated or even created by the syntax of the Greek or Hebrew original.

The early versions of the Bible are discussed in the main article BIBLE. In this article their significance for the method of translation mill be traced.

In the so-called letter of Aristeas (*c.* 100 B.C.) it is asserted that the translation into Greek of the Hebrew text of the Old Testament was made by 72 learned Jews of Palestine, that the agreement of those translators warrants the accuracy of the rendering, and that their version (called the Septuagint), being final, cannot be improved. The view that Holy Scripture should be rendered by a group and not by one person has gained adherents in the last centuries; indeed, many official versions of the Bible have been made by committees specially appointed for this purpose.

Another account of the Septuagint was given by Philo of Alexandria (1st century A.D.), who believed that the 72 translators worked separately, and yet every one of them wrote the same, word for word, as all the others. The translators thus were inspired, a new revelation of God's Word had made a new rendering into another language possible, and the Septuagint therefore replaced the original Hebrew text.

Accepting this view, St. Augustine argued that St. Jerome should make the Septuagint the basis of his new translation of the Bible. But Jerome, who had been requested by Pope Damasus I in 382 to revise the Old Latin version (*Vetus Latina*), was convinced of the superiority of the Hebrew text of the Old Testament. As a philologist he could not accept the view that a translation could replace the original. He therefore made from the Hebrew Old Testament and from the Greek New Testament a new Latin version of Holy Scripture, known as the Vulgate (completed *c.* 404), which soon began to be used for church services and which was the only Bible known in the west during the middle ages. Medieval exegesis and medieval translation derived from this text, which, authorized by the Council of Trent in 1546, remains the official Bible of the Roman Catholic Church.

The new learning in the 15th and 16th centuries revived the study of Greek. About 1449 Lorenzo Valla, comparing Greek manuscripts of the Bible with the Vulgate, found that there were differences between the Latin translation and the Greek original and that the Greek wording was generally preferable. His *adnotationes* on the subject were published in 1505 by Erasmus, who independently had come to similar conclusions. The first edition of Erasmus' New Testament, containing the Greek text, his own translation into Latin and his commentary, was published in 1516. Further editions followed quickly. (See also ERASMUS, DESIDERIUS: The New Testament.) J. Reuchlin had already published a Hebrew-Latin dictionary (1506) and a new Latin translation of the penitential psalms (1512), asserting that the Hebrew text was preferable to the Vulgate. Both Erasmus and Reuchlin objected to a translation or an exegesis not derived from the original Hebrew or Greek. Clearly the humanists, especially Erasmus, seriously undermined the authority of the Vulgate, with the view that, since every language possessed a character of its own, the translator should render sense for sense and not word for word. This view inaugurated a new era in biblical translation.

Two other 16th-century translations may be mentioned since they had a certain influence on the English Bible. In 1528 S. Pagninus, a Dominican, published a Latin word-for-word translation of the whole Bible from the original Hebrew and Greek. His knowledge of Greek was limited but his version of the Old Testament forms part of the important edition of the Bible by Robert Estienne (Stephanus) of 1557. In 1534–35 S. Münster edited the Hebrew text of the Old Testament with commentaries and a Latin literal translation. In spite of the inelegant and crude Latin style it was reprinted several times. (WE. S.)

ENGLISH

The mystery of meaning that attaches to any translation is infinitely heightened when the words are those of Holy Scripture. Every translation is an act of creation; a translation therefore may be an act of impiety if it implies modifying the creative impulse of God himself. These primary sanctions have operated strongly in the history of English translations of the Bible, and to them have been added other powerful considerations, theological, liturgical and social.

Against the powerful conservative forces forbidding translations two contrary impulses have led to the constant renewing of the Scriptures in the vernacular. The first acknowledges the primacy of the Bible as the source of doctrine and hence the necessity of shaping the nuances of translation in accord with the subtleties of theological speculation. Successive Reformation versions throughout western Europe influenced the course of controversy on the doctrine of the Trinity, of the church and sacraments, of the status of holy orders. The second impulse acknowledges the centrality of the Bible in Christian worship: in rhe epistle and gospel of the Eucharist, in the iections of the divine office, in every variant of private meditation. Here originates a paradox: with the development of vernacular liturgies in the period of the Reformation (and the renewed impetus of the "liturgical movement" throughout the Christian world in the 20th century) a new conservative force was unwittingly established. A liturgy quickly assumes its own life and integrity, estabiishing a formal context, highly charged both intellectually and emotionally, for the reading of biblical passages and for the biblical texts quoted in sermons. All this argues for the strongly established status of an "authorized version" and an equally strong reluctance to modify the words that have acquired such potent associations.

The conditions establishing and limiting ihe English translations then are complex but clear. Major changes in semantic associations in the languages and development in theological speculation both demand revision of the Bible; yet even where linguistic or historical scholarship demonstrates that the Greek or Hebrew originals or the inteliectual milieu of the original authors required a sense different from that implied by the current translation. long association is strong against change in an "authorized version."

One further issue adds depth and significance to the problem in the English-speaking world. Many fragments of biblical translation are embedded in English works of a high order of creative imagination: in works of "vision" and "dream" in Old and Middle English; in "poetry of meditation" from the 15th to the iith century and in allegory throughout English literature. These exert a strong if indefinable influence on subsequent translations. Even in cases in which the literary values are questionable, as in some of the numerous metrical versions of the Psalms. a powerful conservative tradition is being cumulatively established.

Old English. — The spare but moving story of biblical translation in the Old English period is an epitome of many of the factors that influenced later translators. It turns upon three figures: the illiterate poet Caedmon of the 7th century, the learned Bede (d. 735) and the great preacher Abbot Aelfric (10th century). Caedmon may stand for all those whom the words of the Bible inspired to creative work of their own. He did not of course actually translate. but. after hearing the Scriptures expounded by the scholarly monks of Whitby he composed alliterative poems based on their words. It is uncertain how much is genuine of the paraphrases from the Pentateuch and Daniel extant under his name. In the first half of the 8th century the Venerable Bede undertook translations and glosses (based on the Vulgate), of which unfortunately nothing survives, as part of his far-reaching life of scholarship. Meanwhile partial translations, especially of the psalter. were in progress.

Finally, Aelfric provided extensive versions of passages from the Old and New Testaments in his homilies (*c.* 990–996), and translated the whole of the Hexateuch from the Vulgate. His ambivalent attitude to translating the Scriptures is characteristic of much later orthodox thought. He wished to expound the faith to his people, and for this exposition the Scriptures in the vernacular tongue were essential; at the same time he mas inhibited from a full translation of the Bible, "lest peradventure the pearls of Christ be had in disrespect."

Aelfric's Easter day homily was published in 1567. and in 1571 John Foxe edited an 11th-century translation of the four Gospels from the Vulgate into West Saxon. The object of this publication, made under the patronage of Archbishop Matthew Parker and dedicated to Elizabeth I, was to demonstrate that "the religion presently taught and professed in the church at thys present, is no new reformation of thinges lately begonne . . . but rather a reduction of the Church to the Pristine state of olde conformitie." The links across the centuries are as much linguistic as theological; for as the 16th-century translators struggled to render the flexible Greek into suitable native English forms so this Anglo-Saxon version translated the Latin by the Old English compound: sometimes with lively effect; *e.g.*, "learning cnicht" for *discipulus*, "aerist" for *resurrectio*, "gesamnung" (gathering together) for *synagoga*.

Middle English.—Two new conditions affected scriptural versions in the later middle ages: the impetus toward private judgment based on study of the Bible, fostered by growing criticism

of ecclesiastical corruption; and the intensified movement of mystical pietism among the religious orders. A greater variety in sermon forms and varying attitudes toward scriptural citation and analysis make this a complex period to summarize. But it is significant that the psalter, in prose and metrical versions, received the greatest attention and that the mystic Richard Rolle of Hampole (d. 1349) produced an important translation of it with commentary.

John **Wycliffe** and **Lollardy.**—Later in the 14th century appeared the translations associated with the controversial figure of the learned Wycliffe (d. 1384), who had the authority and the energy to promote an English version that should stand with the Vulgate. It is a matter of nice scholarship to determine the part played in the two Wycliffite versions (one following the Vulgate closely, the other in more natural English style) by John Purvey, Nicholas of Hereford (both Lollard sympathizers and learned men) and Wycliffe himself. Nor is it possible in brief space to examine the text of the Vulgate available to them or their scholarly use of other manuscript material and of commentaries, including those of the influential Franciscan h'icholas of Lyra (d. 1349). Of more importance is the reaction of authority. Wycliffe's contemporary, the chronicler Knyghton, deplored a movement that ensured that the Bible, "the jewel of the church, is turned into the common sport of the people," a view repugnant to Wycliffe, who declared (echoing Jerome) that "ignorance of the Scriptures is ignorance of Christ." At Archbishop Thomas Arundel's instance the Synod of Oxford in 1408 forbade further translation into English without diocesan or provincial approval, and, at the dawn of printing and of the Reformation, the Scriptures in English became equated with dangerous heresy.

William **Tyndale.**—With the labours of Tyndale (d. 1536) the English Bible enters its richest century. The coincidence of the invention of printing with the meticulous critical scholarship to ahich classical texts were being subjected made it inevitable that translation should be vigorous and even revolutionary in implication. After graduating at Oxford Tyndale may hare studied Greek under Erasmus at Cambridge, and certainly he entered into the humanist tradition of critical scholarship. Visiting Wittenberg he probably encountered Luther, whose German translation of the New Testament mas published in 1522. To the massive urbane scholarship of J. Reuchlin and Erasmus now was added the fire of continental reform.

In 1525 Tyndale was in Cologne. where the first sheets of his English translation from the Greek New Testament were printed; then he had to move to Worms, where the work was completed in the next year. He was then free to begin work on his translation of the Old Testament from the Hebrew text, and when he was arrested at Vilvorde in 1535 he had reached the end of Chronicles. Of this only his Pentateuch was published, 1531 (new style; 1530, old style), the rest surviving in manuscript. He also translated Jonah (1531).

Tyndale's approach in producing his powerful and influential version can be gauged from his prefaces, "the pestylent glosses in the margentes" (so described by Henry VIII) and the quality of his vocabulary. He had declared that the theological judgment of ordinary man, in which he trusted, could not be informed "except the scripture were plainly laid before their eyes in their mother tongue," and to that end. borrowing where it pleased his judgment from the Vulgate or from Luther to amplify his reading of the original text, he produced a translation in sinewy contemporary English. Two linguistic problems (with their allied theological overtones) he tackled with vigour and originality. As late as 1542 Bishop Stephen Gardiner of Winchester judged it expedient that certain "ecclesiastical words" should be left as they appeared in the Vulgate, chief among them being *ecclesia, episcopus, caritas* and *gratia.* Tyndale had already settled the problem in his onn uay, translating them frequently against the sense of current orthodoxy, rendering the first of these terms as "congregation" rather than "church" and the third as "love" rather than "charity." At the same time he appealed to his readers' sense of the church year in the colloquial "good frydaye" (Matt. xxvii, 62), "ester holydayes" (Acts xx, 6) and "whitsontyde" (I Cor. xvi, 8). The pungency of his style was seen at its most provocative in the marginal comments (*e.g.,* on Gen. xxiv, 60: "To blesse a mans neyboure is to praye for him and to wissh him good: and not to wagge ii fingers ouer him") and in some of his single phrases, which, though not adopted later (*e.g.,* "babble not moche" for the "use not vain repetitions" of the Authorized version, Matt. vi. 7), established the tone and rhythms of the spoken word as the appropriate language of Scripture.

Miles Coverdale. — In 1534 King Henry VIII was petitioned by the Canterbury convocation to have the Bible translated, and in 1535 Miles Coverdale published his complete translation, dedicating it to the king. In the history of English translation this is an important mediating text. It has the scholarly cast of the humanists, for it was "purely and faythfully translated . . . out of fyue sundry interpreters": the Vulgate, Pagninus' Latin translation, Luther's and Zwingli's German versions and Tyndale's English one. Most important in establishing the temper and rhythms of these versions in the 16th century was Coverdale's undogmatic temper. He omitted or toned down Tyndale's offensive marginal notes and was less intransigent in translating such terms as "church" and "penance." Above all, the beauty of his prose in the psalter established his translation, still used in the Book of Common Prayer, as a central heritage of the English tongue.

"Official Bibles," of the 16th **Century.**—Official translations now began to show a determination to preserve, as nearly as linguistic and theological scholarship permitted, the words of former translations. This conservatism had notable consequences both in the history of biblical translation and in the more general history of the language For the text became a slow. organic growth, by the very unobtrusiveness of its changes commending itself as a standard of spoken and written prose. The four Bibles known as Matthew's (1537), the Great (1539), the Geneva (1560) and the Bishops' (1568; rev. 1572) show the course of this tendency. Matthew's Bible, edited by John Rogers. is based mainly on Tyndale (*i e.,* the unpublished translation of Joshua to Chronicles as well as the published Pentateuch and Jonah) and on Coverdale, with some revisions and additions influenced by the French Calvinistic version of Olivétan (1535). Matthew's Bible was in turn subjected to two revisions, that of R. Taverner in 1539 and that supervised by Coverdale under the patronage of Thomas Cromwell, which appeared as the Great Bible in the same year. Coverdale relied on Erasmus' Latin translation for the New Testament and on S. Münster's for the Old.

Meanwhile—and cutting across these conservative versions—Sir John Cheke, tutor of Edward VI, used his Greek scholarship to make a translation of Matthew and part of the first chapter of Mark (first published 1843) which returned to essentially native idioms and words. In technical vocabulary this verged on eccentricity, "crucified" being rendered as "crossed" and "proselytes" by the remarkably academic "freshmen." But its style was on occasion remarkable in simple dignity: "Come to me all that labour and be burdened and I will ease you" (Matt xi, 28).

The main stream of conservatism, however, was continued in the Geneva Bible (1560), also called the Breeches Bible from its name for the first garments made for Adam and Eve (Gen. iii, 7). It was a new translation made from the original texts by English exiles at Geneva and was strongly influenced by the scholarship of Theodore Beza and Calvin. Its return to polemic in the marginal notes brought reaction in the Bishops' Bible. produced by the English bishops and based on the Great Bible, which 'became in turn the foundation of the King James or Authorized version.

Reims-Douai Version.—An important work of Roman Catholic scholarship, again conservative in its principles of translation. was the Reims-Douai version (N.T. 1582; O.T. 1609–10), prepared by Gregory Martin under the direction of William (later Cardinal) Allen of the English college at Douai. This version, made specifically for priests, was based mainly on the Vulgate (though the original texts were consulted also), of which it gave an authoritative rendering. But its Latinate forms were essentially unacceptable and it was more a scholarly instrument than a stylistic influence, though it was consulted by the translators of the King James version,

King James or Authorized Version. — The Hampton Court conference in 1604, at the urging of the Puritan John Rainolds, proposed a new translation of the Bible, and 54 translators were invited to undertake the work, at Oxford, Cambridge and Westminster. The translators' principles were important: the Bishops' Bible was to be altered as little as possible, though earlier versions were to be consulted; the old "ecclesiastical words" (as "church" for "congregation" and "charity" for "love") were to be kept; and the marginal comments were to be textual, not theological. The manuscript (since lost) was bought by the king's printer for £3,500. The Bible appeared in 1611, dedicated to James I, in large folio volumes, selling for 30s. bound.

It is difficult to exaggerate the influence of this translation, which came to be known as the Authorized version because it was "Appointed to be read in Churches" (in the United States it is more commonly called the King James version). It established the rhythms of spoken English as the standard for English prose; it gave a pattern of great variety, from bare clarity to the ornate parallelism of Hebrew poetry; it avoided uniform literalness of translation in favour of a rich use of synonym.

Later 17th- and 18th-Century Translations. — Subsequent modification in the authority of the Authorized version arose, more from increasing biblical scholarship than from changing values of English prose. Interesting experiments in colloquial translations took place in the next century and a half, but the main pressures for a new, authoritative version came about as a result of a second renascence of Greek scholarship and the 18th-century rediscovery of Hebrew poetry.

The Quaker A. Purver made a literal translation of the whole Bible from the original tongues (1764). The Greek New Testament was translated by two classical scholars, D. Mace, who made a colloquial version (1729), and E. Harwood, whose "liberal" translation is an expansion of the original (1768). John Wesley's English New Testament (1755) is based on the Authorized version.

Revised Version. — In the 19th century, further advances in biblical scholarship and the growing unfamiliarity of the language of the King James version made its revision imperative to both Great Britain and the United States. Though some scholars of the eminence of B. F. Westcott still advocated further radical work on the original Hebrew and Greek texts, a British revision committee consisting of two companies, one for each testament, was set up in 1870. The New Testament appeared in 1881. the Old in 1885; the Apocrypha were issued in 1895. A U.S. committee working in close co-operation with the British revisers brought out the American Standard version in 1901.

In considering the somewhat indifferent reception accorded the Revised version, its title is an important consideration. As a scholarly revision of the King James version in modified Jacobean English, it occupied a vulnerable position: it rejected many of the loved phrases and rhythms, it appealed to no living idiom and its detailed scholarship was continuously under question. Although accepted as more accurate than the King James version, for academic study in schools and universities, it rarely replaced the latter in public worship. Much the same may be said of the American Standard version.

20th Century. — Twentieth-century official translations have been prepared as well as various "private" versions, especially of the New Testament or of parts of it. Two American translations established new approaches; R. F. Weymouth's *New Testament in Modern Speech* (1902) took some tentative steps toward justifying its title, but James Moffatt's version (N.T. 1913; O.T. 1924: revisions 1935) was in a modern idiom and made use of the growing knowledge of Hellenistic Greek. After Moffatt the may was clear for thoroughgoihg stylistic experiment, in which two versions have been outstanding: that by Ronald Knox (N.T. 1945; O.T. 1949), which is officially approved by the Roman Catholic Church; and *The* New *Testament in Modern English* (1958) by J. B. Phillips. Knox, who translated the Vulgate but consulted the Creek and Hebrew texts, is terse and scholarly, and while undertones remain from Jacobean speech the idiom is recognizably modern (*e.g.*, "I may speak with every tongue that men arid angels use; yet, if I lack charity, 1 am no better than echoing bronze, or the clash of cymbals"; I Cor. xiii, 1). Phillips is racier, and on occasion he paraphrases rather than translates the original Greek, but he is triumphant in the intensely personal tones of the Pauline Epistles (*e.g.*, "Don't be under any illusion: you cannot make a fool of God!"; Gal, vi. 7). Another private modern translation is *The Bible, an American Translation,* with New Testament by E. J. Goodspeed (1923), Old Testament by J. M. Powis Smith (19351 and Apocrypha by Goodspeed (1938).

The copyright of the American Standard version was acquired in 1928 by the International Council of Religious Education (U.S. and Canadian, interdenominational), which in 1937 authorized a revision of the work that would "embody the best results of modern scholarship as to the meaning of the Scriptures, and express this meaning in English diction which is designed for use in public and private worship and preserves those qualities which have given to the King James version. a supreme place in English literature." *(Revised Standavd Version* of the *Holy Bible,* copyrighted by the Division of Christian Education of the National Council of Churches [1946, 1952].) Thirty-two scholars served on the revision committee. and their work was reviewed by an advisory board of 50 representatives of the co-operating denominations. The Old Testament and New Testament groups. in addition, reviewed each other's work, and all changes were agreed upon by a two-thirds vote of the whole committee. In 1946 the Revised Standard version of the New Testament appeared, and in 1952 the Revised Standard version of the Bible, with both testaments; the Apocrypha were published separately in 1957. The Revised Standard version won wide acceptance in the United States.

A British interdenominational committee, translating afresh the whole Bible from the original Hebrew and Greek into modern English, published its version of the New Testament in 1961.

(W. M **ME.**)

OTHER EUROPEAN LANGUAGES

Gothic and German. — The earliest translation of the Bible into a Germanic language is Ulfilas' translation of the Septuagint and the Greek New Testament into Gothic (before 381). (*See* GOTHS.) Ulfilas was the first to coin a Germanic Christian terminology, some of which is still in use, though much has been replaced by expressions originally brought to north Germany by English missionaries such as St. Boniface.

German translations of the Vulgate dating back to the 9th century have survived. The impulse was given by Charlemagne, who, aided by the English scholar Alcuin, aimed at educating the Frankish clergy and at comniunicating some knowledge of Christianity to the people. English influence also can be traced in the German rendering *c.* 835 of the Latin translation of Tatian's *Diatessaron* (a harmony of the Gospels). In the following centuries only the translations of Notker Teutonicus (d. 1022) and Claus Cranc (14th century) are worth mention.

The first German printed Bible (1466), probably a reproduction of a text about 100 years older, was a literal translation from the Vulgate. It ran in revised form into 14 editions before 1518. But it was Martin Luther's rendering of the Bible from the original tongues that influenced subsequent translation almost everywhere. Even new versions in other languages often mere based on his translation. His version of the New Testament. executed in 11 weeks in the Wartburg, was published in 1522 (the *September Bibel*), and his first complete Bible in the autumn of 1534. Throughout his life Luther was busy revising his translation.

He was helped by friends, especially Philipp Melanchthon and M. Aurogallus, who advised him on Greek and Hebrew philology. But it was Luther who did the actual work oi translation. His remarkable handling of the German language, in conformity, as he asserted. with the speech of the common people, influenced and even shaped the development of modern German (*see* GERMAN LITERATURE). No other Protestant translation into German has been able to compete with the popularity of Luther's Bible, and it is still the official one of German Protestants.

In agreement with humanist theories Luther's two principles of translation were that the original languages (Hebrew and Greek)

must clearly be the basis of biblical translation; and that, since every language possesses its own peculiarities in construction and idiomatic usage, no merely literal translation is satisfactory. An elegant turn of phrase in one language must be transferred into another mode of thought without losing its original meaning. Instead of a word-for-word rendering Luther postulated a translation sense-for-sense. A translator who adheres to these principles must possess a thorough and detailed knowledge oi the languages, and he must understand the original in all its details, both grammatical structure and contents.

This theory requires no explanation. It is a formula adopted by modern translators. Luther, however, saw the inherent difficulties. Clearly the translator must know the Bible and be well versed in all aspects of biblical studies, but this by itself is not enough, for it is only by the grace of God that God's Word can be understood in all its profundity.

The interconnection between God's guidance and human endeavour is thus clearly established: the theologian cannot interpret Scripture without learning and the scholar is incapable of writing a commentary on the Bible unless God's grace has illuminated him and revealed the true meaning of the text (W. Schwarz, *Principles and Problems of Biblical Translation*, Cambridge University Press, 1955).

Luther was convinced that no translator could fully understand every word of the sacred text. Therefore he maintained that every translation contained shortcomings and even mistakes and that it could on no account replace the original. -Thus only the original text could be the basis of exegesis and translation. But only the translator who has spiritual understanding of Holy Scripture and who possesses the necessary linguistic knowledge will be able to render not only the "letter that killeth" but also the spirit He will not have to translate word for word, he will not be in "servitude to the words" but will be able freely to transform the peculiarities of the one language into idiomatic expressions of the other.

Roman-Catholic German *Translations.*—Luther's translation was attacked because it did not always tally with Roman Catholic tradition and because it lacked glosses to explain the text. Hieronymus Emser's translation of the New Testament from the Vulgate with glosses was intended to correct these faults, but it remained essentially a revision of Luther's work J Dietenberger's translation of the whole Vulgate (1534) was a revision of Emser for the New Testament and of Luther for the Old. In the revision of 1630 it circulated widely in Germany. H Braun's translation (1788–1805) was revised by J. F. Allioli (1830), and other revisions were made later.

Switzerland.— Luther's translation of the New Testament was printed in 1524, and the complete Bible (*Zürcher Bibel*) in 1529. This version, for which Zwingli's follower Leo Jud had translated the prophets, is still in use. In 1560 J. Bifrun translated the New Testament from the Vulgate into the Romansh dialect of the Upper Engadine.

Dutch.—In the Netherlands medieval translations dating from the 13th and 14th centuries were followed by the Dutch so-called Delft Bible, actually only the Old Testament without the Psalms, translated from the Vulgate (1477). Subsequently two translations were of some importance, that of 1532, a rendering of Luther's translation, and that of 1554 based on Erasmus' Greek text of the New Testament. Until 1951 the so-called *Statenbijbel*, translated by a committee out of the original languages (1637), was accepted alike by the Reformed communities, the Remonstrants and the Mennonites and read in churches. It was superseded subsequently by a new official version, not a revision (N.T. 1939; O.T. 1951). A translation from the Vulgate by Nicolaus van Winghe, first published in 1548, was the accepted Roman Catholic version until 1926, when a new translation from the original languages came into use (Canisius Bible). Another new rendering based on the Greek and Hebrew texts was published in 1961.

Scandinavian Languages.— Little is known of pre-Reformation translations into the Scandinavian languages.

In Denmark Christiern Pedersen's New Testament. published in 1529, was translated from the Vulgate, Erasmus' Latin. and Luther. The complete Bible was commanded by King Christian III and published in 1550, its purpose being to follow Luther as closely as possible. The first version from the original languages, made by Bishop Hans Poulsen Resen in 1607, was often revised (last revision 1872). An entirely new translation of the Old Testament was published in 1931, of the New Testament in 1948.

Until the separation of Denmark and Norway in 1814 the Danish Bible of 1647, a revision of Resen's edition, was in general use in Norway. This was revised several times from 1819 onward. The first complete translation from the original languages was published in 1904 and revised in 1930 (in the so-called national language); since 1938 a version of the entire Bible in the so-called country-wide language also has been in use.

The first printed Swedish translation of the New Testament (1526) and of the complete Bible of 1541 was made from Luther's translation (see SWEDISH LITERATURE). It was revised in 1915.

Roman Catholic translations from the Vulgate were published in Denmark (1893, 1931), in Norway (1902, 1938) and in Sweden (1895).

French.— In the 12th century French translations gained great importance with the rise of the Cathari. Consequently vernacular versions mere under suspicion of heresy and were prohibited in pastoral letters arid decrees. Later biblical translation is the history of revisions of existing versions.

The first Roman Catholic translator was Jacques Lefèvre d'Étaples, whose edition of the Hebrew psalter (1509) and commentary on the Pauline Epistles with a translation made from Greek (1512) exerted a certain influence on Luther. Lefèvre published a translation from the Vulgate of the New Testament (1523) and of the complete Bible (1530) which was often revised and its explanatory notes rewritten until the 17th century. The most important version of the 17th century, again translated from the Vulgate, was that of Port-Royal, mainly by the brothers Lemaistre, especially Isaac Louis called de Sacy (N.T. 1667; Bible 1682–17023. This excellent translation was often revised. Modern translations from the original languages are La Bible *de Jérusalem* (1947–56), a version edited at the abbey of Maredsous (1950) and another under the patronage of Achille Cardinal Liénart (1951).

The Protestants used the version made by Olivétan (1535), a scholar who knew Hebrew well and who relied on Erasmus' Latin translation and on Lefèvre for the New Testament. This translation was re-edited and modernized until well into the 20th century by such men as Calvin, Theodore Beza and. most important of all, Jean Frédéric Ostervald of Neuchâtel (1724; revised 1744). The translation from the original languages by L. Segond (1874–80) is still very popular.

Italian.— The oldest Italian Bibles of which manuscripts are extant belong to the 14th century; they are in all probability connected with 13th-century translations that were influenced by the Provencal versions of the Waldenses.

Of the two translations from the Vulgate printed in Venice in 1471, the one by Niccolò Malermi was often re-edited (ten times before 1500), the latest edition being dated 1773. The translation by the humanist Antonio Brucioli (1532), following the Latin version of Erasmus for the New Testament and of Pagninus for the Old (1528), was destined with some alterations to become the Bible for Italian Protestants (printed in Geneva in 1562). The main Protestant version, translated from the original languages by Giovanni Diodati and first printed in Geneva in 1607, is still in use. In 1769–81 the archbishop of Florence, A. Martini. published the most important Roman Catholic version of the Vulgate.

Spanish.— Translation of the Bible in Spain shows one remarkable, even unique feature, a version of the Old Testament by Rabbi Moisés Arragel made from 1422 to 1430 at the request of Don Luis Guzmán, grand master of the Order of Knights of Calatrava. It contains biblical exegesis by Christian and Jewish authorities without, however, evaluating their merits. A Catalan translation from the Vulgate by Bonifacio Ferrer (1478) was destroyed by the Inquisition in 1198 and only a few fragments survive. The first printed Spanish translation of the New Testament was made by the Reformer Enzinas (Dryander) from the original Greek (1543). In 1569 C. de Reyna, also a Reformer, translated the Old Tes-

tament from the Hebrew with the help of Pagninus' Latin version, largely for the benefit of Spanish-speaking Jews. This was revised by C. de Valera in 1602. In 1793 a Roman Catholic translation of the Vulgate was produced. New translations were made from the original languages by E. Nácar and A. Colunga (1944) and by J. M. Bover and F. Cantera (1947).

Slavonic Languages. — The first translation of the Bible or of parts of it into Church Slavonic was made by Cyril and Methodius, who were sent as missionaries from Constantinople to Moravia in the 9th century. This version was made from the Greek Bihle; that is, from the Septuagint and from the original Greek of the New Testament. The earliest extant Church Slavonic Bible, a manuscript of 1499 named after Gennadius, archbishop of Novgorod, contains books translated at different periods from Hebrew, Greek and Latin. Revisions of this Bible were publiihed in 1581, 1663 and 1751.

The first translation of the New Testament into Russian was published together with the Church Slavonic version in 1821. It was made from the Greek original. Previously some books of the Bible had been published in White Russian, beginning with Job, which was translated from the Vulgate and the Church Slavonic versions. The first Russian translation of the whole Old Testament, made from the Hebrew, was published in 1875. Since the Revolution emigrants from Russia have made new Russian versions.

In the western half of the Slav territory. where the people embraced the Roman Catholic faith, the Vulgate was translated into the vernacular languages comparatively early. The Czechs as well as the Poles possessed translations in the 14th century, and John Huss, at the beginning of the 15th century, revised earlier Czech versions and modernized their antiquated language. The first printed Czech translation. made from the Vulgate. was published in 1475. In 1579–93 the Unitas Fratrum published the Kralitz (or Kralice) Bible, translated from the original tongues, which set a standard for the Czech language (see CZECHOSLOVAK LITERATURE; MORAVIAN CHURCH).

The first printed Polish New Testament (1553) was translated from the Greek original by J. Seklucyan. a friend of Luther. The firsi Polish Bible, translated from the Vulgate, was published in 1561 (the Cracow Bible).

Finnish. — The New Testament was first translated from Greek into Finnish by Bishop M. Agricola (1548), who also revised for publication the translation of the psalter by P. Justen (1551). The whole Bihle was translated from the original tongues nearly a century later (1642 j. It has been repeatedly revised. Between 1820 and 1900 the four Gospels were translated into Karelian, the south Finnish dialect, for the use of Orthodox Finns.

Hungarian. — Parts of the Vulgate were translated in the 15th century, and the first book printed in the Hungarian language was a translation from the Vulgate of the Pauline Epistles (1533). In 1541 the Protestant J. Erdosi translated the New Testament from the original Greek, and in 1590 the whole Bible was published by G. Károli, who translated it from the original tongues. This version, which is of importance for Hungarian literature, has been frequently reprinted (see HUNGARIAN LITERATURE). The Roman Catholic translation from the Vulgate by G. Kaldi (1626) also has been reprinted. (WE. S.)

NON-EUROPEAN LANGUAGES

Since 1800 the translation of the Bible into non-European languages has been closely related to the development of Protestant missions. Before 1800 the Bible in whole or in part had been translated into no more than 20 lion-European languages. Of these. Syriac, Armenian, Coptic, Ethiopic, Georgian, Persian and Arabic were spoken in areas or' the middle east and of the Nile valley where Christianity first penetrated. Nothing has remained of the translations made by the Orthodox monks at work in centra! Asia or by the Roman Catholic missionaries who followed the steps of the great explorers of the 15th century. The other extant pre-1800 translations resulted from the labours of pioneer Protestant missionaries, such as John Eliot, who translated the Bible (1663) for the Massachusetts Indians; B. Ziegenbalg and J. E. Griindler, who translated the New Testament (1715) into Tamil; and B. Schultze, who translated the Gospel of John (1758) into Dakhini (a form of Hindustani).

As against this almost static situation prior to 1800, translations of the Bible, in whole or in part, appeared in about 400 non-European languages between 1800 and 1900. And in the following half-century more than 500 were added to the list, so that by the end of 1960 some part of the Scriptures had appeared in a total of 1.005 non-European languages (the British and Foreign Bible society alone being editorially responsible for more than 600 of them): the whole Bible in 172 languages. the complete New Testament in 258 more languages, and at least one complete book of the Bible in a further 575 languages. At the same date it was reckoned that translation and revision work was in progress in nearly 500 languages, of which approximately 200 previously had had no translation of the Scriptures. The whole Bible then existed in languages understood by about 90% of the world's population, and either the Bible. the New Testament or a portion in languages understood by about 95%.

In order to help missionaries and nationals engaged in translation and revision work, many of whom had little or no knowledge of Greek and Hebrew (as is still the case), the British and Foreign Bible society as early as 1817 appointed a translation secretary and in 1830 established a specialized translation department. Other Bible societies, such as the American and the Dutch, followed with similar programs early in the 20th century. The tasks of such translation departments include: ensuring the best and most scholarly help to meet translators' problenis; establishment of guiding principles for the benefit of translators and revisers: formation of local translation or revision committees with a suitable balance of denominational representation; occasional provision of financial support; training and sending out of translation and linguistic experts to help missionaries in the field; holding of translation conferences; preparation of "translational helps," etc. After 1950 this last activity received new impetus through the publication in London, under the auspices of the United Bible societies, of a quarterly, the Bible *Translator*.

In addition to the Bible societies, the Wycliffe Bible Translators (also known as Summer Institute of Linguistics) also specialize in work of Bible translation. This organization was founded in 1935 with the specific aim of training and sending missionaries to translate the New Testament into all of the estimated 1,500–2,000 languages and dialects of the world in which no part of the Bible had as yet appeared.

'Translation work developed first in languages that already possessed a written literature, and in this group the pioneer translator was William Carey, who with his colleagues at Serampore produced 28 translations in Indian languages. The whole Bihle was translated out of the original languages into Sanskrit by Carey (published 1822), into Chinese by Robert Morrison (published 1823) and into Burmese by Adoniram Judson (published 1834). Though most of these early translations were later revised, they were significant contributions to the literature of the languages, for they introduced to these areas an entirely new world of faith, thought and culture.

Translation into unwritten languages implies a host of special problems, including the preparation of adequate alphabets, the analysis of complex morphological and grammatical structures and the development of a "literary style" based on an orsl tradition.

The pioneer work of missionaries in the field of translation was a major factor in the creation in the west of most of the schools and institutes oi oriental and African languages. The British and Foreign Bible society, for example, has always maintained very close relations with the School of Oriental and African Studies of the Cniversity of London. The advice of their scholars has been constantly sought both in relation to specific questions raised by translators and to the quality of a translation awaiting publication.

In the United States, on the other hand. the growth of the science of descriptive linguistics during the first half of the 20th century led to a new development in biblical translation. This. together with a concentration of attention on symbolism and com-

munication in the related fields of anthropology, psychology and cybernetics, has resulted in significant advances in the whole field of communication through languages. The American Bible society and the Wycliffe Bible Translators have done pioneer work in this field as part of their endeavour to produce more adequate versions of the Scriptures. (See also BIBLE SOCIETIES.)

Bible translating is closely related also to literacy. On the one hand Scripture production has in many languages stimulated literacy; on the other hand the spread of literacy has led to demands for translations into more colloquial speech, especially in areas where the spoken language differs widely from the literacy standard, as Arabic, Japanese and Haitian Creole. The Japanese colloquial version published in 1955 is notable as the first revision in a major non-European language done entirely by nationals. Widespread literacy also has stimulated the production of translations into simple forms of language; *e.g.,* "popular Spanish" for Latin America and "simple French" for Haiti. (O. P. BE.)

BIBLE SOCIETIES are nondenominational religious organizations concerned with the wider circulation of the Bible and parts thereof in the languages of all men at a price everyone can afford.

Early Societies. — At all times the Bible has been an expensive book to produce. For centuries it remained accessible only to the wealthy, yet again and again individuals and groups of people moved by evangelistic zeal made funds available for editions of the Holy Scriptures to be circulated at low cost. The Protestant attitude to the Bible as the property of all Christians, not merely of an educated elite, made more general the demand for cheap vernacular editions of the Bible, but it was not until 1710, with the establishment of the Canstein Bible institution (Cansteinsche Bibelanstalt) in Halle. Ger., that there was an organization devoted solely to the production of cheap editions of the Scriptures. This institution had three main characteristics that were to become paramount for the Bible societies a century later. First, its founders were concerned with the purity of the text. Second, a new method — already used in Holland for an English Bible — that of printing from standing type, was applied, by which the whole Bible was set at once and the composition kept for later reprints. Third, it was founded out of an evangelistic and social concern, being part of a series of social and educational institutions known as Francke's Orphanage (Waisenhaus), and deeply rooted in the biblical and pietistic revival of that time.

During the 18th century the evangelical movement spread all over Europe and even reached the new world. The best-known and most powerful evangelical organization was the Evangelical society, centred in Basel but with branches all over southern Germany and Switzerland. In Great Britain the evangelical movement gave birth to a series of organizations such as the Society for the Promotion of Christian Knowledge Among the Poor (1750); the Society for the Support and Encouragement of Sunday Schools (1785); a Bible society later called the Naval and Military Bible society (1780), specializing in Scripture distribution among soldiers and seamen; and a French Bible society (1792), for the supply of Scriptures to French people in France. Some of these societies had their counterparts in America. All of them were concerned at least in part with meeting the increasing demand for cheap Scriptures that had arisen as a result of the evangelistic revivals and of the contemporary spread of literacy among poor people. At the same time interest and concern for missionary work abroad was growing also as a result of the evangelical movements.

19th Century. — It is at the junction of these two concerns — to make the Scriptures available at a price all could afford and to all men all over the world in their own tongue — that the British and Foreign Bible society (B.F.B.S.), the first Bible society in the fullest sense, was founded in 1804 as a result of a proposal made by Thomas Charles (*q.v.*) and members of the Clapham sect (*q.v.*) to the committee of the Religious Tract society. To the evangelistic and social preoccupation of the founders of the Canstein Bible institution a new dimension was added, the world-wide missionary outlook.

The step taken in London was quickly imitated elsewhere. Soon each Protestant state in Germany, each protestant canton of Switzerland had its own local Bible society, just as each main city of England and Wales had its auxiliary to the B.F.B.S. The movement also spread rapidly to Scotland, Scandinavia, the Netherlands. France, several of the states in the U.S., Canada, the main cities of India, Freetown in Sierra Leone, Belize in British Honduras, Cape Town, Mauritius and later Australia and New Zealand. In 1816 most of the local societies of the U.S. joined to form the American Bible society. All the time London was providing subsidies to encourage and help new societies to establish themselves. In less than 20 years the Protestant world was dotted with Bible societies and Bible society auxiliaries. many of them remaining heavily dependent upon the subsidies provided by London. Short-lived Roman Catholic Bible societies were established around this time in Pressburg (Bratislava) and in France. With the collaboration of the Orthodox Church an interconfessional Russian Bible society was established in 1814, replaced in 1828 after the withdrawal of the Orthodox by a Protestant Bible society, which closed down at the end of World War I.

Two features were particularly characteristic of this new type of organization as represented by the B.F.B.S. First, it was interdenominational. The wide circulation of the Scriptures "without note or comment" was the sole aim. Thus any person interested in the society's object could co-operate. Moreover an equal balance was maintained between the Anglican and the free churches in the membership of both general committee and staff. The international character of the society was also expressed by the presence in the committee of six representatives of the foreign churches established in London. Second, it was a lay society. All committee members were, and have remained, laymen of distinction from different walks of life. All Bible societies have maintained this characteristic, though a number of them also have opened their ranks to the clergy in the course of time.

The original fellowship within the Bible society movement was deeply shaken in 1826 by the decision of the B.F.B.S. to exclude formally from its program the circulation of the Apocrypha and to cease supporting or collaborating with societies that would not take a similar decision. This meant a break in relations with the majority of the continental European Bible societies. Cut off from their source of inspiration, hampered by the political and social struggles that were constantly shaking the continent and by a much slower economic progress than in Britain, the continental Bible societies for more than a century remained self-centred and paid little or no attention to work abroad. The Netherlands Bible society alone formed an exception and started work in Indonesia. The Stuttgart Bible institution (Privilegierte W'iirttembergische Bibelanstalt) also deserves particular mention for its publication of R. Kittel's scholarly edition of the Old Testament in Hebrew, A. Rahlfs' of the Septuagint and E. Nestle's of the New Testament in Greek. In the meantime the B.F.B.S., the National Bible Society of Scotland and the American Bible society were continually expanding their fields of operation. Year after year new translations were published and new agencies mere opened. By the 1820s. before the coming of the first evangelical missionaries, colporteurs related to those societies were working

throughout Latin America. In the following decade systematic colportage started in France, spreading to other countries in Europe and to the other continents. By 1900 nearly 2.000 colporteurs were at work on behalf of those Bible societies in almost all countries of the world.

20th Century. — The 20th century has been marked by five important developments. First, whereas contacts between the Bible societies in the British Isles, the United States and the Netherlands had been on the whole purely superficial and formal, business discussions became increasingly frequent after 1900. In order to avoid overlappings and frictions. "territories" were exchanged, countries divided into zones of activity — another form of the "comity" principle well known in missionary circles. Later, in the 1930s, joint agencies were formed, administered by one society. supported jointly by two or more. At the same time basic principles were worked out that regulated terms of co-operation in various technical matters such as translation, production, price calculation. etc. These principles subsequently were adopted by nearly all Bible societies throughout the world.

Second. in the first quarter of the century the local auxiliaries in the British dominions were federated to form national societies and received the status of independent Bible societies. After the 1940s former national agencies also were granted administrative autonomy in Japan, Korea, China, Indonesia, India, Belgium and Brazil, or, as in the case of France. Austria and Finland, were integrated in or closely associated to the national Bible society.

Third, the continental European Bible societies began by the middle of the century to emerge from their self-centredness and to recapture the world-wide missionary outlook that had inspired the Bible society movement at its inception.

Fourth, in 1946, under the name of the United Bible societies, a world fellowship of Bible societies was formed that soon embraced all the existing national Bible societies. Its main purpose was the furtherance of consultation, co-ordination and co-operation among the Bible societies in their common purpose of obtaining the widest possible circulation of the Holy Scriptures. Its creation broadened on a world-wide scale the agreements passed by the British. American and Dutch societies. It offered a place where supporting and supported societies could meet outside the realm of their mutual dependency. and it provided the impetus for the revival of the European continental societies.

Fifth, hy a series of papal statements and encyclicals of which that of 1943 was the climax, the Roman Catholic Church encouraged the translation. study and reading of the Bible. A similar movement encouraging the reading of the Scriptures also took place in the Greek Orthodox (Zoë movement) and Coptic churches (Friends of the Bible).

When the B.F.B.S. was founded, the Bible in whole or in part had been printed in 72 languages. By 1960 the whole Bible had appeared in 219 languages and dialects. the whole New Testament in 271 more, one or more whole hooks of the Bible in 601 additional ones. a total of publication of 1.151 languages. About 1,200 Bible translators engaged in translation or revision. working singlehanded or in teams, were related to the Bible societies. Between 1950 and 1960 the average annual world circulation of Holy Scriptures by the Bible societies amounted to 3.037.898 Bibles, 3.223.986 New Testaments and 18.417,989 portions. As Scriptures are generally sold at a loss. or at most at the bare cost of paper, printing and binding. the cost of translation, composition and plates, handling, colportage and general overhead expenses had to he covered hy donations. The average amount thus collected annually throughout the world from churches and individuals for the years 1955–60 was over £2.000,000. Bible societies are at work directly or through agencies and depositories in over 100 countries.

Parallel or complementary to the work of the Bible societies, various organizations originating mainly in Great Britain or the United States also have specialized in Scripture distribution. Some, like the Scripture Gift mission (1888), circulate in addition to Gospels and Sew 'Testaments a large variety of selection? irom the Scriptures. Others have specialized in specific types of distributions: among these is the Gideons International (1899), which supplies hotels, hospitals and prisons with free copies of the Bible or of the New Testament. Still others. which gained great momentum after World War II, such as the Pocket Testament league (1908), have engaged in extensive campaigns of Gospel free distribution. Finally. the Wycliffe Bible Translators Inc. (1935) have specialized in providing training for missionary translation and supervision of translating work with the aim of publishing one Gospel at least in every spoken language of the world. It was estimated in 1960 that there were 2.000 languages and dialects spoken by about 25.000.000 people into which no part of the Bible had yet been translated.

BIBLIOGRAPHY is the anglicized form of the Greek *bibliographia,* which means "the writing of books" in the literal sense; the Greek *bibliographos* was a copyist of manuscripts. The word has passed through various meanings and still covers too many activities to be very exact in definition. However. in modern times the nord bibliography is ordinarily associated with two sets of activities: (1) enumerative (or systematic) bibliography. the listing according to some system or reference scheme of hooks that have a formal relationship; and (2) analytical (or critical) bibliography, the examination of books as tangible objects with a view to the recovery of the details of the physical process of their manufacture, and the analysis of the effect of this production process on the physical characteristics of any specific copy of a book.

Analytical bibliography can be pursued independently of any limited objective; that is. it may he studied as a pure discipline concerned with recovering and interpreting evidence about production processes as preserved in the physical features of books of various periods. The application of such information, however, usually takes the iorni of (*a*) descriptive bibliography; or (*b*) textual bibliography.

Ancillary to analytical bibliography (in that evidence from these sources may on occasion be utilized to assist in the drawing of correct conclusions) are the numerous fields concerned with the study of printing and its processes both as nrt and as craft, and with the mediums for the distribution or publication of its products. These studies may range irom the art of typography to formulas for printer's ink or the methods of manufacturing paper in different places and centuries; from biographical notices of printers. bookbinders and publishers to inquiries into the mechanical development of printing presses; from the publishing of book advertisements in 18th-century periodical.: to the contract between a 20th-century author and his publishing firm. These studies may include histories of printing, of hook illustration. hookhinding. hook distribution, even of book collecting, and many more areas of association.

In this article "book" will be used loosely to denote any printing or facsimile reproduction. Manuscripts and their study are customarily removed from the province of bibliography, but this exclusion represents a false distinction. except in such matters as historical studies of paleography that do not properly concern bibliography. Since one of the functions of textual bibliography is the recovery of the characteristics of the lost manuscript that served as printer's copy, it is evident that bibliography has an intimate connection with certain forms of manuscript study. Moreover, the striking information yielded by analysis of the physical characteristics of manuscripts (as in certain Walt \Vhitman and Emily Dickinson documents) demonstrates that this investigation follows the same logical methods of analysis ax the study of printed books and can scarcely he distinguished from it.

ENUMERATIVE (OR SYSTEMATIC) BIBLIOGRAPHY

Enumerative bibliography lists material according to some useful scheme of classification and provides conventional identifica-

tion of the books, articles or other material that it organizes. The purpose of this form of bibliography is to disseminate information by the systematized notation of material having some special purpose or sufficient common characteristics to he of significance to human knowledge when thus collected for reference. The operative word is "systematic"; that is, there must he some formal system or rationale for the association of the listed material in a bibliography.

Almost any attempt at classifying kinds of enumerative hihliographies n-ill raise objection, since often there is considerable intermixture. However, as a working classification it may be possible to separate bibliographies into: (1) general, the listing of essentially miscellaneous material in which the relationship is merely chronological, geographical or linguistic, or according to some other external criterion: (2) association chiefly by the form of the material: (3) association by the subject, that is, some feature of the contents of the listed material: (4) association of material as the work by or about a single author.

General.— Here the material itself is miscellaneous and the principle of selection for listing is only in respect to the production of the material within a given span of time, or in a given geographical area, or language or the like. Thus the *Gesamtkatalog des Wiegendrückes* ("Complete Catalogue of Incunabula") proposes, on completion, to list, alphabetically by author, every hook printed anyn-here in the west before 1500 (*i.e.*, incunabula). Because of the enormous quantities of books and manuscripts produced since the "cradle" or incunabular period, l e arrangements in which the central classification is purely chronological are practicable; and usually there is some further limitation, if no more than by nation or by language within the general chronoloaical scheme. Thus in J. E. Wells's *A Manual of the Writings in Middle English, 1050–1400*, chronological limits are added to a linguistic criterion. In the Pollard and Redgrave *Short-title Catalogue of Books Printed in England, Scotland and Ireland and of English Books Printed Abroad, 1475–1640*, limits of time are added to the restriction of the listing to books printed in Great Britain in any language and to books in the English language printed abroad. The various annual national bibliographies in which the world's production of books is regularly recorded, such as *The English Catalogue of Books*, restricts the listing by national bounds within the general system of the calendar year. *Cumulative Book Index*, published in the United States, undertakes to list all books published in English, anywhere in the world.

Form.——In the bibliographies of miscellaneous material unified only by temporal, geographic or linguistic association, and the like, an external and indeed almost fortuitous consideration governs the selection for listing of material othern-ise quite without association. A somen-hat more organic principle restricts selection by association of materials in similar forms, or genres, even if for practical reasons the same limitations as in general bibliographies may be placed on the extensiveness of the enumeration. On the most literal level the periodic *Dissertation Abstracts*, or the W. Gregory *Union List of Serials in Libraries of the United States and Canada* or the same author's *American Newspapers, 1821–1936*, or R. S. Crane and F. B. Kaye's *A Census of British Newspapers and Periodicals, 1620–1800* select their material for listing on the initial criterion of form, as announced in the title, before imposing further limitation. In this grouping the similar form of the material inay mask the widest variety of content.. as in 'Theodore Besterman's *A World Bibliography of Bibliographies* or R. Tanghe's *Bibliography of Canadian Bibliographies;* or the form may itself impose a considerable unity on the contents, as in A. Esdaile's *A List of English Tales and Prose Romances Printed Before 1740*.

Subject.— In the subject bibliography the unifying principle is internal since it is associated with the contents of the hooks enumerated: the association arises from within and is organic. The degree of unity varies widely, of course. Obviously the association of material is closer and more specific in a bibliography of material about fishing, say, than in *The International Bibliography of Historical Sciences* or *British Scientific and Technical Books, 1935–1952*.

One kind of subject bibliography associate.; hooks that are secondary material, such as critical or historical accounts concerned with some central subject matter, narrow or broad; an example is the *Annual Bibliography of English Language and Literature* issued by the Modern Humanities Research association, which does not list the primary new creative literature n-ritten each year but rather the scholarship arid criticism devoted to the study of literature. Similar compilations are the annual "Check List of Gibliographical Scholarship" published in *Studies in Bibliography* or the annual "Victorian Bibliography" published, in *Modern Philology*.

Another kind of subject bibliography may associate records of basic original documents with critical or historical accounts of these documents. The classic example here would he *The Cambridge Bibliography* of *English Literature*, which is certainly a subject bibliography in that it excludes all English hooks that are not classifiable as literature; however, it proceeds then to list the original and early editions of the selected writers of English literature together with secondary accounts of these authors and their writings both in particular and in general, as in critical material about literary forms, history of ideas, etc. Thus subject bibliographies, in a manner ordinarily not encountered in general or in form bibliographies, may treat only primary documents, or only secondary documents, or a mixture of the two.

Author.—Author bibliographies are accorded a separate heading chiefly because they represent a narrow kind of compilation and are very popular. Ordinarily they list the primary documents, that is, the author's n-orks, and add to these a list of writings about the author and his works, or about the painter and his portraits, the musician and his compositions, etc. The description of the primary documents may become so detailed and definitive as to approach a descriptive bibliography that has extensive supplementary subject lists.

Other Lists and Guides.— The current products of historical, scientific, artistic or literary research are usually n-ell served by periodic bibliographical subject lists, hut artistic and literary creative work in the making is more difficult to follow since most bibliographical lists are highly selective of such material and are often aimed only at advising a general library on books suitable for purchase. However, something can be done with such aids as the *Subject Index to Periodicals*, the *Fiction Catalog* or the *Index of Plays, 1800–1926*, with their periodic supplements, the *Book Review Digest*, the *Library of Congress Subject Catalog*, the *British National Bibliography* and the *Reader's Guide to Periodical Literature*.

An enumerative bibliography may attempt to he complete within its particular field of limitation, or it may adopt some rationale of selection. It may sometimes offer annotations describing the contents or assessing the value of the material noticed. Because of some relative completeness or because of some featurrs of special value, 3 few catalogues may be considered on an equal plane with enumerative bibliographies, despite the conventional differentiation that such catalogues list or describe only books in one collection and therefore have an arbitrary and not a reasoned method of selectivity for listed materials. However, no one could deny the prime importance, for instance, of such catalogues as the British museum's printed general *Catalogue* or the *Catalogue of Hooks Printed in the XVth Century Now in the British Museum*, because of their wide scope: or of William A. Jackson's *Catalogue of the Carl H. Pforzheimer Collection*, for its informative commentary and research.

There is an extensive group of reference materials peripheral to enumerative lists. Some are in the form of indexes; examples are the annual *New York Times Index*, *A Cumulative Index to Biographical Material in Books and Magazines*, first-line indexes to poems and the various dictionaries of quotations, pseudonyms and the like. Some take the form of guide.; to the use of reference material and of enumerative bibliographies; an example is Constance Winchell's *Guide to Reference Books*, based on the classic I. G. Mudge *Guide to Reference Books*. Other materials are designed to assist the student in mastering the technique of utilizing enumerative lists for dehnite scholarly research projects.

as A. G. Kennedy's *A Concise Bibliography for Students of English* or T. P. Cross's *A Bibliographical Guide to English Studies*. More general assistance is provided in such treatises as A. Esdaile's *A Student's Manual of Bibliography* and H. B. van Hoesen and F. K. Walter's *Bibliography: Practical, Enumerative, Historical*.

Various United Nations agencies contribute to bibliography. In 1953 the United Nations Educational, Scientific and Cultural organization (UNESCO) started a series of instructional manuals aimed at general improvement of bibliographical methods and designed to help with the creation of basic services; the series includes reports on bibliographical services throughout the world and international bibliographies on such subjects as economics, political science, sociology and social and cultural anthropology. Other UN organizations and the U S headquarters library publish subject bibliographies; the library also publishes indexes to proceedings of the general assembly and various councils.

ANALYTICAL (OR CRITICAL) BIBLIOGRAPHY

Analytical bibliography studies the physical evidence of printed books (and manuscripts) with a view to recovering the principles of the reproduction process and ultimately of applying information thus gained to the problems of specific books. The evidence utilized is circumstantial and physical, and would often be legally valid.

In its purest state analytical bibliography divorces itself completely from all literary. historical or critical-aesthetic considerations and confines its attention to the physical evidence of a book without regard for the nature, purport or intelligihility of the contents. For example, some copies of Gervase Markham's play *The Dumbe Knight* (1608) have a title page in which the author's name is present; in other copies the name is absent. A literary critic once argued that Markham was disgusted when he learned that his play was to be printed with additions not his own and demanded that his name be withdrawn from the title. An analytical bibliographer did not concern himself with motive and inference but instead ascertained the physical facts of the printing. 'These demonstrated that the title page without the name was the original, firmly conjugate with its opposite leaf in the folded sheet that made up the first gathering of the book. Consequently, the title page with the name was a substitute, or cancel. bound in after the original first leaf without the name had been excised. The physical facts about the printing demonstrated clearly that the name in point of time was added and not subtracted.

Physical evidence gained from identifying hundreds of pieces of slightly bent or broken type, and from following them in and out of the printers' cases as they were typeset, distributed and typeset again in different family groups on various pages, enabled C. J. K. Hinman to establish the fact that the Shakespeare First Folio was not composed and printed in normal order but instead in a leapfrog manner: the somewhat widely separated typeset pages had been forced to conform to an estimate of the space required for their contents marked off in advance in the printer's copy. Moreover Hinman, by following the varying contents of the printer's cases as indicated by these known types, added decisive evidence to that derived from analysis of characteristic spelling habits of the various workmen. He thus was able to identify positively the exact lines set by each of the five compositors of the First Folio. As a result. not only the workmen who set the type but the order of composition of each page and the order in which it went through the press can now be determined for English literature's most important single book. (*See* SHAKESPEARE, WILLIAM: *Textual Criticism.*)

Physical evidence enabled W. W. Greg to demonstrate that certain quartos of Shakespeare, known as the Pavier Quartos after their printer, were printed in 1619 and not a decade or so earlier. On the evidence that some lines of the title pages of these books were in an identical typesetting, though ostensibly printed years apart, it was established that they were the work of one printer in 1619 and not of various printers of earlier years. 'This discovery assigned the correct order to the early editions of some of Shakespeare's important texts that had been placed in a mistaken order on metacritical evidence.

Physical evidence enabled John Carter and Graham Pollard to establish that certain 19th-century pamphlets by prominent literary figures could not have been published according to the dates on their title pages since they were printed with type that had characteristics not yet developed and on paper containing esparto grass not yet in use at the alleged dates. On this sure factual foundation was reared the sensational exposure in the 1930s of the Thomas J. Wise forgeries. Wise, a British bibliographer, collector and book dealer. with considerable standing in the book world, in the 1890s forged and sold over 50 "first editions," several for substantial prices. The forgeries were done with great skill and are now becoming collector's items in their own right.

In method the foregoing examples have varied from studies of presswork, as in *The Dumbe Knight*, through studies of the typesetting, as in Hinman's First Folio investigations, to analysis of the chemical constitution of the basic material of the book, the paper, as in the Wise case. What they all have in common is the technique of investigating, books as tangible objects without regard for their contents. This analytical bibliography and its study of physical printing evidence is the backbone of descriptive bibliography and of textual bibliography, in both of which it finds its most fruitful application.

DESCRIPTIVE BIBLIOGRAPHY

In at least one important fundamental, a descriptive bibliography differs from an enumerative bibliography: a descriptive bibliography has little point unless it confines itself to the ordered arrangement and description of primary documents, whereas an enumerative bibliography may list primary, or secondary documents or a mixture of both. To be precise, Sir Walter Greg's *A Bibliography of the English Printed Drama to the Restoration* lists only the primary documents; *i.e.*, the texts of the plays in their various editions. issues and states printed before 1660. On the other hand, *The Cambridge Bibliography of English Literature* enumerates a large selection of the pre-Restoration editions of these plays but adds a listing not only of modern editions of the texts but also of secondary documents about them; *i.e.*, the critical and historical studies that examine these works, their individual significance and their literary history.

If a descriptive bibliography is compared with an enumerative bibliography devoted to the same primary documents, however, three major differences may be discerned. all of which represent a greater rigour of scholarship devoted to the descriptive form: (1) a descriptive bibliography is usually more definitive in respect to the number of primary documents listed; (2) a descriptive bibliography is more definitive in the identification and arrangement of the material; and (3) a descriptive bihliography may contain information of interest to more purposes than the immediate one of identification.

Primary Documents. — Since the major purpose of an enumerative bibliography is the provision of a useful source of reference material, the compiler may content himself in some part by copying references in secondary sources such as catalogues, either to the exclusion of any other means of inquiry or as a supplement to personal examination of the documents listed. In either case, he cannot guarantee either completeness or accuracy. A descriptive bibliographer, on the other hand; must guarantee fullness and accuracy by relying exclusively on searching inquiry and personal examination, since his purpose is to create a permanent descriptive listing, that will never become outmoded, of important basic documents.

Identification and Arrangement. — An enumerative bibliography contents itself with the absolute minimum of identifying information. For modern books a short title and date of publication may he all that is required, since the user may then refer to any library catalogue for further information. The enumerative bibliographer has ordinarily performed his proper service by noticing the simple existence of such and such a title. Progressing farther into the past, the enumerative compiler may find that the possibilities of confusion are so increased as to call for somewhat more extensive identification, and some lists may add the place

of publication and even the name of the publisher or of the printer. publisher and seller. The descriptive bibliography, on the other hand. offers a series of relatively minute physical descriptions with the following aims: (1) to establish the physical form of the book listed; (2) to differentiate this physical form in the matter of variations within the edition. and then from the forms of other known editions; enough detail is given that a user presumably will be able to identify a specific copy held in his hand as either similar to an edition. issue or state described in the bibliography, as an imperfect copy, or else as a form that has not been seen by the bibliographer; (3) to provide a body of descriptive information to the general student of printing and publishing or of bibliographical practice.

In the process of contriving this physical drscription a descriptive bibliographer differentiates himself from a cataloguer, or enumerator. in two particular respects: First, the descriptive bibliographer is concerned to describe the "ideal copy" of any particular edition. with an account of all variations from this definitive ideal norm. whereas a cataloguer ordinarily confines himself to the description of a specific copy without inquiring whether this copy is truly representative of the edition as a whole. Second. the descriptive bibliographer. in the process of discovering the form of the "ideal copy" and its variants, must compare sonic numbers of duplicate copies. personally, in an effort to exhaust the possibility for the discovery of further, unknown variations. In this process. of course, he will not only learn and record issues and states within an edition not to he ascertained by less searching investigation but will also discriminate between closely similar editions previously confused, as the three 1670 editions of Dryden's *Indian Emperour*, lumped together as two before bibliographical inquiry began.

Variety of Information.— The illustrative notes often appended to descriptions may serve as a storehouse of information about the details of the printing as revealed by the analytical bibliographer's explanation of the process that produced the book and its variants under discussion. the identification of the printer and of his types and ornaments, the transmission of the test or the artistic values of the production. details of the contents. some account of the publishing history and a listing of the collections where the editions were consulted and the characteristics of their copies.

The physical description of a hook may differ in the details chosen. though not greatly in the methods for describing these details. according to whether the book is an incunable (*i.e.*, printed before 1500), a later hand-printed book or a contemporary product of machine typesetting and presswork. In all cases the edition is chosen as the unit for description, and within each edition the variant issues and states are distinguished. Most descriptive bibliographies include as a minimum a transcript of the title page (preferably in quasi-facsimile form); a collational formula that describes the format, the number of gatherings and the signing and paging; and a listing of the contents in their formal sections. As much as possible, for precision and brevity. these details are presented in formulary terms. A typical brief description would be as follows:

A | TRAGI-COMEDY: | Called, | *Match mee in* LONDON. || As it hath becne often Prefented; Firft, | at the *Bull* in St. IOHNS-ftreet; and lately, | at the Priuate-Houfe in DRVRY-Lane, | called the PHŒNIX | *Si non, His vtere Mecum.* | Written by THO: DEKKER. | [printer's device] | LONDON. | Printed by B. ALSOP and T. FAVVCET, for H. SEILE, | at the *Tygers*-head in S^t. *Pauls* Church-[yard. 1631,

4°: A" B-K^4 L^2; $3 signed [A2, D1 in italic; missigning K3 as K2], 40 leaves, pp. [4] 1–53 45 54 56–76 [=76] (*variant:* misprinting 44 as 4, 54 as 46 instead of 45).

X1: title. A1^v: *'Drammatis Perfonæ'* (*var: 'Dramatis'*). *A2:* [ornament] | TO THE NOBLE LOVER, | (and deferuedly beloued) of the Mufes, | LODOVVICK CARLELL' | . . . . (8-line initial), signed 'THO: DEKKER.' || B1: [ornament] | 'MATCH MEE | IN LONDON. || ACTVS, I. ' || (j-liue initial). On L2^v: || *'FINIS.'* || (*var:* omitting second rule)

For a more complete *description* of this hook, *see* W. W. Greg, *A Bibliography of the English Printed Drama to the Restoration*, no. 440 (1940); and for the methods by which such a description is contrived, see Fredson Bowers, *Principles* of *Bibliographical Description* (1949).

TEXTUAL BIBLIOGRAPHY

Textual bibliography is the backbone of textual criticism (*q.v.*). It may be defined as the application of analytical bibliography to the three major specific problems of the textual critic: (*a*) the analysis of the physical characteristics of an extant manuscript; (*b*) the recovery of the characteristics of a lost manuscript from the details of the print; and (*c*) the study of the transrnission of the text. In each case the immediate purpose of the inquiry is to estimate the specific effect, on the correctness and completeness of a text. of the printing or inscription process as a whole and in any particular.

The range and variety of this complex form of bibliography are so great as to permit mention of only a few typical examples.

Physical Characteristics of Manuscript. — A careful study made by Thomas Johnson of the physical evidence of the papers and inks. plus the changing characteristics of the author's handwriting, oiiered relatively exact information about the dates of inscription of a number of Emily Dickinson manuscripts and thus provided a guide to the choice of texts.

Details of Print.—111 Shakespeare's *1 Henry VI,* as printed in the First Folio of 1623, spelling tests and type-case evidence established that compositor A set most of the first hali of the play and compositor B most of the second half. The variant spelling "Joane" and "Jone" for Joan of Arc has no immediate significance since it is established as a compositorial characteristic varying according to the bibliographical units oi the typesetting by each workman: the "Joane" spellings all appear in pages set by A, and the "Jone" spellings all appear in pages set by B. However. in acts i and ii, "Burgundy" is spelled with a "d," but in act iii as "Burgonie": and in act i Joan is referred to as "Puzel" but in act iii as "Pucell." In each instance the name spellings alter with the literary division act iii, and both forms appear in the pages set by each compositor so that variation is not bibliographical. In contrast to "Joane-Jone," therefore. these spellings can be established as noncompositorial and therefore as characteristic of the lost printer's-copy manuscript. It must follow thnt this manuscript was heterogeneous. inscribed by two hands, with the point of division at the start of act iii.

Transmission of **Text.**—The study of the transmission of the text can be associated with the effect of the printing process on the printer's copy. as in the foregoing example. or with the settlement of larger questions affecting the authentication of specific textual readings. For the first, the demonstration that in *Hamlet* act i, scene 2 the Second Quarto "sallied flesh" (meaning "sullied") is correct and the Folio reading "solid flesh" is corrupt ultimately came to rest on the bibliographical evidence thnt the second edition (Q2) was set by two different compositors and printed on two presses. Hence the workman who set in type the debated "sallied" at i, a. 129, was different from the workman who set in type the accepted "sallies" (for "sullies") at ii. 1. 39, and one could not have influenced the other; nor could both be the result of one workman's misreading a hypotheticul malformation of the letters in the manuscript (*see* Allardyce Sicoll [ed.], *Shakespeare Survey*, vol. 9 [1956]).

For the second. the question of whether Hamlet's phrase is correctly "good kissing carrion" at ii. 2. 182, as in both Q2 and Folio, or "god kissing carrion." as in Warburton's generally adopted emendation. will in some considerable part rest on whether it can be demonstrated that the printer's copy for the Folio was an independent manuscript or else a print of Q2 scribally annotated and altered by comparison with some manuscript. In the first case, the concurrence of two independent authorities in the reading "good" would need to he explained complexly as some form of common error if Warburton's emendation were to be adopted; whereas in the second case, it would merely be assumed to have been an error in Q2 which escaped the scribe-annotator's attention and was carelessly passed on to the Polio. If direct connection between Q2 and the Folio printer's copy could thus be established, the emendation n-ould need to pass far less severe scrutiny for acceptance. A number of other readings in *Hamlet* will he in-

volved in the settlement of this basic question of the transmission of the Folio text, especially when the readings differ in the Folio from those in the Second Quarto. The decision as to the exact nature of the transmission will rest only on a minute bibliographical analysis of the appearance or nonappearance in the Folio print of hundreds of Q_2 minor characteristics of spelling, capitalization and punctuation, as well as the question of the readings or words themselves, as these minor characteristics can be proved to filter through the known habits of the identified Folio compositors or not to appear when they should be expected.

In other periods, the bibliographical study of transmission may weed out errors as in the complex textual history of the Addison and Steele *Spectator* papers in the first three editions in folio, octavo and duodecimo as shown by Donald F. Bond, or in the Shelley *Posthumous Poems* of 1839 edited by Mrs. Shelley and long sccepted as authoritative. Subsequent study of the text showed, however, that it incorporated errors from pirated editions of the 1824 first edition overlooked by Mrs. Shelley when she collated her proofs against her manuscripts.

Such study may even serve to establish the final wording of a modern text like that of Sinclair Lewis' *Babbitt* as indicated in its transmission history; it performs the further service of warning critics against any printing of this book after a duplicate set of plates was put into use that restored most of the errors of the first-impression state of the original plates (corrected in these original plates in the second, third and fourth impressions).

BIBLIOGRAPHY.—Bibliographical journals contain a considerahlc quantity of investigation of the kind treated in this article. The principal journals arc *The Library, Studies in Bibliography* and *Papers of the Bibliographical Society of America.* The *Gutenberg Jahrbuch* specializes in bibliographical articles about incunabula. The principal textbooks arc Konrad Haebler, *Handbuch der Inkunabelkunde* (1925), trans. by Lucy E. Osborne as *Thr Study of Incunabula* (1933); Ronald B McKerrow, *An Introduction to Bibliography for Literary Students* (1927); Fredson Rowers, *Principles of Bibliographical Description* (1949). Because of the rapid rate of bibliographical investigation after World War II, earlier textbooks will need supplementing and updating from research published in bibliographical journals and the monographs issued by bibliographical societies, and such'sources as the published Sandars, Lyell and Rosenbach lectures, or the various library journals like the *Harvard Library Bulletin.* Enumerative bibliography is treated in A Esdaile, *A Student's Manual of Bibliography* (1932): H. B. van Hoesen and F. K. Walter, *Bibliography: Practical, Enumerative, Historical* (1928); Theodore Besterman, *The Beginnings of Systematic Bibliography,* 2nd ed. (1936). (F. T. H.)

BIBRACTE, an ancient Gallic town, the modern Mont Beuvray, 13 mi. W.S.W. of Autun, in the French *département* of Saône-et-Loire. It was the capital of the Aedui in the time of Julius Caesar and the site of his defeat of the Helvetii, the climax of his first campaign in Gaul (58 B.C.). The Helvetii were marching at first northwest along a route leading from the modern Macon to Autun. then bearing farther westward toward Toulon-sur-Arroux. Caesar, who had been pursuing at a deliberate distance of a few miles, was forced from lack of supplies to strike off northward to Bihracte, whereupon the Helvetii, discovering his difficulty, turned and harassed him until he had to give battle at a hill just short of the town. Posting two newly raised legions and the auxiliaries with the baggage on the crest of the hill, he formed the veteran legions in three lines. The Roman javelin throwing was effective in breaking up the assault and enabled the legionaries to press the Helvetii steadily back in the close quarter combat. But as the legions followed up the retirement of the Helvetii. they exposed the rear ranks. A large body of the allied Boii and Tulungi, who had been guarding the wagon park of the Helvetii, seized the opportunity to attack the Romans in the rear while the Helvetii returned to the attack in front; Caesar turned his third line about and after a long struggle repulsed the double attack now launched. The wagon park was eventually captured and a few days later the Helvetii surrendered.

Excavation has revealed remains of rectangular dwelling houses, a temple of Bibractis, and workshops of iron and bronze workers and enamelers. Augustus moved the inhabitants to his new town Augustodunum (Autun) in 12 B.C. to destroy the native traditions.

See T. Rice Holmes, *Caesar's Conquest of Gaul (1911)* and *The Roman Republic and the Founder of the Empire,* vol ii *(1923).*

BIBULUS, a cognomen or surname of 'the Roman gens Calpurnia. of which the following are the best-known members.

MARCUS CALPURNIUS BIBULUS (d. 48 B.C.) was colleague of Julius Caesar (*q.v.*) as aedile in 65, praetor in 62 and consul in 59 B.C. Bibulus voiced the conservative element in the senate that was opposed to Caesar's legislation. During his consulship he was overpowered by physical violence in an attempt to veto Caesar's agrarian proposals in the senate, whereupon he tried to stop them becoming law by announcing that he was looking for omens (an act which. according to the constitution, should have brought all public business to a standstill). Caesar, however, disregarded this, and Bibulus did not emerge from his house for the remaining eight months of his consulship or take any part in public business beyond issuing edicts against Caesar's proceedings.

When Caesar and Pompey quarreled Bibulus supported Pompey and joined in proposing his election as sole consul (52 B.C.). In 51 he went to Syria as proconsul. In 49 Pompey gave him command of his fleet in the Ionian sea, but he proved unsuccessful and died soon afterward.

He married Porcia, daughter of M. Porcius Cato (Uticensis) and later wife of M. Junius Brutus.

LUCIUS CALPURNIUS BIBULUS '(d. c. 32 B.C.), youngest son of the above. surrendered to Antony soon after the battle of Philippi (42 B.C.) and was by him appointed to the command of his fleet. He died while governor of Syria. L. Bibulus wrote a short memoir of his stepfather Brutus, which was used by Plutarch.

BICAMERAL SYSTEM. The phrase "bicameral system" means a legislature consisting of two houses. Historically, the modern bicameral system dates back to the beginnings of constitutional government in 17th-century England and to the later 18th-century on the continent of Europe. The English parliament became bicameral in recognition of the distinction between the nobility and clergy and the common people. When the British colonies were established in America, the colonial assemblies were likewise bicameral because there were two interests to be represented: the mother country. by the governor in council, and the colonists. by their chosen deputies. After the Declaration of Independence, bicameral systems were established in all the states but Georgia, Pennsylvania and Vermont. In these three states single-chamber legislatures were set up, but these were replaced by bicameral legislatures in 1789, 1790 and 1836. respectively. All the new states subsequently admitted into the Union came in with two-house legislatures. Although the Continental congresses and the congress of the confederation had been unicameral, the federal convention of 1787 decided that the new national legislature should consist of two branches in order to preserve the identity of the separate states. safeguard the influence of the smaller states and protect the interests of property.

With the extension of constitutional government throughout the world, most countries set up bicameral legislatures on the English or U.S. models, with large first chambers chosen by popular vote and smaller second chambers whose members were either elected or appointed and often represented political subdivisions such as the Swiss cantons. The bicameral plan is usually found in federal governments such as Argentina, Australia, Brazil and Canada. Bicameralism was also the prevailing governmental pattern in the cities of the United States during the 19th century.

Theoretically, this dualism is justified as an application of the principle of checks and balances. A bicameral system is desirable, it is argued. to avoid hasty and harsh legislation, limit democracy and secure deliberation. The expanding role of the U.S. senate as critic and overseer of the administration is particularly regarded as vindicating the design of the founding fathers. The senate, said Woodrow Wilson, is "one of the effectual checks, one of the real balances, of our system."

Although bicameralism remained the prevalent practice, the 20th century witnessed a reaction against it both in the United States and elsewhere. Unicameral councils or commissions came to predominate in U.S. cities and were credited with marked improvements in the quality of municipal government. Widespread dissatisfaction with state legislatures led to numerous proposals for a single-chamher system during the second decade of the

century, but the adoption of a unicameral legislature by Nebraska in 1934 marked the only departure from the bicameral system among the U.S. states.

Constitutional trends after World War II, meanwhile, reflected a growing preference for the unicameral system in nonfederal states of the world. Unicameral national legislative bodies were set up in Bulgaria, both Chinas, Czechoslovakia, Denmark, Finland, Greece, Hungary, Israel, New Zealand, Spain, Turkey and several Latin American countries. In England, where the house of lords had been weakened, and in France, where the council of the republic (renamed senate in 1958) was practically impotent, the government operated in effect on the unicameral principle. Genuine coequal bicameralism appears to be incompatible with a cabinet system of government which cannot tolerate deadlocks between its branches.

In the United States both houses of congress had substantially the same representative character after adoption of the 17th amendment in 1913, while the need of a second chamber as a means of curbing democracy and protecting property rights was no longer felt. Thus, the decline of bicameralism was a worldwide phenomenon, but most of the modern constitutional states still retained two chambers. (G. B. Gy.)

Bibliography.—George B. Galloway, *The Legislative Process in Congress* (1953); Walter H. Mallory (ed.), *Political Handbook of the World* (1958); Harrison Boyd Summers, *Unicameral Legislatures* (1936); Arnold J. Zurcher (ed.), *Constitutions and Constitutional Trends Since World War II* (1951).

BICARBONATE, in chemistry, an acid carbonate, a salt in which one only of the two hydrogen atoms in the molecule of carbonic acid has been replaced by metal. Na_2CO_3 is the formula of normal sodium carbonate, washing soda; $NaHCO_3$ is that of sodium bicarbonate, or baking soda. *See* Carbonates.

BICEPS, the name given to one of the muscles of the upper arm, from which the latter derives its rounded appearance in front. It has two heads or origins, the shorter attached to the coracoid process of the shoulder blade, the longer to the edge of the glenoid cavity of the shoulder joint. The two heads unite to form a central portion or belly, which ends in a tendon, the distal end of which is inserted on the radius in the forearm. The muscle on contraction has the effect of bending the forearm and assisting in the rotation of the hand. *See* Muscle and Muscular System.

BICESTER, an urban district in the Henley parliamentary division of Oxfordshire, Eng., 13 mi. N.N.E. of Oxford by road. Pop. (1961) 5,513. It lies in pastoral country on the northern edge of the open plain of Ot Moor. The name may derive from *beorna* and *ceaster,* meaning "fort of the warriors"; *ceaster* does not mean that the district was the site of a Roman camp.

There are records of the settlement (Berncestre, Burencestre, Bissiter) from the time of Domesday. In 1182 Gilbert Basset founded an Augustinian priory which was the centre of industrial life until its dissolution in 1538. Richard II granted a fair and a Monday market, and in 1440 an additional market was granted, to be held in that part of the town called Bury-End, from this date known as Market-End. In the 16th century the cattle market was especially famous; it is still held on Mondays. The church of St. Edburg contains examples of Norman and each succeeding style, and the vicarage dates from the 13th century. There are scanty remains of the Augustinian priory.

Bicester never possessed any manufactures of importance, though a large army ordnance depot nearby has brought many employees into the area. It has considerable agricultural trade and is famous as a hunting centre, the hunt now known as the Bicester and Warden Hill hunt becoming well known in the 1780s. The urban district was extended in 1932.

BICHAT, MARIE FRANÇOIS XAVIER (1771–1802), French anatomist and physiologist whose systematic study of human tissues helped found the science of histology, was born at Thoirette (Jura) on Nov. 14, 1771, the son of a physician. He studied anatomy and surgery under M. A. Petit (1766–1811), chief surgeon to the Hôtel Dieu at Lyons. The revolutionary disturbances drove him to Paris in 1793. He there became a pupil and then assistant of P. J. Desault, who died in 1795.

He completed the fourth volume of Desault's *Journal de Chirurgie,* to which he added a biographical memoir of its author. He then wrote the *Oeuvres chirurgicales de Desault, ou tableau de sa doctrine, et de sa pratique dans le traitement des maladies externes* (1798–99), in which, although he professes only to set forth the ideas of another, he develops them with the clearness of one who is a master of the subject.

In 1797 he began a course of anatomical demonstrations, and then began to lecture on operative surgery and physiology. His *Anatomie générale* (1801) contains the fruits of his most profound and original researches. His *Anatomie descriptive* (1801–03), in which the organs were arranged according to his peculiar classification of their functions, was completed by his pupils, M. F. R. Buisson (1776–1805) and P. J. Roux (1780–1854).

Before Bichat had attained the age of 28 he was appointed physician to the Hôtel Dieu, a situation that opened an immense field to his ardent spirit of inquiry. He engaged in a series of examinations with a view to ascertaining the changes induced in the various organs by disease. A fall from a staircase at the Hôtel Dieu resulted in a fever, and he died on July 22, 1802.

See Anatomy, Microscopic: *The Rise of Histology.*

BICKERDYKE, MARY ANN (1817–1901), variously called "Mother Bickerdyke," "General Bickerdyke" and "the General in Calico," was the organizer and chief of nursing, hospital and welfare services for the western armies under the command of Gen. U. S. Grant during the American Civil War. Born Mary Ann Ball on July 19, 1817, in Knox county, Ohio, she attended Oberlin college and later studied nursing. Before the Civil War, Mrs. Bickerdyke, a widow and the mother of several children, set herself up as a "botanic physician" in Galesburg, Ill. Early in the war she attracted Grant's attention with her vigorous attack on filth, malnutrition and disease at the Cairo (Ill.) military installations, and he thereafter supported her work with military authority. She followed Grant's army down the Mississippi, setting up rear-area hospitals as they were needed.

Mrs. Bickerdyke later served with Gen. W. T. Sherman's 15th army and made extensive and careful preparations for Sherman's march through Georgia to the sea. There was no dropping off of tired or ill men during that campaign. Provisions were made for frequent medical examinations and for transporting men who were unable to walk. Under Mrs. Bickerdyke's supervision, about 300 field hospitals were built, staffed and equipped with the help of U.S. sanitary commission agents.

After the war, at the age of 50, she became a pension attorney for veterans, and also organized a veterans' homestead plan. Mrs. Bickerdyke died in Bunker Hill, Kan., on Nov. 8, 1901.

See Florence S. Kellogg, *Mother Bickerdyke* (1907); Marjorie Barstow Greenbie, *Lincoln's Daughters of Mercy* (1944).

BICKERSTAFFE, ISAAC (*c.* 1735–*c.* 1812), British playwright whose farces and comic operas were popular in the late 18th century, was born in Ireland *c.* 1735. There is no apparent connection between his name and the pseudonym earlier adopted by Swift and also used by Addison and Steele for the *Tatler.* The real Isaac Bickerstaffe is said to have been a page to the lord lieutenant and to have become an officer in the royal marines. His first theatrical success, *Love in a Village* (1762), was followed by many others, including *The Maid of the Mill* (based on Richardson's *Pamela*), *The Padlock* and *The Hypocrite.* A frank plagiarist, he depended for his success on his lively lyrics and his sparkling dialogue.

Bickerstaffe's future appeared bright when in 1772 he was forced into exile by allegations of sodomy, then a capital offense. He lived in great poverty for many years, probably in France. The exact date and place of his death are unknown.

Bibliography.—Preface to "The Maid of the Mill," *British Theatre,* ed. by J. Bell, vol. viii (1797); S. Jones, *Biographia Dramatica* (1812); R. Guiet, "An English Imitator of Favart: Isaac Bickerstaffe," *Modern Language Notes,* vol. 38 (1923).

BICKERSTETH, EDWARD (1786–1850), English clergyman, a leader of the evangelical party in the Church of England, was born on March 19, 1786, at Kirkby Lonsdale and ordained in 1815. Prolific as author and preacher, he worked for the Church

Missionary society as secretary from 1816 to 1830, compiled a popular hymnbook, *Christian Psalmody* (1833), and vigorously attacked the Oxford movement and the Roman Catholic Church. He was rector of Watton, Hertfordshire, from 1830 until his death there on Feb. 28, 1850. His son, EDWARD HENRY BICKERSTETH (1825–1906), bishop of Exeter (1885–1900), was famous as a hymn writer.

See T. R.* Birks, *Memoir of Edward Bickersteth (1851).

(*G.* F. A B)

BICYCLE, a light, two-wheeled steerable vehicle propelled by human power. The wheels are mounted in line in a steel frame and the front wheel is held in rotatable forks. The rider, sitting on a flexible saddle and steering by handle bars attached to the forks, turns a driving sprocket attached to two cranks which he rotates with his feet. Power is transmitted from this sprocket to a second sprocket on the rear wheel by means of an endless chain running over both sprockets.

Bicycles are the most numerous class of vehicle on the roads of England, France, Germany, the Netherlands, Italy. Belgium and Denmark, and they are widely used in North America and elsewhere. The bicycle is easily mastered and can be ridden with little effort at 10–12 m.p.h. by any normal person. Being easy to house and carry, inexpensive to purchase and maintain, and simple in construction, it is a valuable instrument of self-transport, and provides pleasant recreation and exercise even while being used for purposes of utility. Cycle touring is most widely practised in England, but has a large and increasing number of followers in Germany, France and other European countries. Bicycles are also widely used for racing in France, Germany, Belgium and to a lesser extent in England and the United States (*see* CYCLISG).

Experiments in adding engines to bicycles to render them independent of human propulsive power began in the 1880s. For a discussion of these powered devices, *see* MOTORCYCLE

Early Types.—The first ridable bicycle was made by Kirkpatrick Macmillan of Dumfriesshire, Scot., in 1839, but many less efficient and similar inventions had preceded his work. Early devices lacked any form of steering and had to be propelled by pushing the feet against the ground. Machines of this type appear on bas-reliefs in Babylon and Egypt and on frescoes in Pompeii. Another picture of an early bicycle in a stained glass window, dated 1580, in the parish church at Stoke Poges, Buckinghamshire, depicts a cherub astride such a crude machine. A *célérifère* of this type. demonstrated by the comte de Sivrac in 1791, consisted of a wooden bar connecting two wheels, on which the rider sat A velocipede built by M. Blanchard and M. Masurier in 1779 was described in the *Journal de Paris.*

In 1816 J. N. Niepce of Paris and in 1817 Karl von Drais de Sauerbrun produced steerable devices; Niepce's machine was called a *célèripède,* and Drais' device a *laufmaschine.* The enterprising Drais' machine became popular under the name of draisine and within a year or two Dennis Johnson of London was manufacturing it for the regency dandies—including the prince regent—under the name of dandy horse or hobbyhorse. Several varieties of these machines were made in the United States but the vogue did not last long. After five years of experimenting, Macmillan produced a hobbyhorse which could be propelled without the rider's feet touching the ground. He had added reciprocating cranks at the front, which were connected by rods to the rear wheels. The machine had wooden wheels with iron tires, the leading wheel being about 30 in. in diameter and the driving wheel about 40 in. in diameter. It was copied in the 1840s by Gavin Dalzell of Lesmahagow, Lanarkshire, who later made several of these bicycles.

Bicycle design was retrogressive during the next two decades, because the next type to be introduced employed rotating cranks integral with the front hub. This type of machine was built by Pierre and Ernest Michaux of Paris following an experiment with a hobbyhorse in 1861. They adapted the idea from the crank handle of a grindstone, according to the account written by Henry Michaux in 1893. In 1862 Karl Kech of Munich built such a machine (it is preserved in the Deutsches museum, Munich). In 1861 the Michaux family produced two *vélocipèdes,* in 1862, 142, and by 1865 they were making 400 bicycles a year. In 1866 one of their mechanics. Pierre Lallement, became disgruntled by their treatment of him and emigrated to the 'United States, where, with James Carrol of Ansonia, Conn., he took out the first bicycle patent in the United States.

The Michaux concern had placed France in the forefront of bicycle development. and new companies for their manufacture sprang up rapidly. One of these. Tribout and Meyer, is said to have produced a chain-driven bicycle as early as 1869. In this year the first cycle show (in Paris) and the first cycle road race (from Paris to Rouen) took place. The 83-mi. road race was won by an Englishman, James Moore. At the show, primitive forms of freewheel and speed-change mechanisms were also displayed. Meanwhile Rowley Turner, the Paris agent of the Coventry Sewing Machine Co., persuaded the company to begin making the *vélocipèdes* in Paris, and in 1868 he rode one from Coventry station to the factory, as a demonstration. An order for 400 bicycles was obtained from France and work was started under a new name, the Coventry Machinists' Co. Ltd. However, when only a few "bone shakers" (as they came to be called) had been delivered, the Franco-German War began and the firm was obliged to find a market for the bicycles in England, where the new machines were accepted and races began.

The "Ordinary" Bicycle.—Many men, such as Thomas Humber, Henry Sturmey and Dan Rudge, began to make bicycles at this time, but the man who is known as the "father of the cycle industry," James Starley, became associated with cycling indirectly, as a 67-year-old foreman at the Coventry Sewing Machine Co. His inventive brain soon thought of improvements which were incorporated in the bicycle. In 1870 Starley patented a tension-spoked wheel in which the rim and the hub were connected by looped wire spokes. By rotating the hub in relation to the rim, equal tension could be obtained over the whole wheel. That same year he designed a light bicycle with a large driving wheel and a smaller trailing wheel. which established the shape of the bicycle for the next ten years. Introduced in 1871. his Ariel bicycle could be equipped with a gear which allowed the wheel to revolve at twice the speed of the cranks. This was the "ordinary" bicycle, known colloquially as the "penny-farthing." The ordinary bicycle gained ground even more rapidly than its predecessors because of its simplicity and because, as improvements such as tubing were incorporated, it became lighter in weight.

The next great improvement was the patent by W. J. Grout of London for spokes which were threaded into eyed nipples, followed in 1874 by his patent for threaded nipples, as on the modern bi-

cycle. and Starley's patent for the tangential spoked wheel. These inventions greatly improved the performance of the ordinaries because their immense driving wheels were so hard to turn at first. In 1873 four riders traveled frorn London to John o'Groats, about 690 mi., in 15 days, demonstrating the reliability of the ordinary.

An average ordinary weighed slightly less than 50 lb., but some were made which weighed only 21 lb. Front wheels varied between 40 and 60 in. in diameter according to the leg length of the rider. The machines were unstable and falls were frequent. Because of the peculiar skill needed and because of the smooth "ride" of the huge front wheel, however, ordinaries endeared themselves to riders and were widely used for some years after the introduction of the safety bicycle. But the fact that only long-legged men could attsin any real speed meant that cyclists of average build turned to other forms, such as the tricycle.

The Safety Bicycle.––This was the name given to the first chain-driven bicycle. which n-as designed by H. J. Lawson in 1874. It had two medium-sized wheels of equal diameter, the rear wheel being driven by a chnin running on two sprockets. Further experiments followed in England and France and it was about this time that the cycle industry was established in the United States; in 1877 Col. Albert A. Pope of Boston. Mass., organized the Pope Manufacturing company to produce ordinary and. later. safety bicycles, and it was with this company that the pioneer Lallement ended his working career.

The safety did not become fully established until the advent of the Rover safety in 1885. This; the first practical production machine, was manufactured by John K. Starley. a nephew of the original Starley. After its successful introduction, the days of the ordinary were numbered. In four years the safety dominated the market and within another few years no more ordinaries were being made.

An invention which made the bicycle a more comfortable means of transport was that of the pneumatic tire by John Boyd Dunlop, a Belfast veterinary surgeon, in 1888. Although a patent specification hnd been filed in 1845 by R. W. Thomson, Dunlop's was the first application of the idea. He met with opposition, hut racing prover! the worth of the new tires and, as the methods of attaching tires to the rims improved, the pneumatic tire became established until. within five years. solid tires and the semihollow cushion tires had been virtually eliminated.

The combination of the pneumatic tire and the stable safety bicycle gave the industry an immense impetus. During the 1890s the young cycle industries of Europe and the United States boomed; then came a slump and the industry was reorganized to build inexpensive, practical machines. By 1893 the design of the bicycle had been stabilized into the modern diamond frame with roller-chain drive and pneumatic-tired wheels. Thereafter, only accessory changes were made.

The **Modern** Bicycle.—A contemporary bicycle can be expected to carry up to ten times it. own weight and can be bought equipped with four gear ratios. constant-voltage lighting. internal expanding or caliper brakes (see *Brakes,* below), a completely protected transmission and full weather and touring equipment It will run nith a minimum of attention for many years Bicycles vary from about 15 lb to nearly 40 lb. depending on the needs of the rider; the lightest are only suitable for special tracks.

Frames.—There are three types of bicycle frame. The commonest is the diamond pattern, formed by three triangles of steel tubing. One triangle is formed by a horizontal (top) tube joined to a nearby vertical (seat) tube, the two ends being linked by the tube which forms the third side. The seat tube is also the base for the other two triangles, which project rearward from it in a narrow V. They are formed by the seat stays, which project downward from the top of the seat tube, and the chnin stays, which are nearly horizontal and which project from the base of the seat tube. At the top and bottom of the seat tube are the saddle and the driving sprocket. The apex of the forward triangle holds the steering forks and that of the rear triangles holds the rear wheel. Each tube is subjected only to compressive stresses along its length, with the exception of the steering forks, which are deliberately arranged so as to afford a measure of springing.

The second type of frame is the cross, a single main member, usually made of pressed steel. to which are attached the steering forks and the seat tube. This type of frame is frequently used ior motor-assisted bicycles. popular on the continent oi Europe.

The third frame is the loop type, in which the top rube and down tube of the diamond frame are curved in parallel to give clearance for women's skirts. It is commonly found in the United States in a compact form.

Frames are built either by brazing or by welding, the latter being cheaper and stronger. The Dayton Cycle Co. developed a system of electrically fused joints, employing the resistance crcatcd at the junction of two tubes and using no solder. In brazing. the tubes are fitted into lugs or sockets which can be obtained in a variety of angles. generally about 70°, which is upright enough for the bicycle to he light and easy to steer while still doped enough for the forks to be self-centring. The tubes are first cut to the correct shape so that there is a mitred joint between upright and horizontal tubes. Then the tubes are fitted into the shaped lugs—usually made of pressed or cast steel—and heated. and the slight space between the lug and the tube is filled with a molten. brass alloy. In welding the same preparatory steps are followed, hut no lugs are used; the tubes are directly joined with molten steel rod instead of brass. Welding gives a joint which is actually stronger than the tubes it joins, but it is not often found on mass-produced frames in Britain, although it is common elsewhere in Europe and in the United States. Some frames are assembled partially by using bolted seat stays made from D-shaped seamed tubing, but this method is used only for cheap frames.

Bicycle tubing is seamless and frequently butted at each end to a heavier gauge to provide extra strength at the joints. Mild steel was originally used but this has largely been replaced by special alloy steels; as a result, most contemporary bicycles are lighter and more responsive than their pre-World War II counterparts.

Accessories.—Bicycle accessories are usually made so that rhey may be clipped or bolted onto the frame, but in continental Europe small lugs are frequently brazed onto the frame to form permanent brackets for extra fittings. In this way a clean outline is preserved and the fittings cannot shake loose. Typical items which may be attached to brazed lugs are pannier (basketj carriers, mudguards and chain guard. lamps, gear cables and brake cables. a *dérailleur*

gear and even brake levers. In Britain, items like this are fitted with small spring or bolted clips. which reduces the cost of frame building while making the range of attached accessories more flexible.

Wheels.—Wheels consist of rims attached to central hubs by tensioned wire spokes; the spokes are threaded at one end and screwed into nipples in the rim so that tension may be maintained. Any combination of spokes—in multiples of four—may be used; in England 32 are put in a front wheel and 40 in the rear, though elsewhere 36 are used in both wheels. Other combinations are used for some racing machines. Spokes are usually made from 15-gauge wire, but on many bicycles rustless spokes are used which have only the ends made of 15-gauge, the centres being thinner. Extra-heal? machines use heavier-gauge spokes.

Rims are made from steel or aluminum alloy and are frequently hollon-. There are three patterns. The largest is the Westwood, which is so shaped that the stress from the brake shoes is in the same direction as the stress imposed on the spokes by the nipples. It is made from steel strip rolled over at the edges to provide two shoulders to contain the wired edges of a tire. The Endrick pattern. square in cross section with the brake shoes pressing against the vertical sides, is often similarly rolled. but may be of extruded aluminum alloy. The third shape of rim is formed from an extruded tube with a shallow depression worked into its periphery to hold a onr-piece tire. The tube is frequently reinforced by the insertion of specially shaped washers or a wooden strip. Light alloy and stainless steels are easily kept clean, and plain steel rims are usually chromium plated. Westwood rims are more common when "balloon" section tires are used or when internal expanding brakes are fitted, as in the United States. Rims are made in 26- and 27-in. sizes, the size being the total diameter of the wheel when the tire is inilated.

The hub consists of a steel or light alloy, barrel flanged and drilled at each end to accommodate the spoke heads. Through the barrel passes a hardened steel spindle equipped with two cones which bear on balls running in cups pressed into the barrels. Adjustment is effected by screwing the cones on the spindle.

The rear hub is threaded to hold the driving sprocket or freewheel. Where the sprocket is fixed, two threads, right- and left-hand, are used to provide for a locking ring to secure the sprocket. Most hubs are threaded only on the right-hand side, but some have both types of thread, or twin threads of the same type. Almost universal acceptance of variable gears has led to the disappearance of the single-fixed-sprocket hub, except in highly specialized bicycles.

There are three specialized hubs; one contains an epicyclic variable gear. one has the freewheel mechanism built in and the third is the coaster or back-pedaling brake employing a phosphor-bronze expandable ring actuated by a tapered member sliding on a quick thread. The cyclist may freewheel. but if the sprocket is moved backward relative to the frame. to which the other side of the hub is bolted. then the taper slides across to force the ring against the hub shell and stop the mheel.

Variable Transmission.—Devices to improve the speed of the machine for a given pedaling rate are of two types: the *dérailleur*, which requires movement of the chain from sprocket to sprocket, and the epicyclic. which alters the speed of the driving sprocket relative to the rim.

A *dérailleur* is simple. strong and easily varied in range for different types of terrain. It consists of a mechanism which can move ("derail") the chain from one sprocket wheel to another of different size. By varying the relative size of the driving sprockets, the rear wheel can be made to pass through more or fewer revolutions for each turn of the crank. Cyclists can use up to six sprocket wheels an the rear freewheel and three on the cranks, providing up to 18 different ratios. For the tourist, who may encounter long, steep climbs and long descents. this type of gear can be invaluable. Save for one or two special types of race—as on a track—racing cyclists invariably employ five or ten gears by use of a *dérailleur*. The mechanism is spring loaded to absorb the chain slack and is controlled by cable from the frame or handle bars. Gears may be fitted to the chain stays or screwed into a lug integral with the fork end.

An epicyclic gear is more complex and fragile, but since it is totally enclosed it is less susceptible to accidental damage. It employs constant-mesh epicyclic gear trains working on this principle: The driving sprocket is connected to a central "sun" wheel in the hub. The hub barrel has cogs in the form of an annulus ring on its inner surface. Between the sun wheel and the annulus are "planet" wheels. As the driving sprocket is turned, the annulus ring (*i.e.*, the hub) revolves in the same direction. If the planet wheels are allowed to revolve round the sun, the hub revolves more slowly than the driving sprocket. If the planet wheels are fixed, it revolves more quickly. If the whole mechanism is locked with a dog clutch, the hub revolves at exactly the same speed as the driving sprocket. Thus three speeds are obtained with a single hub. The use of a second epicyclic train provides four speeds, an extra-low gear being available. This principle has been used in many types of gear, both in the rear hub and in the crank axle. It has proved to be the most popular and was patented by J. J. H. Sturmey and J. Archer under a variety of headings between 1901 and 1906. It weighs, in hub form, about 2 lb. and can be obtained in three- or four-speed form with the gear ratios widely, moderately or narrowly spaced to suit the rider's preference. The four-speed form uses two epicyclic trains linked and was developed in the late 1930s. These hubs are made in combinations—gear and dynamo, gear and internal expanding cable-operated brake, and gear and coaster brake. The epicyclic gear can also be combined with a *dérailleur* gear to give a selection of eight gear ratios. (See GEARS.)

Tires.—Pneumatic tires made under the patent of J. B. Dunlop are invariably fitted to modern bicycles. They are in two sections, the inner tube and the outer cover. Inner tubes were for years made from pure rubber. but research initiated during the rubber shortages of World War II led to the development of butyl, a synthetic rubber which has about one-tenth the porosity of natural rubber and does not deteriorate with age. The outer cover is

made from cotton, nylon, silk or similar tough fabric on which is molded a tread of butyl or of rubber having a high carbon content. Outer covers have stiff wire rings molded into the inner perimeters. These rings are the same size as the rim and are forced against the shoulders of the rim by the pressure of the air. The rim includes a well which enables the tire to be moved eccentrically during fitting.

Some tires, made for racing bicycles, are fitted with outer covers that do not have wired edges. These tubular tires have sewn or glued edges, so that the complete tire presents the appearance of being in one piece. They are attached to the shallow tubular racing rim with adhesive and. since they constrict on inflation, so long as they are correctly applied and inflated there is no danger of them coming off. They are built with narrow treads and usually have sides of waterproof fabric instead of being all rubber. Light fabrics are used, such as sea-island cotton or silk, and the tires can weigh as little as $3\frac{1}{2}$ oz. each. *(See* TIRE.)

Brakes.—Brakes function in two ways: either externally, by the contraction of calipers containing brake shoes against the rim of the wheel, or internally. by the expansion of similar shoes against a drum mounted on the hub or in the hub itself.

The simplest of the internal brakes is the coaster hub, which needs no maintenance and has no part which could be damaged in a minor accident. With little adjustment such a brake will last the probable lifetime of a bicycle. For this reason, and for the fact that it is probably the most powerful brake, it is popular for utility use in the United States and in Europe. Other internal brakes with special drums are used in the manufacture of small powered bicycles and in some touring machines, where their advantage of being unaffected by water makes them particularly useful for faster traveling, or on heavily loaded machines.

External brakes are operated either by stirrups or calipers. Stirrup brakes are applied by rods on Westwood rims and are positive in action, but impede the rider when he has to remove a wheel. Caliper brakes are applied by cable and press brake shoes against the flat sides of Endrick or tubular rims. Another cable-operated brake. patented in 1929, is the cantilever, which employs twin bell crank levers and a duplex cable. The brake shoes on this type of brake are extremely long and it is the most efficient of the external brakes.

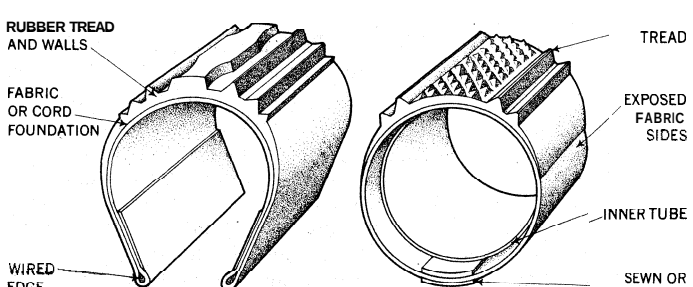

FIG. 5.—PNEUMATIC TIRES: (LEFT) WIRED-ON TIRE COVER FOR ROAD USE: (RIGHT) TUBULAR TIRE WITH INNER TUBE FOR RACING

Transmission.—Though shaft-driven bicycles have been made, transmission normally consists of a chain and two sprockets. The chain is made of steel plates $\frac{1}{2}$-in. long linked by rivets of hard steel; the rivets are bushed on rollers which turn freely when pressure is applied. The width of the driving surface is normally $\frac{1}{8}$ in.; however. heavy bicycles, such as mopeds (motor bicyclesj and commercial carrier machines, employ $\frac{3}{16}$-in. chain, and racing bicycles with a *dérailleur* gear employ a specially made flexible chain with driving plates $\frac{3}{32}$ in. apart.

The chain runs over a front driving sprocket attached to the cranks. The cranks are on a hardened steel axle mounted on ball bearings running in cups which screw into a cylindrical barrel at the junction of the down and seat tubes and the chain stays. In the United States the two cranks and the axle are in one piece, and this method is favoured in Europe on utility bicycles. The cranks are usually forged, and the front sprocket or chain wheel screws onto a thread on the cranks.

In England and on touring or racing machines in Europe the cranks are separate from the axle and the chain wheels bolt onto arm extensions of the crank. More and more commonly cranks are made from heat-treated aluminum alloy forgings which fit on square tapers on the axle, forming a light, firm and rigid driving unit which is easily removed in the case of racing machines. When the cranks are made of steel, they are fitted with a cotter pin, which is a bolt having a wedge action against a flat area on the axle. Such cranks are invariably chromium plated. Cranks are 6–7 in. long to suit the rider.

The rear sprocket may be in the form of a freewheel of two concentric members, one carrying the thread and the other the cogs. The outer member runs on ball bearings and incorporates a ratchet against which spring-loaded cams play so that drive can only be in one direction. Freewheels are made in combinations up to six sprockets having from 13 to 28 cogs each.

Projecting from the extremities of the cranks at right angles (*i.e.*, parallel with the hubs and the axle) are the pedals, consisting of footrests mounted on hardened axles with ball bearings. The axles screw into the cranks with right- and left-hand threads so that the pedaling action is self-tightening.

Thus, to drive the bicycle, the rider places his feet on the pedals and rotates the cranks. This turns the driving sprocket, which usually has about 48 cogs. The chain runs over this and the rear sprocket, which usually has about 18 cogs. For each revolution of the cranks, therefore, the chain is pulled forward 48 links. Since

each link represents one cog, the rear wheel is thus turned through about two and two-thirds revolutions. This is the principle on which the *dérailleur* gear is based.

Saddles.—For comfort the rider sits on a saddle made of a resilient material such as leather, rubber or plastic. The frame of the saddle is either made from spring steel or it holds springs which act as shock absorbers. Saddles are made in many shapes and are probably the most important part of the machine from the point of view of the rider.

Lighting.—Originally bicycles were lighted by an oil lamp or at least a lamp using a flame as the source of light. The development of the dry-cell battery led to simple, lightweight, battery-electric lights which are cheap and easily replaceable. A more common form of lighting is provided by a dynamo, which is usually bolted onto one of the forks with a spring-loaded connection so that the dynamo driving pulley can be set to rub against the side of a tire and thus revolve as the machine proceeds. A single lead suffices to supply the current, the frarne acting as the ground return for the electricity.

In England the Sturmey Archer concern, which had been producing light, compact dynamo equipment, introduced in 1937 a hub which incorporated a dynamo. This combination, though turning relatively slowly and producing only 25-cycle alternating current, was virtually frictionless and waterproof. The dynamo is also produced in combination with an epicyclic gear. After World War II the manufacturer removed the obstacle of 25-cycle "flutter" by fitting a voltage regulator connected to a dry-cell battery so that the lighting is constant instead of fluctuating with the speed of the bicycle.

Luggage Accommodation.—Luggage is carried in containers, usually leather or canvas bags slung on the bicycle. The most common mounting is that of a bag slung from two loops in the rear of the saddle frame. Baskets are frequently slung from the handle bars. Touring bicycles have additional accommodation in the form of a steel- or light-alloy frame mounted over the rear wheel which enables two bags to be slung vertically, one on each side of the rear wheel. This has the advantage of lowering the centre of gravity when loads are heavy.

Multiple Bicycles.—Though at one time these were common, the only type left is the tandem. on which two riders sit one behind the other, the front one steering. Most parts are duplicated on the machines. even to the extent of a separate hub brake operated by the foot of the rear rider. Tricycles and even tandem tricycles are found, mainly in Great Britain. The development of the tricycle contributed materially to automobile design through the invention of the hub brake and the differential.

See C. F. Cauntcr, *The History* and *Development of Cycles: As Illustrated by the Collection of Cycles in the Science Museum London* (1955–). (AL. H. *G.*)

BICYCLE RACING: see CYCLING.

BIDA, a town in the Niger province of the Northern Region, Nigeria, Africa. and a former Fulani emirate capital, lies at 400 ft. above sea level in the broad valley of the Niger in wooded savanna country. Pop. (1960 est.) 22,222. The town, which is well shaded by trees, is divided roughly into four by two main streets, and the mud houses are grouped into customary family compounds. The town wall encloses about 5 sq.mi. The emir's palace, outside the west gate, is in traditional northern architectural style, and the few modern buildings include a hospital and a secondary school. Bida is 10 mi. W. of the Baro-Minna branch of the Lagos-Kano railway and on the main road from Jebba to Jos and the east. There is a landing strip for light aircraft north of the town.

Bida is famous for its native crafts: brass, copper and white metal work (notably the Bida goblets), glass beads and bangles, straw hat and mat weaving and cloth dyeing. The craftsmen work by hand on their own premises and are organized into close-knit guilds which originated in the military requirements of the emir.

Bida was founded by the Nupe in the 15th century and conquered by the Fulani in the 19th century. Under the Fulani emirs, the Nupe people continued to dominate this stretch of the Niger until the defeat of the Fulani army in 1897 by the British, who assumed effective control of Bida in 1901.

BIDAR, a town in Mysore state. India, the headquarters of Bidar district. lies 2,300 ft. above sea level 68 mi. N.W. of Hyderabad. It is reached by northward branches of the main Hyderabad-Bombay road and railway. Pop. (1951) 31,341. The town is celebrated for Bidri ware—gun metal articles damascened in floral and geometric designs with silver wire. The craft.. once applied to sword hilts. produces bowls, flasks, salvers and ash trays.

Bidar, a place of some importance under the medieval Hindu dynasties, was captured by the Muslim prince Fakhr-ud-din Juna (later Sultan Mohammed ibn Tughlak of Delhi) in 1324. When the Deccan broke away from the sultan under the Bahmanis in 1347, Gulbarga (*q.v.*) was at first their capita!; but in 1430, because of ill-health. Sultan Ahmad Shah Bahrnani moved to Bidar. When the Bahmani kingdom disintegrated about 1492, the sultans retained a small principality around Bidar, though real power was in the hands of the Barid family. their ministers; by 1531 Ali Barid had openly proclaimed himself sultan of Bidar. About 1619–20 the Barid Shahi territory was annexed by the 'Adil Shahi sultanate of Bijapur. Bijapur held Bidar. with one interruption (1624) when it was pillaged by troops from Ahmednagar. until its capture by the Mogul viceroy Aurangzeb in 1657. In lo86 it was formally annexed to the Mogul empire. On the breakup of that empire about 1724 Bidar fell to the nizam of Hyderabad. When Hyderabad was partitioned under the 1956 linguistic reorganization of states, Bidar town and district were transferred to Kannada-speaking Mysore.

Ahmad Shah Bahmani's fortress at Bidar has a triple moat, strong laterite walls and a ditch. Within are the remains of the Rangin Mahal or "painted palace." so called from its decoration with coloured Persian tiles; the Takht Mahal or throne room; and other palaces. There are also the Jami Masjid or great mosque and the Sola Khumba or "Sixteen-pillar" mosque. typical Bahrnani buildings without minarets or prominent domes. Another notable Bahmani monument is the great *madrasa* or college built in 1472–81 and now a massive ruin. Northwest of the town are the splendid domed tombs of 12 Bahmani kings, and to the west the royal necropolis of the Barid Shahi sultans.

BIDAR DISTRICT, the northernmost of Mysore, has an area of 2,072 sq.mi. Pop. (1961) 656.590. The main crops are *jawar* (millet), wheat, oilseeds and pulses. Soapstone. red ochre. red and yellow laterite and black basalt building stone are extracted, also a gypsumlike mineral used for waterproofing flat roofs. Kalyani, 42 mi. W. of Bidar town, was the capital of the second Chalukya dynasty (*q.v.*) in the 10th–12th centuries A.D.

BIBLIOGRAPHY.—G. Yazdani. *Antiquities of Hidar* (1947); and, for an eyewitness account of Bidar under the Bahmanis, the notes of the Russian merchant Athanasius Nikitin, *India in the 15th century* ed. by *R.* H. Major (1858). (S. AH.)

BIDAULT, GEORGES (1899–), French statesman distinguished as a foreign minister in the fourth republic. was born at Moulins (Allier) on Oct. 5, 1599, and educated at the Jesuit college in Turin, Italy, and at the faculty of letters in the University of Paris. A history teacher, he entered politics as a writer for the Christian Democratic paper *L'Aube*. Active in the resistance to the Germans during World War II, he became president of the national council of the Résistance in 1943. In Sept. 1941, when Gen. Charles de Gaulle appointed him foreign minister, he started to play a major part in the revival of France as a diplomatic force.

Having helped to found the new Christian Democratic party, the Nouvement Républicain Populaire (M.R.P.), Bidault was elected a deputy in Oct. 1945 and was a leading member of parliament throughout the fourth republic. He remained foreign minister for more than two years, until Dec. 1946, serving also as prime minister for the last six months. He became foreign minister again in Jan. 1947, hut as the supporters of conservatism at home and integration in Europe gained strength his influence waned, and in July 1948 he was replaced by his M.R.P. rival. Robert Schuman. In the economic crisis of autumn 1949 he proved himself a mediator between the Socialists and the other centre parties and was prime minister again for seven months. After his defeat in June 1950 he was a

vice-premier in three of the subsequent cabinets. He was still considered a man of the left-centre, but after returning to the foreign ministry in Jan. 1953 he moved to the right, accepting the settlers' *coup d'état* in Morocco and vigorously supporting the war in Indochina. In June 1954 the fall of Joseph Laniel's government ended his career as a minister of the fourth republic. He became a vigorous advocate of the settlers in Algeria and was associated with the movements that caused the collapse of the fourth republic. *(See* FRANCE: *History.)*

In the fifth republic Bidault, now out of sympathy with many in the M.R.P., created a new Christian Democratic movement, supported by former Vichyites holding views on Algeria similar to his own. Re-elected a deputy in Nov. 1958, he vehemently opposed General de Gaulle's Algerian policy because of its liberalism. (P. W. C.)

BIDDEFORD, a city of York county, Me., U.S., on the west bank of the Saco river, 15 mi. S.W. of Portland.

In 1630 Capt. Richard Vines led the first settlers to the site. After 1718 the town was called Biddeford for the home of early settlers who came from Bideford, England. In 1762 the communities on the two sides of the river separated, that on the east bank becoming Saco. Biddeford received its city charter in 1855.

The abrupt drop of the Saco river furnished power for Biddeford's economic development. The milling of lumber and, after mid-19th century, the manufacture of cotton textiles have been important industries.

For comparative population figures *see* table in MAINE: *Population.* (WM. B. W.)

BIDDING PRAYER, the name applied to various sets of prayers in Anglican and Lutheran usage, in which the minister tells the people what to pray for. Such formulas of exhortation are of great antiquity in both eastern and western churches. One of the oldest surviving forms is that traditionally appointed for Good Friday. Bidding prayers include intercessions for the church, the state, the Jews and the ministry of the church. Originally "bid" meant "to pray," but this has become obsolete and the "bidding" has come to mean the exhortation itself. (J. J. PN.)

BIDDLE, JAMES (1783–1848), United States naval officer, and nephew of Capt. Nicholas Riddle of the Continental navy, was born in Philadelphia, Pa., on Feb. 18. 1783, and in 1800 was appointed a midshipman in the navy. His early training was under Thomas Truxtun on the frigate "President." Retained in 1801 when the navy was reduced, Biddle served on the "Constellation" in the Mediterranean in 1802. He had the misfortune to be on the "Philadelphia" when that frigate ran on the rocks off Tripoli, and spent 19 months in prison there with William Bainbridge. David Porter and other officers. Following the Barbary Wars, he secured leave and made a voyage as a mate in the China trade. Upon his return he was promoted to lieutenant and was second in command of the "Wasp" when that vessel took the "Frolic" in one of the famous single-ship actions of the War of 1812. When a British 74-gun ship captured the "Wasp" and retook the "Frolic," Biddle had a second experience as a prisoner of war. When he was exchanged. in 1813, he found himself a master commandant and in command of the brig "Hornet." In this vessel he engaged the "Penguin," of equal weight of metal, and on April 27, 1815, escaped an enemy ship-of-the-line for the last naval engagement of the war. In 1817 Biddle, serving in the Pacific. took formal possession of the Oregon territory. Subsequently he served in the South Atlantic, Mediterranean and Gulf of Mexico. In 1846 he negotiated the first treaty between the United States and China and during the Mexican War was in command on the Pacific coast. He died at Philadelphia on Oct. 1. 1848.

See *Charles Biddle's Autobiography* (1883); *Brown's American Naval Heroes* (1899); Theodore Roosevelt, *The Naval War of 1812* (1882). (W. B. CK.)

BIDDLE, JOHN (1615 or 1616–1662), often called the father of English Unitarianism. was born at Wotton-under-Edge, in Gloucestershire. He was educated at the grammar school of his native town and at Magdalen hall, Oxford. being subsequently appointed to the mastership of the free school in Gloucester. A treacherous friend obtained the manuscript of his *Twelve Arguments Drawn out of Scripture, Wherein the Commonly Received Opinion Touching the Deity of the Holy Spirit Is Clearly and Fully Refuted*; and in Dec. 1645 he was summoned before the parliamentary committee then sitting at Gloucester, by which he was committed to prison. He was released on bail after a short imprisonment but in July 1647 was called before parliament, which desired to inquire into his views. After tedious proceedings Biddle was committed to custody, and his *Twelve Arguments*, which he had now published. was ordered by parliament to be seized and burned. Biddle's tracts attacking the doctrine of the Trinity were suppressed, and the Westminster assembly of divines eagerly pressed for the death penalty for heretics like him. This was resisted by the army and by many of the Independent parliamentarians, and after the death of the king Biddle was allowed to reside in Staffordshire under surveillance. In Feb. 1652 the general act of oblivion gave him complete freedom. and his adherents soon began to meet regularly for worship on Sundays. They were called Biddellians, or Socinians, or Cnitarians. the name which has now become associated with their opinions. Biddle was not left long in peace. He translated some Socinian books, among others the *Life of Socinus*, and published two catechisms which excited a fury of indignation. He was summoned before the parliament in Dec. 1654 and imprisoned. The dissolution of that body again set him at liberty, but he was presently rearrested and was only rescued by Cromwell, who sent him (Oct. 1655) to one of the Scilly islands, allowed him 100 crowns a year. and in 1658, on the solicitation of many friends, released him. For a few years he lived and taught in the country, but. returning to London, he was again arrested, in June 1662, and fined £100. As he was unable to pap this sum, he was at once committed to prison, where he died of fever on Sept. 22, 1662.

The "Unitarianism" of Biddle professed to be a restoration of primitive biblical teaching, but with his stress upon the Bible he combined a rationalism that showed affinities with the Deism of his time. Thus his overt attacks were directed against the traditional doctrine of the Trinity of persons in the Godhead, but the ultimate issues at stake were the Christian understanding of salvation and the Christian doctrine of revelation. *See* also UNITARIANISM.

See J. Toulmin. *A Review of the Life, Character and Writings of the Rev. John Biddle, M.A. (1791).* (J. J. PN.)

BIDDLE, NICHOLAS (1786–1844), **U.S.** financier and litterateur who, as president of the Second Bank of the United States from 1822 to 1836, made it the first effective central bank in U.S. history, was born in Philadelphia, Pa., on Jan. 8, 1786. A precocious student of the classics and of French literature; he completed his studies at the University of Pennsylvania at the age of 13, and at 20 he contributed to *Port Folio,* the first Cnited States literary periodical, of which he later was editor. From their notes, he wrote the *History of the Expedition of Captains Lewis and Clark.*

Making law his profession, he had an early career in diplomacy, becoming secretary of the U.S. legation in London (1806) under James Monroe) with whom he formed a lifelong friendship. In 1811, then a member of the state senate. Biddle prepared Pennsylvania's reply to the address of the Hartford convention, which had proposed a number of amendments to the federal constitution limiting the power of congress and of the executive. In 1819 Biddle completed for the U.S. department of state *Commercial Regulations*—a digest of foreign legislation affecting United States trade.

As president of the Second Bank of the United States. Biddle helped to develop the theory and practice of central banking. Among the bank's accomplishments were regulation of the supply of money; restraint of the expansion of bank credit; government of the exchanges; safeguarding of the investment market; protection of the money market against disturbances arising from treasury operations and imbalance in international and interregional payments; facilitation of treasury operations; organization of the discount market; and provision of a safe depository for government moneys.

However. the Jacksonians, assisted by Biddle's political ineptitude. were able to unite elements opposed to the hank's

restrictive policies and terminate it in 1836 (for the issues in this controversy, *see* BANKING: *History of Banking: The United States*). It was rechartered, by Pennsylvania, with Biddle as president, but expired in 1841, partly because of his poor business judgment.

In 1839 Biddle retired to Andalusia, his country estate, subsequently celebrated for its *salons*. He died in Philadelphia, Feb. 27, 1844.

See Bray Hammond, *Banks and Politics in America, From the Revolution to the Civil War* (1957). (J. J. S.)

BIDEFORD, a municipal borough market tonn and small port of north Devon, Eng., 9 mi. S.W. of Barnstaple by road. lies mainly on the left bank of the wide Torridge estuary in the centre of Bideford Say. Pop. (1961) 10.265. The small harbour is dry at low tide. Near it the stone bridge across the Torridge has 24 uneven arches and replaced an earlier wooden one of about the 15th century. There are some old houses, a museum and an art gallery. Bideford's few industries include timber importing. boat-building, the making of gloves and concrete products, and tourism. In Domesday Book the town appeared as Bediforda and from the days of William II to i757 the manor (now owned by the borough council) was held by the de Granville (or Grenville) family, to which Sir Richard Grenville, the naval commander, belonged. Like Bernslaple. Bideford had a large woolen trade (chiefly serges) until the 18th century and a shipbuilding industry in connection with it; pottery was also made. The town received its main charter in 1573 and prospered early in the tobacco and salt fish trade with America. After the railway came in 1856 Bideford became less seafaring and more agricultural and residential, as well as a holiday resort, with the romantic associations fostered by Charles Kingsley's writings. One of his novels gave its name to the "little white town" of Westward Ho, which lies 3 mi. N.W. and has a long. sandy beach on the Atlantic coast..

BIDJUGO (known also as BIJOGO or BISSAGO), an African people of the Ilhas dos Bijagós (Bissagos Islands), off Portuguese Guinea, west Africa, numbering 9.211 (1950 census) and speaking an individual language of the western Atlantic group. They are very different from the mainland tribes, whom, for centuries, they used to raid in remarkable war-canoes. The Bidjugo have great artistic skill, especially in wood carving, and perform animal dances in masks. They are divided into clans. and women have considerable freedom and influence, especially the priestesses, who have sometimes been queens. A largely animistic religion strictly regulates their individual and social life, and they exist chiefly on palm tree products. Very conservative: they have assimilated much less European influence than the other tribes of Portuguese Guinea.

BIBLIOGRAPHY.—H. A. Bernatzik, *Äthiopen des Westens* (1933), *Im Reich der Bidyogo* (1944); A. J. Santos Lima, *Organisação Económica e Social dos Bijagós* (1947). (A. T. DA M.)

BIDPAI, FABLES OF, the name under which a famous collection of Indian fables has become known in Europe. They are called after an Indian sage Bidpai, the narrator, and illustrate practical wisdom under five heads in the form of animal stories. The original Sanskrit work composed about A.D. 300 is lost. The oldest knon-n Indian version is the *Tantrakhyayika* ("Book on Cases of Wisdom") and there is another version, the *Panchatantra* ("Five Cases of Wisdom"), and a recension of this, the *Hitopadesa* ("Book of Good Counsel").

The original five stories; together with some later Indian additions! were translated into Pahlavi (middle Persian) by the Persian royal physician Burzoe in the 6th century. Although this work also is lost a Syriac translation of it has survived, together with the famous 8th-century Arabic translation by Ibn al-Muqaifa known as *Kalila wa-Dimna* after the two jackals that figure in the first story. The *Kalila wa-Dimna* led on to various other versions, including a second Syriac version and an 11th-century version in Greek, the *Stephanites kui Ichnelates,* from which translations were made into Latin and various Slavonic languages. The 17th-century Turkish translation. the *Humayun-name,* was based on a 15th-century Persian version, the *Anwar-i Suhayli.*

In Europe a version was written in Latin hexameters by the fabulist Baldo in the 12th(?) century and in the 13th century a Spanish translation was made on the orders of Alfonso X of Castile. It was the 12th-century Hebrew version or' Rabbi Joel, however, that became the source of most European versions. First translated into Latin by John of Capua as the *Liber Kelilae et Dimnae* or the *Directorium Vitae Humanae,* it led to various European versions including another Latin version. the *Liber de Dinn et Kalila* by Raimond of Béziers, in the 14th century and the *Buch der Beispiele der alten Weisen* by A. von Pforr in the 15th century. Sir Thomas North's *The Moral Philosophie of Doni* (1601) is a translation of A. F. Doni's 16th-century Italian version.

BIBLIOGRAPHY.—The *Tantrakhyayika* was ed. by J. Hertel (1910); German trans. by J. Hertel (1909). The *Panchatantra* was ed. by F. Edgerton, with Eng. trans. (1924); Eng. trans. by A. W. Ryder, 6th ed. (1925). Ibn al-Muqaffa's Arabic *trans.* was first ed. by A. Silvestre de Sacy (1816); Eng. trans, by W. Knatchbull, *Kalila and Dimna* (1819). The later Syriac version was ed. by W. Wright (1884); Eng. trans. by I. G. N. Keith-Falconer, *Kalila and Dimna* (1885). Sir Thomas North's Eng. trans. was ed. by J. Jacobs (1888). *See* also J. Hertel, *Das Pancatantra, seine Geschichte und seine Verbreitung* (1914); C. Brockelmann, "Kalila wa-Dimna," *Encyclopaedia of Islam* (1927). (S. M. SN.)

BIÉ-CUANDO CUBANGO, the largest district (area 101,-826 sq.mi.) of Angola, Africa, covers the central rind southeastern regions of that E'ortuguese overseas province. Pop. (1950) 474,-491, which included 4.211 Europeans and 2,412 persons of mixed race. It includes five *concelhos* (counties j: Bié, Chinguar, Andulo, Camacupa and Menongue; and four circumscriptions: Alto Cuanza, Cuito-Cuanavale, Baixo Cubango and Cuando. The capital is Silva Porto ((pop.[1955 est.] 12.146), and other more important towns are Nova Sintra, Andulo, Vila General Machado, Chinguar, Vila Serpa Pinto, Chitembo and Cuangar. The four northern *concelhos* (the first four mentioned above) are served by the Benguela railway and arc very productive; crops grown on the settlers' *chitacas* ("farms") include wheat, maize (corn'), rice, broad beans, potatoes, peanuts, sisal. coffee, vegetables and fruits. The Africans cultivate cereals, tobacco and sugar cant' and gather honey and beeswax. Livestock is also abundant. Industries are agricultural: milk products, hides and skins, rice husking, oil extraction, milling and pork products. The southern areas lack communications and are sparsely inhabited. They produce some cereals. oilseeds, fruits, honey and beeswax, hides and skins, etc. The economic potential of Baixo Cubango, Cuando and Cuito-Cuanavale is great, hut development awaits the continuation of the Moçamedes—Vila Serpa Pinto railway. (A. A. G. P.)

BIEDERMEIER STYLE, in art and design, echoed the tastes of the middle classes, especially in Germany, Austria and the Scandinavian countries, during a period of economic impoverishment from the late 1820s to the late 1830s. It ended when the so-called Second Rococo or Louis Philippe style was introduced in France after 1830.

The term Biedermeier, derived from a political caricature in *Fliegende Rlatter* and later featured in satirical poems by Ludwig Eichrodt published about 1850, described a Philistine ignorant of art and poetry. The furniture derives from the Empire style, developing more sober and utilitarian shapes, mostly executed in fruit woods and avoiding the use of bronze ornament. The painting, either genre or historical. antiromantic and yet not realist, is sentimentally or humorously anecdotal. The best representatives are F. Kruger, F. G. Kersting, J. Oldach, C. Spitzweg and F. Waldmüller. Biedermeier style owes its appeal to its simple and cheerful unpretentiousness.

BIEL, GABRIEL (c. 1425–1495), German scholastic philosopher. theologian and economist, was born at Speyer and studied at Heidelberg and Erfurt. Having been cathcdrnl preacher at Mainz (1466'). he entrred the Order of the Brothers of the Common Life in 1167 and became prior of Urach (1482), professor of philosophy and theology at Tiibingen (1484) and prior of Schonbuch (1492). His *Collectorium,* a commentary *on* Peter Lombard's *Sentences,* gives a clear arid methodical exposition of the teaching of William Ockham and was so influential that Ockhamists at the universities

of Erfurt and Wittenberg were known as Gabrielistae. Left unfinished by Biel, it was completed by his follower W. Steinbach at Tdbingen in 1520 and the complete work printed at Brixen in 1574. after many incomplete editions.

Biel, in addition to theological treatises, also wrote a progressive work on economic theory, *De potestate et utilitate monetarum* (printed 1516; Eng. trans., *Treatise on the Power and Utility of Moneys,* 1930). He has been called *ultimus scholasticorum* ("the last of the scholastics"), a title which ignores outstanding scholastics who came after him.

See P. Bohner, *G. Ockham: Quaestio prima principalis prologi in primum librum Sententiarum cum interpretatione Gabrielis Biel (1939);* E. Bonke, "Doctrina nominalistica de fundamento ordinis moralis apud Gulielmum de Ockham et Gabriel Biel." *Collectanea Franciscana* (1944). (S. J. C.)

BIEL (Fr. BIENNE), an important industrial town in the Swiss canton of Bern, at the northeastern end of Lake Biel, where the Suze or Schuss river issues from a deep cleft (the Taubenloch) in the Jura range, 30 km. (19 mi.) N.E. of Neuchâtel, and 34 km. (21 mi.) N.W. of Bern. The population, which in 1850 was but 3,589 and rose in 1960 to 59,216. was mainly Protestant and two-thirds German-speaking. The parish church of St. Benedict dates from 1451 but was restored in 1775; it has some fine 15th-century painted glass. In the town is the Schwab museum, chiefly notable for its fine collection of objects from the pile-dwellings. The West Cantonal Technical institute gives instruction relating to the industries carried on in the town.

To the northwest. two funicular railways lead up to Évilard (or Leubringen) and Macolin (or Magglingen), both situated on the slope of the Jura. Biel's chief industries are watchmaking, chainmaking and the manufacture of machines for use on railways and in other industries.

First mentioned in the 12th century, Biel was for centuries under the jurisdiction of the prince-bishop of Basel. In 1279 (permanently in 1352) it made alliance with Bern, in 1334 and 1344 with Solothurn, and in 1311 and 1382 with Fribourg. It failed to gain admission into the Swiss confederation, though after it adopted the Reformation in 1528 it was closely associated with the Protestant cantons. In 1798 it was seized by the French, but in 1815, with the greater part of the bishopric of Basel, it became part of the canton of Bern. *(See* BERN.)

Lake Biel (LAKE OF BIENNE or BIELERSEE) is situated at the foot of the Jura range. It is 73 mi. long, 23 mi. wide, 243 ft. deep, 1,407 ft. above the sea and has an area of 15 sq.mi. In it is the Isle of St. Pierre with many traces of lake dwellings. It receives the Suze and Thible or Zihl rivers (from the Lake of Neuchbtel). The Hagneck canal leads the waters of the Aare river into the lake and the Nidau conducts them out again.

BIELEFELD, a town of Germany, which after the partition of the nation following World War II was located in the district of Detmold in the *Land* (state) of North Rhine-Westphalia. Federal Republic of Germany. It is situated on the northern edge of the Teutoburger Wald, 111 km. (69 mi.) W.S.W. of Hanover. Pop. (1959 est.) 174,752. During World War II Bielefeld was occupied by the Allies in April 1945. The town, which sustained considerable damage, was rebuilt after the war and a subway was constructed under the central Jahnplatz. The Altstadter Nikolaikirche (14th century), with a carved Flemish altar, was restored after the war. The Neustädter Marienkirche (14th century) contains the tombs of Count Otto III of Ravensberg and Count Wilhelm von Jülich. Other historic buildings include the Jodokuskirche, the Grest'sche Hof (now a grammar school), the Spiegel'sche Hof, the Gothic Cruwell house and the Renaissance house in the old market place, now a bank. Cultural institutions include the Rudolf-Oetker Concert hall, the municipal opera and playhouse, the farmhouse museum, the playing card museum and several libraries. Bielefeld is on the main railway line from Hanover and Minden to Hamm and the Ruhr. The town is the centre of the Westphalian linen industry which dates from the 13th century; the first mechanical mills were established in 1854. There are silk and plush weaving mills. Manufactures include clothing, sewing machines, bicycles, cash registers, adding machines, machine tools, cereals, food products and pharmaceutics.

First mentioned as Bilifelde in the biography of Bishop Meinwerk of Paderborn between 1015 and 1036, the old town was probably founded in 1214 by Count Hermann of Ravensberg. The so-called "new town" arose from a charitable foundation settlement around the Marienkirche toward the end of the 13th century. In 1250 Count Ludwig of Ravensberg built Sparrenberg castle for the protection of the town. The towns were united in 1520. In the 14th century Bielefeld joined the Hanseatic league, and in 1346 the town, with the countship of Ravensberg, passed to the margravate and later the duchy of Julich and in 1609 to Brandenburg (made definite in 1666). (U. N.)

BIELLA, a city of Vercelli province, Piedmont, northwest Italy, is situated on the Cervo river at the foot of the Alps, with the flat Po valley to the east. 72 km. (45 mi.) N.E. of Turin. Pop. (1957 est.) 46,167. Biella is divided into the upper (Piazzo) and lower (Piano) town, joined by a cable railway. There are many medieval and Renaissance houses in the upper town while in the lower town is the 15th-century cathedral adjoined by the 9th-century baptistery. To the south are the Renaissance basilica of San Sebastiano, the modern city, the art gallery and a park with a fine collection of rhododendrons. On Alpine slopes above the town are the Santuario d' Oropa, a pilgrim resort, and a winter sports station. The industries of Biella are wool, silk and cotton manufactures. Biella was occupied in prehistoric times and became in turn a Gallic and Roman city. On the committee of Vercelli during the middle ages, Biella passed to Savoy in 1379. It became part of Italy in 1860 and during World War II was occupied by the Allies in April 1945. (P. To.)

BIELSKO-BIALA, the chief town of the district of the same name in the *wojewodztwo* (province) of Katowice, Pol., lies 60 km. (37 mi.) from Katowice on the border of the Carpathian mountains and the sub-Carpathian plain. Pop. (1960) 76,000. It is a communications centre for tourists in the western Carpathians. Until 1951 Bielsko-Biala consisted of two separate towns divided by the Biala river, a tributary of the Vistula. Bielsko, in Silesia, was the seat of the Sulkowski entail and obtained town rights in the 18th century; Biala, in the Cracow *wojewodztwo,* obtained its rights at the same time. Both towns were once under Austrian rule: as part of Silesia, Bielsko became Austrian in 1526, while Biala passed to Austria in 1772. They were returned to Poland in 1919.

Sheep-rearing in the nearby mountains provides raw materials for the weaving industry, which developed in Bielsko as early as the 16th century. Bielsko-Biala became one of the largest centres of the textile industry in Poland, and produces high-grade wool which is widely exported. The town is on a branch railway line from Katowice via Oswiecim, and is linked by main road with Krakoxv and Brno, Czech. (K. M. WI.)

BIERCE, AMBROSE GWINNETT (1842–1914?), U.S. newspaperman, misanthrope, wit, satirist and author of sardonic short stories based on themes of death and horror, was born on June 24, 1842, in Meigs county, O., and reared in Kosciusko county, Ind. After about a year in high school, he became printer's devil on a Warsaw paper, then moved to Elkhart. In April 1861 he enlisted in the 9th Indiana volunteers, was in action at Shiloh, Corinth, Stone's River, Chickamauga and Nashville, was seriously wounded at Kenesaw mountain in 1864 and served until Jan. 1865. Rising from private to first lieutenant, he received a merit promotion to major in 1867. In 1866 Bierce served as engineering attach6 to the expedition of Gen. William B. Hazen. In San Francisco he soon began contributing to periodicals, particularly the *News Letter,* of which he became editor in 1868. In Dec. 1871 he married Mary Ellen Day, and from 1872 to 1875 the Bierces lived in England, where he wrote for the London magazines *Fun* and *Figaro* and edited the *Lantern* for the exiled empress Eugénie. English friends called him "Bitter Bierce."

In 1877 he became associate editor of the *San Francisco Argonaut,* but left it in 1879–80 for an unsuccessful try at placer mining in Rockerville, in the Dakota territory. Thereafter he was editor of the *San Francisco Wasp* for five years. In 1887 he joined the staff of Hearst's *San Francisco Examiner* and continued that association for 20 years. In 1900 Bierce moved to Washing-

ton. D.C., where he continued newspaper and magazine writing. In 1913 he joined the army of Pancho Villa in Mexico and in December sent the last word received from him. His end is a mystery, but a reasonable conjecture is that he was killed during the siege of Ojinaga in Jan. 1914.

A troubled man, Bierce separated from his wife, lost his two sons and broke many friendships. As a newspaper columnist he specialized in critical attacks: on amateur poets, clergymen, bores, dishonest politicians, money grabbers, pretenders, frauds of all sorts. His principal books are: *In the Midst of Life* (1891), *Can Such Things Be?* (1893) and *The Devil's Dictionary* (1906). The first two were collections of tales, grim, vivid, often sardonic, and often with ingenious surprise endings. The last is a volume of ironic definitions. His *Collected Works* was published in 12 volumes. 1909–12.

Grattan, *Bitter Bicrce* (1929); Bertha Clark Pope (ed.), *The Letters oj Ambrose Bierce* (1922); C. McWilliams, *Ambrose Bierce* (1929); W. Neale, *The Life of Ambrose Bierce* (1929). (P. FT.)

BIERSTADT, ALBERT (1830–1902), **U.S.** landscape painter, whose pictures of the western part of the United States, and particularly the Rocky mountains, made him widely popular, was born in Solingen, Westphalia, Ger., on Jan. 7, 1830, and was taken to the United States when about a year old. In 1853–56 he studied painting at Diisseldorf. His "Estes Park, Colorado" was bought by the earl of Dunraven. His "Sierra Nevada" (1878) is in the Corcoran gallery in Washington, D.C., and "The Valley of Yosemite" in the Metropolitan museum in New York.

He rendered panoramic views with a certain ability, though his work was somewhat more topographically correct and impressive than artistic. He was a member of the National Academy of Design of New York, and is represented by two historical paintings, "The Discovery of the Hudson River," and "The Settlement of California," in the Capitol in Washington. He died in New York city on Feb. 18, 1902.

BIGAMY is the unlawful contracting of a marriage by or with a person who is already married to another. In earlier times it was dealt with by ecclesiastic courts. After the Reformation the English parliament, followed by the American states, enacted statutes defining and punishing the offense. The statutes vary in form and substance. Typically, they forbid marriage by or with any person "having a husband or wife living." with specified exceptions for cases where the earlier marriage was invalid or was terminated by divorce, or where the prior spouse has disappeared and is believed dead.

The principal problem arising under this legislation in modern times is what shall be done in case the earlier marriage has ended in divorce but the divorce turns out to be invalid. This problem is acute in the United States because of the great diversity of divorce laws and the frequency of "migratory" divorce. *i.e.*, where a resident of one state goes temporarily to another state or foreign country to take advantage of its lax divorce law. If the circumstances and duration of the sojourn in the divorcing state fall short of the legal requirement of "domicile," the migratory divorce may be treated as a nullity in other states. Thus, where two residents of North Carolina went to Nevada to divorce their respective spouses, married each other in Nevada and returned to North Carolina to live as man and wife, they were convicted of bigamous cohabitation in North Carolina. In a leading decision, *Williams* v. *North Carolina, 325 U.S.* 226 (1945), the supreme court of the United States refused to set aside this conviction. notwithstanding its recognition that the parties' divorces and remarriages were valid under Nevada law. The federal constitutional obligation upon the states to give "full faith and credit" to the laws and judicial proceedings of other states was held inapplicable to dissolution of marriages by a state in which the parties were not "domiciled."

Where a person is legally domiciled may be a difficult question, and it will often happen, as in the Williams case, that a person remarries in the erroneous but good-faith belief that his former marriage was dissolved. This raises the problem whether bigamy (commonly punishable in the C.S. as a felony by imprisonment up to five years) can be committed in innocence or whether it is a defense that the person acted in good faith. Most states allow no such defense. but recent revisions of penal lams tend to limit the offense to remarriage by one who is aware of his ineligibility. Some states do not excuse even for reasonable belief that a missing spouse has died. unless the missing spouse has been absent for a period of years specified in the bigamy statute. The contrary was held in the famous English decision, *Regina* v. *Tolson,* 23 Q.B.D. 168 (1889). Nearly all statutes make it clear that an unmarried person entering a marriage which may be bigamous because his partner is already married cannot be convicted without proof that the accused knew of the bar.

In English statute law bigamy is defined by s. 57 of the Offences Against the Person act, 1861. It is punishable by seven years imprisonment. There is a very important proviso to the definition of the offense, excluding its application to "any second marriage contracted elsewhere than in England or Ireland by any other than a British subject": to cases where a spouse has been continuously absent for seven years and was not known by the person accused to be alive; or to a person whose former marriage has been dissolved or declared void by a court of competent jurisdiction.

See American Law Institute, *Model Penal Code, Tentative Draft no. 4,* sec. 207.2 and comments (1955); C. S. Kenny *Outlines of Criminal Law,* ed. by J. W. Cecil Turner, pp. 170–176 (1952). (L. B. S.)

BIG BERTHA. The original Big Berthas were 42-cm. howitzers produced at the Skoda works in Austria-Hungary and used by the Germans in battering the forts at Liège and Namur, Belg., in 1913. It was assumed that this artillery originated from the Krupp works in Germany — hence the nickname, after Frau Bertha von Bohlen. head of the Krupp family. In 1918, when the Paris gun began shelling the French capital from the forest of Coucy at a range of 76 miles, newspaper correspondents resurrected the title and applied it to this gun. The bombardment began March 23 and extended over 140 days, firing taking place about every third day. In all. 256 people were killed; the most serious loss was caused on Good Friday. March 29, when 156 were killed or wounded in the church of St. Gervais. The Paris gun was a high-velocity piece of 8.26-in. calibre (later retuhed to larger bore), was about 110 ft. long, weighed 142 tons, and fired a 264 lb. shell.

BIG DIPPER or GREAT DIPPER. popular names for a group of seven stars in the circumpolar constellation of Ursa Major (*q.v.*) in the northern hemisphere. The two end stars of the dipper's "bowl," α and β, are called the Pointers; an imaginary line drawn through them and extended about five times toward the north pole will pass approximately through Polaris, the North star.

BIGELOW, ERASTUS BRIGHAM (1814–1879) U.S. inventor and industrialist who developed power looms for the manufacture of carpets, was born in West Boylston, Mass., on April 2, 1814. His family was in poor circumstances and he was obliged as a child of ten to seek employment as a farm hand and clerk. and to forgo his ambitions for a formal education. Naturally adept in mathematics and mechanics, he was only 23 when he invented his first loom for the manufacture of lace. This device was followed by other power looms for the weaving of a variety of figured fabrics — counterpanes, ginghams. silk brocatel and tapestry carpetings. In 1839 he began experimental work at Lowell, Mass., which led to invention of the first power loom for weaving carpets of an ingrain type. From 1845 to 1851 he developed the greatest of his inventions. a power loom for the manufacture of Brussels and Wilton carpets. In 1843 he and his brother; Horatio Bigelow, established a mill for the manufacture of ginghams, and around this plant grew the town of Clinton, Mass. Several years later he founded the Uigelow carpet mills in the same town.

His inventions provided an enormous impetus to the manufacture of carpets not only in the U.S. but in Europe, where his looms for a while gave English manufacturers an important advantage over their French competitors. Bigelow was also an economist of note and was one of the small group of men who incorporated

the Massachusetts Institute of Technology at Boston in 1861. He died at Boston on Dec. 6, 1879.

BIGELOW, JOHN (1817–1911), U.S. diplomat, editor and journalist, was born in Malden, N.Y., Nov. 25, 1817. He graduated from Union college, Schenectady, N.Y., at age 17, practised law in New York city, wrote for liberal magazines. was active in New York prison reform in the 1840s, and became part owner and managing editor under William Cullen Bryant of the *New York Evening Post* (1849–61). He made his greatest public contribution when as American consul in Paris, 1861–64, he prevented the delivery to the Confederate states of warships constructed for them in France with the knowledge of the French government. If delivered, they might have broken the Union blockade. His record of this episode in *Frunce and the Confederate Navy* (1888) is an exciting account of diplomatic sleuthing. As consul he influenced skilfully French opinion on the American Civil War by cultivating the liberal press and writing *Les États-Unis d'Amérique en 1863* to show French businessmen the importance to them of northern commerce. As minister to France, 1864–67, he handled with discretion the negotiations leading to the withdrawal of the French from Mexico.

In later life he became editor of the *New York Times* (1869), then secretary of state of New York, 1875–77. In the 1880s and 1890s he helped establish the New York Free Public Iibrary and advised Philippe Bunau-Varilla during negotiations leading to the Panama Canal treaty. He died in h'ew York on Dec. 19, 1911.

His editions of Benjamin Franklin's long-lost autobiography (1863) and of Franklin's complete works (1887–88) were his principal literary achievements; of use to historians were his biography of Samuel J. Tilden (1895) and editions of Tilden's works (1885, 1908); of special interest to Swedenborgians were his religious writings, as *The Bible That Was Lost and Is Found* (1893) and *The Mystery of Sleep* (1897). An autobiographical work, *Retrospections of an Active Life,* appeared in three volumes in 1909, and two volumes in 1913.

See Margaret Clapp, *Forgotten First Citizen: John Bigelow* (1947). (MA. CL.)

BIG GAME HUNTING: *see* HUNTING.

BIGGLESWADE, an urban district and market town of Bedfordshire, Eng., 11 mi. E.S.E. of Bedford by road, lies on the Ivel, a tributary of the Great Ouse, in a plain noted for market gardens. Pop. (1961) 8,047. The Romans made a ford there for their road, part of which is now the main street of Biggleswade (Biccel's wade or ford). An ancient borough by prescription, Biggleswade was the scene of many fairs, but only the horse fair on St. Valentine's day survives in the market place. Straw-plaiting and lace-making have been replaced by engineering, brewing and the manufacture of trailers and agricultural implements. Biggleswade lies on the main railway line from London through Peterborough. The Ivel was navigable almost to the town until the 20th century.

BIGHORN (MOUNTAIN **SHEEP),** either of the two species *(Ovis canadensis; O. dalli)* of sheep native to h'orth America. The body is compact and muscular; the muzzle narrow and pointed; the ears short and pointed; the tail very short. Both sexes have massive, transversely ribbed, spirally curved horns, which in the male may exceed 45 in. along the outer curvature. The fur is not wooly as in domestic sheep but is more like that of a deer; it is usually a shade of brown, but in the Dall sheep may be white to almost black.

Bighorns live in the remote crags and cliffs of mountainous areas but formerly occurred also in the foothills, whence they have been driven by man and his livestock. Formerly the Canadian bighorn ranged from northern Mexico to the Canadian Rockies. Now it is reduced to small bands protected by inaccessible habitat or by refuges. The Dall sheep ranges from Alaska to northern British Columbia.

The bighorns' food consists mainly of grasses, herbs and tender shoots, but in the desert mountains of the southwest they eat shrubs and even cacti. They are exceedingly sure-footed, leaping from rock to rock and climbing seemingly sheer cliffs. The cloven hooves, resembling hard rubber in elasticity, are sharp-edged and concave, forming suction cups. One small lamb—sometimes two—is born in the spring after a gestation period of six months. Bighorns are gregarious, but in the summer the rams live separately from the ewes and lambs. They reach their prime in about eight years. (K. R. KN.)

BIGHORN MOUNTAINS, a U.S. mountain range extending in a great anticlinal arch for 120 mi. in a northwest-southeast direction across north-central Wyoming; to the north the range reaches into southern Montana. These mountains consist of a partially exposed Pre-Cambrian core with Paleozoic and Mesozoic sedimentary rocks dipping away on the east and west flanks. The range lifts abruptly 4.000 to 5,000 ft. above the Great Plains and Bighorn basin that surround it. The average height of the mountains is from 11.000.to 13,000 ft. above sea level; Cloud peak at 13.165 ft. is the highest in the range. The Bighorn National forest, with headquarters at Sheridan, Wyo., includes a gross area of more than 1,000,000 ac.; it has many camp and picnic areas and several winter sports areas. (H. B. HA.)

BIGHORN RIVER, the largest tributary of the Yellowstone, drains west-central Wyoming and a small area of south-central Montana. Topographically, it includes three subbasins, known in downstream order as the Wind river in Wyoming, the Bighorn in Wyoming and Montana, and the Lower Bighorn in Montana.

Wind. river, master stream of the upper basin, originates in the high areas of the Wind River and Absaroka mountains in northestern Wyoming. Flowing southeast to a lowland area in west-central Wyoming it is joined by the Popo Agie and Little Wind rivers near Riverton. Turning north it passes out of the upper basin through Wind River canyon, a deep and spectacular gorge through the Owl Creek mountains. Boysen dam is located in the upper portion of the canyon.

Below the canyon the stream name is Bighorn river. Continuing northward it flows through the Bighorn basin—collecting its two principal tributaries the Greybull and Shoshone rivers—to the Wyoming-Montana boundary where it turns northeastward through Bighorn canyon to cross the Lower Bighorn basin and empty into the Yellowstone at Bighorn, Mont.

Little Bighorn river joins the main stream at Hardin, Mont., in the lower basin. It was near the mouth of this stream that Col. George A. Custer and the officers and men of five companies of the 7th U.S. cavalry were annihilated, June 25, 1876, in action against the Indians of the Great Plains. Custer Battlefield National monument marks the site of this historic incident. (G. V. SK.)

BIGNONIACEAE, a family of dicotyledonous (having two seed leaves) plants, chiefly shrubs, trees and vines, mostly with large showy flowers. The family is particularly developed in tropical America, although also fairly well represented in tropical Africa and in the Indo-Malaysian region. A few genera, *Catalpa, Campsis, Incarvillea,* occur in temperate regions. There are about 100 genera and more than 800 species many of them cultivated in tropical countries for ornamental or other purposes. The tropical American calabash tree belongs in *Crescentia,* the sausage tree to the African genus *Kigelia* and the African tulip tree to *Spathodea. Jacaranda* is widely planted in subtropical regions as an ornamental shade tree. *Campsis radicans,* the common trumpet creeper, is a well-known ornamental climber throughout most of eastern United States. (E. D. ML.)

BIGOD, the name of an English family conspicuous for its opposition to the crown in the 12th and 13th centuries. Descended from a modest Norman family, the founder of the English line, ROGER BIGOD (d. 1107), acquired soon after 1066 extensive estates around Framlingham castle in Suffolk and in Norfolk where he was among the greatest of the lay landowners. His heir, WILLIAM, was drowned in the wreck of the "White Ship" in 1120, and Roger was succeeded by his second son, HUGH *(c.* 1095–1177). Despite his rebellion against King Stephen in 1140, Hugh was created earl. of Norfolk (Dec. 1140 or Jan. 1141) by Stephen, and fought with him at the battle of Lincoln in Feb. 1141. Soon afterward he deserted to Matilda, the rival claimant for the throne, and later joined Geoffrey de Mandeville in ravaging eastern England (1144). He grew restless under the rule of Henry II, and was a leader of the rebellion'of 1173–74, which in England was centred on his estates.

But he was restored to favour heiore his death on about March 9, 1177. His son ROGER (d. 1221), who was not recognized as earl until 1189, proved a faithful servant of Richard I, but joined the barons against King John in 1215, and was among the lords elected to maintain Magna Carta.

The short-lived 3rd earl. HUGH (d. 1225), enriched his family fortunes by marriage to Matilda, coheiress oi William Marshal, earl of Pembroke. Matilda brought their son ROGER (*c.* 1212–70), 4th earl, the marcher lordship of Chepstow, and in her right he was recognized marshal of England (1246). He was prominent among the barons who between 1258 and 1265 wrested control of the government from Henry III and who assisted Simon de Montfort. Roger's brother HUGH (d. 1266) was justiciar for the baronial regime from 1258 to 1260. The brothers gradually drew apart from De Montfort, and Hugh fought for the king at the battle of Lewes in 1264. Roger died childless and was succeeded by Hugh's son ROGER (*c.* 1241–1306), 5th earl of Norfolk and marshal of England.

This Roger is best known for his quarrel with Edward 1 (1297), whom lie dehed with the stubborn pride characteristic of his family. With the constable, Humphrey de Bohun, earl of Hereford, he refused to serve abroad unless the king personally led the expedition, and to the angry king's threat "By God. earl. you shall either go or hang," Bigod retorted "By the same oath, king, 1 will neither go nor hang." (Walter of Guisborough's *Chronicle,* ed. by *H.* Rothwell. 1957.) Self-interest was not Bigod's only motive, for the two earls, with considerable public spirit, led the movement which forced Edward I to confirm the charters (1297). His finances drained by the dispute, the childless marshal granted his estates to Edward I in 1302 and received them back for life only, but was relieved of his debts. Koger's death in Dec. 1306. therefore. brought his estates and title:, to the crown. His lands were given (1310) by Edward II to his own younger brothers. Edmund and Thomas. Thomas was later created earl of Norfolk (1312) and marshal of England (1316). Although a cadet branch of the family long survived in Yorkshire, at Roger's death the Bigods disappeared from high politics. (C. D. R.)

BIGSBY, JOHN JEREMIAH (1792–1881). English geologist and physician who carried out extensive and important geological researches particularly in the fields of stratigraphy and paleontology of Canada and New York state. was born at Nottingham on hug. 14. 1792. Educated at Edinburgh: he joined the army medical service and in 1817 was stationed at the Cape of Good Rope. He moved to Canada in 1818 and in the following year was appointed to report on the geology of Upper Canada. In 1822 he became British secretary and medical officer to the Boundary commission. contributing papers to the *American Journal* oj *Science* and other scientific journals. He returned to England in 1827. His *Thesaurus Siluricus* was published with the aid of the Royal society in 1568 and the *Thesaurus Devonico-Carboniferus* in 1878. In 1877 he iounded the Geological Society of London's Bigsby medal to be awarded biennially as an acknowledgment of eminent services in any department of geology, the recipients not to be over 45 years old. He died in London on Feb. 10, 1881.

BIG STONE LAKE, source of the Minnesota river, is located on the Minnesota-South Dakota boundary about 300 mi. W.N.W. of Minneapolis. Its name comes from red granite outcrops in the vicinity. Its waters are impounded in a narrow glacial spillway by the delta of the Whetstone river. The lake is 26 mi. long and $\frac{3}{4}$ to $1\frac{1}{4}$ mi. wide. Its level is regulated by water diversion from the Whetstone river and by a dam at the lake outlet nith spillway altitude of 964 ft. The lake is used as a storage reservoir for spring flood waters which might inundate the Minnesota valley. (H. A. C.)

BIHAR (BEHAR) is one of the constituent states of the Republic of India. Bihar was the heart oi the empire of Asoka (*q.v.*) and later under the British regime it long formed part of Bengal Presidency. In 1912 the province of Bihar and Orissa was separated from Bengal and was divided into separate provinces. Bihar arid Orissa. in 1936. When India became independent in 1947 the province of Gihar became a group A or governor's state with an area of 69,745 sq.mi. in 1948 the small states of Saraikela and Kharsawan (623 sq mi.) were absorbed. At that time the northeastern corner of Bihar adjoined East Pakistan. thus separating the state of West Bengal into a main southern part and a detached northern part. To remedv this. a the major reorganization of state boundaries of Nov. 1, 1956, parts of Purnea were transferred to West Bengal together with parts of Manbhum. Kihar state thus has a present area of 67,198 sq.mi. The state stretches from the borders of Nepal in the north to Orissa in the south and is bordered on the east by West Bengal and on the west by Uttar Pradesh and Madhya Pradesli. The state capital is Patna (*q.v.*) on the south bank of the Ganges (Ganga).

Physical Geography.——.\part from the foothills of the Himalayas, built up of folded Tertiary sediments. in the extreme northwest, the whole of the northern part oi the state is part of the great monotonous alluvial plain of the Ganges and its tributaries. 'The Ganges itself flows from west to east near the southern margin of the plain. It is joined just above Patna by the Gandak draining from Nepal and farther upstream on the opposite bank by the Sun from the southwest. Farther west the Ghaghra (Gogra) joins the Ganges from the northwest and for some distance both rivers form the state boundary, the angle of land between them being part of Uttar Pradesh (formerly United Provinces). Another important tributary joining the Ganges from Nepal much farther east is the Kosi. The southern half of the state is very different in character. coinciding n-ith the main part of the Chota Nagpur plateau and ranging from 1,000 to 4.000 ft. above sea level. This plateau is part of the great gneissic-schistose plateau of peninsular India. In late Paleozoic times it was partly covered by lower Gondwana rocks, including coal-bearing strata. which subsequent faulting have preserved in down-faulted basins. The main coal fields lie partly in West Bengal. partly in Bihar, notably along the Damodar valley. The principal field Jherria (Jharia j-Asansol-Raniganj, shared by the two states. yields up to nine-tenths of India's coal. Interbedded lavas as well as dykes of igneous rock also occur and the Chota Nagpur plateau is characterized by a succession of flat-topped hills, partly structural in origin, partly due to the development of erosion platforms at different levels. The scenery of the eastern part of the plateau has been transformed both by the development of coal mining and industry and by the creation of a series of lake-reservoirs forming part of the Damodar valley scheme (*see* DAMODAR).

Climate.—Nine-tenths of the total rainfall comes in the summer monsoon from June to October. The middle Ganges plain in Bihar is intermediate between the dry upper Ganges plain in Uttar Pradesh, where irrigation is needed. and the very wet delta lands of West Bengal and East Pakistan. The total fall in Gihar ranges from about 40 to more than 60 in.; irrigation is not essential but is a valuable insurance against delayed or inadequate rains and enables the season of cultivation to be extended. The Chota Nagpur plateau also enjoys a moderate rainfall. above 40 in, and reaching 50 to 60 in. in the central parts. Temperatures on the plains may fall almost to freezing point and rise above 110° F. on occasions. but on the whole the plains escape both the extreme heat of districts farther west and frost. On the plateau cloud cover by day tends to limit rises oi temperature while elevation results in a generally lower average.

Vegetation and Animal Life.––On the northern margins of the state adjoining Nepal are stretches of Terai country. a marshy jungle still the haunt of tigers, but over the densely peopled and well-cultivated plains the natural vegetation has almost entirely disappeared. The natural vegetation of the plateau is a deciduous monsoon forest. the trees losing their leaves in the hot season from February to May. 'These forests are the home of the sal (*Shorea*), yielding a valuable timhcr. 'The Chota Nagpur plateau still has some of the least accessible forest country of India and this is the main reason for the continued existence of primitive forest tribes such as the Santal as well as for a rich mammalian fauna. There is a national park and game reserve 3 mi. N. of Hazaribagh. (L. D. S.)

Xistory.— The state of Bihar roughly corresponds to the ancient kingdoms of Videha, north oi the Ganges, and Magadha, south of the river. References to it occur in the Ramayana and

the Mahabharata but the first authentic dynasty is that of the Saisunagas of Slagadha, who became important under Bimbisara in the 6th century B C. It was during this period that Vardhamana Mahavira, the founder of Jainism, and Gautama, the founder of Buddhism. preached against the sacerdotalism and social exclusiveness of Brahmanism. Magadha became the paramount power under the Mauryas from Chandragupta to Asoka (c. 322–232 B.C.). A pillar inscription of Asoka still survives at Rampurva in northern Bihar. With the decline of the Maurya empire after the death of Asoka the history of Bihar becomes obscure for many centuries. During the 4th and 5th centuries A.D. it formed part of the great Gupta empire of northern India. The rule of the Guptas witnessed the revival of Brahmanism and is known as the golden age of Hinduism. A description of Bihar has been left by Fa-Hsien (*q.v.*), the Chinese Buddhist pilgrim nho resided for three years at Pataliputra (Patna) during the reign of Chandragupta II and traveled extensively throughout the Gupta empire between 405 and 411. In the first half of the 7th century Bihar was annexed to the kingdom of Harsha, of mhose reign a detailed description has been recorded by Hsuan Tsang (q v.). another famous Chinese Buddhist pilgrim. From the death of Harsha (A.D. 64i) little is known of Bihar until the end of the 8th century when the Gurjara-Pratiharas of Kanauj, the Rashtrakutas of the Deccan and the Palas of Bengal began their three-cornered struggle for paramountcy. About the middle of the 8th century Magadha was conquered by Gopala, who founded the imperial dynasty known as the Palas of Bengal. They were zealous Buddhists. and under them Magadha was once more an active centre of Buddhist influence. Mahendrapala I (885–*c* 910) enlarged the Gurjara-Pratihara kingdom at the expense of the Palas. From his inscriptions, which extend as far east as Paharpur, it may be inferred that he controlled the greater part of Magadha.

In 1194 Bihar was overrun by Muslim invaders. The monasteries and universities of Cddantapura, Nalanda and Vikramasila were ruthlessly sacked and the monks slaughtered. It remained part of the sultanate of Delhi until the disintegration of the Tughlak empire in the second half of the 14th century. In 1529 it was wrested from its Lodi rulers by Babur, the first of the Mogul emperors. At the beginning of Akbar's reign Bihar was ruled by an Afghan. Sulaiman Kararani, but by 1576 both Bihar and Bengal had been annexed to Akbar's extensive empire and remained under Mogul rule until the decline of that empire in the 18th century. Bihar came under British rule in 1765 when the province was united with Bengal (*q.v.*). (C. C. D.)

People and Administration. — Nextto Madhya Pradesh state, Bibar contains the largest tribal population in India, constituting about 10% of the national total. There are 29 scheduled tribes, of nhom the Oraon (*q.v.*), Munda, Santal (*q.v.*) and Hol are the chief. The majority of the peoples of Chota Nagpur division are either Munda or Oraon. The remainder are principally those who speak the Bihari language (*q.v.*). The chief occupation is agriculture, particularly in the Ganges valley. In south Bihar there is a rapidly growing industrial and mining population, drawn from both inside and outside the state.

Population.—The total population at the 1951 census (corrected to the present boundaries) was 38,733,778 and 46,457 042 in 1961. The largest tonns are Patna ([1961] 362,817), the iron and steel town of Jamshedpur (332,134), Gaya (150.884). Bhagalpur (143,-994), Ranchi (139,437), Muzaffarpur (108,759), Darbhanga (103.106) (*qq.v.*).

Administrative Divisions.—Bihar is divided into four administrative divisions and 17 districts, listed below with the names of district headquarters in parentheses.—Patna division: Patna (Patna); Gaya (Gaya); Shahabad (Arrah). Tirhut division: Muzaffarpur (Muzaffarpur); Saran (Chapra); Champaran (Motihari); Darbhanga (Lahariasarai). Ehagalpur division: Bhagalpur (Bhagalpur); Monghyr (Monghyr); Purnea (Purnea); Santal Parganas (Dumka); Saharsa (Saharsa). Chota Nagpur division: Ranchi (Ranchi); Hszaribagh (Hazaribagh); Palamau (Daltonganj); Singhbhum (Chaibassa); Dhanbad (Dhanbad). See also separate articles on most of the districts. (S. Ch.)

Social Conditions. — In the early 1960s about 30% of the male population and 7% of the female population were literate, the result of extended free compulsory primary education (see India: *Education*). Social welfare facilities are provided through welfare extension projects and welfare centres for industrial workers and through such special ameliorative measures as the construction of wells, free hostel facilities. loans and subsidies to people of scheduled castes, tribes and other backward groups. (S. B. L. N.)

The Economy.—*Agriculture and* Industry. — On the fertile alluvial soils of the northern plain rice is the chief crop, normally occupying more than half the land in crops. About 20% of the cultivated land is double cropped. In the plateau region rice is grown on the terraced valley sides and. as a result of the Damodar valley scheme, on formerly flooded valley floors. Other crops in the plain include maize; with wheat and barley of increasing importance toward the drier west and jute on the wetter Bengal margin especially in the Purnea district. Bihar ranks second only to Uttar Pradesh in the production of white sugar, and in the early 1960s supplied one-quarter of India's total. Tobacco cultivation increased after the Peninsula Tobacco company erected one of the largest cigarette factories in the world at Monghyr. Oilseeds are important.

Coai mining is the leading mineral industry, 20,000.000–23,000,000 tons of coal being produced annually. approaching two-thirds of India's total. The coal fields in Dhanbad district, continuous with those of West Bengal, underwent the greatest development but in the 1950s new fields were developed at Ramgarh, Bokaro and Raranpura in Hazaribagh district. In the old crystalline rocks of this latter area are also the mica-bearing deposits which make this the most important mica-producing region in the world, including the neighbouring parts of Gaya and Monghyr districts. The juxtaposition of rich iron ore deposits with good coking coals. in the Singbhum or Chaibassa district and the southern border of the state, led to the establishment in 1911 of modern blast furnaces by the Tata family at Jamshedpur (*q.v.*), where a former village is now a large city. Subsidiary industries have been established and the comprehensive development under the Damodar Valley authority is leading to much industrialization on and near the coal field and main lines of communication. Other minerals in Bihar include bauxite, kyanite, copper ore. manganese ore and chromite; Singbhum district is especially rich. Cement is produced from the limestone deposits of Palamau and Shahabad districts. The production of lac and the manufacture of shellac is an old-established industry in the forest districts. There is a large output of timber and wood fuel, especially from the 15,000 sq.mi. of reserved forests.

Communications.—As elsewhere in India little use is now made of waterways but the Ganges remains a serious obstacle to both rail and road. The plains north of the river are served by the narrow-gauge lines of the North Eastern railway. South of the Ganges the main line of the broad-gauge Eastern railway runs from Homrah (Calcutta) through the main coal field and across the corner of the plateau. via Gaya or northward via Patna, to the famed bridge at Moghul Sarai opposite Benares (Banaras; Varanasi) and so to Delhi. The direct line from Howrah to Bombay runs via Jamshedpur and across the northern part of the state. As in other parts of India road development came later but has done much to open areas of the plateau which nere among the most primitive parts of India. The Grand Trunk road from Calcutta to Delhi and to the old northnest frontier followed roughly the line of the Howrah-Benares railway route. An important north-south trunk road runs from the Ganges opposite Patna (at Hajipur) northward to Katmandu, capital of Nepal, while southward from Patna it passes through Ranchi to Cuttack in Orissa. Patna (at Bankipore) has an international airport.

BIHARI LANGUAGE (properly *Bihārī*). the most western speech of the eastern group of modern Indo-Aryan languages,

spoken by about 40,000,000 people. "Bihari" means the language spoken in the state of Bihar in India. To the west it extends over the district of Agra as far as the longitude of Benares. and to the south it covers nearly the whole of the region of Chota Nagpur. It is also the language of the inhabitants of the neighbouring Tarai districts of Nepal. While an outer language, it shows points of contact with the intermediate ones. In declension and conjugation, Bihari follows Bengali more closely than Eastern Hindi. Bihari has three main dialects, which fall into two divisions. The eastern division includes Maithili or Tirhutia and Magahi. Magahi is considered to be the modern representative of Magadhi Prakrit. It is closely related to Maithili. Maithili is the dialect of the old country of Mithila or Tirhut, famous from ancient times for its learning. It has retained numerous antiquated forms, and parts of its grammar are extraordinarily complex. The western division consists of the Bhojpuri dialect which has extended southeast into the southern half of Chota Nagpur. Very few words in the Bihari vocabulary are borrowed from Persian. Arabic or other languages. (Abbreviations: Mth. = Maithili, Mg. = Magahi, Bh. = Bhojpuri, B. = Bihari, Bg. = Bengali, Skr. = Sanskrit. Pr. = Prakrit, Mg Pr. = Magadhi Prakrit.)

Phonetics. — The stress-accent of Bihari follows the usual rules of modern Indo-Aryan vernaculars. As a general statement we may say that Bihari spelling is not fixed.

The Bihari language is adverse to the existence of a long vowel more than two syllables from the end of a *tadbhava* or evolved word. This is subject to various subsidiary rules. The principle is most important in all Indo-Aryan vernaculars, but it is carried out with the greatest thoroughness in Bihari. The whole system of declension and conjugation is subject to it.

Declension.—Bihari has a stronger sense of gender than the other languages of the eastern group. In the modern language the distinction is in the main confined to animate beings. Except in the case of the interrogative pronoun, there is no neuter gender—words which in Skr. and Pr. were neuter being generally treated as masculine. The plural can everywhere be formed by the addition of some noun of multitude to the singular. Case relationships are indicated, as elsewhere, by suffixing postpositions to a general oblique base. The agent construction. as in Hindustani. is not used, the subject of all tenses of all verbs being always in the nominative. Every noun can have three forms, a short, a long and a redundant. The short form is weak or strong. Occasionally both the weak and strong forms occur for the same word. The long and redundant forms are familiar and often contemptuous. In the feminine they are much used to form diminutives. The singulars of the personal pronouns have fallen into disuse. The plurals are used politely for the singulars, and new forms are made from these old plurals to make new plurals. All the pronouns have numerous optional forms.

Conjugation. — In all three dialects the verb makes little distinction of number: but there is a distinction between nonhonorific and honorific forms. In Mth. and Mg. this distinction applies not only to the subject but also to the object.

Forms in which the object is nonhonorific may be, as in the case of nouns, short, long or redundant.

There are numerous irregular verbs. There is a long series of transitive verbs, formed from intransitives and of causal verbs formed from transitives. Compound verbs are numerous.

The Bh. conjugation is simple. In the first and second persons the plural is generally employed for the singular, but there is no change in the verb corresponding to the person or honour of the object. The termination of the present changes in sympathy with the old present to which it is attached. Irregular verbs, the formation of transitive and causal verbs and the treatment of compound verbs are on the same lines as in Mth.

Literature. — In all three dialects there are numerous folk epics transmitted by word of mouth. The only dialect which has any real literature is Maithili. The earliest writer is Vidyāpati Ṭhakkura (Bidyāpati Thakur), who lived at the court of Raja Śiva Simha of Sugaona in Tirhut in the 15th century. His fame rests chiefly on his dainty lyrics in Maithili dealing with the loves of Rādhā and Krishna. These have exercised an important influence on the religious history of eastern India. They became the home poetry of the Bengali-speaking lower provinces. The most admired of Vidyāpati's successors is Manbōdh Jhā, who died in 1788. He composed a *Haribans*, or poetical life of Krishna. Many dramas have been composed in Maithili.

Since 1947 there has been an increasing interest in Maithili literature and culture. A number of literary organizations have been active both in Bihar and in other parts of India, among them the All-India Maithili Parishad of Darbhanga.

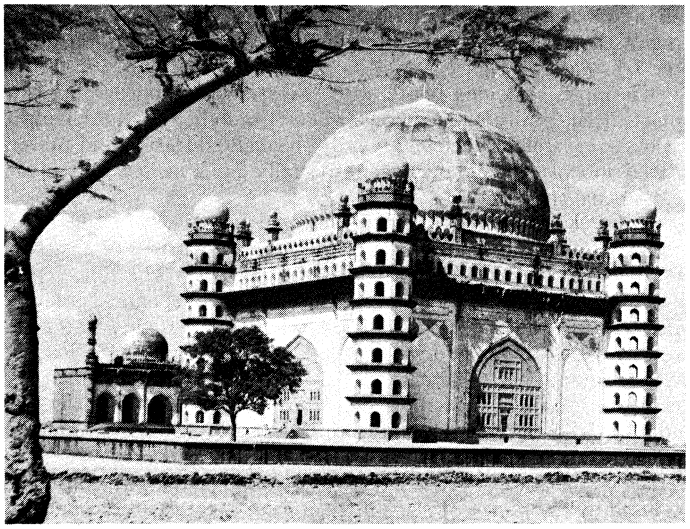
Reid, *Report on the Settlement Operations in the District of Azamgarh* (1881), containing, in appendices, full grammar and vocabulary of Western Bhojpuri

No special works have been written about Magahi. (ET. B)

BIJAPUR, a town in Mysore state, India. and headquarters of Bijapur district, lies 250 mi. S.E. of Bombay. Pop. (1951) 65.734. The capital of the Yadava kings for over a century before its conquest by the Delhi Khaljis in 1294, it became a small Muslim outpost with its only Muslim buildings (mosques, guardrooms) constructed out of temple spoil. During the Bahmani rule of the Deccan. Bijapur's importance increased, but in 1489 Yusuf, an alleged son of the Ottoman sultan Murad II, established his independence and built his citadel in Bijapur, taking for his dynasty the name 'Adil Shah. The dominions were extended to include Goa, where a navy was maintained. In 1565 the combined Bijapur, Ahmednagar and Golconda armies defeated the Hindu Vijayanagara forces at the battle of Talikota. The Maratha leader Sivaji (*q.v.*) attacked Bijapur and seized many fortresses between 1646–48, and in 1686 Aurangzeb conquered Bijapur which remained annexed to the Mogul power until in 1724 the Nizam became independent in the Deccan and included it in his dominions. It was ceded to the Peshwa in 1760, passing into British hands in 1818.

The 'Adil Shahi sultans were patrons of the arts, and especially developed building; theirs is structurally and aesthetically the most satisfactory of the Deccan styles. There are thus more significant and excellent buildings in Bijapur than in any other Indian city except Delhi. There are two main phases: firstly rubble-and-plaster, steadily progressing to finely sculptured stonework. Most noteworthy features are the doming system with a striking treatment of pendentives; profuse employment of minarets and pinnacles as ornamental features; elaborate cornices; and reliance on mortar of extreme strength. Domes were first hemispherical. later three-quarter spheres, on tall drums, with their springing surrounded by a ring of vertical foliations so that the whole resembles a bud surrounded by petals. A characteristic façade decoration is the filling of the arch spandrels by medallions on a flat bracket-shaped device. The arches themselves are struck from two centres, the curves stopping some way from the crown. continued to the apex by straight tangents. The building stone is the local brittle trapstone. There is evidence to show that architects were imported from north India and that free use was made of local Hindu craftsmen. In the reign of 'Ali I (1558–80) were built the city walls, suburbs and his great Jami mosque (418 by 251 ft.), sparsely decorated hut dignified in its severity. The palace complex dates from 1582 in the reign of Ibrahim II, but in 1599 this monarch proposed moving his capital three miles west to where the water supply was better; this new town. Nauraspur, was sacked in 1624 before its completion. The 'Adil Shahis' greatest work was



BY COURTESY OF THE DEPARTMENT OF ARCHAEOLOGY, GOVERNMENT OF INDIA
GOL GUMBAZ. THE TOMB OF SULTAN MOHAMMED 'ADIL SHAH. BIJAPUR; 1626–56

the mausoleum of Ibrahim and his family. the Ihrahim Rauza, completed 1626: within a garden 420 ft. square stand a tomb and mosque on a common plinth, perfectly balanced, in elaborately sculptured gray stone. An exquisite building of the end of Ibrahim's reign is the Mihtar-i-Mahall, really a mosque gateway, narrow of façade (vertical double-square), rich in stone diaper patterns, nith balconies supported on long stone struts, superb cornices and elaborate minarets, all richly carved. In the reign of Mohammed (1626–56), the style deteriorated through attenuation of drum and dome, but Mohammed's own tomb, the Gol Gumbaz (familiar to many from the old six-anna stamp) is one of the supreme triumphs of Islamic building: on a 156-ft. cube, with pagodalike octagonal corner turrets, rests a hemispherical dome of 144 ft. external diameter, supported by intersecting arches; the floor area, over 18,200 sq.ft., is the largest in the world covered by a single stone dome.

Curious in the Bijapur coinage is the larin or "fish-hook" money, a standard currency in 16th-century Indian ocean trade.

The town is the seat of Vijay college (1945), connected with Karnatak university.

BIJAPUR DISTRICT was formed in 1864, with an area of 6,590 sq.mi , and had in 1961 a population of 1,658,453. There is grain and cattle trading and some cotton milling. Cotton, millet and wheat are the chief crops. The district was transferred from Bombay to Mysore state in the 1956 redistribution.

BIBLIOGRAPHY.—H. Cousens, *Bijapur and Its Architectural Remains*, Archaeological Survey of India, vol. xxxviii (1916), is the standard work. General stylistic appraisal of architecture in Percy Brown, *Indian Architecture (the Islamic Period) (1943). See* also *Encyclopaedia of Islam*. (*J.* B-P.)

BIJNOR, a town and district in the Rohilkhand division of Uttar Pradesh, India. The town lies 75 mi. N.E. of Delhi. with which it has rail and road connections, and is situated about 3 mi. E. of the Ganges river. Pop. (1951) 30.646. It was controlled in turn by the Moguls, the Marathas and the East India company, to which it was ceded in 1801.

BIJNOR DISTRICT, roughly triangular in shape. is bounded on the west by the Ganges and on the northeast by the foothills of the Himalayas, and has an area of 1,866 sq.mi. It is mainly a level plain but the northern part rises somewhat, the greatest elevation being 1,342 ft. above sea level. The Khoh and Ramganga are the principal streams. In 1961 it had a population of 1,186,001. The chief towns are Najibabad, Nagina and Kiratpur. Most parts of the district are watered by streams, supplemented by a series of small canals; irrigation from wells is also important. Rice, wheat, sugar cane, pulses and barley are the main crops. Sugar is produced in quantity, and there are three sugar factories in the district. (S. S. BH.)

BIKANER, a town and district and a former princely state in Rajasthan, India. The town, now a divisional headquarters, is 240 mi. W. of Delhi. Pop. (1961) 150,494. The city is surrounded by a stone wall, 6 ft. thick, 15 to 30 ft. high and 3½ mi. in circumference, with five gates and three sally ports. The citadel, ½ mi. N.E. of the city, is surrounded by a rampart with bastions and contains an interesting series of palace buildings of different periods, and a fine library and collections of Rajput paintings. Bikaner carpets are famous, and fine blankets and sugar candy are also manufactured. The educational institutions include five colleges connected with the University of Rajasthan.

BIKANER DISTRICT (pop. [1961] 444,183; area 10,501 sq.mi.) is a desolate tract overspread with undulating sand hills that rise 20 to 100 ft. above the plain and are so loose that men and animals stepping off the beaten track sink as if in snow. There are no permanent streams, and water is very scarce and is raised from wells of from 150 to 340 ft. in depth. A few shallow salt lakes are filled by rain water, but they dry up in hot weather, leaving a thick crust of salt on their beds, which is used for commercial and domestic purposes. The inhabitants live chiefly by pasturage, rearing camels, horses and sheep. The other industries are sugar refining, ivory carving, gold, iron: brass and copper work, stone masonry, tanning, weaving, dyeing and carpentry.

BIKANER STATE. In the 15th century the territory which later formed the princely state of Bikaner, of which the modern district is part, was occupied by Rajput clans, partly Jats, partly Muslims. About 1465 Bika, a Rathore Rajput, sixth son of Rao Jodha, chief of Marwar, started out to conquer the country. By taking advantage of the rivalries of the clans he succeeded; in 1485 he built the small fort at the capital which still bears his name: and in 1488 began building the city itself. He died in 1504, and his successors gradually extended their possessions. In the reign of Akbar the chiefs of Bikaner were loyal adherents of the Delhi empire, and in 1570 Akbar married a daughter of Kalyan Singh. Kalyan's son Rai Singh, who succeeded him in 1571, was one of Akbar's most distinguished generals and the first raja of Bikaner his daughter married Selim, afterward the emperor Jahangir. Wars between Bikaner and Jodhpur raged intermittently through the 18th century. On May 9, 1818, a treaty was concluded, and order was restored in the country by British troops.

During the 19th century unrest continued, centring on the rebellious behaviour of the thakurs, or subsidiary chiefs, and leading up to the permanent location at Bikaner of a British political agent in 1883, when the state was made subject to the Rajputana agency. Its military force included the famous camel corps. which distinguished itself in China in 1900 and in the middle east during World War I.

After India became independent, Bikaner was incorporated into the enlarged state of Rajasthan (March 30. 1949) and divided into the three districts of Bikaner, Churu and Ganganagar. (S. M. T. R.)

BIKINI, the site of several atomic bomb tests conducted by the United States. an atoll in the Ralik chain of the Marshall Islands in the Pacific ocean. 6° N. of the equator, about 190 mi. E. of the island of Eniwetok and 225 mi. N.W. of Kwajalein. The atoll is a coral ring of more than 20 islands, of which the principal one is Bikini Island. It was known before World War II as the Escholtz atoll.

The tests of July 1946, called Operation "Crossroads," the first peacetime atomic weapons tests, were held to obtain precise data on the effects of atomic explosions, particularly on naval vessels. The targets included battleships, aircraft carriers, submarines and landing craft, anchored in careful arrangement in the 25-mi.-long lagoon so that the effects of the explosions could be measured at different distances. Thousands of simple and complex instruments, along with pigs, goats and rats, were placed on the ships and on the islands. About 42,000 men participated in the tests. Operation "Crossroads" was observed by representatives of news organizations of the United States and of the 11 countries represented on the United Nations Atomic Energy commission.

The first test of Operation "Crossroads" took place on July 1, 1946. An atomic bomb! with an energy yield equal to approximately 20.000 tons of TNT, was dropped from an airplane and exploded in the air over the target ships. Five of the 90 target ships

were sunk. The second test, held on July 25, was the first underwater atomic explosion. A bomb of the same energy yield was suspended beneath a ship anchored in the lagoon and was there exploded. Nine ships were sunk. Radioactive water thrown into the air from the underwater burst drenched the other ships and contaminated them. While damage to the hulls from this explosion was about as predicted, the level of radioactivity was higher than expected and was a major problem on the target ships for several weeks after the test.

Much valuable information was obtained from Operation "Crossroads," particularly as to the effects of atomic explosions upon naval ships and other military equipment. Important data on radioactivity were obtained from remotely controlled, unmanned airplanes and boats which were moved into the centre of the explosion area as soon as possible after the detonation.

When Bikini atoll was chosen for the tests the 166 natives on the island, of mixed Melanesian-Polynesian stock, were moved with their belongings to Rongerik Island, 130 mi. E. of Bikini. The natives were later moved to the larger Ujelang Island, 290 mi. S.E. of Bikini and 400 mi. W. of Rongerik.

On March 1, 1954, a very powerful nuclear device was exploded at the Bikini atoll. Radioactive fallout seriously contaminated an area about 240 mi. long and 40 mi. wide. An unexpected shift of wind occurred after the detonation with the result that 31 U.S. test personnel and 236 Marshall Islanders on Rongelap and Utirik islands were exposed to radiation from the fallout. They were immediately evacuated. Some suffered skin burns and temporary loss of hair. The last of the evacuated natives mere returned to their home island in June 1957. A series of medical examinations extending over a period of years after the explosion showed that there was no reason to expect permanent aftereffects upon the health of these people. Not until mid-March of 1954 was it realized that the 23-man crew of the Japanese fishing vessel "Fukuryu Maru" (Fortunate Dragon) had been in the area about 85 mi. from the explosion. All of the crew were hospitalized for a year from the effects of radiation, and one died as a result of complications.

In i956 Bikini was the site of the test of the first hydrogen bomb dropped by a U.S. airplane.

Bikini has been administered by the United States since 1947 as part of the United States Trust Territory of Pacific Islands under United Nations trusteeship. Since 1953 the atoll has been part of the Eniwetok proving ground, site for further testing of United States atomic weapons. See also ATOMIC ENERGY.

(F. Du.)

BIKOL (BICOL), the fifth largest cultural-linguistic group in the Philippines, whose homeland is commonly considered all of "Bicolandia," a region comprising six provinces in the Bicol peninsula and neighbouring islands of southeast Luzon. Field studies indicate that the Bikol-speaking area is actually more restricted: its core is Albay, Camarines Sur and Catanduanes, while Masbate and southern Sorsogon are more closely allied to adjacent Bisayan areas, and northern Camarines Norte, to the Tagalog. Despite regional dialect differences, inhabitants of the Bikol area, who numbered about 1,560,000 in 1957, recognize as standard the speech of Naga (about 66,000), Bicolandia's political, ecclesiastical, educational and commercial centre since the founding of the city (1571) by the Spaniards.

The Bikol area is largely agricultural and rural. Of the gainfully employed 70% are in primary industries, especially rice, coconut and abaca farming (35% of iarm operators are tenants); 20% engage in tertiary industries such as commerce and government service. The concentrations of population at Naga, Legaspi City, Daet, Sorsogon and Tabaco should not obscure the fact that 80% of the people live in barrios (about 840) and that only 15 out of 74 towns have more than 5,000 residents (1948 census). The average density is about 4 persons per hectare, or 1,000 persons per square mile, of cultivated land. The area is nearly self-sufficient in basic food production.

In 1948 only 31% of the people spoke the national language (basically Tagalog), while 39% spoke English; there is not, however, any manifest antipathy to Tagalog. The literacy rate is 57%, slightly lower than the Philippine average. The percentage of Roman Catholics (98) is one of the highest area averages in the country (the national figure is 83%).

Kinship is reckoned bilaterally. Marriage is monogamous and most often locally endogamous. Social mobility in the basically two-class system is achieved mainly through education and preferential job placement arranged especially by kinsmen and upper class ritual sponsors.

See Frank Lynch, *Social Class in a Bikol Town (1959).* (F. LY.)

BILASPUR (KAHLUR), a town and headquarters of a district of the same name in Himachal Pradesh, India. The town (pop. [1951] 3,745) was the capital of the former independent state of Bilaspur in the Himalayan foothills. In 1814 the state was overrun by the Gurkhas and its raja, a Chandel Rajput, expelled; he was reinstated by the British in 1815 and from 1846 the state was controlled through the Lahore residency. From 1948 Bilaspur was administered through a chief commissioner; on July 1, 1954, it became a district of Himachal Pradesh.

BILASPUR DISTRICT (pop. [1961] 158,544; area 448 sq.mi.) is crossed by the valley of the Sutlej and its geography and agriculture resemble those of other parts of Himachal Pradesh (*q.v.*). Upon the completion of the Bhakra dam (see PUNJAB [India]) in the neighbouring district of Hoshiarpur in the Punjab, all land under 2,000 ft. above sea level will be submerged; this will include the town of Bilaspur and virtually all agricultural land in the district. A decision on the future boundaries of this and neighbouring districts had not been reached by the early 1960s. (B. AL.)

BILASPUR is a town and district in Madhya Pradesh, India. In 1951 the town, which is the headquarters of the district, had a population of 38,099. It is a railway junction, and has three commerce and arts colleges connected with the Saugar university (1959). Until captured by the Marathas in the 18th century, the town was the capital of a Gond kingdom. Its size and importance have grown with the development of the railways.

BILASPUR DISTRICT (area 7,615 sq.mi.; pop. [1961] 2,022,072) occupies the northern portion of the upper Mahanadi basin. It forms part of the Chhattisgarh plain, being closed in on the north, west and east by ranges of hills. On the north the Maikal hills, rising to 3,493 ft. at Amarakantak, contain the sources of the Narbada (*q.v.*) and Son (Sone; *q.v.*) rivers. It is well cultivated and closely dotted with villages surrounded by mango groves. The Mahanadi, with its tributaries Seonath and Hasdeo, drains the area. Flowing north from Raipur this river later turns east forming the southern boundary of Bilaspur district for 25 mi. The rainfall averages about 50 in. annually, and forests chiefly of sal occupy about one-third of the district. These are the home of various tribal groups including the Gond and Baiga. Rice occupies about three-fourths of the remaining cultivated land, and the district produces about 15% of India's lac and contains most of the lac factories of Madhya Pradesh. Coal is found around Korba, where it is worked in small quantities and where the installation of an electric generating plant was begun in 1959. *Tasar* (tussah) silk is produced by a small-scale cottage industry. (S. S. BH.)

BILBAO, a city and port in northern Spain, is 12 km. (7.5 mi.) from the Cantabrian coast at the point where the Nervión or Ibaizábal river becomes tidal and navigable and is encircled by mountains. Bilbao is the capital of Biscay, one of the three provinces forming the Spanish Basque country. Pop. (1960 est.) 267,293, the second largest urban concentration in Spain. Bilbao has an old and a modern part. The old town is on the right bank of the river, its nucleus being formed by the Siete Calles (Seven Streets), a series of parallel streets leading to the river bank. These formed the limits of Bilbao during the middle ages until, breaking through the walls which enclosed the Siete Calles, the town expanded into the surrounding areas, but without crossing to the other side of the river. In this part of the town are the oldest churches: those of Santiago (a cathedral since the creation of the bishopric of Bilbao in 1949) in Gothic style with a fine 15th-century cloister; San Antonio; Santos Juanes; and San Nicolás. There are also many houses bearing coats of arms, and the Plaza Nueva, constructed during the early part of the 19th century, deserves mention.

On the left bank of the river the township of Abando, once independent. was annexed to Bilbao in 1890. This was the period of the town's great expansion to the other side of the river where the new Bilbao grew up with wide streets and spacious plazas. The Gran Vía cuts across the new part of the town and is the commercial and banking centre of Bilhao. and the site of the enormous offices of the provincial government. The town hall is on the river bank. There is the largest of the town's parks. within which is the Fine Arts museum, specializing in modern Spanish paintings. Another museum is that of ethnography and archaeology, devoted to the history and folklore of the Basques. The six bridges which link old and new Bilbao were all reconstructed after the civil war. Bilbao has had since 1955 a faculty of economic sciences attached to the University of Valladolid. There is also a technical school for industrial engineers, and a school of mining and mercantile studies, together with a centre for training lawyers anti economists run by the Jesuits in the Deusto district. Three other towns, Begoña, Deusto and Luchana-Erandio, close to Bilhao. were annexed to the municipality after Xhando in 1890 to form. with it. the modern extension of the town. Begoña possesses the most venerated Marian shrine in Biscay—that of the Virgin of Begoña. Deusto and Luchana-Erandio are both industrial areas.

Rilbao is one of the most important ports in Spain. with an average daily entry of 15 ships. The Santurce breakwater and the countermole at Las Arenas-Algorta, engineered by Evaristo Churraca, ended the danger to shipping from the Portugalete bar. The Abra or exterior port can handle big transatlantic ships. Economically Bilbao is important as one of the higgest concentrations in Spain of heavy and chemical industries and as a financial centre. Metallurgical industries predominate; the metal industry was founded in the 19th century. based on the rich iron ore deposits to the west of Bilbao. The export of ore to England and the commercial activities of the inhabitants provided the basis for its modern industry. The chemical industry became prominent in the second half of thc 20th century. Other aspects of the economic life of the port include the fishing industry. conducted at the neighbouring ports of Santurce, Bermeo and Ondarroa. and shipbuilding and repairing.

History.—Bilbao originated as a settlement of seafaring people on the banks of the estuary, from which they began the export of iron ore and the products of their ironworks. The latter n-ere very well known. and Shakespeare refers to the excellent swords of "bilbos" made from the steel of Bilbao. The sea captains and mariners of Bilbao were famous in the middle ages as the best freight carriers of the Cantabrian coast. To this settlement of mariners and ironworkers Diego Lbpez de Haro, lord of Riscay, in 1300 gave the charter and privilege of self-government in an independent municipality. Other Castilian monarchs awarded privileges 'and franchises to Bilbao. Burgos used Bilbao for the export of wool from the interior of Castile to Flanders. In 1511 Bilhao obtained the right, like Burgos. to possess a consulate or commercial tribunal which could issue laws in the form of ordinances. The last of these. issued in 1737, formed the basis of the first Spanish commercial code in 1829. In the 18th century Bilbao enjoyed great prosperity. dealing intensively with the produce of the Xmerican colonies. In the 19th century the town was involved in the Carlist wars and was besieged four times—1835. 1836 (twice) and 1874. These struggles produced a strong communal spirit which, after 1874, directed itself toward industrialization.

(M. B. F.)

BILBERRY (BLAEBERRY or WHORTLEBERRY), known botanically as *Vaccinium myrtillus* (heath family, Ericaceae), a low-growing shrub, found in open woods, copses and on heaths. chiefly in hilly districts of Great Britain and northern continental Europe and Asia. The stiff stems, from 6 in, to 18 in. high, bear small ovate leaves with serrated margins, and small, globose, rosy flowers tinged with green.

The berries. ripening in July and August, are dark blue, with a waxy bloom, and are about one-third of an inch in diameter; they are used for tarts, preserves. etc., and are a principal food of the grouse. The berries are borne singly in contrast to those of the cultivated blueberries of the United States (different species of the same genus). which are borne in racemes, hence being much more productive than the bilberry. V. *myrtillus* is frost susceptible, in part at least self-sterile and has been hybridized with V. *prunus idaeus*.

Cowberry, mountain cranberry, partridgeberry, foxberry or whimberry is a circumpolar allied species, *V. vitis-idaea,* growing in similar situations. It is distinguished by its evergreen leaves and red acid edible berry. *See* BLUEBERRY; CRANBERRY; VACCINIUM.

(G. M. D.)

BILDERDIJK, WILLEM (1756–1831), Dutch poet whose ideas had great influence. not only on poetry, but on the intellectual and social life of the Netherlands. Born in Amsterdam, Sept. 7, 1756, of a strongly Calvinist and monarchist family, he had a crippled foot and spent a precocious childhood among books. After studying law at Leiden, he practised as an advocate at The Hague until 1795, when, as an Orangeist, he was forced into exile by his refusal to take the oath of allegiance to the republic established by the French. He went to Germany and then to London, where he met Katherina Schweickhardt, herself a poet, whom he married in 1802 after divorcing his first wife. In 1806 he returned to the Netherlands. After the restoration he hoped in vain for a professorship at Amsterdam. In his later years he was a disappointed man, feeling that he had been overlooked. He died at Haarlem, Dec. 18. 1831.

Bilderdijk was a romantic personality. To him emotion was the mainspring of life and poetry a divine gift, the poet being a prophet. His romantic arrogance was sometimes in conflict with the humility enjoined by his Christian belief. He regarded himself as a descendant of the Knight of the Swan and in his attitude to marriage considered himself above the civil law. As a historian he had a romantic conception of the monarchy and rejected the idea of government by the people. His contempt for the oligarchs who ruled the Netherlands during the golden age of the Dutch republic is expressed in his *Geschiedenis des Vaderlands* (1832–51). His extreme view of the importance of authority enables him in his unfinished epic, *De ondergang der eerste wareld* (ed. 1820), to condemn forcibly the rebels against God. His own submission to God is expressed in his famous poem *Gcbed* (1796).

Bilderdijk began to write at the period of the Gothic revival and his early poems and letters showed the influence of ballads and romances and of the songs of Ossian. Later he attacked the poetic rules of the neoclassicists; while honouring Homer as the greatest poet of all time. In his didactic poem *De Kunst der Poczy* (1809) he recalled his fight for poetical freedom. Other didactic poems are *De zickte drr geleerden* (180j) and *De Dieren* (1817). Like many Romantics, Bilderdijk was haunted by the idea of his own death and wrote about it in several poems, notably *Afscheid* (1811) and *Uitvaart* (1827).

See R. A. Kollewijn, *Bilderdijk, zijn leven en werken* (1891); H. Bavinck, *Bilderdijk als denker en dichter* (1906). (J. C. B. C.)

BILECIK, a town of northwestern Turkey and centre of an *il* (province) of the same name, lies on the upper slopes of the valley of the Karasu, a tributary of the Sakarya (Sangarius). Pop. (1960) 7,535. Taken by the Turks at the close of the 13th century.' the ton-n was important as the first capital of the Ottomans. Some 14th-century mosques still exist. Bilecik became prosperous and was a centre of the silk industry up to the time of the Turkish war of independence (1920–22) when it was heavily damaged and lost its economic importance. The town consists of the remains of the old town on a hill and the modern quarter around the railway station on the Ankara-Istanbul line. It is also linked by road with Ankara through Eskisehir (53 mi.) and with Istanbul.

The *il* includes some rough country lying between the Marmara and central Anatolia regions. It had a population in 1960 of 145.747 and an area of 1.829 sq.mi. Stock raising is the principal occupation; crops include cereals and, in the valleys, vines. cotton and vegetables. (N. TU.; S. ER.; E. TU.)

BILE DUCTS, the tubes by way of which bile is carried from the liver to the gall bladder and from both liver and gall bladder to the duodenum. *See* GALL BLADDER; GALL BLADDER, BILIARY TRACT AND LIVER, DISEASES OF; LIVER.

BILFINGER (BIELFINGER or BÜLFINGER), **GEORG BERNHARD** (1693–1750). German philosopher, mathematician and statesman, whose importance lies not in his mathematical, astronomical, physical, botanical and theological investigations but in his position in "Leibniz-Wolffian philosophy." He was born on Jan. 23, 1693, at Canstatt in Wiirttemberg. Ger. Bilfinger studied at Tiibingen university and then under Christian Wolff at Halle, where he concentrated on mathematics. Returning to Tiibingen, he was appointed court preacher and, in 1721, extraordinary professor of philosophy there; and in 1724 he was appointed ordinary professor of moral philosophy and mathematics. In 1725 he went to St. Petersburg as professor of logic, metaphysics and moral philosophy, becoming at the same time a member of the St. Pctersburg academy.

The Paris academy awarded Bilfinger the highest prize for his dissertation *De causa gravitatis* (1728). In 1731 he returned again to Tiibingen as professor of theology. He was granted a pension (because of his book on fortifications) and became superintendent of the theological seminary (1731); privy councilor (1735) and president of the consistory (1737). He died at Stuttgart on Feb. 18, 1750.

Bilfinger was one of the most accomplished men and one of the acutest intellects of his time. Although he was the pupil, friend and defender of Wolff, it was rather on Leibniz that he concentrated his attention, whether critically or favourably. Two points of difference from Leibniz are especially important. Whereas Leibniz had held each monad to be at once body and spirit, Bilfinger insisted on the heterogeneity of material and spiritual substances, nith the consequence that he could not regard all monads as percipient: some of them rather were endoned only with moving force (the more realiitic character of his philosophy is shown by his temporary attempt completely to replace the *vis percipiendi* of the Leibnizian monads by *vis motrix*). His other major deviation from Leibniz was on the question of pre-established harmony, which he held to apply not to the whole universe but only to the relation between soul and body and to consist in a correspondence of inner states in the percipient and in the nonpercipient monads.

Bilfinger's major publications were: *Dissertatio de harmonia praestabilita* (1721); *De triplici rerum cognitione* (1722); *De axiomatibus philosophicis* (1722); *De harmonia animae et corporis humani maxime praestabilita* (1723); *De origine et permissione mali* (1724); and his most important work, *Dilucidationes philosophicae de Deo, anima humana, mundo et generalibus rerum affectionibus* (1725 and later editions). (M. O. G.)

BILHARZIASIS: *see* SCHISTOSOMIASIS.

BILINGUALISM. The learning of one language is a universal trait of human behaviour; the mastery of two or more languages—bilingualism or multilingualism—is a special skill. Bilingualism and multilingualism are relative terms since individuals vary greatly in types and degrees of language proficiency.

The Bilingual Individual. — What makes a person bilingual? It is usually regular contact with people who speak another language. Such contact may come from intermarriage, immigration, trade, colonization, religious conversion, military conquest, travel or residence in a foreign or bilingual community. A person may also become bilingual through foreign language study; in many countries the mastery of a second language is an indispensable part of education.

Bilinguals differ in the skill with which they use their languages and in the environments in which they use them, in the age and order in which they learn them and in their ability to switch from one language to another and keep both languages apart. Between the language of the home and the language of the school there is often a difference which may force a bilingual. for the rest of his life, to pray in one language and count in another. Bilinguals generally experience periods in which one language becomes more prominent than the other. When this process continues in one direction it may eliminate one of the languages—even the mother tongue.

The Bilingual **Community.**—When a community which speaks one language lives in contact with a community which speaks another. a proportion of one or both communities becomes bilingual. The linguistic frontiers between the communities may correspond with geographical or political borders or may exist within the same national boundary, as is the case in such officially bilingual countries as Belgium where Flemish (a Germanic language) is spoken in the north, an area which corresponds to that occupied by the Germanic invaders—the Franks in the 4th century A.D. and the Germani in the 1st century; whereas Walloon French (a Romance language of Latin origin) is used south of a line which marked the limits of the Roman occupation.

There are also historical explanations for the distribution of French and English in Canada, of Czech and Slovak in Czechoslovakia, of Swiss German, French, Italian and Romansh in Switzerland, of Afrikaans and English in the Union of South Africa, and of Serbian, Croatian and Slovenian in Yugoslavia, all of which countries are officially bilingual.

Because a country is officially bilingual does not necessarily mean its entire population is. Bilingualism in certain unilingual countries may be more widespread, although perhaps less permanent. In the United States more than 20,000,000 persons reported in 1940 that the language of their childhood was not English. These were mostly immigrants or descendants of immigrants who, on arrival in the new country, joined others of the same language and formed isolated communities. In many cases the demands of mass communication in an industrial society put an end to their isolation, forcing them into bilingualism. If their children receive their schooling in the language of the surrounding majority, the whole community eventually becomes bilingual and the immigrant language, no longer needed in communication, is neglected by succeeding generations and may eventually die out. In such cases bilingualism functions historically as a transition from one general language to another.

The history of many countries shows a number of these bilingual transitions. France had the Gallo-Roman period (Celtic and Latin) at the rise of the Roman empire, and the Frankish period (Germanic and Latin) at its downfall. England too, after the Viking and Norman conquests, experienced periods of bilingualism. After 1066 it was in the interest of the conquered Anglo-Saxons to learn the French of their Norman masters who, when cut off from France after about 1250, started taking an interest in the language of the English-speaking majority. By about 1300 many children of Norman ancestry had English as their first language, and a large section of the nobility had become bilingual. These bilinguals often mixed their English speech with French words, such as *court, saint, music* and *beauty*, which now form a large and essential part of the English vocabulary.

Effects on Language.—Nearly every sentence of English shows traces of the languages which the English people. have had to learn in the past—French, Norse and Latin. In fact, any prolonged period of bilingualism leaves some trace on the vocabulary, grammar or phonemes of one or both languages.

Vocabulary is the most readily transferred, especially the names of objects for which there is no exact equivalent in the borrowing language. When they appear, the borrowed words are not necessarily placed in the same part of speech from which they came; nouns may turn out as verbs, and verbs as nouns. Thus the old French verb *demorer*, "to delay," appears as an English noun, *demurrer*; and the English participles *dancing, parking* and *smoking* appear as nouns in French. Borrowed words must be made to fit the grammar of the language borrowing them. English nouns must appear as either masculine or feminine if used in French. The English word *gang* was put in the masculine in France—but in French Canada it appeared as feminine. Verbs must be placed into a certain conjugation in French; since most new verbs go into the first conjugation *(-er)*, English *stop* became the French verb *stopper*. Borrowed words must also be made to fit into the sound patterns of the language. So the English word *store* appears differently in some of the immigrant languages of the United States: *storo* (Italian). *estor* (Spanish), *sztór* (Hungarian), *stoori* (Finnish), *štòras* (Lithuanian), *sztor* (Polish), *štor* (Serbian), *star* (Syrian).

Bilingual contact may change the meaning of a native word. Acadian French has extended the meaning of *introduire* ("to insert." "to admit") to include that of the English *introduce* (someone to somebody), in French *présenter*.

Certain grammatical features may also be attributed to the bilingual influence of neighbouring languages. Suomi Finnish and Estonian were almost identical in the 13th century. In modern times their differing passive forms are due to the fact that Estonian was influenced by German and Suomi by Swedish.

Finally bilinguals may transfer sounds and phonemic patterns from one language to another. The replacement of [f] by [h] in Spanish came from the speech of the Therians and of bilingual Basques. who became prominent when their country was a centre of Spanish culture and resistance during that period when most of Spain was under Moorish occupation. The fronting of Latin [u] to French [y] as when Latin *murus* becomes French *mur,* has been attributed to the pronunciation habits of the bilingual Gauls Such features of languages long extinct may thus survive in the modern languages.

BILL. The term "bill" has three distinct meanings: (1) a written, originally sealed. document; (2) a long-handled cutting weapon *(see* HALBERT); and (3) the beak of a bird (*q.v.*).

In the sense of a ducument the word is used in various connections in law and commerce.

In legislation a bili is a draft oi a proposed statute which is introduced in the legislature and which if passed and signed by the executive becomes an act (*see* LEGISLATION; STATUTE LAW).

A bill in chancery or bill in equity is a written statement of the plaintiff's case and a prayer for relief upon which a suit in equity is based. In Great Britain it was abolished by the Judicature acts of 1873 and 1875 and its place was taken by a writ and statement of claim. In the United States it was abolished in federal practice with the merger or' the forms of action under the Federal Rules of Civil Procedure (1938) and disappeared even earlier in most of the states. Where the distinction between lam and equity remains, however, the term is still in use. *(See* PRACTICE AND PROCEDURE.)

A hill of indictment is a written accusation against a prisoner, charging him with an offence, and presented to the grand jury *(see* INDICTMENT; CRIMINAL LAW: *Criminal Procedure;* JURY).

A bill of exceptions is a statement in writing of objections to the rulings of a judge who, at a civil trial, has mistaken the law, either in directing the jury. or in refusing or admitting evidence or otherwise. In England the bill of exception.; was abolished by the Judicature act of 1875, and a "motion for a nevi trial" substituted. In the United States rule 46 of the Federal Rules of Civil Procedure makes exceptions unnecessary by making it sufficient for a party to object to the judge's ruling by stating the ground of his objection at the time the ruling is made. In some of the practice acts of the states the filing of a bill of csceptions is still a requirement for appeal. though there is a marked trend toward liberalizing the requirement.

A bill of health is a document given to the master of a ship by the consul or other proper authority of the port from which he clears. describing the sanitary state of the place. A bill of health may be either "clean," "suspected" or "touched." or "foul." A "clean" bill imports that at the time the ship sails no disease of an infectious or contagious kind is known to exist; a "suspected" or "touched" bill that no such disease has yet appeared but that there is reason to fear it; a "foul" bill that such a disease actually exists at the time of the ship's departure. Bills of health are necessary where the destination of rhe ship is a country whose laws require the production of such a bill before the ship is allowed into port and where, in default of such production. the ship is subjected to quarantine.

A bill of particulars is a supplementary statement in writing requested by a party to an action when pleadings filed by the opposing party are so larking in details that they fail to inform him of the nature oi the case he must meet. In U.S. federal practice the bill of particulars was abolished by a 1948 amendment to the Federal Rules of Civil Procedure, which substituted a motion for a more definite statement. In the states bills of particulars are stiii used. even in some oi the more recent codes of civil procedure. The bill of particulars = retained in the Federal Rules of Criminal Procedure. but they are rarely granted.

BILLAUD-VARENNE, JEAN NICOLAS (1756–1819), French revolutionary politician notorious for his extreme republican views and a leading figure during the Reign of Terror, was born at La Rochelle on April 23, 1756, the son of a barrister, He studied at the Collège d'Harcourt in Paris and then at Poitiers. qualifying as a lawyer in 1778. Returning to La Rochelle, he staged a comedy that he had written, but without success. After teaching at the Oratorian college at Juilly, he was called to the Paris bar. Th 1786 he married Angélique Doye, the illegitimate daughter of a farmer-general. It was at this period that he became acquainted with Gcorqes Danton and wrote several works anonymously, notably *Le Despotisme ties ministres de France . . ,* 3 vol. (1789), which was seized by the police.

Billaud-Varenne was from 1790 one of the most ardent of the "patriot" orators at the Jacobin club *(see* FRANCE: *History;* FRENCH REVOLUTION). After the flight of Louis XVI he called for the establishment of a republican government, putting his views forward in two pamphlets, *L'Acéphocratie* and *Éléments du républicanisme.* Secretary to the Jacobin club 2nd then vice-president: he was elected to the commune of Aug. 10, 1792, and became assistant to the public prosecutor. As deputy for Paris in the convention. he denounced the generals N. Luckner and A. R. Dillon and later, during the trial of Louis XVI, added new charges against the king. voting for death "within 24 hours." On June 2, 1793. he proposed the decree of accusation against the Girondins. On June 9, at the Jacobin club, he demanded the punishment of defeated military leaders, the detention of wives of *émigrés,* the formation of a revolutionary army and the levying of a forced loan on the rich. In August he went as representative *"en mission"* to the northern *départements* and caused numerous political suspects to be arrested at Dunkerque and at Calais. A member of the war committee, he was secretary of the Paris assembly, then its president (Sept. 5), and called for the trial of the ministers E. Clavière and C. F. Lebrun and of the queen. Msrie Antoinette. On Sept. 6. together with his friend J. Collot d'Herbois, he became a member of the Committee of Public Safety, In Feb. 1794, he went to Saint-Malo to supervise an expedition against Jersey.

Billaud-Varenne helped bring about the fall of Danton, of the Hébertistes and of Robespierre. He had originally supported Rohespierre, but on 8–9 Thermidor (July 26–27, 1794) he delivered a vehement attack on him. Subsequently he was himself attacked by the Thermidorians and prosecuted as a terrorist. Despite his courageous defense, he was found guilty and deported to French Guiana. After the *coup d'état* of 18 Brumaire (Nov. 9, 1799) he refused the pardon offered by Napoleon Bonaparte and remained at Cayenne, developing his small estate. He made his way to New York in 1816, but later sought refuge in Haiti, dying near I'ort-au-Prince on June 13, 1819. The *Mémoires* that he wrote in his youth appeared in the periodical La *Révolution française* in 1888. Further *Mémoires* written in Cayenne were published by A. Bégis (1893). (MA. BO.)

BILL BROKER, a broker who deals in bills of exchange. Bill brokers specialize in bill discounting. and their operations are very varied in character. They may deal for themselves as principals or for others as agents. When they sell bills of exchange on commission. they are purely brokers; this function has become almost obsolete. When they buy bills of exchange to sell again at a profit they become, in effect, bill merchants. *See* BILL OF EXCHANGE: DISCOUNT; DISCOUNT HOUSE; MONEY MARKET.

BILLIARDS, an indoor game of skill, played with various numbers of balls and a long stick, called a cue, on a rectangular

table that map or may not have pockets.

In the modern form of this game, the playing surface is covered with a tight-fitting green cloth and surrounded by rubber-cushioned rails.

The various games of billiards include pocket billiards, more commonly called pool, played nith 15 coloured number balls and a white cue ball on a table with 6 pockets; snooker, played with 21 balls and a cue ball on a table with 6 small pockets; carom, or cannon, also known as French billiards, played with 3 balls on a table with no pockets; and English billiards played with 3 balls on a table with 6 pockets. In addition there are numerous varieties of each game particularly of French billiards and pool.

This article is divided into the following sections and subdivisions:

I. ORIGINS

Various fanciful accounts have been given of the origins of billiards. Some of these, indeed, trace it back to classical times, quoting as evidence some such witness as the Scythian philosopher Anacharsis, who mentions a game analogous to billiards that he watched while traveling in Greece. Other dubious, if not bizarre, resemblances allegedly exist in games played by the Greeks and Romans. In this connection, Jacques Bonhomme, writing in 1885, remarked with irony that had billiards been a Roman diversion Horace would assuredly have devoted an ode to it and Nero would have been diverted from his famed incendiary exploit by so agreeable a pastime.

Many countries, among them England, China, France, Italy and Spain, have been credited with inventing the game; but, in fact, nothing is known about the origin of billiards. It may only be inferred that it developed from a variety of games in which propelling a ball was a main feature.

Billiards has been related to such games as *shovilla bourde* or shuffleboard, popular in the time of Henry VIII. Later known as paille-maille or pell-mell, this was an early ball-and-mallet game played on the ground with hoops and is believed to be the origin of croquet.

The confusion in the nomenclature of games in general during the different stages of their development is another obstacle to accurate research. Etymology lends little aid, as the derivation of the word billiards from the French *billard,* or *billart* (O.F.), meaning a curved stick (cue), not to mention the diminutive *bille* (stick), is uncertain. "For myself," writes Maurice Vignaux in *Le Billard* (1895), "*bille,* meaning a ball, is the key, and billard comes from it. And *bille,* whence comes this? From *pila* (Latin) says one authority; and *pila* is derived from. . . ." After this he confesses to being lost in an etymological fog.

Research is on surer ground in the 16th and 17th centuries, however, for allusions to the game are then plentiful and there are old prints, both English and French, to provide corroborative evidence. Poets and dramatists such as Edmund Spenser in *Mother Hubbcrds Tale* (1591); George Chapman (1598), who makes a character say, "Go, Aspasia, send for some ladies who could play with you at chess, at billiards and at other games"; Shakespeare (1623), with his anachronistic "Let us to billiards . . ." from *Antony and Cleopatra;* Ben Jonson (1637); and, later, Samuel Johnson in his *Dictionary* (1755) all cite the game.

John Evelyn (1620–1706) had the habit of noting the billiard tables in country mansions he visited. Historical allusions such as the complaint of Mary, queen of Scots, in 1576, during her captivity, that her billiard table had been taken away, also occur. An interesting reference is to be found in Francis Quarles's *Emblems* (1635), in which one of the engravings depicts two angels playing a table game with balls, hoops and maces (the earlier form of the cue), the table having pockets.

In some of the old prints a number of obstacles are seen on the tables, such as hoops, ivory pegs or "kings," forts, batteries, etc., the player's ball being required either to circumvent such objects without knocking them over or to pass through them, as in the case of hoops. Objects such as forts gave a military flavour to the game, and one such contest bore the name of the "fortification game." A French print shows the duchess of Burgundy playing billiards with a mace in 1694 The first description of billiards in English is to be found in Charles Cotton's *Compleat Gamester* (1674).

Originally only two balls were used in French billiards, and it was thus imported into England. Holes, suggested probably by the iron hoop formerly used, were cut in the bed of the table, first in the centre, then at the corners and sides, into which the balls were driven. About 1775, the third ball, called a "carom," was introduced by the French. This third ball was soon brought over to England. The various terms applied to this phase of the game all mean one thing—striking both balls with a cue ball.

Billiards first became distinctly fashionable in the latter half of the 17th century during the reign of Louis XIV, who was advised by his physician to play the game every day after dinner. The king played with the duke de Villerdi and Monsieur de Chamillard. Although both were far better players than the king, they were too loyal to win often.

Billiards, shorn of its early crudities and more or less in its modern form, dates back to about 1800. In the first English book devoted to billiards, written by E. White in 1807, the same features are discernible as obtain today.

II. DEVELOPMENT OF IMPLEMENTS

1. Cue.—The cue was superseding the mace by the late 1700s, and about 1760 cues with perfectly flat ends or points came into vogue. Twenty-five years later, a cue cut obliquely at the small end or slightly rounded at one side was produced to enable the player to hit a ball below the centre. Still another change was adopted toward the end of the century when the point of the cue was beveled all around, thus making a still broader surface. The leather cue tip invented by Mingaud did not follow until 1806 when the advantage of using chalk was discovered. The billiard cue finally became, in its most popular form, a tapered wood butt made of an assortment of various-density woods, joined onto a carefully tapered maple shaft. This improvement made it possible to develop cues in various weights and balances. The end of the maple shaft that strikes the ball was fitted with various reinforcements such as fibre, buckhorn, ivory or plastic to which was cemented the leather cue tip, greatly improving durability and uniformity. Aluminum-alloy cues were introduced in the 20th century.

2. Chalk.—Players at one time roughened the cue tip by rubbing it against a whitewashed ceiling. Later, prepared chalk came into use. With a chalked cue tip the player is able to strike the cue ball off centre, imparting "side," as it is called in Great Britain, or "English," as it is called in the U.S. Before the introduction of

chalk it had been possible to strike the ball only at or near its centre.

3. Balls.—The most widely used billiard balls until the late 19th century were of elephant-tusk ivory. In 1868, John Hyatt, in his search for a better billiard ball, discovered that a mixture of nitrocellulose, camphor and a small amount of alcohol when properly prepared becomes thermoplastic, *i.e.*, soft when heated, and can be molded in a hydraulic press. After cooling at ordinary atmospheric pressure it becomes hard and strong. This discovery heralded the beginning not only of the composition billiard ball but of the plastic industry. In the 1920s a new type of plastic billiard ball was produced from cast phenolic resin which proved to be much more durable, ofiered a greater brilliance of colours and gradually replaced the ivory ball. Ivory was credited by the outstanding players with being more sensitive, but composition balls were found to be unaffected by weather and did not become imperfect and untrue as did those made from ivory.

4. Cloth.—Early in the history of billiards, billiard cloth was developed into a finely woven green woolen cloth with a lustrous nap. Because of its appearance, billiard cloth has also been referred to as a felt instead of a woven fabric.

5. Rubber Cushions.—John Thurston founded a billiard equipment firm in 1799 and, in 1835, he introduced an india rubber cushion to replace the old stuffed cushion built up with layers of list (strips of cloth) or felt. This rubber cushion was a great improvement, but cold weather affected its resilience. In 1842, however, the process of vulcanization was discovered, and in 1845 Thurston obtained letters patent for applying the process to billiard cushions.

6. Slate Beds.—A year after his introduction of the rubber cushion Thurston, in collaboration with Edwin (called Jonathan) Kentfield, introduced the slate bed (beds had formerly been made of wood). The slate sections were secured with brass dowels to form a perfectly flat surface. Accurate running of the balls was thereby greatly facilitated. Thurston also effected improvements in cues, balls, lighting and other equipment.

III. BILLIARD TERMS

Although some terms used in printed accounts of and books of instructions for billiards and expressions used by players are in common usage, there is considerable variation among certain terms as used in Great Britain and in the United States.

The following are terms having specific meaning when used in reference to billiards.

All-Round Cannon.—See Carom below.

Bank Shot.—A bank shot results when a player banks the cue ball or, in pocket billiards, drives an object ball against a cushion and then into a pocket.

Carom (*U.S.*) or Cannon (British).—A score or a count, the result of the cue ball bounding from one object ball to another. A carom may be made by the cue ball glancing off one object ball directly into the second (or third) object, or by glancing off first object ball into a cushion and then into the second (or third) object. A cannon in which two, three or more cushions are struck in between contact with the first and the second object balls is called an all-round cannon.

Centre Spot.—A spot in the exact centre of the table on which a cue ball or an object ball may be spotted in games requiring the use of that spot.

Cushion.—The felt-covered resilient ridge which borders the inside of the rails on carom and pocket billiard tables. Also, a cushion can be an '.objectn" in billiard games such as cushion caroms and three-cushion, which require cushion contact for legal scores.

Dead Ball.—One that stops or rolls "dead" upon contact with an object. A cue ball, for example, which stops upon contacting an object ball is called a dead ball.

English (*U.S.*) or Side (British).—Stroking influence a player is able to put on a cue ball to control the action of that ball either after or before it hits an object ball. Sometimes referred to as spin. English "left" is applied by striking the cue on the left side; "right" on the right side. Experts warn against the use of excessive English.

Frozen (*U.S.*) or *Touching* (British).—A term used to describe balls that are touching each other on the table. When object balls are frozen they remain in play as they are. When the cue ball is frozen to an object ball, player proceeds according to the rules of the game being played. A hall may also be frozen to a cushion; that is, resting against the cushion.

Full-Ball.—Aim taken through the cue ball centre at the centre of the object ball.

Half-Ball styoke.—A basic stroke for aiming, aim being taken through the centre of the cue hall at the edge of the object ball.

Hazard.—A basic scoring stroke, called winning or losing depending on whether the object or cue ball is pocketed.

Inning (*U.S.*) or Break (*British*).—A turn at the table. The duration of a player's stay at the table from the time he legally makes the first shot of a turn until he ends his turn. either by missing, fouling, scoring the maximum number of balls allowed or terminating the game.

Long *Loser*.—A losing hazard off a hall centrally situated into a top pocket.

Long *On-Off* (*U.S.*) or Long *In-Off* (*British*).—A loser off a bail situated between the pyramid spot and the top cushion.

Massé.—Extreme application of English downward on a cue ball, applied by elevating the cue. Half massé is applied by elevating cue to about a 45° angle. Full massé is applied by elevating the cue to an angle up to go°. Massé is used to drive the cue ball around or through one object ball to strike another, or to apply extreme follow or draw w-lien position of balls prevents the ordinary application of English.

Miscue.—Faulty stroke; faulty contact of the tip of the cue against the cue ball. A stroke in which the cue tip slips from the cue ball, because of a defective tip, improper chalking or, in many instances, excessive English.

Miss.—Playing the cue ball without contacting another ball.

Rack (*U.S.*) or Triangle (*British*).—The wooden triangle used to pyramid balls on thr foot spot for the opening shot in pocket billiard games. Also, the grouping of balls on the foot spot in pyramid formation after the wooden triangle has been removed. For example, the player, on the opening shot, drives the cue ball into the rack (racked balls).

Run-Through.—Making the cue ball follow- through the path of the object ball, either for a cannon or a losing hazard.

Safety.—A defensive measure used by a player when confronted with a difficult shot. He sacrifices an opportunity to score, as well as his turn at the table, in an attempt to leave a difficult shot for his opponent.

Scratch (U.S.) or Coup (*British*).—Running the cue ball into a pocket.

Screw.—Making the cue ball recoil at less than the natural (half-bail) angle off an object ball, by low striking; *i.e.*, at about one-quarter of its height.

Side.—See English.

Stun and Stab.--Causing the cue bail to remain stationary or nearby (after contact with the object ball) by hitting the cue ball dead centre, if the object ball is close, or below the centre to give it reverse rotation until it reaches the object hall, ii the object ball is some distance away. These two strokes, very similar. are almost the mainstay of break making in modern snooker.

IV. VARIOUS GAMES OF BILLIARDS

The game of billiards while using the same basic equipment of the table. the cue and the balls, has developed into several important variations

A. English Billiards

1. Table.—English billiards is played on an eight-legged table of oak or mahogany. 12 ft by 6 ft. 1½ in. in the area marked by the outside of the cloth part of the rail and measuring 2 it. 9½ in to 2 ft 10½ in from the door to the top of the wooden rail which surrounds the playing surface The slate bed is covered with billiard cloth which has a strong nap running irom the balk end (bottom) of the table to the spot end (top) The table has six net pockets. one at each corner and one at the centre of each of the long sides. The slate bed is cut away at each pocket to permit the balls to enter Rubber cushions also covered by the cloth and formed to project not more than 2 in. and not iess than 1½ in from the rail over the playing surface. make up a continuous boundary around the table. The edge of the projecting cushion surface slopes inward toward the base so that the balls come into contact with a thin strip of rubber only. The overhang of the cushion on the modern standard table is two inches. Consequently, the actual playing surface measures 11 fr. 8 in. by 5 ft. 9½ in.

The pocket openings must conform to the official templates by which tables are tested. The corner pockets measure 3½ in. across the actual spot where the fall of the slate begins, but manufacturers, when providing a standard table, cut the rubber to conform with the templates and not specifically to measurement.

2. Balls.—Billiard balls must be of equal weight (the average weight is about five ounces) and size (diameter of $2\frac{1}{16}$ to $2\frac{3}{32}$ in.). Two are white, one of them being distinguished by one or two black spots, at opposite points on its circumference. The third ball is red. The marked white ball is called "spot." the other "plain." One player plays with spot and the other with plain. and the I-)all

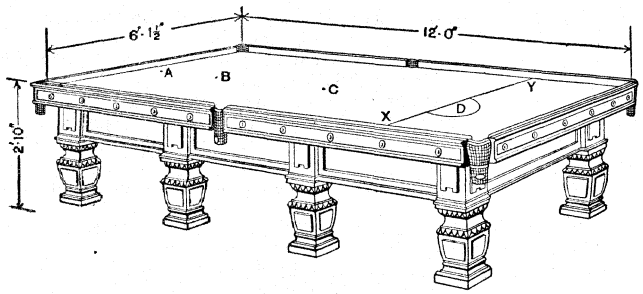

FIG. 1.—STANDARD SIZE ENGLISH BILLIARD TABLE. WITH MEASUREMENTS SHOWN

The length and breadth of the English billiard table are as shown: the height may vary between 2 ft. 9'2 in. and 2 ft. 10½ in. A shows the biliiard spot, on the centre line. 12¾ in. from the top cushion; C. the centre spot, in the centre of the table; and B the pyramid spot. midway between the face of the top cushion ard C: XY is tre talk line, and D the D

being played with--- ha! is. struck with the cue—is called the cue ball. The average length of the cue is 4 ft. 10 in.. and it must not measure less than j ft. Favourite weights are from 16 to 18 oz.

3. Markings.—A line drawn 29 in. from the face of the bottom cushion and parallel to it is called the balk line. The area between it and the bottom cushion is termed llie balk. A semicircle. 11½ in. in radius, with its centre at the middle of the balk line, is marked in the balk; this is called the D. The cue ball, retrieved from a pocket when the player has scored a losing hazard, mu-t then be played from within or on the lines of the D (called "playing from hand") and must be sent out of, riot into, balk.

Four spots (marked try silk wafers) are placed as follows: the billiard spot, 12¾ in. from the face of the top cushion and equidistant from the two long cushions; the centre spot, halfway between the centre pockets: the pyramid spot. halfway between the centre spot and the face of the top cushion; and the spot on the middle of the balk line. Thus all four spots are on an imaginary central longitudinal line. There is also a similar spot at each end of the D line; these are used only in snooker. To play up the table is to play with the cue pointing toward the billiard spot; to play down the table is to play with the cue pointing toward balk.

4. **Scoring.**—The player's ball is called the cue ball; the other two balls, the opponent's ball and the red, are called object halls. There are three ways of scoring: (1) the losing hazard or loser. a stroke in which the striker's ball is pocketed after contact with another ball; (2) the winning hazard or "pot," a stroke in which a hall other than the striker's ball is pocketed after contact with another ball; and (3) the cannon. a stroke in which the striker's ball contact. the two other halls successively or simultaneously. Two points are scored for a losing hazard off white. three lor one off red. Three points are scored for a winning hazard if red is potted; two if white. Two points are scored ior a cannon. If the red ball is potted twice in succession. it is spotted on the centre spot: if once: on the billiard spot.

The object of the game is to score more points than one's opponent. The skill involved consists of leaving one scoring stroke after another. A player continues at the table for as long as he succeeds in scoring.

A succession of scoring strokes is called a break. Losing hazards are limited to 25 in succession, or 1 j in professional and amateur championships. Consecutive cannons are limited to 35, after which the player must make either a losing or a winning hazard, a direct cannon in conjunction with a hazard or an indirect cannon (one in which the striker':, ball. aiter contact with the first object ball, strike: a cushion or cushions before making contact with the second object hall).

B. Carom or French Billiards

The game or' carom billiards is played on a pocketless table that is twice as long as it is wide. Balls and cues are the same as those used in English billiards.

For the layout of the table, which has no pockets; see *fig.* 2.

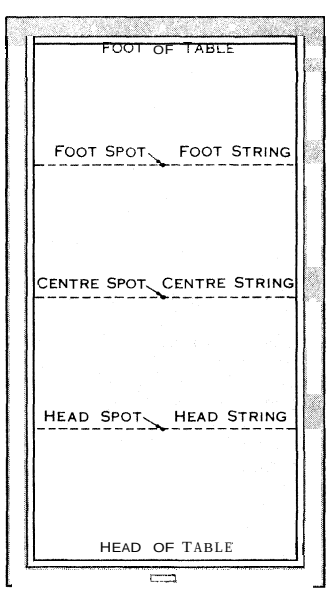
1. Three-Cushion Billiards. — All carom games, including three-cushion. are begun by lagging to determine rotation of play. If more than two players arc involved, rotation of play may be determined by drawing lots. When the game is played by two players (or sides) each player (or side) selects a cue ball (spot or plain) which is placed on the table within the head string. The red ball, meanwhile. has been spotted on the foot spot. The players, one lagging to the left of the red ball and the other to the right, stroke tire white halls to the foot cushion and return. The player whose ball comes to rest nearest the headrail wins the lag. The 11-inner has his choice of cue balls and also has the right to shoot first or assign the break shot to his opponent.

A count is made in three-cushion billiards (1) when the cue hall strikes an object ball and then strikes three or more cushions before striking the second object ball; (2) when the cue ball strikes three or more cushions before contacting the two object balls: (3) when the cue brill strikes a cushion. then the first object ball, then two or more cuchions and then the second object ball; (4) when the cue ball strikes two or more cushions, then the first object ball, then one or more cushions and finally the second object ball.

The number of cushions struck does not mean three different ones; a count may be executed on one cushion with the required number of contacts by the cue ball. Each three-cushion carom counts one point.

2. Straight-Rail Billiards. — In straight rail. the player must drive hi5 cue ball against the two object halls to score a carom for one point. He may contact both object halls at the same time or alternately. Cushion contact is not required. although a count is legal if one or more cushions are contacted. When object balls are crotched (standing in the corner of the table no more than 4½ in. out from either rail), three counts are allowed. The player then must drive an object ball out of the crotch. Failure to do so is a miss and ends the inning.

3. 14.2 **Balk-Line** Game. — To mark the tahle properly for 14-in. balk line! lines are drawn on a 5-by-10-ft. table from each of the first diamond sights on the end and side rails to the corresponding diamond sight on the opposite end or side rail. The large centre space on the table is not a balk space. The object balls are in balk whenever both have stopped within any one of the balk spaces The reieree then calls "in" and nhen one or hot11 object balls are driven out of balk space the reteree calls 'out" A ball on the line is in balk It is on the line only when its centre or point of contact with the table touches this line When two object balls are on the same line the striker has the option of determining in which ball, the) are to be called and must govern his play accordingly. But two shots are allowed when two object halls are within the same balk space; hence the name 14 2 balk line. At least one of the object balls must be driven out of balk on one of these shots Points are scored for caroms as in straight-rail billiards



BY COURTESY OF BILLIARD CONGRESS OF AMERICA

FIG 2 — PLANOF THE CAROM TABLE

4. 18.2 Balk-Line Game.— The game of 18 2 balk line is played on a 5-by-10-ft. table with the balk lines drawn 18 in from the edges of the cushions. In addition there are eight anchor spaces each seven inches square to which the same rulei apply as to the larger balks Two each are located on the headrail and on the footrail and two each on the side rails with the 18-in balk lines across the ends of the table as centres.

The general rules of 18 2 balk line are similar to those of the 14 2 balk-line game.

C. Pocket Games

Pocket games are played on billiard tables that are twice as long as they are wide and have six pockets, or openings—one in each corner of the table and one in the centre of each side rail. Most of these tables also contain ball returns to bring the balls from the individual pockets back to a rack at the end of the table. and sometimes are known as subu-ay or gully tables.

1. Snooker.-—In snooker, 22 balls. $2\frac{1}{8}$ in. in diameter, are used: 1 white ball (the cue hall), 1 j red balls and 6 numbered "colours," which are (with their values'): black. 7 points; pink. 6; blue, 5; brown, 4; green. 3; yellow. 2. The scheme of play is as follows: a player must first pot a red ball (one point). then try to pot any colour he may choose, scoring the value of the potted colour. Then, alternately potting reds and colours, he reaches the stage at which only the six colours remain, as each red, when potted, remains in the pocket, while the colours. when potted (as long as, any reds remain on the table), are placed on their respective spots. Finally, in potting the six colours the player must follow this order: yellow, green, brown, blue, pink and black. When this last is pocketed the game ends. This pocketing of the 21 object balls constitutes a frame. A match consists of a selected number of frames.

Snooker is related to the games of pyramids and pool, out of which it developed. The word snooker refers to a position in which a player cannot hit the ball which the rules require him to play at, because of obstruction by another ball or balls. He is therefore said to be snookered, and loses his turn. If he is snookered after a foul by his opponent, he may nominate to play at another ball. This is termed a free (nominated) ball.

2. Pocket Billiards or Pool.—The game of pocket billiards, commonly called pool and by far the most popular of all the billiard games, has a large number of players, particularly amateurs, in the United States. A white cue ball and 15 coloured number balls are used, with the balls from 1 to 8 in solid colours and from 9 to 1 j striped. The fundamental object of pocket billiards is to pocket the object balls.

Basic pocket billiards can be played by individuals or sides. One individual or side seeks to pocket eight balls before the opponents do. On all strokes following the opening shot, the player must call the ball or balls he intends to pocket. although he is not compelled to call the pocket.

Rotation, a popular game with the average amateur player, requires that the 15 object balls be pocketed in numerical order. The individual or side first scoring 61 points wins the game.

There are a number of other games of pocket billiards. Among those recognized with formal rules by the Billiard Congress of America are 15-ball pocket billiards, eight ball, line-up, bottle pocket billiards, cowboy, cribbage, forty-one, golf, Mr. and Mrs., one and nine balls, baseball, and poker pocket billiards. The Billiards Association and Control council of Great Britain has established rules for English billiards, snooker. volunteer snooker, pyramids, pool and Russian pool.

FIG. 3.—PLAN OF CHAMPIONSHIP POCKET BILLIARD TABLE

3. Continuous Pocket Billiards.—This is the championship game requiring the highest degree of skill. Players lag for break, and the winner may decide whether he or his opponent shall begin to play. For the first shot, all 15 object balls are racked in a triangle, the apex of which is on the foot spot of the table. The starting player on the opening stroke must drive tao or more object balls to a cushion or cause an object ball to drop into a pocket.

This is a call-shot game and the player must designate the ball he intends to pocket and the pocket in which he intends to score. If the player misses the shot called, it is an error and ends his inning. In the 14.1 pocket game, a player may pocket 14 balls successively. The 15th ball remains on rhe table as a break ball. The referee then racks the 14 pocketed balls, leaving the space at the foot spot vacant in the triangle. The player then continues, making the ball outside the triangle the break ball. The procedure is to pocket the break ball in a designated pocket and carom the cue ball from the break ball into the triangle of racked balls. The player can continue pocketing the 14 balls, having them reracked and breaking until he misses, scratches or scores 150 points.

4. **"Bumpers."**—After World War II, the game of billiards developed into a game widely played in the home. During the early 1950s a variation of the game known as "bumpers," or bumper pool. was introduced. In this game, cushioned pegs or bumpers were added to the playing surface, necessitating an emphasis on bank shots in order to dodge these obstructions. Following the wide acceptance and the reintroduction of this age-old game. it became an increasingly popular family game played in the home. mostly on small tables measuring 4 by 8 ft., $3\frac{1}{2}$ by 7 ft. and 3 by 6 ft. Tables for the home were made both with bumpers and in the standard pocket-billiard style.

V. CHAMPIONSHIP PLAY AND PLAYERS

The various games of billiards have been dominated for long periods of time by relatively few players. Since many billiard games were played primarily within certain geographical or national areas, international competition has not been as common as in many other sports. Record keeping in international cornpetition dates back only to the late 19th century.

A. England and Europe

The important games in England and European countries have been English billiards, snooker and French billiards

1. English Billiards.—Jonathan Kentfield was the first outstanding player (highest break, 196). In 1849, however, John Roberts Sr . father of the great John Roberts, challenged Rentfield who doubting his chances at his advanced age. refused to settle the issue by a match, and so Roberts became champion. He, in his turn. defeated all rivals until. in 1870, in the first official championship, he was beaten by a younger player. W. Cook. John Roberts. Jr , dominated the game in every respect for the rest of the 19th century. He brought to the game a pot-and-cannon sequence around the billiard spot as an antidote to the spot stroke (potting the red ball into the top pockets) uhich threatened to make billiards a one-stroke game.

A new era of great players began about 1900; namely, C Dawson. H. W. Stevenson. M. Inman, T. Reece. C Falkiner, Willie Smith. C Harverson and E Diggle. Willie Smith in 1928 compiled nhat is considered the finest "all-round" break (meaning without concentrated top-of-the-table play and without sequences of close. or nursery cannons; that is, cannons played with the three balls bunched together against a cushion and taken gradually along it). 2,743.

Red-ball play (in-offs) gradually became the dominating form after the turn of the century and in 1911 George Gray, an Australian, using this stroke extensively, again threatened the equilibrium of the game. Gray, who came to England for the 1910–11 season, made twenty-three 1,000 breaks by consecutive losing hazards off the red ball.

The period 1925–35 constituted the third golden era of professional play. Its dominating figure was the Australian Walter Lindrum. To his credit stands the record break (apart from one-stroke repetition breaks) 4,137, and many other records. The other outstanding players of this time were Joe Davis, Tom Newman and Clark McConachy. This period was notable for the reign of the nursery cannon.

Expert execution of certain strokes has, throughout billiards history. menaced the popularity of the game as a public attraction. Mastery at such play as the spot stroke (with the red ball spotted

on the billiard spot). the losing hazard and the nursery cannon, by its growing effect of monotony, became a real threat to public interest.

The rule making it compulsory to transfer the red ball to the centre spot, after being potted twice from the billiard spot, rendered the spot stroke impossible. The push stroke, in which the cue ball was shoved rather than struck with the cue, was prohibited and made a foul in 1898.

To counteract excess red-ball play, the Billiards association in 1926 limited consecutive losing hazards to 2j (later, 1j for championship play), while in 1932 the baleful effect of the nursery cannon was further countered by a rule which made it obligatory for a player to cross the balk line after every 150 points. In 1935 the rule was altered so that a player had to send the cue ball across the line during the last 20 points of each zoo points in a break. The balk-line proposals. welcomed at first by the professionals, were afterward strongly criticized, but, as nothing better could be suggested. the rule remained.

Amateur billiards after the early days of the amateur championships (1888–1900) improved remarkably, and in 1953: another Australian, Robert Marshall set a new amateur break record of 702.

2. Governing Bodies. — The first body formed to govern the game was the Billiards association (1885). Prior to this the professionals had been a law unto themselves. But, as the large amateur element in the game was still unrepresented. matters were far from satisfactory. Eventually: in 1908, the Billiards Control club was founded by an influential body of amateurs. Dual control, however, inevitably led to friction, rivalry and confusion. The two bodies amalgamated in 1919 and the Billiards Association and Control council became the sole governing body for the xport.

The Billiards Association and Control council promotes the interests of all concerned in the game, frames conditions and rules, and publishes the Billiard Player, which first appeared in 1920.

Billiards is extensively played by amateurs throughout Great Britain and the commonwealth; and, though snooker has the greater professional following, the older game has countless adherents.

3. Snooker. — About 1930 the billiard professional Joe Davis began to study snooker seriously. as he foresaw its potentialities as public entertainment. By studying the technique of the game, enriching it by development of positional play and increasing the control of potting, he was instrumental in bringing it new popularity. In doing this his billiard knowledge helped enormously, since he brought cue-ball control into the game by incorporating billiards craft, building the profitable red-and-black sequence (the most remunerative scoring force in snooker and basis of 100-point breaks) on the famous top-of-the-table sequence in billiards. In 1955 he achieved the "perfect" score of 147, so clearing the table. By 1960 Davis had compiled more than 650 "century" breaks at snooker.

Other professional snooker players included Horace Lindrum, Fred Davis, Walter Donaldson, Albert Brown, Alec Brown. John Pulman, Jack Rea, John Barrie, S. Smith, K. Kennerley and R. Williams.

Amateur snooker advanced greatly after the 1930s and several amateurs play a type of game which differs only in degree and not in kind from professional standards.

B. North and South America

Two basic types of billiards are played extensively in North and South America: carom billiards and pocket billiards, or pool. They can be easily distinguished by the tables on which they are played; pool tables have pockets at each corner and in the centre of the long rails (sides) and carom tables have no pockets. The rectangular tables for both forms must be twice as long as they are wide; 4-by-8-ft., 4½-by-9-ft. and j-by-10-it. sizes are authorized.

Tom Foley, an authority on billiards, dated the real start of the game in the United States from the year 1859. The first national match was played at Detroit, Mich., on April 12 oi that

FIG. 4.—CHAMPIONSHIP CAROM BILLIARD TABLE WITH DIMENSIONS
The playing surface of championship tables in the U.S. is 5 ft. wide by 10 ft. long. Other tables are 4½ ft. by 9 ft. and 4 ft. by 8 ft.

year between John Secreiter of Detroit and Michael Phelan of New York city. The game was for 2,000 points caroms. with 4 balls, the 4th ball being light red: on a 6-by-12-it., 6-pocket table. Pushing and crotching were allowed.. Phelan won this first championship event. Beginning in 1869 the championship was played for at 4-ball caroms on a 5½-by-11-ft. pocket table for 1,200 points. Pushing and crotching were barred; single caroms counted 3 and double caroms 6. In 1876 the rules were changed to what was called straight-rail play. three balls on a 5-by-10-ft. carom table. William Sexton was champion in 1876–78 and following him was Jacob Schaeier. Sr., known as the "Wizard," who was champion in the years 1879–82. In 1883 the 5-by-10-ft. table was in use with an 8-in. balk line to prevent nursing. Schaefer won in 1883–84. In 1885 the balk line was widened from 8 to 14 in. and Schaefer won again in the years 1886–90.

As the long reign of Jake Schaefer, Sr.. drew to a close. Willie Hoppe won the 18.1 balk-line world title from Maurice Vignaux of France in 1906. Hoppe dominated in world carom title play from that time until his retirement from championship competition in 1952.

Charles C. Peterson was known as the missionary of billiards, in addition to being the world's fancy-shot champion and for years holder of the red-ball title. Peterson did more, perhaps, to sell the game than any other billiard figure in the U.S. He made personal appearances at U.S. universities and became closely associated with both the Intercollegiate and Boys Clubs of America championships.

In pocket billiards, Alfredo DeOro and Thomas Hueston held sway around the turn of the 20th century, with Ralph Greenleaf dominating in the 1920s. In the following two decades, world titles were held, for the most part, by Erwin Rudolph, Andrew Ponzi and James Caras. Willie Mosconi won the first of his many world titles in 1941 and was the titleholder in the 1950s.

BILLINGHAM, an urban district (1923) in the Sedgefield parliamentary division of Durham, Eng., on the river Tees about 4 mi. N.W. of Middlesborough by road. Pop. (1961) 32.130. Billingham, still a hamlet after World War I, was founded in the 9th century; St. Cuthbert's church has a 10th-century tower. The building of the Port Clarence railway, begun in 1833, was the first step in the growth of Billingham. By 1837 an iron foundry and a glass works had been established at Haverton Hill

(part of the present urban district). The production of salt followed and by the early 1960s more than 70% of the adult population was working for Imperial Chemical Industries Ltd. During World War I the North Tees power station, a small garden village, and a shipyard at Haverton Hill with a model village for the workers were built. A bypass over the railway for the Stockton-Sunderland road was constructed during World War II.

BILLINGS, JOHN SHAW (1839–1913), U.S. surgeon and librarian, who achieved excellence in no fewer than six different fields—military and public hygiene, hospital construction and sanitary engineering, vital and medical statistics, medical bibliography and history, medical education, and the practice of medicine—was born on April 12, 1839, in Switzerland county, Ind. He graduated from Miami university. Oxford, O., in 1857 and from the Medical College of Ohio, Cincinnati, in 1860. During the Civil War he served as a surgeon in the field and in hospitals until 1864, when he entered the surgeon general's office in Washington, D.C. In this position he had charge of the army medical museum and library, and he developed the latter into one of the largest medical libraries in the world, for which he prepared an unusually valuable index catalogue.

Billings was one of the organizers of the Carnegie Institution of Washington and played an important part in the reorganization of the U.S. marine hospital service in 1870. In 1896, upon the consolidation of the Astor and Lennox libraries and the Tilden trust into the New York Public library, he became its first director. He died in New York city on March 11, 1913.

See F. *H.* Garrison, *John Shaw Billings* (1915).

BILLINGS, JOSH (pseudonym of HENRY WHEELER SHAW) (1818–1885), U.S. "cracker barrel" philosopher-humorist who reached an extensive audience during several decades following the Civil War through his newspaper pieces, books and comic platform lectures. His unique contributions to American humour were his rustic aphorisms ("The biggest phool in this world haint bin born yet; thare iz plenty ov time yet.") and his droll delineations of animal life. He was born at Lanesboro, Mass., April 21, 1818, was expelled from Hamilton college, Clinton, N.Y., in his second year and drifted about in the west and midwest for some years before settling in Poughkeepsie, N.Y., in 1858 as an auctioneer and land dealer. He began writing comparatively late in life, with slight success until he attempted the misspelled humour then in vogue. An "Essa on the Muel" made him suddenly famous, and after joining Street and Smith's *New* York *Weekly* in 1867 as an "exclusive" contributor he grew into a national idol. His books, apart from a 10-year series of burlesque almanacs (1870–79), were hasty agglomerations of his newspaper writings; the most comprehensive was *Everybody's Friend* (1874). For a time he contributed to the *Century Magazine* as "Uncle Esek," but his best work was done for Street and Smith. He died in Rlonterey, Calif., Oct. 14, 1885.

Shaw wrote almost no narratives and resembled only externally such contemporaries as Artemus Ward and Petroleum V. Nasby. His humour was intended as timeless, not topical.

See Joseph J. Jones, "Josh Billings: Some Yankee Notions on Humor," University of Texas, *Studies in English*, pp. 148–161 (1943); Jennette R. Tandy, *Crackerbox Philosophers in American Humor and Satire* (1925). (J. J. Js.)

BILLINGS, a city in south central Montana, U.S., on the Yellowstone river, 3,119 ft. above sea level; the seat of Yellowstone county. It is an important junction for air, rail and highway travel. Named for Frederick Billings, it was established in 1882 by the Northern Pacific railway upon its arrival in the Yellowstone valley.

Billings is the metropolis of the "midland empire," a productive region of Montana and Wyoming, with expanses of range land and broad irrigated river valleys. Sugar beets, wheat, wool and livestock are leading products of the area and there are large crude oil refineries in the vicinity. Other manufactures of importance include meat packing and flour milling. Billings' manufacturing plants employ more than one-tenth of the state's manufacturing employees rind its wholesale houses distribute to a large area. Its livestock commission sales and facilities are among the largest in the west. The Midland Empire fair is held there each year.

The Eastern Montana College of Education (founded in 1927), Rocky Mountain college (one branch of which was founded in 1883) and the first orthopedic hospital established in the northwest are situated there.

Billings is a gateway to the Beartooth division of the Custer national forest, one of the picturesque regions in the northwest, in which is Grasshopper glacier with millions of grasshoppers embedded in its ice. There are many vacation resorts in and near the forest including numerous dude ranches.

The population (1960) was 52,851. (For comparative population figures *see* table in MONTANA: *Population.*) The Billings standard metropolitan statistical area (Yellowstone county) had a population of 79.016 in 1960. (M. G. Bu.)

BILLINGSGATE, the most ancient city market of London, Eng., takes its name from Belin's gate, where royal tolls were collected on various goods as early as A.D. 980. It has been primarily a fish market since the 16th century. Statutorily established in 1699, the existing market on the north bank of the Thames was completed in 1876 and is now the clearinghouse ior the British fishing industry. Between 400 and 650 tons of every variety of fish are dealt with between 5 and 10 A.M. daily. Most of the fish is carried by land, and by the early 1060s there was little renewal of the water-borne supplies that ceased before World War II. The word "Billingsgate" was proverbially the coarse vituperation of scolding fish women. (H. G. B.)

BILLITON (BELITUNG), an island of the Republic of Indonesia lying between Bangka and Borneo. The Gaspar strait separates it from Bangka and the Karimata strait from Borneo. With Bangka it forms a division of South Sumatra province. Roughly square in shape, Billiton is 55 mi. long and 43 mi. wide, and its area, is 1,866 sq.mi. Included with it are 135 small adjacent islands with an area of 95 sq.mi., which are separated by narrow and mostly unnavigable channels. In physical structure and products it resembles Bangka (*q.v.*). Its coasts are sandy and marshy. In the centre a height of 1,673 ft. is reached (Mt. Tanjem) but most of the land lies less than 130 ft. above sea level. Groups of hills of granite or sedimentary formation rise from the fat or slightly undulating country; in the central parts there are treeless plains covered with alang-alang grass. The geological formation is Devonian and granitic, with laterites. The average annual rainfall is 114.5 in., with an average of 192 rainy days; the average temperature is 77°. Billiton has extensive tin deposits and forms the southern limit of the occurrence of this metal. Most of the tin ore is taken from alluvial deposits but there is some lode mining.

The estimated population of Billiton in 1956 mas 92,444, including many foreign Asians, largely Chinese. The aborigines (Muslims with some pagan beliefs) are akin to those of Bangka, resembling the Bataks of Sumatra; on the coast there are *Orang laut*, or sea gypsies. The coast is a difficult one. beset with rocks and coral banks, but one river, the Cheruchup, is 1,300 to 1.600 ft. wide at its mouth (barred by a sandbank), and is tidal for seven miles and navigable as far as Cheruchup village. The best harbour is that of Tandjungpandan (pop. [1958] 42,765), the capital of Billiton, on the west coast. Billiton was formerly under the sultan of Palembang, Sumatra, by whom it was ceded to the British in 1812. The British recognized the Dutch claim in 1824. Tin was discovered on the island in 1851. At first it was exploited by a private Dutch company, later with participation of the government in the profits. The ore was formerly sent to the Straits Settlements for smelting, but after 1936 it went to a new tin smelter in Holland. The Indonesian government has taken over the enterprise, but the actual mining is done largely by Chinese. (J. O. M. B.)

BILLITONITE: *see* TEKTITE.

BILL OF EXCHANGE, a form of negotiable instrument, defined by s. 3 of the English Bills of Exchange act, 1882, as an unconditional order in writing "addressed by one person to another, signed by the person giving it, requiring the person to whom it is addressed to pay on demand or at a fixed or deter-

minable future time a sum certain in money to or to the order of a specified person, or to bearer." Sec. 126 of the U.S. Negotiable Instruments law is identical, except that there a bill may only be made payable "to order or to bearer." The bill was in general use in English foreign commerce by the end of the 16th century. Since then it has also been widely used in domestic or so-called inland transactions. See CHECK; COMMERCIAL PAPER; INTERNATIONAL PAYMENTS. (R. T. S.)

BILL OF LADING, a document executed by a carrier, such as a railroad or shipping line, acknowledging receipt of goods and embodying the agreement to transport the goods to a stated destination. Bills of lading are closely related to warehouse receipts. which contain an agreement for storage rather than carriage. Both may he "negotiable" when they provide that the goods are to be delivered not to a fixed individual but (typically') to the "order" of a stated person; this person may eqdorse the document and deliver it to another, who will then be entitled to receive the goods. The rights of purchasers of such negotiable documents of title have been strongly protected by legislation. Such a negotiable document of title. which calls for the delivery of goods, must be distinguished from negotiable commercial paper (such as notes and bills of exchange) which calls for the payment of money. See AFFREIGHTMENT; COMMERCIAL PAPER; SALE OF GOODS.

(J. O. Ho.)

BILL OF RIGHTS, ENGLISH, is the name by which the "Act. declaring the Rights and Liberties of the Subject and Setleing the Succession of the Cron-ne." 1689 (1 Will. and Mar., Sess. 2, c. 2), is commonly known. It incorporated the provisions of the Declaration of Right, acceptance of which had been the condition upon which the throne held to have been vacated by James II was offered to the prince and princess of Orange. afterward William III and Mary II. The act began by reciting the unconstitutional proceedings of James II and its main stipulations were intended to prevent their repetition by future monarchs. They are as follows:

(1) That the pretended Power of Suspending of Laws or the Execution of Laws by Regall Authoritie without Consent of Parlyament is illegall; (2) That the pretended Power of Dispensing with Laws or the Execution of Laws by Regall Authoritie as it hath beene assumed and exercised of late is illegall; (3) That the Commission ior erecting the late Court of Commissioners for Ecclesiastical1 Causes and all other Commissions and Courts of like nature are Illegall and Pernicious; (4) That levying Money for or to the Use of the Crowne by pretence of Prerogative without Grant of Parlyament fur longer time or in other manner than the same is or shall be granted is Illegall; (5) That it is the Right of the Subjects to petition the King and all Commitments and Prosecutions for such Petitioning are Illegall; (6) That the raising or keeping a standing Army within the Kingdom in time of Peace unlessc it be with Consent of Parlyament is aoainst Law; (7) That the Subjects which are Protestants may have Arms for their Defence suitable to their Conditions and as allowed by Law; (8) That Election of Members of Parlyament ought to be free; (9) That the Frecdome of Speech and Debates or Proceedings in Parlyament ought not to be impeached or questioned in any Court or Place out of Parlyament; (10) That excessive Baile ought not to be required nor excessive Fines imposed nor cruell and unusuall Punishments inflicted; (11) That Jurors ought to be duely impanelled and returned and jurors which passe upon Men in Trialls for High Treason ought to be Freeholders; (12) That all Grants and Promises of Fines and Forfeitures of particular persons before Conviction are illegall and void; (13) And that ior Redresse of all Grievances and for the amending strengthening and preserving of the Lawes Parlyaments ought to be held irequently.

The act settled the succession upon the heirs of Mary, the heirs of Princess Anne (Mary's sister), and then upon the heirs of William, provided that they were Protestants. It prescribed the new oaths of allegiance and supremacy, and limited the practice of dispensation by *non obstante, i.e.*, by royal licence, to those statutes which explicitly allowed it.

The Bill of Rights. together with the Toleration act. 1689. the Triennial act. 1694 (later modified by the Septennial act. 1716), and the Act of Settlement, 1701. constituted the renovated foundation upon which government rested after the revolution of 1688. It sought to introduce no new principle into English government. but purported to declare the existing law. repairing some of the omissions and removing some of the obscurities which were thought to have been exploited by James II. Though possibly less important for deciding the future character of monarchy in the 18th century than the other parts of the revolution settlement. and certainly less so than the conditions which now made annual parliaments essential. the Bill of Rights has, nevertheless. considerable significance. In addition to clarifying the existing lam, particularly. perhaps, in respect of the suspending and dispensing powers of the crown, it clearly placed the monarchy upon a parliamentary and conditional basis: and though leaving the monarch the chief executive officer of government, still endowed with considerable power, it provided the foundation for that freedom from arbitrary government of which most 18th-century Englishmen were so proud and many foreigners were so envious. In theory, and before long in practice, it served to remove from the monarchy both the aura of divine right and something of the actuality of an obscure but extensive prerogative. It was not, however. intended to make monarchical government impossible, but only conditional. The positive role of monarchy was taken for granted rather than forgotten, but the question of the proper relation between king, ministers and parliament, so often agitated during the 17th century, was left undefined and unsolved by the Bill of Rights, to be answered as need arose in terms of the changing forces and interests of politicians and politics. In practice. the limitations imposed upon the monarchy eventually necessitated considerable changes in its functions. At the time, however, the ambiguities of the constitution and the uncertain distribution of political power provided no insuperable obstacles to the working of "mixed" regal and parliamentary government in a period when the conventions of constitutional behaviour were more monarchical and the demands upon government for swift and continuous legislative action mere less persistent than they subsequently became.

(RO. R.)

BILL OF RIGHTS, UNITED STATES, a term applied to the first ten amendments to the U.S. constitution, which were adopted in 1791. The term is also applied. by extension, to a larger composite of about 40 mutually reinforcing guarantees of individual rights and of limitations on federal and state governments found in the body of the constitution of 1787 and in various later amendments, as well as in the first ten amendments. The Bill of Rights derives from Magna Carta, the English Bill of Rights, the colonial struggle against king and parliament and a gradually broadening concept of equality among the American people. Virginia's 1776 Declaration of Rights, drafted chiefly by George Mason, was a notable forerunner. Besides being axioms of government, these guarantees have binding legal force. Acts of congress in conflict with them may be voided by the United States supreme court when the question of their constitutionality arises in appropriate litigation.

The constitution in its main body forbids suspension of the writ of habeas corpus except in cases of rebellion or invasion (i, 9), prohibits state or federal bills of attainder and ex post facto laws (i, 9. 10), requires that all crimes against the United States be tried by jury in the state where committed (iii, 2), limits the definition, trial and punishment of treason (iii, 3). prohibits titles of nobility (i, 9) and religious tests for officeholding (vi), guarantees a republican form of government in every state (iv, 4) and assures each citizen the privileges and immunities of the citizens of the several states (iv, 2). Popular dissatisfaction with these limited guarantees, expressed in the state conventions called to ratify the constitution, led to demands and promises which the first congress of the United States satisfied by submitting to the states 12 amendments drafted by James Madison. Ten were ratified. Individual states being subject to their own bills of rights, these amendments were limited to restraining the federal government. The senate refused to submit Madison's house-approved amendment protecting religious liberty, freedom of the press and trial by jury against violation by the states.

Under the first amendment, congress can make no law respecting an establishment of religion or prohibiting its free exercise. or abridging freedom of speech or press or the right to assemble and petition for redress of grievances. Hostility to standing armies found expression in a guarantee of the people's right to bear arms and in limitation of the quartering of soldiers in private houses.

The fourth amendment secures the people against unreasonable searches and seizures and forbids the issuance of warrants except upon probable cause, directed against specific persons and places. The fifth requires grand jury indictment in prosecutions for major crimes and prohibits double jeopardy for a single offense. It provides that no person shall be compelled to testify against himself, forbids the taking of life, liberty or property without due process of law or the taking of private property for public use without just compensation.

By the sixth amendment, an accused person is to have a speedy public trial by jury, to be informed of the nature of the accusation, to be confronted with the witnesses against him and to have the assistance of counsel. Excessive bail or fines and cruel or unusual punishment are forbidden. The ninth amendment protects unenumerated residual rights of the people, and by the tenth, powers not delegated to the United States are reserved to the states or the people.

After the Civil War, slavery was abolished by the 13th amendment (1865). The 14th (1868) declares that all persons born or naturalized in the United States and subject to its jurisdiction are citizens thereof. It forbids the states to abridge the privileges or immunities of citizens of the United States, or to deprive any person of life, liberty or property without due process of law, or to deny to any person the equal protection of the laws. The 15th (1870), last of the "Civil War amendments," outlaws racial discrimination in voting rights and the 19th (1920) forbids such discrimination based on sex. In 1954 racial segregation in public schools was held to violate the increasingly important equal protection guarantee. The due process clause of the 14th amendment is construed to prohibit the states from violating certain rights—notably those of the first amendment—which also are protected against federal violation by the Bill of Rights. This effectuates the major portion of Madison's unaccepted 1789 proposal. There has been varying minority support in the supreme court for the contention that the 14th amendment. by its wording and legislative history, makes the federal Bill of Rights generally applicable to the states.

BILL OF SALE, a written document transferring the ownership of goods. The function of a bill of sale corresponds roughly to that of a deed for the conveyance of land, but the bill of sale is of less importance for the transfer of property in the form of goods since this may be readily accomplished by physical delivery without further formality. In addition, the parties to a sales transaction may transfer property rights by a sales agreement without delivery of the goods and, under some circumstances, without the agreement being in writing *(see* SALE OF GOODS). In England the term has come to be applied to mortgages as well as to sales. and the expression "bill of sale" generally signifies a document evidencing a sale or mortgage of personal chattels unaccompanied by an actual transfer of possession. In the United States, however, the instrument most widely used for the assignment of personal property to secure a debt has been the chattel mortgage (*q.v.*) rather than the bill of sale.

In England and in some states of the United States, legislation has been enacted which denies effect to bills of sale against third persons, such as creditors, unless the bill of sale has been registered in a public office. The first English law on the subject: only slightly modified by subsequent legislation, was the Bills of Sale act of 1854, which provided that bills of sale would be void against execution creditors (those acting on a judgment against the debtor) unless registered. In a few states of the United States there is similar legislation, but in most states the effect of a seller's remaining in possession after a sale is left to case law. In some jurisdictions the transaction is held void against the seller's creditors, and in many the buyer has the burden of establishing that the sale is what it purports to be and not a sham designed to mislead or to defraud creditors. If the parties to the transaction do not contemplate a permanent transfer of ownership but, instead, merely an interest to secure the repayment of a debt, chattel mortgage statutes will generally render the "sale" ineffective against the debtor's creditors unless the transaction has been recorded in the prescribed manner in a public office. *See* also DEBTOR AND CREDITOR LAW; INSTALLMENT CREDIT.

(J. O. Ho.)

BILLOPP, CHRISTOPHER (1638–1726), British ship captain, traditionally supposed to have won Staten Island for the state of New York. The story is that in granting New Jersey to Lord Berkeley and Sir George Carteret, the duke of York did not make clear whether Staten Island was to be included in New York or New Jersey. He therefore ruled that all islands in New York harbour which could be circumnavigated in a day should continue to belong to him. Billopp succeeded in sailing around Staten Island in the appointed time, and as a reward the duke gave him 1,163 ac. of land at the foot of the island: the territory which became Tottenville. On that land, Billopp erected what was later to be known as the Conference house. He spent the next years as a minor officer of the duke's army and of the state of New York, but he was eventually discharged from both positions for political misconduct. Shortly thereafter he is thought to have left for England, from which he never returned.

His grandson, Christopher Billopp (1737–1827), was the owner of the Billopp or Conference house during the Revolutionary War. There, in Sept. 1776, Lord Howe, Benjamin Franklin and Edward Rutledge met to try to establish peace between the colonies and England. The second Christopher Billopp sided with the Tories as a member of the continental congress and served in the British army during the Revolution. After the American victory, he went with a number of other loyalists to Canada, where he remained for the rest of his life.

BILLROTH, (ALBERT CHRISTIAN) THEODOR (1829–1894), Viennese surgeon who is generally regarded as the founder of modern abdominal surgery, mas born on April 26, 1829, at Bergen, on the island of Rügen, his family being of Swedish origin. He studied at the universities of Greifswald, Gottingen and Berlin. Ger.. and received his degree from the last in 1852. From 1853 to 1860 he was assistant in B. R. K. Langenbeck's surgical clinic in Berlin, and in 1860 received the double appointment of regular professor of surgery and director of the surgical clinic in the University of Zurich, Switz. He remained there until 1867, when he joined the faculty of the University of Vienna.

In 1872 he made his first resection of the esophagus, and in 1881 the first resection of the pylorus for cancer. which was successful. In 1873 he made the first complete excision of the larynx, and is said to have been the first to perform the "interilio-abdominal" amputation (1891). He did a large number of intestinal resections and enterorrhaphies (1878–83). All these operations upon the gastrointestinal tract did much to elucidate the pathology of those regions.

Billroth had a strong artistic bent and was a life-long friend of Johannes Brahms. His publications include *Die allgemeine chirurgische Pathologie und Therapie* (1863) and *Wer ist musikalisch?* A posthumous edition of his *Briefe* was first published in 1896. He died in Abbazia, Yugos., on Feb. 6, 1894.

BILLUNG, the leading ruling dynasty in Saxony in the 10th and 11th centuries. founded by Hermann Billung, who in 936 received from the German king Otto I a march on the lower Elbe river to be held against the pagan Wends. From the year 961 Hermann used the title duke of Saxony, which on his death (973) passed to his son and thereafter to his descendants. Although the family extended its conquests toward the Oder river, thus preparing these territories for Christianization, their lands comprised only the northeastern part of the former stem duchy of Saxony. Within the boundaries of the duchy the Billungs under Bernard II (d. 1059) and Ordulf (d. 1072) had to defend their territories against the encroachments of Adalbert, archbishop of Bremen, while externally the family came to embody the Saxon national resentment to the Salian kings, Henry III and particularly Henry IV, who wished to re-establish royal authority in Saxony. In Aug. 1106, with the death of Magnus Billung, the family died out; its alodial lands were divided between the Ascanians and the Welfs while the Saxon count: Lothair of Supplinburg (the future emperor Lothair III) received the duchy of Saxony from King Henry V.

BILMA, a Saharan oasis, is 60 mi. by 10 mi. in extent. The name Bilma belongs strictly to the south part near the chief settlement, Bilma or Garu. which is 800 mi. S. of the town of Tripoli and about 350 mi. N. of the northwest corner of Lake Chad. The water of a number of lakes on evaporation yields large quantities of fine salt, the object of an extensive trade with western Africa. North of Bilma is the town of Dirki, said to date from the 11th century. Near Bilma is a small oasis, kept green by spring water, but to the south marked desert conditions prevail. The inhabitants are Tibbu and Kanuri.

By the Anglo-French declaration of 1899 Bilma was included in the French sphere of influence in west Africa. Turkey claimed the oasis and garrisoned Bilma in 1902. In 1906, however, a French force occupied the town without opposition. In 1907 the district was created a circle of the French territory of the Niger, which became the Republic of Niger in 1958.

BILNEY, THOMAS (1495?–1531), leader of the group of Cambridge men who were the vanguard of the English Reformation, was born probably at East Bilney near Norwich in Norfolk. He was educated at Trinity hall, Cambridge, and became a fellow of his college. Converted by reading the Latin New Testament of Erasmus (1516), he became leader of a group of younger dons who walked on Heretic's hill (as it came to be called) and talked of the new learning in the White Horse and who were known for their frequent communion and devotion to the needy, particularly those in hospitals and prisons. Bilney was ordained priest on Sept. 24, 1519. At the end of 1525 the group was in trouble for bold preaching against the invocation of saints, and after an informal hearing before Cardinal Wolsey in 1526, Bilney faced formal trial at Westminster in Dec. 1527. He abjured and did penance but returned to Cambridge from prison, a year later, a broken spirit. He found relief only by defying authority once again and was burned as a relapsed heretic in the Lollard's pit, Norwich, on Aug. 19, 1531. Among those present was his friend Matthew Parker, later archbishop of Canterbury. Historically interesting is his appeal to the new title of Royal Supremacy which caused embarrassment to the spiritual authorities at his death. Conservative in many opinions, he seems to have moved from Erasmian humanism to the views later championed by his converts, the martyrs Robert Barnes, John Lambert and Hugh Latimer. Innocent and austere, Latimer's "Saint Bilney" concealed stubborn strength in slender body.

See John Foxe, *Acts and Monuments,* 4th ed., vol. iv, pp. 619–656 (1877); C. H. Cooper, *Athenae Cantabrigienses,* vol. i (1858). (E. G. Ru.)

BILOXI, a small tribe of Siouan Indians (*q.v.*), who formerly lived in lower Louisiana and Mississippi. In the early 1960s a reported 125 Biloxi and Choctaw lived intermingled in central Louisiana. Their existence was first recorded by Pierre le Moyne d'Iberville in 1699, at which time they were settled on Biloxi bay, Mississippi. In 1702 they moved east to Mobile bay but in 1763, when the English took over that territory from the French, the Mobile tribes transferred to Spanish territory in Louisiana, and it is likely that the Biloxi went with them. In the next years they were mentioned by writers as being found in Mississippi, Louisiana and Texas. The Biloxi lived in tents and made tools and implements of wood and bone. Their society was matrilineal.

The Biloxi were never a large tribe and by the early part of the 20th century they had become nearly extinct. In 1886 a study of their language proved that they were Siouan Indians rather than Muskogians as ethnologists had previously thought.

BILOXI, a city of Harrison county, Miss., U.S., on a narrow peninsula extending into the Gulf of Mexico about midway between Mobile, Ala., and New Orleans, La. (For comparative population figures see table in MISSISSIPPI: Population.)

In 1699 Pierre le Moyne, Sieur d'Iberville (1661--1706) planted the French flag across the bay from the present city of Biloxi. The settlement there, at Ft. Maurepas, was the first capital of the French territory. In three different periods Biloxi served as the capital of the French territory (1699–1702, 1719–20. 1720–22). The site took its name, meaning "the first people," from the local tribe, the Biloxi, of Sioux Indians. In the War of 1812 the British fleet anchored off Ship Island, preparatory to its attack on New Orleans, and during the American Civil War Ft. Massachusetts (now abandoned), an important base of federal operations, was built on the island by Union forces. One of the most interesting historic sites within the city of Biloxi is Beauvoir, Jefferson Davis' home. For many years it was a Confederate soldiers' home but is now operated as a Confederate shrine and administered by the Sons of the Confederacy.

Biloxi was incorporated as a village in 1872 and as a city in 1896.

Biloxi is a popular year-round resort. Its streets and parkways are characterized by gigantic old live oaks, dripping with Spanish moss, longleaf pines, magnolias, oleanders, camphor trees and palms. More than 900 boats and 10,000 persons are employed in fishing: packing and shipping shrimp, oysters, crabs and other fish products. The blessing of the shrimp fleet each June, a ritual observed since the 17th century. is a festive occasion for the whole area. Other industries include boatbuilding, marine repair, machine shops and the manufacture of storage batteries.

Keesler air force base and a large U.S. veterans administration centre, with a soldiers' home and hospital, are in the city. (J. T. D.)

BILSTON, a municipal and parliamentary borough of Staffordshire: Eng., 3 mi. S.E. of Wolverhampton. Pop. (1961) 33,077. The coal and ironstone mines in the vicinity have been worked since 1315. The principal trades are in metal products of all kinds, especially in founding, for which foreign ores and south Wales coke are used. Shoes, glassware, enameling (since 1760) and earth-moving equipment are a few of the many manufactures. A museum, library and art gallery were opened in 1937 and a modern health clinic in 1940. Although the town appears in Domesday book, it was not incorporated until 1933.

BIMETALLISM, a term denoting a monetary standard or system based upon the use of two metals rather than one (monometallism). Traditionally these metals have been gold and silver, although the term could include the use of any two metals. Theoretically, bimetallism may take several forms: a coin standard that makes both gold and silver coins legal tender; a bullion standard that uses bars or ingots but not coins; or an exchange standard that ties one nation's monetary system to that of another for the purpose of settling international obligations. Only the first form has been used in actual practice. The typical bimetallic system of the 19th century included several main features: it defined the monetary unit of a nation (dollar, pound, franc, etc.) by law in terms of fixed quantities of gold and silver; it provided a free and unlimited market for the two metals; it imposed no restrictions on the use and coinage of either metal; and it made all other money in circulation redeemable in either gold or silver.

Defining a monetary unit in terms of both gold and silver automatically establishes a rate of exchange between the two metals. For example, when the United States in 1792 defined the dollar as a unit containing 24.75 grains of fine (pure) gold or 371.25 grains of fine silver, the exchange ratio was set at 15 to 1. In 1834, the gold content of the dollar was reduced to 23.2 gr. while the silver dollar remained unchanged. This altered the ratio between the two metals to approximately 16 to 1 (more exactly, 16.002 to 1). A slight adjustment was again made in 1837 which reduced the ratio to 15.988 to 1. This exchange ratio was then maintained in the United States until bimetallism was officially abandoned in 1900. Under the laws of 1834 and 1837, silver practically disappeared from circulation for many years.

The bimetallic monetary system was extensively used by most western nations during the latter part of the 18th and most of the 19th centuries. The United States and France operated under this standard for almost a century, whereas Great Britain changed to the gold coin standard as early as 1816. The great discoveries

of gold in California (1848) and Australia (1851) brought about the displacement of silver by gold in many nations and the continuance of gold as the principal currency metal in the United States. Most countries officially or unofficially abandoned bimetallism during the 1870s and 1880s. British opposition to it, together with the numerous difficulties encountered in its administration, accounted in part for its ultimate downfall.

One of the major problems associated with the use of bimetallism on an international basis was that each nation acted independently in setting its own rate of exchange between the two metals. These rates often differed so widely that local and international problems resulted. For instance, it was possible in the period 1803–08 to exchange silver and gold on a 15½ to 1 basis in France, 16.06 to 1 in Germany, 15.5 to 1 in Portugal, 16 to 1 in Spain and 15 to 1 in the United States.

Operation of Gresham's Law.—These differences in exchange rates made it possible for enterprising individuals to take advantage of price differentials by buying and selling the metals in different markets. Since the officially established mint ratio in the United States favoured silver, only that metal was taken to the mint; gold, on the other hand, was sold either in the free market or was exported to foreign countries where the exchange ratio was more favourable. This demonstrates what is often referred to as Gresham's law (*q.v.*) which, in its simplest terms, states that poor money tends to drive good money out of circulation. A more sophisticated definition explains Gresham's law as stating that metal which is overvalued at the mint tends to drive out of circulation metal which is undervalued at the mint. During most of the period from 1792 to 1834 the United States maintained an exchange ratio between gold and silver of 13 to 1, whereas the exchange ratio in European countries varied from 15½ to 1 to 16.06 to 1. It thus became profitable for owners of gold to sell it in the European market and take their silver to the United States mint. During this same period practically no gold was acquired by the United States mint, though its purchases of silver during the years were very large. This trend was reversed after passage of the acts of 1834 and 1837, when the U.S. ratio was changed to about 16 to 1 while the average for most European countries remained at about 15½ to 1. For many years thereafter, only gold was taken to the U.S. mint; silver was sold in the free market or in the foreign markets.

Latin Monetary **Union.**—Difficulties in administering the bimetallic system on a national level led to the suggestion that it be tried on an international scale. The first concerted effort to accomplish this objective was taken in 1865 when the Latin Monetary union was formed by France, Belgium, Italy and Switzerland. These countries entered into an agreement to create an international bimetallic monetary system. A mint ratio of 15½ to 1 between the two metals was established and provision was made for the coinage of both gold and silver. The union even provided for use of the same standard units and issuance of coins which were to be uniform in weight, size and fineness. It was expected that these coins would be uniformly accepted in each participating country.

Unfortunately, however. Italy soon began issuing large quantities of irredeemable paper money which drove specie out of that country and increased the supply of coins in other countries. Later, after Greece was admitted to the union, its monetary manipulations also proved to be a detriment rather than a benefit. The Franco-German War (1870–71) brought a speedy end to this monetary experiment and no successful atternpt was made after that time to revive international bimetallism.

Developments Following **1870.**—The future of the bimetallic standard apparently was sealed at an international monetary conference held in Paris in 1567, when most of the delegates voted in favour of adopting the gold standard. This vote was particularly interesting in light of the fact that Great Britain was then the only country using gold as the basis of its monetary system. Within a period of five or six years, Sweden, Norway, Denmark and Germany all adopted the gold standard. Moreover, the United States in 1873 dropped the silver dollar from the list of coins to be struck at the mint, This step relegated silver to a position of secondary importance and for all practical purposes took the Gnited States off the bimetallic standard. The Bland-Allison act (1878) and the Sherman Silver I'urchase act (1890) required the U.S. treasury to purchase specified amounts of silver each month. The bimetallic legislation was not repealed until 1900, when the Gold Standard act was passed. This measure legally placed the United States on a single or monometallic gold standard system.

William Jennings Bryan (*q.v.*) the Democratic candidate for president in 1896, campaigned vigorously for restoration of the bimetallic standard. It was his intention to re-establish bimetallism at the old ratio of 16 to 1. His loss of the election virtually ended active campaigning for this standard, though Bryan also worked for it in the election of 1900. The issue was again resurrected during the depression of the 1930s. One of the provisions of the Thomas amendment to the Agricultural Adjustment sit of 1933 gave the president authority to re-establish bimetallism at whatever ratio he might select, but this power mas never exercised. The president chose instead to appease the silver interests by offering to buy silver at prices considerably above existing market levels.

The most comprehensive of all silver-purchase legislation in the U.S. was the Silver Purchase act approved on June 19, 1934. This act authorized the secretary of the treasury to continue the purchase of silver until its total monetary value (at $1.29 per ounce) would equal one-fourth of the combined value of the nation's gold and silver stocks; *i.e.,* until the total monetary stocks of the treasury would reach the ratio of 3 parts gold to 1 part silver. It should be pointed out that while this act provided a government market for silver it did not re-establish bimetallism. Actually, it relegated silver to a position of secondary importance. The monetary standard of the U.S. is more properly characterized as a managed gold bullion standard with limited convertibility.

Arguments Favouring Bimetallism.—Supporters of bimetallism offer three main arguments in favour of this monetary standard. It is claimed that such a standard will provide: (1) greater monetary reserves; (2) greater stability in the general level of prices for all participating countries; and (3) greater ease in determination and stabilization of exchange rates among countries using gold, silver or bimetallic standards.

The first of these arguments was advanced by Alexander Hamilton.' his principal reason for supporting the use of this standard. He reasoned that the newly established government of the Cnited States did not have enough gold or silver independently to support a monetary system, so the reserves of both metals should be combined. Unfortunately, he failed to foresee that because of the disparities in exchange rates for gold and silver and the operation of Gresham's law, the United States mould soon be faced with the problem of having only silver turned in to the mint while gold moved to the foreign markets.

The second argument assumes that any nation which uses the two metals will have a larger monetary base to begin with and that accordingly any future additions to or withdrawals from this base will have proportionately less effect on total reserves than would be the case if only one metal were used. Moreover. the argument runs, if total reserves can be maintained at a relatively constant level, prices in general will also remain relatively stable. The assurnption here is that price changes are a result of changes in monetary reserves and the total volume of money in circulation. While this conclusion is subject to question, under certain (but somewhat limited) circumstances it could have merit.

The third argument has meaning only in those instances where different countries throughout the world are actually using gold, silver or bimetallic standards. In such instances, bimetallism does offer a convenient mechanism for establishing pars of exchange among the various currencies. Such standards, however, are rarely found,

Arguments Against Bimetallism.—The main arguments advanced against the use of a bimetallic standard are: (1) that it is practically impossible for a single nation to use such a standard nithout having international cooperation; (2) that such a system is wasteful; and (3) that it does not provide greater stability of

prices than does a monometallic or even a properly regulated fiat system.

The operation of Gresham's law has demonstrated that it is not feasible for any one nation to use a bimetallic standard independently of what others might be doing. Nor does it appear likely that agreement can be reached to establish bimetallism on an international scale. Accordingly, this standard commands very little support throughout the world.

Any standard which calls for the mining, handling and coinage of two metals rather than one incurs added costs. Such added expenditures might be justified if the resulting standard provided greater income and price stability than could be obtained by use of a different standard. But opponents of bimetallism contend that stability of the price level and the economy as a whole can be achieved only by carefully regulating and controlling all segments of the economy and that it actually makes little difference which type of monetary standard is used. They point out that even a fiat monetary standard may be used effectively as long as the monetary authorities exercise prudence in regulating the volume of money and credit used in the economy.

A proposal, sometimes confounded with bimetallism, is that for a standard composed of both gold and silver, which is better described as the joint standard or as symmetallism.

See also GOLD STANDARD; MONEY.

BINARY NUMBERS. Binary numbers, such as those used in digital computing machines, are numbers expressed digitally in the usual radical system using 2 as a base. Only two different digital values are required, 0 and 1. (Using the base 10 for decimal numbers requires ten different digital values from 0 through 9.) Just as the decimal number $237.4375 = (2 \times 10^2) + (3 \times 10) + 7 + (4 \times 10^{-1}) + (3 \times 10^{-2}) + (7 \times 10^{-3}) + (5 \times 10^{-4})$, the ordered digits of a binary number are to be multiplied by appropriate powers of two and added to give the value of the number represented. The fractional part of the number is separated from the whole part by the binary point or radical point. The binary form of the number above is 111 01101.0111.

To convert a whole decimal number to its binary form, repeated division by two is used; initially the number itself is divided by two and in each later step the quotient obtained from the preceding step is divided until a quotient of 0 remains. The remainders, which are all 0 or 1, are the digits of the binary form of the integer reading to the left from the binary point. Proper fractions are converted to binary form by an analogous process involving doubling the fractional part of each number obtained; the succession of digits to the right of the binary point is given by the largest integral part of the product, which is always 0 or 1. Thus the sequence of quotients and remainders for 237 is (118, 1) (59, 0), (29, 1), (14, 1), (7, 0), (3, 1), (1, 1), (0, 1), as obtained in the following steps:

(1) 118 / 2)237 / 236 / 1

(2) 59 / 2)118 / 118 / 0

(3) 29 / 2)59 / 58 / 1

(4) 14 / 2)29 / 28 / 1

(5) 7 / 2)14 / 14 / 0

(6) 3 / 2)7 / 6 / 1

(7) 1 / 2)3 / 2 / 1

(8) 0 / 2)1 / 0 / 1

The remainders, in the order of their occurrence, give the binary expansion reversed, that is, reading from right to left away from the binary point, or 111 01101. In writing binary numbers, a space is left after every fifth unit to the left or right of the binary point.

The overflows and fractional parts for .4375 as given in the example above are (0.8750), (1.7500), (1.5000), (1.0000). (Note that the whole parts are dropped before doubling in each step.) The binary expansion of the fraction is the set of whole parts in their order of occurrence, reading from left to right from the binary point, or .0111. Conversion in the other direction using decimal arithmetic is easiest with a decimal table of powers of 2.

To convert a binary number to a decimal number, start with the first digit at the far left in the binary number and proceed one place at a time to the right, multiplying each figure by 2 and adding either 1 or 0 to the product as indicated in the next place to the right before multiplying by 2 again. For example, the whole part of the binary number given above is converted to a decimal number in the following steps:

(1) (3) (5) (7)
1 1 1 0 1 1 0 1
(2) (4) (6)

(1) $1 \times 2 = 2$, $2 + 1 = 3$

(2) $3 \times 2 = 6$, $6 + 1 = 7$

(3) $7 \times 2 = 14$, $14 + 0 = 14$

(4) $14 \times 2 = 28$, $28 + 1 = 29$

(5) $29 \times 2 = 58$, $58 + 1 = 59$

(6) $59 \times 2 = 118$, $118 + 0 = 118$

(7) $118 \times 2 = 236$, $236 + 1 = 237$

Binary numbers may be handled arithmetically by methods analogous to those used in handling decimal numbers. The addition and multiplication tables necessary are spectacularly simple, however: $0 + 0 = 0$, $0 + 1 = 1$, $1 + 1 = 10$: $0 \times 0 = 0$, $0 \times 1 = 0$, $1 \times 1 = 1$. Nonrestoring division is also possible because of the paucity of digital values; this amounts essentially to expanding the quotient in a binary fashion using digits 1 and -1 and converting easily to a standard digital form.

The simple nature of the addition and multiplication tables for binary numbers and the ease and reliability with which a digit that may have only one of two values may be represented electrically or electronically has led to widespread use of binary arithmetic in automatic computing machines. Many electronic digital machines using decimal numbers represent these numbers in a code whose groups are sets of four binary digits.

Negative numbers are frequently represented by complements. A common method is to replace each digit in the binary expression for the absolute value of a negative number by its complement (that is, replace 1 by 0 and 0 by 1) to express the negative number. This leads to ambiguity unless it is agreed that the number will have a fixed number of digits with the leading digit having value 0 for positive and 1 for negative numbers; zero is still ambiguously represented by a number all 1's or all 0's. Thus in ten binary digits the decimal number 237 becomes 00111 01101 and the decimal number -237 becomes 11000 10010. Most arithmetical operations are convenient in this system, but provision for "carry" from the most significant place to the least (cyclic or end-around carry) must be provided. If the computing device used subtracts but does not add, the representation of zero by a number whose digits are all 1's does not occur naturally. Most electronic machines either add or subtract, but do not do both. The complementation usually found on a desk calculator also has an analogue in binary numbers.

Binary digits also occur in Boolean algebra, and this algebra

is formally used in the development of computer circuits. This is the algebra of propositions, where a proposition is either true (has truth value 1) or false (has truth value 0). Two propositions can be connected with a conjunction to form a compound proposition, the conjunctions used in computers being "and" and "or." The truth value of the resulting proposition depends on the truth values of the components and the conjunction used; using the standard symbols A for "and" and $\vee$ for "or" the tables in terms of truth values are: $0 \text{ A } 0 = 0$, $0 \text{ A } 1 = 0$. $1 \wedge 1 = 0$; $0 \vee 0 = 0$, $0 \vee 1 = 1$, $1 \vee 1. = 1$.

Any binary operation can be generated by the Boolean operations mentioned above; in particular the arithmetic operations on binary digits can be generated. Electronic equipment for carrying out the binary operations is simple and reliable, and this is the basis for much design of electronic computing circuitry.

Much binary arithmetic antedates the current uses; an old schrrne of multiplication attributed to Russian peasants is equivalent to expansion of the multiplier to its binary form. (The multiplicand is repeatedly doubled and the multiplier halved; if the remainder in the division is 1 the value of the multiplicand term before doubling is added into a sum which is the developing product.)

BINARY SYSTEM, in astronomy, a system composed of two stars revolving around each other under the influence of their mutual gravitational attraction. In some cases (visual binaries') a telescope will show the two components separated.' In others !spectroscopic binariesj the duality is detected by observing the changing motion in the line of sight of one or both components. *See* STAR.

BINCHOIS, GILLES (EGIDIUS; GILLES DE BINCHE) (*c.* 1400–1460). Flemish composer of secular *chansons* and church music. was born at Mons in Hainaut, *c.* 1300. In 1424 he was in the service of William de la Pole. earl of Suffolk, in Paris, and must have been in contact with English musicians. He went with Suffolk to Hainaut in 1425, and joined the chapel of Philip of Burgundy in 1330. The text of Johannes Okeghem's *Déploration* on his death affirms that he was a soldier in his youth, calls him *"le père de joyeuseté"* and suggests that he wrote some of the verses he set, since both *"Rhétorique"* and *"Musique"* are represented as mourning his loss. He died in Sept. or early Oct. 1460. near Mons. In the manuscript of Martin le Franc's poem *Le Champion des dames* (1440) Guillaume Dufay is depicted next to a small organ. symbolizing church music while Binchois holds a harp, symbolizing secular music. However, Le Franc's comment that both took John Dunstable as their model applies equally to tlie sacred and secular music of Binchois. In both he cultivated the gently subtle rhythm, the suavely graceful melody and the smooth treatment of dissonance characteristic of his English contemporaries. Some of his church music is related to English liturgical use. and his techniques in these works have English affiliations. While his sacred music has historical importance at a time of interchange between English and French traditions. his secular *chansons* are among the finest examples of their genre, notable for their elegance of line and grave sweetness of expression.

BINDWEED. Any trailing or climbing (rarely erect) herbaceous vine of the genus *Convolvulus,* an assemblage of about 180 species, nearly world-wide in distribution; closely related to the morning-glory, and many of them persistent and pernicious weeds. A feu; are cultivated for ornament, especially C. *mauritanicus,* a blue-flowered perennial used for hanging baskets in the greenhouse or as an outdoor ground cover in California; C. *tricolor,* the dwarf bindweed. an erect annual from southern Europe. and C. *cneorum,* a pink-flowered, handsome species also from southern Europe, cultivated more in England than in the United States. The only species of any economic importance is C. *scammonia* from the eastern Mediterranean region, the fresh rootstocks of which furnish the violent cathartic scammony.

RUTHERFORD PLATT

HEDGE BINDWEED (CONVOLVULUS SEPIUM)

European field bindweed (*C. arvensis*) is one of the most invasive and persistent weeds. It is widely naturalized in the United States. It is a deep-rooted perennial, whose prostrate vine is difficult to control by tillage or hoeing. and can be killed only by applications of weed-killing chemicals such as 2. 3-D. Less difficult is the ubiquitous hedge bindn-eed (C. *sepium*), originally European but widely naturalized throughout North America. Its shallow roots are easily killed by tillage or hoeing. An interesting freak is tlie double-flowered Japanese bindweed (*C. japonicus*), often called California rose, introduced for ornament, but usually weedy in lawns. (S. TR.)

BINET, ALFRED (1857–1911), French psychologist, famous for his experiments on the psychology of reasoning and intelligence, was born at Nice. France, on July 8. 18j. At Paris he studied law, medicine and biology, and. after collaborating with C. Féré and H. E. Beaunis at the Sorbonne, he succeeded the latter as director of the new psychological laboratory. French psychology was still largely dominated by the views of the English empirical school, especially by the theory of mental association as systematized by James and John Stuart Mill and the later biological and physiological interpretations developed by Herbert Spencer and other evolutionists. Binet began by accepting these general principles, but sought to establish them (if necessary with due modifications) on a sound experimental basis. Unlike the German experimentalists, he saw little value in laboratory researches on elementary processes of sensation or reaction and endeavoured to adapt experimental techniques to the "higher mental processes," and above all to study their manifestations in everyday life. The "brass instruments of the German band" he soon discarded, and displayed great ingenuity in devising instructive experiments with the simplest materials—paper, pencil, illustrative pictures and portable objects, such as could be used in the school or the workshop. His early work, *La Psychologie du raisonnement* (1886), already reveals a growing dissatisfaction with the purely mechanical theories of the associationist school, and it was followed by entirely original work on "imageless thought." Binet was equally alive to the effect of emotional and other nonrational influences on thought processes. and published a number of important investigations of suggestibility, hypnotism. mental fatigue and semipathological "alterations of personality." In 1895 *L'Année psychologique* began its career as the main organ of Binet's school; and most of his work (often undertaken in collaboration with other specialists, including Féré, V. Henri. N. Vaschide and T. Simon) appeared year after year in this periodical.

About the same time, in conjunction with Belot and Vaney, he opened a laboratory at Paris for child study and experimental teaching. He had been much impressed by Francis Galton's endeavour to establish individual psychology on a scientific basis by means of standardized tests, and adapted the method in a series of experimental studies of eminent writers, artists. mathematicians and chess players, often supplementing the more formal tests with observations on body type, head measurements, handwriting, etc. In this new field his most notable work was his *Etude experimentale de l'intelligence* (1905), which was planned as an investigation of the mental characteristics of his two daughters and developed into a systematic study of two contrasted types of personality. Here his skillful use of selected pictures, inkblots and

the like paved the way for what later became known as "projection tests!' and tests of "thematic apperception." His well-known scales (1905–11) for the measurement of intelligence and educational attainments of school children were developed at the request of the Paris education authority, but were largely inspired by his interest in the mental differences between individuals, subnormal as well as normal. He was still engaged on a revision of his scheme when he died in Paris on Oct. 18, 1911. *See* PSYCHOLOGICAL TESTS AND MEASUREMENTS.

See R. Martin, *Alfred Binet* (1925). (CY. B.)

BINGEN, a town of Germany which after partition of the nation following World War II was in the *Land* (state) of the Rhineland-Palatinate, Federal Republic of Germany. It is situated at the confluence of the Rhine and the Nahe, 26 km. (16 mi.) W. of Mainz. Pop. (1959) 18,724. Klopp castle, dominating the town, and the Nahe bridge are on Roman sites. The parish church of St. Martin was built in 406 (rebuilt 1403 in Gothic style after a fire). The local history museum has instruments of a Roman doctor. Nearby are the rocky ledges and swift currents of the Rhine whirlpool, the Binger loch. Bingen is on the main line from Cologne to Mainz and Frankfurt; other lines run to Kreuznach and Simmern. There are brandy distilleries and trade in wine and spirits. Bingen is an important tourist centre. The Roman Bingium became a free town of the empire, and was made a part of the electorate of Mainz by Emperor Otto II. In 1105 the emperor Henry IV was held in Klopp castle; in 1301 the town and castle were besieged by King Albert I. In World War II Bingen was captured by the Allies (March 1945). (J. A. S.-K.)

BINGHAM, GEORGE CALEB (1811–1879), U.S. painter, whose work represents the best-known American genre painting of the mid-19th century, was born on March 20, 1811, in Augusta county, Va., and later settled in Missouri. His best genre paintings were produced from 1840 to 1857. The large, tightly composed pictures, crowded with details of local colour, developed in two themes: river life, as shown in "Jolly Flatboatmen"; and political life, as shown in "County Election." His later paintings were either polemical or sentimental. He died on July 7, 1879.

See A. W. Christ-Janer, *George Caleb Bingham of Missouri* (1940). (A. W. C.-J.)

BINGHAM, HIRAM (1875–1956), U.S. politician, historian, explorer and discoverer of the lost city of the Incas, was born in Honolulu. Hawaii, on Nov. 19, 1875, the descendant of missionaries to Hanaii and Polynesia. Following his education at Yale and Harvard (Ph.D. in history, 1905) he joined the faculty of Yale university in the field of Latin-American history. A devotee of field trips, he retraced in 1906–07 Simon Bolivar's route across Venezuela and Colombia and two years later explored the old Spanish trade route from Buenos Aires to Lima. In 1911. while on a trip to southern Peru, Bingham made one of the most sensational discoveries of modern times when he found Machu Picchu, the legendary Inca citadel, located high on an impregnable mountain peak near Cuzco (*q.v.*) and unknown for four centuries. Bingham described his explorations in a series of books, beginning with *Journal of an Expedition Across Venezuela and Colombia* (1909) and ending with *Lost City of the Incas* (1948).

The latter years of his life were devoted to politics; he was elected governor of Connecticut in 1924 and served one partial and one full term in the U.S. senate. He died in Washington on June 6, 1956.

BINGHAMTON, a city of New York, U.S., on the Susquehanna river, at the mouth of the Chenango, 125 mi. S.W. of Albany, near the Pennsylvania border; seat of Broome county. Pop. (1960) city, 75,941; standard metropolitan statistical area (Broome county) 212,661. The metropolitan area includes Johnson City (*q.v.*) and Endicott, which with Binghamton are known as the Triple Cities. (For comparative population figures *see* table in NEW YORK: *Population.)*

The site of Binghamton was in Indian territory until 1779, when a decisive victory was won by Gen. James Clinton and Gen. John Sullivan at Newtown (now Elmira). An Iroquois village known as Ochenang was situated there, and the white settlement, established in 1787, was first called Chenango Point. The greater part of the city stands on land originally included in the Bingham patent, a large tract on both sides of the Susquehanna, owned by William Bingham (1751–1804), a merchant of Philadelphia, Pa.

A village was laid out in 1800. It was incorporated in 1834 and received a city charter in 1867.

Easy access to large markets, sea and lake ports, and coal, steel and raw materials favoured industrial development. By 1837 the Chenango canal provided a waterway to the Erie canal at Utica. In 1851 the Erie railroad linked Binghamton to Buffalo and Jersey City. Binghamton's leading manufactures include cameras and film, footwear, dairy and bakery products, clothing, furniture, forgings and stampings, hardware, valves, industrial machines, aircraft parts, small boats and cosmetics.

The sale of dairy products (largely milk for the New York metropolitan market) is the leading source of agricultural income, followed by livestock, poultry and poultry products. The largest crop acreage is devoted to hay. The Broome County Farm bureau (1911) is the oldest in the country.

Institutions of higher education in the Triple Cities region include Broome Technical Community college (founded 1947), at Binghamton, and Harpur college (founded as the Triple Cities College of Syracuse university in 1946) since 1950 a unit of the State University of New York, at Endicott. (R. C. HE.)

BINGO, a lottery game played in many variants and under several difterent names. As a game of chance, bingo is said to claim more devotees than any other gambling game in the United States in spite of its being banned in many states. The more recent name given this game before the current one was keno, developed by traveling carnivals in the 1880s from a game for children called lotto (also spelled loto), which in Great Britain is popularly known as house. The origin of lotto is thought to be the Italian game *tumbule,* the word "lotto" meaning "lot" in Italian. In the United States the names keno, bingo, beano, lucky, radio, fortune, po-keno, screeno and many others are applied to games which are essentially the same as lotto. Latin Americans play a similar game called *bolito.*

Whatever the name or the variant, each player pays to receive a card bearing rows of numbers, no two cards being identical. Numbers are then drawn by lot, in one fashion or another. The first player on whose card five of these numbers appear in a row—vertically, horizontally or diagonally—is the winner.

The original lotto card was divided into five horizontal rows of nine squares each. There were five numbered squares on each row, the other squares being blank. The first vertical row contained numbers from 1 to 10, the second row numbers from 11 to 20 and so on. Small numbered disks were drawn at random from an enclosed bowl. and a player having a corresponding number covered it on his card, until some player, having all five numbers on a horizontal row covered, cried "lotto" and won the stakes of the other players, or the prize if one was offered.

The keno card contained only 25 squares in a 5-by-5 grid, with a number from 1 to 90 in each square, there being no blank spaces. Players were seated at long counters and bought one or more cards each. The operator of the game drew numbered balls from a "keno goose" which permitted only one ball to escape at a time. There were no duplicate numbers in the goose, and each number called was marked off on a master board so that a winning player's card might be verified.

Bingo is almost identical with keno except that only 75 numbers are used and the central square on the bingo card is a free number. It is generally customary for entry fees to be collected before a game or series of games. The house retains this fee and awards prizes of cash or merchandise to the winners. Bingo attained its greatest popularity in the 1930s, when depressed business conditions turned people from higher-priced gambling games.

The variant known as screeno and by other names was designed to be played in motion-picture theatres. With screeno began the custom of designating one night in the week to be "bank night" at the theatre; patrons received free screeno cards with their tickets of admission to the theatre. Prizes amounted in cash or in value to hundreds of dollars. (A. H. MD.; S.M.M.; F. HN.)

BINIOU: *see* BAGPIPE.

BINNEY; THOMAS (1798–1874), English Congregational minister, hymn writer and a leader of the liturgical movement in his denomination, was born of Presbyterian parents at Newcastle upon Tyne. He entered the theological college at Wymondley, Hertfordshire (afterward New college, Hampstead). and after a one-year pastorate at the New Meeting, Bedford, he moved (1824) to the St. James's Street Independent chapel, Newport, Isle of Wight. He received a unanimous call to become minister of the Weigh House chapel, London (1829), where he drew such large congregations that a new chapel mas built. Binney's speech on laying the foundation stone (1833) provoked contro ersy with the Church of England; but although soundly convinced of its errors (he published *Twenty-Four Reasons for Dissenting From the Church* of *England* in 1835), he actively sought reunion, and while visiting Australia (1857) he corresponded with the bishop of Adelaide about the occasional interchange of ministers. He wrote much devotional verse. published *The Service* of *Song in the House of the Lord* (1848), and brought his chapel services closer to those of the established church by introducing the chanting of psalms taken from the Authorized Version of the Bible. Binney was chairman of the Congregational union in 1843. He resigned his pastorate in 1869 and died in London on Feb. 23, 1874.

BINOCULAR INSTRUMENT. An optical device that permits simultaneous vision n-ith both eyes. Such instruments are usually designed to make use of the stereoscopic phenomenon of binocular vision. There are two general classes of such instruments, namely. (1) those for viewing objects in three-dimensional space; and (2) those for viewing pairs of flat prints. transparencies or projected images for the purpose of creating a visual perception in three dimensions.

In either type of instrument. it is essential for stereoscopic vision that each eye receives an image that originates from a viewpoint laterally displaced from that seen by the other eye. These dissimilar images are mentally fused into a single three-dimensional image. Man's lifelong experience with such binocular images results in perception of objects in three-dimensional space. A complete understanding of the creation and interpretation of binocular images involves a knowledge of physiology and psychology as well as physics. Severtheless. the fundamentals of stereoscopy can be made clear by geometrical methods.

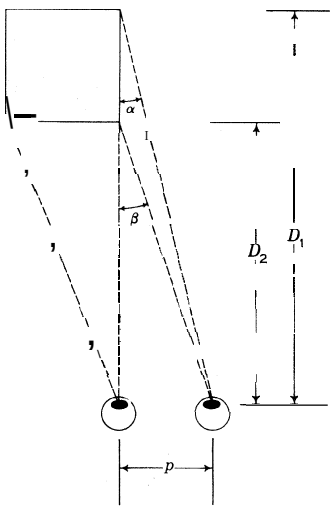

FIG. 1.—BINOCULAR VISION
The right and left eyes see different views of the cube, the parallax angles for the right-hand corners being respectively α and β

For example. objects at distances D_1 and D_2 viewed by eyes with an interpupillary separation p (fig. 1) have different parallax angles α and β for the two eyes. If the objects are sufficiently far away in comparison with p, these angles will be simply $\alpha = p/D_1$ and $\beta = p/D_2$ in radians, one radian being equal to 206,265 sec. of arc The minimum detectable difference in binocular parallax angles is generally assumed to be 30 sec., but there is some evidence that it may be as low as 4 sec. for trained observers. This minimum angle difference determines the minimum perceptible difference in distance D. Since the parallax angle for objects at infinity is zero. the limit of stereoscopic vision is the distance D_1 at which $\alpha = \frac{30}{206.265} = \frac{p}{D_1}$. For a standard interpupillary distance of $p = 65$ mm. this limit, often called the radius of stereoscopic vision. is found to be 450 m. The purpose of binocular telescopes is to increase this quantity. This may be accomplished by two methods. used singly or together.

In the first place, a magnification m increases the parallax angles of all points in the images by a factor m, making objects appear closer by a factor $1/m$. Hence, smaller differences in parallax angles can be perceived. Secondly. the centres of the objectives may he farther apart than the pupils oi the eyes by a factor n, which increases parallax angles by the same factor. The combined effect of magnification and lens separation is to increase the radius of stereoscopic vision to *inn* times that for the unaided eyes. This also enhances stereoscopic discrimination at distances below the limit.

Opera glasses and inexpensive field glasses consist of two telescopes of the Galilean type. These have a converging objective lens, usually achromatic. and a diverging eyepiece lens. Since the objective: are the same distance apart as the eyes. the radius of stereoscopic vision is increased solely by a factor equal to the magnification m. As usually constructed. Galilean telescopes suffer from several optical defects and have a characteristically small field of view at the larger magnifications. Hence their usefulness is generally restricted to magnifications of only $2\frac{1}{2}$ to 4.

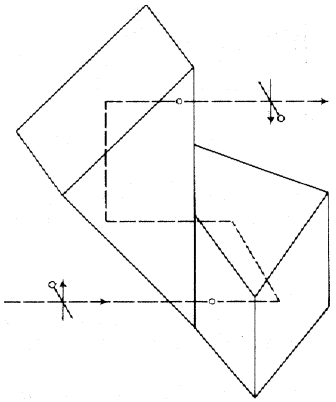

FIG 2.—PORRO PRISMS
Light is totally reflected inside two 45°–90° prisms at right angles to each other. This inverts and reverses the image

Telescopes n-ith converging lenses as eyepiece. and objectives potentially give sharper images and a larger field of view than those of the Galilean type. but their images are inverted and reversed. The reinversion is usually accomplished by a series of four total reflections inside glass prisms. The most common system of prisms. the Porro (fig. 2!. consists of a pair of 45°–90° prisms with the light entering the hypotenuse fsce of each in turn and being totally reflected at the two smsller iaces. One such prism inverts the image. the other. being at right angles, causes a reversion of the image. Light emerges parallel to its original direction but is displaced laterally. The lateral displacement permits a greater separation of objectives than of the eyepieces. thus increasing the stereoscopic effect iiig. 3 ι. The folded optical path in the prisms permits the use of objectives of longer focal length. and therefore greater magnification, without unduly increasing the length of the telescope.

Magnifications of 6. 7 or 8 are common in hand-held binoculars. With powers greater than 8. it is advisable to use a tripod to hold the binoculars steady. In the common designation of binoculars as 6×30, 7×50 or 8×30. for example. the first number is the magnification and the second number is the dianieter of the objective in millimetres. The quotient of the second number divided by the first is the diameter of the esit pupil. which is the ring through which the light passes into the eye of the observer. It may be seen as a circular patch of light just behind the eyepiece ~ ~ h the binoculars are held at arm's length and pointed at the sky. If the exit pupil is as large or larger than the eye pupil, one obtains ideally (neglecting light losses in the instrument) as bright a retinal image as without the binocular. This is called normal brightness. Conversely, if the exit pupil is smaller than the eye pupil, the image brightness is diminished by a factor equal to the ratio of the squares of the diameters of the exit pupil and the eye pupil. For example, the exit pupil of a 6×30 binocu-

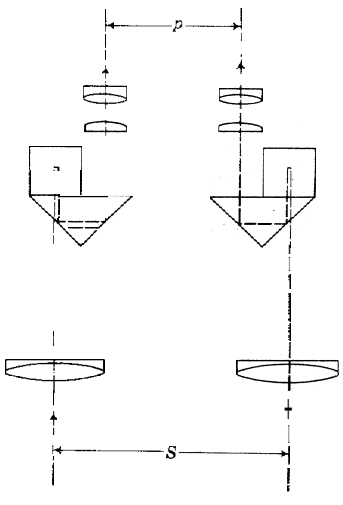

FIG 3 —PRISM BINOCULARS
Light from the object enters the two objectives whose centres are a distance S apart. The Porro prisms erect the images which are seen through the two eyepieces at a separation p equal to that of the observer's pupils

lar has a diameter of 5 mm. and the pupil of the normal human eye varies in diameter from 2 mm in bright daylight to 7 mm. at night In daylight, then, a 6×30 binocular gives an image of normal brightness but at night the brightness is 25/49 or about half the ideal. A 7×50 binocular on the other hand having an exit pupil of 7– mm. diameter gives images of normal brightness at night as well as by day and is often called a night glass. While it is superior to the 6×30 when used at night, the brightness oi its image is no greater in the daytime. Moreover. being heavier it is less comfortable to hold over extended periods and it is considerably more expensive. The above statements referring to image brightness apply to objects having a perceptible area. The brightness of objects seen as points. such as the stars, often greatly exceeds normal brightness.

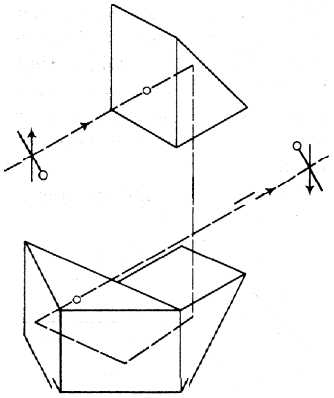

FIG 4 — MODIFIEDPORRO PRISMS
Used in periscopes and stereobinoculars

The quality of a binocular may be easily tested by viewing some distant structure with clear-cut vertical and horizontal detail. First the best focus possible in the centre of the field should be obtained. Vertical and horizontal lines should focus sharply and simultaneously. Ii the image is of high quality, the range will be small.

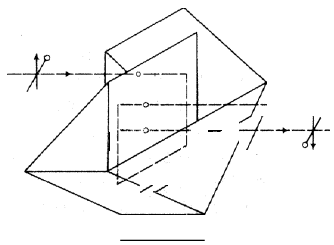

FIG. 5.— PORRO PRISMS OF THE SECOND TYPE
A compact combination of rectifying prisms

Next, the telescopes should be turned to bring the centrally focused object toward the edge of the field of view. The image should remain sharp. It may, however. show some colour boundaries between light and dark objects. but this should not be so large as to seriously reduce the definition. There may be zome distortion of straight lines near the edge of the field. but this should be small.

The two telescopes of a binocular should have exactly parallel axes and should have exactly the same magnification. Large deviations make the binocular useless and smaller deviations lead to eyestrain with prolonged use. The eyepiece separation should be adjustable since the interpupillary distance may vary from 55 to 72 mm. ior different observers. Binoculars for sports use often have a crossbar between the eyepieces to permit focusing both telescopes simultaneously. This is convenient but may allow entrance of dust and moisture into the telescopes. On the other hand, individual focusing, while slower, is more adaptable to adjustment for eyes that require different corrections.

Several types of prism systems, other than that shown in fig. 2, are employed to reinvert images in binocular instruments. One of these. the modified Porro system, is shown in fig. 4. This is used in stereohinoculars in which the two telescopes and prisms may be rotated to obtain a large separation between objectives, leading to a greatly enhanced stereoscopic effect. With the telescope tubes vertical the instrument becomes a binocular periscope for viewing over a projecting parapet. Tank sights employ a similar prism effect but with a fixed separation between objectives.

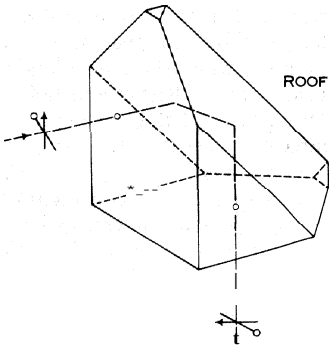

FIG. 6.—AMICI PRISM
A 90° roof is ground on the hypotenuse of a 45°–90° prism to correct inversion and reversion in a single prism. The 90° deviation is useful in telescopes for observing objects overhead

Porro prisms of the second type (fig. 5) are sometimes used in telescopes of high magnification.

The Amici prism (fig. 6) is often used in military binoculars. It is a 45°–90° prism with a 90° roof on the hypotenuse face. The angle on the roof must be accurately 90° within a tolerance of ±2″, to avoid a double image, and it must have a sharply ground ridge. This prism is very difficult to manufacture because of the stringent requirements. When used in a telescope without other prisms. the light is deviated through 90°, making the instrument useful for tracking planes flying overhead.

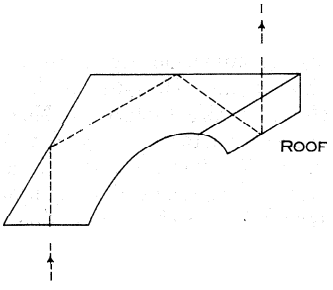

FIG. 7.—LEMAN OR SPRENGER PRISM
Often used to rectify images in various types of gun sights

The roof angle principle is also applied in prisms of other form, of which the Sprenger prism (fig. 7) is one example. This prism is often used in gun sights of various kinds. Other varieties of roof angle prisms are the Daubresse (fig. 8) and the Koenig or Brashear-Hastings prism (fig. 9).

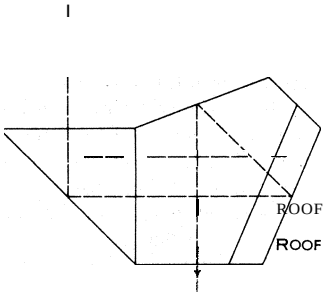

FIG. 8.—DAUBRESSE PRISM
Used in some prism binoculars

Binocular Microscopes.— Many modern microscopes have a binocular optical system. Frequently. in the higher power instruments, the prism arrangement (fig. 10) merely permits the use of both eyes simultaneously but without binocular parallax and therefore without stereoscopic effect. Its purpose is to make extended viewing more comfortable than with monocular instruments. The eyepiece separation is usually adjustable and one eyepiece can be focused to accommodate eyes with different refractive corrections.

In some instruments the light passing through the right half and the left half of a single objective is directed by prisms through the respective eyepieces. If the light from the right half of the objective passes through the right-hand eyepiece simply, *i.e.*, without reinversion of the images, the view is pseudoscopic: depressions appear as elevations and vice versa. For correct stereoscopy one must either effect a crossover of the beams of light to opposite eyepieces or reinvert the images.

Low-power binocular microscopes. used for dissection, study of insects, etc., usually have two separate. matched objectives with Porro prisms in front of each of the two eyepieces. These provide true stereoscopic vision as well as the comfort of binocular viewing. Pairs of objectives may be mounted on a rotating nosepiece to permit rapid change in magnification. The eyepiece separation may be adjusted by rotating the Porro prisms about the axis of the beams from the objectives.

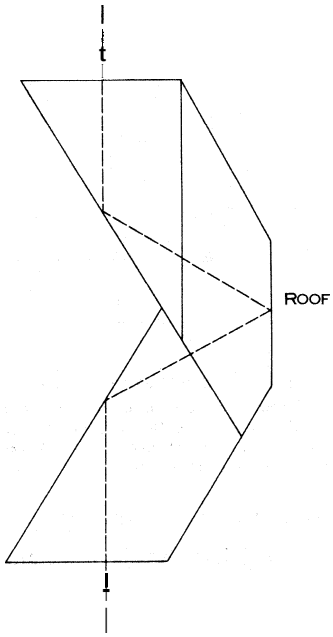

FIG. 9.—ABBE, KOENIG OR BRASHEAR-HASTINGS PRISM
produces an erect image without displacement or deviation of the beam

Stereoscopes. — Stereoscopes are binocular instruments for viewing pairs of drawings or photographs made from laterally

displaced centres of perspective for the purpose of obtaining a three-dimensional view of objects or scenes. Since it is very difficult to make drawings of anything but simple objects with the required accuracy, photography is generally employed. Stereophotographs may be taken by successive exposures from laterally displaced positions of the camera if the object is a still-life or an architectural subject. For other objects a stereocamera or a pair of cameras that record the two views simultaneously is required.

In the stereoscope of Wheatstone (fig, 11) the two drawings or prints are mounted opposite each other and viewed by means of two mirrors. The mirrors are inclined so that each *eye* sees one of the mirror images directly ahead of and superimposed on the other. Since mirror images reverse rights and lefts, the view is pseudoscopic unless the drawings are printed reversed or are interchanged.

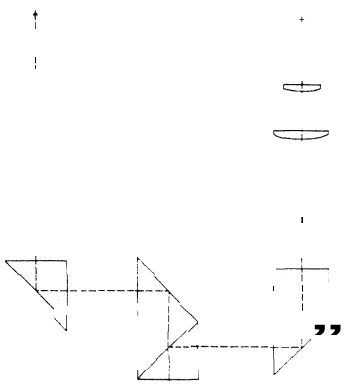

FIG. 10.— BINOCULAR MICROSCOPE PRISMS AND EYEPIECES

These permit more comfortable vision than in possible monocularly, but vision is not stereoscopic

It can be proved by purely geometrical considerations that to obtain orthostereoscopy. *i.e.,* fidelity of depth-to-width ratio and apparent distance. the interval between centres of the lenses in the stereocamera must equal the interpupillary separation of the observer's eyes; furthermore, the apparent magnification must be unity.

Apparent magnification is the ratio of the angles subtended by the images in the stereoscope to the angles subtended by the corresponding objects at the camera location. For unit magnification photographic contact prints must be viewed from a distance equal to the lens-to-film distance in the camera. Since most cameras have focal lengths considerably smaller than the normal reading distance, one must use, in front of the eyes, lenses having a focal length approximately equal to that of the camera lenses. If the prints are enlarged by a factor *m* before insertion into the stereoscope. the proper viewing distance becomes *m* times as large as for contact prints. Thus. for example. ii pictures taken with camera lenses of j cm. focal length are enlarged five diameters: one obtains orthostereoscopy by viewing them from the normal reading distance of 2j cm.. provided that the distance between the lenses of the taking camera was equal to the interpupillary distance oi the observer's eyes.

The Wheatstone stereoscope has been generally supplanted by that of Brewster (fig. 12) in which lenses and prisms. or off-centre lenses. are used instead of mirrors to superimpose the two stereoimages. The lenses should have a focal length that enables the observer to see the prints clearly without undue eye strain from a distance equal to the lens-to-film distance in the camera, when contact prints are used Since the equivalent prismatic powers of rlcccntred lenses are proportional to the lateral shift of their optical centres, observers with different interpupillary separations will obtain different prism powers with a fixed separation of the lenses. This may create some difficulty in fusing the two images unless the lens separation is adjustable.

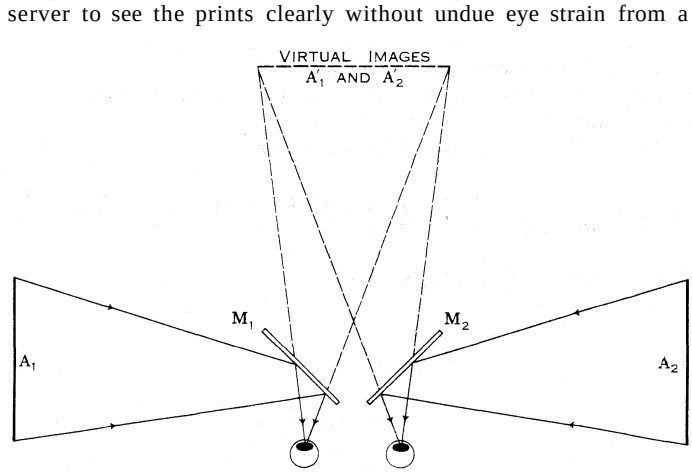

FIG. 11.— WHEATSTONE STEREOSCOPE

The inclined mirrors M_1 and M_2 enable the observer to fuse the images of two stereoscopic drawings or photographs A_1 and A_2

The Helmholtz stereoscope (fig. 13) is a refinement of Brewster's in which it is possible to vary the distance between the viewing lenses by means of a micrometer screw and to choose between one of two focal lengths by removing or retaining one of the lens components in each eyepiece.

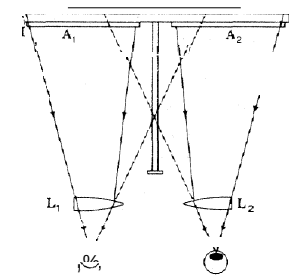

FIG. 12 —BREWSTER STEREOSCOPE

The two off-centre lenses L_1 and L_2 enable the observer to fuse the two magnified images of the views A and A2 stereoscopically

To produce srereoscopic images that may be seen by several people at the same time, one method is to project one of the images through a red filter and the other through a complementary bluish-green filter with the images nearly overlapping. Each person in the audience is provided with a viewing device consisting simply of a red filrer over one eye and a bluish-green filter over the other. Through the red filter one eye sees only the blue-green image while the other eye sees only the red image. If the images are properly constructed stereopairs. the observer sees them fused into a three-dimensional image in monochrome. Alternatively, the two stereoviews may be printed on a card with inks of the appropriate colours. Such stereograms are called anaglyphs.

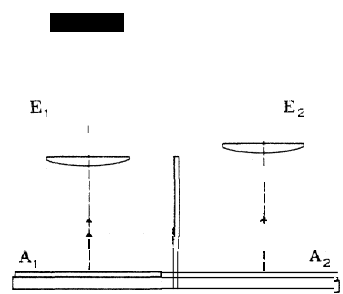

FIG. 13.—HELMHOLTZ STEREOSCOPE

Two compound magnifiers E_1 and E_2, with adjustments for focusing and interpupillary separation, enable the observer to fuse the two images stereoscopically. The focal lengths of the magnifiers may be selected to make the view orthostereoscopic

An analogous process employs projection of the stereopairs through polarizing filters oriented so as to transmit light at right angles to the light vibrations in the other. By means of polarizing viewing filters properly oriented in front of each eye. the observer sees one of the images with one eye and the other image with the other eye. This principle has been applied to the projection of motion pictures in three dimensions and in colour, the latter being impossible with anaglyphs. The projection screen must have a metallic coating so that the reflected light retains its original polarization.

Another stereoscopic process, invented by E. H. Land in 1940, employs a stereopair of vectographs. Vectographs are prints or transparencies in nhich variations in degree of polarization replace the usual variations in degrees of absorption. Using a photochemical process invented by Land, an ordinary photographic negative is printed onto a sheet of special polarizing material to obtain a positive in which there are gradations in degree of polarization from 100% in the shadows to 0% in the highiights. When such an image is esamined through a polarizing filter that is turned so its direction of polarization is at right angles to the direction of maximum polarization in the image, the image is seen with maximum contrast. As the polarizer is rotated from this position, the image decreases in contrast and fades out completely when the polarization direcrions of the viewer and image are parallel.

To obtain a stereoscopic effect, two vectographs. made respectively from each hali oi a stereonegative, are superposed with a slight lateral shift and with the planes of maximum polarization

in the two vectographs at right angles to each other. The vectograph pair is viewed through a polarizing device of the spectacle lens type with polarizing filters oriented in the frame so that each eye sees just one of the images. Incidentally. if one makes the wrong choice as to which image is to be seen with which eye, the view is pseudoscopic.

Vectographs may be mounted on metallized sheets of paper or they may be mounted between glass as transparencies. If the transparencies are to be projected as lantern slides. the projection screen must be metalized. usually with aluminum paint, to prevent depolarization of the diffusely reflected light.

Stereoscopic Measurements. — The stereoscopic range finder (fig. 14) consists of two horizontal. oppositely directed telescopes with rectifying prisms of the modified Porro type. A large distance between the end mirrors M_1 and M_2 and a high magnification provide greatly enhanced stereoscopic perception. In front of the eyepieces are reticles, R_1 and R_2, consisting of stereoscopic transparencies that are seen as a three-dimensional array of three rows of vertical marks. one row running from left to right and the other two rows crossing obliquely at the centre. This field of marks is seen superposed on the stereoscopic image of external objects observed through the telescopes. By means of a prism combination P of variable deviation inside one of the telescopes, the target is made to coincide with the intersection of the three rows of marks

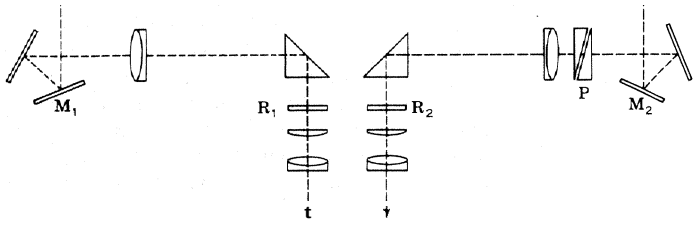

FIG. 14.— STEREOSCOPIC RANGE FINDER

A stereoscopic view of distant objects is seen superimposed on a stereoscopic pattern of marks on the reticles R_1 and R_2. The deviation by the pair of prisms P is adjusted by rotation of the prisms in opposite directions to make a selected object coincide with the central mark. The necessary rotation indicates the distance of the object

at the centre of the field oi view. The required variation in prism deviation is obtained by rotating the two narrow. oppositely directed prisms in opposite senses. The amount of rotation needed for coincidence depends on the distance of the target, this being indicated directly on the prism-rotation scale.

Stereoscopy is also employed in determining the elevation of objects photographed from an airplane flying over them. The photographic exposures are made at regular intervals from an airplane in uniform, horizontal flight. Any two successive photographs are then viewed by a suitably designed stereoscopic unit in which differences in elevation are perceived. To measure these, the operator uses a stereocomparator which consists essentially of two parallel. short-focus telescopes with special reticles in front of their eyepieces. Each reticle contains a centrally located spot,

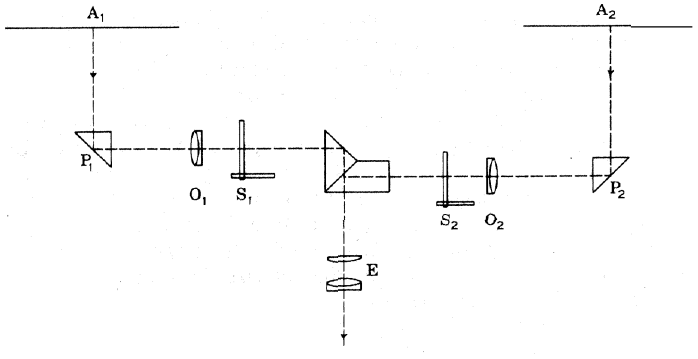

FIG. 15.—PULFRICH'S BLINK MICROSCOPE

The two photographs at A_1 and A_2 are seen either simultaneously or alternately by operating the shutters St and S_2. Even slight differences n the two photographs are easily detected by fluctuations in their position or intensity

and one or both of the spots may be moved laterally by means of a micrometer screw. The binocularly fused image of the spots is thus made to move forward or backward and may be set to coincide with the stereoimage of objects at different elevations. The micrometer is usually calibrated to read elevations directly. Greater precision is obtained by the use of glass diapositives instead of paper prints.

Horizontal as well as vertical distances are measured to construct a topographical map.

The so-called blink microscope (fig. 15) is an instrument that is useful in detecting changes in objects such as stars or terrain held by the enemy in warfare. Two photographs, A_1 and A_2, taken at difierent times, are viewed as if they were stereopairs. While binocular vision may be used, this is often not the case, as in fig. 15. If the shutters S_1 and S_2 in the two light paths periodically obscure first one and then the other of the two images, any detail in the photographs that had changed in the time interval between exposures is seen to flicker. This immediately calls the observer's attention to that particular object even if the photograph contains much detail, as in wide-field star pictures and long-range reconnaissance photographs.

Thus astronomers are aided in the discovery of novae and variable stars or stars with a large proper motion. By taking one photograph through a red filter and the other through blue, it is possible to locate stars that radiate abnormally in the red or blue regions of the spectrum.

In military applications, the device is useful in detecting new trenches, gun emplacements, etc., constructed under cover of darkness.

BINOMIAL THEOREM. By the term binomial theorem is meant the expansion of the nth power of the sum a + b; more generally by the term multinomial theorem is meant the expansion of the nth power of the sum of the k numbers $a_1, a_2, \ldots, a_k$.

Positive Integral Exponents. — Let n be a positive integer. Then the binomial theorem may be stated as

$$(a+b) = \sum_{r=0} \binom{n}{r} a^{n-r} b^r \qquad (1)$$

where the coefficients

$$\binom{n}{r} = C_r^n = \frac{n!}{r!\,(n-r)!} \qquad (n! = n(n-1)\cdots 1, 0! = 1)$$

are the so-called binomial coefficients. The notation C_r^n is sometimes used because of the combinatorial interpretation of the coefficients: C_r^n is the number of combinations of n things taken r at a time.

The coefficients $\binom{n}{r}$ have the properties

$$\binom{n}{r} = \binom{n}{n-r}, \quad \binom{n}{0} = \binom{n}{n} = 1, \quad \binom{n+1}{r} = \binom{n}{r-1} + \binom{n}{r}$$

They occur in the Pascal triangle:

```
1  1
1  2  1
1  3  3   1
1  4  6   4   1
1  5  10  10  5  1
. . . . . .
```

Formula (1) is readily proved by mathematical induction.

If $k \geq 2$ and n is a positive integer, then the multinomial theorem may be stated as

$$(a_1 + \ldots + a_k)^n = \sum \frac{n!}{r_1!\, r_2! \cdots r_k!}\; a_1^{r_1} a_2^{r_2} \cdots a_k^{r_k} \qquad (2)$$

nhere the summation is over all nonnegative integers $r_1, r_2, \ldots, r_k$ such that $r_1 + r_2 + \ldots + r_k = n$.

The numbers a, b in (1) and $a_1, \ldots, a$, in *12)* may be thought of as arbitrary real or complex numbers. (More generally they may be numbers in any commutative ring.)

Arbitrary Exponents. — If a and x are arbitrary complex numbers, we have the expansion

$$(1 + x)^\alpha = \sum_{r=0}^{\infty} \binom{\alpha}{r} x^r \qquad (3)$$

where now we define

$$\binom{\alpha}{r} = \frac{\alpha(\alpha - 1) \cdots (\alpha - r + 1)}{r!}, \quad \binom{\alpha}{0} = 1$$

For a $= n$, a positive integer, the expansion in the right member of (3) reduces to a finite sum and the result coincides with (1). In the general case, however, the expansion is infinite. Also it is necessary to explain what is meant by the left member. For any complex number $w \neq 0$, we can find a unique complex number $z = x + yi$, x and y real, such that $-\pi < y \leq \pi$ and $w = e^z$; z is called the principal value of the logarithm of w and we write $z = \log w$.

We now define

$$(1 + x)^\alpha = e^{\alpha \log (1 + x)} \qquad (x \neq -1)$$

We may now state the following fundamental result. If α is a nonnegative integer, the sum in the right member of (3) is finite If a is not a nonnegative integer, the series converges absolutely for $|x| < 1$ and diverges for $|x| > 1$; for $|x| = 1$, we have, irhen $R(a)$ signifies the real part of a,

(a) if $R(\alpha) > 0$. the series converges absolutely;
(b) if $R(\alpha) \leq -1$, the series diverges;
(c) if $-1 < R(\alpha) \leq 0$, the series diverges at $x = -1$ and converges conditionally at every other point on the unit circle.

When the series converges the sum is equal to the principal value of $(1 + x)^\alpha$; in particular the sum is 0 when $x = -1$.

Analogs of the Binomial Theorem. — S. H. Abel in 1826 gave the following extension of (1):

$$(x + \alpha)^n = \sum_{r=0} \binom{n}{r} \alpha(\alpha - r\beta)^{r-1} (x + r\beta)^{n-r}$$

where n is a nonnegative positive integer while x, a, β are arbitrary. The formula reduces to (1) where $\beta = 0$.

If we define the descending factoral

$$x^{(n)} = x(x - 1) \ldots (x - n + 1), \quad x^{(0)} = 1$$

we have the formula

$$(x + y)^{(n)} = \sum_{r=0}^{n} \binom{n}{r} x^r y^{(n-r)}$$

This identity is known as Vandermonde's analog of the binomial theorem. It is of course assumed that n is a nonnegative integer.

The expansion

$$(1 + x)(1 + qx) \ldots (1 + q^{n-1}x) = \sum_{r=0} \begin{bmatrix} n \\ r \end{bmatrix} q^{\frac{1}{2}r(r-1)} x^r,$$

where

$$\begin{bmatrix} n \\ r \end{bmatrix} = \frac{(1 - q^n)(1 - q^{n-1}) \cdots (1 - q^{n-r+1})}{(1 - q)(1 - q^2) \cdots (1 - q^r)}$$

is knonn as the basic or q-generalization of the binomial formula. it reduces to (1) when q = 1. The coefficients $\begin{bmatrix} n \\ r \end{bmatrix}$ are polynomials in q with integral coefficients and have properties analogous to those of the binomial coefficients $\binom{n}{r}$. It may be of interest to mention also the formulas

$$\prod_{r=0}^{n-1} (1 - q^r x)^{-1} = \sum_{r=0}^{\infty} \begin{bmatrix} n + r - 1 \\ r \end{bmatrix} x^r$$

$$\prod_{r=0}^{\infty} (1 + q^r x) = \sum_{r=0}^{\infty} \frac{q^{\frac{1}{2}r(r-1)} x^r}{(1 - q)(1 - q^2) \ldots (1 - q^r)}$$

$$\prod_{r=0}^{\infty} (1 - q^r x)^{-1} = \sum_{r=0}^{\infty} \frac{x^r}{(1 - q)(1 - q^2) \cdots (1 - q^r)}$$

Historical Note. — The general formula (arbitrary n) was first given by Newton in letters to H. Oldenburg dated June 13, 1676, and Oct. 24, 1676. Newton apparently gave no proof. Special cases of the binomial theorem occurred long before Newton. The Indians and Arabs used the expansions of $(a - b)^2$ and $(a + b)^3$ for root extractions. Vieta knew the expansion of $(a + b)^4$. Blaise Pascal was familiar with the "arithmetical triangle" described above; however this triangular array is found in 1303 in a Chinese tract by Chu Shih-Chieh.

The first proof of the binomial theorem for positive integral n was given by Jakob Bernoulli in his posthumous book *Ars conjectandi,* published in 1713. The first rigorous proof of the general formula (3) was given by Abel.

BINTURONG *(Arctictis binturong)*, a catlike carnivore, the single species of a genus of the civet family (Viverridae), ranging from northeast India, northern Burma and Indo-China south through the Malay peninsula and the islands of Sumatra, Java, Borneo and Palawan. It has long, shaggy body hair, tufted ears and a long, bushy, prehensile tail. The colour is generally black with a sprinkling of whitish hairs. Head and body together measure about 30 in. in length; the tail adds 24 to 27 in. more. The binturong inhabits dense forests and is principally nocturnal and arboreal in habits. It feeds upon eggs, small animals, and fruits. (J. N. L.)

BINTURONG (ARCTICTIS BINTURONG)

BINYON, (ROBERT) LAURENCE (1869–1943), English poet. dramatist and writer on art whose rare feeling for beauty was expressed in a language and style of great purity, owing much to his classical training. Born at Lancaster, Aug. 10. 1869. the son of a clergyman of Quaker stock, he was educated at St. Paul's school, London, where he met the poet Mohammed Ghose and thus made his first contact with the east. He was already writing poetry, and at Trinity college, Oxford, won the Newdigate prize for *Persephone* (1890). He combined his lifelong interests — in in books and in painting—when in 1893 he began work at the British museum, London, where later he was for many pears in charge of oriental prints and drawings. He continued to write poetry and to contribute to periodicals.

His first book on oriental art, *Painting in the Far* East (1908). a pioneer work and still a classic, proved the genius for the interpretation of painting in words which was to make his lectures memorable experiences. Later hooks on art included The Flight *of the Dragon* (1911) and *The Spirit of Man in Asian Art* (1935), as well as writings on English watercolours, particularly those of Blake and his followers.

World War I came as a devastating experience and his poem "For the Fallen" (first published in the *Times,* Sept. 21, 1914)

won immediate recognition as the expression of the feelings of a generation. His poetic powers reached maturity before the break with traditional diction marked by the war, though he was much interested in experiments n-ith classical diction and sprung rhythm. His best works were produced after the war, however: The Sirens (1924), *The* Idols (1928) and The *Burning of the Leaves and Other Poems* (1944). Collected *Poems* appeared in 1931. He was also concerned with the revival of verse drama, his works in this form including *Attila* (1907); *Arthur* (1923); and *The Young King* (1934). His translation of Dante's *Divine Comedy* into *terza rima,* the work of many years: was finished just before his death, at Reading, March 10, 1913. (N. GY.)

BÍO-BÍO, an inland agricultural province of southern Chile approximately bisected by latitude 37° 30' S. Created in 1875 from Arauco province. Bio-Bio has an area of 4.343 sq.mi. Pop. (1960) 167.286. Los Ángeles (pop. [1959 est.] 31.812) is the provincial capital and commercial centre. It lies about 300 mi. S. oi Santiago, and 60 mi. S.E. of Concepción. It was founded in 1739 and elevated to city rank in 1852. Los Ángeles was repeatedly attacked and several times destroyed in the long struggle with the Araucanians. Its industries process milk, wine. wheat and sugar beets; cattle and sheep are shipped north. The products arise chiedy from the farms of the longitudinal valley although dairy and meat livestock are raised at higher altitude in the cordilleran part of the province. The state railway and dry-season roads link the city to Santiago. Concepción and Puerto Montt. Hydroelectric power for the province, as well as for the industrial hub of Concepcion, is produced at El Abanico. on the Laja river.

The province is in a zone subject to earthquakes and from time to time Los Ángeles and other towns have suffered severely. (J. T.)

BÍO-BÍO RIVER of southern Chile. rises in the Pino Hachado passes across the Andes. and flows in a general northwesterly direction to the Pacific at Concepción, where it is 2 mi. wide. One of Chile's largest rivers. it has a total length of 236 mi.. nearly one-half of \Vhich is navigable for flat-bottomed boats.

BIOCHEMISTRY, the branch of science that deals with the chemistry of living organisms. has enabled man to live better and longer through its applications to nutrition, medicine, genetics. agriculture and other fundamental facets of life.

The terms "biochemistry." "biological chemistry" and "physiological chemistry" are often used interchangeably. As a field of specialization. this is a young science; however, although the term "biochemistry" has been in use only since about 1900, the origins of the science can be traced iar back in the early history of organized knowledge. Biochemistry lies in the border area between the biological and the physical sciences. between physiology and chemistry, Its early hi-tory is a part of the early history of these subjects.

History.— The natural development of scientific knowledge has proceeded from the simple to the more intricate. The complexities of living matter are such that a genuine body of biochemical theory in the modern scientific sense could not be developed until the study of simpler inanimate systems had provided a sound theoretical basis for chemistry itself and until the science of biology had progressed from the earlier completely descriptive phase to the study of iunction. Man's interest in living nature has always been spurred by the practical necessities of obtaining an adequate supply oi food and by the desire for good health. The alchemists searched not only for a method of making gold from baser metals but also for an elixir of life. sensing vaguely that knowledge of the chemical transformations of matter might lead to power to cure disease. The iatrochemists of the 16th century taught that the main purpose of chemical studies was to make medicines and thus aid the physician.

Before chemistry could contribute adequately to medicine and agriculture. however. it had to free itself from immediate practical demands in order to become a pure science. This happened in the period from about 1650 to 1780, starting with the work of Robert Boyle and culminating in that of Antoine Laurent Lavoisier, the father oi niodern chemistry. Boyle questioned the basis of the chemical theory of his day and taught that the proper object of chemistry was to determine tlie composition of substances. His contemporary, John Mayow, observed the fundamental analogy between the respiration of an animal and the burning or oxidation of organic matter in air. Then! when Lavoisier carried out his fundamental studies on chemical oxidation, grasping the true nature of the process, he also showed, quantitatively, the similarity between chemical oxidation and the respiratory process. Photosynthesis was another biological phenomenon that occupied the attention of the chemists of the late 18th century. The demonstration, through the combined work of Joseph Priestley, Jan Ingenhousz and Jean Senebier, that photosynthesis was essentially the reverse of respiration was a milestone in the development of biochemical thought.

In spite of these early fundamental discoveries. rapid progress in biochemistry had to wait upon the development of structural organic chemistry, one of the great achievements of 19th-century science. A living organism contains many thousands of diifferent chemical compounds. The elucidation of the chemical transformations undergone by these compounds within the living cell is the central problem of biochemistry. Clearly the determination of the molecular structure of the organic substances present in living cells had to precede the study of the cellular mechanisms whereby these substances are synthesized and degraded.

There are few sharp boundaries in science, and the houndaries between organic and physical chemistry on the one hand and biochemistry on the other have always shown much overlap. Biochemistry has borrowed the methods and theories of organic and physical chemistry and applied them to physiological problems. Progress in this path was at first impeded by a stubborn misconception in scientific thinking — the error of supposing that the transformations undergone by matter in the living organisni are not subject to the chemical and physical laws which apply to inanimate substances, and that consequently these "vital" phenomena cannot be described in ordinary chemical or physical terms. Such an attitude was taken by the vitalists, who maintained that natural products formed by living organisms could never be synthesized by ordinary chemical means. The first laboratory synthesis of an organic compound, urea. by Friedrich Wöhler in 1828 was a blow to the vitalists but not a decisive one. They retreated to new lines of defense. arguing that urea was only an excretory substance-a product of breakdown and not of synthesis. The success of the organic chemists in synthesizing many natural products forced further retreats of the vitalists. It is axiomatic in modern biochemistry that the chemical laws which apply to inanimate materials are equally valid within the living cell.

At the same time that progress was being impeded by a misplaced kind of reverence for living phenomena. the practical needs of man operated to spur the progress of the new science. Medicine and agriculture had long looked on chemistry as a potential ally in man's struggle with nature. The 19th and 20th centuries witnessed the fruition of this hope. As organic and physical chemistry erected an imposing and beautiful body of theory in the 19th century, the needs of the physician, the pharmacist and the agriculturalist provided an ever-present stimulus for the application of the new discoveries of chemistry to various urgent practical problems.

Liebig and Pasteur.—Two outstanding figures. the German Justus von Liebig (1803–73) and the Frenchman Louis Pasteur (1822–95), were particularly responsible for dramatizing the successful application of chemistry to the study of biology. Liebig studied chemistry in Paris and carried hack to Germany the inspiration gained by contact with the former students and colleagues of Lavoisier. He established at Giessen a great teaching and research laboratory, one of the first of its kind, which drew students from all over Europe.

Besides putting the study of organic chemistry on a firm basis, Liebig engaged in extensive literary activity, attracting the attention of all scientists to the new science of organic chemistry and popularizing it for the layman as well. His classic works. *Die Chemie in ihrer Anwendung auf Agrikultur und Physiologie* (1840) and *Die Thier-Chemie,* oder die *organische Chemie* in ihrer *Anwendung auf Physiologie und Pathologie* (1842), were prepared

as a report on the state of knowledge in organic chemistry at the request of the British Association for the Advancement of Science and had a profound influence on contemporary thought. Liebig described the great chemical cycles in nature. He pointed out that animals would disappear from the face of the earth if it were not for the photosynthesizing plants, since animals require for their nutrition the complex organic compound that can be synthesized by the plants alone. Even carnivores are dependent eventually on herbivorous forms. The animal builds a portion of its food into its own body and oxidizes a portion to carbon dioxide and water and other simple products. The animal excretions and the animal body after death are also converted by a process of decay to simple products that can be reutilized only by plants.

In contrast with animals, green plants require for their growth only carbon dioxide, water, mineral salts, a source of nitrogen. such as ammonia, and sunlight. The minerals must be obtained from the soil, and the fertility of the soil depends on its ability to furnish the plants with these essential nutrients. But the soil is depleted of these materials by the removal of successive crops. Hence the need for fertilizers. Liebig pointed out that chemical analysis of plants could serve as a guide to the substances that should be present in fertilizers. Agricultural chemistry as an applied science was thus born.

In his analysis of fermentation, putrefaction and infectious disease. Liebig was less fortunate. He admitted the similarity of these phenomena, but refused to admit that living organisms might function as the causative agents. It remained for another great chemist. Pasteur, to found the science of bacteriology. Pasteur proved that various yeasts and bacteria nere responsible for causing fermeiitation and disease. He also demonstrated the usefulness of chemical methods in studying these tiny organisms. Pasteur put the study of the processes of fermentation and putrefaction on a sound scientific basis.

Bernard.—Not all the men who grasped the power of chemical tools in solving biological problems were trained initially as chemists. The great French physiologist Claude Bernard (1813–78) was trained as a physician. Among his many achievements were the discovery of glycogen or anitnal starch and the demonstration of the role of the liver as a storage depot for carbohydrates. Physiologists trained in the traditions of Claude Bernard could not help recognizing the importance of the chemical approach. It became common for research laboratories devoted to physiological studies to acquire an adjoining chemical laboratory. The chemists themselves, however. were often too busy with their own interesting problems to spend much effort on the problems of most pressing interest to the biologists. A need for a new type of specialist arose. The pressure came particularly from medicine. and physiological chemistry developed, in part, as a kind of applied chemistry. with a principal objective of providing the clinician with aids for the diagnosis and treatment of disease.

Growth of Special Training, Journals and Societies.—The first institute for physiological chemistry was established at the University of Strasbourg in 1872 under the direction of Ernst Felix Hoppe-Sepler. In the United States, the Sheffield Scientific school at Yale university began giving graduate training in physiological chemistry in 1880. After about 1900 the provision of special advanced training in biochemistry at universities became general in many countries. Departments of biochemistry frequently developed as offshoots of departments of physiology. Thus Sir Frederick Gowland Hopkins took charge of the chemistry laboratory in the department of physiology at the University of Cambridge in 1899, and was appointed to the newly established chair of biochemistry at that institution in 1914.

The increase in the number of trained scientists devoting their time to biochemical studies is evidenced by the founding of scientific journals and periodicals. In the absence of any journal; devoted exclusively to biochemical subjects. scientific papers in this field were published in various journals of chemistry, physiology, medicine and related disciplines. In 1871 R. Maly began issuing the *Jahres-Bericht über die Fortschritte der Tier-Chemie,* which appeared in yearly volumes until 1919. With the assistance oi biochemists in other countries, Maly abstracted from various scientific journals published all over the world all those papers that had primarily a biochemical content. The first scientific journal devoted exclusively to the subject of biochemistry was the *Zeitschrift für physiologische Chemie,* founded by Hoppe-Seyler in 1877. The U.S. *Journal of Biological Chemistry* was founded in 1905. and the British *Biochemical Journal* in 1906. In the same year another German journal, *Biochemische Zeitschrift,* also was founded. The French *Bulletin de* la *Société de Chimie Biologique* first appeared in 1914 and the *Journal of Biochemistry* (Japan) in 1922. With temporary interruptions during World Wars I and II, there has been a steady increase in number of new journals containing biochemical papers and in the volume of material published by the older journals as well.

Paralleling the growth of journals was the growth of scientific societies. The American Society of Biological Chemists mas founded in 1906 by a group of members of the Physiological society, spurred. perhaps, by the formation in 1905 of a biochemical section of the American Chemical society. The British Biochemical society. founded in 1911, was also an offshoot of the Physiological society. These two biochemical societies own and control the *Journal of Biological Chemistry* and the *Biochemical Journal* (London). respectively.

Scope.—The field of biochemistry has become so large that many subspecialties are recognized. Some are practised largely as applied sciences. The early growth of agricultural chemistry and clinical chemistry has already been mentioned. These two areas of applied chemistry developed in part independently of each other, in conjunction with colleges of agriculture and with schools of medicine, respectively. Taken a a whole, however, modern biochemistry outgrew the status of an applied science and acquired a place among the pure or theoretical sciences. An attempt will be made in the following sections to outline the scope of modern biochemistry, its working methods and its objectives.

Biochemistry is concerned with all types of living organisms. The ultimate goal of biochemistry is to achieve a complete description of life at a molecular level. The biochemist. therefore, must know the chemical structure of the myriads of substances present in living material. Information must likewise be obtained about the anatomical distribution of these substances within the body and even within the individual cell. The various cellular components that can be differentiated by microscopic examination, such as nucleus and suspended granules, all exhibit characteristic features in their chemical make-up. Construction of a chemical map of this sort, however, gives only a static picture. which is necessarily incomplete, since a fundamental characteristic of all living cells is the occurrence within them of chemical change. One can sometimes arrest this change by bringing a cell suddenly to very low temperatures, without necessarily causing death. Dehydrated forms, such as seeds and spores, also can survive for long periods with very small changes in their composition. Nevertheless, at temperatures compatible with growth and reproduction, and in the hydrated state, a living cell must be regarded as a dynamic changing system.

A description of life at a molecular level must include, therefore, a description of the chemical changes that occur within the cell and of all their complex interrelations. These processes are sometimes termed the intermediary metabolism of the cell. Using the term "intermediary metabolism" in its broadest sense, we may say that the main objective of biochemistry is to achieve an understanding and a complete description of intermediary metabolism. Success in reaching such an objective would be equivalent to acquiring as complete an undersranding of life as man can achieve by his intellect alone. Living processes are sufficiently complex. however. to guarantee the biochemist sufficient unsolved problems to last into the unforeseeable future.

Chemical Composition of Living **Matter.**—Living organisms of diverse types differ markedly in their chemical make-up. In a single individual. moreover, various tissues and secretions, such as blood. muscle, liver: bone and milk. show enormous differences in composition, reflecting their diverse functions. Nevertheless, the living cell itself, apart from secretions, interstitial ma-

terial and supporting structures, shows a pattern of similarity in chemical constitution from species to species and from one tissue to another in the same species.

Every living cell contains, in addition to water and salts or minerals: a large number of organic compounds (*see* CHEMISTRY: *Organic Chemistry*). The organic substances of living cells are composed of carbon combined with varying amounts of hydrogen and usually also of oxygen. Nitrogen, phosphorus and sulfur are likewise common constituents. In general, the bulk of the organic matter of a cell may be classified as (1) sugar or carbohydrate. (2) fat or lipid and (3) protein. Nucleic acids and various porphyrin derivatives are also important constituents. Each of these classes or groups contains a great diversity of individual compounds. Many substances that cannot be classified in any of the above categories also occur, though usually not in large amounts.

The knowledge already accumulated about the chemical composition of living matter is not by any means complete. In the case of substances of low molecular weight, however, the general methods for determining chemical structure had largely been worked out by the early 1960s. The organic chemists achieved marked success in solving many problems of identification of unknown materials that were first detected only by their physiological effects. The determination of the structure of the hormones thyroxine and adrenaline and of the various vitamins may be cited as examples. The development of the chemistry of the steroids, including that of the sex hormones and of the adrenal hormone cortisone, likewise stands as a monument to the skill of the organic chemist. Great gaps still existed by the early 1960s, however, particularly in information about the details of the structural composition of the larger molecules such as proteins and nucleic acids.

Proteins and Nucleic Acids.— In the case of polymers of high molecular weight, the determination of structural detail is extraordinarily complex. Proteins, for example, are composed of long chains of amino acids linked by peptide bonds; *i.e.*, bonds formed between the carboxyl group of one amino acid and the amino group of the next. A protein molecule may contain several thousand amino acid residues. The relative amount of each of the amino acids present in a molecule of protein can be determined by special methods of analysis. It is necessary to know also the order in which the amino acids occur in the peptide chains, and this is a more difficult problem. Even though there are only about 24 different amino acids, it is clear that there is an enormous number of different sequences in which a thousand such units could be arranged in linear order. The sequence of amino acids in the protein hormone insulin was successfully determined, however: and it could be expected in the early 1960s that the newer methods of analysis would be applied successfully to other proteins. Nevertheless, for the larger molecules, this is a formidable task. The structure of proteins involves other problems than the determination of amino acid sequences. The protein in its natural state in the cell is often a very unstable substance. Its properties can sometimes be changed by very mild procedures. In this case it is thought that the folding or arrangement of the peptide chain is somehow altered.

Special physical methods have been devised for the study of protein molecules. These methods include the use of the electrophoresis apparatus to measure migration in an electric field, and the use of the ultracentrifuge to measure migration in a gravitational field. From these and other physical measurements, information is obtained about molecular size: shape and electrical charge. X-ray analysis of fibres and crystals has also been applied to determine certain aspects of the geometric arrangement of atoms in the molecule. This area of study is sometimes considered a part of biophysics rather than of biochemistry, as are other fields that involve the application of physical methods to biological problems.

The great importance attached to proteins by the biochemist is partly attributable to the demonstrated functional role of these substances in the cell. The chemical reactions that occur in the living cell are catalyzed by substances called enzymes. and these key substances all appear to be proteins. In fact, a large proportion of the protoplasmic protein must have some enzymatic function.

The nucleic acids constitute another group of cellular constituents of high molecular weight. They are composed of chains consisting of alternating units of carbohydrate and phosphate with each carbohydrate residue linked to a nitrogenous base, which may be a purine or a pyrimidine. The nucleic acids exist in the cell in combination with protein, as nucleoprotein. The chromatin of the nucleus consists of nucleoprotein, and it is highly probable that the genes, the carriers of hereditary characteristics, are nucleoproteins or nucleic acids. The difficulties encountered in determining the chemical structure of nucleic acids are similar in some respects to those encountered in determining protein structure. In both instances, an enormous variety of different molecules are possible because of the high molecular weight. (See NUCLEIC ACIDS.)

Different types of living organisms may contain identical materials of low molecular weight, but the proteins and probably the nucleic acids are characteristic of a species. It is here that the chemical basis for the more obvious anatomical differences between divergent forms of life is found.

Nutrition.— Biochemists have long been interested in the chemical composition of the food of animals. The practical value of knowing what must be present in the diet to ensure good health is self-evident. The fact that knowledge of essential dietary constituents may help in an understanding of the nature of life processes, however, requires emphasis.

All animals require organic material in their diet, in addition to water and minerals. This organic matter must be sufficient in quantity to satisfy the caloric or energy requirements of the animals. Within certain limits, carbohydrate, fat and protein may be used interchangeably for this purpose. In addition. however, animals have nutritional requirements for specific organic compounds. Certain essential fatty acids. about ten different amino acids (the so-called essential amino acids) and a heterogeneous group of compounds called vitamins (*q.v.*) are required by many higher animals. The nutritional requirements of various species are similar but not necessarily identical. Thus man and the guinea pig require vitamin C or ascorbic acid. whereas the rat does not.

In all cases. the need for a specific substance in the diet indicates that the organism requires this particular substance for proper cellular function and that the tissues of the animal are unable to synthesize the substance from any other available material. In the absence of a particular vitamin or amino acid, the cells cannot carry out certain necessary chemical reactions. Such chemical deficiencies underlie the functional and anatomical changes that are so often characteristic of vitamin deficiency. The chemical functions of some of the vitamins in the cell are known. Thiamine (vitamin B_1), riboflavin (vitamin B_2), niacin and pyridoxine (vitamin B_6) all function as components of specific enzyme systems. Vitamin A aldehyde forms a part of visual purple, the retinal pigment responsible for vision in dim light. Hence vitamin A deficiencies lead to night blindness. Thus, the demonstration of a nutritional requirement can actually serve as a tool to help elucidate the chemical mechanisms operating in the cell.

The photosynthesizing plants differ from animals in requiring no preformed organic material. Instead they make all their cellular material from simple substances, carbon dioxide, water, salts and a source of nitrogen such as ammonia or nitrate. The energy for this process is furnished by sunlight. The process of photosynthesis (*q.v.*) itself is primarily concerned with manufacture of carbohydrate, from which fat can be made by animals that eat plant carbohydrates. Protein can also be formed from carbohydrate precursors provided ammonia is furnished.

In spite of the large apparent differences in nutritional requirements of plants and animals, the patterns of chemical change within the cell are the same. The plant itself manufactures all the materials it needs. but these materials are essentially similar to those which the animal cell uses and are often handled in the same way once they are formed. Plants could not furnish animals with their nutritional requirements if the cellular constituents in the two forms were not basically similar.

Digestion. — The organic food of animals and men consists in part of large molecules. In the digestive tracts of higher animals these molecules are hydrolyzed or broken down to their component building blocks. Proteins are converted to mixtures of amino acids, and polysaccharides are converted to monosaccharides. In general, all living forms use the same small molecules, but many of the large complex molecules are different in each species. An animal, therefore, cannot use the protein of a plant or of another animal directly, but must first break it down to ainino acids and then recombine the amino acids into its own characteristic proteins. The hydrolysis of food material is necessary also to convert solid material into soluble substances suitable for absorption. The liquefaction of stomach contents aroused the early interest of observers, long before the birth of modern chemistry, and the hydrolytic enzymes secreted into the digestive tract were among the first enzymes to be studied in detail. Pepsin and trypsin, the proteolytic enzymes of the gastric and pancreatic juice, respectively, continue to be intensively investigated.

Absorption and Secretion. — The products of enzymatic action on the food of an animal are absorbed through the walls of the intestines and distributed to the body by the blood and lymph. In organisms without digestive tracts. substances must also be absorbed in some way from the environment. When a substance passes across a cell membrane in either direction (*i.e.,* from the outside to the inside, or from the inside to the outside) the problem of the mechanism of this reaction arises. Examples of this problem include the mechanisms whereby the kidney forms urine; the plant roots take up minerals from the soil; and a bacterium takes up some materials from a medium in which it is growing, excludes others or even secretes or excretes certain substances from the cell into the medium. In some instances simple diffusion appears to be sufficient to explain the transfer of a substance across a cell membrane. In other cases. however (*e.g.,* in the case of the transfer of glucose from the lumen of the intestine to the blood). transfer occurs against a concentration gradient. That is, the glucose may move from a place of lower concentration to a place of higher concentration. Simple diffusion cannot explain such a process. Some evidence was provided to indicate that glucose is phosphorylated at some site where it is taken up and dephosphorylated at another site where it is released. Whether or not such an explanation is correct. it appears clear that the problem of mechanism here is a chemical one.

In the case of the secretion of hydrochloric acid into gastric juice, it was shown that active secretion is dependent on an adequate oxygen supply (*i.e.,* on the respiratory metabolism of the tissue), and the same holds for absorption of salts by plant roots. The energy released during the tissue oxidation must be harnessed in some may to provide the energy necessary for the absorption or secretion. This harnessing is achieved by a special chemical coupling system. The elucidation of the nature of such coupling systems is an objective of the biochemist.

Blood. — One of the animal tissues that has always excited special curiosity is blood (*q.v.*). Blood has been investigated intensively from the early days of biochemistry, and its chemical composition is known with greater accuracy and in more detail than that of any other tissue in the body. The physician takes blood samples to determine such things as the sugar content, the urea content or the inorganic ion composition of the blood, since these show characteristic changes in disease.

The blood pigment hemoglobin has been intensively studied. Hemoglobin is confined within the blood corpuscles and carries oxygen from the lungs to the tissues. It combines with oxygen in the lungs. where the oxygen concentration is high. and releases this oxygen in the tissues where the oxygen concentration is low. The site of combination with oxygen is an iron atom complexed with a porphyrin ring that is bound to a protein. globin. The hemoglobins of higher animals are related but not identical. In invertebrates other pigments may take the place and function of hemoglobin. The comparative study of these compounds constitutes a fascinating chapter in biochemical investigation.

The proteins of blood plasma also have been extensively investigated. Methods have been developed for the large-scale fractionation and purification of these substances. The gamma globulin fraction of the plasma proteins contains the antibodies of the blood and is of practical value as an immunizing agent. An animal develops resistance to disease largely by antibody production. The antibodies are proteins that have the ability to combine with an antigen: *i.e.,* an agent that induces their formation. When this agent is a component of a pathogenic bacterium. the antibody can protect an organism irom infection by that bacterium. The chemical study of antigens and antibodies and their interrelationship is known as immunochemistry.

Intermediary **Metabolism.**—Whether a cell is moving or not, whether it is growing or wasting, it is the site of a constant. complex and orderly set of chemical changes. One may visualize these changes in the following way. The structure of the living cell is essentially unstable. It is constantly breaking don-n. There is therefore a constant need for repair. The cell makes the chemical building blocks necessary for this repair from its nutrients, and rehuilds its own substance. Such synthetic processes as well as work done on the external environment require energy. The energy must be obtained by the breakdown of other food molecules. In aerobic organisms. energy is obtained by the oxidation of the food; in anaerobic organisms. other chemical changes yield the energy. In photosynthetic organisms, the cell manufactures its own food with the energy of sunlight. Nevertheless, the patterns of breakdown and repair are similar in all living forms.

This process of chemical change. called metabolism. is associated with a release of heat. Precise measurements have been made of the heat released by both higher and lower organisms, and these measurements have been compared with the net chemical changes that occur simultaneously. The heat released is the same as that obtained if the same chemical change is brought about outside the living organism. This confirms the fact that the laws of thermodynamics apply to living systems just as they apply to the inanimate world. However, the pattern of chemical change in a living cell is distinctive and different from anything encountered in nonliving systems. This difference does not mean that any chemical laws are invalidated. It resides rather in the extraordinary complexity of the interrelations of cellular reactions.

The body has been likened to a machine rhat is driven by the combustion of some fuel provided from the outside. The fuel is likened to the food an animal eats. Such an analogy has only a superficial validity. To improve it, one must try to imagine a machine in which it is necessary that some oi the structural components be broken down and repaired automatically during operation, this breakdown and repair being interineshed with the combustion of the fuel in such a way that it often becomes meaningless to inquire whether a particular component of the process represents one or the other, combustion of the fuel or breakdown and repair of mechanical parts.

Methods of Study.—Many different methods have been used to study intermediary metabolism. Early studies were concerned with the analysis of food and excretions. The net chemical change occurring in the body could thereby be ascertained. but this gave no information about the detail of the over-all process. More was learned from studies of the effect of metabolic diseases (*q.v.*), such as diabetes. on excretory products. In another type of approach, chemical substances foreign to an animal were administered and the special excretory products were identified. Valuable hints n-ere thereby obtained concerning the chemical transformations occurring in the body under more normal circumstances.

At a later stage, isolated tissues and organs were examined, as were slices and extracts prepared from various tissues. The chemical processes occurring in the body do not terminate with the death of the organism. Minced liver and muscle continue to consume oxygen and to convert foodstuffs to carbon dioxide and various other end products. Examination of the chemical changes occurring in such preparations has given much information about metabolic processes. (*See* ANIMAL **CELL** [TISSUE] CULTURE.)

Empirical procedures were developed for obtaining parts of a reaction system separated from other parts. Poisons or inhibitors may be added to stop certain reactions and cause substances normally present at \-ery low concentrations to accumulate in such

quantity that they can he isolated and identified.

For the final determination of a detail of a particular reaction mechanism. it may be necessary to separate the enzyme causing the reaction from all other enzymes. Such procedures necessarily involve a complete destruction of the organization of a living cell. and they have been likened to the procedure of smashing a watch with a hammer in order to find out how it works. This' analogy implies some doubt of the validity of these procedures. and it is indeed necessary to devise other means to determine whether the information obtained by studying the enzymes in a tissue extract gives useful information about the metabolism of the intact organism. Determinations of nutritional requirements and of excretory products are often helpful in this connection! but they have only limited applicability.

Among the most useful tools for studying the metabolism of the intact organism are radioactive and stable isotopes of the elements most commonly found in living matter. These became generally available after World War II. Radioactive carbon (C^{14}), heavy nitrogen (N^{15}), radioactive phosphorus (P^{32}) and heavy hydrogen or deuterium have been applied with particular success to the study of biochemical problems. The usefulness of these substances rests on the fact that the heavy or radioactive isotopes react chemically just as do the normal elements, but can be distinguished from the normal elements by sensitive physical analytical methods. A substance such as glucose may be "labeled" or "tagged" n-ith C^{14}. by incorporation of the C^{14} into some particular position in the molecule. The glucose may then he fed to an animal. and, at various time intervals, the distribution of the C^{14} in various body constituents is determined. The fate of a particular atom in the glucose molecule can thereby be determined. The information thus gained can be compared with the results that would he predicted from iacts learned by studies of extracts, or, when insufficient facts are available, the tracer results may serve as a valuable guide ior enzyme studies with extracts. The two methods of approach supplement each other. The tracer procedure proved a rich source of new information and provided excellent evidence that the analytical methods of the enzymologist have validity for the intact organism.

Carbohydrate Metabolism. — The second quarter of the 20th century witnessed a striking advance in the elucidation of the manner in uhich living cell.; handle small molecules. The processes of breakdon-11 and synthesis of carbohydrates, fats and many of the naturally occurring amino acids are in part understood. The metabolism of carbohydrate in the mammal may he discussed first from the point of view of the interrelations between diilerent organs.

The sugars rind amino acids absorbed from the intestine are carried by the portal vein first to the liver. In the liver, the sugars and some amino acids are converted to glycogen or animal starch. a high-molecular-weight substance made up of many glucose units. Glycogen is the storage form of carbohydrate in the liver. The concentration of glucose in the systemic circulation that takes blood to all parts of the body is under the control of the liver. In the normal individual, blood sugar concentration is held remarkably constant at about So mg. per 100 ml. When the blood sugar tends to drop below this concentration. the liver feeds more sugar into the blood stream, breaking down stored glycogen for the purpose.

The muscles of the hody also store sugar as glycogen, hut they cannot reconvert the glycogen to blood sugar. They degrade the sugar in order to obtain energy for work. If the oxygen supply to the muscle is adequate, the sugar is oxitlizecl completely to carbon dioxide and water. If oxygen is in short supply, as may happen during vigorous exercise, the glucose is converted to lactate which may he returned by the hlood stream to the liver and reconverted to glycogen. Other tissues of the body use glucose also, of course, but the largest consumer is muscle.

In diabetes mellitus there is a deficiency of the pancreatic hormone insulin. Insulin is necessary for the proper regulation of the blood sugar concentration. In its absence the sugar levels become abnormally high. arid some of the sugar spills over into the urine through the kidney. Fat metabolism is likewise interfered with in diabetes. Besides glucose, the so-called ketone bodies — acetone, acetoacetic acid and β-hydroxy butyric acid — also accumulate in the blood and urine. The ketone bodies are products of the incomplete oxidation of fats.

Glycolysis and Fermentation. — The term "glycolysis" denotes the process of converting glucose or glycogen to lactate. This occurs anaerobically; *i.e.*, no oxygen is required. Glycolysis may be regarded as a special kind of fermentation. Fermentation. then, is a more general term referring to a group of anaerobic processes that involve a conversion of carbohydrate to a variety of end products. Glycolysis occurs in muscle and most other tissues of the animal body. In muscle this process has excited interest because of its apparent relation to muscular contraction. It was observed very early that the muscles of animals killed after a hunt contained appreciable amounts of lactic acid. Further studies showed that excised muscle. caused to contract repeatedly by electrical stimulation, also accumulated lactic acid, at the expense of the stored glycogen.

The reactions of glycolysis are understood in considerable detail. The over-all reaction can be expressed by the equation:

$$\text{glucose} + 2 \text{ adenosine diphosphate} + 2 \text{ phosphate} \rightarrow 2 \text{ lactate} + 2 \text{ adenosine triphosphate}$$

Each glucose molecule is converted to two molecules of lactate. and at the same time two molecules of adenosine diphosphate each acquire a molecule of inorganic phosphate to form two molecules of adenosine triphosphate.

This net change actually occurs in a sequence of 11 separate steps. Each of the 11 different reactions is catalyzed by a separate, specific enzyme. Each reaction in itself is simple. consisting. for example, of a transfer of phosphate or of hydrogen from one molecule to another or from one position to another in the same molecule. a gain or loss of water or a splitting off of carbon dioxide. The reaction may proceed in either direction, depending on the relative concentration of the reaction components. Some of the reactions, however. proceed in only one direction; *i.e.*, irreversibly. Now. the body can convert lactate to glucose. but it cannot do so by means of the identical path used ior the conversion of glucose to lactate. The reversible steps in the latter process are used in the back reaction. hut the irreversible steps must be circumvented.

Another feature to he emphasized is the interlinking of the reactions. Xtlenoxine triphosphate (ATP) and diphosphopyridine nucleotide (DPN) participate at several places. A step in the forward direction involves a conversion of DPN to DPNH. For example, glyceraldehyde transiers hydrogen to DPN, thereby reducing it. Other steps involve a conversion of DI'SH to DPN. For example, pyruvate accepts hydrogen from DPNH. thcrehy oxidizing DPNH and thus regenerating DPN. In an analogous manner, those reactions that involve a conversion of adenosine triphosphate (ATP) to adenosine diphosphate (ADP) may be linked with the steps that convert ADP to ATP.

Glycogen and glycerol are also formed from glucose. Other reactions are known to occur with some of the substances formed during glycolysis. Many other enzymes cause oxidation-reduction reactions with DPN and TPN, and phosphate transfers from ATP. To discuss these details further is beyond the scope of this article. The purpose of the discussion has been mainly to give some concrete notion of what is meant when the processes of intermediary metabolism are described as a "network" of chemical reactions.

Some or all of the reactions occur in microorganisms and plants as well as in animal tissues. Thus. the process whereby yeast converts glucose to ethyl alcohol is identical with the process of lactate formation in muscle up through the formation of pyruvate. Here the processes in yeast and muscle diverge. Yeast contains an enzyme, pyruvic carboxylase, which is not present in muscle. This enzyme splits a molecule of carbon dioxide from pyruvate, thereby forming acetaldehyde. The acetaldehyde then reacts with DPNH to form ethyl alcohol and DPN in the presence of another enzyme called alcohol dehydrogenase, which is quite distinct and different from lactic dehydrogenase, the muscle enzyme. Other fermentation processes proceed by a similar sequence of interrelated reactions. Some of the individual reactions may be the same as those

of glycolysis, but others may not, so that the end products of the various types of fermentation are different, although the processes themselves may have many individual reactions in common.

Energy Utilization. — One of the most important features of glycolysis is the phosphorylation that accompanies the conversion of glucose to lactate. For every molecule of glucose that is degraded, two molecules of adenosine triphosphate are formed from adenosine diphosphate and inorganic phosphate. The energy released in the conversion of glucose to lactate is stored as chemical energy in the adenosine triphosphate. If it were not for this storage mechanism, the energy of the degradation would be lost as heat.

Muscular work requires energy, and this energy is obtained from carbohydrate breakdown by way of adenosine triphosphate. In the process of transferring energy to the muscle fibre, the adenosine triphosphate is reconverted to adenosine diphosphate and inorganic phosphate. Biochemists are currently concerned with the elucidation of the precise manner in which the chemical energy of the phosphate bond is converted to the mechanical energy associated nith the contraction and relaxation of the muscle fibres.

Biological processes other than muscular contraction likewise require energy. The synthesis of complex molecules, the transfer of molecules across cell membranes and the conduction of an impulse along a nerve may all be cited as examples. In these and other instances, the chemical mechanism of energy utilization constitutes an interesting problem. Though the final steps in energy utilization may be of very different nature in the individual cases, it appears that the adenosine phosphates play a central role in linking the chemical reactions that release energy with the processes that require energy.

Carbohydrate Oxidation. — When carbohydrate is oxidized to carbon dioxide and water in an animal tissue, the first steps in the breakdown are identical with the steps of glycolysis, up through the formation of pyruvate. The steps whereby pyruvate is oxidized to carbon dioxide and water are known collectively as the tricarboxylic acid or citric acid cycle. They also are sometimes called the Krebs cycle in honor of their discoverer. (See KREBS, SIR HANS ADOLF.) Specifically, pyruvate condenses with oxaloacetate to form, in succession, citrate and carbon dioxide, cis-aconitate, isocitrate, oxalosuccinate, or-ketoglutarate and carbon dioxide, succinate and carbon dioxide, fumarate, malate and finally oxaloacetate. One of the starting materials is thus regenerated by a cyclic path. Pyruvate is not regenerated. however, so that the net effect of going once around the cycle is to form three molecules of carbon dioxide at the same time that pyruvate, a three-carbon compound, disappears.

Oxygen is required for the operation of the tricarboxylic acid cycle. Several of the steps in the cycle require a removal of hydrogen atoms from organic combination, and this hydrogen (H) is eventually transferred to inolecular oxygen to form water. The transfer occurs again over a sequence of reactions. The individual steps are all oxidation-reduction reactions, and the enzymes that cause them may be termed respiratory catalysts. An oxidation involves a removal of hydrogen or electrons or both, and a reduction involves an addition of hydrogen or electrons or both. In the first step in hydrogen transfer, diphosphopyridine nucleotide (DPN) (or triphosphopyridine nucleotide, TPN) takes up hydrogen from one of the organic acids of the cycle to form DPSH (or TPNH). Then a flavoprotein takes the hydrogen from the DPSH to form DPN and reduced flavoprotein. This substance is reoxidized by a special group of catalysts, the cytochrome-cytochrome oxidase system. (See PROTOPLASM: *Chemistry* of *Protoplasm.*)

The cytochromes are similar to hemoglobin, the oxygen-transporting pigment of the blood, in that they consist of proteins linked to iron-porphyrin complexes similar to the iron porphyrin of hemoglobin. The protein portions of hemoglobin and of the cytochromes are quite different. however, and account for the differences in chemical behaviour of these substances. When the cytochromes are functioning in tissue respiration, the iron atoms in the molecules alternate between the ferric (Fe^{3+}) or oxidized form and the ferrous (Fe^{2+}) or reduced form. Reduced flavoprotein transfers electrons to the ferric iron, which is thereby converted to ferrous iron. The ferrous iron is oxidized back to the ferric form by oxygen, which is converted to water.

While these reactions are taking place, adenosine diphosphate and inorganic phosphate are simultaneously converted to adenosine triphosphate. This latter reaction is of the utmost importance just as in the case of the anaerobic reactions: since it represents the mechanism whereby the energy released in the oxidation process is stored as chemical energy that can then be made available to other reactions. Many molecules of adenosine triphosphate are formed during the oxidation of one molecule of glucose. The aerobic phase of carbohydrate breakdown provides far more energy in this way than the anaerobic phase, but in both cases the energy is stored in identical chemical form and must consequently be utilized by the same chemical mechanisms.

The reactions of glycolysis and of many other anaerobic processes are catalyzed by soluble enzymes. The aerobic reactions of the tricarboxylic acid cycle, on the other hand, are catalyzed by a set of enzymes built into the structure of certain cytoplasmic granules, sometimes called mitochondria. Such granules occur in plants as well as in animals. Closely related is another set of plant particles, the chloroplasts. These contain the green pigment chlorophyll and are the site of the photosynthetic process (see PHOTOSYNTHESIS). The electron microscope, with its enormous powers of resolution, is providing a wealth of information about the fine anatomical structure of such particles.

Fats and Amino Acids. — A detailed picture is available of the metabolism of fatty acids and also of the synthesis, breakdown and interconversion of many of the amino acids. The path of oxidation of fatty acids terminates in the same tricarboxylic acid cycle used for oxidation of carbohydrate. The metabolic paths of the amino acids are interlocked also with the metabolism of fat and carbohydrate. This is an area subject to active current research, and each year sees marked further progress. In principle, however, the manner in which these substances are handled is similar to that in which carbohydrate is handled. Although the details are different, the chemical changes take place as an inter. laced sequence of individual simple steps, each catalyzed by a specific enzyme. The question of how these enzymes are formed may next be considered.

It is characteristic of the action of enzymes (*q.v.*) that they are not consumed during the reactions they catalyze. The enzymes must. however, be synthesized initially from their building blocks, mainly amino acids. The mechanism of protein synthesis or of enzyme synthesis was not completely understood in the early 1960s. It was certain, however, that the problem had greater complexity than the problem of the metabolic fate of small molecules. It is in the chemistry and metabolism of small molecules that the basic similarities among living forms are apparent, but in the chemistry and metabolism of the large molecules, the proteins, nucleic acids and some polysaccharides, researchers must at some stage reach a level of investigation where differences rather than similarities will be emphasized.

Hormones. — These substances, which may be regarded as regulators of metabolism, are investigated at three levels, to determine (1) their physiological effects, (2) their chemical structure and (3) the chemical mechanisms whereby they operate. The study of the physiological effects of hormones is properly regarded as the province of the physiologist. Such investigations obviously had to precede the more analytical chemical studies. The chemical structures of thyroxine and adrenaline are known. The chemistry of the sex and adrenal hormones, which are steroids. has also been thoroughly investigated, and the pancreatic hormone, insulin: has yielded more information about its structure than any other known protein. The structure of the pituitary hormones such as ACTH (or adrenocorticotropic hormone). was being worked out in the early 1960s. Auxin, a growth hormone of plants, is known to be indoleacetic acid.

The first and second phases of the hormone problem have thus been well though not completely explored. but the third phase is still in its infancy. It has been suggested that hormones control function by regulating the activity of various enzymes, but

this must be regarded as a working hypothesis rather than as an established fact.

Genes and Heredity.—Genetic studies have shown that the hereditary characteristics of a species are maintained and transmitted by the self-duplicating units known as genes, located in the chromosomes of the nucleus. Since the chromosomes consist of nucleoproteins, it seems likely that the genes themselves are nucleoproteins or nucleic acids. Support for such a view has been provided by the discovery of the bacterial transforming principles. These substances are nucleic acids. They possess the property of inducing certain strains of bacteria to carry out specific synthetic reactions; *e.g.,* the manufacture of a particular capsular polysaccharide. *(See* HEREDITY: *Heredity of Biochemical Characters.)* The transforming principle in this case is obtained from a strain of bacteria which themselves manufacture the polysaccharide. Furthermore. the transforming principle multiplies or reproduces itself within the cell in which it has induced the ability to form polysaccharide. The manner in which a nucleic acid duplicates itself and also induces the formation of an entirely different substance in the cell was not clear in the early 1960s. This question lies at the core of the problem of reproduction in living systems. It has been suggested that nucleic acids are in some way responsible for the synthesis of proteins and enzymes.

The relation of genes to enzymes has been shown by an entirely different type of experiment. It is possible by special techniques to obtain strains of microorganisms that differ from the parent strain in nutritional requirements. Such strains arise as a result of a mutation or change in the genetic make-up of the parent strain. A mutant bacterium may, for example, require a particular amino acid that the parent strain does not require. This does not mean that the proteins of the mutant must contain a special amino acid not present in the proteins of the normal parent. It means, rather, that the mutant has lost the ahility to synthesize the amino acid. It cannot carry out some essential step in this synthesis. presumably because there is an inhibition or loss of some one enzyme.

The development of techniques for the isolation of mutants with specific nutritional requirements led to a special procedure for studying intermediary metabolism. Suppose information is wanted about the chemical mechanism whereby an organism synthesizes a particular amino acid represented by the symbol *AA*. This compound is formed from various precursors by a sequence of chemical steps represented by the diagram.

$$\ldots \rightarrow A \rightarrow B \rightarrow C \rightarrow AA.$$

Only one of these steps is interfered with in a given mutation. When a particular step is blocked, the mutant carries out the preceding steps in the synthesis, up to the point beyond which it cannot go. Thus, a mutant blocked at the step $A \rightarrow$ B can still form compound *A,* and a mutant blocked at step B $\rightarrow$ C, can still form compound B. Under these circumstances. compound *A* may be accumulated by the first mutant, and compound B may he accumulated hy the second. The requirement. of the first mutant for AA will be satisfied by *B* or *C* also, whereas the requirement of the second mutant for *AA* will he satisfied by *C,* but not by *B.* Blocks at other stages will lead to the accumulation of other substances. One rnny obtain a family of mutants. all requiring *AA* but blocked at different stages in its synthesis. Each member of such a family will accumulate different precursors. Isolation and chemical identification of the precursors can then lead to a demonstration of the nature of the chemical reaction sequence whereby the normal strain synthesizes the amino acid. Studies of this kind gave results consistent with those obtained both by the isotope techniques and by the techniques of enzymology. The information thus obtained is of value for the understanding of the intermediary metabolism of higher animals as well as of microorganisms, because of the similarities of metabolic processes in all forms of life. *(See* METABOLIC DISEASES.)

Viruses.—The infectious agents classified as viruses lie in the borderland between the living and the nonliving. Plant. animal and bacterial viruses have been highly purified. Some have a few of the structural characteristics of organisms. Others exhibit less morphological detail. Some plant viruses have been obtained in crystalline form and appear to be made up entirely of nucleoprotein. This is the major if not the only constituent of all viruses. An isolated virus is inert in the sense that it does not multiply on any synthetic mixture of substances yet devised. Within the cells of a susceptible living organism, however, a virus can reproduce itself, using for this purpose many of the enzymatic processes that occur within the host cell. As a self-duplicating unit consisting mainly of nucleoprotein, a virus has an obvious similarity to a gene or to a transforming principle. The chemical mechanism of the reproduction of viruses is a subject of intensive biochemical study, partly with the practical object of learning how to control those that are undesirable pathogens but also with the object of acquiring more information about the essential nature of the mechanisms whereby living cells duplicate their kind *(see* VIRUSES: *Biological Properties).*

BIOGENESIS, a biological term for the theory according to which each living organism, however simple, arises by a process of budding. fission, spore formation or sexual reproduction from a parent organism. *See* BIOLOGY: *Biogenesis Versus Abiogenesis;* REPRODUCTION.

BIOGRAPHY, a narrative which seeks. consciously and artistically, to record the actions and recreate the personality of an individual life. Unlike history it deals with the individual; unlike fiction it records a life that actually has been lived. At the same tinie the biographer shares with the historian a concern for truth and he shares with the novelist the ambition to create a work of art. Thus the great biographies of the world are those which have presented their subjects as they were hut which have gone beyond the mere collection of facts to the creation of a living portrait. Biography is of perennial interest, partly because it deals with famous or notorious or interesting personalities, but more importantly because its subject matter is human nature. Hence biography as an art may legitimately deal with any individual life, no matter how humble, provided it is made the vehicle for a penetrating analysis of human passions and human motives. It is in such biographies that Samuel Johnson saw the greatest value: those "which tell not how any man became great. but how he was made happy; not how he lost the favour of his prince, but how he became discontented with himself" *(Idler,* 84).

Early Biography.—'The development of biography as an art form in western civilization may be said to begin with Plutarch *(q.v.),* but the distinction between history and biography is a modern one and it is doubtful whether any writer of antiquity, including Plutarch, clearly perceived its possible existence as an independent branch of literature. The earliest "biographical records" are royal inscriptions recording. in varying degrees of detail, a ruler's victories or other deeds *(see,* for example. BABYLONIA AND ASSYRIA: *Language and Literature).* Such records tended to be panegyric (as, for that matter. do many later biographies). The *Agricola* of Tacitus, composed near the end of the 1st century A.D., is often cited as the earliest known biography, but it might more properly be termed encomium. since it is a highly flattering account of the achievements of the author's father-in-law, Gnaeus Julius Agricola. The idea of human nature

as interesting in itself is also modern; the writing of a man's life was long considered an opportunity for celebrating certain definite moral qualities and it was in these, and not in the subject's individual characteristics, that his interest resided. For example, the chief sources for a knowledge of Socrates, the *Dialogues* of Plato and the *Memorabilia* and *Symposium* of Xenophon. while preserving much information about the personality and ideas of the philosopher, were not directed solely to biographical ends. In the gospel accounts of the life of Jesus Christ, strictly biographical details are exceedingly meagre; for a discussion of this *see* JESUS CHRIST: *Source Problem.* Even in Plutarch the emphasis was on moral instruction; nevertheless the *Parallel Lives* deserves the reputation it has long held as the earliest and one of the most successful of all attempts at biographical writing.

Plutarch's method was to narrate the life story of an eminent Greek statesman or soldier and that of an eminent Roman leader, concluding with a brief comparison of the two men. There are in the *Parallel Lives* 23 such pairs, together with 4 separate lives. making 50 biographies in all Although admittedly writing with a view to moral instruction, Plutarch attempted to distinguish between apocryphal and authentic sources, and by a skilful selection of anecdote and salient traits of behaviour generally achieved a lifelike and memorable portrait. Since Plutarch's aim was the writing of biography rather than history, he chose whenever possible the revealing anecdote, the characteristic speech, the identifying physical trait which would reveal the man. According to Plutarch in the "Life of Alexander the Great," the most outstanding actions, such as a great battle or a famous siege, are not always the clearest indications of the character of men, but matters of less importance, such as a jest or an expression, sometimes offer better evidence of men's inclinations and their tendency toward virtue or vice.

This emphasis on "the little fact" not only makes Plutarch still one of the most readable of all biographers but begins a tradition which remains in one form or another in all succeeding biographical writing with any pretense to artistic form. The most famous translation of the *Parallel Lives* into English is that of Sir Thomas North in 1579; it was made, however, not from the Greek but from the French of Jacques Amyot (1559). The translation done by several persons under the general editorship of John Dryden (1683–86) was popular in the early 18th century; revised by Arthur Hugh Clough in 1864, it continues to be read Another well-known translation was that of John and William Langhorne (1770); a modern translation is that of Bernadotte Perrin in the Loeb Classical library (1914–26). Besides these there have been numerous abridgments and such imitations as Thomas Mortimer's *British Plutarch* (1762) and *The Revolutionary Plutarch* (1804) testify to the abiding influence of the *Parallel Lives*.

The ethical preoccupation of Plutarch, his interest in "discoveries of virtue or vice in men," is the dominant mark of biographical writing in the centuries which follow—in the very popular saints' lives of the middle ages, in Giovanni Boccaccio's *De casibus virorum illustrium,* and in such works as the *Monk's Tale* of Chaucer. John Lydgate's *The Fall of Princes* and the influential *Mirror for Magistrates* (1559), where "as in a looking glass you shall see if any vice be in you, how the like hath been punished in others, and whereby admonished." The work of the early English historians and chroniclers, nhich occasionally contains brief biographical sketches, is coloured by the same desire to point a moral. John Stow, for example, in writing his *The Chronicles of England* (1580) purposes "to celebrate the worthy exploits of our Kings and Governors," but he regards himself not merely as a historian "It is as hard a matter for the recorder of chronicles, in my fancy, to pass without some colours of wisdom, invitements to virtue, and loathing of naughty facts, as it is for a well favoured man to walk up and down in the hot parching sun and not to be therewith sunburned."

The 16th Century. — Three early examples of biographical writing may be singled out as approaching the art of biography in the modern sense of the word. Although they are marked by a strong ethical purpose and are far from any avowed attempt at impartial portraiture, they may be said to rise above mere factual compilation and to produce in a limited degree a deliberately artistic effect. The first of these, the *History of Richard III,* first published in 1543, was found among the papers of Sir Thomas More (1478–1535) after his execution and has been ascribed to both More and John Cardinal Morton. Whoever was the author, the biographical sketch gives a vivid and damning portrait of the enigmatic king and is written with considerable sense of style, though painted in colours too black to be entirely convincing or artistically effective. Of greater interest is the charming sketch of More himself written by his son-in-law William Roper (1496–1578), which while presenting an undeniably biased picture of the great chancellor is written with sympathy, vividness and obvious sincerity. It may he said to be the first biography in English written of a great man by one who knew him closely and admired him. It had to wait almost 100 years for publication (1626) but it circulated in manuscript during the 16th century. The third 16th-century biography was likewise circulated in manuscript long before it could be published. This is the *Life of Cardinal Wolsey,* written during the reign of Queen Mary by George Cavendish (1500–61), who had been gentleman-usher to Thomas Cardinal Wolsey and who had witnessed both the splendour and the tragic downfall of Wolsey's career. The theme is that of retribution descending upon the haughty cardinal: "If I had served God as diligently as I have the King, He would not have given me over in my grey hairs." The ethical intention is central to the whole work but Cavendish is objective enough to point out both the cardinal's virtues and his faults, so that in effect this early biography succeeds in conveying both the larger moral theme and a Iifelike and dramatic impression of Wolsey's personality and his tragic end. The moving account of Wolsey's last years and downfall is sufficient alone to place this work among the best of early biographies.

The 17th Century. — The 17th century witnessed a tremendous outpouring of historical writing, memoirs, diaries, "characters" and essays, all of which have an obvious bearing upon the development of biography. On the one hand they bear witness to the expression of a fundamental interest—the desire to know human nature. the springs of human action, the relative functions of self-love and benevolence as motivating factors in the human personality. Such diverse writings as the essays of Francis Bacon. the *Leviathan* of Thomas Hobbes (1651), François de la Rochefoucauld's *Maximes* (trans. 1694) and *Les Caractères* of Jean de la Bruyère (trans. 1699) share to a large extent in this "psychological'! point of view, and the same curiosity as to human nature can be observed in the otherwise ponderous French romances of Gautier de la Calpreni.de and others, in the comedies of Molière and in the plays and satirical writings of Dryden. On the other hand, it is true that these genres, rather than pure biography, provided the means of expression for such interest and hence served in a sense to divert the full development of biographical writing. The "character," for instance, modeled originally upon the examples of Theophrastus, developed in the 17th century into a fairly popular mode of analysis of human nature. The subjects—whether men dominated by a single vice or virtue' such as the covetous man; or conventional social types, such as the shopkeeper or milkmaid; or even places and scenes, such as the tavern—lent themselves to brief. unified prose analyses peculiarly satisfying to an age interested in human nature and sharply divided on certain great political and theological issues. The brief biographies of his contemporaries which adorn the great *History* composed by Edward Hyde, earl of Clarendon, are masterly but they show the extent to which the formal "character" had invaded the province of biographical writing. S'aluable biographical sketches are to be found also in the histories produced in the American colonies at this time—notably in William Bradford's *Of Plimouth Plantation* (written 1630–50 but not published until 1856), in Nathaniel Morton's adaptation of this under the title. *New England's Memorial* (1669), and in Capt. Edward Johnson's *Wonder-Working Providence of Sions Saviour in* Sew *England* (1654)—but these are of interest mainly for the information which they give of colonial worthies.

Walton's "Brief Lives"—The most famous series of biographies composed in the 17th century are undoubtedly the "brief lives" written by Izaak Walton (*q.v.*). Though some of the lives—

notably those of John Donne and George Herbert—may be said to belong to the earlier class of encomiums rather than strict biography, Walton is obviously concerned not so much with facts and dates as with building up a unified impression of his subject, and in this he succeeded admirably. In writing the life of Donne, Walton had relatively few resources. He had known Donne only for the last eight years of Donne's life. But he had heard Donne speak, and refers in more than one place to the great eloquence of the sermons; he supplemented this with anecdotes from men such as John Chudleigh and Bishop Thomas Morton, who had known Donne; he utilized Donne's own writings; and, most important of all, he made use of Donne's letters—unfortunately in a somewhat reckless manner, according to modern standards, but the tradition of laying correspondence under contribution for biography can nevertheless be seen in Walton. Apart from its value as a factual biography—and later research has been able to correct Walton on a number of points—*The Life of John Donne* in its emphasis upon the scholar and the preacher succeeds in creating for the reader a unified and living character. Walton has been criticized for inaccuracy of fact and lack of objectivity but his series of biographies continues to be reprinted and read. Part of their charm resides in the author's extreme modesty, approaching naïveté, in the artlessness of his style and in the transparent sincerity and sympathy for his subject.

Other Biographies.—Among other great biographies of the 17th century a high place must be accorded to the learned and engaging Margaret Lucas, duchess of Newcastle (1624?–74), for her delightful biography of her husband William Cavendish, the first duke. *The Life of William Cavendishe, Duke of Newcastle* (1667) seems fulsome and awkwardly naïve—but only by present-day standards; in the devotion with which she portrays her husband and in the vivid picture which she gives of a royalist household of the 17th century she achieves a biographical masterpiece which has delighted readers from that day to this. A valuable companion piece, on the Puritan side, is *Memoirs of the Life of Colonel Hutchinson,* a biography of John Hutchinson written by his wife for their children and not printed until 1806. With a loyalty equal to that of Lady Newcastle, Lucy Hutchinson gives a sincere and truthful picture of her husband, of his relations with other parliamentary leaders and especially of his example to those who regard the Puritans as "an illiterate, morose, melancholy, discontented, crazed sort of men." Among other biographical writings of the century which may still be read with pleasure is the touching *The Life of Mrs. Godolphin,* written by her friend John Evelyn (*q.v.*) the diarist.

Thomas Sprat and Literary Biography.—An interesting example of the 17th-century attitude toward biography is provided by Thomas Sprat, who has the distinction of being the first to attempt the biography of a great literary figure considered solely as a man of letters. In his "An Account of the Life and Writings of Mr. Abraham Cowley," prefixed to the 1668 edition of Cowley's *Works,* Sprat not only recounts the biographical facts of "this excellent man," but also attempts a portrayal of the poet's personality and character and an assessment of his literary work, showing throughout the influences which turned him to writing and the significance of his important productions. In this threefold approach toward the life, the personality and the literary works Sprat interestingly foreshadows the method to be employed later so successfully by Samuel Johnson. Sprat, however, took a solemn view of his subject and destroyed the correspondence of Cowley. Although in his letters Cowley "always express'd the Native tenderness and Innocent gayety of his Mind," such intimate glimpses of the great, Sprat thought, "can scarce ever be fit to see the light." It remained for a later age to recognize the inestimable value of such letters, journals and other private materials.

Biographical Collections.—In one other department of biographical writing the 17th century was to prove a pioneer—the formation of biographical collections. Although John Leland and John Bale had paved the way in the preceding century in compiling lives and lists of writings of the most famous writers in Great Britain, their work was mainly bibliographical and antiquarian and was devoted chiefly to preserving from oblivion the records of manuscripts and books in monastic and private libraries. In the 17th century there was a conscious effort to compile for posterity biographies of great men which would be something more than a mere factual account of their deeds and writings. Of particular importance are the *The Church-History of Britain* (1655) of Thomas Fuller (1608–61), which contains a number of excellent character sketches, and especially his *The History of the Worthies of England* (1662), an interesting forerunner of the *Dictionary of National Biography.* Fuller arranged his "worthies" by counties and interspersed a great deal of nonbiographical material, but the result is a panorama of notable persons which reveals such extraordinary interest in psychological oddities and in biographical detail as to make the collection of absorbing value. "I have purposely interlaced," wrote Fuller, "(not as meat, but as condiment) many delightful stories, that so the reader, if he do not arise, which I hope and desire, *religiosior* or *doctior,* with more piety or learning, at least he may depart *jocundior,* with more pleasure and lawful delight." The *Magnalia Christi Americana* of Cotton Mather (1702) may be regarded as a colonial counterpart of Fuller. In this large compendium Mather records the lives and services of several of the governors of the colonies and of about 60 clergymen of the new world. The biographical sketches are largely factual and well seasoned with eulogy but nevertheless remain a valuable record for posterity. The same resistless urge for recording biographical information and a curiosity for out-of-the-way facts may be seen in the notebooks compiled by John Aubrey (*q.v.*), the antiquary and folklorist, which contain materials for more than 100 biographies of his contemporaries based on observation, on gossip, on all indeed which it seems Aubrey could contrive to collect. His materials were not published until the 19th century and he cannot be termed a biographer in the strict sense of the word. He was credulous and did not exert any consciously critical concern for artistic composition. Nevertheless, in his zeal for acquiring information and above all in his eye for the picturesque and the revealing detail, Aubrey shows more than pedestrian industry and points the way toward a conception of biography which later generations were to find congenial. Some of his materials were utilized by Anthony à Wood (1632–95) in the great biographical collection published at Oxford in 1691–92 as *Athenae Oxonienses: an Exact History of All the Writers and Bishops Who Have Had Their Education in the University of Oxford From 1500 to 1690,* a work of great value and the forerunner of many similar compilations.

The 18th Century.—The great impetus to such biographical collections in the 18th century, however, came from the famous *Dictionnaire historique et critique* (1695–97) of Pierre Bayle, which was translated into English as early as 1710 and inspired a number of similar collections, including the important *A General Dictionary, Historical and Critical* (1734–41) prepared by Thomas Birch. The outstanding example is the *Biographia Britannica* (1747–60), of which 22 articles were contributed by William Oldys. A second edition (1778–93), under the editorship of Andrew Kippis, reached only the letter *F.* This work, a kind of omnium-gatherum, collecting together all the information about "such of our countrymen as have been eminent" and attempting to reconcile the diverse facts about them "in obedience to the laws which reason and the practice of the best authors have established," illustrates the difficulty of compiling a dictionary of national biography; it cannot be said to have furthered the art of biography. A few of the more specialized biographical dictionaries, of which there were so many in the 18th century, may be cited: in the field of literature, Giles Jacob's *The Poetical Register* (1719–20), *The Lives of the Poets of Great Britain and Ireland* (1753), written mainly by Robert Shiels and published under the name of Theophilus Cibber, Horace Walpole's *A Catalogue of the Royal and Noble Authors of England, Scotland, and Ireland* (1758), John Berkenhout's *Biographia literaria* (1777) and David Rivers' *Literary Memoirs of Living Authors of Great Britain* (1798); for the clergy, Edmund Calamy's *An Abridgement of Mr. Baxter's History of His Life and Times* (1702), Nathaniel Salmon's *The Lives of the English Bishops From the Restauration to the Revolution* (1731–33), Richard Rolt's *Lives of the Principal Reformers* (1759) and Erasmus Middleton's *Biographia evangelica* (1779–

86); for naval figures, John Campbell's The Lives of *the* British Admirals (1742–44) and John Charnock's Biographia *navalis* (1794–98); for scientists. John Ward's The Lives of the Professors of Gresham College (1740). John Aikin's Biographical Memoirs of Medicine in Great Britain (1780) and Benjamin Hutchinson's Biographia *medica* (1789); and, in a category of its own, George Ballard's Memoirs of Several Ladies of Great Britain, *Who* Have Been Celebrated for Their Writings or Skill *in* the Learned Languages, Arts, and Sciences (1752). Similar collections did not become frequent in the U.S. until the 19th century, although the series by Jeremy Belknap, American *Biography,* dates from 1794 to 1798. The best-known collection is the Library of American Biography (25 vol., 1834–48), planned and supervised by Jared Sparks, later president of Harvard college. The 60 lives in this series, several of which were done by Sparks himself, are all somewhat formal and designed to edify.

These collections are significant of a growing interest in biography but the uneven materials which they contain show little awareness of biography as a work of art. The 18th century inherited the concern of the preceding century for psychological inquiry and investigations into the nature of man. Daniel Defoe was able to demonstrate how this interest could be combined into narratives which were in part biography and in part fiction, and the creation of the modern novel in the hands of Samuel Richardson and Henry Fielding developed one line of this interest.

North and Johnson.—In the field of biography proper the first great 18th-century name is that of Roger North (*q.v.*), who in the lives of his brothers Francis, Dudley and John North (published in 1742 and 1744) shows an awareness of the interplay of human personality with the worlds of politics, law and learning which makes the series of biographies one of the most vivid and enjoyable of all time. The next major figure is Samuel Johnson. whose theory of biography as a genre, which may not only convey instruction but "enchain the heart," is illustrated in his own work. Particularly important are The Lives of the English Poets (1779–81), in which he brings to bear his ripest critical judgment and succeeds in presenting sympathetic and acute portrayals which are of permanent value, and an earlier and justly well-known work, An Account of the Life of Mr. Richard Savage (1744).

Boswell's Life of Johnson.—Johnson himself is the subject of what has generally been regarded as the supreme achievement in biography, the Life of Samuel Johnson by James Boswell (*q.v.*), published in 1791. The two first met in 1763, when Johnson was already 54, and Boswell spared no pains in documenting himself with all the helps he could muster, through taking notes on the great man's conversation, acquiring and preserving all the correspondence he could find and interviewing all of Johnson's friends who could give information, in order to produce a full and honest record of a life. Although he was not the first to utilize letters as a basis for biography—William Mason had adopted the same practice in 1775 in the "Memoirs" prefixed to the Poems of Gray—Boswell made such extensive use of correspondence that thenceforward every biographer has realized the immense importance of this procedure as an aid to lifelike portraiture. Through this method, and above all through his skilful use of reported conversation, Boswell was able to give an unparalleled effect of actuality and lifelikeness to his portrayal of Johnson. Although the fuller treatment of the last years of Johnson's life makes the work unbalanced, Boswell's untiring industry, his wholehearted sympathy with his subject and the art employed in weaving together his materials produced a work that was completely successful in presenting its subject "as he really was." The discovery in the 20th century of successive portions of Boswell's materials only served to confirm the judgment of earlier readers that the Life of Samuel Johnson is the greatest of all biographies.

The 19th Century.—Boswell's method continued to be practised in the best of the 19th-century biographies—the Letters and Journals of Lord Byron by Thomas Moore (1830), J. G. Lockhart's Memoirs of the Life of Sir Walter Scott (1837–38) and Sir George Trevelyan's The Life and Letters of Lord *Macaulay* (1876). In each of these personal knowledge, great sympathy and an intelligent handling of materials combined to produce creative works of art. A high place must also be accorded to the biographies of Lord Nelson (1813) and John Wesley (1820) by Robert Southey, The Life of Schiller (1825) and the Life of *John* Sterling (1851) by Thomas Carlyle, and Elizabeth Gaskell's The Life of Charlotte *Brontë* (1557). Although the series of critical essays contributed by Lord Macaulay to the Edinburgh Review and later to the Encyclopedia *Britannica* are not solely biographical in form. the vivid presentation and remarkable rhetorical gifts apparent in such essays as those on John Bunyan (1830) and Warren Hastings (1841) reveal Macaulay as a master of the creative gift necessary to the achievement of convincing biography.

In too many 19th-century biographies, however, Victorian ideas of propriety and decorum were allowed to colour the presentation of material so that, even in so good a biography as **A. P.** Stanley's The Life and Correspondence of Thomas Arnold (1844), the reader is left with an impression of moral stature rather than of vitality. The doctrine of "nothing but the good" is as fatal to the art of biography as to that of history. Subsequent research has shown how deceptively facts may be suppressed or actions misinterpreted or the texts of letters silently altered in order to convey one kind of truth but not the whole truth, as in John Forster's impressive Life of Charles Dickens (1872–74) or J. W. Cross's biography of George Eliot (1885). The same uncritical methods may be seen to a very large degree in the works of two mid-century biographers, Agnes Strickland's Lives of the Queens of England and Lives of *the* Queens of Scotland and *English* Princesses . . . (1840–59) and Lord Campbell's The Lives of *the* Lord *Chancellors* . . . (1845–47) and The Lives of the Chief Justices of England (1849–57), in which readability, however, compensated sufficiently to ensure them a measure of popularity. In the United States the chief representatives of the same type would be Washington Irving. whose biographies of Christopher Columbus (1828), Oliver Goldsmith (1849), Mohammed and his successors (1849–50) and Washington (1855–59) were long popular, and James Fenimore Cooper, whose Lives of Distinguished American Naval *Officers* (1846) exhibits some of the narrative gifts which the author displayed in his historical novels.

Frequently the Victorian ideal of biography tended to become that of a "life-and-times" work, in which the biographer's desire to place his subject in the full context of his surroundings allowed the background to assume an ever larger place until the personality of the subject was almost lost sight of. The result. as in Thomas Carlyle's studies of Oliver Cromwell (1845) and Frederick the Great (1858–65), proves to be a massive, undeniably erudite combination of history and biography. The outstanding example of this unfortunate development may be seen in the extraordinary work of David Masson. *The* Life of John Milton: *Narrated* in *Connexion* With *the* Political, Ecclesiastical and Literary *History* of His Time (1859–94), the excessive length and prolixity of which provoked James Russell Lowell's sigh, "We long for the secular leisure of Methusaleh." Many of the "standard" biographies produced in the latter half of the 19th century, and even later, succeed better in presenting all that is known of the subject and his background than in conveying a convincing and lifelike portrait. The biographies of Jonathan Swift (1882) by Sir Henry Craik and of Richard Steele (1889) by G. A. Aitken are still. for example, indispensable for the amount of information which they contain, but their heavily documented and massively erudite approach prompted more than one succeeding biographer to attempt a more concentrated and lively presentation of the human personalities of Swift and Steele. Two important political biographies which in large part successfully resisted the temptation to allow background to obscure the subject of the biography were Viscount Morley's The Life *of* William *Ewart Gladstone* (1903) and the biography of Abraham Lincoln (1890) by John Hay and John G. Nicolay. Other important biographies produced in the U.S. in the 19th century include the Life and Times of Aaron *Burr* (1857), perhaps the best of the numerous works done by James Parton; the Life *of* Albert *Gallatin* (1879) by Henry Adams; Moncure D. Conway's Life of Thomas Paine (1892): and two presidential biographies. The True George Washington (1896) by Paul Leicester Ford and Ida M. Tarbell's Abraham Lincoln (1900).

Another of the biographical landmarks of the late 19th century was the *Dictionary of National Biography,* sponsored by the publisher George M. Smith and edited by Sir Leslie Stephen and later by Sir Sidney Lee; it attempted to include all noteworthy figures from the earliest times (exclusive of living persons). The first volume appeared in 1882; the set as originally projected was completed in 1901 and has been kept up to date by successive supplements. A work similar in scope and plan is the *Dictionary of American Biography,* 20 volumes (1928–37; with supplements), published under the sponsorship of the American Society of Learned Societies and edited by Allen Johnson and Dumas Malone. There are similar works in several European countries.

The 20th Century.—Biographical writing in the 20th century reacted somewhat violently both to the tone of Victorian panegyric and to the academic life-and-times accounts so popular in the preceding century. Signs of the approaching change were discernible in the work of James Anthony Froude, whose biography of Carlyle (1882–84), with its detached and even satiric spirit, excited controversy when it appeared. Froude's vivid and unacademic approach may be seen also in his *Life and Letters of Erasmus* (1893–94). In the U.S. Gamaliel Bradford (1863–1932) cultivated a new kind of biography—or "psychography" as he preferred to call it—which sought to portray the essential "inner soul" of the subject by a skilful selection of important and interesting traits, much in the manner of the 19th century French critic, Sainte-Beuve. *Lee the American* (1912) was the first of a series of successful "psychographs," which included *Portraits of Women* (1916) and *Damaged Souls* (1923), among others. More generally, the revolt against Victorian moral ideals, particularly in the period following World War I, affected the biographer's point of view; and the investigations made by Sigmund Freud and others into the realm of the subconscious inevitably opened a large field of inquiry which could not be ignored by the biographer. The "new biography" in consequence was often the record of the inner life, the revelation of previously unsuspected aspects of character—and sometimes the discovery of feet of clay. In form it tended to be, if not streamlined, at least written with brevity in a style marked, sometimes self-consciously, by wit and irony. The influence of Freud is observable in the two epoch-making works of Van Wyck Brooks. *The Ordeal of Mark Twain* (1920) and *The Pilgrimage of Henry James* (1925), as well as in much of the work of Katharine Anthony, beginning with her *Margaret Fuller* (1920). Examples of the sensational and "debunking" biography, as it was called at the time, may be seen in the lives of Washington by William E. Woodward (1926) and Rupert Hughes (1926–30) as well as in *Lincoln the Man* (1931) by Edgar Lee Masters.

Lytton Strachey.—The greatest share of the credit for opening the new era of biographical writing at the close of World War I goes, however, to Lytton Strachey (q v.), whose first important biographical work—short sketches of Henry Edward Cardinal Manning, Florence Nightingale, Thomas Arnold and Gen. C. G. Gordon—appeared in 1918 under the title *Eminent Victorians.* In the preface Strachey enunciated the twofold principle of selection and scrutiny which was to mark all his work. In place of the life-and-letters volumes of Victorian biography, with their great masses of material and "lamentable lack of selection," Strachey proposed "a brevity which excludes every thing that is redundant and nothing that is significant." His richly ornamented style, with its rhetorical pauses and rhetorical questions, its liberal sprinkling of anecdotes, its exploitation of contrast, is perhaps seen at its best in the biography of Cardinal Manning and at fuller length in *Queen Victoria* (1921), which was awarded the James Tait Black prize for biography. *Elizabeth and Essex: a Tragic History* (1928) is less successful and exhibits more of Strachey's mannerisms without the unity of tone which marked the earlier work. In his conscious striving for artistic effects and his very elaborate style Strachey did more than any other person to set the tone of the new biography, and his influence can be seen in the work of many lesser writers who adopted his irreverent attitude toward the past and attempted to imitate his style.

Problems and Purposes of the Biographer.—The yearly publishers' lists demonstrate the popularity of biographical writing but the really great biography is most difficult of achievement. Sometimes the reason lies in the scantiness of records, as in the case of Shakespeare, but more often in a failure to master the wealth of material. If the biographer has new documents which he has uncovered his path is relatively easy and his work, like Gordon S. Haight's *George Eliot and John Chapman* (1940), may revolutionize the subject. Often, however, he is coping with masses of material already well known, and he may find himself in the end as helplessly swamped as the scholar in the preface to Anatole France's *Penguin Island.* Strachey went so far as to say. in the introduction to *Eminent Victorians,* that the history of the Victorian age would never be written—because we know too much about it. "For ignorance is the first requisite of the historian—ignorance, which simplifies and clarifies, which selects and omits, with a placid perfection unattainable by the highest art." It is clear that the highest requisite in the biographer, whatever his material and whatever his motive in writing—whether to justify or defend his subject, to hold up a certain ideal of conduct, to apply a new psychological approach or to present simply a biographical novel—is the equipment which he himself brings to his task. In the first place he must have some sympathy for his subject. "To know the poet you must love him," wrote William Wordsworth, and this holds true for the biographer. Second, there must be absolute sincerity. If the biographer tampers with the facts, if he omits the unpleasant, if he colours or distorts in either direction, he completely fails. Panegyric was the first motive to biography and the panegyrical note, surviving in so many biographies of the 19th century, produced works differing little from the funeral sermon in their twofold aim of perpetuating the memory of the deceased and inculcating virtue by example. This is the reason why Abraham Lincoln refused to read them. "Biographies as generally written." he once remarked to his law partner William Herndon, "are not only misleading, but false." The biographer "makes a wonderful hero out of his subject. He magnifies his perfections—if he had any—and suppresses his imperfections." Such biographies, he concluded, "commemorate a lie, and cheat posterity out of the truth. History is not history unless it is the truth." In modern times, partly because of the example of Lytton Strachey, the aim of the biographer may fairly be said to be that of representing the whole man, "nothing extenuate nor set down aught in malice," and thus to revert to the aim of the greatest of all biographers, James Boswell, who could say confidently of his subject: "And he will be seen as he really was; for I profess to write, not his panegyrick, which must be all praise, but his Life; which, great and good as he was, must not be supposed to be entirely perfect. To be as he was, is indeed subject of panegyrick enough to any man in this state of being; but in every picture there should be shade as well as light, and when I delineate him without reserve, I do what he himself recommended, both by his precept and his example." (Boswell's *Life of Dr. Johnson,* ed. by G. Birkbeck Hill and L. F. Powell, vol, i, p. 30, Clarendon Press, Oxford, 1934.)

This ideal, which André Maurois, one of the most distinguished 20th century biographers, defined as, on the one hand, the bold seeking after truth and, on the other, the concern for the complexity of human personality, is abundantly illustrated by the best of contemporary biographical writing. Beginning with *Ariel,* ou *la vie de Shelley* (1923) and continuing with a series which includes lives of Disraeli (1927), Byron (1930), Chateaubriand (1938), George Sand (1952), Dumas the Elder (1954) and Victor Hugo (1955), Maurois himself demonstrated that biography may be made as entertaining as a novel without departing from the search for truth and verisimilitude. Among other examples of distinguished work in the 20th century may be cited *Palmerston* (1926) and *The Duke* (1931) of Philip Guedalla; the series of volumes on Lincoln by Carl Sandburg *(The Prairie Years,* two volumes [1926]; *The War Years,* four volumes, [1939]); Lord David Cecil's study of Cowper *(The Stricken Deer,* 1929); *Tennyson* (1923), *Byron* (1924), *Swinburne* (1926), *Curzon* (1934), *Benjamin Constant* (1949), and *King George the Fifth* (1952) by Sir Harold Nicolson; *Lincoln, the President* by James G. Randall, four volumes (1945–55); *George Washington: a Biography,* by Douglas Southall Freeman, six volumes (1948–54); the *Life of Neville*

Chamberlain (1946) by Keith Feiling; *Florence Nightingale, 1820–1910* (1950) by Cecil Woodham-Smith; *Hugh Walpole* (1952) by Rupert Hart-Davis; *Les Frères Goncourt* (1955) by André Billy; Emil Staiger's *Goethe,* three volume? (completed in 1959); James Pope-Hennessy's *Queen Mary, 1867–1953* (1959); Richard Ellmann's *James Joyce* (1959); and Hannah Arendt's *Rahel Varnhagen (1959).*

Thayer, *The Art of Biography* (1920); André Maurois, *Aspects de la biographie* (1928), Eng. trans. by S. C. Roberts (1029); Harold Nicolson, *The Development of English Biography* (1928); Edgar Johnson, *One Mighty Torrent: the Drama of Biography* (1937); Donald A. Stauffer, *The Art of Biography in Eighteenth Century England,* 2 vol. (1941); Dana K. Merrill, *American Biography: its Theory and Practice* (1957).

Indexes: Bea Joseph and Charlotte W. Squires (eds.), *Biography Index: a Cumulative Index to Biographical Material in Books and Magazines, Jan. 1946–July 1949,* published since 1949 and covering publications since 1946, is a comprehensive guide to books in English and biographical articles in a large number of periodicals, both scholarly and popular. For earlier publications, *see* Helen Hefling and Eva Richards, *Index to Contemporary Biography and Criticism,* rev. ed. (1934); Phyllis M. Riches (comp.), *An Analytical Bibliography of Universal Collected Biography* (1934); Marion Dargan, *Guide to American Biography,* rev. ed., 2 vol. (1949–52).

Biographical Directories: For information about living persons see such biographical directories as *Who's Who* (1849–), published annually in Great Britain, and *Who's Who in America* (1899–), revised and reissued biennially in the U.S. These and similar publications, which have proliferated in the 20th century, have no connection with biography as literature but are useful sources of factual information. Specialized directories, such as *Who Knows—and What,* are also useful. A guide to all such publications (and to other biographical sources as well) is Constance M. Winchell's *Guide to Reference Books,* 7th ed. (1951) and supplements. (D. F. B.)

BIOLOGICAL CHEMISTRY: *see* BIOCHEMISTRY.

BIOLOGICAL WARFARE. The military definition of biological warfare is the intentional use of agents for the purpose of producing disease or death in man. animals or crops. and defense against the use of these materials for such purposes. It is essentially public health and preventive medicine in reverse and. except for novel means of deliberately disseminating pathogenic microorganisms. is a form of warfare which nature has waged against man for thousands of years and against which man's modern health practices have produced effective defenses.

Biological warfare—often referred to as germ warfare, bacteriological warfare or BW—represents an attempt by man to examine and control the forces of nature for military use. Unlike the atomic bomb or other blast-effect weapons, biological warfare is essentially antipersonnel in nature, since it does not destroy buildings and machines but is directed at man himself or his food supply.

Weapons of the biological variety are different from other kinds of weapons in that their results are generally delayed over a longer period of time. and it is difficult to determine whether an outbreak of disease among men, animals or plants is the work of nature or of man. For this reason, one cannot say with certainty that a nation has resorted to biological warfare unless documentary or material proof of such use can be obtained, and, because of its very nature. material proof is hard to establish.

Biological warfare has two main divisions. The first includes attacks with "living agents"—different kinds of small living things which may cause sickness or disease in people, animals or plants; these may include disease-bearing or plant-killing insects, bacteria, viruses and fungi. The second type comprises attacks with special kinds of chemicals known as hormones. Called "growth regulators," the best known are those used to kill weeds and other unwanted plants.

Some observers have described biological warfare as an absolute weapon, capable of disabling or destroying the entire population of large cities either directly or by the initiation of self-perpetuating disease epidemics. Other persons have rejected this view and insisted that BW is not even a practical weapon and that it presents no dangers.

The truth probably lies between these two extremes.

It must be assumed that a nation with a reasonably modern scientific program can produce effective agents in adequate quantities. In delivering such agents to the target, either through undercover or open methods, the using nation might (1) attempt to incapacitate a limited number of selected individuals in order to delay military or industrial mobilization and production before the occurrence of open warfare; (2) use biological agents as a part of a general attack in connection with explosives or atomic munitions; or (3) use biological warfare in order to lower efficiency. productivity and morale.

Prevention of an open attack with biological weapons is a military problem, but prevention of sabotage requires constant vigilance by civil agencies. Agents capable of being used or developed for biological warfare may be imported surreptitiously or they may be manufactured within the "target nation" clandestinely. Since biological agents are ideal for covert use, an alert public health system is the keystone to a nation's defense against this type of warfare.

Historical Attacks.—The concept of biological warfare is nut new. for war and germs are no strangers to each other. Even with no help from man, germs have entered practically every major military campaign, and more than once germs rather than generals have decided the outcome of a conflict. Plague cut down the crusaders at the gates of Jerusalem. Typhus riddled the Moors in Spain, and dysentery thinned the ranks oi Napoleon's Grand Armée as it moved toward Moscow. During the Boer War, typhoid fever laid low more soldiers than bullets did. There were many deaths from tainted beef during the Spanish-.American War. and influenza hit military and civilian forces alike during World War I's closing years of 1917–18. In the early days of World War II. malaria and scrub typhus attacked the Allied forces in the South Pacific. These were natural attacks. presumably the accidents of war.

The deliberate employment of germs also has a history of its own. Biological warfare has been recognized and tried since time immemorial. There are enough recorded minor instances of its use to indicate that man has long perceived its value as a weapon. For biological warfare, in a certain sense, can be considered to be aiding nature in the spread of disease and germs. and methods of accomplishing this were available long before the nature of disease and the existence of microorganisms were known.

In ancient times the bodies of cholera and plague victims were dropped over the walls of beleaguered cities. left on ground the enemy was expected to occupy or used to poison water points. Napoleon deliberately flooded the ground near the besieged city of Mantua, in the hope that malaria would weaken the Italians' will to resist. Blankets were contaminated by traders and distributed among American Indians in order to reduce their fighting strength through smallpox epidemics.

These uses of biological warfare in its crudest forms served the purpose of weakening an enemy by decimation of his manpower through means other than actual conflict. Just as in chemical warfare. Germany was one of the first exponents of biological warfare in the modern sense. During World War I. the Germans infected with glanders, an epizootic disease, horses of the Rumanian cavalry and livestock in the United States that were intended for shipment to the Allies in Europe.

The Japanese were alleged to have employed biological warfare against the Chinese during World War II. but these allegations were never substantiated.

In March 1952, during the Korean war. the Chinese communists accused the United Nations, specifically the United States forces, of employing biological warfare against North Korean and Chinese communist forces. These charges were the basis for a propaganda campaign that included protests by the North Korean and Chinese communist foreign ministers, mass "protest" meetings in the Soviet Union and communist China and denunciation by the communist-controlled World Peace council. The United States secretary of state denied the charges. Similar denials were made by the secretary-general of the United Nations, the commander in chief of the UN forces and the U.S. secretary of defense. The U.S. secretary of state challenged the communists to submit their

charges to an investigation by the International Committee of the Red Cross to determine the facts. Refusal of the Chinese and North Korean authorities to permit an investigation by the International Red Cross, together with the categorical denials of the charges by responsible United Nations and United States officials, branded the charges as false.

Types of Agents.—A disease agent must embrace certain characteristics to be an effective biological weapon. It should (1) have a high infectiveness: (2) have a high degree of resistance to such destructive forces of nature as heat. sunlight and drying; (3) be adaptable to rapid dissemination; (4) have the ability to cause high initial mortality or lasting debilitating effects against intended victims, whether man, animals or plants; and (5) be an agent foreign to that particular part of the world against which it is directed so that natural immunity has not been built up against it.

The kinds of germs which might be used in biological warfare attack would depend upon what the user hoped to obtain from its use. If killing large numbers of people was desired, plague, typhus, cholera, smallpox or some similar disease might be used. But if the attacker wanted only sickness, rather than death, diseases such as rabbit fever (tularemia) or undulant fever (brucellosis) (*qq.v.*) could be used. This would not only cripple both fighting and productive forces but would also tie up doctors and hospitals.

Any agent which causes high mortality or morbidity rates and meets the above five requirements might be used against man. These pathogenic agents could he disseminated by a variety of mediums which would cause contamination through bodily contact, air, food or water. The means of dissemination could he aerosol release into ventilation systems; airplane- or free-balloon-dropped bombs or aerosols; and possibly other undetermined means.

In such situations, the majority of biological warfare victims would he those whom the biological agent reached directly. Secondary cases. caused by direct spread of infectious diseases from primary cases to other persons, could occur with the use of some agents. but the greatest danger in biological warfare attack would he to those initially exposed persons.

There are also many diseases that could be used to attack different kinds of animals upon which man depends for both food and clothing. Swine are especially subject to hog cholera. Fowl pest and Newcastle disease might be used against poultry. Rinderpest, sometimes called Asiatic cattle plague, might be aimed especially at cattle or sheep. Foot-and-mouth disease, glanders and anthrax, or woolsorters' disease, could cause untold damage among livestock.

Since meat, dairy and poultry products are important sources of food for both civilians and military personnel, they must be considered as prime potential targets. Other animal products, such as wool and leather, play an important part in maintaining human health. In addition, the production of many biologicals and pharmaceuticals such as adrenalin, liver extract and insulin are entirely dependent upon an adequate supply of glands, organs and secretions from healthy animals.

Many kinds of plant plagues, blights and pests could be used to attnck food crops. Diseases could damage grain and fruit; while specially prepared chemicals might also be used in raids on growing crops. Any insect pests or plant diseases that are present in one part of the world but not in another constitute a threat to the food supplies and economic resources in the latter areas. Some, such as the Japanese beetle, European corn borer, Mediterranean fruit fly, boll weevil, citrus cancer and wheat rust either cause extensive losses or are expensive to control or eradicate even in their native habitats.

The danger is intensified by the fact that the most effective method of keeping down losses from known or native plant disease is often the development of new strains which are resistant to specific diseases. Successful introduction of new organisms to which crop varieties are not resistant could therefore cause a great deal of damage.

Protective Aspects.—The best protection against. the threat of biological warfare is an informed populace and alert. vigorous public health and agricultural organizations. Basically, protection mould consist of detection, immunization, quarantine and inspection in the preventive stage. and individual masks, protective clothing and decontamination during and after an attack or suspected attack.

Although disease can spread quickly, most outbreaks move quite slowly. The plague that swept over London in the 17th century began with a few cases in the autumn of 1664 and took six months to cross from one side of the city to the other. The peak of the epidemic did not come until Sept. 1665. While almost 70,000 people died of the plague, it was not a lightning-quick disaster from which there was no escape. With modern public health organizations the London outbreak could have been stamped out with little or no loss of life.

Nations have come to realize the value of co-ordinated effort in the prevention of epidemics, not only among people but in crops and livestock as well. When a man with smallpox mingled with New York city's crowds for several days in 1947, more than 6,350,000 people living in the area were immediately vaccinated. Only 12 other cases of smallpox resulted. In 1946 Mexican cattle became infected with foot-and-mouth disease. To stamp out the epidemic and prevent it from spreading into the United States, Mexican officials co-operated in the wholesale destruction of infected cattle.

One difficult problem in defensive biological warfare is the rapid detection and identification of disease outbreaks through laboratory methods, since microorganisms and their toxic products cannot be detected by any of the senses. The detection and identification of such agents require laboratory procedure which may take from a few hours to several days.

Mechanical protection against biological warfare is quite similar to that used in defense against chemical warfare. A filtered air supply, either through the use of individual face masks or collective protective shelters, and airtight clothing offer complete protection. However, since it would be impossible for persons to carry on normal living activities for any length of time in impervious suits, such equipment would probably be used only by decontamination squads in areas infected by biological agents.

Military Applications.—Although principally a strategic weapon in a military sense, biological agents could have a tactical use, even though the user might have to wait days or weeks for the effect to be felt. Since tactical plans for major operations must be made well in advance of the projected action in order to control day-to-day tactics and build up supplies and forces, located opponent reserves could be infected so that they would be out of the fight regardless of their location when the attack was launched. The agent's characteristics, the sanitary standards of the intended victims and their protective capabilities against biological agents would have to be of prime consideration for such use.

Biological weapons are uniquely adaptable to sabotage. Very small amounts of biological material could cause extensive damage. They would be inconspicuous in use and their effects would be delayed. Because of the difficulties of detection and the delayed effects, it might be impossible to determine whether sabotage had been committed or an outbreak of the disease was a natural occurrence.

The use of biological agents could be so insidious that it could be done months, or even years, before the actual outbreak of war without detection, thus seriously undermining the fighting strength of a nation prior to open conflict. Biological agents do not destroy manufacturing plants and buildings, but they might effectively neutralize them by making casualties of the workers in the plants, through illness or death, causing a loss in production or other services vital to a war effort. Also possible would be the undermining of the health of a nation by lowering the population's caloric intake through introduction of disease to grain crops or other growing food staples for one or two years before hostilities began.

The value of large-scale use of biological warfare had been neither proved nor disproved by actual military experiences in the 1950s, although research and experimentation had established its advantages as a weapon. It had become known that the quantity

of material necessary to infect varies with the degree of individual immunity. The quantity must be large enough to break through and overcome all the combined immunities, natural or acquired. which may be present. Lower dosages might stimulate body mechanisms and create greater resistance to the particular disease, rather than cause the disease.

The living habits of the peoples of nonsanitary-minded nations, where frequent contacts with animals and disease reservoirs are the mode of life, tend to build up immunities against disease; such populations would not be so susceptible to attack as would the peoples of the more sanitary-minded countries. It would probably be impossible to introduce artificially and spread by epidemic any disease among populations where that particular disease is or has been prevalent. This follows from the intimate knowledge of the disease and its consequences possessed by the natives and the widespread natural immunity that would have built up among such people. Although it can be assumed that the psychological effect of an open biological warfare attack might equal or exceed the material damages, here too the immunity problem must be met. For any group of people living in an area where disease epidemics are common would not be so mentally sensitive to a biological warfare attack as would the people of a section where epidemics are rare. *See* also CHEMICAL WARFARE.

(1956); Theodor Rosebury, *Experimental Air-Borne Infection* (1947), *Peace or Pestilence* contains good magazine article bibliography (1949); Vannevar Bush, *Modern Arms and Free Men* (1949); Otozô Yamada, *Materials on the Trial of Former Servicemen of the Japanese Army* (1950); M. Raginskii, *Bacterial Warfare,* Russian language printing (1950); René J. Dubos (ed.), *Bacterial and Mycotic Infections of Man,* 2nd ed. (1952). (V. L. R.)

BIOLOGY (ARTICLES ON). The article BIOLOGY reviews the development and methods of approach of the biological sciences. with emphasis on those that have wide application. The two major branches of biology, which involve the study from many points of view of over 1,000,000 different species of animal life and over 300,000 species of plants, are treated in additional surveys: ZOOLOGY; ZOOLOGY (ARTICLES ON); BOTANY; and BOTANY (ARTICLES ON).

EVOLUTION, ORGANIC describes the evolution of the concept itself. the observations of animal and plant life by which it has been validated, and its post-Darwinian findings. The rock-recorded phase of the evolution of plants and animals is outlined in PALEOBOTANY and PALEONTOLOGY, and that of Homo *sapiens* in MAN, EVOLUTION OF.

Articles devoted to the key factors of the evolutionary process include SELECTION and VARIATION. Among many other articles illustrative of evolutionary evidences and their interpretation are ADAPTATION, BIOLOGICAL; AKIMALS, PHYLOGENY OF; ANATOMY, COMPARATIVE; PHYSIOLOGY, COMPARATIVE; DARWINISM; DEVELOPMENT, ANIMAL; HORIOLOGY; LAMARCKISM; and NATURALIZATION OF PLANTS AND ANIMALS.

The study of organisms in relation to the environment of which each is to some extent both a product and a shaping factor is represented in many ecological articles, including ANIMALS, DISTRIBUTION OF; MARINE BIOLOGY; ECOLOGY, ANIMAL; POPULATION ECOLOGY; SOCIOLOGY, ANIMAL; ZOOGEOGRAPHY; and the sections on ecology in ZOOLOGY and PLANTS AND PLANT SCIEKCE.

GENE describes the ultramicroscopic units that constitute animated blueprints of heredity. Their laws of function are treated in GENETICS, and broader biological implications in GENETICS OF POPULATIONS and HEREDITY.

The versatile substance that is encountered in various forms of molecular organization as the basic life-stuff of the animal and plant world is described in PROTOPLASM, and its unit of architecture in CELL. Articles dealing with the structure and dynamics of the cell include ANATOMY, MICROSCOPIC; ANIMAL CELL (TISSUE) CULTURE; CYTOLOGY; GROWTH; HISTOLOGY; PLANT CELL (TISSUE) CULTURE; and REGENERATION. Articles discussing life on the single-cell level include BACTERIOLOGY and PROTOZOA.

The gap between the sciences dealing with inanimate matter and those concerned with living organisms has been substantially narrowed by the co-operative researches of workers in the biological and physical sciences; these are summarized in BIOCHEMISTRY and BIOPHYSICS. Some of the techniques of biophysics and biochemistry are' illustrated in the article dealing with the most minute of self-reproducing forms, VIRUSES.

The major types of form and structure of living organisms are described in ANATOMY, GROSS; MORPHOLOGY; PLANTS AKD PLANT SCIENCE: *Anatomy* of Plants; and PLANTS AND PLANT SCIENCE: *Morphology* of *Plants.* Among the studies of function are PHYSIOLOGY; PLANTS AND PLANT SCIENCE: *Plant* Physiology; REPRODUCTION; and SEX. More detailed listings of articles devoted to function are given in PHYSIOLOGY (ARTICLES ON).

Methods of classification of animals and plants are outlined in TAXONOMY, and biological applications of the science of statistics in BIOMETRY. The effect of the daily duration of light on the functioning of animals and plants is discussed in PHOTOPERIODISM.

In its search for a precise and comprehensive description of life, biology applies scientific method to some of the oldest philosophical questions. Among the articles reflecting this quest are DEATH (BIOLOGICAL) and INDIVIDUALITY, BIOLOGICAL.

Many biographical sketches are devoted to leaders of biological thought—for example: ARISTOTLE; DARWIN, CHARLES ROBERT; HUXLEY, THOMAS HENRY; LAMARCK, JEAN BAPTISTE PIERRE ANTOINE DE MONET; LEEUWENHOEK, ANTON VAN: LINNAEUS, CAROLUS; MENDEL, GREGOR JOHANN; WALLACE, ALFRED RUSSEL; WEISMANN, AUGUST.

BIOLOGY, an inclusive term embracing all sciences having to do with living organisms. The biological sciences may be classified according to the nature of the organisms considered, as botany, dealing with plants in all their aspects; bacteriology! with bacteria; zoology, with animals.

Finer subdivisions, such as algology, the study of algae; protozoology, the study of the protozoa; entomology, the study of insects; mycology, the study of fungi; helminthology, the study of parasitic worms; and paleontology, the study of the life of past geologic ages, are frequently employed.

Another method of arrangement involves the mode of approach, as morphology, or the study of form; physiology, the study of function; anatomy, the study of internal structure; cytology, the study of the cell; pathology, the study and treatment of disease; ecology, the study of environmental relations; genetics. the study of inheritance; etc. A complex classification, employing categories such as physiological botany or morphological zoology, will often be found necessary.

Following the old usage of G. R. Treviranus and of Jean Raptiste de Lamarck, biology will be considered as primarily restricted to consideration of problems presented by organisms in general. or at least organisms of many different kinds. The problems of biology are thus the problems common to the three major biological sciences, botany, bacteriology and zoology (*qq.v.*), or to any two of them.

More generally, a problem would be regarded as one oi biology rather than of zoology, or of botany or of bacteriology, if its solution affected ideas in one of the other sciences or even in sciences outside biology.

This article is divided into the following sections and divisions:

I. HISTORY

Biology, in the widest acceptance of the word, is used to cover all those studies which deal with the structure, nature and behaviour of living beings. It is thus in contrast with the word "physics," which is similarly used to cover the study of the structure. nature and behaviour of such matter as is neither living nor a necessary product of the activity of living things. It happens that certain of the studies classed as biological are intimately bound up with the study of medicine, as, for example, human anatomy, the physiology of the warm-blooded animals, bacteriology and the like. This historical relationship has had certain practical results. and these subjects are sometimes tacitly excluded from what is called biology in a narrowed academic use of that term.

For practical convenience these departments are considered in the article MEDICINE, HISTORY OF.

The word "biology" was introduced by G. R. Treviranus (1776–1837) in his Biologie oder *die* Philosophie der lebenden Natur (Gottingen, 1802–22). It was popularized by J. B. de Lamarck (1744–1829; *q.v.*) in his *Hydrogéologie* (Paris, 1802); Lamarck perhaps invented it independently. The first English use of the word in its modern sense was by Sir William Lawrence (1783–1867) in his work On the Physiology, Zoology, and *Natural* History of Man (London, 1819). There are, indeed, earlier uses of the word in English, but they are in relation to biography.

1. Early Greek.—Biology may reasonably be regarded as beginning with the Greeks. At a very early date, and particularly at the hands of Alcmaeon of Crotona (c. 500 B.C.), we hear of independent investigations of the structure and habits of animals. Thus Alcmaeon described the optic nerves and tubes that lead from the nose to the ear (Eustachian tubes), and he made a beginning of the study of the development of the embryo. The theory of Empedocles (c. 490–430 B.C.) of Akragas of four elements, arranged in opposites, came to control medical thought for two millenniums, but more immediately influential was his view that the blood is the seat of the then mysterious "innate heat," taken from folk belief—"the blood is the life." This led to the consideration of the heart as centre of the vascular system and chief organ of the pneuma which was distributed by the blood vessels. Pneuma was identified, in accord with certain philosophical tendencies, with both air and breath. These views of Empedocles were rejected by the important Coan medical school, then becoming prominent, but were widely accepted elsewhere. Notably Diogenes Apolloniates (c. 460 B.C.), a contemporary of Hippocrates of Cos, was led to investigate the blood vessels, and his account of the vascular system is the earliest that is intelligible. The Hippocratic Collection (see HIPPOCRATES AND THE HIPPOCRATIC COLLECTION; MEDICINE, HISTORY OF) attempts some sort of classification of animals as early as the 5th century B.C. The author of an early work of the so-called Hippocratic Collection, On the Sacred Disease, of about 400 B.C., opened the skulls of goats and found their brains to resemble those of men in being cleft into symmetrical halves by vertical membranes. The large veins of the neck are intelligibly described. The arteries are said to contain air, an idea gained from their emptiness in dead animals. The work *On the Nature of Man*, perhaps of about 380 B.C., ascribed by Aristotle to Polybus, son-in-law of Hippocrates, contains the doctrine of the four humours. These--blood, phlegm (*pituita*), black bile (melancholia) and yellow bile (*chole*)—make up the living body as the four elements make up nonliving matter: This doctrine persisted till quite modern times, and traces of it remain in the language and thought of today.

An interesting Athenian biological thinker of the mid-4th century B.C. was Diocles of Carystus. He drew his opinions from many sources, adopting the humours of Polybus and the innate heat of Empedocles, regarding with Aristotle the heart as seat of the intelligence but accepting also Sicilian pneumatism. His observations on the early human fetus are the first recorded. His work On Anatomy, based to some extent on human material, has disappeared, and there is no general early treatise on the subject. The best representative of the anatomy of the 4th century is the tract in the Hippocratic Collection On the Heart, of about 340 B.C. It refers to the anatomical similarity of man and animals and places the innate heat in the heart. Air enters directly into the left ventricle, where some subtle change of blood into spirit takes place and where, too, the intellect resides. The heart valves are described and experiments are suggested for testing their competence. There is the startling statement—verified by experiment!—that, in drinking, some of the fluid passes to the lungs. This false statement might be ascribed to textual confusion were not the same view expressed in Plato's *Timaeus* and other early writings. The Timaeus itself had profound effects on the biological conceptions of the middle ages.

All the early records of biological science before the 4th century B.C. are, however, either completely lost or too fragmentary to permit of adequate reconstruction. Not until Aristotle (384–322 B.C.) do we encounter any complete biological works. Moreover, as our accurate knowledge of Greek biological science begins with Aristotle, so it may almost be said to end with him. The only surviving ancient biological works besides those of Aristotle, prepared without consideration of their application, are by his pupil Theophrastus. A full account of the biological achievements of Aristotle and of Theophrastus would thus contain an almost complete account of our knowledge of pure biological science in antiquity. We shall, however, need to give some consideration to the work of Galen in the 2nd century A.D., though his is applied science.

2. Aristotle as a Biologist.—Of the biological works of Aristotle a considerable number have survived. Among them, four are pre-eminent: (1) on psyche (*i.e.*, on the soul or living principle), usually known as De *anima;* (2) histories about animals, usually known as the *Historia* animalium; (3) on the generation of animals, usually known as De generatione animalium; (4) on the parts of animals, usually known as De *partibus animalium*. There are matters in all these that come rather in the department of philosophy (see ARISTOTLE) but which must of necessity be considered in any account of the history of biological thought, which they have influenced throughout its course. Such is Aristotle's conception of the nature of the living principle or psyche.

The oldest use of the word "psyche" is in the sense of breath, and breathing is the most obvious sign of life. It was, therefore, natural that from breath the word "psyche" came to mean life, then the soul and again the mind. Aristotle used this term for the principle that differentiates living from nonliving substance. When he began to examine different living things he reached the conclusion that there were different kinds or orders of psyche or soul. In the course of this investigation he came to distinguish between (1) the vegetative soul, (2) the animal soul and (3) the rational soul.

The vegetative soul was the lowest. Aristotle regarded plants as the lowest living forms, and the qualities of life that he distinguished in them were growth and the power of reproduction.

Aristotle considered that while animals had these qualities of the vegetative soul, they also had, of their nature, the power of movement. The movements that they made seemed to him to correspond to what they felt. The animal soul thus possessed,

as he thought, not only the qualities of the vegetative soul but also a second order of qualities which were responsible for the sensitive and motive powers of animals.

Lastly, man had all these qualities exhibited in both plants and animals. but he had also certain others. He could reason and his movements and actions were dictated by his thoughts. His soul, therefore, was equipped not only with the qualities of the vegetative and animal souls but also with rational or intellectual powers.

It will thus be seen that Aristotle was, in the fullest and most definite sense, a "vitalist." Apart from the classification of kinds of soul. Aristotle held certain views as to the relationship of this soul or psyche to the living body. This relationship was determined by the existence of an entelechy, a term which may perhaps be translated for biological purposes as "an indwelling purposiveness." The nature of this entelechy is brought out in his work De *anima,* which claims that the soul is neither independent of, nor is it any part of, the body. He says:

> They are right who hold the soul as not independent of the body and yet as not in itself anvthing of the nature of the body It is not body, but something belonging to bodv It, therefore, resides in bodv, and moreover, a particular soul to a particular body Thev were wrong who sought to fit the soul into the hodv without regard to the nature and qualities of that body For the Entelechy of each thing comes naturally to be developed in the potentiality of each thing, and it is manifest that soul is a certain Entelechy and, notional form of that which has the capacity to be endowed with soul

This. then. is the basic thought in Aristotle's biological work. a thought that is still subscribed to by some biologists of the present day *(see* ENTELECHY; VITALISM). But besides Aristotle's finely wrought biological theories, of which this is one. there is much in his biological writing that does not involve these high topics but is restricted to the ordinary investigations of the working biologist as we know him in our own time. Thus on the phenomenological level we may note Aristotle's magnificent observations on the habits of fishes, some of which, doubted for centuries, were verified in our own time. No less remarkable are his observations on the breeding and development of the octopuses and their allies. His discourses on whales, porpoises and dolphins and on the development of dogfish are also very noteworthy. There is much to justify us in classing Aristotle as one of the best observing naturalists of all time.

The whole course of biology may be represented as the history of ideas on the classification of living things. Something must therefore be said on this subject in relationship to Aristotle.

At first, Aristotle entirely separated man from the lower creatures, distinguishing him among living things by the possession of a rational soul. As his knowledge increased, he became less inclined to make this distinction absolute, and ultimately he admitted that animals in their degree share rationality with man. His final position seems to have been that there is no fundamental distinction between life or soul and mind. This is precisely the attitude of an important school of modern biologists.

In ascribing reason to animals Aristotle is sometimes said to have been influenced by his advance toward something that we should now call a belief in "evolution." It cannot justly be said that he ever attained to a clear view of organic evolution. Nevertheless, it is evident that he was moving in that direction, that he was not far from reaching it and that had he lived a few years more he might well have reached it. It is certainly easy to read an evolutionary meaning into much of his biological writing. Moreover. we see him groping at some "natural" manner of arranging the orders of animals. He is, in fact, striving toward what we should call a classification. The scheme that he actually adopted was to arrange living things in a sort of ladder or scale. This *scala naturae* of Aristotle is of great interest and is worthy of all possible respect. He describes a particular part of this as follows:

> Nature proceeds little by little, from things lifeless to animal life, in such a way that it is impossible to determine the exact line of demarcation, nor on which side thereof an intermediate form should iie. Thus next after lifeless things in the upward scale comes the plant. . . . Of plants one differs from another as to its amount of apparent vitality. In fact, the whole of plant kind, while devoid of life as compared with animals, is endowed with life as compared with other forms of matter. Moreover there is in plants a continuous scale of ascent toward the animal, and of some one is at a loss to say whether they be animal or plant. . . . Thus nature passes from lifeless objects to animals in unbroken sequence, so that scarcely any difference seems to exist between two neighbouring group. by reason of their close similarity.

As a working naturalist Aristotle excelled chiefly in his observations on the habits and lives of animals. He was less fortunate in his investigations of their structure, and less fortunate still in his consideration of the functions of parts. He was, in fact, far less an experimenter than an observer. Some of his successors among the Greeks (*e.g.,* Galen) far excelled him in their experimental skill and ingenuity. But neither Gslen nor Aristotle could progress very far without an exact body of knowledge of chemistry and physics on which they could build.

3. Ancient Biology After **Aristotle.**—Aristotle's botanical researches are lost. We have, however, full botanical works of Theophrastus of Eresus (*c.* 371/370–288/287 B.C.), his heir. his favourite pupil and his successor as head of the Lyceum. Theophrastus. like other ancient men of science, felt acutely the need for a technical terminology. He made some attempts to establish one, and at least one technical botanical term, "pericarp," comes to us from him.

Theophrastus understood the value of developmental study, a conception derived from his master. "A plant," he says, "has the power of germination in all its parts for it has life in them all, wherefore we should regard them, not for what they are, but for what they are becoming." He lays much stress on the different modes of reproduction of plants. He distinguishes between the monocotyledons and the dicotyledons. and he has some interesting passages in which sex is discerned in plants, notably in the palms.

The works of Theophrastus are extremely valuable as the most complete biological treatises that have come to us from antiquity. They contain many excellent observations, but are distinctly inferior in depth, range and insight to the biological works of Aristotle. Pure botanical investigation virtually ended with Theophrastus. Biology was studied at the Alexandrian school, but chiefly in connection with medicine (see MEDICINE, HISTORY OF). There was one important development, however. in Alexandrian times to which we must refer. This was the practice of portraying the forms of plants exactly and artistically for purposes of identification. Science owes this most important accessory art to one Crateuas, a herbalist who practised in the 1st century B.C. There are accurate copies of some of the drawings of this artist, and these copies are therefore of the utmost interest to biologists.

The Hellenistic investigator whose writings have had most influence on the course of botany, and in particular on botanical terminology, is the physician Pedanios Dioscorides of Anazarba in Asia Minor. Dioscorides served in the army of the emperor Nero, and a work by him on plants useful in medicine has survived in great completeness and in a large number of manuscripts. Nevertheless. this work is ill arranged, almost devoid of general ideas and steeped in the errors that must always pursue those who follow purely practical ends without regard to theoretical considerations. The work of Dioscorides is essentially a drug collector's manual. Even lower in quality is the *Natural History* of his contemporary, Pliny the elder (C. A.D. 23–79). It is immensely interesting as a storehouse of folklore and as a mirror of the follies and superstitions of his age. It cannot be passed over in silence since it was perhaps more read during the middle ages than any work of antiquity except the Bible. From the point of view of a rational development of biological thought, however, Pliny's work is negligible.

The only other important later figure in the biological thought of antiquity is Galen. His magnificent achievements have been considered elsewhere (see GALEN; MEDICINE, HISTORY OF). Though his interests were mainly medical, the vigour and independence with which he pursued his researches give him a very important place in the history of biology.

Galen elaborated a most ingenious physiological scheme which was accepted until modern times. It involved three kinds of pneuma or spirit in addition to air. The basic principle of life was drawn from the world-pneuma or air by breathing. Entering the body through the windpipe, it passed to the lung and thence to

the left ventricle, where it encountered the blood. His erroneous but ingenious view as to the change that then took place in the blood remained current till the 17th century. He believed that chyle reached the liver. which indued it with pneuma or spirit innate in all living substance, the natural spirit. It was distributed by the liver through the venous system, ebbing and flowing in the veins. One great branch of the venous system was the cavity now called the right ventricle. The venous blood that entered it had two possible fates. Most ebbed back into the liver, having parted with its "fumes" or impurities, which were carried off to the lung and exhaled—hence the poisonous character of rebreathed air. A small portion, however, trickling through minute channels in the heart substance, dripped slowly into the left ventricle. There it encountered air from the lung and thereby the dark blood was made bright and its natural spirit elaborated into a higher type of pneuma, the vital spirit. This blood, charged with vital spirit, was sent by the arteries to all parts, some going to a network of vessels. the *rete mirabile,* at the base of the brain. There it was charged with a third pneuma, the animal spirit, which was distributed by the nerves. It is to be noted that the *rete mirabile,* absent in most animals, is well developed in cattle, on the examination of which Galen developed his system.

The best presentation of Galen's views is in his great works *On Anatomical Procedure* and *On the Uses* of *the Parts* of *the Body of Man.* He introduced many useful terms. Among those still current in anatomy are apophysis, epiphysis, trochanter, diarthrosis, anastomosis and synarthrosis. In fact he provided the bases of the vocabulary of modern anatomy and comparative anatomy.

Perhaps Galen's most remarkable positive achievement was his experimental investigation of the spinal cord, the continuity of which, at different levels, was, he showed, necessary for the maintenance of certain functions. Injury between the first and second vertebrae caused instantaneous death. Section between the third and fourth produced arrest of respiration. Below the sixth it gave rise to paralysis of thoracic muscles, respiration being carried on only by the diaphragm. If the lesion were yet lower the paralysis was confined to the lower limbs, bladder and intestines. Galen's knowledge of the functions of the spinal cord was not extended and indeed was not adequately appreciated until well into the 19th century.

Galen's biological works are among the most influential of all time. Nevertheless he established no school nor had he either disciples or followers. On his death *c.* A.D. 200 anatomical and physiological inquiry ceased completely. The biological dark ages had begun.

4. **The** Middle Ages.—The biological darkness of the middle ages lifted a little with the translation of Greek works from Arabic versions into Latin. These began to appear in the 11th century but were not common till the 13th. The most important for biology were Aristotle's. These were turned into Latin from a very corrupt Arabic version in south Italy by Michael Scot (d. *c.* 1232) with the help of a Jewish assistant who knew Arabic. During the next 100 years some of the physiological works of Galen also appeared in Latin. Of writers of this age the only one worthy of mention is Albertus Magnus (*c.* 1200–80) of Cologne. Though his biological works followed Aristotle very closely, they betrayed some observational capacity.

Much more observationally effective than the scholars of the time were the craftsmen and artists. From the 14th century their work showed a tendency to the more careful observation of living things, especially plants. This exhibited itself in illuminated herbals, in architectural ornaments and in details in paintings. Toward the end of the 15th century this movement showed itself very clearly.

The artists of the Renaissance period, Sandro Botticelli (1444–1510), Leonardo da Vinci (1452–1519), Albrecht Dürer (1471–1528), Michelangelo (1475–1564) and others, exhibited interest in exact portrayal of animal and plant forms as well as curiosity about the structure of the human body. These great Renaissance figures were curious as to the ways of nature, and it is not misusing words. to speak of Leonardo, at least, as a great biologist. The group of movements which came to flower with the beginning of the 16th century placed the student of nature in a peculiarly favourable position. He had the works of science of antiquity on which to start. The craft of printing was at his disposal. He had the representational studies of the great artists before him. He had learned to present details of nature effectively. At last, also, the art of the woodcutter was perfected, so that the figures of the artist could be transferred to the printed page.

5. Revival of Learning.—It was in this happy collocation of circumstances that the first effective biological textbooks of modern times were produced. The movement began in Germany with the botanists. Otto Brunfels (1488–1534) produced the first printed work on plants which relied solely on observation. The drawings are firm and faithful and compare favourably with those of a good modern textbook. As Brunfels was the first, so Leonhard Fuchs (1501–66) was the greatest of the German "fathers of botany." His work appeared in 1542 and is a landmark in the history of natural knowledge. A part of the same movement was the new scientific interest in anatomy. Protagonists of that movement *(see* MEDICINE, HISTORY OF) were Andreas Vesalius and Bartolomeo Eustachio. More in the class of pure "naturalists" in the modern acceptance of that word were the two French observers Pierre Belon and Guillaume Rondelet.

Pierre Belon (1517–64) of Le Mans spent several years wandering in the near east. He kept careful notes of the natural history of the countries that he traversed. Later he produced books on plants, fishes and birds, which, though borrowing from Aristotle, show also much original observation. Belon clearly grasped the general principles of comparative anatomy, especially as applied to the skeleton. These principles had already been elucidated by Vesalius. More accurate as an observer, though less imbued with comparative principles, was Guillaume Rondelet (1507–66) of Montpellier, a friend of François Rabelais. Rondelet's great work is a painstaking investigation of the fishes of the Mediterranean.

The learning of the time was liable to express itself in the form of encyclopaedias. These were mostly little but compilations. An exception must be made, however, for that of Konrad von Gesner (1516–65), the great Swiss naturalist. His history of animals in five folio volumes covers the topics of quadrupeds, birds, fishes and snakes. Most of the matter is borrowed, but much also is original, notably the section on fishes, which contains also figures of a large number of invertebrates. The work of Gesner is regarded by many as the starting point of modern zoology. To his contemporaries, Gesner was best known as a botanist, but his most important botanical works were not published until zoo years after his death. His figures of animals are superb.

Toward the end of the 16th century all the important departments of biology—anatomy, physiology, botany, zoology—were becoming differentiated and making considerable progress. These subjects were being taught in the universities of northern Italy and especially at Padua, the old school of Vesalius, where Hieronymus Fabricius *(c.* 1533–1619) of Aquapendente exercised most influence. Fabricius made extensive embryological investigations, and his works on the subject are the first to be illustrated with figures drawn from the object. He made many physiological researches. Thus he described the valves of the veins and was one of the first to give an accurate account of the structure of the eye. Other important Paduan teachers of the time were Realdo Colombo, Sanctorius, Andreas Caesalpinus and Giulio Casserio.

6. The Rebirth of the Physiological Study of Animals and Plants.—A remarkable pupil of Fabricius was the Englishman William Harvey (1578–1657), the discoverer of the circulation of the blood. His work on that subject, published in 1628, gave the first rational explanation of the workings of the animal body. *(See* HARVEY, WILLIAM; MEDICINE, HISTORY OF.) Science of the early 17th century was illuminated by the work of Galileo, of whom Harvey was a pupil. Another disciple was G. A. Borelli (1608–79), who was primarily a mathematician In his De *motu animalium* (Rome, 1680) he founded the science of muscular mechanics, investigating the motions of animals according to the

laws of statics and dynamics. Many of his conclusions still stand. While Harvey was at work on the special researches associated with his name, optical instruments were being constructed which made it possible to examine the structure of animals more minutely. In 1610 the compound microscope was described by Galileo and through him passed into modern use. The first systematic investigation of living things with the new instrument was made by a group of young men who formed themselves into the first scientific society, under the name of the "Academy of the Lynx." which usually met at Rome at the house of its president. Federigo Cesi. duke of Aquasparta. His early death in 1628 brought the academy to an end. and many of its works perished. We have, however, records of a few of its observations which are peculiarly interesting as the earliest for which the microscope was systematically employed. Cesi himself worked on botanical topics and described the spores of the fern. Other members of the academy issued a work on the newly discovered animals and plants of the new world.

With the collapse of the Academy of the Lynx, systematic microscopical observation ceased for a generation. After 1660, however, there arose a series of great microscopical observers who among them revolutionized the conception of the nature of living things. Of these "classical microscopists," two, R. Hooke and N. Grew, were English; two, A. Leeuwenhoek and J. Swammerdam, were Dutch; and one. M. Malpighi, was Italian. It is interesting to observe that the most important work of all of them, except Swammerdam, was published in England.

Marcello Malpighi (1628–94; *q.v.*) supplemented Harvey's work by describing the capillary circulation which Harvey had not seen. Malpighi demonstrated it in the lung of the frog. He extended greatly the work of Fabricius, and he especially investigated the early stages of the development of the embryo of the chick. He gave accurate representations of the early stages. and notably he showed that in the embryo there are paired branches of the aorta which reunite. These correspond, as we now know, to the vessels in the gills of a fish. Malpighi, who had no evolutionary leanings, had no conception of the nature of these vessels, but his description of them is very good. The bulkiest of Malpighi's contributions are his writings on the anatomy of plants. He gave excellent representations of the cell walls of plants, and he established the broad outlines of the microscopic anatomy of the roots and stems of the higher plants.

In botanical anatomy even more accurate and systematic observations were made by Nehemiah Grew (1641–1712; *q.v.*). Grew placed the study of the anatomy of plants on a firm foundation. He is also remarkable for his statement as to the sexual character of flowers—an observation which he himself ascribes to Sir Thomas Milligan, Savilian professor of geometry at Oxford.

Jan Swammerdam (1637–80; *q.v.*) was perhaps the most accurate and remarkable, as he was the most mentally unstable and short-lived, of the classical microscopists. His first work, *A General History of Insects,* deals chiefly with the modes of transformation of insects and brings out well the different modes of development of the major groups of insects. The text and figures are equally good. and the book itself obtained popular recognition. His magnificent *Bible of Nature,* which is probably the finest collection of microscopical observations ever published, did not appear till long after his death. It is still in current use by naturalists.

Anton van Leeuwenhoek (1632–1723; *q.v.*) made the greatest impression on his contemporaries of all the classical microscopists He published an immense number of observations of a desultory kind, nearly all in the *Philosophical Transactions* of the Royal society. These observations contain many shrewd judgments. Leeuwenhoek's portrayal of bacteria in 1683 and of spermatozoa in 1677 are triumphs of observation with the optical means at his disposal. He drew and described the structure of striated muscle. He investigated in his own peculiar fashion almost every department of animal and plant life No one was more influential than Leeuwenhoek in drawing the attention of observers to the minute complexity and beauty of the structure of the animal body.

Of all the classical microscopists the most gifted was Robert Hooke (1635–1703; *q.v.*). He was, however, only to a limited extent a biologist. His important work, *Micrographia,* appeared in London in 1665. In it he has a figure of the microscopic structure of cork showing the boundaries of the cell walls. He refers to these as *cellulae,* and the word "cell" in modern biological nomenclature is probably derived from this' He shows also the cells on the surface of the stinging nettle and he has a good account of its stinging apparatus. An important botanical observation by him is the growth of a fungus of the group Ascotnycetes on damp leaves. He also gives accounts of the structure of moss and of experiments on the sensitive plant. He gives remarkable delineations of the compounded eye of a fly and two gigantic figures of a flea and of a louse His account of the life history of the gnat is the earliest of its kind and a first-class piece of observation

The work of the classical microscopists stands somewhat apart from that of other investigators and forms a peculiarly isolated chapter in the history of biology.

7. Early Attempts to Classify Living Things. — The early naturalists, whether botanists, zoologists. microscopists. anatomists or encyclopaedists. seldom made any sustained attempt at systematic arrangement. The encyclopaedic naturalists, such as Gesner, arranged their material according to the obvious divisions of the animal kingdom—fishes, birds, reptiles and the like.

The first trace of any systematic arrangement of plants in accordance with their structure is in the work of Matthias de l'Obel (1538–1616), a Dutchman who went to England in his youth and dedicated his first book (1570) to Queen Elizabeth I. L'Obel attempted to group plants according to the form of their leaves. He succeeded fairly well with the grasses, less well with the other monocotyledons and failed with the dicotyledons, with which he confused the ferns.

More promising was the suggestion of the shrewd investigator Andreas Caesalpinus (1519–1603) of Padua and Pisa, who attempted to class plants according to their flowers and fruits. The scheme formed on this basis was by far the best of the kind that had yet appeared. A small part of it was absorbed into the influential work of Gaspard Bauhin (1550–1624; *q.v.*) of Basel. For the most part, however, it fell on sterile ground and was little noticed till the time of Linnaeus.

So far as general arrangement is concerned, Bauhin was distinctly inferior to Caesalpinus. He gives, however, descriptions of about 6,000 plants. The great merit of his book is that in it, for the first time, the species of plants are placed together in small definite groups or genera. The modern conception of genus and species is to be seen in the work of Bauhin more than in that of anybody else of his time: and his system approaches nearer to a binomial one than any before Linnaeus.

Important steps toward a systematic arrangement of living things were made by the two friends John Ray (1627–1705) and Francis Willughby (1635–72). They formed a scheme for a systematic description of the whole organic world. Willughby was to undertake the animals, Ray the plants. Willughby died early, and Ray became the chief founder of the science of systematic biology. His early attempts on the flora of Cambridge and his treatise on birds were followed in 1682 by his important *New System of Plants.* In this he demonstrated the true nature of buds and used the terms dicotyledons and monocotyledons to indicate a division of flowering plants. He based his system largely upon the fruit but also upon the leaf and other characteristics and especially, following Caesalpinus, upon the flowers. In doing this he succeeded in disentangling a number of the larger groupings of plants now known as families. His work in botany was completed by his *Synopsis of British Plants* and followed up by a *Synopsis of Quadrupeds and Serpents* (1693). The latter contains the first truly systematic arrangement of animals. It is based primarily upon the fingers, toes and teeth.

The systematic arrangement of living things was continued especially by the Swede Linnaeus (1707–78), the greatest of the systematists. Linnaeus brought to bear upon his life work an enormous acquaintance with living things, especially plants, gained in the field. His prodigious industry and power of systematic arrangement would alone have given him a high place among naturalists.

He profited from all the best teachers of the day, visiting many parts of Europe, including the Netherlands, France and England. He was a most inspiring teacher and had numerous pupils, one of whom. Daniel C. Solander, accompanied the English explorer Capt. James Cook and was for many years resident in London. Linnaeus became a sort of biological dictator, and for a century after his time most of the biological work that was done in every country was in his spirit. He had a passion for classification and succeeded in assigning to every known animal and plant a position in his system. This involved placing any specimen first in a class, then in an order, then in a genus, then in a species. The broad outline of his system of classification has remained, though its rigid framework has long since been abandoned.

The chief service of Linnaeus to biology is his method — derived from Bauhin and Ray and impressed upon his contemporaries — of arranging living things into genera and species, with his development of the binomial system. His system extended even to man, and he distinguished *Homo sapiens* from *Homo troglodytes*. His *Systema naturae* went into many editions, the most highly prized being the 10th, to which naturalists still refer when they speak of Linnaean genera and species of animals, and the 12th for plants.

Linnaeus held that species are constant and invariable, a view in which he differed from John Ray. He assumed that all the members of a species were descended from a single pair that had been originally created. He afterward modified this view and came to hold that it was the genera, not the species, which had issued from the Godhead.

8. Beginning of the Study of Comparative Anatomy and Physiology. — The first animal whose naked-eye structure was adequately explored was man himself. The anatomy of man was placed upon a sound basis by Vesalius in his wonderful monograph of 1543. For certain organs of the body Vesalius had no adequate access to human material. Thus his account of the eye and that of the organ of voice were taken from the dog. He was aware of differences in structure between man and animals, and he chose several opportunities in his work to adopt a comparative method. 4 similar device was invoked by Pierre Belon. During the 16th century several other observers made dissections of animals and compared them with man. None was more exact than Carlo Ruini, a lawyer of Bologna, who published his monograph on the horse in 1598.

As the 17th century advanced there were a number of workers who further extended comparative studies. Of these the classical microscopists were by far the most important; for the most part they worked upon invertebrates. Monographs on various vertebrates were also prepared, as for instance that on the chameleon by the Italian Francesco Redi and that on the chimpanzee or "pygmy" by the Englishman Edward Tyson. Monographs on invertebrates were prepared by Malpighi on the silkworm, by Swammerdam on the May fly, the bee and the snail and by Leeuwenhoek on the development of the flea.

With the great movement initiated by the work of Harvey, something in the nature of comparative physiology became possible. Harvey's masterpiece is in fact in large part a comparative study of the circulation. Of comparative physiology an important exponent was the English country parson Stephen Hales (1677–1761).

Hales began the study of the functional activity of plants, and his work was the most important in that department until the 19th century. He measured the amount of water taken in hy the roots and given off by the leaves, comparing this with the amount of moisture in the earth and showing the relationship of the one to the other. He made calculations of the rate at which water rises in the stems, and he showed that this has a relation to the rate at which it enters by the roots and transpires through the leaves. He measured also the force of suction in wood and roots; that is to say, "root pressure." He sought to know that these actions of living plants might be explained as the result of their structure. His most important contribution for botanical physiology was perhaps his demonstration that the air contributes something to the building up of the substance of plants, and in this respect he may be said to have been the discoverer of carbon dioxide. Following this up, he showed that air enters the plant not only through leaves but also through the rind. His experiments and conclusions in the physiology of animals were as important as in that of plants. Here he showed that there is a pressure of the blood within the vessels which can be measured, and that it varies in different circumstances and differs in the arteries and the veins. He even estimated the rate of flow in the capillaries. It is especially characteristic of his work that in all his experiments he sought to give a quantitative expression to his results. Hales was thus among the first to adopt exact methods in biology.

The most accomplished naturalist of the 18th century was R. A. F. de Réaumur (1683–1757), who applied his varied talents to the whole range of the sciences. He made important observations on regeneration in Crustacea, locomotion of starfish, electrical apparatus of the torpedo, marine phosphorescence, growth of algae, digestion in birds, silk of spiders and the nature of coral organisms. His great *Mémoires pour servir à l'histoire des insectes* (1734–42) is remarkable for its physiological interests, for he discusses the effect of heat on insect development and has much on the leaf borers and gall formers. Throughout he emphasizes development and metamorphosis.

Two younger contemporaries and correspondents of Réaumur who showed extraordinary skill in limited fields were P. Lyonet (1707–89) and Abraham Trembley (1710–84). Lyonet had astonishing skill in minute dissection In 1740 he produced with incredible labour his famous monograph of the goat-moth caterpillar in which he demonstrated no fewer than 3,000 separate muscles. Trembley is best remembered for his monograph on *Hydra* (1744), to the study of which he devoted many years. He showed that it was of animal nature and disclosed its mode of life and reproduction. His book on it is exceptionally beautiful and contains many drawings by his friend Lyonet.

The comparative attitude in combination with exact experiment in biology was peculiarly characteristic of the investigators of the 18th century and separates them from those of the previous period. None pursued the method with greater enthusiasm than the surgeon John Hunter *(see* HUNTER, WILLIAM AND JOHN). He anatomized more than 500 species of animals, many a number of times, as well as many species of plants. His objective was to trace systematically the different phases of life as exhibited in the structure of animals and plants. Both in precept and example Hunter was the greatest influence in connection nith the establishment of natural history museums, the subsequent development of which followed lines similar to those which he suggested.

Hitherto comparative studies had been the preoccupation of individual workers. Georges Cuvier (1769–1832), by his immensely powerful position in the French intellectual world, was able to establish a complete and organized school of comparative investigators which may be said to have continued to our own time. His influence was stimulating to research, but it cannot be said that he invariably exerted his power with the greatest discernment. He believed strongly in the fixity of species and thus opposed the views of Lamarck (*q.v.*) and of Étienne Geoffroy St. Hilaire (1772–1844). Nevertheless, by the paleontological school which he founded and which extended into every country, he did more than any other man to collect material on which the doctrine of the impermanence of species became formally founded in the next generation. His *Règne Animnle* is still one of the main bases for comparative studies. Among the specific achievements of Cuvier were the creation of the science of paleontology, the exploration of the anatomy of the Mollusca and the systematic treatment of the vast class of fishes.

The tradition of Cuvier was carried to England by Richard Owen (1804–92), who became the first director of the British Museum of Natural History.

While Cuvier and his school led in the comparative study of structure, the comparative study of function, expounded by Hales, was established on a firmer basis by the great German physiologist Johannes Peter Müller (*q.v.*). The latter part of Müller's life was given mainly to zoological research. As a microscopist he

worked out the anatomy of the glandular and cartilaginous tissues and grouped the connective tissues. He was a convinced vitalist. and his doctrine of specific nerve energy remains one of the cornerstones of vitalistic theory.

The study of the paleontology of plants came later than that of animals. A few fossil plants had been described by earlier naturalists. Toward the end of Cuvier's time several figures of plants from the Coal Measures had been published with the generic and specific names that they still bear. Not until 1831 was the technique of their examination sufficiently advanced for microscopic study. The study began to be syste atic in 1858 with W. C. Williamson (1816–95), who demonstrated in coal gigantic forms similar to the higher flowerless plants such as horsetails, ferns and club moss. His results were long neglected, but during the 20th century the paleontology of plants came to be nearly on the same footing as that of animals.

9. Effects of Geographical Exploration on Biological **Development.** — From the end of the 15th century the western nations of Europe were sending forth expeditions east and west: and these brought home knowledge of the natural products of lands newly explored. Thus the idea that each region has its characteristic living things became gradually explicit.

In the 18th century exploratory expeditions began the practice of carrying specially trained naturalists, and thus they enter the history of biology. The three voyages of Captain Cook *(see* COOK, JAMES) mark an era not only in the history of geographic discovery but also in the study of living things. Among the naturalists that Cook took with him were Sir Joseph Banks (1743–1820; *q.v.*) and a pupil of Linnaeus, Daniel C. Solander (1736–82). Both were instrumental in exploring the flora and fauna of the Pacific.

An important voyage which covered the western as well as the eastern hemisphere was that of the "Beagle," which sailed in 1831 and carried the naturalist Charles Darwin (1809–82; *q.v.*). Quite apart from the investigations and theories with which Darwin's name is especially associated, the voyage made known a whole multitude of new forms and helped establish the doctrine of zoogeographical and phytogeographical regions.

By the middle of the 19th century exploration and survey had become recognized as an important duty of the British admiralty. Many scientific expeditions were sent out by that body. The most important was that of the "Challenger" which sailed in 1872. The features of this expedition were, first, the very careful examination of the depth and character of the seas and sea water whereby oceanography was established as a separate science; second, the large number of remote places visited; and third, the magnificent scale on which the scientific results of the journey were published. The reports of the "Challenger" expedition are still in current use by naturalists. The influence of this expedition, coming as a culmination of a series of previous voyages of exploration, was to modify considerably the general view of the range and variety of living things and to enable naturalists to form a picture of life in the ocean, where the geographical regions are distributed vertically rather than horizontally.

10. Reproduction of Plants and Its Comparison With That of Animals. — One of the main gaps in biological thought was the great difference between the nature of animals and that of plants. Especially the mode of reproduction of plants seemed to separate them very widely from animal forms. Because of this, perhaps, have arisen so many legends concerning the "loves of the plants" and vague ideas ascribing sex to these beings. The conception of sex in plants was first lucidly, consistently and accurately set forth, though in elementary fashion, toward the end of the 17th century by R. J. Camerarius (1665–1721). This remarkable observer pointed out that the sex theory could not be made to apply to flowerless plants. The doctrine of the sex of flowers was accepted by Linnaeus and incorporated in a mechanical way into his system. Linnaeus found the sexual parts of plants convenient for establishing his classification.

During the course of the 18th century several botanists succeeded in using the pollen of one species to fertilize the flowers of another species of plants. The existence of hybridization was recognized, and one writer, J. G. Kolreuter (1733–1806) of Karlsruhe. held that the main agent in the fertilization of flowers was the wind, but that some flowers fertilized themselves and that in others insects played a part. With great acumen, moreover, he pointed out that in some plants (*e.g.*, the mistletoe) which did not lend themselves to pollination by the wind, and in which the flowers were of different sexes, the only way of pollination was by insects. Moreover, for this same plant he called attention to the distribution of seeds by birds, later successfully investigated by Charles Darwin. Thus, as he pointed out, the mistletoe depends upon both birds and insects for its existence.

The subject was taken up by several German workers. notably by C. K. Sprengel (1750–1816), who, in his work The *Newly Revealed Mystery of Nature in the Structure and Fertilization* of *Flowers*, paid special attention to cases in which the sexual parts occurring on a single blossom matured at different periods. Sprengel reached the conclusion that some flowers can be fertilized only by insects, that some are so constructed as to injure and even kill insects that serve them, and that yet other flowers are fertilized by wind. He observed that flowers belonging to the last class always produce large quantities of light pollen. whereas in the flowers of the other types pollen is relatively heavy. He demonstrated the relation of the nectary to the process of fertilization and sought to show that his principles explained all the course of flowers — their position. size, odour, colour, form, date of flowering, etc.

The actual process of fertilization was first observed by the extremely acute and versatile Italian microscopist G. B. Amici (1786–1863). In 1823, working with a microscope which he had himself improved, he saw the Lube given off by the pollen grain and its contents perform streaming movements. In 1830 he followed the pollen tube into the ovary and observed it find its way to the micropyle of the ovule. These observations were confirmed by Robert Brown and M. J. Schleiden, and finally in 1846 the process of fertilization in flowering plants was placed upon a firm and recognized basis by Amici himself. Thus the general character of'the vital processes of plants was brought into relation with that of animals.

11. Metamorphoses and Alternation of Generations in Animals and Plants. — An obstacle to the conception of living things obeying general laws has always been the observation of the extrerne changes that some forms undergo. Such metamorphoses were the subject of exact study during the 17th century by Swammerdam and other naturalists. These observations were extended by many observers during the 18th century and notably by John Turberville Needham (1713–81).

A somewhat isolated position was occupied by John Vaughan Thompson (1779–1847), of whom it is said "feu- great naturalists have written so little and that little so good." As an army surgeon he spent several years in the West Indies, where he discovered that land crabs undergo a metamorphosis as remarkable as, though utterly different from, that of insects. Subsequently he was stationed at Cork. Ire., where in six miserably printed fascicules he announced a whole series of discoveries concerning life histories, among the most remarkable being his demonstration that barnacles are! in fact, Crustacea which pass through an active, free-living form.

In the early 1840s J. J. S. Steenstrup (1813–97) of Copenhagen described how jellyfish and parasitic worms produce offspring which at no time resemble their parents but which, on the other hand, bring forth progeny similar to the grandparents. Instances of "alternation of generations," as this process was called, were rapidly accumulated by naturalists from many different groups in the animal kingdom. An instance of such a curious cycle is in the common aphis of roses, in which there is an alternation of parthenogenetic and sexual generations. This had, in fact, been observed in the 17th century.

In 1851, a short time after the appearance of Steenstrup's volume, Charles Darwin published his first important monographs on a living group. In these works on the barnacles and allied organisms, he continued the work of Vaughan Thompson in showing that these creatures go through a remarkable metamorphosis, being

born as free-swimming Crustacea and subsequently settling down to fixed life in which they superficially resemble Mollusca, with which Cuvier had classed them. He also linked the living with the fossil forms. Darwin, moreover, demonstrated the curious feature that while individuals of this group were normally hermaphrodite, yet from time to time forms appeared that were male only, and there was at such times true sexual generation.

The interpretation of the phenomena of alternation of generations was unsatisfactory and vague. The botanist Karl Wilhelm von Nägeli (1817–91; *q.v.*) in the 1840s examined the prothallia of ferns and observed their free-swimming spermatozoa. At last in 1850 Wilhelm Hofmeister (1824–77; *q.v.*) gave a consecutive account of the actual process of generation in the fern, having observed the whole process of development from a single cell into the prothallus. He saw how the prothallus matured specialized cells, which, after conjugation, gave rise to the more conspicuous and well-known asexual form. He had demonstrated alternation of generations in the fern. He went on to show that the mode of production of the embryo in the pines and their allies was in certain ways intermediate between that of flowering plants and that of the ferns. Thus, by 1860, it was established that fertilization in flowerless plants consists in the blending together of the spermatozoid and the egg cell, and that in flowerless plants there is a definite alternation of generations.

Observations on the sexual character of plants, on the alternation of generations and on metamorphoses gave absorbing interest to the investigation of generation in general and stimulated the study of embryology of both animals and plants. These studies led to the firmer establishment and wider application of the cell theory and to the accumulation of facts used as data by the founders of the evolutionary school.

12. Establishment of the Cellular Nature of Animals and Plants. — The appearance of cell ualls is to be seen in many microscopic drawings of plant tissues made in the 17th century by the great classical microscopists. They distinguished between the various tissues of the higher plants, although they knew nothing of the substance within the cell wall. Not until the 19th century was there any adequate attention given to living substance of the cell. In some of the accounts of the microscopic 'appearance of the tissues of animals, cells had been vaguely distinguished, though much less definitely than in plants. During the 18th century little important microscopic work was done. At the beginning of the 19th century, M. F. X. Bichat (1771–1802), perceiving that the different parts of the body such as bones, muscle, nerves, blood vessels, cartilages, etc., had a different macroscopic appearance, succeeded in analyzing them into 21 "tissues," each of which had a certain microscopic unity. Out of this discovery arose the study of histology (*q.v.*), the word being introduced by Richard Owen (1845) and still in current use.

Between the 17th and early 19th centuries advances were made in the knowledge of unicellular organisms. *Vorticella* had been described in 1667, bacteria in 1683, *Paramecium* in 1702 and *Amoeba* in 1755. Several monographs dealing with unicellular plants and animals had appeared, but no advance had been made in appreciation of the real nature of these beings, which was first grasped by Felix Dujardin in 1841. In 1833 Robert Brown in his investigations on plant fertilization had discussed the nucleus and found it a normal accompaniment of the cell, but he had only a vague idea of the nature either of cell or of nucleus.

The term "cell theory," to cover the idea that all living things are composed of these elements, was coined by Theodor Schwann (1810–82) in 1839 and was given popularity by his writings and those of M. J. Schleiden (1804–81). The idea is often ascribed to these two men but was really a very gradual growth in which many workers were involved, among whom the names of J. E. Purkinje (1787–1869), M. H. Rathke (1793–1860), Johannes Mdller and G. G. Valentin (1810–83) should also be mentioned. Schwann has the special merit of showing how the ovum is itself a cell. Finally, he passes to a general statement as to the cellular origin of animals and plants. We may note that he introduced the word "metabolic." The word "protoplasm" was introduced by Purkinje, and the conception of this substance as the physical basis of life was the work of Max Schultze (1825–74).

With the final establishment of the cell theory, histology became a special science and was admirably developed by the Swiss Albrecht von Kolliker (1817–1905), a pupil of Johannes Miiller. The subject was extended into the department of disease by yet another pupil of Miiller, Rudolf Virchow (1821–1902; *q.v.*).

13. Organic Evolution; the Origin of Species. — By most older writers, species were treated as fixed and definite — as though their characteristics had been made once and for all and had never altered. Thus in the opinion of Linnaeus there are "as many species as issued in pairs from the hands of the Creator." Even Linnaeus, despite his systematizing obsession, began to see that it is often very difficult to separate species one from another. He did not move from his original position of creative fixity of species, but simply substituted the genus for the species as the original creation. He thus reached the conclusion that "all the species of one genus constituted at first one species."

Many early naturalists adumbrated the doctrine of the evolution of organic forms. The first who clearly set forth the idea as applied to existing living things was G. L. L. Buffon (1707–88). His great scientific work, *Natural History, General and Particular*, appeared in 44 volumes, and its publication occupied 55 years, 1749 to 1804, being completed after his death by one of his assistants. It aimed at containing all scientific knowledge and was the first modern attempt of the kind. In different parts of his great work and in other works Buffon expressed himself variously on the subject of organic evolution, but he moved further and further from the position occupied by Linnaeus. He finally accepted the conception that species alter in type from time to time, but that at each alteration they retain some marks of their previous type, as the pig, for instance, retains digits now in disuse but formerly used. He thus came to the conclusion that many species are degenerate forms of others; that the ape, for example, is a degraded man and the ass a degraded horse.

Similar views were set forth even more clearly by Erasmus Darwin (1731–1802), the grandfather of Charles Darwin. Erasmus Darwin held that species change in course of time and that these changes are the result of influences upon the individual from without and are passed on to the offspring. Thus he was a believer in the inheritance of acquired characteristics, a conception which was further developed by his younger contemporary Lamarck (*q.v.*), whose *Zoological Philosophy* appeared in 1809. Lamarck held that for living organisms there existed a "natural order." He thought that if all the species that have ever existed were known, they would be found to form a long ladder or scale in which each would differ but little from the next. This view Lamarck derived ultimately from Aristotle. The gaps that he could discern between the existing series he ascribed to the destruction of the intermediate links. These gaps he hoped would be filled in by paleontological discovery. We owe the word "biology" largely to Lamarck, but still more we owe to him the conception of biology as a comprehensive and self-contained study. Since, according to Lamarck, species shade into each other, it seemed to him improbable that they were permanently fixed. In reaching this conclusion, he laid much stress, as did Charles Darwin after him, on the peculiar development of domesticated animals. There must, he thought, be some agent acting to produce variations from the original type. This agent Lamarck believed to be environment.

He thus reached the conclusions, first, that species vary under changing external influences; second, that there is a fundamental unity underlying the diversity of many living things; and, third, that the diversity of living things is subject to a progressive development. The mechanism of that development Lamarck held to be use and disuse of acquired characters.

Discussion of the conception of the progressive development of living things with its corollary, the inconstancy of species, was raised by many writers in the first half of the 19th century, among them the French naturalist Étienne Geoffroy St. Hilaire and the German poet Goethe (1749–1832). In England a writer who attracted much attention was T. R. Malthus (1766–1834), whose important *Essay on Population* was first published anonymously in

1798 during the French revolutionary era; its tone and argument are not unrelated to the social views of the time—views which had their influence upon Darwin. Indeed, it is not too much to say that the *Origin of Species* is one of the secondary products of the utilitarian philosophy of which the chief expohent was Jeremy Bentham and the chief social product was the French Revolution itself.

The *Origin of Species* by Charles Darwin appeared in 1859. For the detailed nature of the views there expressed *see* DARWIN, CHARLES ROBERT. It created a revolution in thought in England and to a lesser extent in France and Germany. As is well known. it. deeply influenced Karl Marx. The cause of that change in opinion was not so much the doctrine of the impermanence of species. which had been voiced by many before Darwin, as that Darwin displayed to his readers the details of a process which could he seen in daily operation. Moreover, in setting forth his hypothesis of the action of natural selection he placed before his public a mechanism which he believed, and they believed, was sufficient to account for the process in question. His theory appealed specially to the practical minds of the English naturalists, who required an explanation of the process before they would altogether accept it. The theory naturally had less effect upon certain more philosophic thinkers, whom the actual evidence for the existence of evolution had already convinced.

In 1852, seven years before the publication of the *Origin of Species*, the philosopher Herbert Spencer (1820–1903) had set forth doctrines of evolution in which that word was probably used for the first time in literature to describe the idea of a general process of production of higher from lower forms. Sir Charles Lyell, of whom Darwin professed himself a disciple and who deeply influenced Darwin's whole thought and work, used the word 20 years earlier in a similar though less general sense. The word "evolution" was seldom used by Darwin himself, but the particular application given to it by Spencer rapidly caught on, and "Darwinism" and "evolution" were often treated as synonymous terms. The doctrines of Darwin, however, applied only and were meant to apply only to the world of life; nor even there can we regard the words "Darwinism" and "evolution" as truly synonymous, for it is quite possible to conceive of organic evolution that is independent of such Darwinian factors as natural selection or sexual selection. The phrase "survival of the fittest" was also coined by Spencer and caught on in the same way as did "evolution." Evolutionary doctrines were diffused by a host of expert biologists who were rapidly converted to the Darwinian point of view. Among them T. H. Huxley (1825–95; *q.v.*) in England and Ernst Haeckel (1834–1919; *q.v.*) in Germany were especially prominent.

Since Darwin, and especially in the 20th century, doubt has been cast on the evolutionary efficacy of those factors on which Darwin himself laid most stress. The conclusion that species do in fact give rise to other species has earned almost universal acceptance, and on the general relation of living things within the larger groups there is no wide divergence of opinion. It cannot be said, however, that any general agreement has been reached as to the process by which the great variation in living things has been produced, nor can it be claimed that there is any consensus as to the relationship of the main groups of living things to each other. Despite these reservations it cannot be gainsaid that the history of biology since the days of Darwin may be treated as in large part a commentary on his work. The stimulus which he gave to comparative morphology has given rise to a truly prodigious literature dealing with plant and animal forms. His work has acted as a less stimulating influence on those departments which deal with function, and comparative physiology remains in a relatively rudimentary state. The study of inheritance and of genetic characters, however, may be traced back directly to his example. A large part of the work since about 1880 in this direction has been done in confirmation or refutation of his views. (*See* DARWINISM.)

14. Biogenesis Versus Abiogenesis; the Origin of Life.—All the older naturalists. following Aristotle and Theophrastus. accepted spontaneous generation at least of the lower forms of life. According to them. spontaneous generation was the normal mode of production of certain organisms. These views were universal until the middle of the 17th century and the advent of microscopic research.

The exploration of' microscopic life soon revealed that many cases of apparently spontaneous generation were, at least, complex Malpighi showed that gall; nere not spontaneously generated but were associated with the larvae of an insect He traced these to their development as free-living forms but failed to infer that each nas the result of an implanted egg. On the other hand, the increasine poner of the microscope revealed the existence of more and more minute organisms which seemed to appear out of nothing Thus Leeuwenhoek saw such organisms in infusions of broth and other substances Such infusions, at first perfectly clear became in a few days turbid with vast numbers of minute. actively moving bodies which were for this reason called Infusoria

The first scientific treatment of the question of spontaneous generation was made by the Italian Francesco Redi (*c* 1626–97) His experiment. nere admirably designed and his conclusions lucidly set forth He exposed fresh meat in jars covered with fine gauze using as controls meat in other jars not so covered Soon in the open jars larvae of flies developed, while eggs corresponding to such larvae mere deposited on the surface of the gauze above the closed jars. but no larvae ever developed nithin the closed jars themselves. Redi traced the larvae to their parent:: and showed conclusively that their generation could be only through parent forms

With the extension of microscopic observation the problem became more complex, and during the 18th century the battle on the subject of spontaneous generation raged back and forth. On the one hand it was shown that by boiling or chemically treating a medium, organisms appeared in it slowly or not at all On the other hand. cases mere adduced in which microscopic organisms did so appear, despite all precautions About the middle of the 18th century the controversy reached an important stage in a discussion between John Turberville Needham and the versatile Abbé Lazzaro Spallanzani (1729–99) Thi- discussion is interesting since it was practically repeated about 100 years later between Pasteur and his opponents In 1748 Needham published what was in effect a repetition—made in conjunction with Buffon—of the experiments of Redi of the previous century His experiments however, nere more refined than those of Redi. since he aimed at excluding even microscopic organisms He came to the opposite conclusion to that of Redi and inferred that microsconic organisms are generated spontaneously in organic substances. Hi= apparatus consisted of a phial filled with broth, the mouth of the phial having been closed with mastic after the broth had been boiled. Needham's observations were good. but his methods were defective and his deductions obscure. He was effectively answered by Spallanzani, an investigator and writer of very great ability, who made important. contributions to several branches of biological science. Some of Spallanzani's experiments to test the truth of spontaneous generation were so exactly like those of Pasteur in the 19th century that the figures of Pasteur might be used to illustrate the memoirs of his predecessor.

The controversy concerning spontaneous generation continued in much the same state until 1859. During the previous year!: Pasteur had shown that putrefactive and fermentative changes in organic substances. and especially in fluids, were attributable to organisms. The question was as to the origin of the organisms Pasteur was well aware of the controversy between Needham and Spallanzani and took the side of Spallanzani. By 1859, the year of the *Origin of Species*, Pasteur was engaged in acute controversy as to the origin of life. The matter was brought to a head by a very fine series of studies which Pasteur published in 1861.

Spallanzani, in his experiments, had heated sealed phials containing putrescible substances. Their contents remained indefinitely without any sign of putrefaction or fermentation. These processes did not take place unless or until the phial was opened. The only effective criticism made on the experiments of Spallanzani was that by heating he had altered not only the infusions themselves hut also the air contained within the phial. To this Pasteur had his answer. It was the most triumphant of his experiments and beautiful in its simplicity. He introduced into a flask

an infusion of fermentable fluid. The neck was then drawn out into a long S shape, narrowed but left open. The flask and its contents were then raised to boiling point repeatedly and finally left at rest. The flask was left for days, weeks, months, undisturbed. No fermentation took place. Finally, the neck was severed, thus exposing the fluid to the fall of atmospheric dust. In a few hours the liquid began to ferment and organisms could be demonstrated under the microscope.

This is the critical experiment in a demonstration that there is no such thing. under present terrestrial conditions, as abiogenesis (spontaneous generation). The issue has been raised in various forms at various times and by various observers. but experiments comparable with those of Pasteur have always been devised in rebuttal. So far as any biological doctrine can be said to be firmly established, it is the doctrine that all living things are the product of living things. It is understood that this doctrine does not prejudge the question as to the first origin of life, nor does it prejudge the question as to whether life may have arisen at more than one date and in more than one place, nor does it prejudge the questions as to whether there are forms of life beyond microscopic vision, nor whether there are forms of existence between the living and the nonliving, nor does it prejudge the nature of viruses. It does, however, give to the biologist a conception of the nature of life comparable in its value as a standard of scientific research with the doctrine of the conservation of energy in the hands of the physicist. By chance, the movements which led to this demonstration on the origin of life were almost exactly contemporaneous with the movement which led to the establishment of the doctrine of organic evolution. Thus the modern period of biology may be said to have opened about the year 1860. (See also REPRODUCTION.)

15. Change in the Biological Outlook to the Modern Stage. — The whole outlook on the nature of living things underwent a complete and profound change in the period of about 20 years following 1860. This change may be ascribed to a variety of causes:

1. The discovery of the essential identity in the mode of reproduction of animals and of plants.

2. The discovery of the essential identity in the living substance of animals and of plants, and the emergence of the conception of protoplasm.

3. The examination of methods of nutrition and of respiration, and the realization that these too are fundamentally the same for all living things.

4. At first the differences of the food supply of animals and of plants seemed an insuperable barrier to this last step. Gradually, however, there emerged the conception that the chlorophyll apparatus was concerned with the manufacture of organic substances necessary for the nutrition of both animal and plant. The elaboration within the plant body, from atmospheric gases, of material for absorption into tissue came to be recognized as part of the mechanism of living nature as a whole. The view of the balance of life and of organic nature as one huge mechanism came to the fore.

5. The reduction of all living processes to terms of the cell.

6. An evolutionary view of life gave a new conception of what may perhaps be called the economics of nature. Thus there arose the tendency to examine the manner of life and habits of living things involving also their relations to other forms of living things.

7. The conviction that, so far as scientific experience extends, all living things are derived from living things and are not generated from nonliving things.

The combination of these conclusions and tendencies introduced so much alteration in the approach of biologists to the material with which they deal that we may speak of entering an entirely new era. During this new era much attention has been concentrated on genetics and the process of heredity. For long, under evolutionary influence, the subject of variation in animals and plants was intensively studied. It is, however, apparent that the real problem to be solved is why the offspring resembles, not why it differs from its parent. This is perhaps the main modern biological problem. It may be observed that Aristotle, the first biologist, most clearly visualized this very problem.

The conceptions of living substance and of organic evolution led naturally to the idea of the historic continuity of the protoplasm of the germ cells. For the protoplasm of the germ cells is clearly in a different position from that of other cells in conveying something of itself directly to the next generation. It is the vehicle of the hereditary elements, whatever these may be. This view was stressed by August Weismann (1834–1914), who gave the name "germ plasm" to the continuous factor. For him the offspring resembled the parent simply because it was derived from the same substance. Adult individuals are temporary fortresses formed to protect the continuous and deathless line of the germ plasm This plasm has passed through the countless generations that have been. Locked in its still mysterious complexity are the possibilities of all the generations that will be.

Is the germ plasm homogenous or do only some parts of it carry the hereditary qualities? The question can be answered only by examination of the structure and behaviour of the germ cells, and notably of their nuclei. This task occupied many observers during the later 19th century and first half of the 20th. Since inheritance comes equally from both parents and since the spermatozoon consists almost exclusively of nucleus, it soon became clear that it is the nuclei that carry the main hereditary elements. Weismann asked whether the germinal nuclei could have characters impressed upon them from without. He concluded, on experimental and theoretical grounds, that they could not, and that acquired characters were not hereditable. Subsequent research supported him in the sense in which he understood the term "acquired." The problem, however, took a new turn with the passage of the 19th into the 20th century.

In the last decade of the 19th century numerous examples of discontinuous variation or "saltations" accumulated. William Bateson (1861–1926) collected these (1894) and gave much attention to them. Papers on such saltations written between 1866 and 1869 by an obscure Moravian priest, the abbot Gregor Johann Mendel (1822–84; *q.v.*), were rediscovered simultaneously by several workers in 1900. Mendel demonstrated that in certain cases these saltations occurred according to certain simple mathematical rules. As it happened, the phenomenon of nuclear subdivision in the germ cells had been the subject of intensive microscopic analysis during the previous decades, and the phenomena of "Mendelism" were soon seen to be explicable in reference to these. A major preoccupation of biologists since 1900 has been the tracing of the parallelism between the deportment of the germinal nuclei and the structure and function of the formed organism; that is, between the "genotype" and "phenotype."

Here we are beyond the range of the historian and within the realm of current science. It may be well to end by summarizing the main streams of biological activity during the 20th century.

1. Intensive study of species — taxonomy and systematics — has become centred mainly in the great national collections. Although no compendious definition of the idea of species has been reached by taxonomic methods, the direction of genetic research suggests that a more exact definition of that term is being approached.

2. The physical, physiological and biological associations of living organisms — ecology — have become main objectives of field studies which have become largely concerned with population problems. The subject is recognized to be of human and practical as well as scientific and theoretical importance.

3. Analysis of the behaviour of the germ-cell nuclei in relation to phenotype characters has developed as the independent science of genetics, with many subdivisions. Genetics is now a main topic of biological research and has already acquired profound implication with almost every department of biology.

4. The process of physiological analysis has gone far. Attention has turned to the consideration of the interdependence of functions and even to their integration so as to consider the organism as a whole. The result is a picture of bewildering complexity in which an immense number of chemical and physical processes go on simultaneously, crossing, recrossing and modifying each other within the limits of each cell. Thus the physiology of

a protozoan is, if anything, more, not less, complex than that of a "higher" organism.

5. Study of viruses has become intensive, leading to a blurring of the conception of "vital" phenomena. It is still doubtful whether a virus can be described as living and, indeed, as to what we mean by living. In any event it is as yet impossible to say whether or not a virus can be said to breach Pasteur's law of universal biogenesis.

6. Underlying much biological thought of the early 20th century was a sense that "the substance of life," like inert matter. must be resolvable into ultimate particles—"quanta" of life, comparable with "quanta" of inheritance (Mendel) and "quanta" of energy (Planck). Thus, with the rediscovery of Mendel (1900), biology entered a stage comparable with that which chemistry had entered far earlier, when the molecular theory was first scientifically expounded. (C. SI.)

II. THE LIVING ORGANISM AS A NATURAL BODY

1. Definition. — It is first essential to understand what is meant by a living organism. The necessary and sufficient condition for an object to be recognizable as a living organism, and so to be the subject of biological investigation. is that it be a discrete mass of matter, with a definite boundary. undergoing continual interchange of material with its surroundings without manifest alteration of properties over short periods of time and, as ascertained either by direct observation or by analogy with other objects of the same class, originating by some process of division or fractionation from one or two pre-existing objects of the same kind. The criterion of continual interchange of material may be termed the metabolic criterion. that of origin from a pre-existing object of the same class. the reproductive criterion.

A few inanimate systems satisfy the metabolic criterion; the best example, and one that has rightly been the source of poetic analogy. is afforded by steady flames. which have a definite boundary. may remain unchanged for an appreciable time and are continually taking up oxygen and producing carbon dioxide and water.

Physical systems not undergoing chemical change and so providing less perfect analogies are provided by waterfalls, the spouts of waters from fountains and whirlwinds, though in the last case the boundary throughout is indefinite. In none of these cases is the reproductive criterion satisfied. The reproductive criterion is necessary to distinguish living organisms from the systems just enumerated. which are known to arise in ways other than by fragmentation of pre-existing members of the class. Since in many cases the history of any particular object to which the definition is to be applied may be unknown, it is necessary in stating the reproductive criterion to introduce the idea of classes of different kinds of organisms that can be recognized by characteristics of form and behaviour.

Logically, the property of the class of living organisms, to subdivide into a number of such classes of lower order, is to be regarded as an empirically established property of the same kind as a number of other general properties investigated in biology. It is necessary to include such a restriction in the definition to make it workable. Otherwise, however well a cat mere fed and however carefully its carbon dioxide output were determined, it would be impossible to ascertain that it was alive, in spite of a continuing capacity to tear the upholstery, unless observations had been made at the moment of birth. Both a cat and an oak tree are known to be alive because the metabolic criterion can at any time be shown to apply to both, and because both are recognized as members of the class Cat or Oak Tree, no members of which have ever been observed to arise except from pre-existing cats or oak trees.

In applying the metabolic criterion. the qualification over short periods of time is introduced because living organisms may grow, positively, or more rarely negatively. When marked disturbance of the metabolic process and its final cessation take place, the organism is said to have died. In practice, the classificatory principle is applied more or less unconsciously in all judgments of the existence of life. Most animals are recognized as alive by power of spontaneous movement. but enough data are available to indicate an overwhelming probability that, if a body can demonstrate complex spontaneous movements, it also satisfies the more general requirements.

Certain difficulties may. however, arise in applying the definition in rare cases. The satisfaction of the metabolic criterion may be suspended in the case of latent or suspended animation, in seeds and in a few small invertebrate animals that can be dried and are then capable of exposure to temperatures little above absolute zero (−273° C.). Such cases could he taken care of by indicating. the conditions under which the experiments implied by the definition were to he performed.

2. Properties **of** Living Matter. — The matter composing the bodies of living organisms may be conveniently termed living matter. This term will he employed to mean the entire material of a living organism, protoplasm (*q.v.*) being used to mean the colloidal organic system of substances in which active metabolic change occurs.

Elements.—When living matter is subjected to chemical analysis in the ordinary way. it is of course killed. but no change in mass has ever been shown to accompany death, so that analysis will at least indicate the elements present. The commonest atomic species is found to be hydrogen, the next commonest oxygen, most of both being combined as water: after these follow carbon and nitrogen. The water that can be removed from an organism by drying at 105° *C.* is quite variable. but usually lies between 50% and 90% of the live weight. Of the dry matter left over, carbon will constitute about one-half except in cases in which there is a massive mineral skeleton. The average content of the other elements can be judged from the mean composition of terrestrial plants. Terrestrial animals will be higher in nitrogen and sodium. lower in potassium, silicon and aluminum; vertebrate and other organisms with calcareous skeletons will have more calcium, marine organisms more chloride, and often more water, than terrestrial.

Mean Percentage Mass of Elements in Terrestrial Vegetation

O (oxygen)	70	B (boron)	0.001
C (carbon)	18	Zn (zinc)	0.0003
H (hydrogen)	10.5	Rb (rubidium)	0.0002
Ca (calcium)	0.5	Ti [titanium)	0.0001
N (nitrogen)	0.3	Cu (copper)	0.0001
K (potassium)	0.3	Br (bromine)	0.0001
Si (silicon)	0.15	Mo (molybdenum)	0.00005
Mg (magnesium)	0.07	Y (yttrium) and rare earths	0.00004
P (phosphorus)	0.07	Ni (nickel)	0.00002
S (sulfur)	0.05	V (vanadium)	∽0.00002
Cl (chlorine)	0.04	Pb (lead)	0.00002
Na (sodium)	0.02	Li (lithium)	∽0.00001
Fe (iron)	0.02	U (uranium)	∽0.00001
Mn (manganese)	0.007	Ga (gallium)	∽0.000003
F (fluorine)	0.003	Co (cobalt)	0.000002
Ba (barium)	0.003	I (iodine)	∽0.000001
Al (aluminum)	0.002	Ra (radium)	0.000000000001
Sr (strontium)	0.002		

It has become customary to divide the elements found in living matter into groups; many schemes have been proposed, but in most cases the general underlying thought may be expressed in the following way:

Water as the dispersing medium: hydrogen, oxygen.

Organic structural elements forming the main organic compounds in the bodies of organisms: hydrogen, oxygen, carbon, nitrogen, sulfur. phosphorus and, in some cases—in much smaller amounts — chlorine, bromine and iodine, and possibly selenium and arsenic.

Elements of the ions involved in regulating water exchange and electrical phenomena: hydrogen, sodium, potassium, magnesium, calcium, chlorine, sulfur as SO_4^{2-}, carbon as HCO_3^-, oxygen in cations. Boron in plants may belong here.

Skeletal elements, forming hard inert structures: silicon, calcium, magnesium and rarely strontium and barium; iron, manganese and possibly aluminum in bacteria. carbon as CO_3^{2-}, phosphorus as PO_4^{3-} and, in small amounts, fluorine. The elements of the organic structural compounds (hydrogen, oxygen: carbon, ni-

trogen and sulfur) may also form skeletal material, such as cellulose, chitin or keratin.

Biocatalytic elements attached to organic compounds as parts of the catalytic machinery of the organism: iron, manganese, copper, zinc, calcium, magnesium, molybdenum and cobalt in some organisms. Gallium and boron in plants may belong here, as may vanadium in plants and animals and possibly scandium in plants.

Elements of no known function: lithium, rubidium, caesium, beryllium, lanthanum and other rare earths, germanium, titanium, antimony, silver, gold, mercury, lead, chromium, nickel, platinum, present in minute amounts in some organisms, also extremely small amounts of the strongly radioactive elements.

Certain organisms have a curious capacity for accumulation of specific elements for no apparent reason. Selenium is thus concentrated in a number of plants, notably certain species of *Astragalus*, in such quantities as to constitute a grave agricultural problem in certain localities. A number of plants, notably club mosses (*Lycopodium* species) concentrate aluminum. Barium is present in great quantities in the inner seed coat of brazil nuts and also accumulates in the chorioid layer of the mammalian eye. Arsenic is concentrated in many marine Crustacea, though in a relatively nontoxic form. Vanadium is likewise concentrated in some of the sea squirts (Tunicata) and in certain fungi.

The abundance or rarity of an element in an organism is no certain indication of its physiological importance. In the mammalian liver, the rarest element of known function is cobalt. Of this there are on an average about 14,000,000 atoms per cell. There is, however, no theoretical reason why an element should not play a part at a much lower concentration. Rubidium is vastly commoner than cobalt, but since it is probably transported with potassium, its abundance is of little direct physiological significance. The rarest element detected in mammalian tissue is radium, with about 23 atoms per cell. In spite of the numerous speculative suggestions that have been made. it is obviously improbable that the radioactivity of radium is of significance in cell physiology, for most cells would have to wait many years before one of their few atoms disintegrated.

Compounds.—When an attempt is made to analyze an organism in terms of compounds. it is found that a large number of relatively simple substances can be obtained, but that the bulk of the material consists of highly polymerized organic compounds colloidally dispersed in a dilute solution of electrolytes. Of these polymerized substances hy iar the most important are the proteins.

The compounds that can be isolated from living organisms are noteworthy for their extraordinary diversity. It would probably be possible to isolate from any organism more different kinds of organic compounds in true solution than there are kinds of inorganic minerals in the earth's crust. The detailed consideration of this vast array of substances belongs to biochemistry. These relatively simple compounds would be found to consist mainly of material undergoing chemical changes, rather than to be the machinery by which such change, termed metabolism, is brought about.

Enzymes.—The metabolic machinery by which chemical changes are brought about consists of enzymes. Essentially an enzyme is an organic catalyst capable of accelerating a specific reaction. All enzymes that have been isolated have proved to be proteins. In many cases special groups. attached to the carrier protein, can be recognized. Such are termed prosthetic groups. The prosthetic group may contain a metal, Fe, Mn, Cu. Zn or, in general, one of the biocatalytic elements, or as a coenzyme it may consist of organic compounds linked in various complex ways. The vitamins thiamin (B_1). niacin (nicotinic acid amide), riboflavin (B_2) and pyridoxin (B,) owe their biological importance to the fact that they are essential components of the prosthetic groups of various enzymes. They are in fact part of the general machinery of living. Until recently it was usually believed that the enzymes constituted a small proportion of living matter. In 1939 W. A. Engelhardt and M. N. Ljubimova indicated that the protein myosin, long known as one of the main constituents of muscle, is inseparable from the enzyme adenosinetriphosphatase. which plays a part in muscular contraction. It is almost certain that the two substances are identical. It is also realized that the respiratory pigments, such as hemoglobin, are not essentially different from enzymes. The view in the early 1960s was that the functional proteins of living matter are for the most part enzymes. Living matter therefore is in its most fundamental aspect a highly organized system of enzymes dispersed in an aqueous solution. It is uncertain to what extent the supposedly unaltered proteins derived from tissue extracts are present in the cell in the forms studied in the laboratory.

Electrical Phenomena.—All biological activity appears to be accompanied by electrical changes. This has long been known in the case of rapid changes in animals and is employed daily in medical diagnosis with the electrocardiogram. It is, however, apparent that electrical phenomena are far more general than this. All living organisms exhibit potential gradients when points on their bodies are led off to sufficiently refined potentiometers. Many biochemical mechanisms exist which might be postulated as giving rise to potential gradients. The elementary fact that various ionized salts play an important part in the composition of living matter would suggest that diffusion and membrane potentials might easily arise. A full explanation of biological potentials is, however, not forthcoming. and many different factors are certainly involved. Some investigators have regarded the electrical fields exhibited by organisms as their most fundamental property. It must, however, be realized that electrical fields can be demonstrated very generally in nature. The whole concept of a field represents a high degree of abstraction. The field is known only by the behaviour of the test objects introduced into it. In the absence of such it is unobservable, and there may well be great objections to basing a far-reaching theory on an unobservable abstraction which is apt to develop exactly those properties that the investigator wishes it to have.

Optical Activity.—A general character of all organic compounds produced in organisms is their optical activity. In almost every case, when an organic compound found in an organism possesses an asymmetric carbon atom, with four different groups attached tetrahedrally, one of the two possible mirror-imaged configurations is found exclusively or in great excess over the other. When the same compound is synthesized in the laboratory from its elements, the two configurations tend to be equally abundant. Louis Pasteur, who investigated this phenomenon, regarded it as a fundamental property of organisms; it is presumably dependent on the structure and extreme specificity of the enzymatic systems involved in biological synthesis.

Dynamic Properties.—Passing to dynamic properties it is clear that the living systems are not in equilibrium. A continual source of energy is necessary to maintain their integrity. If this source of energy is cut off, death intervenes. Two sources of energy are theoretically available to any organism. the chemical energy of compounds in its immediate environment. and the energy of radiation impinging upon the surface of the organism. In general. green plants and some coloured bacteria utilize incoming radiation; all other organisms utilize the chemical energy of compounds directly or indirectly derived from the photosynthetic products of such green plants and coloured bacteria.

Studies With *Radioactive Isotopes.*—The discovery of artificial radioactive isotopes by I. Curie and F. Joliot in 1934 and the separation of natural stable isotopes first achieved by H. C. Urey and others have provided a new biological instrument of immense power which has revolutionized general concepts of the chemical processes of organisms. These discoveries have permitted the marking of chemical compounds passing into the organism in such a way as to make possible the recognition of the metabolic products of the individual dose of material administered. Such a method was indeed first applied by G. Hevesy in 1923 in a study of lead translocation in plants. using lead isotopes from natural radioactive material, and later was extended. notably by Hevesy and A. Krogh. using radiophosphorus, and by R. Schoenheimer, using natural stable isotopes of hydrogen and nitrogen.

The immense development of isotope production in atomic energy plants after 1945 made these techniques available in all large laboratories by the mid-1950s. The resulting addition to biologi-

cal knowledge is comparable only to that resulting from the invention of the microscope in the 17th century.

The most striking general result of these studies was the demonstration that practically every chemical system of the organism is in a continuous state of change, being remodeled with a quite unexpected rapidity. The most spectacular demonstration is perhaps provided by the case of an antibody in the blood of an animal that is gradually losing its immunity. It might be supposed that in such a case the antibody would slowly be destroyed by a relatively simple process. Actually studies with food materials containing the heavy isotope of nitrogen N^{15} indicate that even during the period of loss of immunity the antibody is still being synthesized, though destruction is in excess of production. In every case investigated, the chemical structure of living matter seems to be in a state of continual formation (anabolism) and dissolution (catabolism). When anabolism dominates, growth takes place; when catabolism dominates, a decrease in size takes place and, in its most fundamental aspects, death ultimately occurs.

Cell Structure.—The properties so far discussed are primarily biochemical; prior to their discovery certain other general properties of living matter were apparent. Of these, one, implied in the very term organism, is of great significance, namely the tendency for organisms to have a definite structure. Two fundamental grades of structure are manifested. In the more complex plants and animals individuals are usually constructed of units known as cells. The term was introduced by Robert Hooke in 1665 to describe what would now be regarded as the empty cell walls in a piece of cork, though Hooke was aware of the juices that filled the cells in living plants. Since early in the first quarter of the 19th century it has generally been recognized that such cells are almost universally present in the higher animals and plants, forming the structural units of such organisms. This generalization is usually described as the cell theory and attributed to M. J. Schleiden and Theodor Schwann, though at least in some aspects it was held by Lamarck prior to 1809 and no doubt formed part of the intellectual apparatus of many workers during the succeeding two decades. Each cell typically consists of a central, usually spherical. nucleus and an outer heterogenous region termed the cytoplasm. The substance of the two together is usually termed protoplasm by biologists, though in spite of a distinguished history the term by mid-20th century had little utility and might well be abandoned. Within the cytoplasm a great variety of liquid spaces (vacuoles), reserve materials (metaplasm) and highly differentiated structural elements (mitochondria, vacuoles and plastids in plants, etc.) are often present. The cell is bounded by a membrane, the nature of which has given rise to much discussion; it probably varies from organism to organism and from stage to stage in development. In plants. a cell wall, at least initially composed of cellulose, surrounds the cell membrane.

An important step in the development of the cell theory was the discovery that there exist many organisms which consist apparently of a single unit of general structure comparable with the cells of the higher plants and animals. Such organisms are generally said to be unicellular. There is a modern tendency to speak of them as acellular, meaning not divided into cells. Since the number of cells varies enormously in the many-celled organisms. there is no logical reason why the number should not be one, and the term unicellular will be used. Such usage is in line with G. A. Baitsell's ingenious suggestion that since the cell is the smallest unit, either of a multicellular or unicellular organism. to exhibit all the properties of living matter, it may in some respects be regarded as a molecule of living matter. The transition from the unicellular to the multicellular condition represents one of the great events in organic evolution.

Among the higher unicellular organisms there is no doubt that the fundamental structure of both nucleus and cytoplasm is essentially comparable with that of the cells of multicellular species. Among the bacteria great diversity in cell structure appears to exist and no generalization is at present possible. If cellularity be defined as the condition of consisting of one or more structural units. then it is a characteristic of all living organisms at some stage in their life history; if it implies a definite cell structure with at least nucleus and cytoplasm, it is probably not a universal character. All organisms however, show some degree of structural heterogeneity though in the smallest this can only be demonstrated by means of the electron microscope

As is indicated below. the nucleus, which contains highly polymerized deoxyribonucleic acid combined with protein to form nucleoprotein, is certainly involved in maintaining and transmitting the specific inherited characters of the organism; while it is usually assumed that ordinary metabolic processes largely accur in the cytoplasm.

The evidence for the genetic function of the nucleus is unequivocal, but many investigators have concluded that it also plays an important role in the control of metabolic activities of the cytoplasm During cell division at least in multicellular organisms and in a number of unicellular forms also. the dividing nucleus is seen to form a number of discrete chromosomes. each of which somehow reproduces to provide the chromosomes of the daughter nuclei.

The development of the electron microscope after World War II added greatly to knowledge of the fine structure of the cell.

In general the cytoplasm appeared to consist of a fluid ground substance traversed by a reticulum, or network. of hollow strands or membranes and containing also a number of discrete bodies known as mitochondria, the existence of which had been knonn from ordinary optical studies since the end of the 19th century. The reticulum in the otherwise clear cytoplasm was believed by some workers to be involved in protein synthesis.

The mitochondria have a characteristic structure being divided by large numbers of double-walled partitions. Preparations of relatively pure mitochondria can be obtained by centrifugation They undoubtedly consist in considerable part of the enzymes that are involved in respiratory metabolism and in the mobilization of energy in the biochemically convenient form provided by high-energy phosphate linkages.

Specialized cell organelles, notably the green plastids of plants. Mere found to have very elaborate types of fine structure. A particularly interesting aspect of electron microscopic studies was the discovery that flagellums of motile cells in both the plants and animals have an extremely characteristic structure in which nine fibrils are arranged peripherally and two centrally. Few morphological discoveries have so clearly demonstrated the essential uniformity of living beings as this.

The existence of double refraction and the difficulties that have arisen in attempts to determine the viscosity of cytoplasm suggest that liquid crystals are important.

Size.—There is evidently an upper size limit to organisms of the order of about 325 ft. The nature of the limitation is probably mechanical. but is certainly expressed in many different ways. A tree of ordinary form is unlikely to exceed this limit as Galileo showed in 1638: if it grew taller it would bend under its own weight when displaced ever so little from the vertical by the force of the lightest breeze In the large whales the greatest of marine animals, simple mechanical stability presents little problem in the water. but other difficulties. notably the fact that with a constant shape the volume of the tissues to be nourished increases as the cube of the length while the absorptive surface of the gut increases as the square of the length will ultimately set a limit to the maximum size attainable by an organism of any given form These problems have been discussed intermittently by physicists and biologists since the 17th century. and are most completely treated by Sir D'Arcy Wentworth Thompson in his classical treatise. *On Growth and* Form (1917; rev. ed , 1942), a work as remarkable for the wealth and ingenuity of the illustrative material as for the beauty of its prose style..

The lower limit of size raises more difficult questions. The definition of a living organism that has been given above is framed to exclude the smaller crystallizable viruses. The larger viruses, such as the smallpox virus seem to have properties comparable with those of bacteria suggesting that the lower limit of the mean diameter of an organized cell is unlikely to be less than the order of magnitude of 0 1 μ (ie., $\frac{1}{250,000}$ in.). Assuming

a normal chemical composition, it is improbable that the space enclosed in such a cell could contain the full complement of chemical machinery present in the larger cells of animals and plants.

Growth and Change.—In both reproduction and in the widespread phenomenon of regeneration there is seen a clear tendency on the part of living matter to grow and to change until it achieves or returns to some characteristic form or pattern. This is most strikingly shown in monozygotic twinning in which the two pieces of a very early embryo that has fallen apart, either naturally or artificially, form not two half embryos but two perfect individuals. The degree of development of this property is variable, but some indication of its presence can always be found (*e.g.*, in wound healing).

Irritability and Adaptability.—A general property of living organisms usually recognized but not easy to define is variously known as irritability, adaptation or adaptability. The terms are often used in different senses. By irritability is meant the capacity of an organism or a part of an organism to respond in a specific way to some change, or stimulus, in the surrounding medium. There is no immediate clear-cut distinction between the classical cases of irritability, exhibited by a nerve attached to a muscle which contracts when the nerve is pinched, and the much simpler reaction of a piece of ice, which melts when the temperature of the environment is raised. It is, however, probable that all the cases normally regarded as involving true irritability involve the release of energy in amounts disproportionately large compared with the energy of the stimulus.

By adaptability is meant the capacity of an irritable organism to effect a response of such a kind that the chances of its persistence in a living state are increased. In nonmotile organisms such as cocciform bacteria, adaptability is mainly shown in the possibility of the organism becoming able, in the course of time, to deal metabolically with substances present in its environment in a way that promotes its growth but that initially was impossible. In rapidly dividing unicellular organisms it is obviously difficult to distinguish such individual adaptation of cells from the accidental appearance of adapted mutations. It is therefore quite possible that true irritability and adaptability are not exhibited by all organisms. In motile organisms adaptability is of enormous importance, and is exhibited in a great variety of ways, varying from the simple movements of a unicellular green plant from darkness to light to the most complicated aspects of human behaviour.

Uniformity of Class.—Even in framing the definition of a living organism it has been necessary to introduce the concept of different classes of organisms. It is a remarkable though seldom recognized fact that within a given size range a group of organisms may be the most uniform set of objects in any small volume of inhabited space. Thus a flock of starlings or of juncos is a class of far more uniform objects than the stones in the meadow they are visiting. This uniformity is also shown at a lower level in the cells of a given organ. It may well be an expression of the fundamental molecular mechanism of inheritance and development, for it is doubtful if such specific uniformity is met with in nonbiological structures until a molecular order of magnitude is reached. The number of different biological species is admittedly enormous; more than 1,000.000 animal species and more than 300,000 plant species are known. It is now generally held by those most experienced in the matter that, at least in multicellular organisms, real discontinuities in breeding populations do exist, and that in general plants and animals can be separated into specifically distinct groups.

III. THE BIOSPHERE AND ITS INHABITANTS

1. The Biosphere.—The high temperature of Mercury and the low temperatures of the outer planets would prevent anything like terrestrial living matter from occurring on their surfaces. Mars is the only planet on which there is any reasonable prior expectation of the existence of living matter The atmosphere of Venus appears to be without water vapour and to have an equatorial temperature at the base of the reflecting layer of about 100° C. These circumstances alone make the existence of living matter very unlikely. Mars clearly possesses a little water, perhaps entirely present as solid and vapour. Although the reflection spectrum of the greener patches on Mars is not like that of a green leaf it does resemble that of a lichen or dried moss. At mid-20th century many authorities, notably G. P. Kuiper, beiieved that the possibility of the existence of a low type of plant life on Mars is very reasonable.

The region of the earth in which organisms are found is known as the biosphere, a term introduced by Lamarck, but little employed until the publication of W. I. Vernadsky's remarkable book La *Biosphère* in 1929. The biosphere extends vertically upward in the free atmosphere to a height of at least 32,800 ft., as bacteria and fungal spores have been collected at that altitude. In the vicinity of high mountains, notably Mt. Everest, birds have been observed flying at altitudes as great as 27,000 ft. Terrestrial animals reach 22.000 ft. on Mt. Everest, at which elevation R. W. G. Hingston found immature jumping spiders. In the opposite direction the biosphere extends to the greatest depths of the oceans and to a few thousand feet below the land surface. Bacteria are found in water percolating through newly exposed rocks in mines, and apparently live in petroleum at considerable depths. The vertical range of green plants is less than that of bacteria and animals, the greatest altitude recorded being 20,340 ft. for glacial larkspur (Delphinium *glaciale*) in the Everest region, while in the sea living algae seldom occur below 1,000 ft. The biosphere thus presents a curious fundamental structure, in that the vertical range of consumer organisms is greater than that of the producing organisms on which they depend for energy sources. The greater downward distribution of consumers in the sea is explained by the gravitational sedimentation of particles of organic material ultimately derived from plants. The greater upward extent is probably because of minute organic fragments, such as pollen grains, being carried up mountains by wind. Such particles would be suitable food for minute insects, such as springtails (Collembola) on which the Everest spiders may feed. A tendency to fly upward but at a definite distance from the ground has been observed in some mountain insects and would also bring animals above the limit of vegetation. The biosphere may be characterized as the region in which liquid water can occur, the region in which many interfaces, liquid-solid, solid-gas, gas-liquid, can exist and ihe region in which incoming radiation other than the shortest wave lengths meets opaque matter, and, in the absence of organisms, is dissipated as heat. The importance of liquid water is immediately apparent, since organisms consist so largely of this material. The importance of interfaces is less obvious, but much ecological work suggests that large bacterial populations only occur in natural unpolluted waters in relation to solid surfaces, and the phenomena involved may be of great theoretical interest. The biological importance of soil lies largely in the great surfaces available on the submicroscopic particles of which it is composed. The significance of incoming radiant energy is of fundamental importance on account of the unique properties of the green plant.

2. Energy Cycle in the Biosphere.—The green plants of the biosphere constitute a mechanism by which a part of the solar radiation falling on the surface of the earth is diverted from immediate dissipation as heat and appears as the chemical energy of various organic compounds. The fundamental photosynthetic reactions occur only in the presence of a special pigment that is activated by light. Their over-all effect may be simply written:

$$\underset{\text{carbon dioxide}}{6CO_2} + \underset{\text{water}}{6H_2O} \longrightarrow \underset{\text{glucose}}{C_6H_{12}O_6} + \underset{\text{oxygen}}{6O_2}$$

but glucose is certainly not the primary product of photosynthesis (see PHOTOSYNTHESIS). Moreover, largely owing to the work of C. B, van Neil, a number of reactions of this general type are now known in purple and green photosynthetic bacteria, which do not necessarily produce oxygen. From the standpoint of the general economy of the biosphere the important feature of photosynthesis is that carbon dioxide is made to react with a hydrogen donator in such a way that a more reduced carbon compound is produced and a more oxidized by-product is derived from the hydrogen donator. Oxygen, the typical oxidized by-product, is a gas and

largely diffuses into the atmosphere; the reduced carbon compound forms part of the body of the photosynthesizing organism and on the death of the latter may contribute to solid decomposition products. The result of photosynthesis is thus to maintain an oxidized and a reduced zone in the biosphere. The oxidized zone comprises the free atmosphere, most of the oceans and inland waters; the reduced zone. part of the soil, oceanic and lacustrine muds, many sedimentary rocks and the bodies of organisms themselves. Since oxygen is continually lost in sediment formation when ferrous iron is oxidized to ferric, as is obvious when the reddish crust of weathering on gray or greenish igneous rocks is observed, and since carbon is lost to sediments as coal, petroleum and as more dispersed organic carbon, the supply of CO_2 must either be continually decreasing or must be replenished by volcanoes. The former view leads to difficulties and the latter, which implies that life is dependent upon continued vulcanism, is now usually accepted. If allowance be made for the CO_2 that has gone to make the limestones and other calcareous sediments, the rate of loss is seen to be greatly increased. Viktor M. Goldschmidt estimated in 1934 that the mean annual requirement of volcanic CO_2 is $3 - 6 \times 10^{-6}$ g. per square centimetre of the earth's surface.

The fraction of solar energy reaching the earth's surface that is trapped by the photosynthetic mechanisms of plants is very small. In 1944 Gordon A. Riley, whose estimates allow for the great ocean surfaces of the earth, concluded that between 0.06% and 0.18% of the incident radiation was so used. Later work appeared to suggest that the true value is nearer the lower than the upper limit. The fundamental limitations which reduce this efficiency to so low a value are probably distributions of rainfall on land and distribution of certain essential materials such as combined nitrogen. phosphorus and iron in the ocean. These distributions set limits to the amount of photosynthetic machinery that can exist in the biosphere. About 30% of the energy accumulated by plants is used in their own metabolic processes. According to Raymond L. Lindeman (1941. 1942) approximately 10% of the energy fixed by plants is transferred to herbivorous animals. Most of the remaining energy, roughly 60%, is degraded to heat by bacterial decomposition on the death of the plant body. The amount stored in the sediments is small, and of this the amount that could become available later as fuel is but an insignificant fraction of the total. *(See* also ECOLOGY, *ANIMAL.)*

3. The Self-Sufficiency of the Green Plant.—All the available evidence indicates that most green plants can grow in the presence of light on a medium containing only inorganic compounds. A complete medium thus consists of water, oxygen. CO_2, inorganically combined nitrogen (ammonia or nitrate), phosphate, sulfate, potassium, magnesium and minute amounts of a variety of other elements (trace elements), Fe, Mn, B, Cu, Zn, Mo, possibly Ga and some others. In at least some cases Ca, Na, Cl, Si, Co and Al are also necessary. No organic carbon compounds are needed in the majority of cases.

4. Theories as to the Origin of Life.—Some investigators, notably S. Arrhenius and by implication W. I. Vernadsky, have concluded that life has no historic origin, and that the earth was populated by minute organisms wafted about the universe by light pressure. Present knowledge of the short-wave ultraviolet radiation implied in the excitation of auroras casts doubt on this hypothesis as this radiation would probably destroy such free cosmozoa even if they were perfectly dry. The alleged recovery of bacteria from the interior of meteorites is not generally accepted. It is important to note that no observations clearly indicating the contemporary. genesis of living matter in nature have ever been made.

It might be supposed that since the green plant is self-sufficient, and could repopulate the earth in its present state if all life were destroyed, the initial organism was a photosynthetic organism, capable of coping with an environment that provided purely inorganic compounds. The capacity to do this, however, involves so elaborate a chemical mechanism that such a view is tantamount to accepting an act of special creation, removing the problem from the realm of science.

The antithetic view is to suppose a gradual evolution of organic compounds, some of which could serve as food for the evolving systems derived from others. This view has been ably supported by A. I. Oparin. The chief difficulty that the second theory must face is the nature of the energy sources involved in the evolution of organic matter. Oparin suggested that hydrocarbons. formed by the action of superheated steam on iron carbide. might be the starting point of the chain of synthesis leading ultimately to primitive organisms. This view in effect suggests that the energy source is thermal, some of the energy of the initially hot earth being stored chemically until temperature conditions permitted its utilization. Oparin's views are not entirely in accord with modern geochemical knowledge, in particular his initial source of hydrocarbons is quantitatively inadequate. An intermediate hypothesis, apparently due to J. B. S. Haldane, is that simple photochemical reactions. not involving chlorophyll, preceded the evolution of living matter.

A great advance along these lines was made in 1955 by S. L. Miller, who found that a large number of amino acids and other simple organic compounds are formed when mixtures of methane, ammonia and water vapour are submitted to a silent electric discharge for a few days. Short-wave ultraviolet light, which is less easy to use in the laboratory, would have provided a comparable energy source early in the history of the earth. By the early 1960s it appeared reasonably certain that oxygen was absent from the earth's early atmosphere, and since the exact mixtures of gases. provided it contained carbon and nitrogen compounds, water vapour and no oxygen, apparently svould make little difference to the result, it may be concluded that in the early stages of terrestrial history the liquid water at the earth's surface contained amino acids and other organic compounds in solution, perhaps in appreciable amounts. It appeared likely that solid organic matter, dark in colour and comparable with some of the inadequately characterized components of modern humus, would form at the same time.

The polymerization of the amino acids to form polypeptides and proteins raises certain special chemical problems, but at least the initial stages in the origin of living matter appear to be understood.

5. Plants, Bacteria and Animals.—Though the tendency to form classes of similar objects is characteristic of living organisms, the arrangement of these classes in higher categories presents many difficulties to the biologist. These difficulties are perhaps most acutely felt when an attempt is made to generalize the ordinary idea of plant and animal to cover the microscopic forms of life that have been described in increasing numbers since A. Leeuwenhoek first applied his minute but powerful lenses to infusions and pond water. Among the multicellular forms no difficulty arises. Plants are recognized primarily by their lack of special contractile tissues capable of causing spontaneous movement (except in cases where single-celled stages possess flagellums). by their cellulose cell walls and usually by their possession of the green pigment, chlorophyll. All animals possess special mechanisms that result in movement, though in many cases the movement is that of the water in which they may live rather than movement of the animal through the water. Almost all animals lack cellulose; if they appear to contain photosynthetic mechanisms, as in the case of reef-building corals, some flatworms and some bivalve mollusks, this is due to the presence in their tissues of symbiotic unicellular plants *(see* SYMBIOSIS). Even the criterion of motility has to be defined in a rather arbitrary way. The possession of either ciliated or flagellated epitheliums or of muscle cells is perhaps the most characteristic feature of multicellular animals. Many plants possess conspicuous if limited powers of movement, notably the sensitive plant, *Mimosa pudica.* In such cases, however, the mechanism is totally unlike that found in animals. 4 less obvious, if more fundamental: distinction may be traced in the nature of sexual reproduction in multicellular animals and plants. Although the criteria that separate the two groups may seem formal and arbitrary: there is now no doubt which multicellular organisms are plants and which animals. The plants are arranged in about 12 major groups, the animals in about 22 major groups or phyla. (The number of these groups varies from author to author and is subject to change as knowledge increases. See *Taxonomy* below.)

There is a great array of minute and simple forms that do not have a nuclear membrane. The genetic material, though probably present as chromosomes. certainly bears a different morphological relationship to the rest of the cell from that found in the higher forms with a distinct nucleus and cytoplasm. These organisms are sometimes placed in a group distinct from that of the true multicellular animals or plants. This group, for which the terms Monera or Mychota have been proposed, includes true bacteria and their allies the actinomycetes, the latter being filamentous forms which include *Streptomyces*, from which streptomycin is obtained, and *Mycobacterium*, a genus including the organism causing tuberculosis. The Mychota also include a large group of photosynthetic organisms commonly known as purple and green bacteria and blue-green algae. The purple and green bacteria use either reduced sulfur compounds or preformed organic matter as oxygen acceptors in the photosynthetic reaction, instead of producing ordinary molecular oxygen. The blue-green algae perform ordinary photosynthesis as do the higher plants. They often form massive populations in summer in ponds and shallow lakes. They are certainly more closely related to what ordinarily would be regarded as bacteria than to the other organisms commonly called algae.

The single-celled organisms in which discrete nuclei are present provide a difficult problem in classification. The most logical arrangement at first sight is to place all of them in a single kingdom, the Protoctista (from the earlier term "Protista"), separated from the Mychota by the presence of a discrete nucleus and from the higher plants and animals by their single-celled condition. Unfortunately within a given group of obviously allied forms it is possible to find single-celled species, species forming aggregates of unspecialized cells and multicellular species with quite well-differentiated tissues. It is also possible to find obviously related species, some of which are photosynthetic, some: feeding like animals and some living on dissolved organic matter. By the early 1960s it could be stated with some degree of certainty that all the higher terrestrial plants are derived from unicellular forms which would ordinarily be called green algae. It was quite uncertain from which of the many animallike protoctists the multicellular animals arose.

For the purpose of classification of individual species, which must be defined well enough to permit general recognition, an elaborate system is needed, but this must inevitably be somewhat artificial. For the purpose of understanding the economy of nature, me may roughly divide organisms into:

Typical green plants dependent solely on inorganic foodstuffs and radiant energy (holophytic nutrition).

Typical animals ingesting solid food of plant or animal origin (holozoic nutrition, or in some cases parasitic).

Typical bacteria and colourless plants taking up dissolved food passively or by external secretion of enzymes into the medium (saprobiotic or parasitic nutrition).

When it is remembered that the entire cycle is dependent on the green plant it will readily be understood that the mass of green plants exceeds that of the other types. On account of their small size. bacteria undoubtedly greatly exceed green plants in individual numbers, but the mass is small. Animals are usually relatively selective in their food habits. and may be confined to eating parts of plants, or they may be carnivorous. This permits a much greater diversity of type than found in plants, though the number of individuals is smaller. Whether the specific diversity of bacteria approaches or exceeds that of animals remains uncertain. If all animals have species-specific bacterial diseases. the number of species of bacteria is clearly greater than that of animals. *(See* also beginning paragraphs of PLANTS AND PLANT SCIENCE.)

6. **The** Problem of **the** Viruses. — In 1892 D. Iwanowsky observed that the causative agent of the mosaic disease of the tobacco plant could be passed through filters designed to retain visible bacteria but when a minimal dose of the filtrate was inoculated into a healthy plant, the causative agent behaved like a living parasitic organism, increasing in quantity within the host. During the succeeding 40 years a number of plant and animal diseases were recognized as caused by such filterable viruses. In 1935 W. M. Stanley, reinvestigating the tobacco mosaic virus. which can be obtained in great quantity, found it to consist. when outside the body of the host, of a crystallizable protein. Once in the host the presence of the virus causes the production of more viruses. Subsequently a number of other viruses, mainly causing plant diseases. were obtained in pure crystalline form.

In the early 1960s it was clear that the term virus included a great variety of infective particles which resemble each other only in passing conventional bacterial filters and in multiplying in suitable hosts. Some of the largest are probably comparable with minute bacteria, while the smallest, such as the agents of foot-and-mouth disease or of silkworm jaundice, have a diameter of only 10 $m\mu$ ($\frac{1}{10,000}$ mm) and appear to consist of pure ribonucleoprotein. The tobacco mosaic virus, which mas studied in great detail, consists of rods about 280 $m\mu$ long. These rods were believed to be formed of an outer protein and an inner ribonucleic acid fraction which can be separated and recombined in the laboratory. The protein from one strain can be combined with the nucleic acid of another strain, giving somewhat different symptoms when it infects a tobacco plant. In every case the symptoms follow the source of the nucleic acid. To use the expression of communication engineers, the information required to produce the specific symptoms is carried by the nucleic acid. It is possible even to use the nucleic acid without the protein to produce infection. When this is done the virus recovered from the infected plant consists of protein and nucleic acid. The protein has obviously been produced by the infected plant. It seemed probable that broken strands of nucleic acid under 280 $m\mu$ long cannot carry the information needed to produce an infection; at least when full-length intact rods were absent from electron microphotographs of a preparation, the latter was not infective.

By the mid-1950s a very curious situation became known in the case of some bacteria which carry a latent virus or bacteriophage which can be made pathogenic by ultraviolet light treatment. The latent provirus could not be extracted from the bacterial cell; it appeared to consist solely of nucleic acid and to be incorporated in the nuclear material, genetically known as chromosomes. of the bacteria. When it becomes active it produces bacterial dissolution which spreads through the culture. Some resistant cells may be infected but survive and these may now carry not only the provirus but also other genes apparently associated with it on the chromosome of the original strain from which the provirus was derived. This very peculiar type of hereditary transmission is called transduction. It emphasizes the fact that in the small viruses we have systems which exhibit the reproductive criterion of living matter, but by themselves not the metabolic criterion, stripped to its bare essentials. Though in many ways the crystallizable and other small viruses bridge the gap between dead and living matter they can only reproduce in pre-existing cells and so cannot represent an evolutionary stage in the history of life on earth. In the early 1960s it appeared by no means unlikely that some viruses have arisen by escape from the genetic material of the organisms that harbour them. *(See* VIRUSES.)

IV. THE METHODS OF APPROACH OF THE BIOLOGICAL SCIENCES

1. Morphology is the study of form. By itself, applied to a single organism, it can give but a momentary picture of the structure of the organism, proceeding from the larger features to the organization of the tissues (histology; *q.v.*) and of the cells (cytology; *q.v.*). The introduction of increasingly powerful methods, notably electron microscopy and X-ray diffraction analysis, has begun to give, in certain special cases, information on structure between the microscopic level and the molecular level. The results of such studies indicate that fibrous protein molecules play a great part in ultramicroscopic morphology. as for instance in muscle. The opening up of globular protein molecules to form fibrous molecules, and the reverse process. may be of considerable importance in the life of the cell. There is much indirect evidence that even the most fluid-looking cytoplasm is structurally oriented at a submicroscopic or molecular level.

In some very simple cases the morphology of an organism can

be analyzed not merely formally, but causally also, by geometrical or mechanical methods. The spherical form of marine eggs is doubtless entirely explained by the tendency of a liquid drop to possess a minimum surface.

It is, however, by no means certain that whenever a form is encountered for which a simple physical explanation can be given, that explanation is inevitably correct. There is much evidence that organisms by quite elaborate growth processes develop forms that simulate the forms due to much simpler physical forces. In such cases it is probably legitimate to assume that the final form is less subjected to physical strain than would be some other structure no harder to build embryologically, but not suggesting a simple physical process.

Of itself morphology usually raises questions, but does not answer them. Only when morphology (*q.v.*) becomes either comparative, physiological or developmental does it acquire significance.

2. Taxonomy. — Comparative morphology leads to the immediate recognition of a limited number of fundamental structural plans. Within such plans an immense diversity is possible, but groups of individuals tend to form populations of considerable uniformity, which in the higher organisms with sexual reproduction form interbreeding units. The study of the classificatory arrangement and the rational placing of newly discovered types within it constitutes taxonomy or systematics. Even among the higher plants and animals in which the criteria for classification are reasonably well established, the process of description is by no means complete. The comparatively recent (20th-century) discovery of the okapi and the giant panda indicates how large animals living in inaccessible regions may remain unknown. Birds are doubtless more completely studied than any group of like size and importance. yet the African peacocklike bird, the type of a new genus, *Afropavo congensis,* remained undescribed until 1936.

In the ocean there are doubtless many surprises still in store. A new major group of Crustacea, the Cephalocarida, was discovered by H. L. Sanders in 1953 in Long Island sound, a body of water studied for a century by naturalists. When the taxonomy of fossil forms in relation to recent species is taken into account! remarkable cases of unexpected affinity continued to be uncovered. The most extraordinary event of this kind in the 20th century was the capture of a coelacanth fish *Latimeria chalumniae* off the southeastern coast of South Africa; the group was previously supposed to have been extinct since the Middle Mesozoic. A somewhat comparable case is provided by G. E. Pickford's demonstration that the black octopuslike animal *Vampyroteuthis infernalis,* encountered by several deep-sea expeditions, and apparently a common animal at great depths in tropical latitudes. is not an octopus but the last survivor of a Jurassic group of cephalopod mollusks, differing radically from both the octopod and decapod types, though rather more closely related to the ten-armed cuttlefishes than to the Octopoda. An even more dramatic discovery was announced by R. Kozlowski in 1938. Examining particularly favourable material of the fossil group of graptolites, which had previously usually been regarded as coelenterates, he discovered that the skeleton is more complex than had been thought, and corresponds in its detailed structure with that of the living marine organism *Rhabdopleura,* which in fact can hardly be other than the last surviving graptolite; yet its soft parts place it in the phylum Hemichordata, the group of invertebrates most closely related to the vertebrates. The great graptolite populations of the early fossiliferous rocks thus appear to be offshoots from the same stock that must have been evolving to produce the vertebrates at the same time.

The justification of interest in taxonomy is not. however, dependent solely on these dramatic discoveries of affinity, nor on the great practical importance of taxonomy as the keystone of economic biology. Modern taxonomists are much concerned with the nature of their fundamental unit, the species. and of how species came into existence. This matter cannot be discussed until the problems of genetics have been considered. (*See* TAXONOMY.)

3. Embryology. — While morphology can give but a momentary static picture, the introduction of time as well as the three spacial dimensions permits the study of the dynamics of morphology. The individual is seen to run through a series of complicated stages, starting with a superficially simple cell. that finally reaches in the case of higher plants and animals an extremely complicated structure of many cells. The process normally involves growth or increase in size, cell multiplication, and differentiation or specialization and arrangement of cells in various ways to form the different tissues and organs of the adult body. The process by which this orderly series of changes takes place has fascinated biologists from Xristotle to the present day, but in spite of much of the best intellectual effort of the past century having been expended on the matter, it is still extremely difficult to understand. Normally, in the higher animals and plants. the process of development is initiated by the fusion of two cells, the egg or ovum derived from the female parent, the spermatozoon derived from the male parent. This fusion. or fertilization. seems to have a twofold function. The entry of the sperm appears to act as a stimulus to division by the egg cell. This stimulus is not always needed; some eggs develop unfertilized, and are said to be parthenogenetic. In many cases artificial stimuli such as shaking. heat shocks or a great diversity of chemical treatments suffice to start the egg dividing, though rather special conditions have to be fulfilled to obtain well-developed organisms from such eggs. Such special conditions are set by the fact that in the formation of most eggs and of almost all sperm, the cells from which they are derived lose half the normal complement of chromosomes. The second function of the sperm is to restore the full complement of chromosomes to the zygote or fertilized egg. Sometimes the haploid, reduced or halved number of chromosomes, is sufficient for further development. Sometimes in artificial parthenogenesis a division of chromosomes without a division of the egg cells restores the correct number. More usually debilitated haploid embryos are produced which die young.

It is very important to note that the egg cells differ, at least in the higher animals, from the other cells of the animai forming them in their competence to produce all types of cells appropriate to the species. In most cases the adult cells cannot do this. The difference, however. is not entirely sharp because many highly organized animals are capable of regenerating parts that have been removed accidentally or experimentally. It is apparent that the different cells of an animal undergoing regeneration differ widely in their capacity to take part in the process, and it is rare to find clear evidence that any cell other than a fertilized or parthenogenetic egg can give rise to all specifically appropriate tissues. During development the competences of the dividing cells of an embryo are more and more restricted. It is natural to inquire whether in the embryological history of the egg cell itself this restriction has occurred, the whole set of competences being restored as the egg matures, or whether a certain group of dividing cells is separated from the others, as germ plasm, retaining a full set of competences to be expressed by some when a new generation of gametes is formed. August Weismann's theory of the continuity of the germ plasm implies the special isolation of such an immortal group of germ cells within the soma. or nonreproductive body of the organism. As of the early 1960s no clear answer to this question had yet been obtained. It is certain that young unripe eggs cannot develop, but it is not certain that this is due to loss of competence, to be regained during later development.

In practically all multicellular organisms division of the egg produces a ball or mass of cells. In multicellular animals the ball, or blastula. becomes two layered, by one of a number of possible processes of gastrulation, and later begins to show, in all bilaterally symmetrical forms. a marked anteroposterior and dorsoventral polarity. In vertebrates and in echinoderms and a few other animals, the cells of the embryo can be shown to have become irreversibly determined to produce one particular kind of tissue shortly after polarity is established. In many other animals, including most mollusks and segmented worms, determination apparently proceeds much earlier. In the vertebrates this determination process has been shown, mainly through the work of Hans Spemann during the first quarter of the 20th century, to depend initially on a particular region of the upper side of the aperture, or blastopore,

through which the inner layer of the embryo has turned during gastrulation. Experimental transplantation of this organizer region from one embryo to another permits the production of secondary axes, expressed as nervous systems, eyes. ear vesicles and other structures. Joseph Needham, C. H. Waddington and their collaborators demonstrated in 1935 that the major effect of this organizer region can be imitated by a substance extracted from a variety of animal tissues with the chemical properties of a sterol. A number of other materials unrelated to natural sterols are also effective. A renewed attack on the problem by M. C. Niu strongly suggested that nucleoproteins are involved. It is, however, certain that the full process of determination of the axial structures involves far more than the mere local production of a specific evocator substance. Evidence of the existence of a variety of such substances exists, but above all it is the cells of the egg, as the reacting system, that are probably of greatest importance. Just as, in fertilization, an unstable system is stimulated to divide by the entry of a spermatozoon or by other agents, so in embryonic development the production of the main axis is doubtless the response of an unstable system of immense complexity to a stimulus that normally is provided by the local appearance of certain substances in the dorsal blastopore lip.

Much of the subsequent development of the organism can be shown to depend on the presence of secondary and tertiary organizers that are formed in local regions of the body. Thus in the usual method of formation of the eye, an organizing stimulus from the developing eye cup causes the epidermis above it to develop into a lens.

An interesting hint of the way that polarity is developed can be derived from the remarkable experiments of Ross G. Harrison. By rotating the region of a salamander embryo that would normally form a limb or an ear, or by transplanting the region to the opposite side of the embryo with or without rotation, Harrison was able to show that the three spacial dimensions of these organs are not determined at the same time. The tissue is set on its way to becoming a leg or an ear before it is restricted to becoming a right or left leg or a right or left ear. Joseph Needham ingeniously indicated that this phenomenon discovered by Harrison is comparable with the stages in the orientation of molecules in the formation of liquid crystals.

As well as considering the nature of the processes by which qualitative differences in different groups of cells are established, embryologists have been much concerned with problems relating to progressive form change during development, due to differences in rate of growth of different parts of the developing organism. Such differences have long been known in the human organism. It is easy to see that the young fetus has a disproportionately large head. In later development, both prenatal and postnatal, the trunk must therefore grow more rapidly than the head to establish the adult form. All embryological development of organs, as opposed to internal development of special cell structures, may in fact be regarded as due to the existence of a system of differential growth rates. Such systems are, however, best analyzed in the later stages of development. In many cases it is found that a rule connects the dimensions reached by any part y, in relation to the size of the whole organism x, such that

$$y = bx^k$$

In such a case if $k = 1$, the growth of the organism is uniform or isoauxetic (isogonic in older literature), if $k \neq 1$, the growth of the part is heterauxetic (heterogonic in older literature). The general application of this rule is due to J. S. Huxley. In cases in which the value of k remains constant during phylogeny or evolutionary change, any evolutionary size change will result in a change in shape. In such cases the adult of the smaller species will have a form comparable with an earlier smaller stage of the larger species. It is probable that many cases of extreme development of horns have resulted merely from high values of k in an evolutionary line that is increasing in size. D'Arcy Thompson pointed out that if a drawing of a plant or animal structure he made on graph paper, by applying a uniform transformation or distortion to the co-ordinate grid of the paper it is often possible to derive close representations of allied genera. This implies a geometrical ordering of growth rates as we pass from organism to organism.

A remarkable aspect of heterauxetic growth has been considered by Needham, who found that the equation $y = bx^k$ held not merely for the morphological aspects of development, but for the biochemical aspects also. Thus over a great variety of vertebrates the total calcium of the growing embryo increases as the dry weight raised to the power of 1.17 ± 0.04. Such results suggest a fundamental biochemical ground plan for growing embryos.

For many years after the publication of Charles Darwin's *Origin of Species* in *1859*, the chief interest of embryology lay in the aid given by comparative studies of development to the tracing of phylogenies or lines of descent. The fundamental postulate on which this work was based is the belief that the embryos of related organisms are more closely alike than the adults. This generalization, based on the work of C. H. Pander and K. E. von Baer early in the 19th century, is undoubtedly true as a statistically probable statement, but many clear exceptions exist. The basis of the principle is probably to be found in the simple proposition that any variation introduced early in the development of a pattern will have a greater ultimate effect than one produced later.

The extraordinary self-regulative powers of organisms. however, may make possible the development of two almost identical structures by diverse means. This is seen not only in comparative embryology. but in many cases in which the mode of development of an organ is strikingly different from the mode of its regeneration after operative removal.

Such problems introduce the concept of homology, which is conveniently mentioned in relation to embryological studies. The fundamental concept involved in homology is related to the ideas employed by mathematicians in the study of the very primitive geometry known as topology. Here ail lines that form closed curves on a plane, without crossing each other, are equivalent to circles. This is essentially the type of geometry employed when a morphologist says that the wing of a bat and the arm of a man are homologous, meaning that although the bones have different shapes, at least all the principal parts of the skeleton, with many of the associated soft parts, bear the same relationship to each other *(see* HOMOLOGY).

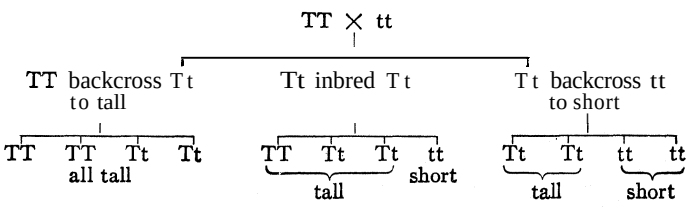
The concept of homology is less sharp than that of topological equivalence; where organs are so different in adult life as to permit no point to point comparison of the relationship of parts, the possibility of such comparison in the embryo or the existence of a similar relationship of the part to the whole is often used as a criterion of homology. The reverse situation of different modes of development, leading to two clearly homologous and similar organs, is also known. The modern biologist regards homology as based on community of descent, and so is apt unconsciously to regard structures as homologous on account of an evolutionary relationship postulated on other grounds. The idea of homology is, however, older in its topological than in its evolutionary aspects. Though no theorems of topology have found a place in biological theory, the general elementary topological point of view is of great assistance in understanding the comparative aspects of form and development. *(See* EMBRYOLOGY; INVERTEBRATE EMBRYOLOGY; VERTEBRATE EMBRYOLOGY; EMBRYOLOGY, EXPERIMENTAL.)

4. Genetics. — That like in general produces like has been known from time immemorial; that the process is not entirely regular has also been realized at least since attention was paid to the breeding of domesticated plants and animals, as is testified by the expression sport or throwback. The obscurity that enveloped the whole process of variation and inheritance is an extraordinary example of the difficulty of arriving at a clear description of even a relatively simple phenomenon without carefully controlled and logically planned experiments. Even though the practice of circumcision, let alone foot binding or head deformation, should have indicated that direct interference with the body of an organism has no effect on its offspring, the idea was retained with an extraordinary tenacity by many biologists in the face of a wealth of negative evidence.

Though some insight into the phenomena of inheritance was gained by plant hybridization in the first half of the 19th century, it was not until 1865 that Gregor Mendel published his series of classical experiments on peas, which laid the foundations of modern knowledge. It is remarkable that, athough these experiments were certainly known to some continental investigators, their profound significance entirely escaped notice until 1900, when Hugo de Vries, Carl Correns and Ernst Tschermak rediscovered the forgotten paper and provided confirmation from their own results.

The principles enunciated by Mendel were extended to animals by L. C. M. J. Cuénot in 1902 and by William Bateson and R. C. Punnett in 1903–05.

In its simplest expression Mendel's results *(see* GENETICS) may be described in the following way. If a tall pea be crossed with a short pea, the resulting progeny are all tall. If such hybrids be inbred, the statistical composition of the resulting population approximates to three tall to one short. If the tall hybrids are backcrossed to the original tall stock, all the offspring are tall. If the backcross is made to the original short stock, the resulting population approaches the ratio one tall to one short. Mendel's success was due primarily to his incisive choice of a simple alternative situation, and to his application of numerical enumeration to the resulting populations. The general scheme of inheritance was explained as depending on a pair of factors, or genes, as they are now called. In every individual one member of the pair comes from one parent. In the case under consideration, whenever the tall gene (T) is present the plant is tall, so that a short pea is characterized by both members of the pair being short (t). Tall is said to be the dominant member of the pair of alleles, short the recessive. In sexual reproduction the two alleles separate sharply. Schematically we have:



Further experiments can be done to indicate the difference between the pure homozygous dominant TT and the heterozygous Tt. When Mendel performed experiments with several pairs of characters at once, yellow or green seed, smooth or wrinkled seed, he found that the distributions of the different characters were entirely independent of each other. In the simplest case, usually used in such experiments today, that of the backcross to the pure recessive, four equal classes would result. In 1906 Bateson and Punnett found that this was not invariably true. Some pairs of characters tended to be "attracted," as did their opposite alleles, so in a backcross of this kind two classes are larger and two smaller than would be expected. Though the explanation given by Bateson and Punnett has proved erroneous, the discovery was of the most fundamental importance. In 1902–03 W. S. Sutton, and also C. Correns, M. F. Guyer, U. A. Cannon, T. Boveri and H. de Vries, had pointed out that the distribution of the chromosomes in sexual reproduction corresponded with the distribution of the Mendelian factors in, inheritance. Mainly as the result of the domestication of the fruit fly *Drosophila melanogaster,* the small fly often seen around bananas and other fruits in shops and pantries, T. H. Morgan, C. B. Bridges and A. H. Sturtevant were able in 1913 to indicate that although many more characters than chromosomes existed, the chromosomal nature of the genes could be accepted on the supposition that each chromosome consisted of a string of genes, the alleles paired one by one along homologous chromosomes, but that at certain stages interchange of segments of the string could take place. The attraction observed by Bateson and Punnett, now called linkage, is thus explained by a linear cohesion of the genes. Where attraction is strong the chain between the genes is rarely broken, where weak, more often broken. Since the chance of breakage might be expected to increase with the length of the chain, the frequency of crossing over between linked genes was used as a measure of their hypothetical distance. By 1914 it was apparent that four linkage groups existed in *Drosophila melanogaster.* One group followed the sex determination pattern in the way that would be expected if it were associated with the X sex chromosome. Of the other three, two were large groups, that were reasonably associated with the two large pairs of V-shaped chromosomes. the fourth very small and reasonably associated with the small fourth pair of chromosomes. Cases then were found that seemed best explained by the abnormal presence of extra chromosomes in certain flies, and cytological examination confirmed these findings. The whole structure received a most dramatic confirmation by the discovery in 1933 by T. S. Painter, E. Heitz and H. Bauer that in the salivary glands and other cells of the larval *Drosophila,* as in certain other flies, the chromosomes become enormously enlarged, and when appropriately stained exhibit a fine characteristic banding The bands vary in width and are recognizable as individual structures from cell to cell. Painter and Bridges both found that in cases in which abnormal arrangements of genes in the linear linkage groups occurred, there were similar abnormal arrangements in the banding. In this way it was possible to correlate positions of genes in the linkage map with position of bands on the chromosomes. The linear order was demonstrable in both cases. but the initial assumption that the distance is strictly proportional to the frequency of breaks was found to be incorrect. Essentially similar results are indicated by studies made in almost all major groups of organisms from bacteria to man.

The establishment of the detailed chromosomal theory of inheritance was perhaps the most remarkable autonomous achievement of biology in the first half of the 20th century. It tells, however, nothing about the nature of the changes. or mutations, in the inherited complex of characters that are the raw material of genetic research. Such changes take place rarely; any one gene mutates about once in 100,000 to 1,000,000 chromosome generations, but since there are many genes the frequency of any kind of change is high. Most mutations. however, are recessive lethals; they lead to the death of the organism which is homozygous for them, and can only be detected by specially devised experiments. Visible changes occur less frequently, and again are mainly recessive.

The commonest type of dominant to appear is one in which the heterozygote shows a marked difierence from the original stock, but in which the homozygous dominant never appears, dying early in development. Such cases where the mutant is a visible dominant, but a lethal recessive, are generally due to losses of small sections of a chromosome (deficiency). The ordinary type of mutation is also called a point mutation, and clearly does not consist of a mere loss or deficiency, for in some gene loci a great array of different alleles are known.

In 1927 H. J. Muller showed that the frequency of occurrence of changes of all these kinds can be greatly increased by administration of X-rays. Later L. J. Stadler found that point mutations could be induced by ultraviolet light, the wave lengths most effective being those most strongly absorbed by nucleic acids. Though the radioactivity of the earth and the incoming cosmic radiation produce ionization, as do X-rays, the natural mutation rate is too high to be explained on the basis of natural ionization of this sort. M. Delbrück concluded that random molecular changes because of thermal agitation are responsible for point mutations.

The most striking insight into the nature of the gene is, however, derived from unicellular organisms. Immunological studies have shown that the bacteria of the genus *Pneumococcus,* the causative agent of ordinary bacterial pneumonia. can be divided into a number of types which differ in the antibodies called forth by their presence in experimental animals. The virulence and antibody-producing properties of the bacterium appear to be due to the presence of a carbohydrate sheath. which is chemically different in the different strains. Under some conditions the sheath is lost in culture.

Certain sheathless strains derived from one type can be converted into a sheathed strain of another immunological type by treatment nith extracts of this second type. In 1944 O. T. Avery

and his co-workers isolated the effective material in the extract and found it to consist of a highly polymerized deoxyribonucleic acid. Such substances, combined with proteins, form the nucleoproteins of chromosomes. It is therefore not unnatural to suspect that the specific sheath-inducing material is chemically and functionally related to at least a fraction of a gene, and that part of the diversity exhibited by genes is due to diversity in the chemical structure of the enormously complex polymers of deoxyribonucleic acid. This belief is strengthened by the extremely high dilution in which the substance acts, apparently implying self-perpetuation of its molecules once they are in contact with the bacterium.

It is generally believed that the cytoplasm plays a part in heredity, though its role is hard to define. In 1943 T. M. Sonneborn found that, in a race of the single-celled animal *Paramecium*, a gene exists which cannot act in the absence of a particulate cytoplasmic factor: possibly comparable with a virus, but that this factor cannot be formed in the absence of the gene. In yeasts the ability to metabolize certain sugars depends on genetic constitution; but there is evidence that, even in the absence of the appropriate genes, the requisite enzymes are transmitted in cell division, provided the substrate sugar is present. In the hen's egg the supply of glycine is independent of the glycine content of the food of the parent. but when this food is deficient in the amino acid, the egg appears to be deficient in the mechanism for making more glycine, and chondrodystrophic chicks result. Cases of this kind promise to provide much further information as to the ultimate mechanism of gene action in development.

By the latter 1950s it was suggested that certain materials. probably deoxyribonucleic acids, act as templates or patterns on which specific enzymes and other substances are constructed. The templates may be activated in some way by the initial presence of a small amount of enzyme to be synthesized. or may be inactivated by certain molecules which form more or less stable combinations that block further synthesis. (*See* also NUCLEIC ACIDS.) The limitation of potency of embryonic cells as development occurs may be attributable to the inactivation of inappropriate templates. There was a little direct evidence of a process of secretion by localized regions of chromosomes at specific times in development. and also for significant changes in nuclear function during early development. The science of developmental genetics had made a good beginning but an enormous amount remained to be done. (See GENETICS; HEREDITY; GENE.)

5. Evolution. — The idea that the various forms of living organisms, including man himself, have arisen by gradual transformation of pre-existing types is very old. In its beginning it no doubt merges into mythology. As a scientific hypothesis it was sporadically held by a number of 18th- and early 19th-century biologists. Apart from considerations based on a belief in the literal interpretation of the Old Testament, the main objection to such a hypothesis of evolution lay in the lack of any obvious mechanism by which the process might be brought about. The modern history of the evolutionary hypothesis may be taken as beginning on July 1, 1858, when a joint paper by Charles Robert Darwin and Alfred Russell Wallace mas communicated to the Linnaean Society of London. The paper was the result of Darwin's long preoccupation with the matter of the origin of specific differences, starting with his speculation on the nature of the peculiar fauna of the Galapagos Islands. Wallace had spent much time in both South America and Malaya. He conceived his ideas rapidly and communicated them to Darwin by letter. Both authors had been influenced by T. R. Malthus' famous *Essay on the Principle* of *Population,* 1798. Darwin and Wallace suggested that since all organisms tend to increase geometrically, there must always be a large mortality. Since variation is known to take place extensively, and some at least of the variations are inherited, the mortality will be differential, removing the poorly adapted and favouring the well adapted. A progressive increase in adaptation should therefore take place. The whole hypothesis was examined in a masterly way in Darwin's *Origin* of *Species,* 1859. At the time that this work was written. practically nothing was known as to the origin of variation, as Darwin fully realized. The nature of the hereditary process was also misunderstood. Nevertheless the fundamental process of natural selection as put forward by Darwin and Wallace remains the keystone of modern evolutionary theory, and can now be rigorously applied to the theoretical treatment of populations containing given proportions of individuals carrying Mendelian genes that alone or in combination promote or diminish the chances of survival of the individuals bearing them.

The main arguments in favour of the evolutionary hypothesis are that it gives a rational interpretation of the uniformity in both general structure and in function found throughout vast groups of organisms; that it accounts for the gradual specialization, observed when the fossils of a given group, such as the horses or elephants, are arranged in temporal sequence; and that it explains the orderly geographical distribution of species and higher groups of plants and animals on the surface of the earth. No really serious objections to the hypothesis have ever been successfully advanced, and the occurrence of evolution is now accepted as a matter of course by practically every serious student of biology.

The acceptance of the general principle, however, indicates nothing about the uniform or multiple origin of life. Moreover, even in those phyla normally provided with hard and easily fossilized shells, the fossil record is extremely imperfect, so that there is often much doubt as to the course that the process has taken. The most extraordinary of the imperfections is the complete lack of any instructive fossils covering the first two-thirds of the earth's history. after which practically all the large phyla or major groups of animals, with the exception of the vertebrates, appear in a reasonably advanced condition in the Cambrian rocks. The immense Pre-Cambrian hiatus has received many explanations. none of them entirely satisfactory. The most reasonable of such explanations is that until fairly effective carnivorous animals were developed, fossilizable hard parts were unnecessary and so did not evolve. For example, a norm or arthropod could develop a hard chitinous jaw which might not fossilize, but which might provide the conditions for evolution of skeletal armour that would fossilize. It must be accepted as an important, though rather mysterious. fact in the biological history of the earth, but cannot be used as an argument against subsequent evolution in the 500,000,000 years that have elapsed since the fossil record began.

The evidence pointing to the occurrence of evolution tells us nothing about its mechanism. Investigations beginning about 1920, notably by J. B. S. Haldane, R. A. Fisher and Sewall Wright, of the theoretical properties of populations composed of individuals bearing different genes conferring different survival values, have greatly developed the original Darwinian hypothesis. The fate of a particular variant is found to depend largely on the size of the population in which it occurs. In small populations there is a significant chance of new types becoming established by chance mutation, whatever the origin of such may be. In large populations change can only be effective through natural selection. G. G. Simpson in 1944 reviewed the available evidence derived from the study of fossils, and concluded that the initiation of a new direction in evolution is often a matter of chance variation in a small population, which, consisting of rare individuals, seldom leaves fossil remains, while the stately progression of more and more adapted forms, as exhibited in the evolution of the horse, is a slow transformation controlled by natural selection in large populations.

The main uncertainty in modern evolutionary theory would appear to concern the origin of discontinuous breeding populations or species, and the role of geographical isolation in such a process. Some zoologists, notably Ernst Mayr, have assembled much evidence to show that while one species can be transformed out of all recognition by the evolutionary process, it can only produce a single successor type unless its population is split by some external barrier. This view is probably sound in the case of most groups of animals. In plants, numerous complications provided by chromosomal variation of a kind little known in animals possibly make geographical isolation a less important prerequisite for multiple production of species. Since two isolated groups will rarely vary in identical ways and will usually be subject to dif-

ferent ecological (environmental) conditions, they will tend to evolve differently. At a subsequent meeting, if they have become sufficiently different genetically they will be unable to interbreed successfully. (See EVOLUTION, ORGANIC; SELECTION.)

One of the most remarkable results of studies of the genetics of natural populations is the discovery of the widespread abundance of recessive lethal genes. It is probable that in many cases heterozygotes have selective advantage not only over the homozygous lethal (which is obvious) but also over the homozygous nonlethal or wild type. The most dramatic case of this sort is sickle-cell anemia in man in which the heterozygotes exhibit immunity to certain forms of malaria.

6. Physiology. — The results of the study of the physiology of the simplest organisms are almost exclusively biochemical. General physiology, if it is to embrace the functioning of all forms of life, must be regarded largely as the physiology of cell metabolism. The results of such studies indicate that certain types of reaction catalyzed by enzymes take place in the protoplasm of the most disparate organisms. There is evidently a common set of reactions characterizing the metabolic activity of all organisms. Individual parts of the whole system may be omitted in one species or another. This is made possible in part by the normal presence of more than one set of machinery for gaining the same end, though under different conditions. The widespread occurrence in the same cell of enzyme systems permitting oxidative metabolism or anaerobic glycolysis as sources of energy is an outstanding example.

Superimposed on the basic machinery there is a quite fantastic diversity of mechanisms by which particular materials can be used as sources of matter or energy, and by which specific products of metabolism are elaborated. There is little doubt that the general diversity of such processes reaches its maximum development in the free-living bacteria, which may be regarded as specialized on the biochemical level.

Though bacteria may possess motile flagellums or show a capacity for independent movement in other ways, the group as a whole is at the mercy of electrostatic and molecular forces. The larger unicellular organisms, however, have been liberated from such forces by virtue of size alone; they are too big to be absorbed on clay particles or to be pushed around by the thermal agitation of the perennial Brownian dance. They begin, therefore, to show directed movement in response to external changes in the medium, and so become subjects for classical physiological studies.

The increase in size which puts such organisms outside the range of molecular agitation introduces its own problems. The organism in moving meets a new element of the external world which first acts on its surface, at an appreciable distance from some or all of the machinery involved in producing the movement. The distance may only be a few thousandths of a millimetre, a fraction of the length of a cell; but it is evident that, whatever the scale of the phenomena, the molecular structures at the surface of the part moving forward first receive a stimulus, or indication of a change in the outer world. It is not necessarily this part of the cell that produces the movement that will be modified by the stimulus. Thus we find even in single-celled organisms clear evidence of a receptor mechanism receiving stimuli, the result of which is transmitted by a conductor mechanism to an effector mechanism producing an appropriate change in the movement or other activity of the organism. In both the Flagellata and the Infusoria among the Protozoa (*q.v.*) a visible fibrillar conductor path may be developed. The receptor organelles are less conspicuous except where they are represented by red "eye spots" or stigmata in green flagellate cells, which apparently are light sensitive. Presumably the whole external surface may act as a receptor organ to chemical or tactile stimuli. In the best-developed cases the effector organs of unicellular organisms are cilia or Aagellums. We have thus developed within a single cell a system of the same general kind that is built out of cellular units within the bodies of multicellular animals. In the latter the system consists of sense organs of more or less complexity, of the nervous system and of muscles and other kinds of effector organs (glands, electric organs).

The highly organized nervous systems of multiceliular animals apparently always consist of aggregates of nerve cells or neurons, drawn out into long conducting fibres. These fibres do not anastomose (interjoin). The nervous impulse is transmitted from cell to cell across a special boundary region or synapse. in which the rate of conduction is low and at which complete blocking of the impulse may occur. It is usually supposed that the properties of the more elaborate nervous systems are as dependent on the nature of the synapses as on the arrangement and nature of the fibres.

In the higher plants, which show limited power of motion, the effective stimuli are usually constants such as gravity, acting on growing and changing organs, or slowly changing events, such as length of daylight. The response is usually expressed in terms of growth rather than in any movement of fully developed cells. There can be little doubt that whatever the nature of the nervous impulse, similar if slower types of conduction can pass from cell to cell wherever cytoplasmic bridges or connections exist between such cells. This is certainly true of the cells of ciliated epitheliums covering the gills of bivalve mollusks. Cytoplasmic bridges occur between plant cells no less than in animals, and presumably are involved in what is loosely called protoplasmic conduction. Some such phenomenon may therefore probably be regarded as general in all but the smallest organisms.

The transmission of stimuli by cytoplasmic conductors, either unspecialized bridges or highly specialized nerve fibres, is not the only form of co-ordinating mechanism whereby the different parts of the body of a large organism can be maintained in functional relationship with each other and with the external world. Wherever there is a movement of fluid from one part of the organism to another, there is a possibility of the transport of hormones or chemical messengers. This mode of conduction is naturally developed most completely in organisms with well-developed vascular systems. It is best known in the higher or vascular plants, in which form is largely regulated by the local production of a hormone, auxin; in the arthropods (insects and Crustacea). in which a complex of organs in the head regulate moulting, metamorphosis and the maturation of the genital organs; and in the vertebrates, where a very elaborate endocrine system is developed. There are indications of comparable phenomena in some worms and in the cephalopod mollusks (squid, cuttlefish, octopus, etc.).

In proceeding from the simplest organisms to the more complex, the physiologist passes from a realm in which the enzymatic biochemistry of cell metabolism is paramount to a realm where the co-ordination of cell activities becomes more and more emphasized. In plants this is expressed largely in the elaboration of growth patterns and in responses to the slowly changing ecological variables of the seasons. In animals the effects of free movement, of the exploration of the external world by receptor organs, with subsequent action of an increasingly discriminating kind, become more and more apparent. The process reaches its highest development in man, the human nervous system presumably being the most complicated structural and functional pattern yet to appear in the material universe.

The study of animal behaviour does not strictly fall within the meaning of biology adopted at the beginning of this article, since it is by nature practically confined to examination of motile organisms included in the animal kingdom. In the present century a strong school of psychologists, the Behaviouristic school, has insisted that a scientific psychology can be elaborated only in terms of externally observable behaviour, without any reference to the subjective condition of the organism studied. Insofar as this condition is only known in terms of verbal behaviour, the restriction was less radical than might at first appear.

Any observed response given by an organism to an environmental change may be innate (instinctive) or independent of previous experience, or learned or dependent on previous sensory stimuli received in the life of the animal. It is probable that certain of the protozoa or unicellular animals can exhibit very simple kinds of learning. Following W. H. Thorpe, it is possible to distinguish four types of learning. Habituation is the disappearance of an innate response to repeated mild stimulus (*e.g.*,

odorous or mild mechanical irritation) that initially causes reactions of avoidance or inhibition of movement. Associative learning is the transference of the capacity to elicit an innate response from its normal stimulus to some previously indifferent stimulus that is associated with the normal stimulus. Latent learning is transfer of the property of eliciting response from one stimulus to another under conditions that do not permit the production of the response until the association has been formed. Thorpe regards the process of imprinting of K. Lorenz as a special type of learning. This process, discussed below, seems legitimately regarded as a peculiar type of latent learning. Insightful learning is the term given to production of entirely new responses to new situations, integration of diverse elements of previous experience presumably always being involved. Habituation and association occur throughout the mobile members of the animal kingdom with polarized nervous systems. Latent learning certainly occurs in both arthropods and vertebrates. There is no evidence of insightful learning except in the highest vertebrates, and the exact level at which it appears was not certainly established as of the early 1960s. *(See* PHYSIOLOGY; ANIMAL BEHAVIOUR; PSYCHOLOGY, COMPARATIVE.)

7. Ecology, Biocoenology, Biodemography and Biosociology.—The study of the relations of individual organisms to their environments is very ancient; much unsystematized information on what is now called autecology (the study of the relation of the individual organism to its environment) is included in the traditional lore of hunters, fishermen and agriculturalists. The realization that different requirements of different species led in any given kind of habitat to the formation of rather constant mixtures of populations in dynamic relationship and characteristic of the habitat may also have had a prescientific history. It did not, however, play any great part in scientific thought until the early part of the 19th century. The first contributions to what is now called synecology (the study of the relation of groups of organisms to their environment), or perhaps better biocoenology, or the study of biological communities, by Alexander von Humboldt, A. Grisebach and other workers early in the 19th century, were devoted solely to plants. The idea of the animal community and of the fully integrated biological community or biocoenosis is largely the result of the study of shallow water populations in the sea, notably by A. F. Mobius. During the closing years of the 19th century the very fertile idea of an inevitable sequence of communities leading to a climax characteristic of the climatic conditions of the region was developed, largely by E. Warming in Europe and by H. C. Cowles and F. E. Clements in the U.S. between 1895 and 1910. The introduction of animals into the scheme followed, largely due to the work of V. E. Shelford. The developed descriptive science of synecology has been admirably set out by Clements and Shelford in their book *Bioecology.* The successional method of study, though intending to be dynamic, never developed a truly quantitative mode of approach. During the third and fourth decades of the 20th century biodemographic investigations, *i.e.*, studies of the dynamic properties of nonhuman populations, proved particularly important. The most notable contributions to this subject have been due directly or indirectly to Raymond Pearl, A. J. Lotka, V. Volterra, G. F. Gause, Thomas Park and A. C. Crombie.

In the simplest case, if we consider the growth of a population of an organism reproducing by simple division at a constant division rate with an infinite food supply, and no external limitations, the rate of increase will be proportional to the number of organisms (n) and to the division rate (b), or formally,

$$\frac{dn}{dt} = bn$$

No such rate is possible for long in any real case. Some limitation is always present. If we assume that a given volume of space or habitat can support a maximum population k, the simplest mathematical expression giving a continuous function for the population asymptotically approaching k is:

$$\frac{dn}{dt} = \frac{bn\ (k - n)}{k}$$

Here we have the rate of increase governed by the initial reproductive rate (b), by the number of individuals *(n)* which are available to reproduce and by the proportion of vacant spaces as a fraction of the maximum population $\frac{k-n}{k}$ Although in any given case there is no a priori reason to suppose that the reproductive rate is depressed by this fraction, the resulting integrated form of the equation, which gives a sigmoid curve known as the Verhulst-Pearl logistic, is, in general, observed in the growth of populations, of many individual organisms, of some human institutions and probably of whole biological associations also.

We may regard the expression $(k-n)/k$ as what engineers would call a negative feedback term. The equation set up assumes that the environmental effect implied by this term operates instantaneously. In practice this is most unlikely. If any appreciable time lag in the operations occurs the system is thrown into oscillations, though these may fade away. Experimental verification of this was achieved in populations of the water flea Daphnia.

The simplest and most fundamental result to be obtained from investigations involving more than one species indicates that if two species co-occur in the same habitat, they cannot form permanent stable populations if they occupy identical niches in the habitat; *i.e.*, if their requirements are identical, save in rare cases in which some external factor keeps both populations at levels far below those appropriate to the available food supply. This can be easily established by maintaining protozoa in a culture tube with a single species of food bacterium or yeast. If two species are cultivated separately they both may form stable populations of as many individuals as the food supply can support. If they are mixed together one species always displaces the other. In some cases it has been shown that environmental factors varying within limits tolerated by either species separately can determine which species will survive and which disappear in competition. If the artificial niche is diversified either by provision of a refuge into which the less successful competitor can go and the more successful cannot, or by introduction of two kinds of food, one of which the less successful competitor alone can eat, stable mixed populations are possible, but in such cases two niches are in effect available.

In nature, when two species are found apparently occupying the same niche, it is reasonable to conclude that actually they have slightly different ecological requirements, or that the mixed population is not stable, environmental changes now favouring one species, now the other.

Other results derived from the same type of investigation relate to interaction of two species, one of which feeds on the other. In such cases, under some conditions, fluctuations will be set up, the predator first increasing at the expense of the prey, then decreasing as the latter becomes so rare that it can seldom be captured, and later increasing as the supply of prey recovers during the period when most of the predators have died of starvation. Though very regular fluctuations do occur in some animal populations, it appears that the classical cycle of the kind just described seldom is realized in nature. The ten-year fluctuations observed, for instance. in the arctic hare or snowshoe rabbit of Canada must have some other cause.

The mathematical investigation is here justified because it provides a number of criteria by which actual cyclical variations can be compared with theoretical ideal cycles. The main difference between model theoretical systems and actual populations seems to be in the greater proneness of the former to oscillation, suggesting that in nature special mechanisms exist which stabilize the biological community.

Studies of both ecology and population genetics have made clear the importance of differences between small and large populations. It is however, primarily among animals that the existence af active interrelations among freely motile organisms has permitted the development of true social phenomena. A good many cases have been reported of animals living best at a certain population density, below which adverse effects of undercrowding appear. This has been claimed many times among the Protozoa, and although many of these claims are unconfirmed by subsequent work, it seems

probable that some are correct.

W. C. Allee was particularly assiduous in demonstrating the beneficial effects of definite minimum numbers of metazoan species under unfavourable surroundings and rightly regards this as a widespread property of living organisms. That such effects operate in nature has been demonstrated by an ingenious experiment of W. T. Edmondson, who found that the tube-building wheel animalcule, or rotifer, *Floscularia conifera* has a higher expectation of life if as a larva it settles on an older animal than if it attaches to a neighbouring fragment of a water plant. These effects of aggregation are, however, merely possible prerequisites to sociality. No special socially integrated behaviour is exhibited by the component members of the group. True social life exhibiting such behaviour has been developed only in the Hexapoda, or insects, and in the vertebrates. The manifestations of sociality are, however, very different in the two groups.

The social insects are mainly found in the Isoptera, or termites, and in the Hymenoptera, or wasps, ants and bees. In both cases the colony is to be regarded as an immense development of the family, in the termites the patrogynopedium or association of both parents with offspring, in the wasps, ants and bees the gynopedium or association of the female parent alone with the offspring. The family group is specialized so that very few members are potentially capable of reproduction, the majority forming a sterile caste which includes infertile members of both sexes in termites and infertile females only in the social Hymenoptera. It is usual for the sterile caste of termites to be divided into two subcastes, the more numerous workers and the less numerous soldiers. Similar or more elaborate division into subcastes occurs in many but by no means all ants.

The mechanisms by which the fundamental caste distinction between fertile queen and infertile worker is established, even among a single group such as the bees, turn out to be astonishingly varied. In some cases, notably the stingless bees (*Melipona*) of South America, caste appears to be determined genetically. In other cases, such as the familiar bumblebees (*Bombus*) of the northern hemisphere, the main difference between queens and workers lies in the amount of food that they received as larvae. In a third group of cases, there appears to be a social hormone produced by the integument of the queen that alters the behaviour of workers which receive the material and inhibits the development of their ovaries. In the honeybee (*Apis mellifera*) this queen substance prevents workers from building royal cells in which specially fed queens are reared. In some species of ants very complicated situations involving seasonal growth patterns appear to be involved in caste production.

Extremely specialized stereotyped behaviour is developed along with this morphological specialization of individuals. The behaviour may change, young bees being nurses, older bees food gatherers, and elaborate sets of fixed reactions permit remarkable responses such as the solar compass reaction of ants or the honey and pollen dances of bees. Though these responses may depend on past experience, there is no unequivocal evidence that any integration of previous fragments of past experience to meet a radically new situation is ever exhibited by insects. The small size of the body, and so of the nervous system, probably limits the possibilities of learning in the social insects. In the social vertebrates no morphological polymorphism (capability of wide variation of form) other than sex has been developed. In man, the species showing the most elaborate social development, complex inherent responses are so little developed that their existence is a matter of debate. All forms of learning are greatly developed, insightful learning reaching its maximum manifestation. The whole series of vertebrate classes show examples of social species, and, although the level of organization of all species save the primates is low compared with the highest social insects, several special properties of vertebrate groups clearly foreshadow certain human developments. Whenever a group of a vertebrate species occupies a restricted space, the phenomena of prostasia or social dominance tends to develop. This phenomenon was first described systematically by T. Schjelderup-Ebbe, working on domestic chickens. In this case, in a unisexual flock, a pecking order tends to develop, bird *A* pecking all the members of the flock, bird *B* all save *A*, etc. In such cases the order usually becomes linear, except when there are so many birds that the chance of every bird encountering every other often enough to establish the order is very small. The phenomenon is independent of sex, though when both sexes are present the males are usually higher in the hierarchy in the forms studied. Prostasia is known in fishes, reptiles and mammals, as well as in birds. The phenomenon is well developed in wild social groups of primates and elaborations are easily observed in human society. It seems probable that it is not often found in a well-developed form outside the vertebrates.

Another phenomenon apparently widespread among the higher vertebrates is the development of tradition, in the sense of a set of techniques for performing certain functions in the life history, not based on innate behaviour. The problem has been little studied in mammals outside man, but appears to be well developed in certain species of birds. There is, for example, evidence that in such species the song or the method of nest building is based not on innate behaviour but on experience of the bird in associating with older individuals of the same species. This phenomenon is even more clearly restricted to the vertebrates than prostasia, and has become one of the leading characters of the Hominidae.

Related to the development of tradition, there is a very remarkable phenomenon in birds, termed imprinting by Lorenz. If certain species of birds are reared by foster parents, they early learn to behave toward the foster parent as if they belonged to that species. This behaviour may persist for months after removal from the foster parents. At the first breeding season the bird will seek a mate of the species by which it was reared rather than that to which it belongs. In certain cases birds may learn to regard human beings or inanimate objects as their normal companions, and go through mating ritual in the presence of such persons or objects. This phenomenon appears comparable with the establishment of fixation and fetishism in human psychopathology.

Early imprinting of a comparable type is doubtless involved in learned traditional behaviour of all kinds in both birds and mammals that exhibit the phenomenon, and is certainly of fundamental importance in maintaining the cultural characteristics of human groups. (See ECOLOGY, ANIMAL; POPULATION ECOLOGY; SOCIOLOGY, ANIMAL.) (G. E. HN.; X.)

8. Economic Biology.—The application of life principles to the control, development and improvement of living things for the financial, physical or aesthetic benefit of man has been termed economic biology. All animals, plants, bacteria and viruses are involved whenever they affect man or his possessions. Man has always used the animals and plants around him for food, clothing, shelter and recreation. Many animals and plants also cause annoyance and disease or destroy man's accumulated possessions. All of these complex relations between man and living organisms are the concern of economic biology.

Numerous subject matter disciplines have been established for developing and expanding knowledge in particular areas. Only the principal ones are dealt with here.

Animal Husbandry—the feeding, care and breeding of domestic animals: horses: mules, oxen, water buffalo and camels for transportation: cattle for meat and dairy products; sheep for meat and wool; swine for meat; and poultry ior meat and eggs. Numerous by-products result from the processing of animals for meat! such as hides and fertilizer. (See ANIMAL BREEDING; FEEDS, ANIMAL.)

Wildlife Management—the control and management of wild animals (mammals and birds) to maintain ample numbers ior hunting and trapping. The commercial hunting of wild game for food is of minor importance, but hunting for sport is a major recreational activity in the United States and elsewhere. Pelts for fur are obtained either by trapping or by rearing animals, such as mink and fox, on "fur farms." (*See* FISH AND WILDLIFE SERVICE; WILDLIFE CONSERVATION.)

Animal Pest Control—a special aspect of wildlife management concerning the control oi mammals or birds that are injurious. Rats and mice infest dwellings, warehouses and grain storage facilities; the destruction **and** contamination of grain by these rodents causes a tremendous annual financial loss. Other examples are predators, such as coyotes, wolves, foxes and bears; starlings and English sparrows, which are 2 nuisance in cities; and pocket gophers, which destroy agricultural crops.

Fisheries—the propagation, management and harvesting of fish and

other aquatic animals (whales, crabs. lobsters, shrimp. oysters and clams) for food, sport (recreation) and numerous nonedible products such as pearls, glue, cod-liver oil, fish oil, iertilizer, etc. Commercial food fisheries are of major importance on an international level since many nations depend on their fisheries for a considerable portion of their food supply. (See FISHERIES, FISH CULTURE)

Economic *Entomology*—the control or eradication of insects injurious to man or his possessions All plants, all mammals and birds (both domestic and wild), all stored products (grain, processed food, lumber) and all wood structures are subject to insect attack. Insects also are vectors of animal and human diseases (malaria. yellow fever) and plant diseases (Dutch elm disease, curly top of sugar beets).

Control of an insect pest is accomplished when its numbers are reduced to a point at which financial loss is negligible. Eradication presumes that all pest individuals have been killed in a given area Numerous insecticides, both organic and inorganic, are applied as sprays, dusts and fumigants. Cultural methods (time of planting, summer *fallowing*) have been used successfully in the control of insects attacking agricultural crops. Varieties of crop plants resistant to insect attack have been successfully developed. There are instances in which it is possible to alter some iactor of the environment (temperature, moisture) resulting in unfavourable conditions ior insect development. Some outstanding successes of insect control have been accomplished by the promotion of insect disease epidemics and by the introduction, propagation and distribution of parasites and predators of the injurious insect. (See ENTOMOLOGY.)

Apiculture—a branch of entomology concerned with the care, management and breeding oi the honeybee ior the production of honey and wax, and for pollinating agricultural and horticultural crops. (See BEEKEEPING.)

Sericulture—a branch of entomology concerned with the care, feeding, management and breeding oi the silkworm moth for the production of silk. This industry is most highly developed in such countries as Japan, China and Thailand.

Parasitology—the investigation and control of the internal and external parasites of man and of domestic and mild animals. Most of the internal animal parasites are included among the roundworms (Nemathelminthes), flatworms (Platyhelminthes) and Protozoa. Most of the external animal parasites are either insects or near relatives (chiggers, mites, ticks). (See PARASITISM AND PARASITOLOGY.)

Veterinary Medicine—the care, alleviation and prevention of disease of domestic animals primarily, but of wild animals on occasion. (See VETERINARY SCIENCE.)

Agronomy—the planting, culture, development of improved varieties and harvesting of field crops for food (wheat, corn or maize, barley, rice, sugar beets, sugar cane), forage (hay and pasture for livestock) and fibre or oil (flax, soybeans, peanuts). Here plant breeding is a most important tool The development of hybrid corn is an outstanding example of the improvement of crop plants by plant breeders. (*See* CROPS; PLANT BREEDING)

Soils—a study, often considered a part of agronomy, that concerns itself with the chemistry. biology, classification and improvement of the medium in which plants grow The proper handling of soil (plowing, cultivation, fallowing), use of natural and commercial fertilizers and the use of plants for improving the soil (preen manures, legumes) are the domain of the soils expert (See SOIL)

Horticulture—the planting, culture, development of improved varieties and harvesting of fruits, vegetables, ornamental trees and shrubs and flowers. Here again the plant breeder has been of invaluable assistance in developing new and greatly improved varieties. (See HORTICULTURE.)

Weed Control—the controlling of unwanted plants by chemicals or other means. Numerous chemi als are available commercially ior use as sprays or ior treating soil prior to planting ior the control of weeds. Many of these are selective and effective against only certain types of plants. (See WEED.)

Plant Pathology—the control of plant diseases that often reach epidemic proportions and cause tremendous financial loss. Many of these diseases are caused by other organisms (fungi, bacteria and viruses). Two principal lines of attack have been developed: the breeding of immune or resistant varieties of plants (*e.g.*, wheats resistant to black stem rust); and the use of chemicals, applied either as sprays or dusts, to destroy or inhibit the disease organisms. (See PLANT DISEASES.)

Forestry—the planting, culture, management and harvesting of forest trees for lumber, wood pulp, poles, railroad ties and numerous other commercial products. (See FORESTS AND FORESTRY.)

V. THE PHILOSOPHY OF BIOLOGY

Good biological work has been accomplished by investigators of the most varied philosophical outlook, from Neo-Thomism to sceptical naturalism. No inevitable rnetaphysic evolves from the study of biology, or indeed from that of any other natural science. Nevertheless some of the general conclusions that have been set out in the preceding discussion have a philosophic interest, defining the limits of reasonable belief about the nature of the external world.

As far as scientific method permits the exploration of the human environment, it seems impossible to recognize definite categorical discontinuities. The difficulty of defining a living organism is an example of this. The definition adopted is arbitrary to the extent of depending on the linking of two properties, metabolism and reproduction, which logically might be independent. Moreover, in the course of analysis it becomes necessary to arrange all the phenomena of nature in a more or less linear continuous sequence of classes, and then to describe events comprised in the class of more complex phenomena in terms of events in the classes of less complex phenomena (principle of hierarchical continuity). Within each class, however, there are numerous interrelations observed between events of the same order of complexity. It is thus possible to recognize a number of more or less autonomous disciplines, each permitting generalization, but ordered so that the more complex events treated by one discipline can also be analyzed in terms of less complex events treated by another discipline.

It is thus possible to establish a body of generalizations about human society independent of the behaviour of individual men, a number of generalizations about individual behaviour without consideration of the physiology of the sensory, conductor and effector mechanisms involved and a large body of generalizations about muscle or nerve physiology without considering the molecular mechanisms involved. Such autonomous disciplines may seem sterile and uninteresting; it is, however, important to realize that they can be constructed.

It is considered by a growing minority of biologists that the various phenomena studied by parapsychologists may indicate that at a certain level of complexity properties of the universe become apparent that are not demonstrable in simpler systems. The simplicity postulate, or law of parsimony, commonly called Occam's razor. that theoretical entities used in explanations must not be multiplied beyond necessity, should always be kept in mind in dealing with this difficult field. All the evidence that has accumulated since 1858, in astrophysics and cosmogony no less than in geology, biology and anthropology, suggests that the simpler systems were in existence prior to the complex. The hierarchical arrangement of the sciences thus is apparently correlated with a temporal order of kinds of events.

It is a particularly striking property of the hierarchy that the events of a more complex kind involve the emergence of new qualities. The maintenance of the nonequilibrium steady state of metabolism, reproduction, irritability, modification of response by previous experience, tradition and social phenomena represents such new emergents. The emergence of such new properties, as evolution proceeds, must be regarded as a general property of the universe. Fortunately again a variety of philosophic systems provide for such a recognition.

A further point of interest is that photosynthesis on the one hand and reproduction followed by natural selection on the other provide a mechanism by which the local emergence of physically less probable systems from physically more probable can take place. Though it has frequently been supposed that physical evolution is at an end, there is no reason to suppose that this is true of social evolution. The period of time since the first stone implements were made is perhaps 300,000 years, one-fifteen-hundredth of the time since the animals that have left the oldest fossils lived. There is then a good right to hope that social evolution is only in its early stages.

These stages, moreover, have for the most part taken place in a period during which systematic knowledge was undeveloped. Vernadsky regarded the envelope of the earth as now passing from a stage determined primarily by biological processes to one determined by conscious human effort.

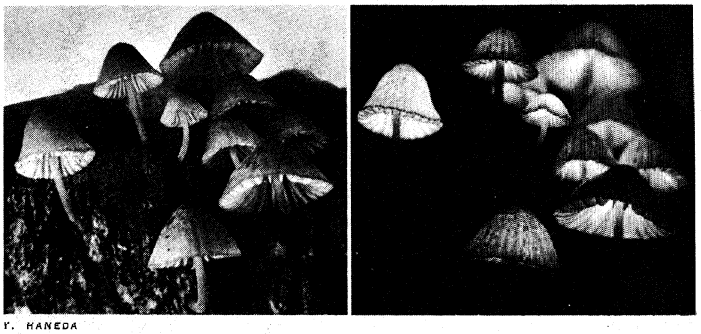
BIOLOGY, MARINE: see MARINE BIOLOGY.

BIOLUMINESCENCE. Any light with a negligible amount of accompanying heat is spoken of as a luminescence or a cold light. It is to be contrasted with an incandescence, where the heat production is large and the light is directly associated with the high temperature. Luminescences may result from various procedures and the word is usually accompanied by such prefixes as radio-, electro-, crystallo-, tribo-, chemi-, etc. These prefixes indicate, respectively, luminescence from previous exposure to radiation of various kinds, or from electrical excitation, from crystallization, from rubbing materials together, or during a chemical reaction. Fluorescence is a type of radioluminescence in which materials emit light while they are being irradiated, whereas in phosphorescence the light continues after the irradiation.



Y. HANEDA

FIG. 1.—FUNGUS **MYCENA** LUX-COELI PHOTOGRAPHED **BY** DAYLIGHT (LEFT) AND BY ITS OWN LUMINESCENCE AT NIGHT (RIGHT)

The word phosphorescence, then, strictly applies only to light production at low temperatures by certain substances called phosphors, after previous exposure to light or radiation of other kinds. However, common usage has applied it incorrectly to the glow of phosphorus, or of the firefly: the sea, dead fish or meat, or wood, the so-called fox fire of forests. Light of the sea, or of fish, flesh or wood, is always due to living organisms of various kinds and should more properly be called bioluminescence or biophotogenesis. Such light is the result of a slow oxidation of material manufactured by the organism and hence is an example of chemiluininescence.

Luminous Organisms.—At least 40 different orders of animals and two groups of plants' contain luminous species.

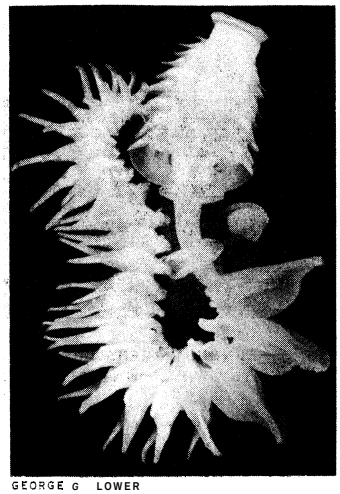
Plants.—The plant groups are the bacteria, which are responsible for the luminescence of flesh, and the fungi, responsible for the luminescence of wood. Either the fine strands of fungus mycelium, which penetrate the wood, or the fruiting body, the mushroom, or both, may be luminous.

Luminous bacteria are so small that individuals cannot be seen by their own light, although natural colonies are easily visible. They may be cultured on artificial media, and they form excellent material for the experimental study of bioluminescence. They are not pathogenic to man 'but are known to infect living animals; giving rise to a natural luminescent disease of sand fleas; shrimp, midges, caterpillars and some other insects that is eventually fatal. Luminous bacteria may also live symbiotically in light organs of fish. It was at one time believed that the luminescence of all luminous animals, even the firefly, was due to symbiotic luminous bacteria, but this view is incorrect.

The characteristic of the light of bacteria and fungi. which distinguishes them from all other luminous organisms, is its uniform intensity, shining night and day, independent of stimulation. Other organisms light only when disturbed or stimulated in some way. This stimulation produces the glow in the wake of a ship, or as waves break on a shore or when a school of mackerel swims through a mass of luminous organisms.

Animals.—Phosphorescence of the sea is largely due to protozoa, of which the radiolaria and dinoflagellata (including *Noctiluca*) are luminous. The latter may develop in such enormous numbers that the sea is a pink or red by day and a vivid sheet of flame by night. Larger patches of light in the ocean are mainly due to coelenterates, jellyfish, siphonophores, or ctenophores (comb jellies). The latter are often very abundant and show the interesting phenomenon of loss of luminescence in sunlight or on bright illumination by electric light. The luminescence again appears on stimulation after about one-half hour in the dark. The ctenophores and coelenterates probably contain more luminous species than any other group, the sea pens or pennatulids showing an especially brilliant luminescence that travels over the colony of polyps in the form of a wave. Nerves carry the impulse that sets off luminescence of each polyp, giving rise to the wave of light. The scintillating light, that appears when the marine growth on old piles or rocks is gently stroked frequently comes from colonies of hydroids, some species of which are luminous. (See OCEAN AND OCEANOGRAPHY : *Phosphorescence.*)

One nemertean worm (*Emplectonema*) is luminous. It lives coiled on an ascidian at depths of 120 ft. in bays along the coast of Japan. Among the true worms or annelids, some earthworms and many marine forms (*Chaetopterus, Polynoe, Tomopteris, Polycirrus* and *Odontosyllis*) are luminous. *Odontosyllis* is the well-known fire worm of Bermuda, which swarms in great numbers during certain months of the year, a few days after full moon. The worms rise to the surface of the sea from coral rock 55 minutes after sunset and shed their eggs and sperm with an accompanying brilliant display of luminescence. The swarming lasts 15 to 30 minutes.



GEORGE G LOWER

FIG. 2.—LUMINESCENT PARCHMENT WORM (CHAETOPTERUS)

Although the worm *Chaetopterus* lives in a parchmentlike tube buried in the sand and never comes out in the open, its body is covered with gland cells that secrete a bright luminous slime when the animal is disturbed. *Tomopteris* is pelagic, but *Polynoe* and *Polycirrus* live among other marine animals. shells and sponges, The luminescence of sponges may be due to luminous animals living on them. but at least one species appears to be self-luminous.

Luminous mollusks are represented by *Pholas dactylus* (a bivalve). *Phyllirrhoe* and *Plocamopherus* (nudibranchs), a land snail (*Dyakia*), a fresh water limpet (*Latia*) and a marine gastropod (*Planaxis*), together with the cephalopods, of which many members produce light. The cephalopods and deep-sea fish possess the most complex lanternlike luminous organs. Among the echinoderms, only the brittle stars (ophiuroids) possess luminous members.

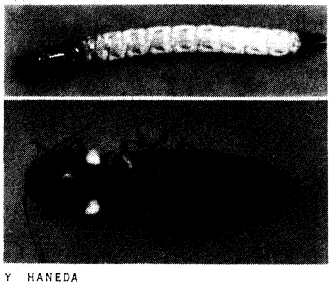
Among the crustaceans. mysids, copepods and ostracods (*Cypridina*) contain many luminous forms. while the schizopod and decapod shrimps possess members with true luminous organs or photophores, often consisting of lens. reflector and pigment screens — veritable lanterns on a microscopic scale. These light organs once were mistaken for eyes. The ostracods and some shrimp eject into the sea an abundant luminous secretion from large glands. thus surrounding themselves with a liquid fire.

Some myriapods and springtails are luminous, as are the larvae of the fly *Arachnocampa* that live in New Zealand caves and beetles (firefly. glowworm and the elaterid *Pyrophorus* of the West Indies). All stages of metamorphosis, including the egg. of some fireflies are luminous. The word glowworm is applied to the larva of the firefly, or to some adult female fireflies that are wingless and hence look like a worm.

The most remarkable luminous insects are beetles of the family *Phengodidae*, related to lampyrids. The males are like any other beetle in appearance, while the fertile females are grublike and larviform, often two inches long. In the North American genus *Phengodes*, the female and larvae possess a row of bright greenish luminescent spots on each side of the body, while the South American form. *Phrvxothrix*. has in addition a red light on the head. hence its local name of *ferrocarril* or "railroad" worm The red light is the colour of a glowing cigarette.

Balanoglossus and the ascidians (*Salpa* and *Pyrosoma*) are also luminous. The latter forms large colonies of minute animals floating on the sea, each individual possessing two luminous spots.

Finally, mention should be made of the fish, both elasmobranchs and teleosts that contain luminous members The deep-sea forms are often bizarre in appearance and sometimes contain the luminous organ on the end of a long process dangled before the animal. Others have rows of lights like portholes along the sides of the body. Most fish are self-luminous, but some forms. such as *Photoblepharon, Anomalops, Monocentris, Equula, Acropoma* and *Physiculus* give off light by virtue of symbiotic luminous bacteria. They possess luminous organs especially designed to nourish the bacteria. In *Photoblepharon* and *Anomalops* from the Banda Islands in Indonesia. the large oval light organs are situated just under the eye and contain rows of long tubular cells full of bacteria A copious netnork of blood capillaries supplies oxygen. The light is constantly emitted, as with other luminous bacteria. but the fish can turn off the lights so that as the fish swim the lights blink on and off in a regular rhythm. This is accomplished in *Photoblepharon* by a black fold of skin drawn over the light spots like an eyelid. In the closely related *Anomalops* the whole light organ is hinged at one end and turned inward toward a groove or pocket to obscure the light.

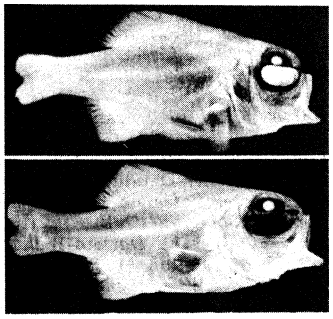


Y HANEDA

FIG 3.— LUMINOUS ELATERID BEETLE (PYROPHORUS HAVANENSIS) (ABOVE) LARVA: (BELOW) ADULT

The sponges, alcyonarians, bryozoans, May flies, termites and spiders contain forms reported to be luminous but light production by these species is still doubtful.

It is rather surprising that it is chiefly land or marine animals that are luminous. No phosphorescence is to be noted in great inland bodies of fresh water, no matter how ancient geologically. and despite the fact that they are deep and contain organisms closely related to marine species that areluminous. In Lake Suwa, Japan, there is a luminous shrimp. but luminescence in this case has been shown to be due to infection with luminous bacteria, not to self-luminosity. The only fresh-water luminous animals are the New Zealand limpet (*Latin*) and the larva of a firefly that lives in tropical pools and streams and breathes by tracheal gills.



HANEDA

FIG. 4.—LANTERN-EYE (PHOTOBLEPHARON PALPEBRATUS): (ABOVE) ORGAN GLOWS WITH LUMINOUS BACTERIA; (BELOW) ORGAN BY FOLD OF SKIN

In general, luminous organs or regions are glandular, and the luminous material may be ejected (extracellular luminescence) as a slime or a secretion, which in the deep-sea squid, *Heteroteuthis dispar*, replaces in function the black ink of the common squid. On the other hand, the luminous material may remain within the photogenic cells (intracellular luminescence) as in the firefly and organisms possessing photophores. There is always a mechanism — either trachea or a rich blood supply — for supplying the organ with abundant oxygen, a fact that indicates light production is usually an oxidation. However, in the ctenophores dissolved oxygen is not required.

Use of Animal Light.—Regarding the use of luminescence to the animal. very little can be said with certainty. In deep-sea forms that live in perpetual darkness. it would seem that. the organs must be lanterns for seeing or recognition. Many luminous forms live where light penetrates, and it has been suggested that the luminescence may be used at night as a warning to scare away predaceous animals that might molest the luminous forms. or as a lure to attract creatures upon which the luminous animal feeds. These suggestions remain to be proved: but it is known that in the firefly the light acts as a signal or attraction to bring the sexes together, and that the different species of fireflies can be recognized by the characteristic length of the flash and interval between the flashes. On the other hand, who can suggest the use of light to a luminous bacterium, an organism $\frac{1}{25,000}$ in. in diameter with no nervous reactions of a higher form. or the use to a protozoan who lives on the surface of the sea and is blown hither and thither by the wind? The logical conclusion seems to be that in these cases the light is fortuitous, a chance phenomenon that accompanies some necessary organic chemical change occurring in the organism.

Chemistry of **Bioluminescence.**—Knowledge about the chemical nature of bioluminescence has accumulated in four steps:

1. R. Boyle (1667) showed that fungi and bacteria require air (oxygen) for luminescence, becoming dark under an air pump and luminescing again when air is readmitted. He drew an interesting comparison between a glowing coal and phosphorescent wood, although oxygen was not known and combustion was not understood at that time.

Y. HANEDA

FIG. 5 —GLOWING DEEP-SEA SHRIMP (SERGESTES PREHENSILIS)

2. R. de Réaumur (1733) showed that water is necessary, that luminous cells can be dried and preserved, and can then be made to produce light by being moistened. This proves also that bioluminescence is not a process involving definite structural peculiarities of the cell, as is the contraction of a muscle or the conduction of a nerve impulse, which mill not occur after drying and moistening. Excellent material for chemical studies of bioluminescence is the dried ostracod *Cypridina,* which gives a bright luminescence in water after being dried for 40 years.

3. R Dubois, in 1887, found that the photogenic material of *Pyroplzorus* and of *Pholas* can be separated into two constituents, luciferin and luciferase, because of their marked difference in chemical behaviour. The latter is destroyed on boiling and behaves like an enzyme or catalyst; the former resists heat and can be oxidized These substances can be precipitated by certain reagents and redissolved in appropriate solvents.

4. E. N Harvey (1918), working with extracts of dried *Cypridina,* showed that after the luminescence had disappeared, due to the oxidation of luciferin in the presence of oxygen, addition of various reducing agents that can add hydrogen to the molecule would reform luciferin. Partial reversibility of the reaction was established. since light again appeared if the newly formed luciferin were reoxidized by luciferase and oxygen. Continued oxidation appears to result in an irreversible oxidation product.

It has been observed that luciferin of one luminous species *(Cypridina)* will not react with luciferase of another unrelated luminous species *(e* g., the lampyrid firefly) or vice versa, but there is interaction between luciferin and luciferase of two different genera of ostracods or of two different genera of lampyrids. Only rarely does the luciferin of *Cypridina* react with a distantly related species such as a fish *(Apogon)* and vice versa. Quite a few different luciferins and luciferases appear to have evolved in different phyla of the animal kingdom, so that these words now stand for groups of unrelated substances rather than for a single compound. Three totally different luciferins are now fairly well known—luciferin of bacteria, of the firefly and of *Cypridina.*

In luminous bacteria, the chemical structure of luciferin is a combination of reduced flavin mononucleotide and a long chain (greater than six carbon atoms) aldehyde. When these substances in aqueous solution are mixed with bacterial luciferase in oxygen-containing water, light appears, even though no cells or cell fragments are present. Both firefly luciferin and *Cypridina* luciferin have been crystallized. The empirical formulas have been given as $C_{13}H_{12}N_2S_2O_3$ for the former and $C_{21}H_{28\,30}N_6O_2Cl_2$ for the latter. Firefly luciferase has also been crystallized, but its relationship to other enzymes is not known. The luciferins and luciferases of some other groups of luminous animals are undoubtedly different, but not enough research has been carried out to determine their chemical structure. It seems fairly certain that among luminous bacteria the luminescent reactions have evolved in connection with the cell respiratory mechanism. In other forms also, the luciferins probably represent a slight change in a group of compounds important in the life of the cell.

In luminescence some molecules must absorb energy, thereby attaining the excited or energy-rich state. On return to normal this excess energy appears as a light quantum. The luminescence intensity is determined by the number of quanta emitted per unit of time. In a fluorescent lamp, molecules of fluorescent ponder on the glass walls of the tube are excited by the energy of incident radiation; with many organic substances the energy of chemical reaction may lead to excitation of molecules, giving such a brilliant bluish chemiluminescence as that of 5-amino-2, 3-dihydro-1, 4-phthalazinedione (luminol) or the yellow chemiluminescence of dimethylbisacridinium nitrate (lucigenin). Many other organic compounds capable of oxidation emit light. such as pyrogallol, lophine. esculin and various essential oils In fact, the whole process of light production by luminous organisms can be so perfectly imitated by such purely chemical reactions that bioluminescence can no longer be considered a mysterious or unusual phenomenon.

Efficiency of Light Production. — Bioluminescence is often spoken of as "cold light." This does not mean that no heat is produced but only that very little appears as compared with the ordinary methods of illumination, which depend on the incandescence of carbon particles in flames or of wires through which a current is passing. The rise of temperature in some luminous animals is less than 0.001° C.

The luminescence spectra of luminous animals consist of bands of different widths and in different positions in the visible region of the spectrum; hence the variation of colour of different luminous animals. which may be reddish, yellow: green, blue or violet. The light is no different. physically, from any other kind of light—it will affect a photographic plate: can induce chemical reactions and can be polarized, although it is never polarized as produced by the animal. No infrared or ultraviolet radiations and no penetrating radiations are produced. Hence the luminous efficiency. *i.e.*, the percentage of the radiant energy which is visible, is very high, nearly 100%. This does not tell, however, what the radiant efficiency is, *i.e.*, the percentage of the energy (chemical) of the oxidation process that appears as a radiant energy; nor does it tell the over-all efficiency, *i.e.,* the energy (chemical) in the food of the animal that appears as visible radiant energy. This is the efficiency in which an illuminating engineer is interested, and studies on luminous bacteria have shown that the over-all efficiency of these forms is at least slightly and probably considerably greater than that of a nitrogen-filled incandescent lamp, when calculated from the energy of the coal necessary to run the dynamo that supplies current to the lamp. Neither the radiant efficiency nor the over-all efficiency of the firefly is known.

It has often been suggested that firefly light, or living light, might someday be used for residential lighting. The intensity is sufficiently great, provided large enough areas are covered. In fact, the modern trend in lighting has been toward larger surfaces of less intrinsic brilliance, as in the fluorescent lamp. Although no chemiluminescence had been used in commercial lighting by the early 1960s, the fluorescent tube, perfected around 1938, seemed destined to replace the electric filament because of higher efficiency, little heat and diffuse illumination. By this change mankind has adopted the principle if not the actual light of the firefly.

(E. N. H.)

BIOMETRY. The word "biometry" comes from the Greek words *bios,* "life." and *metron,* "measure." Thus, etymologically, it means measurements of living phenomena. The word was apparently coined by Karl Pearson, together with the name "Biometrika" as the title for a periodical on biometry, the word initially appearing in print in the first issue of the periodical in 1901.

The etymological meaning of the word is too vague. A much too narrow meaning, now only of hiitorical interest. was given to it by some of its founders: the study of heredity by statistical methods, specifically by the use of correlation coefficients. Francis Galton wrote somewhat vaguely in *Biometrika* (1901) that "the primary object of biometry is to afford material which shall be exact enough for the discovery of incipient changes in evolution which are too small to be otherwise apparent." However, he also stated that "biometry is . . . the application to biology of the

modern methods of statistics." At that time modern methods of statistics meant the use of correlation coefficients. More precisely, biometry is the ensemble of experimental techniques and of conclusions that involve living phenomena and require statistical methods. It pertains to populations of living beings as opposed to individuals.

The experimental techniques range over the whole field of biology, biochemistry and biophysics. The statistical methods range over the whole field of statistics. In fact, most of the basic concepts and methods of modern statistics are due to biological investigations, and the names of Galton, William Sealy Gosset (who wrote under the pen name "Student"), Pearson and R. **A.** Fisher are indissolubly linked to modern statistics as well as to biometry. *(See* STATISTICS for statistical methods, and articles on biological sciences for experimental techniques.)

There are many branches of biometry. Description, classification, regulation and changes, interactions, responses, etc., of living populations form the main part. The populations may be of animals (including humans). plants, bacteria, etc. Their description involves statistical estimation; for instance: forest inventories, estimating mobile populations such as those of fish, insects, etc.

Determination of biological response is a new branch of biometry. For example. in the early 1960s techniques, designs and conclusions for vitamin tests. comparison of toxicities and animal feeding were well developed and in everyday use. Yet physiological biometry as well as biochemical biometry, while common, were in their scientific infancy. For example, the so-called normal ranges were too frequently ill defined and obtained by inadequate experimental and statistical techniques.

Biometry plays an ever increasing role in taxonomy. Populations of the same species may differ according to habitat. or two populations may overlap in some characters; or a population may be a mixture of species. In any of these cases, the investigations and the conclusions must be of a statistical nature.

Studies of competition or, more generally, interactions between species were first based on theoretical models of a deterministic character. It was only at mid-20th century that probabilistic models were introduced. Thus these studies became statistical by the very nature of the phenomena as well as by the unavoidably statistical nature of observations.

The study of heredity was founded by Galton and his followers on correlation analysis, but this basis was soon abandoned in favour of the Mendelian theory. Genetics became a continuously interacting combination of probabilistic models and of biometrical methods; the experimental techniques and the results—for example, estimation of gene frequencies, investigation and changes of breeding structures of populations, or of effects of radiations on body cells or on viruses—are part of biometry.

Although biometry is a young science, by the mid-20th century it was playing a basic role in life sciences and their applications, and giving rise constantly to new experimental and statistical problems and techniques. (ML. LE.)

BION (fl. *c.* 100 B.C.), one of the Greek bucolic poets, was born at Phlossa, near Smyrna, and is stated by the author of the *Lumenf* for *Bion* (wrongly attributed in some manuscripts to Moschus) to have lived in Sicily. Seventeen extracts from his *Bucolica* have been preserved, all but one by Stobaeus. They vary in length from a single line to 16 lines; some seem complete, but others may come from longer poems. The pastoral colouring is superficial, but Bion wrote simply and gracefully about love and sometimes about mortality. A very different poem, the *'Lament for Adonis,* in *98* hexameters. was first attributed to Bion by the German scholar Camerarius (1500–74), chiefly on the ground that the *Lament for Bion* contains clear references to the earlier *Lament.* An Adonis-song forms the conclusion of Idyll xv of Theocritus, hut the *Lament* attributed to Bion owes more to Callimachus' technique as shown in some of his *Hymns.* The treatment is emotional and in its way effective. A fragmentary *Epithalamius* for Achilles and Deidameia in a bucolic setting. which is sometimes attributed to Bion, is probably not by him.

BIONDO, FLAVIO (1392–1463), Italian humanist, a forerunner of modern historical and archaeological scholarship. was born in Forlì in late 1392; he signed himself Blondus or Blondus Forliviensis. After playing an important political role in papal foreign affairs as apostolic secretary to Eugenius IV, he devoted himself to travel, study and writing. His works. distinguished for critical spirit, careful examination of sources, reliability and emphasis on the relations between ancient history and contemporary civilization. include his monumental *Decades,* covering the years 412 to 1410; *De verbis Romanae locutionis* (1435), making Italian a natural continuation of ancient Latin; *Roma instaurata* (1444–46) and *Roma triumphans* (1457–59), describing systematically and accurately the topography and the public and private institutions of ancient Rome; *Italia illustrata* (1453), giving a truthful historical and geographical description of mid-15th century Italy. Other works include further contemporary historical studies. He died in Rome on June 4, 1463. (L. T. SE.)

BIONOMICS, the study of an organism in relation to its environment. *See* ZOOLOGY; ECOLOGY, ANIMAL; PLANTS AND PLANT SCIENCE: *Plant Ecology.*

BIOPHYSICS, in a broad sense, is the physics of living things; that is, it comprises all physical knowledge of the structure and activities of organisms or groups of organisms. In a narrower, more practical and commoner sense, the word is restricted to that scientific specialty which deals with those aspects of organisms that require, for their understanding and investigation, a specialist's competence in contemporary physics. This is the sense in which the word will be used in this article.

Relations to **Other** Sciences.—Some persons regard biophysics as part of physics, others as part of biology. Thus in some universities it is administered with the physical sciences, in others with the biological sciences. Choice of viewpoint is largely a matter of convenience. Clearly, any biophysical research or teaching unit, whether composed of one person or of more, must be competent in both physics and biology, as these broad fields are usually defined.

Biophysics, in its physical aspect. is primarily concerned with the organization and activities of living matter in relation to space, time and mass-energy. Accordingly, it is complementary to biochemistry. which deals primarily with the atomic and molecular composition of organisms and especially with the changes in composition that occur in the course of the organism's activities. The two fields overlap and cannot be sharply separated, particularly in their concern with energy transformations. just as is the case with the physics and chemistry of inanimate objects.

In its biological aspect, biophysics may contribute to scientific understanding of practically any structure or activity pertaining to any organism, part of an organism or group of organisms. It has made fundamental additions to botany, zoology. microbiology and virology; to morphology and physiology, in their broadest senses. The informational content of biophysics, as defined above, increases continually through research, as does that of any other scholarly specialty. However: it also decreases through research, because certain phenomena or certain methods, originally comprehensible only to a specialist in physics. may become so adequately elucidated that the information can be wholly or partly assimilated into the conventional subdivisions of biology that do not demand specialization in physics.

This is illustrated by the history of visible-light microscopy. The great pioneer microscopists of the 17th century had to engage in biophysics. Many of them built their own instruments, and all of them. in order to improve their microscopes and get maximum information from them, used a specialist's understanding of contemporary optics. In the 20th century, tens of thousands of persons use microscopes daily and routinely. They see with little effort much more detail than did the pioneers. but the overwhelming majority. because of the confidence they can place in the physical design and constructional adequacy of modern microscopes. give no thought to (and indeed have little or no knowledge

of) the physics involved in the instrument or in the interpretation of nhat they see The microscopy done by such persons is obviously not biophysics. On the other hand. there is alnays a comparative handful of persons who are continually pushing the microscopy of organisms to new levels of achievement, for instance in such fields as ultraviolet micrography and microspectrophotometry, polarization microscopy. phase-contrast and interference microscopy. Here the resources of contemporary physics are brought to bear not only on the improvement of instruments with respect to their use on biological objects. but also in the interpretation of the spatial and other physical properties that the instruments reveal or measure. Thus, although the total factual content of microscopy is enormously greater in the 20th than in the 17th century and the biophysical portion of this collection of facts has changed through the years, the biophysics of microscopy continues to consist of those aspects of biological microscopy that demand. for their understanding and investigation, a specialist's knowledge of the physics of the times.

Illustrative Contributions of **Biophysics.**—The ultimate goal of biology is a thorough understanding of all types of living things. Chemical analysis of organisms reveals that they contain the same kinds of atoms as are found in the inanimate universe, and that from these are derived a great many kinds of ions and molecules. some of which are encountered also in inanimate objects and some not. The properties and behaviour of these chemical species are the concern of physics and chemistry. It is the task of biophysics and biochemistry to determine how these building blocks are put together into successively larger and more complexly functioning aggregations until ultimately living cells and organisms are produced. In this stupendous undertaking, biochemistry and biophysics must complement each other. The variety and significance of biophysics' contribution toward an understanding of the ultimate structure and workings of living things can be indicated by citing a few examples.

Most cells have dimensions of the order of microns or tens of microns (abbr. μ; $1\ \mu = 1/10.000$ cm.), and the limit of resolution for the visible-light microscope is in tenths of a micron under the most favourable conditions. The ultimate building blocks of cells (atoms. inorganic ions and small molecules such as water, amino acids. fatty acids, sugars, pyrimidine and purine bases, etc.) have dimensions of the order of angstroms (abbr. Å: $1\ Å = 1/10.000\ \mu$). It is thus clear that techniques much more delicate than those of light microscopy must be used to reveal the detailed structure of living things. Of many such techniques. two will be briefly discussed: electron microscopy and X-ray diffraction.

The electron microscope is in principle analogous to the light microscope, except that the wave lengths of the electrons are so short that the limit of resolution is theoretically a small fraction of an angstrom. provided that a perfect machine could be built. In practice the limit of resolution is about 10 Å and resolutions a few times as large are realized routinely. Thus. even if the instrument can be improved no further. it takes the investigator a long way from the dimensions of cells toward those of atoms. It has furnished definite information about the sizes and shapes of the various viruses. those self-duplicating entities whose characteristics lie between those of inanimate things and those of undoubtedly living beings and whose dimensions are mostly of the order of hundredths or tenths of a micron. Perhaps even more important, from the advent of extremely thin sectioning (slicing) techniques in the late 1940s. the electron microscope progressively revealed information concerning the details of cells of conventional size..

Cell parts so small that little or no internal structure can be seen with the light microscope have been found to be meticulously organized systems. For instance. the mitochondria—which appear in the light microscope merely as fine dots or threads—often feature a very striking internal "bookcase" arrangement. the "shelves" of which provide a relatively enormous surface. This feature may help to explain the specialization of the mitochondria. revealed by biochemical methods. for certain subtle catalytic processes that have long been known to be of primary importance in the cell's energy transformations. Again. a structural provision for much surface is found inside the chloroplasts—those green bodies in plant cells that have been recognized for man?; decades as the sites where light is captured, some of the energy being stored in the cheinical bonding of sugars and other organic substances built up from the simple molecular species carbon dioxide and water by the complex biophysical and biochemical process of photosynthesis. which. since the 1920s, has been known to involve not only simple photochemical processes but catalytic ones as well. A striking similarity was discovered between the detailed structure of the chloroplast and that of certain structures in the retina of the eye which have to do, as does the chloroplast, with the capture of light and its transformation to chemical energy. Although the electron microscope can be used only on killed material. it makes major contributions to an understanding of living things. In the application of this instrument to more and more exacting tasks, biophysics in the most sophisticated sense has to play a leading role.

Among the important structures not directly revealed by the light microscope is the cell membrane, a thin layer that forms the boundary between the cell and its environment and regulates in an amazingly complex fashion the exchange of materials between the two. By the early 1930s a variety of biophysical data—such as measurements of high-frequency electrical conductivity of cell suspensions and careful determinations of the rates at which highly diverse ions and molecules permeate the membrane—led to the theory that the membrane consists of a layer of lipid (fatty material) about 50 % thick sandwiched between tn·o thin layers of protein. In the early 1950s the electron microscope revealed several types of cellular membranes to be about 200 Å thick. consisting of a layer 50% thick between two layers each about 70% thick. Thus a new biophysical approach yielded data that support a theoretical model proposed on the basis of a variety of observations made by less direct biophysical methods. The problems of the structure and workings of cell membranes are extremely complex. but the simple example just given demonstrates in a general way how biophysics contributes to scientific progress.

X-ray diffraction is a powerful tool that reveals the spatial relations among atoms or groups of atoms when their arrangement is such that those of a certain sort repeat at definite intervals in definite directions. This technique has been extremely successful in elucidating the atomic configurations in inanimate crystals. including those of comparatively simple cell constituents. such as sugars and amino acids. Although its application to the more complex structural elements of cells yields much less elegant results, the information gained is usually unobtainable in any other way. In the 1920s the method first began to play a leading part in working out the spatial arrangements of the glucose (sugar) molecules that are chemically linked together to form the greatly elongated molecule of cellulose. which is the basic component oi typical plant cell walls and therefore of wood. Applied to proteins, the method yielded astonishing results. Biochemistry built up a formidable store of information about the composition of these numerous. complex and characteristically "biological" substances. including the fact that all of them are composed of a class of molecular building blocks called amino acids. of which only about 20 kinds are found in nature. Chemical procedures yield, more or less routinely, the relative numbers of molecules of the different amino acids that compose a given protein. and in the case of the protein hormone insulin, biochemistry has even been able to determine the exact order in which individual amino-acid molecules of the different kinds are linked together in a polypeptide chain to form the molecule of protein.

However, chemical procedures are not of a nature to yield information about the exact spatial configuration of the polypeptide chain. On the other hand, the physical approach. featuring X-ray diffraction data. has made stimulating contributions in certain favourable cases, for instance that of α keratin, a protein that is the main constituent of certain relatively stable biological structures. such as hair, nails and feathers. This work. started in the 1920s. advanced to the point that in the early 1960s it could be concluded with a high degree of probability that in α keratin the chain of amino-acid residues forms a helix that has about 3.6

residues per turn and a pitch of about 5.4 Å, the helical form being maintained largely by hydrogen bonds between adjacent turns of the spiral. Certain other proteins have been found to have different but equally characteristic configurations. X-ray diffraction studies, incidentally, furnish a good example of a research area that is likely to remain for a long time as sophisticated biophysics. One does not obtain directly. as for instance with the electron microscope. a fairly undistorted, highly magnified picture of the object studied. Instead one gets, on photographic film: patterns of spots. arcs, rings. etc.. whose dimensions. intensities and relative positions must be subjected to highly mathematical interpretation in order that the actual structures may be deduced. Thus. a critical understanding of these matters is accessible only to those thoroughly trained in the pertinent physics.

Innumerable problems arise in attempts to understand how the nervous system correlates the functionings of the various parts of a many-celled organism, such as a man. Among the most basic of these problems is that of how a "message" is transmitted along a single nerve fibre, which is a long cylindrical protruding portion of a single cell (neuron) and usually has a diameter of a few microns. In rare instances, however, fortunately for the investigator, this dimension may be in hundreds of microns. Like all other cells, the unstimulated neuron maintains a potential difference (resting potential) across the cell membrane. the inside of the cell being negative with respect to the outside. About 1930, through an ingenious combination of electrical techniques with a functional isolation of single fibres by patient and skilful microdissection. it was clearly demonstrated that each "message" transmitted along a fibre is characterized by a series of electrical disturbances (impulses) that are propagated at uniform speed. At each point along the length of the fibre. each impulse is manifested by a transitory change in the magnitude, and even in the sign of the potential difference between the inside and the outside of the fibre. Each impulse passes a given point in a matter of milliseconds.

In any given fibre the change in potential difference is of the same magnitude for all impulses. regardless of the nature and magnitude of stimulus used to produce them. The frequency of the impulses within a series (volley) does, however, vary with the stimulus, so that information about the magnitude of the latter can be included in the message. These and similar basic biophysical facts revolutionized the concept of nerve function and laid the groundwork for a field of investigation so far-reaching that it is in itself a major scientific specialty devoted to answering such questions as: How, in terms of atoms, molecules and ions, does the stimulus initiate the impulse? How does the impulse propagate itself? What is the ultimate basis of the observed transitory change in potential difference from the resting value for an unstimulated fibre? Among numerous interesting partial answers was the demonstration, about 1950, that the impulse is intimately correlated with migration of potassium ions across the cell membrane, this movement being meticulously correlated with an opposite migration of sodium ions.

Progress.— The foregoing examples, although few, amply illustrate the fundamental nature and significance of the contributions that biophysics, by virtue of its characteristic methods and points of view, has made and is making to an understanding of organisms.

Biophysics demands an unusual versatility. Effective biophysical research on any aspect of an organism demands not only competence in contemporary physics but a broad grasp of general biological principles and a detailed mastery of the available information about the specific object under investigation.

Since such versatility is difficult to achieve, even at the doctoral level of formal education, unless the training of the student is planned and integrated from the baccalaureate stage or earlier, it is not surprising that biophysics has mostly been practised by persons whose initial professional training was not specifically directed to that purpose. There have been many instances in which a professional physicist and a professional biologist have formed a productive team. The chief drawback here is in communication. One or each must learn considerable about the other's basic field if the work is to be effectively planned and executed. There have also been numerous instances in which a professional physicist or biologist has achieved adequate versatility by intensive postdoctoral training in the field of his deficiency. The chief difficulty here is that this late training. usually informal and largely self-supervised, is likely to be relatively narrow. Nevertheless, the results are frequently surprisingly good. Since, in most cases. it is easier for a postdoctoral physicist to become trained in biology than for a biologist to achieve comparable training in physics. with its considerable mathematical prerequisites, converted physicists are the more likely to be effective in their contributions to biophysics. It is thus very encouraging to note that, after about 1930. more and more physicists were attracted to investigations on organisms.

Naturally the persons best qualified to advance biophysics are those specifically trained for it. Despite the versatility demanded. doctoral training can be achieved in a reasonable time if it is planned well and is started not later than the baccalaureate stage. Starting about 1930, both students and university authorities became increasingly aware of this fact and acted accordingly. The resulting yield of professional specialists was of great importance for progress in biophysics.

BIOPSY, a medical diagnostic procedure in which cells or tissues are removed from a patient and examined visually, usually with a microscope. The material for the biopsy may be obtained by several methods and with various instruments, including aspiration through a needle, swabbing with a sponge, scraping with a curette, trephining a bone or excision with a forceps or electric snare. The biopsy is a standard step in the diagnosis of malignant and benign tumours. *See* CANCER: *Diagnosis;* TUMOUR: *Diagnosis of Tumours.*

BIOT, JEAN BAPTISTE (1774–1862). French physicist, best known for his work in polarization of light, was born in Paris on April 21, 1774. In 1800 he became professor of physics at the Collège de France, through the influence of Laplace, from whom he had sought and obtained the favour of reading the proof sheets of the *Mécanique céleste.* In 1804 he accompanied Gay-Lussac on the first balloon ascent undertaken for scientific purposes. In 1806 he was associated with D. F. J. Arago (*q.v.*), with whom he had already carried out investigations on the refractive properties of different gases, in the measurement of an arc of the meridian in Spain, and in subsequent years he was engaged in various other geodetic determinations. In 1820, aith Felix Savart, he discovered the law knonn as "Biot and Savart's law" *(see* ELECTRICITY: *Magnetic Fields of Direct Currents).* He died in Paris on Feb. 3, 1862. He was especially interested in questions relating to the polarization of light, and his observations in this field, which gained him the Rumford medal of the Royal society in 1840, laid the foundations of the polarimetric analysis of sugar. *See* also STEREOCHEMISTRY: *Early History of Stereochemistry.*

BIOTITE is an important rock-forming mineral belonging to the mica group. The name was given in honour of the French physicist J. B. Biot. Biotite, a hydrous silicate of potassium, magnesium, iron and aluminum, with small amounts of other elements, is a common constituent of many igneous and metamorphic rocks; it is stable over a large range of geological conditions. Sometimes called black mica, it is found in both deep and shallow intrusive rocks and persists in some lava flows. It may be abundant in dikes, veins and in pegmatites, where crystals may grow to exceptional size. One crystal 14 ft. in diameter and 33 ft. long has been found. Biotite appears in the lower grades of regional metamorphism of the clayey sediments, and in many of the contact metamorphic aureoles developed in sediments around igneous masses. Some varieties of biotite have been synthesized. The iron-free synthetic and natural varieties are useful in the electrical and electronics industries.

The biotites possess a perfect basal cleavage and two partings.

The crystals are usually lamellar or six-sided prisms. The colour is usually black, brown, green or yellow, but some varieties are colourless. The biotites exhibit several polymorphic forms based on the stacking of the simple, layered, crystal structure. Common biotite usually has a one-layer monoclinic structure; however, several polymorphs may be found in the same hand specimen. The hardness ranges from 2.5 to 3, the specific gravity from 2.8 to 3.4, and the indices of refraction from 1.535 to 1.690. Birefringence (or double refraction) and pleochroism (or the appearance of different colours under polarized light) are strong. Inclusions are common and may give rise to the appearance of starlike rays. The biotites are decomposed by sulfuric acid, leaving a silica residue. They alter readily to chlorite; other products may include potash feldspar, rutile, magnetite, quartz and hematite. Weathering reduces biotite to vermiculite, or to a clay, quartz and hematite. Biotite is complex in composition and may be expressed by the general formula $XY_{2-3}Z_4O_{10}(OH, F)_2$, where X is K, Na and small amounts of Rb, Cs and Ba; Y is mainly Mg and Fe^{2+}, with Al and Fe^{3+} and small portions of Mn and Ti; and Z is Si and Al, usually in the ratio of 3:1 but extending to about 2:1 in some varieties.

For further discussion of crystal structure, polymorphism, composition and mineralogical properties *see* MICA. *See* also GEOCHEMISTRY: *Geochemistry of the Lithosphere;* MUSCOVITE; PHLOGOPITE. (H. S. Y.)

BIPRISM, FRESNEL'S, two prisms of exceedingly small vertex angles placed base to base so that two slightly separated virtual images are seen, or may be projected, of an illuminated slit placed in the plane of contact of the two bases. Along the area where the two virtual images of the single slit source overlap, interference fringes may be observed almost identical to those produced by reflecting—from two polished mirrors set not quite coplanar—two overlapping virtual images of a single slit source. Augustin Jean Fresnel (*q.v.*) devised the method of mirrors and biprism to support the experiments of Thomas Young (*q.v.*) and others in favour of the wave theory of light, which at that time was being attacked without factual support by the adherents of the corpuscular theory of light set forth by Isaac Newton. *See* INTERFEROMETER; LIGHT: *Age of Fresnel.* (H. B. LM.)

BIQUADRATIC, an adjective used in mathematics to refer to the fourth power of a quantity; that is, to the square of a square. It is used in connection with equations or algebraic functions. The equation $ax^4 + bx^3 + cx^2 + dx + e = 0$ is a biquadratic equation, since the highest power of the unknown quantity (x) is the fourth; that is, x^4 is the square of x^2, or the square of the square of x (the *bi,* "two" + *quadratus,* "square"). The general biquadratic equation was first solved by Lodovico Ferrari (1522–1565) and was published by Geronima Cardano in his *Ars Magna* (1545). Except in the above cases and in connection with a few geometric figures the word "quartic" is used instead of "biquadratic." *See* EQUATIONS, THEORY OF: *Formulus for Solving Equations of Low Degree;* FERRARI, LODOVICO.

BIRBHUM, the northernmost district of the Burdwan division of West Bengal, India. Pop. (1961) 1,447,638. Area 1,757 sq.mi. The western half of the district is an undulating upland rising to 3,000 ft., its surface being diversified by hot springs and hills of granite and basalt, while the eastern half is a flat, densely populated alluvial plain. The Ajay, Mayurakshi, Bakreswar and Dwaraka are the principal rivers. The Mayurakshi project provides water for irrigating about 600,000 ac. of arable land, and 2,000 kw. of power throughout the year for electrifying towns and countryside. Rice is the main crop. There are stone quarries at Dubrajpur and Nalhati. Silk and shellac are the principal industries. Suri (pop. 22,864), the district headquarters, has a beautiful carved brick temple. Rampur Hat (pop. 19,733) is a market town and contains a college and a hospital. Bolpur (pop. 23,361) is the chief rice-exporting town, and the nearest railway station for Santiniketan, the seat of Visva-Bharati university, founded by Rabindranath Tagore (*q.v.*). Dubrajpur and Sainthia are small market centres. (S. P. C.)

BIRCH, THOMAS (1705–1766), English historian and biographer, whose numerous works are valuable source-books for 17th-century history, was born at Clerkenwell on Nov. 23, 1705. A priest in the Church of England, he held a succession of country benefices, and from 1744 until his death was rector of St. Margaret Pattens, London. In 1735 he was elected fellow of the Society of Antiquaries and of the Royal society. From 1752 to 1765 he was secretary to the Royal society, of which he wrote the *History* (1756–57). He was killed by a fall from his horse in London on Jan. 9, 1766. He left his books and manuscripts to the British museum.

Birch's output was enormous. He invariably consulted original sources, and although he was derided for his pedestrian style by such contemporaries as Samuel Johnson and Horace Walpole, the value of his work is increasingly recognized. His *Collection of the State Papers of John Thurloe* (1742) is the chief source for the political history of the Protectorate. He contributed 618 lives to *A General Dictionary* (1734–41), of which he was the main editor.

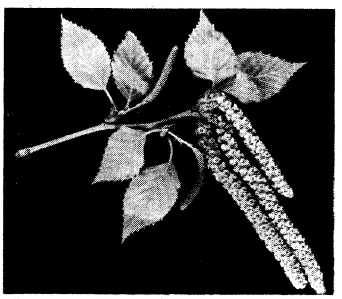
See A. Kippis, *Biographia Britannica* (1778–93); J. M. Osborn in *Modern Philology,* vol. xxxvi (1938).

BIRCH, the name applied to about 40 species of trees and shrubs belonging to the genus *Betula* of the Betulaceae. Widely scattered through the cooler regions of the northern hemisphere, the birches are readily distinguishable from their forest associates. Their alternately disposed, simple, deciduous, ovate, oblong or triangular leaves feature toothed margins, while their inconspicuous unisexual flowers, borne in unisexual catkins (monoecious), appear before leaf emergence in the spring. The fruit is a multiple of tiny, one-seeded, winged nutlets borne in conelike clusters that disintegrate at maturity. A wintergreenlike aroma emanates from the bruised twigs of several species. The bark, especially on most young trees, peels off horizontally into thin sheets of varying hues and texture.

There are at least eight birches indigenous to North American forests, three of which are timber trees of primary importance. The foremost, the yellow birch (*B. lutea*), with yellow-bronze bark, is a tree 60 to 80 ft. tall and 24 to 36 in. in diameter (maximum 100 ft. by 48 in.). Ranging from Newfoundland to western Minnesota and over the Appalachian highlands to northern Georgia, it contributes about 75% of the American harvest of birch timber, the bulk of which is produced in New York, the Great Lakes states and southern Canada.

The hard, strong, reddish-brown wood is manufactured into furniture, flooring, millwork and plywood. In finishing, it is often stained to simulate either walnut or mahogany. The wing, fuselage and *empennage* skins of the renowned British Mosquito bombers used in World War II were molded with yellow birch plywood. Sweet birch (*B. lenta*), also called cherry birch in allusion to its cherrylike bark, attains neither the stature nor the broad distribution of yellow birch. Lumber production of this species is centred in Pennsylvania and West Virginia. The woods of both species are similar and are used for essentially the same purposes. Commercial birch oil, marketed as oil of wintergreen and now made synthetically, was originally derived from the bark and twigs of sweet birch.

Paper birch (*B. papyrifera*), including its western varieties, is a widespread transcontinental species extending from Labrador to 70° N. in Alaska and south to New England, New York, Nebraska and Washington. Rarely exceeding a height of 60 ft. or a diameter of 20 in., the tree is easily distinguished by its creamy-white bark, once universally used by northern American Indians as a skin for their canoes. The wood of paper birch is white, moderately hard, and is largely consumed in production of spools, shoe findings, dowel rods, toothpicks, swab sticks and tongue depressors. River birch (*B. nigra*), the only birch in southern United



BY COURTESY OF U.S. DEPARTMENT OF AGRICULTURE

PAPER BIRCH (BETULA PAPYRIFERA) LEAVES AND (LEFT) FEMALE AND (RIGHT) MALE CATKINS

States at low elevations, and gray birch *(B. populifolia)*, of the northeast, are trees of secondary commercial importance.

White birch (B. *pendula*) is indigenous to the greater part of Europe and abounds in Asia Minor and Siberia. Comparatively short lived and seldom exceeding a height of 50 ft. or a diameter of 12 in., it flourishes on light soils and is one of the few trees that will grow with heather. It is one of the most useful trees in the U.S.S.R., where the wood is employed for many purposes. The water-impervious bark is fashioned into several kinds of liquid and food containers and is the principal roofing material in many villages. The bark is used in general tanning, and an empyreumatic oil extractive, also from the bark, is employed in making Russian leather. Several horticultural varieties of white birch are prized ornamentals. Included among them are var. *purpurea,* with purple leaves; var. *dalecarlica,* with deeply lobed leaves; var. *tristis,* with slender pendulous branchlets; var. *fastigiata,* with closely appressed, ascending branches forming a narrow columnar crown; and var. *gracilis,* with pendulous branchlets and finely dissected leaves.

Two Japanese birches, B. *maximowicziana* and *B. grossa,* are productive of timbers the equal of the yellow and sweet birches; both are important to the Japanese plywood industry. B. *alnoides* is the common birch of northern India.

A few unrelated species bearing superficial resemblances to *Betula* are also known locally as birch. Among these are the West Indies birch (*Bursera simaruba*); the bog birch *(Rhamnus caroliniana)*, a small tree in southeastern United States; and four Australian species, known respectively as cherry birch (*Schizomeria ovataj*, ivory birch *(Baloghia lucida)*, golden birch *(Endiandra compressa)* and streaked birch *(Strychnos arborea)*.

(E. S. HR.)

BIRD, the name for any animal of the class Aves, which comprises 10.000 to 12.000 living species. Birds are most easily distinguished from their nearest relatives, the reptiles, and their more distant relatives, the mammals, by being clothed in feathers. without exception.

A more elaborate definition is as follows: A bird is a warm-blooded vertebrate animal with a four-chambered heart (shared with all mammals); with forelimbs modified into wings (shared with some mammals; *i.e.*, bats); with a body covered with feathers (unique); with reproduction by calcareous-shelled eggs; and with keen vision — the major sense relied upon by the bird for information about its environment.

The historical development of the study of birds is traced in the article ORNITHOLOGY; the present article; dealing with the animal itself, is divided into the following sections:

I. BIRDS AND MAN

Since earliest times birds have helped to satisfy man's material needs and to provide him with recreation. They have also been sources of inspiration and have been used as symbols. This close association between man and birds can be traced back through recorded history and its earlier existence can be inferred from the activities and beliefs of present-day primitive peoples.

A. Birds in Literature and Legend

1. Early Interest. — Birds as objects of general interest have always been woven into the writings and art of man There are a few bird figures on the walls of the Lascaux cave (France). relics of the work of Old Stone Age man Long before ornithology emerged as such, man's interest in birds and his knowledge of them found expression in the general conversation and stories of the people which crystallized into the records of their general culture. Bird figures are found in ancient Egyptian hieroglyphs and paintings The Bible also is rich in references to birds. including Noah's use of the raven and then the dove to bring him information about the state of the flood Aesop's fables abound in bird characters. The *Physiologus* and its descendants, the bestiaries of the middle ages, although considered serious natural history by some, read more like moralistic writings using birds as symbols for conveying ideas: they indicate little knowledge of birds themselves

Supernatural beliefs in regard to birds probably took hold on the mind of primitive man as early as did recognition of the fact that birds are good to eat The Australian aborigine still drives a black and white flycatcher from his camp lest it overhear his conversations and carry tales to his enemies; peoples of the Pacific islands use figures of frigate birds in their carvings. as the Pacific coast Indians use the raven and the Indians of Central America worshiped the quetzal.

2. Contemporary **Interest.**—With increasing leisure and education in the 20th century, more people have become interested in their environment. As birds are one of the most attractive features of animate nature, a tremendous amount of writing and reading about birds is done each year. and many people watch birds, band birds and study birds as a hobby.

It is not possible to separate all that is written about birds into scientific nritings and popular nritings. Ornithology more than any other science, except anthropology, has had the help of the nonspecialist. Important data on birds are contained in many papers written for the general reader, and many specialists have imparted literary style to their writings. It is in this great middle ground that students of birds have been successful in putting the knonlcdgc of their science before the general public. James Fisher estimated that more than 100,000 persons in Great Britain and 250,000 in North America own at least one bird book, and in Great Britain one bird book is published each week. The leading American bird journal, the *Auk,* has a circulation of about 3,000. and the *Audubon Magazine,* originally a bird journal, but now one that embraces all popular natural history. reaches 30.000. *See* also BIRD WATCHING; MIGRATION, BIRD: *Bird* Banding.

B. USES OF BIRDS

1. Food.—Many birds have tasty flesh and palatable eggs, which probably were eaten by most primitive people when opportunity offered Rut it was only nhere birds were especially plentiful, as at nesting colonies of sea birds, or where there nere species of considerable size such as the rhea of South America and the emu of Australia, that they nere important as food. Birds are economically important today in some parts of the world. In Greenland, the Eskimos take quantities of eider ducks and dovekies in the summer and store them for the minter, when they are an important part of the food supply. The Faeroe islanders annually take one-half million puffins in addition to other birds and eggs for food, salting the birds in brine and preserving the eggs in water glass. and the islanders of Tristan da Cunha make annual trips to bird colonies for supplies of the meat, fat and eggs of penguins and petrels.

In the orient certain swifts that nest in great numbers in caves use in making their nests a salivary gland secretion that hardens into a solid. A soup made from these nests is prized and the packaged nests are even available in markets in occidental cities (see BIRD'S NEST. EDIBLE). On the islands off southern Australia an industry in muttonbirds, or shearnaters. has been carried on for over a century. In a good season about 750,000 young birds are captured, and their carcasses are either salted in barrels or canned (squab in aspic) for the commercial trade.

In Europe, where wild birds are not really essential as food, many small songbirds are killed and eaten each year. In North America an abundance of ducks, geese. shore birds and passenger pigeons was exploited relentlessly by hunters shooting for the market until the early part of the 20th century. when such practices were outlawed (see WILDLIFE CONSERVATION). In most places, domesticated birds, or poultry, rather than wild birds. make the chief bird contribution to man's diet, either as flesh or as eggs.

2. Domesticated Birds.—There are four major domesticated birds, or poultry: domestic fowl (chickens), ducks, geese and turkeys.

Chicken.—The chicken provides the greatest contribution to man's larder, and its egqs are probably more important than its flesh. Although many difierent-looking breeds have been developed under domestication, all are descended from the red jungle fowl, *Gallus gallus,* one of the four species of jungle fowl, in southern Asia. Domestication probably took place in India or Siam before 2500 B C., and the birds were brought to central Europe by about 1500 B C. Chickens are raised in most parts of the civilized world and also by many primitive peoples in Africa, South America and the Pacific islands.

Duck.—Most domestic ducks—even such widely different breeds as the Indian Runner and the Pekin—are descendants of the common mallard of northern Europe. Although it has been suggested that ducks were domesticated even before chickens, they have never become so important as a source of food. The muscovy duck of tropical America also has been domesticated and has been carried by man to many parts of the world. Except for white or piebald varieties the muscovy duck has changed little in appearance from its wild progenitor.

Goose.—The graylag goose of Europe and Asia was the ancestor of all the common geese of the barnyard except for those called Chinese or African, including the white breed with a knob on its bill; the latter's ancestor was the swan goose of China. Geese. it is suggested, were the first domesticated poultry.

Turkey.—This American contribution to the poultry yard was domesticated in Mexico before the coming of the white man. The Spaniards carried it to Europe, from where it was introduced into the United States.

Others—A few other birds have been domesticated on a lesser scale, among them the pigeons. descendants of the rock dove of Europe, with many much modified varieties; and the guinea fowl, little modified from its African ancestor. Ostriches have been raised on ostrich farms for their plumage. Peacocks and other ornamental pheasants, swans and waterfowl are better classed as ornamentals (see below).

3. Feathers in Clothing and Ornamentation.—Although the feather coat of a bird may be warm, the skin is usually fragile, so the use of bird skins for clothing has never assumed much importance Eskimos, however, do make warm undergarments of some duck and auk skins.

The down of the eider ducks of the North Atlantic provides a light, resilient, warm material for the padding of quilts, sleeping bags and outdoor jackets. Eider down, gathered from the nest of the duck, is the down the female has plucked from her breast and put into the nest to form a blanket for her eggs. The harvesting of these feathers has been put on a continual-yield basis in such countries as Iceland through legislation regulating the amount harvested each year. The feather cloaks worn by people in the more temperate regions, such as the cloaks of feathers of some of the original Hawaiian islanders. were apparently emblems of rank rather than useful articles of wear.

Parts of the whole bird art: worn by primitive man in many regions of the world: a necklace of parrot feathers by a South American Indian; a war bonnet of eagle plumes by a North American Indian; a hat decorated with bird feathers by an African tribesman; a hornbill or cassowary head ornament or an elaborate bird of paradise dance ornament by a New Guinea native. In some cases these bird parts may be simple ornaments, comparable to the hibiscus flower worn behind a Papuan's ear; in others they may be fancy dress; and in still others an indication of rank or achievement by the wearer.

4. Pets and Ornamentals.— The cage bird, used like the potted plant in enlivening a dwelling, has been much more popular in Europe and Asia than in North America, and many species of birds of bright colour, cheerful voice or engaging habits have been caged. The most widely popular songbird is the canary, a yellowish descendant of the wild, more sparrowlike bird of the Canary Islands, and many varieties of it have been developed. Parrots are often kept in captivity, either in cages or, as with some of the larger species. chained to a perch, indoors or out. The three most commonly tamed parrots are the African gray; the green and yellow Amazons of various species; and the small budgereegah (budgerigar) of Australia, all of which add to their other interesting habits by having the capacity, in varying degrees, of imitating human speech. In the orient various starlings called mynas are popular cage birds, and these, especially the wattled myna, which may speak a few words, have some vogue in the western world.

Swans. living on ponds in city parks, are the best known of the ornamental birds, but many other species of waterfowl—especially the males with the brightest colours—also are used, and colourful pheasants such as the golden and the Lady Amherst are kept to add interest to estate grounds. The peacock. a semidomesticated bird, is probably the best known of the pheasant group. In more tropical climates flocks of flamingos are sometimes kept to ornament race tracks. and macaws and cockatoos are perched on balconies or in gardens for decoration.

Birds as decorations have been popular in modern societies. too, especially as adornments for women's hats. This use reached its peak about the beginning of the 20th century, and plumes and whole birds of many species from all parts of the world appeared in the millinery trade. This fashion was responsible for a worldwide trade in feathers and bird skins, a traffic that subsequently

dwindled almost to nothing. Although feathers are still used in women's hats. they are more likely to be the feathers of domesticated birds, chicken, pheasant, guinea fowl and turkey, rather than those of wild birds.

5. Sport. — Before the days of firearms, hawks, falcons and eagles were used in capturing other birds and smaller mammals. The hawks were tamed rather than domesticated: when the prey was sighted, the hawk was loosed; it followed and struck down the prey and stayed with it until the huntsman came up. Falconry mas very popular in Europe in the middle ages, and an elaborate social code and special vocabulary grew up about it. The sport continues to be popular in Arabia and India, where it has flourished for centuries, and it has experienced a modern revival in the United States and Europe (see FALCONRY). Netting of waterfowl was carried on in ancient Egypt, as shown by pictures decorating the tombs, and in a different form has been carried on in present-day Japan.

With the advent of shotguns, the hunting of birds for sport changed in the western world, where people could afford firearms and ammunition Hunting with a shotgun was abused for a time in North America and degraded into market shooting and in competitions to kill as many birds as possible. But by the mid-1900s the size of a sportsman's bag ceased to be regarded as the mark of his skill. Small bags and a short open season are the rule and are compatible with the continued existence of waterfowl. Nonmigratory game birds such as quail and grouse present other problems of management which state and federal governments attempt to solve by restocking and by providing controlled public shooting grounds (see WILDLIFE CONSERVATION). Locally, commercial preserves are stocked with birds that are available to the public at a fee. Trapshooting and skeet shooting, in which clay disks called clay pigeons are thrown into the air as targets, have nearly but not completely replaced an earlier practice of releasing live pigeons as targets.

Just as literature and science grade imperceptibly into each other in some writings on bird watching, so do sport and science in some bird listings. In 1955 a national magazine in the United States, reporting on the annual co-operative Christmas day bird census in North America, classified the account under "sport." This census. instituted in 1900 by the American naturalist Frank M. Chapman as a substitute for the then popular Christmas day shoot, provides a record of bird abundance over a 50-year period, which is of considerable scientific importance.

6. Guano Fertilizer. — Great bird rookeries, or colonies, found in some dry regions bordering the sea, become incrusted with piles of excreta of birds. This dried excrement, called guano, provides a fertilizer rich in phosphates and nitrogen. The deposits are exploited commercially in Australia, Republic of South Africa and, most important, by Peru. The birds that build up the deposits vary with the locality, but various species of cormorant and booby (gannet in England) are usually most important. (See GUANO.)

7. Messengers. — Before the days of radio and telephone, birds were of some importance in transporting messages quickly. Some South sea islanders used frigate birds as messengers. Patrons of sporting events in early Rome took swallows from their nests to the arena, attached coloured threads to them and then released them to fly home and announce the winners of various events. The pigeon, however, was the chief bird messenger of the western world, being used in wartime as early as the beginning of the Christian era, according to Pliny, and commonly for a long time afterward. The outcome of the battle of Waterloo, in 1815, was brought to the Rothschilds by pigeon messenger. Pigeons are no longer commonly so used, but they continue to have some value as quick, secret conveyors of messages; they were used extensively by the German, British and American forces in World Wars I and II, and by the United States in the Korean conflict. In the latter action, pigeons were used by seven groups of agents parachuted behind enemy lines, and during a four-month period not a single message was lost (see also PIGEON).

8. Values, Pro and Con. — The influence of birds in maintaining the balance of nature is hard to weigh. They eat both harmful and beneficial insects, and seeds and fruits. To try to assess the value of any single element in the whole web of life is impracticable. It may be demonstrated perhaps that a certain flower is pollinated by a certain nectar feeding bird, and that the numbers of one type of insect are checked by the predation of certain birds; these situations, however, are not viewed from the vantage point of evolution — they may or may not be significant in the long run.

With man's cultivated crops and domesticated animals, the case is different. When a hawk takes a chicken, or a heron or a kingfisher takes to living on the fry in a fish hatchery, or a flock of birds descends on a field of grain, the damage is immediately apparent to the man involved and steps are usually taken locally to prevent such loss. Notable cases of this include the invasion of emus into the wheat fields of western Australia and the appearance of great swarms of queleas (weaverbirds) in the grain fields of Africa. But some outcries against birds. such as those against the fish-eating cormorants thought to be harming the commercial fisheries in such widely separated localities as Canada and Australia, prove to be unfounded upon investigation.

II. NATURAL HISTORY AND HABITS

A. LOCOMOTION

Because of their body structure and their feathery body covering, birds are the best fliers among animals, better than the insects and the flying mammals, the bats. There are, however, considerable differences in flying ability among various birds. Penguins cannot fly, but spend much of their time in the water swimming with their paddlelike wings; such birds as ostriches and kiwis have rudimentary wings and are permanently afoot. At the other extreme are the long-winged swifts and frigate birds that move from their perches only to fly, never to walk. Most birds alternate some walking or swimming with their flying.

Birds usually fly when they have any considerable distance to travel; there are exceptions, however. The mountain quail of California make their annual migrations up and down the mountains by foot. The murres, or guillemots, of the Greenland coast migrate southward by swimming; they begin their journey before the young have grown their flight feathers and before some of the adults at least have regrown their recently molted ones. The Adélie penguins may ride northward on drifting ice floes; at the approach of nesting time they swim back to the antarctic continent and then walk over the ice to their breeding grounds many miles inland.

1. Flight. — Birds fly by flapping their wings, steering mainly with their tails. A goshawk, pursuing its prey through the forest, uses its long tail in making quick turns, and the barn swallow uses its deeply forked tail in making the involved patterns of its graceful flight. Ducks with their short tails have a swift but direct flight. There is, however, such great diversity in birds' tails that the precise size and shape probably is not of critical importance.

Comparing a bird to an airplane, a bird's wing is both wing and propeller. The basal part of the wing supplies most of the supporting surface, the wing tip most of the propelling force. A bird's wing has many adjustable features: it can be shortened or lengthened by flection; the feathers of the tip can be spread or closed; the angle of the whole wing or its parts, on one side or the other or on both sides, can be altered. All these adjustments make the aerodynamics of a bird's wing much more complicated than those of the airplane; consequently, the flight of a bird is much more varied and adaptable.

Flying ability varies widely among birds, and different types of wings correlate with different types of flight. Many songbirds use their short, rounded wings mostly to move with quick wing beats from perch to perch or from ground to perch. Ducks have pointed wings that, beaten at high speed, provide rapid flight for long distances. Swallows, terns and frigate birds have long, pointed wings that enable these birds to fly and maneuver gracefully for hours with leisurely wing beats. Large herons with long, broad wings travel far with slow, measured wing beats, while buzzards soar high in the sky on their long, broad wings. Gulls and albatrosses with long, narrow wings sail along the beaches or over the waves with infrequent wing strokes. A hummingbird can whir

its tiny wings so rapidly that it can hover as it thrusts its long bill into a blossom; it can even fly backward as it leaves the bloom.

Speed.—The speed with which birds fly varies greatly from species to species, and of course individual birds can vary their speed. The data on the speed of birds' flight are difficult to evaluate. One of the complicating factors is that a bird's speed in relation to the ground may depend on the force of the wind. A bird flying at 40 m.p.h. with a 60-m.p.h. mind behind it would travel at 100 m.p.h. The same bird flying into a 60-m.p.h. wind would be losing ground at the rate of 20 m.p.h. Despite the variables involved in determining a bird's speed of flight, the following generalized speeds, based on level flight in calm air, appear to be sound:

10–20 m.p.h.—many small songbirds such as sparrows and wrens
20–30 m.p.h.—many medium-sized birds such as thrushes and grackles, and larger, long-winged birds such as herons, pelicans and gulls
20–40 m.p.h.—many small- and medium-sized birds such as starlings, chimney swifts and mourning doves
40–60 m.p.h.—the faster-flying birds such as falcons, ducks, geese and domestic pigeons

There are many faster records, often disputed, such as that of 200 m.p.h. for an Indian spine-tailed smift in level flight, and 570 m.p.h. for a golden eagle in a dive. A homing pigeon has been timed at 94.3 m.p.h.

Range.—The record long-range flight of a bird species in a single season is undoubtedly held by the arctic terns that migrate from a summering ground in the arctic to a wintering ground in the antarctic, traveling more than 7,200 mi. one way. Some long-range flights are made very quickly: a blue-winged teal banded in Canada was recovered 3,800 mi. away in Venezuela only 30 days later; a Manx shearwater, trapped at its nest in Wales and transported 3,200 mi. to Massachusetts and released, returned home in 12½ days. Some very small birds regularly make long water crossings in a single flight. Ruby-throated hummingbirds fly across the over 500-mi.-wide Gulf of Mexico, and many warblers fly from the American coast to Bermuda, a journey of about the same distance. (See also FLIGHT [NATURAL].)

2. **Flightlessness.**—Flight, so characteristic of birds, is maintained during the molt in most species by a gradual replacement of the flight feathers. However, ducks and geese, some rails and loons (divers) and auks shed all of their flight feathers at one time, immediately after the nesting season. Not until these feathers are replaced are the birds able to fly again. Most of these are birds that find their food by walking or swimming, as would be expected. Some ducks living in the marshes become very shy and retiring at this season, skulking in the reeds, but geese nesting in the arctic barrens continue to walk about over the tundra, feeding. In another group of birds, however, the hornbills of Africa and Asia, only the females lose both flight and tail feathers at once; they stay in the nest until the feathers grow out again, being fed during this period by the males.

Some birds have completely lost the power of flight during the course of evolution. The close similarity in basic structure of both flightless and flying birds indicates, however, that they all had a common flying ancestor. The rudimentary wings and the flightless condition of the ostrichlike birds and the penguins is a secondary, specialized condition. That flightlessness is a secondary condition is made still more apparent in other flightless birds that belong to families most of whose members are capable of flight. The extinct great auk of the North Atlantic is one of the best-known examples of such a flightless bird; the rail family also is noted for having many flightless species living on islands in the Pacific and the South Atlantic. Loss of flight seems to occur most often on isolated islands where there are no mammal predators. In New Zealand, where there are no native land mammals: not only are there many species of extinct flightless moas but also flightless kiwis, penguins and rails and a duck, an owl and several songbirds that are nearly flightless.

The ostrichlike birds of continental distribution present an apparent contradiction to this correlation of mammal-free island habitats with bird flightlessness. Another adaptation, however, their great size, has enabled these forms to escape the predation of mammals.

3. Walking, Hopping and Swimming.—Terrestrial birds such as pheasants tend to walk; arboreal songbirds tend to hop as they travel from branch to branch. Parrots often walk along branches, and house sparrows hop when they come to the ground, while palm warblers walk on the ground and some songbirds, such as American robins and European blackbirds. may both walk and hop. Some birds with small feet, such as swifts hummingbirds, bee eaters and many hornbills, use their feet only for perching and rarely walk at all. Other birds with robust feet, such as guinea fowl and rails. do most of their moving about on foot. Jaçanas with their greatly elongated toes and nails walk over floating waterweeds, and herons with long legs made in shallow water. The ostrich is probably the fastest running bird; some investigators have credited it with a speed of 50 m.p.h. at which time the length of its stride was about 25 ft.

The usual position of a bird's body in walking is more or less horizontal to the ground. But the penguins. with their feet far to the rear of their bodies, stand upright as they waddle along When the Adélie penguin, however, makes its trek of many miles over the snow-covered ice to its breeding grounds. it may vary its awkward waddle with periods of tobogganing; *i.e.*, sliding along on its breast and propelling itself with thrusts of its feet

Some nater birds have become so adapted to swimming that they are practically helpless on land In this class are loons, which shuffle awkwardly the few feet from the water to their nests. Swimming in birds is usually correlated with webbed feet, but coots and grebes, with only lobes on their toes, also swim and dive, and gallinules, without either webs or lobes on their toes, commonly swim. On the other hand, frigate birds. with partly webbed feet. never swim. Penguins swim through the water with their wings and use their webbed feet only for steering. Auks use their wings and webbed feet in swimming underwater.

Some birds such as the mallard usually swim at the surface, feeding only as far underwater as they can reach by dipping their heads. Other ducks, such as scoters and pochards, commonly dive to the bottom for their food, and cormorants. auks and loons pursue fish underwater. Sometimes loons are taken at remarkable depths in fishermen's nets and on set lines. indicating that they may dive as deep as 200 ft.

Pond ducks, such as mallards and teals, spring straight up from the water's surface into the air in flight, but many swimming birds —for example, coots, grebes, cormorants and diving ducks—take off with a long spattering run along the surface.

B. Preening and Resting

To serve their function, a bird's feathers must lie smooth and neat. The grooming or preening of the plumage starts as the nestling's feathers are breaking out of the sheaths. The young birds spend a great deal of time combing the feathers with the bill, and freeing them from bits of sheath. Similar behaviour continues throughout adult life. Oil glands, or preen glands, located on the back, just in front of the tail, are present in many birds. It is probable that the oily secretion of these glands helps keep the plumage in good condition; indeed, many birds nibble at these glands and rub their heads against them as though spreading the secretion on their feathers. It has also been suggested that this oil, after exposure to the sun, may be accidentally swallowed by the bird in preening and hence a source of vitamin D. Some birds, however, such as some pigeons and parrots, have no oil glands but do not seem to suffer from vitamin D deficiency.

1. Bathing With Water, Dust, etc.—To aid its preening, a bird often bathes. A land bird may thoroughly soak itself by crouching down in water and ducking and flicking its wings. Ducks and gulls, with their waterproofed plumage, may bathe also, often nhen swimming. Sometimes birds bathe on wet grass or in a fine rain or under a garden spray; in tropical forests where predators lurk in the waters, birds may bathe by fluttering among the wet leaves of the trees.

Dust serves instead of water for some birds, such as the domestic fowl and larks. They crouch down on the dry soil and scratch and fluff and shake their feathers until they are full of dust, then they stand up and preen themselves. This is not always an

efficient cleaning process; nevertheless, the dust may help groom a bird's feathers as the furrier's sawdust helps recondition a fur piece. A few birds, including the house sparrow, both water bathe and dust bathe.

In sun bathing a bird may rest on the ground, spread out its feathers and remain still as though it were enjoying the warmth of the sun on its body. Possibly related either to sun or dust bathing is anting. In this process the bird places living ants among its feathers. It may substitute for the ants such things as bits of orange peel or a moth ball, substances that the bird rubs on its wings or the posterior part of its body. What purpose this toilet serves is unknown. but perhaps the bird likes the feeling of some ant secretion or a substitute on its skin.

2. Resting, Sleeping and **Hibernating.**—*Resting.*—Many small birds are active throughout most of the daylight hours, birds such as the titmice that flit and hop through the branches and the swifts that keep moving on the wing, but some small birds perch quietly ior considerable periods, for example, the hummingbirds. Some large birds may sit quietly for hours—a hawk on its perch, a heron on the edge of a pond and a duck on the water.

Many birds have such poor night vision that they sit quietly all through the hours of darkness. Exceptions are many owls, nightjars and some herons, which sleep by day and hunt by night. Some ducks visit grain fields to feed by night in order to avoid hunters. Cormorants swim and dive for fish to eat, but as their plumage is imperfectly waterproofed these birds come ashore periodically to spread their wings and dry out their feathers. Scoters. which feed on mussels along salt-water coasts. may time their feeding and resting activities to take advantage of optimum tidal conditions.

Sleeping.—The habitat in which a bird feeds during the day may serve as its resting place at night: a cover of grasses for a sparrow, twigs of a tree for a warbler and the surface of the ocean for a petrel. A bird may sleep where it perches during the day, a hawk or crow in a treetop and a tern on a beach. Some ground-frequenting quail, however, sleep in trees. and American blackbirds and starlings that have wandered all day, feeding on the ground and perching in trees, may swarm into a cattail marsh to sleep. Some ducks and geese escape hunters by seeking out a habitat they would not otherwise use—for instance: one far out on broad stretches of open water.

Some birds seek a roosting place at night that is similar to that in which they were hatched or raised. Thus chimney swifts on migration sleep in chimneys, hut in their winter home in the tropics they undoubtedly revert to the ancestral use of a hollow tree for sleeping. Woodpeckers sleep in holes in trees, some of them freshly chiseled out by the birds as winter approaches. Wrens may make dormitory nests. The roosting behaviour of a species is not always consistent. While starlings may roost in great numhers in a cattail swamp at one time, at another they may roost in trees and even on buildings. The ruffed grouse often roosts in trees, but, especially in stormy weather, it may roost on the ground or in the shelter of a log. and in winter it may burrow into the snow.

In sleep a bird conirnonly bends its head over its back with its bill nestled among its feathers, but some birds, such as storks, sink their bills among their breast feathers. Water birds, sleeping afloat, retain a swimming pose except that they, too, hold their heads over their hacks and tuck their bills among their back feathers. Ducks ashore may rest on their breasts, pulling up their legs into their feathers, an obvious advantage when the birds are resting on an ice floe. hlany birds commonly rest on one leg; this posture is especially noticeable in such long-legged birds as shore birds and storks. Sometimes a stork may vary its pose and instead of standing on its toes in the usual fashion may rest on its heels with the shank (tarsus) stretched out in front.

A bird on a branch retains its grip without effort: for the bending of the leg autoniatically tightens certain tendons that strengthen the grip; rather, there must be an effort to straighten the leg and loosen the grip. Small-footed nightjars may perch lengthwise on a large branch, instead of crosswise, grasping a twig. and bat lorikeets of the orient sleep not by perching on a branch but by hanging below it, as bats do.

Sociability may be more pronounced at sleeping time than during waking hours. The flocks of American blackbirds streaming into a marsh to sleep, the herons congregating at a roost, and the morning arid evening fights of flocks of parakeets to and from their roosts may be conspicuous features of a landscape. Even birds that are largely solitary hy day may gather together at night, as when a dozen or so creepers sleep in a single crevice in winter. Bat lorikeets of the orient, colies of Africa and wood swallows of Australia may gather so closely together at night that they form tight bunches. As the colies also do this during the day in cold or wet weather, this habit may actually be an adaptation for keeping warm.

Hibernating.—The question as to whether birds hibernate as mammals do has been debated for many years. In the middle ages it was commonly thought that swallows and other birds hibernated in the mud at the bottom of ponds when winter approached, but advancing knowledge showed that the birds' annual disappearance was due to their migration. A few birds, *e.g.,* swifts, hummingbirds and colies. have long been known to sink into a torpid state during the night when the weather is cold.

In 1948. however. it was discovered that one of the American nightjars, the poorwill, really does hibernate. One of these birds was found in a cavity in the wall of a canyon in the Colorado desert in a torpid condition. In subsequent years additional observations definitely established that this species does hibernate, one poorwill having been observed in hibernation over a period of 80 days.

C. Food and Feeding

1. Food Getting. — Food getting has been a major factor. in the course of evolution, in shaping bird structures and habits to lit the environments into which birds have spread. The habitats used by birds are not so many or so varied as those occupied by other vertebrates: no birds burrow in the ground for their food as do some mammals, nor do any birds live in the great depths of the oceans as do some fishes. But birds do feed in the air, in the water and on the land.

Types *of Food.*—Birds, like other animals, ultimately depend on plants to synthesize inorganic material into organic compounds they can use as food. Some birds eat plant material directly: seeds and fruits are the staple foods of many species, and bulbs, roots. grass. leaves, the nectar of flowers and the sap of trees are eaten by others. The ptarmigan oi the arctic even eats lichens; a parrot in New Guinea eats fungi; and flamingos eat tiny plants and animals living in the mud. Many birds, however, eat other animals that have fed on plants. Insects supply food for many birds, including many songbirds; fishes of fresh and salt water also supply food for many more. Worms, mollusks, crustaceans, spiders. squids, amphibians, reptiles and mammals and other birds are the specialized food of still others.

The food items may be small, such as the algae sieved from the mud by ducks and the flying midges snapped up by swallows; or bite-sized, such as many insects. seeds or berries eaten by many songbirds; or large enough to need breaking or tearing into pieces, such as the monkeys eaten by a certain Philippine eagle; or very large, such as the whale carcass over which scavenging petrels quarrel.

While many birds take a variety of foods, both plant and animal, some have a very specialized diet, such as the everglade kite that eats only fresh-water snails of a particular genus; and others specialize within wider limits, such as the sharp-shinned hawks that typically eat birds. Some larger insectivorous birds eat tree frogs and lizards as readily as they do insects of a similar size Doves that ordinarily eat seeds have been found with their crops filled with small snails. Domestic chickens picking up seeds and grasshoppers will also eagerly gobble down small frogs from a drying pond. and a hungry heron or marsh hank (harrier) does not distinguish between a crayfish, a grasshopper, a frog or a mouse, taking whichever appears.

Availability seems an important factor in determining diet. Within limits a bird eats what is available. This may underlie certain seasonal shifts in food shown by the American robin for

example. During the spring robins are often seen on lawns catching earthworms: later they come into gardens and eat cherries; and on their wintering grounds in Florida they may live on palmetto berries. Crows, which feed on cutworms in the spring, may turn to grasshoppers in late summer and eat waste grain in the winter.

Certain adaptations of wings and feet fit different birds to seek their food in certain habitats: the graceful swifts catch insects on the wing; cormorants, auks and ducks dive for food underwater; quail grub for food on the ground; songbirds snatch food in shrubbery. But the bill, the grasping organ of the birds, is most closely linked with food gathering, and has been modified in many ways for catching, holding and manipulating food. There are often remarkably precise correlations between bill structure and the type of food taken.

Bill and Food.—Extremes in bill shape are many. The bill of a crow or jay may be considered a good example of an all-round tool; it is stout and of fair size, strong enough to use in killing small mammals and in opening nuts but fine enough at the tip for picking up small insects. Some songbirds have slender bills for picking insects off leaves or out of cracks; others have broad, flat bills for catching flies; and still others have strong, thick bills for cracking the shells of seeds. (The force exerted by a hawfinch in breaking open an olive pit with its bill has been estimated at 100 lb.) Woodpeckers. which search for wood-boring insects, have chisellike bills for cutting holes in tree trunks. The hooked bills of birds of prey are for tearing flesh; this kind of bill finds its counterpart in the bill of the shrike, which eats large insects and mice, and in the bills of the cormorant and frigate bird, which catch fish. Parrots also have strong, hooked bills, which are usually used for eating fruits and cracking seeds—though some parrots eat flowers. Sandpipers. and especially woodcocks and snipes, have long, probelike bills for probing worms and other invertebrates out of mud. The long daggerlike bills of terns, herons and kingfishers are used for catching fish and frogs.

Another adaptation is shown by the broad, flat bill of the duck, which has a sievelike fringe along the sides. When a mouthful of water is taken and the mouth closed, the water and fine mud are forced out through the fringe and the small food items—snails, insects, seeds, etc.—are retained and swallowed. Certain petrels, the prions or whalebirds, have a similar arrangement for sieving small crustaceans from sea water, and one of their names is derived from the resemblance of its food-straining apparatus to that of the whale-bone whales. The flamingo also has in its bill a sieving apparatus much like that of a duck, but the bill of the long-legged bird is sharply bent in the middle so that it is actually upside down when in use in the mud around the flamingo's feet.

Yet another extreme in bill design is seen in the nightjars, swifts and swallows, which catch insects on the wing. In these birds a great reduction of the horny bill is concomitant with a great increase in the size of the gape. A similar wide gape is seen in trogons and oilbirds, which may pick the fruit they eat by hovering in front of the twig on which it grows and seizing the fruit in their mouths. On the other hand, the greatly enlarged and lengthened bills of the toucans and hornbills may, in extending the reach of these birds, help them get the fruit they eat.

The tongue of some birds is a horny flap with taste buds at its base. It seems to be of minor importance in many species. It may serve a sparrow as a scoop in getting kernels out of seeds, or a jay as an aid in swallowing. The tongue is of major importance, however, in some birds. The fleshy tongue of ducks and flamingos helps force water out of the mouth through the strainers on the edge of the bill. The woodpecker's long tongue, barbed at the tip and capable of great extension beyond the bill. is a great aid in extracting grubs out of burrows. The hummingbirds, sunbirds and honey eaters have tubular tongues, brushy at the tips, which aid in getting nectar out of flo ers. The brush-tongued lories have fleshy tongues that open into a brush when extended—an adaptation that helps the birds collect nectar and gather various flower parts.

2. Ways of Feeding.—Despite the apparently fine adjustments between food and structure the same structure is sometimes used for surprisingly different purposes. The tree swallow that has caught insects all summer by flying back and forth and snapping them up in its wide gape may be found in the autumn clinging to twigs and eating berries. Most vultures, because of special adaptations, usually feed on carrion, but a west African species feeds largely on oil palm fruit.

On the other hand, birds of quite different structure may feed on the same types of food; *e.g.*, an African vulture, a West Indian tree duck and the South American oilbird all feed on the fruit of palm trees.

Snails and clams, with their succulent parts enclosed within hard shells, seem well protected from predation by birds, but many different kinds of birds have solved the problem of using them for food. Some ducks simply swallow shellfish whole and grind them up in their gizzards; oyster catchers wait until the bivalve gapes open. then stab and cut the strong hinge muscles, exposing the animal; crows drop clams on hard ground to break them open; a European thrush and a Philippine kingfisher smash open a snail's shell by holding the snail in the bill and pounding it on a rock; a South American hawk holds a snail in its foot and waits for the snail to open up, then jabs its bill into the exposed animal and shakes it out of its shell.

Along a stretch of stream a kingfisher watches from a branch, waiting to plunge headfirst into the water and seize a fish in its long, pointed bill; a heron, with a similar bill, stands on long legs in the water and uses its long neck like the shaft of a spear to jab its daggerlike bill into a fish. A passing osprey or fish hawk hovers, then drops feet first to catch a fish in its talons, while a merganser duck swims underwater in pursuit of a fish which it seizes between the serrate margins of its bill. The cormorant gets its fish underwater with a snap of its hook-tipped bill.

Along the coast, terns in graceful flight plunge headfirst into the water to seize fish in their slender bills; pelicans also dive from flight to scoop up fish in their pouched bills; and the frigate bird, with its swallowlike shape and long hook-tipped bill, either hovers over the water and snatches up its fish without getting its plumage wet or robs the terns of their fish. Most unusual is the fishing of the skimmer. This bird, which has a long, bladelike lower mandible and a much shorter upper one, flies over the water with the lower mandible submerged. When the mandible hits a fish, the bird's head is thrust down so that the upper mandible is engaged in seizing the prey.

Change of Habits.—Although birds' feeding habits tend to be stereotyped, they often change with the season and with temporary changes in environment. The black parrots that raid a Madagascar corn (maize) patch certainly did not do this before corn was introduced from the Americas. The kea parrot of New Zealand is a familiar example of a vegetarian turned carnivore after the introduction of sheep to the islands. Some of these parrots, after having learned to feed on the flesh of recently dead sheep, finally learned to kill them as well. Titmice in England have learned to open milk bottles to get at the milk.

Preparation of Food.—Food is swallowed whole or piecemeal. A jay may break off the legs of a grasshopper and discard them before swallowing the body. A hawk may pluck off the feathers of a bird before bearing off chunks of the flesh to swallow. A bee eater may hammer an insect against a hard surface, perhaps to quiet the captive or to break up the exoskeleton before swallowing the insect. Secretary birds are said to drop a snake from aloft to kill it. Nuthatches may wedge a nut into a crevice to shell it, while a jay may do the same with a nut held under one foot. Like the birds that smash shellfish on rocks, the lammergeiers of Europe are said to drop bones from a height to break them in order to get at the marrow. Gulls in the Falkland Islands are said to drop eggs to get at the contents, while in Australia a hawk is said to drop a stone in an emu's nest to break the eggs.

A cormorant has been known to swallow a fish too big to fit into its stomach all at once. When this happens the bird sits quietly until the head end of the fish is digested, and then swallows the rest of the fish. This lack of preparation of food to be swallowed can be dangerous, however, and a heron has been recorded as dying when a catfish with erect spines lodged in its gullet. Mice and insects, swallowed whole, carry much indigestible material into

the bird's stomach. This roughage is cast up in the form of pellets. Under an owl's perch one can find such pellets containing fur and bones. In late summer crows feeding on grasshoppers commonly cast up pellets composed of the exoskeletons of those insects.

Storage of Food.—The most striking case of food storage is that of the acorn woodpecker of California, which chisels holes in the bark of a tree and fits an acorn in each hole. Another American woodpecker, the redheaded, not only puts an acorn in a hole but tamps it in with a piece of soft rotten wood. Many jays and crows store seeds. The nutcracker in Europe buries nuts in the forest floor during the autumn, as a provision for the winter.

The shrikes of northern countries and of east Africa impale insects, mice and smaller birds on thorns; the butcherbirds of Australia do the same thing. Undoubtedly this is a way of storing food, but just as surely it is also a part of food preparation, for the birds that lack a firm grip with their feet often impale their prey so that it is firmly held as they pull it to pieces with the bill.

The ground squirrels and rabbits strewed about an eagle's nest, or the mice about an owl's, could be considered stored food, but perhaps the carcasses are simply a surfeit of food. Relatively few birds store food; for the most part they live from day to day.

3. Water and Salt Requirements.—The frequency with which garden birds visit a birdbath leaves no doubt that birds enjoy water, which is important to most species in the care of their plumage. Physiologically, birds are essentially less dependent than mammals on drinking water, because they need less in voiding their nitrogenous waste in the form of insoluble uric acid. Birds may not need bodies of water, but may drink droplets of rain or dew from leaves or grass, or may get what they need from moist foods without any source of free water. However, two modes of life do pose the problem of water supply in acute forms: grain eating in deserts and life at sea.

Some animals, such as the desert kangaroo rats, have been able to escape the need of taking in water, and this they have done by adjusting their metabolic processes so as to manufacture needed water from dry food stuffs. Birds, however, need to take in water at frequent intervals. It is probable that drinking water is a factor in determining the local distribution of quail in the American deserts, and a supply of water is especially important for the young. In the arid regions of Africa and southern Asia sand grouse are able to live and breed in deserts by making long flights to water daily, morning and evening. On their return they bring water to their young. One opinion is that they carry it in the gullet and regurgitate it for the young; another, that they wet their breast feathers and the young get water from these feathers. Perhaps both methods are used.

Although drinking sea water may prove fatal to man, it has long been known that sea birds drink sea water with impunity. In the 1950s a series of experiments showed that sea birds can drink sea water without dangerously raising the level of salts in the body because the excess salts are rapidly excreted by large nasal glands as well as by the kidneys.

Many herbivorous mammals visit salt licks for the mineral content in the soil, but only a few birds are known to do this. The fruit-eating colies of Africa eat soil that is rich in salts. The habit of eating salt is especially well known for some northern finches such as the crossbills.

D. Enemies and Diseases

1. Predators.—Some of the animals that eat birds are other birds, the most persistent predators on small birds being certain species of hawks. The peregrine falcon, or duck hawk, is a good example; it can overtake and catch on the wing even such fast-flying birds as the teal. Some short-winged hawks, such as the goshawk, prefer to capture birds by surprise dashes from concealment. Many other hawks, those that are slower or clumsier in flight, and owls, which ordinarily feed on mammals, lizards or insects, sometimes take small birds when the opportunity offers. Birds of other groups, such as cuckoos, shrikes and frogmouths, occasionally eat other birds; and some, such as jays and crows, sometimes rob other birds' nests for the eggs and young.

Carnivorous mammals, such as foxes and weasels, are more likely to be predators on eggs or young birds. It is probably the predation pressure of such mammals that has confined sea bird nesting colonies in the north to islets or cliffs. Similarly, in warm climates, herons nest on islets or on tall trees because such sites are relatively immune from ground predators such as raccoons or civets. Continental land birds that nest on the ground do so singly, trusting to concealment as protection against predation; the colony nesters among land birds build their homes in reeds over water or high in trees.

Reptiles, such as snakes, sometimes take birds' eggs, and certain species of snakes of the old world tropics have even developed special processes in the throat for puncturing the eggshell. Crocodiles may occasionally take a swimming duck or cormorant, and alligators are said to wait about heron rookeries, snapping up unwary young that fall into the water. Among the amphibians, bullfrogs have been known to snap up small birds. Aquatic birds are occasionally taken by large fish, and surface feeding fish, such as bass and pike, may take young ducks or even songbirds flitting low over the water.

2. Parasites.—The parasites that occur in birds are best illustrated by those found on the pigeon, or rock dove, of city parks and dovecots. There have been reported about 70 species of plants and animals living on (as exoparasites) or in (as endoparasites) a pigeon. These include species of ticks and mites, a fly, a bug, lice, roundworms, tapeworms, flukes, protozoans, fungi, bacteria and viruses. Doubtless many more pigeon parasites remain to be found. Ignoring the smallest microscopic animals and plants, the number of individuals of some of the larger animals (the flies and ticks that may be as large as houseflies and the tapeworms that are several feet long) is impressive. A single pigeon has been found to have 1,000 tapeworms in its intestines, 30 flies among its feathers and as many as 20 bird lice on a single feather.

The food of the different members of the community of parasites is as various as their form. Flies, ticks, some mites and some lice may suck blood; some lice may eat downy parts of feathers; some mites may feed on the pith within quills, others may eat skin debris; intestinal worms absorb partly digested food; some roundworms (filaria) and protozoans may feed on blood.

Probably all birds support sizable groups of parasites: Some, like lice, undoubtedly are passed from one bird to another through contact. The antiquity of some of these parasites may be judged by the fact that a certain species of louse may be found on only one species of bird. The passenger pigeon, for example, had an endemic louse, and when the last passenger pigeon died, the last of this species of louse presumably died with it.

Among the illnesses suffered by birds are psittacosis (ornithosis), coccidiosis, a form of botulism called western duck sickness, cholera and several respiratory diseases of unproved cause. Poultry and other domesticated birds are, of course, more susceptible to disease because of the more or less unnatural conditions under which they live. Although man may contract some of these diseases from his domesticated birds, rarely does he do so from wild birds. In any event the incidence of bird-borne diseases in man is so low that it represents only a minor public health problem. See PSITTACOSIS; COCCIDIOSIS; POULTRY AND POULTRY FARMING: Diseases and Parasites of Poultry.

III. FORM AND FUNCTION

A. External Features

To understand how birds cope with their environment it is necessary to have an outline of the structural modification that fits the bird for this. The bird's head is of moderate or small size; the neck slender; the forelimbs modified into wings for flight; the body oval and large; the hind limbs modified for bipedal movement; the tail, short or long, with most of its length consisting of a few feathers (and hence light); and the body clothed in feathers that smooth body contours into a streamlined shape, conserve body heat and also provide protection.

1. Topology of the Body.—Head.—The bill, composed of upper and lower jaws, or mandibles, serves in seizing, carrying and manipulating food and nest material; in fighting; and in grooming and preening. The jaws are covered with horny sheaths. There

may be teethlike projections, or notches, on the edges of the mandibles but never true teeth, except in some ancient fossil birds (see Origin and Evolution below). A few birds, such as hawks and parrots, use their feet to supplement their bills in handling objects.

The eyeballs of birds are relatively large as befit animals that depend almost completely on vision. In many birds binocular vision is limited since the eyes are on the sides of the head and the eyeballs have little mobility. Most birds, therefore, see a considerably different view with each eye. In some birds, however, such as owls, the eyes are in the front of the head, and the bird looks forward. Although the owl's eyes are immovable in bony sockets, these birds have considerable binocular vision. Some other birds, such as bitterns and starlings, can turn their eyes down or forward to increase binocular vision, some of which is imperative in judging distance — especially when the bird is attacking prey or alighting on branches.

The ear is represented externally by an opening on the side of the head just behind the eye; it is covered by a special patch of feathers, sometimes distinctively coloured, called ear coverts, or auriculars. There is no fleshy ear flap, or pinna; the so-called ears or horns of some owls are really tufts of feathers having nothing to do with hearing.

Neck. — A bird has more neck vertebrae than the usual seven of mammals; as a result its neck is more flexible. The long-necked swans may have as many as 25 vertebrae, and some perching birds, *e.g.*, cuckoos and parrots, may have as few as 13. Additional neck flexibility is afforded by the saddle-shaped articulating surfaces of the vertebrae. A striking example of this flexibility is the owl's ability to turn its head through about 270°, or three-fourths of a circle.

Wings. — In the course of avian evolution the primitive vertebrate forelimb has become an airfoil, a wing: the humerus of the upper arm, and the radius and ulna of the forearm have been retained, but the many bones of wrist, hand and fingers have been fused into a few elements for rigidity. The single line of large, overlapping flight feathers that form the surface of the spread wing are attached to the posterior edge of the ulna and to the fused wrist-finger bones.

Breast. — Whereas flexibility is important in the neck, rigidity is necessary in the chest to withstand the strain of the powerful wing strokes. The rib cage, which joins the backbone to the breastbone (sternum), is strengthened by a tonguelike process extending backward from each rib to overlap the next. The breastbone in strong flying birds is broad and bears a deep keel to which the great flying muscles (the white meat on the breast of a chicken) are attached. These muscles (the pectorals) may be as much as 15% of the total weight in a mourning dove. The wishbone (fused clavicles) and the adjacent coracoids that brace the front of the sternum add to the rigidity.

Legs. — The legs, used in bipedal locomotion, have four toes at most — usually three directed forward and one backward. Some birds, however, such as some woodpeckers and cuckoos: have two in front and two behind. A reduction to three toes is not uncommon, as in some woodpeckers and kingfishers, though only one bird, the ostrich, has as few as two toes.

The bird's shank, or tarsus, is usually covered, as are the toes, with scales rather than feathers. The tarsal bone is compound, formed by the fusion of ankle and foot bones. This is in effect a running foot, designed for speed, and is more comparable to the hind foot of a deer or a horse than to that of a man or a bear. The joint at the upper end of the shank is comparable to the ankle rather than the knee joint.

Above the tarsus is the shin (the drumstick of poultry), composed of the tibia and the much reduced fibula. This section of the leg is more or less feathered. Above the shin is the thigh, or femur. Both the thigh and the knee joint are usually completely concealed under the flank feathers.

Hips. — The hip, or pelvic girdle, on which the legs articulate, is noted for its rigidity, the lower back being nearly one solid piece, with the sacral vertebrae: paired ilium, and ischium and pubis all fused together. This extensive fusion with the vertebrae is perhaps necessary because the pubic bones, which in mammals and reptiles may unite in front to form a solid ring, do not unite in birds, but are separate in front. This nonunion of pubic bones may be an adaptation for egg laying: the ends of these bones can spring apart and allow passage of relatively large and inflexible eggs.

Tail. — The tail of a modern bird is considerably shorter than that of the ancient Archaeopteryx, a Jurassic ancestor, and the tail bones are fused rather than separate. In modern birds there are only a few caudal vertebrae (usually six or seven) and a terminal plowshare bone, or pygostyle, the latter formed by the fusion in the embryo of a number of vertebrae. It is to the plowshare bone that the main tail feathers are attached.

2. Skin and Feathers. — The skin of a bird is soft, flexible and usually thin and tender. Most of it is thickly overlaid with feathers, but in some birds. such as vultures, there are areas of bare skin on the head and neck. This bare skin is sometimes brightly coloured. and in some birds — pheasants, cassowaries and some songbirds — forms fleshy wattles.

Oil *Glands.*—The only skin glands of birds are the oil, or preen, glands. These consist of a pair of glands just above the tail that secrete an oily substance used in grooming the feathers. Although present in many birds and best developed in water birds. oil glands are absent in some species, such as some parrots and some pigeons (see Preening and Resting above).

Feathers. — The coat of feathers, or the plumage, that covers a bird is this animal's single most distinctive feature. Feathers are horny epidermal structures derived in the course of evolution from the scales of reptiles. from which birds are descended.

A bird's overlapping feathers smooth its contours, and are important in making the bird an efficient flying machine. Long flight feathers form the main supporting surface of the wing. No less important is the insulating value of the feathers, one of the fundamental adaptations by which the body temperature is held high and constant.

Feathers show diversity in size and structure, but typically a feather has a slender tapering shaft with a vane or web on either side. The short, basal part of the shaft, the calamus, or quill, has no vanes and is round and hollow. The distal part of the shaft, the rachis, bears the vanes and is solid and angular in cross section. Each vane is composed of a close set series of parallel barbs; each barb has two rows of branches called barbules; and each barbule, in turn, bears two rows of still smaller branches, the barbicels, some of which end in tiny hooks. The barbicels overlap and hook together to form a strong but light vane.

There are several kinds of feathers, each modified to serve a special use. The ordinary feathers that cover the bird are called contour feathers, of which the flight quills are especially large and stiff. The downy feathers are those with a very short calamus, no rachis and with fluffy barbs; they are usually hidden beneath the contour feathers, and afford additional insulation. Filoplumes are hairlike feathers scattered among the contour feathers. Bristles are vaneless feathers; they occur about the mouth of many insect catchers, in the eyelashes of the hornbill, and elsewhere in other birds. Some contour feathers have a part of the basal web downy.

Arrangement and Number of *Feathers.*—A few birds such as penguins have the feathers uniformly distributed over their bodies. But in most birds the contour feathers are distributed in well-defined feather tracts that occupy restricted areas (pterylae) on the surface of the bird. From these pterylae the contour feathers fluff out and cover the naked areas (apteria).

The long flight feathers (remiges), which edge the posterior portion of the wing and overlap to provide most of the wing's surface, have a definite number that varies among the different groups of birds. The primaries (remiges attached to the digits) vary from 9 in such groups as the new world sparrows and the tanagers to 10 in most songbirds and 12 in the grebes and storks. The secondaries (remiges attached to the ulna) vary from 9 in most songbirds to as many as 32 in the long-winged albatross. Smaller feathers called coverts overlap the bases of the remiges above and below to give the wing a smooth contour.

Most of the length of the tail is formed by long tail feathers (rectricesj, of which in most groups there also is a definite num-

ber. In most birds there are 6 pairs of rectrices, but some have as few as 4 pairs, as in some rails and cuckoos, and others have as many as 16 pairs, as in some pheasants.

Counts of total number of feathers have been made for some birds. The smallest count was 940 feathers, on a hummingbird. Many songbirds have between 1,500 and 3,000 feathers, and a whistling swan has about 25,000. Birds of the arctic regions probably have a larger number of feathers than do their relatives of comparable size in the tropics, an obvious adaptation against the cold.

Molt.—Feathers push out of the skin as dark blue, blood-rich pin feathers with a scaly covering. As they grow they burst the sheath. and the vane expands. Once the feather is full grown and dry, it is a dead structure, unable to repair damage caused by wearing or fading; to compensate for this, feathers are molted and replaced periodically. This replacement, in which old feathers are pushed out by new ones, usually takes place once a year, just after the breeding season. There are, however, many notable exceptions to the usual one molt a year. Many songbirds have an additional partial molt in the spring, and ducks have two complete molts of the body feathers yearly.

Molting is usually a gradual process, only a few feathers at a time being shed and replaced by new ones. Thus most birds are always adequately covered with feathers and can fly even in the middle of the molt. On the other hand, ducks and a few other birds that molt all their flight feathers at once, usually after the young are hatched, are flightless for a short time during the molt. (See also FEATHER.)

3. Coloration.—The colour of bill, feet and eyes may harmonize with that of the feathers or may contrast sharply with it. The colour of feathers is caused mostly by two factors: pigment in the feather and the microscopic structure of the feather. The latter factor, responsible for the scattering and reflecting of light, modifies the underlying pigmentary colour.

The common pigments in most birds' feathers are the melanins, ranging from yellow-brown to black, and the carotenoids (lipochromes), ranging from yellow to red. The white colour of feathers is structural, the result of the reflection of all the light. Blue results from structure and the presence of the underlying pigment melanin; pure green is usually the result of the same structure that produces blue, but a yellow pigment underlies it. A different structure produces iridescence.

Occasionally among birds that normally produce coloured offspring a white, or albino (*q.v.*), individual may appear, owing to the lack of any pigment. In other cases a bird may be conspicuous among its fellows by showing an excessive red or yellow coloration, the result of abnormally large amounts of such pigments. So-called adventitious colours may be found in birds of certain localities or under special conditions: sparrows living in cities acquire a dark, sooty plumage not seen in country sparrows; some white snow geese acquire a reddish stain as a result of contact with iron-rich water.

Colour Change.—A feather on completion of its growth is a dead structure like hair, unable to add to or subtract from its pigmentation. Certain colour changes, however, do occur. These changes are the result of fading, well illustrated by the gradual loss of the salmon pink colour of the breast of the freshly molted merganser. The brown of the desert thrasher becomes paler as the season advances; this may be caused not only by fading but also by the wearing away of some of the feathers. The effects of wear are much more evident in a bird such as the snow bunting. In the autumn the bird is buffy brown; by spring the brownish tips of the feathers have been worn away, revealing the black and white main parts of the feathers. Most of the pronounced colour changes, *e.g.*, that of the scarlet tanager, which is red in the summer and green in winter, are the result of molt; the feathers of one colour replace those of another.

Range *of Colours.*—Coloration in birds ranges from all white to all black; from predominantly bright shades—red, yellow, green, blue, etc.—to pale and drab ones—buff, brown, olive, purplish, ochre, etc. Some birds are solidly coloured, whereas others are patterned in various ways. There would seem to be an endless variety in colour arrangements, but the same ones tend to repeat themselves. This similarity in colour markings occurs not only in birds that are closely related, as is shown by the streaked pattern in many sparrows, but also in birds that are more distantly related, as is shown by the black chin patch of house sparrows and chickadees (titmice or tits) and the white rumps of some woodpeckers and some sandpipers. Resemblances of eyebrow stripes, wing bars, neck rings and white outer tail feathers also occur in many unrelated species.

Although a particular type of plumage colour characterizes each species, this generalization needs qualification. Most species have colour variations based upon sex, age, season and climate.

In some species the sexes are alike; in others they are quite different. The brown wrens are birds in which both sexes are the same dull colour. Some parrots have both sexes bright green marked with red or yellow; in the eclectus parrot the male is mostly bright green and the female bright red. In many ducks and pheasants the male is brightly coloured, the female dull; in the button quail (*Turnix*) and the phalaropes the females are brighter. Some of these colour differences are correlated with the different parts the sexes play in reproduction, as will be discussed below.

When both parents are dull coloured, the young usually resemble them. as in wrens; when one sex is bright and the other dull, the young usually resemble the dull parent, as in the American red-winged blackbird; and when both parents are bright. the young may show a slightly duller plumage. In the American robin, in which adults of both sexes have a reddish breast, the duller spotted breast of the young is reminiscent of the adult pattern common in many thrushes.

Many young birds, when they are only one year old, resemble their parents, but some take several years to acquire the adult plumage. The bald eagle takes about ten years to acquire the pure white head and tail characteristic of the adult bird.

Some birds look much the same the year round, as, for example, crows and jays. Others change their appearance considerably from summer to winter; the common starling of North America and western Europe, for example, is black with many pale spots on the tips of the feathers in winter, but by spring is completely glossy black, the spots having worn off. The scarlet tanager changes from a red summer plumage to a green winter one and back again, and the arctic ptarmigan molts alternately to white in winter and brown in summer.

Within a species, birds that live in arid regions tend to be pale; those that live in regions with high rainfall tend to be dark. The song sparrow of North America is a classical example of this. The birds from the dry country in the central part of the continent are light brown; those from the humid, foggy islands of the Bering sea are almost blackish brown.

Adaptive Coloration.—Certain colours and patterns seem to be an advantage to the bird in concealing it from its enemies, or in enhancing the male's courtship displays. A bittern standing among dead reeds on the edge of a marsh harmonizes so well with his background that he is all but invisible to a predator's eye. Such protective coloration involves several principles. Countershading is one of them: the bird's under parts, in shadow when the bird is on the ground, are paler than the upper parts, which are in bright light. This countershading gives the bird a more uniform appearance and greatly lessens the shadows that would define the bird's body.

The brown-streaked plumage of the bittern matches, both in colour and pattern, the reedy habitat in which the bird lives. A similar matching of background is seen in the brown-streaked plumage of some sparrows, snipe and quail that live among the grass, and in the mottled browns and grays of the owls that perch among the branches of trees.

In some birds disruptive coloration, the presence of large markings of contrasting colour, breaks up the animal's outline; an example of such coloration is seen in the white and black markings on the necks of some small plovers.

Shape and pose of the bird adds to the effectiveness of matching colour, as shown by the tall thin bittern that stands upright against the vertical patterns of the reeds, and the "eared" owl that stands motionless on a branch, its ear tufts giving the im-

pression of the jagged end of a broken stub.

The many species of birds that live in desert regions often are pale in colour, corresponding to the general colour of their background. This coloration is carried still further in some larks of the arid parts of Africa and Asia; these birds even have the tint of the soil on which they live.

Some conspicuously coloured birds have flesh that is less palatable than that of duller coloured ones. Possibly, these conspicuous markings, such as the black and white plumage of some desert thrushes of Asia, are actually labels warning predators of the bird's disagreeable taste.

Some bold patterns are displayed only in flight, like the white rump of the flicker and the black and white pattern of the turnstone; these markings may serve to confuse a marauding hawk. The hawk follows a turnstone only to find that on alighting the boldly marked bird changes to a more plainly coloured one; the resulting confusion of the hawk may make the difference between escape and capture of the turnstone.

Colours and patterns undoubtedly aid birds in recognizing others of their own species. Further, the white outer tail feathers of a vesper sparrow, the white wing bars of some crossbills and the bold back pattern of the turnstone may make the birds' movements conspicuous to others of the same species, thus conveying information, as when one bird flees from danger and warns the others.

Bright colours, sometimes in patches or on special plumes, such as the elaborate flank plumes of the birds of paradise and the bizarre ornamentation of the pheasants and manakins, are displayed at mating times and in fighting.

B. Internal Systems

1. Circulatory System.—Blood.—The blood, which distributes food and oxygen to all parts of the bird's body and carries waste products to the kidneys, is notable for the red corpuscles being oval and, unlike those of mammals, possessing nuclei. Blood is carried by tubular blood vessels through which it is pumped by a four-chambered heart (as in mammals). The oxygenated blood leaves the heart by a right aortic arch (instead of the left as in mammals), the only one that remains of the primitive six pairs of aortic arches. Birds are warm-blooded, their temperatures ranging from about 105" to 111° F., which is 2" to 14° higher than the normal range of temperature in mammals.

Heart.—The heart is relatively larger in birds than in mammals, and is relatively larger in smaller birds than in larger ones. The exact weights published by anatomists vary greatly in absolute values, presumably due to different techniques, but some of the most often quoted percentage weights of bird hearts are as follows: goose 0.8% of body weight; pheasant 4.7%; raven 10%; sparrow and starling 13%–14% ; hummingbird 19.8%–22%.

The normal heartbeat of a resting bird is generally higher than that of a mammal of similar size. The following are some examples of heartbeats per minute of adult birds at rest: sparrow 460; robin 570; pigeon 218; crow 342; turkey 43. In general the rate tends to be lower for larger species; of course, many factors can increase the individual rate, and strenuous exercise may double it.

2. Respiratory System.—Lungs and Air Sacs.—The respiratory system of birds is notable for its relatively small lungs, with little expansion and contraction, and a series of large thin-walled air sacs in the body cavity. The air sacs have pouches (diverticula) that commonly extend into the femur, humerus and vertebrae, but in some species may extend into almost any part of the skeleton, even the toes. Birds, unlike mammals, have no diaphragm to assist in breathing; they rely instead on the expansion and contraction of muscles of the body wall.

During inspiration air enters through mouth or nostrils, passes through the windpipe (trachea) and the two bronchial tubes and enters the lungs, much of the air going beyond into the air sacs. Some students believe that during expiration much of the air in the air sacs passes through the lungs again; others think that the air bypasses the lung tissue via the bronchial tubes and goes directly to the mouth.

The precise course of the air in the lungs during inhalation and exhalation, and just when most exchange of oxygen and carbon dioxide occurs, has been the subject of considerable experimentation and much conjecture. The only undisputed point seems to be that the bird's system of breathing is a very effective one.

The breathing rate of a bird is variable, depending on activity, excitement and environmental factors. The rate given for the domestic fowl is 12 to 37 per minute, and for the canary 96 to 120; this rate varies, however, with the bird's temperature. A pigeon has been shown to breathe at the rate of 46 times a minute when its body temperature was 107° F., and 510 times a minute when its temperature was raised to 110°. It has been postulated that air sacs, in addition to their function in gaseous exchange, are also important as cooling devices (birds cannot cool themselves by sweating).

Voice Producing Organs.—These organs, in birds, are not in the larynx, at the top of the windpipe, as in mammals, but are at the junction of the windpipe and the bronchial tubes. The voice box of birds is the syrinx; it consists of cartilaginous rings and membranes. The membranes are moved by certain special paired muscles, whose number varies with the type of bird. The passing stream of air causes the vibration of the membranes to produce sound (see Songbird).

3. Digestive and Excretory **Systems.**—*Alimentary* Tract.—Food passes through the gape and into the gullet, or esophagus, a structure often capable of considerable expansion. In some birds, such as pelicans, the gullet is permanently expanded as a gular sac; in others, such as domesticated fowl and sparrows, the lower portion of the gullet is enlarged as the crop. In both cases these expansions serve for carrying or storing food.

The gullet leads to the stomach, of which the fore part, the proventriculus, is glandular and secretes digestive juices. The hind part of the stomach, the ventriculus, is thick walled and sometimes extremely muscular, in which case it is called a gizzard. There, with the aid of grit swallowed by the bird, hard food is ground up. In effect, the gizzard and its grit take over some of the functions of the teeth in mammals.

The liver is large, and there may or may not be a gall bladder, depending on the species. The coiled small intestine may or may not have a pair of caeca at its lower end, where it joins the short, straight large intestine. The large intestine ends in a cloaca into which the urogenital system also empties.

Excretory System.—There is no urinary bladder in birds; therefore the waste matter (chiefly uric acid) from the kidneys passes as a semisolid into the cloaca, where it is mixed with the feces and is excreted through the vent. A pair of nasal glands, well developed in some birds, *e.g.,* cormorants, that live on salt water, aids the kidneys in excreting surplus salt taken into the body.

4. Reproductive and Endocrine Systems.—Sex *Glands.*—The sex glands, or gonads, lie in the body cavity on the forward edge of the kidneys: a pair of oval testes in the male, a single ovary on the left side in the female.

The sperm passes from the testes to the cloaca via the deferent ducts and is transferred from the male to the female by contact of the birds' cloacae. Sometimes a penis is present in the male.

The true egg, a single, giant, yolk-filled cell, is fertilized in the upper part of the oviduct of the female; as it passes down the duct it receives its protective coats of albumen and membranes, its shell and finally its colours. When it arrives at the cloaca, the egg is expelled through the vent.

Hormonal System.—The importance of the ductless, or endocrine, glands to the biology of the bird is out of all proportion to the small size of these glands. They secrete hormones that are carried, via the blood stream, to various parts of the body. Among the important effects of these hormones are influences on growth, physiology and seasonal behaviour. The ductless glands may affect each other, and their secretions may have multiple effects.

The pituitary, located below the floor of the brain, is called the master gland, for its secretions, in addition to influencing directly many bodily functions on its own, also regulate other glands. Since the pituitary may be affected by seasonal variations in light intensity, it may act as a timing mechanism in controlling cyclic activities such as reproduction and migration.

The thyroid gland, in the neck, can be influenced by diet: a

deficiency in iodine causes goitre, or enlarged thyroid, in chickens as well as in man. The thyroid secretion regulates feather growth, colour deposition and other bodily processes.

The parathyroid, also in the neck, affects various physiological processes. The function of the adrenals, paired glands situated on the kidneys, is little known in birds.

In addition to the four endocrine glands listed above. there are several other organs that secrete hormones in addition to performing their other functions. These organs include the pancreas. in the first loop of the intestines, which produces insulin, and whose secretions influence metabolism; and the gonads, situated on the kidneys, whose secretions control such secondary sexual characters as the type of plumage (male, female or neutral).

C. Senses

Birds, together with anthropoid mammals, are the only animals that combine excellent eyesight and hearing with a poor sense of smell. Knowledge of the presence and importance of a bird's senses depends on the interpretation of bird structure and behaviour.

1. Sight.- he faculty of sight in birds is comparable to that in man. There are two main differences, however. The first is that most birds have predominantly monocular vision because their eyes are on the sides of their heads. These birds receive a visual picture that is flat, two-dimensional and without perspective, in contrast with the three-dimensional visual picture of man and of a few birds such as owls. Such a bird must move its head to obtain depth of vision For example, a robin, in cocking its head to look at a worm from two angles, is unwittingly using parallax to judge distance. Even in those birds with chiefly monocular vision. however, a small field directly in front of the bird may be viewed binocularly. Binocular vision, however limited, is of considerable advantage to birds that pursue prey.

The other notable difference is that the bird's visual picture, judging by the structure of the bird's eye, is clear and detailed throughout, in contrast with the condition in man in which only a small part of the visual field is seen in detail at one time

Some birds, especially diurnal ones, see the whole range of the spectrum of colours much as man does. It has been suggested that night birds actually see their prey as self-luminous sources of infrared light, but this seems to he without foundation. Owls do catch prey in complete darkness, but they do this by using their acute sense of hearing (*see* below). The owl's night vision has been estimated to be about 10 to 100 times better than that of man, which is the equivalent of saying that owls probably can see by starlight what a man can see by full moonlight. This night vision presumably enables an owl to find its may about and to avoid trees and branches, but is hardly enough to enable it to find its prey. Diurnal birds may have very poor night vision.

The visual acuity of birds with the keenest vision is probably two or three times that of man. It is also probable that colour sense plays a more emphatic part in the vision of diurnal birds than it does in man (judging by the density of colour-sensitive cones in the peripheral retina of the bird's eye). In detecting motion, too. birds seem to be much more successful than man.

2. Hearing. — Hearing is also keen in birds, and usually second to sight in importance. Birds probably hear a range of sounds equal to that of bird vocalization, that is, from 200 cycles per second to 10 or more kilocycles per second. Experiments have shown that a hen can locate a hidden, peeping chick nith the same degree of accuracy shown by a dog or a cat.

Still more interesting are the experiments showing that barn owls can catch mice in complete darkness by locating them by ear, listening to the faint noises that the mice make.

It has also been shonn that the South American oilbird, ahich nests in the darkness of deep caves, guides its flight in caves by uttering audible calls and listening to the echoes from the surrounding obstacles. This compares with the better-known echolocation of bats in which, however, supersonic frequericies are used.

3. Other Senses. — The sense of smell is not well developed in most birds. The flightless kiwis, however, with nostrils uniquely placed near the tip of the bill, are said to locate worms by scent rather than by sight. The sense of taste, located in the base of the tongue and in the oral cavity, is developed to different degrees in various birds. Some birds show a definite preference for a certain kind of food; for instance, a barred owl that eats frogs may reject a toad.

Apparently there is some use of the bill as an organ of touch; this is especially evident in snipe, which probe for worms in the mud. The feet are rather insensitive to touch.

The inner ear, which has large connections with the cerebellar portion of the brain, provides a mechanism for balance and for orientation to gravity.

Other senses that have been postulated for birds include those of direction, time and magnetism. These senses must await more experimental evidence before they can be accepted.

IV. BREEDING

A. Reproduction

Reproduction is as important to the species as food getting is to the individual. Except for the primary sex characters: the gonads and gonaducts, the physical adaptations for reproduction are largely those used in courtship and display. Most other adaptations for breeding are those of behaviour; they include such complicated behaviour patterns as those concerned with the building of elaborate nests.

The cycle of reproduction involves the laying and incubating of eggs and the raising of the young to maturity. This cycle may take only several weeks in many songbirds, but it may take nearly a year in some birds such as albatrosses. Some songbirds may raise two or three broods in quick succession and then rest for months. The albatross may let a year or more elapse between each breeding cycle.

1. Breeding Seasons. — Birds have a definite breeding season followed by a resting period, an alternation that provides a natural rhythm of activity. Each species has its own particular time of year for breeding, but an annual cycle with one breeding season every 12 months is the rule. A notable exception, however, is the sooty tern on Ascension Island that breeds every nine months.

The onset of the breeding season is apparently governed by external factors, foremost among them being light. In temperate climates, breeding usually starts with the advancing spring, at a time when food is becoming more abundant. This timing assures that when the young are ready to fend for themselves, food is readily available.

Experiments have shown that the changing amount of daylight in the spring can start the growth of the bird's gonads, which growth is accompanied by other physiological changes. But in many places in the tropics the breeding seasons may correlate with the end of the dry season and the beginning of the wet one, when the vegetation begins to grow and insects begin to be plentiful.

Even when some external factors are favourable for breeding, other factors may delay or even prevent breeding that year. This is particularly apparent in the arctic, where food supply is an important consideration: snowy owls and skuas, which depend on the hamsterlike lemmings for food, do not breed during certain years when their prey is scarce.

Some birds breed at any time of the year, even in a northern winter, as the crossbills do when the conifers have a good crop of seeds, or as birds in the Australian interior do after rain at any season. In the humid tropics, where conditions are always favourable, sorne birds may breed the year round — but in general the breeding seasons are surprisingly well marked.

2. Territory and Pairing. — As the time for breeding approaches, birds that are permanent residents, *i.e.*, nonmigrant birds, begin to select their special breeding areas called territories; migrant songbirds return to temperate climates from the tropics and establish their territories; and far-ranging sea gulls and albatrosses gather at their breeding colonies to begin their annual breeding cycle.

The establishment of a territory is the preliminary step in the breeding cycle of many songbirds. A territory is an area defended against competing members of the same species. It is an acre or more in extent for many songbirds, and may serve for

EXOTIC BIRDS

Top *left:* **Sulphur-crested** cockatoo (***Kakatoe galerita***), found in Australia, Tasmania and New Guinea. It is about 20 in. long

Top centre: **Swainson's lorikeet** (***Trichoglossus*** haematod ***moluccanus***), an 11-in. long bird of **eastern** and southern Aurtralia and Tasmania

Top right: **Toco** toucan (***Rhamphastos toco***), the **largest** of the toucans, is about 24 in. In length. **Its** habitat is South. America

Centre: Giant oriole or **black** and yellow **troupial** (***Gymnomystax mexicanus***) lives in open areas of the Guianas and northqrn **Brazil** and on the plains of **Venezuela.** It is about 12 in. long

Bottom *left:* Golden **pheasant** (***Chrysolophus pictus***), found in the **mountains** of western China, is **about** 40 in. long

Bottom centre: **Crowned** crane (***Balearica pavonina***), a **35-in.** long African bird

Bottom right: Greater **flamingo** (***Phoenicopterus ruber roseus***), **lives** in southern **Europe,** southern Asia and **Africa.** It **grows** to 50 in. in height

RARE AND EXOTIC BIRDS

Top left: Shoe-bill (*Balaeniceps* rex), a bird of the Niie region of Africa which reaches a height of about 5 ft. It is related to the herons

Top centre: Scarlet cock of the rock (*Rupicola* species), about 13 in. long. Found in western Colombia and Ecuador

Top *right:* Indian hill, or talking, mynah (*Eulabes religiosa*), about 11 in. long. This is the famous imitator of the sound of the human voice, and can be trained to speak

Centre left: Hartlaub's touraco (*Tauraco* species), about 18 in. long, native to Africa. The red coloration of the wings is unique among birds in that it is caused by a pigment containing copper

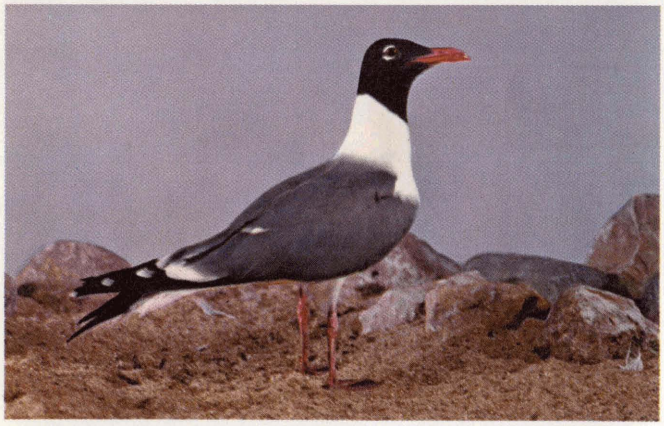
Bottom left: Blue gallinule (*Porphyrio* species), about 18 in. long, found near lakes and rivers of Asia

Bottom *right:* Marabou (*Leptoptilus crumeniferus*), a large African stork. Adults attain a height of 4 ft.

A colony of cormorants (Phalacrocorax carbo) nesting on a flat rock near the water's edge. A sea bird, the cormorant is found throughout the world. It is about 36 in. long

Fulmar (*Fulmarus glacialis*), an **arctic** sea **bird which visits land** only to breed. Its nests are usually found on rocky ledges and cliffs at the water's **edge.** Size: 18–20 in.

Semipalmated, or ringed, plover (*Charadrius hiaticula*). A mall **(about** 7 **in.) shore bird** found **on** beaches and **salt** marshes **of** the **Atlantic coast** of the US. **and northern Europe**



Laughing gull (*Larus atricilla*), **found** along the Atlantic and **Gulf** coasts of the US. from Maine to Texas. About **16 in.**

Green heron (Butorides *virescens*), most common small heron of the US, found in most of the eastern half of the country and along the **Mexican** border. Size: 16–22 in.

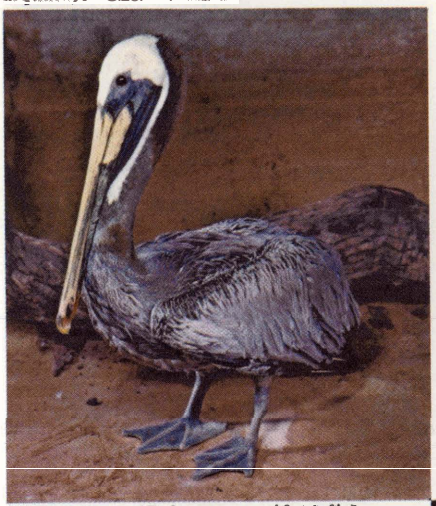
SHORE **AND WATER BIRDS**

PHOTOGRAPHS, (TOP) ERIC HOSKING, (CENTRE LEFT, CENTRE RIGHT) JOHN MARKHAM, (BOTTOM LEFT) EDWARD VAN BAERLE, © ENCYCLOPÆDIA BRITANNICA, (BOTTOM RIGHT) JOHN H. GERARD

Long-billed curlew (*Numenius americanus*), found in US on Gulf coast, occasionally on the Atlantic. Resembles the European curlew (*N. arquata*). Size: 20–26 in.

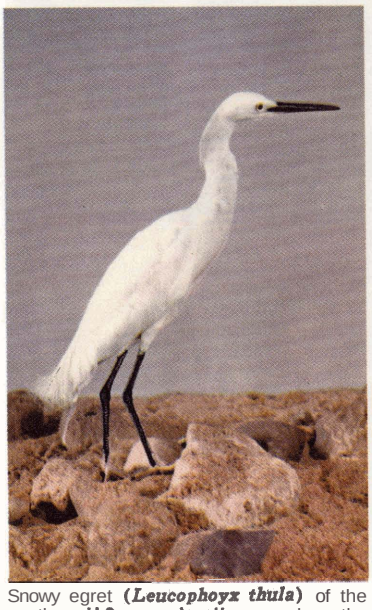
Black-necked stilt (*Himantopus mexicanus*), a long-legged wading bird found on south Atlantic and Gulf coasts of the U.S.

Western gull (*Larus occidentalis*), found along the Pacific coast of the U.S. About 26 in. long



Brown pelican (*Pelecanus occidentalis*), stands 3½–4½ ft. tall with a wino span of 6½ ft. Found on south Atlantic and Gulf coasts of the U.S.

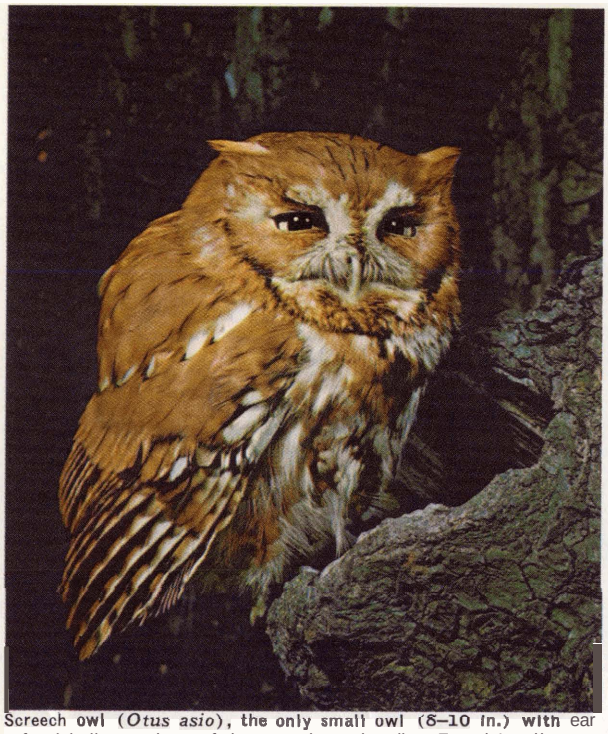
Oyster catcher (*Haematopus ostralegus*) and nest on a rocky seashore of England. Size: about 17 in. Resembles the American oyster catcher (*H. palliatus*)



Snowy egret (*Leucophoyx thula*) of the southern U.S., occasionally seen along the Atlantic coast to New England and in the Great Lakes region in summer. Size: 20–30 in.

Colony of gannets (*Moris bassana*) on a rocky cliff above the sea. Found throughout northern Europe, Iceland and the full length of the Atlantic coastline of the US. Often seen far out in the ocean. Adults reach a size of about 40 in.

SHORE AND WATER BIRDS



Screech owl (*Otus asio*), the only small owl (8–10 in.) with ear tufts (similar to those of the great horned owl). Found in all parts of continental U.S. May be either reddish (as shown) or gray in general coloration

Detail of head of a golden eagle (*Aquila chrysaëtos*), found in mountainous regions of the U.S. and most of the rest of the northern hemisphere. It reaches a size of about 30–40 in.

Bronzed grackle (*Quiscalus versicolor*), an American blackbird found in Canada, New England and the Mississippi valley. Very similar to the purple grackle (*Q. quiscula*) and formerly considered to be a subspecies. About 12 in.

Scarlet tanager (*Piranga olivacea*); 6½–7½ in. Found throughout most of the eastern states in woodlands. Migrates to South America in the winter

The American robin (*Turdus migratorius*), probably the best known of all U.S. birds. A member of the thrush family, it is found in all continental states. It is about 10 in. long

Brown thrasher (*Toxostoma* rufum). Somewhat larger than a robin (10–12 in.), thrashers are related to the mockingbird. Found throughout the central and eastern states

FAMILIAR BIRDS OF THE U.S.

courtship, nesting and all food getting. However, in colonially nesting sea birds and herons and in solitary doves, it may enclose scarcely more than the nest itself. In polygamous birds, such as the black grouse and ruff of Europe and many birds of paradise, there is no enduring pair formation and the territory is no more than a display and mating station. The territory is defended primarily by giving highly specific warning signals, such as the song of songbirds, but seldom by actual fighting. The male commonly establishes and defends the territory. in which he is later joined by the female, but the female of some species chooses the territory and may help in defending it.

The primary significance of territory seems to be social, that is, to reduce disturbance of the breeding pair during reproduction. But it may have secondary effects, such as providing exclusive feeding areas among some songbirds, and it certainly helps to spread out the breeding population in species with well-defined large territories. The importance of these secondary effects is doubtful, for certainly the size of a territory can vary considerably for any one species. In some places the populations may be dense and the defended territory small, while in others the population of the same species may be sparse and the territories large.

There are still other types of loosely defined areas, and other ways of pair formation. For instance, in the canvasback ducks many of the birds may already be paired before they reach their breeding grounds on the prairie marshes. pairing having taken place while the birds were in the winter flocks much farther south; a few canvasbacks, however, pair after the flocks have arrived on the prairie marshes.

When the canvasback pair is ready to nest it takes possession of a small area of water as its territory. This has been chosen by the female and is defended by the drake. The nest usually is outside this territory, and when the female makes a nest and begins laying the male may accompany her and wait nearby until she rejoins him. The male usually abandons the territory and leaves his mate while she is incubating to go off with others of his kind.

3. Display and Song. — Both display and song are very important in the early mating activities. Song is uidely used by dull-coloured species, uhile it is of lesser importance in birds that have elaborate displays. Displays may include the use of bright patches of coloured plumage; elongated, ornamental tail feathers; flank tufts, or other feathers; wattles; bare gular skin; and bright coloured feet.

Display and song are usually. but not always, the function of the male. In many songbirds a simple display, consisting of partly spread wings and raised head feathers, may be used along nith song to defend the boundaries of a territory. There the display may replace actual fighting, and thus the birds are spared the dangers of physical combat. A male's song may serve to attract the female to the territory and to influence her to make a union that will last for one breeding cycle. In cases in which the male, however, is highly ornamented and gives an elaborate display. and the female is dull the male often has little to do with the female after mating or egg laying; the display has most to do with attracting the female and stimulating her to mate. Voice may be used in this case, also, but it takes a simple form as compared with the elaborate songs given by some birds that make little or no display.

Among the more elaborate displays are those of the birds of paradise (*q.v.*), some of which clear a solitary display area. These birds call lrequently and display occasionally in isolation; when a female arrives, however, the male displays violently, exhibiting all his bright plumes. If the female approaches and indicates her readiness by posturing herself, mating takes place, after which a further display is given before she leaves. Other birds of paradise dance in groups. recalling the performances of manakins in the forests of tropical America; and those of black grouse, prairie chickens and ruffs on their communal display areas.

Even though a pair of birds has already established a bond that will last at least one breeding season, a display is sometimes given during actual copulation. This may include precopulatory and postcopulatory display and courtship feeding. An instance of courtship feeding may be seen among the road runners, a species in which male and female are very similar. The male, with a lizard dangling from his bill, approaches the female who is crouched down, fluttering her wings. After the male mounts the female and copulation takes place, the female seizes the lizard and eats it while the male runs quickly around her several times and then runs off. Sometimes in such ceremonies the male may carry nesting materials such as grass in his bill.

Some grebes with elaborate head ornaments in both sexes may pair for the duration of the breeding cycle and periodically display to each other in a variety of poses during the early part of the cycle. This pairing seems to serve to hold the birds together, to reinforce the bond between them until the care of the young directs their activity elsewhere.

In some species, such as herons for instance, in which both sexes have ornamental plumes, nest relief is accompanied by an elaborate mutual display ceremony. *(See* also COURTSHIP, ANIMAL: *The* Courtship of *Birds.)*

4. Nests and Nest Building. — Form and *Placement.* — *A* bird's nest is a cradle for the eggs and often a nursery for the young. The basic plan for a nest is a saucer- or cup-shaped hollow, but even this sort of nest may be rudimentary or even absent in some species. whereas very elaborate nests may be made by others.

The nest site chosen by a particular species varies according to geographical location. This is well illustrated by certain herons that make their nests in tall trees in Florida, but on the ground on islands off the Texas coast. There are even differences in sociability from place to place. In eastern Canada the osprey is a solitary bird that places its nest on the top of a lofty dead tree. But farther south, on islands off the coast, the osprey may nest on the ground and in loose colonies.

As a result of man's interference there have been marked changes in the nesting sites chosen by some birds. The use of bird houses for hole-nesting birds such as wrens, titmice, swallows and martins is commonplace. Chimney swifts now nest almost exclusively in chimneys instead of in hollow trees; many cliff swallows now nest on buildings instead of on cliffs; and the peregrine falcon even nests on ledges of city buildings.

Ordinarily birds select a fixed site for a nest, with movement limited to the swaying of a branch in the wind. But there are a number of records of birds that have nested on moving objects. Tree swallows have nested on the ferry boats that ply the St. Lawrence between Ogdensburg, N.Y., and Prescott, Ont., a distance of more than a mile. The nests were tucked into suitable openings on the ferries, and the frequent trips across the river and the docking at different piers did not seem to disturb the birds A somewhat similar example has been reported from northern British Columbia, where a pair of barn swallows nested in a freight car used on short runs.

As related earlier, in many songbirds the female of the pair selects the actual site of the nest, as in the yellow wagtail of England. But in some species, as the phainopepla of western North America, the male chooses the site and has already started the nest before the female comes to join him. She then adds the lining to the nest that he has started. Among other groups of birds the female canvasback also chooses her nest site, but in the mourning doves both birds try out likely looking places in the branches of trees.

Many birds make their nests in or near their normal feeding habitat; warblers make a nest among the branches through which they flit in search of insects, and terns and many auks and loons make their nests close beside the water where they feed. Grebes even make floating nests on the water.

In some cases the habitat of the nest site may be quite different from that normally used by the bird in feeding. This is well illustrated by the large herons that feed by wading in shallow water, but nest in the tops of tall trees, and by some auklets of the North Pacific that feed in salt water, but fly far inland in Alaska to nest on the mountain slopes above timber line.

Nest Building. — In species in which the sexes meet only for mating, as the hummingbirds and some birds of paradise. the female has charge of all the nesting duties. Even in cases in which a monogamous, enduring pair is formed, the female may do all of

the nest building, as in the red-eyed vireo; but in such cases the male often accompanies the female on her trips for building materials, and sometimes assists her. In the mourning dove the female does all the building, using the material that the male may bring her. In some African weaverbirds and in phainopepla the male builds the framework of the nest, even before he gets a mate, and the female provides the lining. The members of a pair of woodpeckers may share equally in excavating a nest site.

The male long-billed marsh wren builds extra dummy nests without linings; these seem to serve no useful purpose unless some of them are used for sleeping. Some weaverbirds, however, make additional nests after the first has been accepted by a female; these attract other potential mates.

The time that it takes a bird to make a nest varies considerably even among members of a single species. Early in the season a songbird may take several weeks to complete a nest, but later in the season, a pair of the same species nearly ready to lay may make a nest in as many days. Work on the nest does not always cease completely with the laying of the eggs. Occasionally, an incubating bird may add to or rearrange nesting material. A Madagascan weaverbird usually continues to add more fresh grass around the entrance to its retort-shaped nest. Purple martins and some hawks often bring twigs with fresh green leaves to their nests. (See NEST.)

5. **Eggs and** Egg Laying. — Development of Egg. — The new chick actually begins its existence when the egg cell, or oocyte, enormously swollen with yolk, is released from its follicle in the ovary, and fertilized by the sperm that has swum up the oviduct. As the fertilized egg cell descends the oviduct the following materials are added to it, in order: layers of albumen, enclosing parchmentlike membranes and finally the hard, calcareous shell and its coloration. At this time the living portion of the egg cell has developed into a many-celled, minute disc or blastoderm that lies on the side of the yolk. The blastoderm gives rise to the chick embryo. During its life in the egg the embryo will draw its food from the yolk and albumen. There is no air cell in the warm, newly laid egg, but it appears at one end of the egg as the contents cool and contract and increases in size as evaporation of the moisture through the shell causes the egg's contents to decrease in volume.

Size and Shape. — Although the size of the eggs does not correlate exactly with the size of the birds that lay them, the largest eggs are certainly laid by larger birds and the smallest eggs by smaller birds. They vary from the hummingbird's tiny pea-sized egg, less than ½ in. long and weighing less than ½ g., to the ostrich's large egg, about 6½ in. long and weighing about 1,500 g. For comparison, a common leghorn hen's egg may measure about 23 in. and weigh about 60 g.

In general, smaller birds lay relatively larger eggs than do larger birds. But other correlations exist, too. Birds whose young hatch in a well-developed state (precocial) lay relatively larger eggs than do those whose young hatch in a less developed state (altricial). This is illustrated by a spotted sandpiper, with precocial young, that lays an egg averaging 1.25 × .95 in.; while the American robin, about the same size but with altricial young, lays an egg averaging only 1.1 × .8 in.

For shape, a hen's egg is taken as standard, and is called ovoid. Its longitudinal outline is a distorted ellipse with one end more pointed than the other. This is a very common shape for birds' eggs, but some eggs are much more pointed at the small end than are others; some are really elliptical or long elliptical; and a few, such as those of owls, are round.

The auks and shore birds lay eggs that taper quickly to the small end, eggs that will roll in a small circle. This may be an advantage to auks that lay their eggs on sea-cliff ledges since it tends to reduce the chances that an egg may roll over the edge. This shape also enables four relatively large eggs (the usual clutch of northern shore birds) to fit snugly together, small end in, thus facilitating incubation by the parent.

Colour.—Commonly, the surface of the eggshell has only a slight gloss. but the eggs of the tinamous of South America have a highly glossy, porcelainlike surface, and those of cormorants have a white, chalky outer layer that flakes off to show the blue shell colour underneath. Other variations include the coarsely granulated shell of the cassowary's egg and the pitted surface of the ostrich's egg.

The range in colour of birds' eggs is not as great as that of birds' plumage, but many eggs are beautifully coloured and marked. Depending on the species, the eggs may be white or pale bluish, greenish, buffy, olive or brown; uniform in coloration or spotted, speckled, blotched or scrawled with dark brown or rusty brown. Some colour spots are pale gray or lavender — actually brownish spots beneath the surface of the egg and overlaid with the colour of the shell itself.

The eggs of many songbirds have a wreath of spots around one end. If the shell is white, the newly laid egg may have a rosy tinge from the yellow yolk within. Sometimes, as in the ptarmigan, the markings may cover more of the shell than the ground colour does. The guira cuckoo's egg is a strikingly different one: dark blue with white lines on it. The highly glossed tinamou eggs, which are uniformly green, blue, yellow or chocolate, are also striking.

Although each species of bird tends to lay one type of egg, there may be considerable individual variation. The Atlantic murre, or guillemot, provides one of the extreme examples of this. Its eggs may have a ground colour of white, green or blue, and the shell may vary from nearly unmarked to heavily mottled.

Birds that nest in holes — kingfishers, barbets, woodpeckers and the like — usually lay immaculate white eggs, whereas birds that nest in the open often lay coloured or spotted eggs — most songbirds, gulls, grouse and many others. This generalization suggests that the shell pigmentation may serve a function; perhaps to shield the contents of the egg from the adverse effects of light as well as to make them less conspicuous to a predator's eyes. But it is also true that some birds that do not nest in holes, such as pigeons, lay white eggs, and some hole-nesting birds, such as starlings and nuthatches, lay coloured eggs, so the generalization does not always hold.

Number of Eggs Laid. — The number of eggs a bird lays is more or less constant for each species in a particular area. Some birds, such as albatrosses and shearwaters, some penguins and some tropical pigeons, typically lay but a single egg. Two eggs is the normal clutch for the mourning dove, ruby-throated hummingbird and nighthawk. Northern shore birds commonly lay four eggs. Many ducks, grouse, rails and quail lay larger clutches, up to 20 or more in some quail.

The birds that live in the tropics often lay fewer eggs than do their nearest relatives in more northern latitudes. Thus many tropical songbirds lay only two eggs but most northern songbirds lay four or five. This may apply within a single wide-ranging species. Thus clutches of the European robin vary rather regularly with latitude, from an average of 3.5 eggs in the Canary Islands (30° N.) to 6.3 in Scandinavia (60° N.).

Pattern of Egg Laying. — The usual pattern of egg laying is for a bird to lay an egg each morning until the clutch is complete, but this is not invariable. Some birds customarily lay eggs every other day, or several days apart, and if incubation starts with the first egg, this results in the young hatching on different days. Because of this a brood of young marsh hawks, barn owls or road runners, for instance, may contain individuals of considerably different sizes and ages. This may be a disadvantage to the smallest young, who, being incapable of competing with their hardier kin for food brought by the parents, may suffer from malnutrition.

Some birds apparently lay a specific number of eggs and then stop, regardless of whether some eggs have been taken from or added to the nest, thus disturbing the normal number of eggs in the clutch. The herring gull is such a species. On the other hand, some birds will replace an egg that has been removed from the nest during laying. The yellow-shafted flicker that was induced to lay 71 eggs in a 73-day period has become a classical example of this.

6. Incubation. — Heat must be applied to the egg so that the embryo within will develop. The heat is normally provided by the parent sitting on the eggs and holding her warm breast against

them. To facilitate this warming of the eggs. incubation or brood patches may develop on the parent's skin at the proper season. These are areas of skin with increased blood supply, and from which feathers have been shed.

The incubation period, or time it takes an egg to hatch, varies widely, from 11 days to nearly 3 months. depending on the species.

In many songbirds the incubation period is 11 to 15 days, but in some it may approach 3 weeks. Woodpeckers. cuckoos and pigeons have about the same incubation period as songbirds, whereas hummingbirds, swifts and nightjars have 16 to 20 days. A 3–4 week incubation period is usual for plovers, sandpipers, grouse, pheasants. grebes, cormorants and herons: a 6 week period for ducks. geese and swans; a 4–8 week period for hawks and eagles; and a 9–11 week period for albatrosses.

As might be expected, the shortest incubation periods generally are shown by small birds: the longest by large birds. These differences are not attributable to size alone, for small hummingbirds have a relatively long incubation period of 16 to 18 days; the thrush-sized storm petrels, a period of as much as 7 weeks; and the ostrich, a period of only about 6 weeks.

Usually the female incubates, and the male may or may not share this duty with her. But in some groups, such as the button quails (*Turnix*), some ostrichlike birds and the phalaropes, the male does all the incubating.

When the male and the female share incubating, alternating on the nest, the eggs may only rarely be left uncovered. When the female does all or most of the incubating her mate may bring her iood. Short periods of cooling do no appreciable harm to the eggs except in very cold weather, and they are often left uncovered while the female goes to feed. In some groups, such as some ducks, the female is deserted by her mate early in the incubation period, and she then carries an alone: in most grouse and pheasants. the female is deserted by the cock even earlier, immediately after the eggs are laid.

In some species when the eggs are periodically left untended by the bird they are camouflaged in various mays The female eider duck pulls the edges of the downy lining of the nest over the eggs when she leaves, and the grebe covers its eggs with material from the side of the nest. This covering is apparently only for the concealment of the eggs.

A most unusual case is that of the Egyptian plover, or courser. It nests on sand bars and normally buries its eggs in the sand. The bird has been seen to sit on the sand above the buried eggs and to regurgitate water on the nest. Since she is nesting under a tropical sun, without shade, she may do this in part to protect the eggs from excessive heat.

The megapode's eggs. buried in the ground, hatch by the heat of decaying vegetation or of sunwarmed or volcanic sands, depending on the location. and neither sex incubates.

The time that individual birds of different species spend continuously on the nest. incubating eggs, may vary greatly. Some extremes are as follows: in many small. active songbirds the incubating birds may leave the nest twice an hour or even oftener; in many hawks, periods of continuous incubation may last for hours; in some gallinaceous birds the bird may leave the nest only once a day. In some pigeons the two parents may alternate incubating, the male incubating during the midday hours, the female the rest of the time. In albatrosses the attentive periods of each parent may last several days, during which time the setting bird fasts completely. In some parrots the female incubates almost continuously, being fed by the male. In some hornbills the female walls herself in the nest and is fed throughout incubation by the male. In the emperor penguin the male alone incubates. and continuously. for the whole 60-day period. and eats nothing the while.

B. The Young

1. Hatching and Development.——As the time for emerging from the egg approaches. the chick makes small movements and utters little chirps or calls within the egg. The young bird. using the egg tooth, a little protuberance on top of the end of the upper bill, pips the shell as it moves its head and rotates its body within the egg. From the time the first puncture appears in the shell until the young struggles out may take nearly a day, even in small songbirds; in some larger birds several days may be needed.

A young songbird at hatching is naked (or nearly so) and blind. and for some days it: activities are limited to gaping for food, which the parents thrust into its mouth, and resting quietly in the nest. Young hatched in this helpless condition are termed altricial. or nidicolous. Among the larger birds cormorants and birds of prey are altricial.

A young quail, duck or killdeer, on the other hand. is covered with down when it hatches. and as soon as it is dry is able to walk about, follow its parent and pick up its own food. Birds hatched in such an advanced state are called precocial, or nidifugous. Included among them are grouse and pheasant. Young megapodes show the extreme of precocial development. They burrow out on hatching and fly as soon as their plumage dries. Between these two extremes. the altricial and the precocial, are many birds whose young hatch in intermediate stages. For instance. young nightjars, terns and gulls at hatching are downcovered and soon are able to move a little but depend on their parents to bring them food.

The development of precocial young at hatching is so far advanced, both physically and in behaviour, that it is equivalent to that of young altricial birds when they leave the nest. This, of course. leads to great differences in the infancy of the two types.

2. Parental Care.——The period of dependency in the nest for a young songbird may be as short as two weeks. During this time a coat of ieathers appears, the eyes open and an awareness of the environment develops. The young may sit up and look about. beg vociferously when it. sees the parent approaching with food. preen its feathers, flap its wings and when alarmed crouch down into the bottom of the nest. For the first few days the parents brood them. *i.e.*, cover and warm them, most of the time. After that they are brooded only at night.

Among the birds with altricial young, many songbirds bring food in the bill and simply stuff it into the gaping maw of the young bird. The young of hawks and owls nibble bits of meat held in the parents' bills. but they soon learn to tear to pieces the whole carcasses of small animals that the parent brings to the nest. Gulls regurgitate food in front of their young, which help themselves to it. Cormorants and pelicans bring fish in their gullets, but in these groups the young puts its head into the throat of the parent and rummages about for the stored and largely undigested fish. Hummingbirds reverse this process: the female inserts her long bill into the throat of the young bird and injects nectar and tiny insects into its gullet.

More completely processed food is provided by pigeons. which, in the early days of the nestling period, provide "pigeon milk," a secretion of the crop. The young puts its bill in that of the parent which pumps the food into the gullet of the young. The petrels feed their young in a similar manner but on a diet of semiliquid, partly digested material from the stomach.

Small, active songbirds are busy all day carrying food to their young. a mouthful at a time. The two parents of a group. or brood, of swallows may make as many as 40 trips per hour with food. In the phainopepla. in which the adults carry as many as seven berries in the throat at once, and regurgitate them for the young; the feeding rate may be as low as two or three trips an hour. The American robin brings worms in its bill six or seven times an hour. In some hawks food may be brought only a few times a day. and often there is an abundance of food lying on the top of the nest. The European sparrow hawk may make only two or three trips a day for food when the young are small. but make trips more often when the young are well along in growth. and need more food. Gulls may make several trips per hour; cormorants, one per hour; tropic birds, only two or three trips per day; whereas albatrosses may make trips several days apart.

To prevent the nest from becoming foul with excrement. two methods of nest sanitation are used. One is well illustrated by those songbirds in which the young, after being fed, raises the rear part of its body and voids the excrement in a gelatinous sac. The parent bird waits for this sac and either eats it or carries it away and drops it. The other way is illustrated by young hawks and

other birds that turn and void forcibly over the edge of the nest so that the excrement falls clear of it. Although the immediate vicinity of the nests of some birds. such as kingfishers and hoopoes, that lay their eggs in holes may become much fouled, the young birds remain clean. The odour of rotting fish and excrement. present in the colonies of such birds as herons and cormorants, seems to have no effect on these birds, for, like most birds. they have little or no sense of smell.

3. Leaving the Nest.—The altricial young of most songbirds leave the nest before they can fly well. For several days they sit quietly in trees, shrubbery or grass, and the parents bring them food. When they are able to fly better they may follow the parent, and it is no uncommon sight in the spring to see a full-grown young robin begging food from an older bird. Even young swallows that are able to fly well when they leave the nest sit on perches, and the parents feed them for a while.

The situation with some auks and shearwaters is very different. The young have a long period in the nest, during which time the parents care for them. Then, long before the young can fly, the parents desert them and may even start off on migration. The young stay in the nest and complete their growth by using the fat they have accumulated; then, without parental care or guidance, they set out into the world by themselves.

In such precocial birds as the pheasants. quail, shore birds and ducks, the downy young leave the nest on hatching and accompany their parents, who lead them into suitable habitats; the parents call them to come to food that has been found, break up food for the young, call an alarm when a predator appears and may even brood the young at night. Young grouse and quail grow their feathers quickly, and in a few days are able to fly short distances. Young ducks, however, delay the development of their wings until they are nearly full grown. The young of the megapodes. as described earlier, are down-covered at hatching and go their independent way without ever knowing a parent's care.

4. Social Parasites (Cuckoos, etc.).—One of the most aberrant types of nesting behaviour is that of the social parasites, birds that lay their eggs in the nests of other birds and leave them to be incubated and the young reared by the foster parents. This habit is best known in the European cuckoo and in the North American cowbird (a new world icterid blackbird), but some other cuckoos and cornbirds. honey guides, some African weaverbirds and a South American duck also have this habit.

Remarkably enough, in the European cuckoo, for which about 50 different birds have served as foster parents, some individual females are said to lay their eggs in the nests of only a single species of foster parents; moreover, the eggs of this female cuckoo bear a close resemblance to the eggs of the special foster parent. Instinctively, when the cuckoo lays her own egg, she completes the deception by removing one of those already in the nest. The young cuckoo. upon hatching. ejects the other occupants of the nest, eggs or small young, by backing them to the rim of the nest and letting them roll out. Thus, the young cuckoo becomes the sole recipient of the attention of the foster parents.

The cowbird, for which 160 host species and subspecies have been recorded, has none of the cuckoo's methods of getting rid of eggs or young in the nest. Instead, the young cowbird grows so rapidly that it soon surpasses its nest mates in size and strength; thus it usually takes so large a share of the food that the other young birds may starve to death.

Not all chosen foster parents of the cowbird accept the role selected for them. Some may desert the nest when a strange egg is placed there, and some may build a new floor on the nest, thus burying the cowbird egg. The yellow warbler has been known to do this several times in succession. Other birds, such as the American robin and the catbird. may throw out a cowbird egg.

Many birds, however. are obviously unaware that the cowbird's egg is not their own, and these foster parents raise the strange young even though, in some cases, their charges greatly outsize them. It is remarkable that the young of these social parasites develop all the traits of their own species; they are completely uninfluenced by the very different voice and habits of their foster parents.

V. BEHAVIOUR

The behaviour of birds is caused by both instinct and learning. There no doubt is a broad range of bird activities the patterns of which are inherited. But just where and how the bird uses these activities may be greatly modified by the individual bird's experience. Each bird gains some of this experience through direct contact with its environment, some through association with its parents or its fellows.

1. Instinct and Learning.—Instinctive *Behaviour*.—Those habits or behaviour patterns that are as rigidly inherited and as inflexible as is the bird's structure are termed instinctive. Individual variations and aberrations in habits occur, just as they do in structure, but aside from these the behaviour pattern is constant for each species. This rigidity of behaviour is nowhere better illustrated than in nest building activities: the nest is considered as the concrete record of an elaborate pattern of behaviour, for each species has its own type of nest.

The instinctive control of elaborate behaviour patterns is apparently particularly strong in activities regarding reproduction. Rigid, built-in behaviour patterns that assure the continuance of species are obviously of considerable survival value to animals that have short average life spans and rapid turnovers in population. (See also INSTINCT.)

In matters of enemy recognition and in feeding, behaviour is apparently less rigidly controlled by instinct and more affected by learning. The enemy-recognition response is generalized: the young bird flees from any large object, a response that more or less assures that the inexperienced young will escape when a predator approaches it. The method of picking up food is instinctive; however, response to types of food is not so rigidly controlled, for it might well be a disadvantage should one type of food become scarce.

The study of bird behaviour has been given much impetus since the development of ethology, an interdisciplinary science that focuses its attention on instinctive behaviour patterns, the elaborate specific patterns of action. (See ANIMAL BEHAVIOUR for a discussion of the concepts involved in instinct.) The original outline of the sequence of events involved in an instinctive action, formulated by K. Lorenz in the 1930s, was beautiful in its simplicity and its avoidance of certain undesirable psychological implications. Lorenz' concept of instinct, particularly under the stimulus given it by N. Tinbergen, has been the basis of modern comparative ethology; however, it has been greatly modified, particularly in that drives feature more prominently in the study and in that learning is incorporated into appetitive behaviour.

Learning.—In the first quarter of the 20th century it was commonplace to read that birds were creatures of instinct, with very limited intelligence. By mid-century it had been demonstrated that the learning ability of birds may be as great as that of any animals except the highest mammals. Research continues, and another quarter century probably will see drastic revision of many of the mid-century concepts. (See also LEARNING.)

Maturation.—Care must be taken not to confuse the maturation of a behaviour pattern with learning. It is commonly said that the flapping of the wings of a young bird in the nest is connected with the bird's learning to fly. But young birds experimentally prevented from flapping their wings during their infancy flew just as well the first time as did those that had been allowed freedom to flap.

Trial-and-Error Learning.—A young bird, without experience of water, often goes through the motions of bathing outside the water; it is only by accident that it learns to associate these movements with bathing in water. Similarly, a young bird pecks at all sorts of things in its environment and finds that only some of them are edible; finally it learns to prefer only the edible objects. The actions themselves are instinctive: but their application is modified by experience. Similar trial-and-error learning surely plays an important part in other adjustments to everyday living. even in those birds that instinctively restrict their activities to a narrow section of possible habitats.

Puzzle boxes and mazes have been used to demonstrate this type of learning. Siskins have learned, by trial and error, which one

of a row of similar boxes to open for food. Mazes like those used in testing rats are less suitable for testing birds because of the very different habits of the two animals. Pigeons and sparrows. however. have shown considerable skill in learning a route through a maze.

Habituation.—Learning not to respond when a response is unnecessary is termed habituation. A good example of habituation is seen in enemy recognition. While a few types of enemies may be instinctively recognized and responded to, there is a more widespread. generalized response to danger. Gradually, however, a bird learns that certain things initially feared are not dangerous. This is well seen in the birds that come to a winter feeding station just outside a window. At first they flee at the slightest movement within the house, but as winter progresses they become bold and tame and come to disregard such activity.

Insight or Latent *Learning.*—In this type of learning, the experience gained earlier is used in a delayed response. Perhaps the simplest case is that in which a bird has become familiar with its territory and travels back and forth through it easily It can go directly to the nest even though it cannot see the nest until close to it. The nutcrackers of Europe that bury nuts in the autumn and dig them up in the winter are good examples of birds using a long-delayed response.

Detour *Problems.*—Comparatively little has been done in studying detour behaviour (*i.e.*, going around an obstacle) in birds, though the domestic hen has demonstrated a lack of it: the hens peck at a piece of glass covering food without attempting to get around the glass.

Tool Using—Tool using, as exemplified by the Galapagos finch that uses a stick or spine to get insects from cracks. can be attributed to either instinct or insight But the string pulling of some birds. such as chickadees and jays that quickly pull up a string to get food attached to the end of it. perhaps qualifies as a better example of tool using.

Counting.—There is also good evidence that birds have some concept of quantity or number. Counting of course is done only by human beings, who have names for the numbers, but the recognition of numbers of things such as marks on a paper, without counting is possible. This is a prelinguistic number sense Although individual performance varies, birds can recognize, nithout counting, up to eight units, though some reach only five. (Interestingly, this is about the same as a man does.) A raven was shown to recognize up to six spots by matching the number of spots on a card nith the same number of spots on a box containing food and choosing it from among other boxes without food and nith different numbers of spots.

Imitation.—That a bird can learn to solve a problem by seeing another bird solve it has not been demonstrated (though the manner in which the ability to tear the tops from milk bottles spread through British populations of blue and great tits suggests it). True visual imitation in learning, therefore, is not accepted as playing a part in bird behaviour. Birds, however. do profit by the activities of other birds that they see, but in a different way. Crows in a flock seeing one of their number shot or poisoned, become very shy of a man with a gun, or of the situation in nhich the poisoning occurred. This type of learning through social facilitation is probably very widespread in birds. The role of a few tame birds can be very important in getting wild birds used to a sanctuary. Becoming tame or wary through habituation is very evident as is also the manner in which birds pay attention to the warnings of other birds.

Another type of imitation is found among birds such as mockingbirds that repeat many of the sounds they hear, and parrots that learn to imitate human speech. This is apparently imitation used in play.

The manner in uhich some young birds learn their song from the adult is imitation of a special sort, mentioned below.

Imprinting—This is an innate disposition for birds to learn certain things only at early periods of their lives. A good example of imprinting is the manner in which young geese reared from the egg in isolation follow their keeper, the first moving object they see; they regard him as they would their parent, and later as a mate or rival. Imprinting can happen in a very short time, and it used to be considered permanent and irreversible, but this is not always true. There is no definite boundary between it and other types of learning. Imprinting. as a disposition to learn certain things in a certain way at an early stage, is recognized in the singing of some birds. Although the song of some species is largely innate, in others. when the young birds are raised in isolation and do not hear the song of their own species, they do not develop the typical song of the species. They may invent a song of their own or may copy that of some other species that they hear singing.

2. Play, Flocking, Dominance, **etc.**—*Play.*—Like the concept of instinct, that of play has been in and out of fashion. The concept mas in vogue again in the mid-20th century. Certainly play is a very real component of some birds' activities. A flock of swallows flying about and carrying a feather. each one holding it for a few moments, then dropping it and another seizing it, and so on, is a good example. Other activities considered as play are the talking of parrots: the seizing of twigs as though they were prey by young raptorial birds; the juggling of fruits by hornbills; and the soaring of pelicans on an updraft of air. Such activities, apparently done for their own sake as leisure activities, are comparable perhaps to the exploratory activities of many birds that apparently need to be active. As a secondary effect play activities can be of importance in developing skills.

Flocking.—Since birds are able to move about easily. have keen eyesight and a wide awareness of their surroundings it is not surprising. in areas where they are abundant, to find numbers of them coming together naturally as American robins do to a cherry tree, gulls to a fishing boat, or ducks. terns and American blackbirds to a favourite habitat in a prairie marsh. On the other hand. when a flock of sandpipers gathers on one part of a beach. or a flock of American blackbirds drifts across an October landscape, they are obviously held together by a liking for each others' company, a gregariousness.

This gregarious flocking is especially evident in the nonbreeding season and usually involves birds of one species. in larger or smaller numbers. But the liking for company often transcends species limits as is well seen in the winter flocks of chickadees that are often accompanied by a nuthatch or two, or in the woodpecker that has shunned the company of its own kind for that of the chickadees. The great mixed flocks of birds of the tropical forest in which are included a dozen or more species and scores of individuals are good examples of interspecific gregariousness.

Sometimes single birds or a few individuals of one species join the flocks of other species and. as though caught up in the larger flock. may live and travel with it for some time. A few mallard ducks have been reported to have thus consorted with a sand grouse flock. an association that is remarkable considering the differences in habits and habitat between these species. Strays far from their normal haunts occasionally take up with quite different birds. An albatross from the southern oceans found its way to the North Atlantic and lived for 34 years with the gannets of the Faeroe Islands. Flocks of birds often derive advantages from co-operative feeding and from acting together to avoid their enemies.

There are some regular associations between different bird species, and between birds and mammals, that are advantageous for the birds. The hornbills in the Congo forests follow bands of monkeys for the sake of the insects that the monkeys stir up. The most extreme case of a bird-mammal association is that of the oxpecker of Africa that feeds entirely on the parasites of big game animals and cattle

Dominance—Within a flock made up of one species there may be a well-defined rigid social hierarchy This has been demonstrated in the so-called peck-order in the domestic hen In a flock of hens the dominant hen (A) asserts its authority by pecking any hen below it, *i* e., all the others in the flock; the next (B) pecks all the hens except hen A; and so on to the lowest bird in the hierarchy, which has no other he11 to peck. The place of the birds in this social order is determined through aggressive encounters early in life, but the relationships do not always remain constant.

Low-ranking birds may become more vigorous and fight their way up to a higher rank. That this is sometimes the result of a physiological change has been demonstrated experimentally by the injection of hormones. Not all dominance is the straight-line A to B to C type. For example, in some birds, although A may peck B and B peck C, C may peck A, but not B. Canada geese families may behave as units, one family being dominant over another family.

Dominance, both between birds of a single species and between those of diffierent species, can be observed easily at a feeding station, where, among a group of birds, the dominant bird is the first to feed. It has been thought that dominance is of value in reducing the amount of fighting in a flock, once the social hierarchy is established.

Although flocking is much less common during the breeding season, some species display in groups as do the blackcock, the ruff and the prairie chicken. Other birds nest in close colonies, as do terns on a sandbar, auks on a cliff and weaverbirds in a tree, even though many other, apparently equally suitable nesting places exist. In colonial nesting behaviour there may be advantages in numbers of birds to fight off predators; furthermore, the presence of such close neighbours may stimulate breeding.

In nesting, social aggregations may transcend species limits, as in feeding. This is well shown in the arid country of Central America, where a single, thorny tree may hold the nests of each of several species of birds including doves, orioles and flycatchers, while other trees nearby, each apparently equally suitable, are not used.

Species Recognition.—The first social contacts of the young bird are of course with its parents. All birds (except the megapodes, which start their lives without parental supervision) have some parental care. In geese the family, male, female and young, may stay together for nearly a year. In some grouse the family parties lose their identity in the autumn. Among most of the ducks, the male is never part of the family group, which breaks up when the young become full-winged. The same post-fledgling dispersal is probably true of most songbirds.

In some petrels and auks the young, cared for by the parents in the nest for a time, are soon deserted and left to follow their species' way of life without the influence of their parents. The young of the parasitic cuckoos and cowbirds, raised by foster parents, start their lives under the care of these parents and later form flocks with other young birds of their own kind.

Thus species recognition may be instinctive, but within a flock in which there is strict social dominance it is obvious that each bird recognizes every other bird, probably by minute individual differences in appearance. Voice may be important in species and individual recognition as well as in communicating between individuals. Certainly solitary plovers will come to a whistled imitation of their call, and a nesting gull will recognize the call of its returning mate. Also much information may be transmitted by signaling movements. An alert, upraised head, a flick of the wings or a sudden starting into flight of one member of a flock may alert the other members or send them fleeing even when they are unaware of any danger. One of the best examples of visual acuity and the rapid use of visual clues is the manner in which a flock of shore birds will twist and turn in unison, apparently taking their cue from the birds in front.

3. Migration.—Some birds have adapted their behaviour to living in one region part of the year and in another the rest of the year. Often their annual journeys back and forth, their migrations, take them to temperate or arctic regions for the favourable summer season when they breed, and to the more uniform tropical regions for the rest of their year when they do not breed. (See MIGRATION, BIRD.)

4. Summary.—The above is a short survey of some of the recent trends in the investigation of bird behaviour. To delve still deeper into the subject leads to speculation about what goes on inside the bird, especially inside its brain. There are the questions of how messages are received from the environment. how the data are organized and how the responses are initiated and controlled. All these internal processes may be influenced by hormones and by other physiological changes.

In every period of time there are fashions in terminology and in interpretation. in methods and in goals. Some students concentrate on the inherited aspects of the bird's activities; some try to analyze the extent of instinctive *v.* learned behaviour; some study learning; and some merely record what birds do.

Various approaches are used: observational, experimental, psychological and physiological. Philosophical discussions centre on directions and meanings in their widest sense. All these add to the richness of our understanding of a bird's activities. But such a diversity of approaches and schools of thought, of interpretation and language of presentation, make much of the work on bird behaviour the province of the specialist.

In everyday accounts of what we see, it is difficult to avoid subjective interpretations or anthropomorphizing. Indeed many of the exploratory activities of birds in trial-and-error learning and in latent learning could be discussed under the heading "curiosity." "Antagonism," "pugnacity" or "anger" would seem to express the quarrelsomeness of some woodpeckers, normally solitary in nature, when kept in captivity in close contact with each other. "Fear" could be the heading and theme of the paragraph on enemy recognition and avoidance. Indeed the "drives" of the psychologist sometimes appear to be synonomous with the "moods" and "emotions" of more general terminology. See also PSYCHOLOGY, COMPARATIVE. **(A.** L. RD.)

VI. TYPES OF LIVING BIRDS

Mammals are specialized for various modes of life: on land (as the deer and mouse), in water (as the whale), in the air (as the bat), in the ground (as the mole), etc. But most birds are specialized only for existence or progression through the air. Although it is common for birds to nest in holes or tunnels in the earth, which, in many cases, are excavated specially for this purpose, no bird has been able to adapt itself to continuous life underground, probably because its covering of feathers is not designed to withstand the constant abrasion that would take place in burrowing. Also, though many birds frequent the water, none are so wholly adapted to life beneath the surface as the whales. Birds thus have failed to utilize as completely as mammals the ecological environments that have been available to them—an example of the way in which greater specialization makes for inferior adaptability.

1. Land Forms.—Birds adapted to a terrestrial existence are found in many widely separated groups, as, for example, ostriches, quail, bustards, plovers, larks and pipits. Most of these appear to have adopted a terrestrial habit to secure food and safety from enemies. They run about on the ground and, though the greater number retain the power of flight, often trust to their legs to escape ordinary pursuit. Most of them show the greatest variety in regions of extensive plains, prairies or broad, open downs. The wholly terrestrial forms that have entirely lost the power of flight are comparatively few, and (as far as continental areas are concerned) are birds of considerable size and strength. Among living forms they include the ostriches of Africa, which ranged formerly to Arabia (extinct there by 1941); the cassowaries of the forests of New Guinea and adjacent areas; the emus of Australia; the kiwis of New Zealand; and the rheas of South America. These birds, though they appear to be united by certain peculiarities, differ widely from one another, and seem to represent ancient types of bird that were formerly more abundant, as a number of fossil forms are known. It will be noted that large flightless birds exist in modern times in all of the continents except North America, where they have not been represented since the Eocene.

The kiwis (Apteryx) of New Zealand, the most unbirdlike of living birds, are nocturnal and have different habits from the other species mentioned. They have long bills with the nostrils at the extreme tip, and move about by using the bill to test the ground before them as a blind man uses a cane, noting their surroundings partly by touch and partly by smell. On casual examination they seem to have no wings, but on investigation the wing is found concealed beneath the feathers, a tiny structure, a little more than three inches long when fully extended, and entirely without

flying function, as the bird is heavier than an ordinary fowl.

The cassowaries, like the kiwis, inhabit forest areas, but are far less peculiar. The wings are small, with heavy, naked quills nearly concealed beneath the long, hairlike feathers, and there is a curious casque on the head. It is said that the bird uses both casque and wing quills to fend off entangling vines in traveling through the jungle. The wings of emus also are small, but ostriches and rheas have larger wings, which they may extend while running, though they are wholly without power of flight. In all these birds the body is heavy and the legs are large and strong. With those fleetest in running there is a tendency to reduction in the number of toes, so that none has more than three and the ostrich only two. That these birds have come from flying ancestors is indicated by the wing, which, while small and weak, has the bones formed as in flying species. All the species discussed have the external surface of the breastbone smooth: without the great keel so characteristic of the flying birds. This is associated with there being no necessity for large muscle attachment because in flightless birds the muscles usually concerned in flying have little development.

There is another type of terrestrial bird that has developed more recently than those just discussed, found mainly on oceanic islands. This includes various species of flightless rails, and some other birds that have lived under conditions in which they had no enemies from whom it has been necessary to escape by flying. Thus these birds evolved into flightless forms; however, the wing retains the same form encountered in flying birds and the breastbone still has a keel, though this may be greatly reduced in size. The weka rails of New Zealand are the most striking living examples of this group; they are nearly as large as a fowl, and run with great ease and rapidity. Some other flightless rails are much smaller, for example the recently extinct Laysan rail (*Porzanula palmeri*), formerly native of Laysan Island in the Hawaiian Islands, which was not much larger than a newly hatched chicken. In running fast this bird extended its wings and flapped them rapidly, but was unable to rise from the ground. Many other insular birds show a tendency to degeneration of the wing but still can fly.

2. Water Forms. — Among birds adapted to life in the water, the penguins are pre-eminent. These include about 15 species found in southern seas, ranging in size from the great emperor penguin (*Aptenodytes forsteri*), which is *48* in. long and weighs up to *94* lb., to the little blue penguin (*Eudyptula minor*) of New Zealand, southeastern Australia and the Chatham Islands, which is only 16 in. in length. Penguins have thick, heavy bodies, more or less elongated, and are covered uniformly with dense, soft feathers, without the bare spaces or apteria that in other birds divide the feather growths into distinct tracts. The wing is a short, broad paddle, without developed quills, the feathers being close-set and stiff, almost like the scales of a reptile. In the water the penguin rests comparatively low. Beneath the surface it progresses literally by flying, the flattened wings driving the bird through its aquatic medium swiftly and gracefully, while the feet are extended behind and serve as a rudder. Penguins seem to have possessed their present type of body since Eocene time; but they must have come originally from a flying stock.

Other types of birds developed for life in the water include loons, or divers, and grebes, whose progress beneath the surface is accomplished, usually, by the use of the broad feet alone, the wings being held close to the sides, except when the birds are frightened or under other unusual circumstances. The downy young dive by use of both wings and feet, indicating that "flying" under water is perhaps a primitive method. The auks and guillemots use the wings beneath the surface as in the air above. The cormorants and snakebirds progress by use of feet: though wings may be partly open. Diving ducks, as mergansers, scaups, redheads, pochards and goldeneyes, regularly use the feet, though in the same group old squaws (long-tailed ducks), scoters and eiders may use both wings and feet beneath the surface. The curious diving petrels (*Pelecanoides*) of the southern hemisphere fly swiftly beneath the water and may burst out through the surface in full flight.

3. Night Flyers. — Birds adapted for life at night are fairly numerous and are typified especially by members of the nightjar and owl families, though specialized forms occur among a number of other groups. Most nocturnal birds have large eyes that usually reflect light with a prominent reddish or orange colour. The eyes of many nightjars glow like dull coals of fire by the reflected light of a flaihlight and may be seen for a considerable distance. One of the American nighthawks (*Chordeiles acutipennis*) is an exception since the eyes shine only faintly with a yellowish green hue. Most nocturnal birds actually see at night by a specialized eye adapted to collect the faintest rays of light. Only the kiwis (*Apteryx*) among habitually nocturnal species appear almost blind

VII. GEOGRAPHIC DISTRIBUTION

The laws governing geographic distribution (*see* ANIMALS DISTRIBUTION OF) through which each faunal area has its own peculiar forms apply to birds as to all other animals in spite of the easy method of travel possible for the bird Few birds are cosmopolitan As an example may be mentioned the sanderling (*Crocethia alba*) which at some season may be found along nater almost anynhere on the earth, but which nests only in the arctic regions, passing southward in migration throughout the world, to return in spring to its breeding area. The barn owl (*Tyto* species'), resident through wide areas in the temperate and tropical regions of the earth so that it reaches all the continents, has reacted to its environment in such a way that more than *50* geographic forms, some sufficiently distinct to be called species, have been recognized. In contrast to this, many kinds are confined within very narrow limits, as the very distinct Laysan teal (*Anas laysanensis*), found onky about the shores of one small lagoon on Laysan Island in the Hawaiian Bird reservation, where it has a range of only about one square mile.

Birds, in general, have attained a vast distribution over the surface of the globe because of their ability in flight and their specialization for life on both land and water. As a result of this versatility and adaptability some form of bird is found at some season everywhere over the world, except perhaps in the centre of the great unexplored antarctic continent. Broad areas of the sea, away from the great ocean currents that flow like rivers through this aquatic medium, may appear birdless for days and weeks, but are crossed at certain seasons by some of the petrels in their wanderings. The seas and lands within the Arctic circle are visited by many birds, some of which, like the raven and snow bunting, nest far north in Greenland, and some, like ducks and gulls, in summer traverse the solitudes of the north polar sea.

As individuals, birds may be tremendously abundant in temperate regions, but it is within the tropics that the greatest variety of forms occur within small limits. The largest aggregations are found in regions of diversified topography, where the life zones change within a comparatively few miles from tropical to alpine. The greatest density and variety of birds have been reported from certain areas in South America. (A. WT.)

VIII. VITAL STATISTICS

1. Populations and Numbers. — The relative number of individuals of different species of birds is usually expressed in comparative terms: rare, common, abundant, etc. Of course, actual counts of birds seen per unit of time or unit of area are more satisfactory, and many data of this sort are used for estimates of populations over large areas.

In a few cases in which the bird species has small numbers and a limited range, or the members are large and conspicuous, reasonably accurate counts of the whole world population are possible. Some examples of North American species with very small numbers, and thus facing extinction; are the whooping crane (*33* individuals in 1960), California condor (*60* in 1950) and ivory-billed woodpecker (possibly extinct in the early *1960s*). In a precarious state in other parts of the world are the cahow petrel of Bermuda, the shore plover of New Zealand and the Nene goose of Hawaii.

There are reasonably close counts of some species with larger numbers but with restricted wintering or breeding grounds: Ross's goose (2.000 birds nesting in arctic Canada in *1949*). Kirtland's warbler (breeding only in Michigan, 1,000 birds estimated in 1959)

and greater snow goose (about 42,000 in 1954, on their wintering grounds in the eastern United States).

Some very numerous species with restricted breeding grounds have also had fairly close estimates made from counts: the greater shearwater, which breeds only on the island of Tristan da Cunha in the mid-south Atlantic, numbered 2,000,000–2,500.000 pairs in 1952; the gannet, which nests on islands on both sides of the North Atlantic, approximated 83,000 pairs in 1939.

But these numbers are small compared with the "millions" of such pelagic sea birds as Wilson's petrel and the whalebirds nesting in the antarctic and fluttering over the oceans. Many single roosts of common blackbirds (several species) in the central United States have been estimated to contain from 1,000,000 to 15.000.-000 birds; a single roost of house sparrows in Egypt was estimated to contain 100,000 birds, gathered to their sleeping perches from a four-mile radius.

Censuses of breeding birds have provided interesting data on the density of some species. For instance. a census in a forest area in the eastern United States indicated that 26 species of birds occurred in the area and that their density ranged irom 2 to 55 pairs per 100 acres. with a total density of all species reaching 325 pairs per 100 acres. Different habitats of course give different results, and the results vary from year to year.

Using such data as these, and estimating the extent of available habitat, it has been calculated that there are about 5,000,000,000 breeding land birds in the United States and 120,000,000 in Great Britain.

2. Ages and **Sex** Ratios.— Age at Sexual Maturity.— It is a common conception that most birds reach sexual maturity several months short of a full year and breed in their second year. In view of the known short life span of many birds this would seem to be essential for carrying on the species. That the period up to sexual maturity may be considerably shorter, however, is indicated by records of captive birds that have laid eggs at three to six months of age. At the other extreme there are some species, especially large birds, in which the young do not breed in their first year. Many hawks and gulls do not breed until they are two years old. Some large hawks and storks may be six years old, and some albatrosses eight, when they first breed. The age at first breeding also may differ between males and females of particular species. In some American blackbirds females commonly breed in the season following their birth, but the males do not breed until a year later.

Sex Ratio.— The preponderance of drakes over ducks in some hunters' bags and in traps operated for banding birds, and the preponderance of females in breeding colonies of some American blackbirds in which polygamy is practised. have led to much speculation regarding the sex ratio of birds at hatching and at later stages in life. In some species an approximation of the expected 50% males and 50% females has been found in young birds, for instance. barnyard fowl, some quail and the boat-tailed grackle. In 1940 an unbalanced sex ratio of 30% males and 70% females was reported for the young boat-tailed grackle; however, work reported in 1960 disproved that estimate in favour of the 50% male–50% female ratio.

Irrespective of the sex ratib in the whole population, units of populations may have a preponderance of one sex or another. In the blackbird breeding colonies mentioned above: there are two or three females to every male, in part at least because the earlier maturing first-year females are present and the first-year males absent. Drakes are often found in greater numbers than ducks since, while ducks are incubating their eggs, the drakes gather by themselves in flocks, sometimes far from the breeding grounds. In the nonbreeding season flocks of birds may be composed predominantly of one sex or the other, and such flocks may differ in migration, feeding and roosting patterns. For instance. in the southeastern United States flocks of male grackles commonly visit city parks, but the females stay in farming country out of town. In the northeastern United States the early arriving flocks of red-winged blackbirds are composed entirely of adult males.

Age *and* Mortality.——Compared with many lower animals birds are specialized in having fewer young and in giving the young considerable parental care to aid them in getting a start in life. Even a quail with 20 eggs or a robin with several clutches of 4 or 5 eggs a season represents conservation when compared with a frog that lays several thousand eggs each year. But despite the solicitude of adult birds for their young. mortality is high. and in the first year of life 35%–80% may die. The mortality rate of the survivors drops in subsequent years, as among the ducks. in which the first-year mortality rate is 50%–85% while in subsequent years it is 40%–65%. In gulls the death rate is 40%–60% in the first year and 18%–30% in following years. Average mortality per year for adults. however, expressed in percentage of those alive at the first of the year. remains high for many birds: 60%–80% for gallinaceous birds and 40%–70% for songbirds, pigeons and ducks. It drops to 20%–30% for swifts, owls, gulls and penguins, however. This gives a low average longevity after the bird reaches adulthood. The average life expectancy of adult gallinaceous birds has been estimated at one-half to one year; of songbirds and ducks. one to two years; of swifts, five years; and of gulls and terns, two to five years.

Some older birds do live considerably longer and continue to breed. Potential longevity is indicated by old-age records of banded birds which include those of a common tern 24 years old; an osprey 21; a mallard 15; a barn swallow 16; a blue jay 14; and a black-capped chickadee (or willow tit) 10. The ages recorded for birds in captivity. especially those of larger birds, are of course considerably greater. A pelican, an eagle and a sulphur-crested cockatoo are recorded as having lived past the half-century mark, and an eagle owl of Europe as long as 68 years. Among small birds a canary has reached 18 years, and there is a report of one having lived to 24 years. There have been records of parrots. ravens and eagles reaching much greater ages, but these are not adequately documented.

To evaluate the relative importance of the many various factors responsible for bird deaths is almost impossible. In the northern United States deep snow, covering nesting ground and food, is probably more important in keeping down the bobwhite quail population than is predation by either fox or hawk. It has been reported that in some areas more pheasants and king rails are killed by motor traffic on the roads than by natural predation. An example of decimation of populations caused by inclement weather in winter or in the migration season has been shown in the purple martins during occasional years in the New England states. (In a few years, however, the martins regain their former numbers.)

Man as a predator is able to control the numbers of many bird species, especially game birds. But man as a modifier of habitat is still more important: draining of a breeding marsh means death to the ducks: American blackbirds, black terns and willets breeding there just as surely as if every one of them had been shot. Destruction of hedges means the loss of the songbirds and quail that occupied them.

The mortality factors that keep the life expectancy of an adult quail at less than two years or a hawk at live years are not easily established. But it is probably a food and shelter factor balanced against predation, weather and disease. An area under normal conditions supports a certain number of birds. When the population is heavier, the extra birds are vulnerable and more likely to die. When disaster decimates a songbird population, it builds back to an optimum, then levels off.

3. Extinction.— Extinction is commonplace in evolution. But with man's ascendancy. the lives of some species have been cut off abruptly. There are 45 species and 43 subspecies which have become extinct since the beginning of the 18th century, and another 12 species and 7 subspecies probably are extinct. These represent such diverse groups as emus and certain parrots and sparrows. Almost all of the extinct forms lived on islands. Only six are known to have lived on the North American mainland: the Labrador duck (extinct in the late 1870s), the heath hen (early 1930s), eskimo curlew (1930s). passenger pigeon (1914). Carolina parakeet (two subspecies; 1914), and the great auk. which lived throughout the North Atlantic area (last recorded in 1850).

No birds are known to have become extinct on the South American or African continents, and only one has become extinct in

Europe—the great auk. In Asia there is one. the crested sheldrake of Korea (last recorded in 1916); and in Australia a species of grass wren has become extinct (last recorded in 1875). By contrast. 12 species and subspecies have become extinct in the West Indies. 13 species and 13 subspecies in the Hawaiian Islands. 14 species and 12 subspecies on central and western Pacific islands.

It is probable that direct killing by man was the immediate cause of extinction of only a few of these birds. such as the great auk and the passenger pigeon. In most cases extinction is the result of the change that man brings about in the environment. destroying habitats and introducing foreign predators and perhaps diseases. (A. L. RD.)

IX. ORIGIN AND EVOLUTION

1. Bird Ancestry. — Bizarre as the idea may seem at first. birds are more closely allied to reptiles (*q.v.*) than to any other living group of vertebrates. The bird, while similar to the reptile in much of its structure! in its superior mental capacity. and in the concomitant adaptations that this has permitted, has far outstripped its lowly cousins, and so has flourished and multiplied while its cold-blooded relatives with decreasing numbers have fallen behind in the race of life.

The origin of the class Aves, the birds, is now generally accepted as found in the Archosaurian subclass of the Reptilia, more particularly in the suborder Pseudosuchia of the order Thecodontia. The known fossils of this group were of small size with relatively large heads. slightly built bodies, and slender hind limbs twice as long as the tiny front pair, so that the animals were dehnitely bipedal in locomotion. They come from deposits of early Triassic time, and are supposed to have been ancestral also to the pterodactyls, flying reptiles that existed until the Cretaceous period.

2. Fossil Birds. — The bones of birds are so poorly preserved in the fossil state that there is record now of only about 825 fossil forms, including some of questionable identity. The earliest fossils known are *Archaeopteryx* (*q.v.*) and *Archaeornis* of the Jurassic beds of Bavaria, creatures with toothed jaws, long, bony tails with feathers projecting along the sides and free fingers, that in spite of their reptilian form. were birds, since they were covered with feathers and were able to fly or at least to soar on their feathered wings. In the Cretaceous period two types of birds are known from nearly complete skeletons, *Hesperornis* (*q.v.*) and its allies, toothed, diverlike species that lived in water and seemed to have had no functional wings, and *Ichthyornis* (*q.v.*), with the articular surfaces of the vertebrae concave, which was aerial and may have had the habits of a gull. These four types are the most peculiar fossil birds known at present, since others. while often strange, are allied more closely to modern families.

From the beginning of the Tertiary period the fossils found are suggestive, in form, of existing birds, though in the Eocene some were highly peculiar. and are placed in extinct families. The species known from the Oligocene are more like living groups, and in the Miocene there occur a number of birds closely similar to those existing today. In Pleistocene beds there are found bones of numerous species still in existence, in addition to many that differ from modern forms.

The progress of the avian group since the coming of the Pleistocene ice seems to have been mainly one of decimation rather than of consistent evolutionary progress! since peculiar types seem to have been exterminated in numbers during the Pleistocene, and there is no indication that others have developed during this period to take their places except for the minor characters that distinguish subspecies or poorly marked species. The story of fossil birds still is far from complete, and much work remains to be done on many of those at present discovered, to establish their relationships.

X. CLASSIFICATION

It is difficult to arrive at an exact figure for the number of kinds of birds now known, but at a conservative estimate there are about *8,700* species, with at least *30,000* geographic races or subspecies.

The primary group or class. Aves, is one of the great divisions of the vertebrates and is equal in rank to the sharks and rays, bony fishes. amphibians, reptiles or mammals. This class is divided into two subclasses. the first, the Archaeornithes, containing the most primitive birds which are very close to reptiles. and the second, the Neornithes. all other known birds. The Neornithes are divided again into four major divisions or superorders. the Odontognathae. containing forms with teeth, the Ichthyornithes for the group of fossil species of the Cretaceous with vertebrae like those of fishes. the Impennes for the penguins and the Neognathae. including the remaining species with a more ,specialized modern type of palatal structure. These superorders are divided again into orders, suborders. superfamilies and families. An arrangement embodying modern ideas of classification follows.

Class Ares, Birds

Subclass ARCHAEORNITHES, ancestral birds
- Order Archaeopterygiformes, *Archaeopteryx, Archaeornis* (fossil)
  - Family Archaeopterygidae, *Archaeopteryx, Archaeornis* (fosril)

Subclass NEORNITHES, true birds

Superorder Odontognathae, new world toothed birds
- Order Hesperornithiiormes, Hesperornithes
  - Family Hesperornithidae, *Hesperornis* (iossil)
  - " Enaliornithidae, *Enaliornis* (fossil)
  - " Baptornithidae, *Baptornis* (iossil)

Superorder Ichthyornithes, *Ichthyornis* and allies
- Order Ichthyornithiformes. Ichthyornithes
  - Family Ichthyornithidae, *Ichthyornis* (iossil)
  - " Apatornithidae, *Apatornis* (iossil)

Superorder Impennes, penguins
- Order Sphenisciiormes, penguins
  - Family Spheniscidae, penguins (southern hemisphere)

Superordcr Neognathae, typical birds
- Order Strutbioniiormes, ostriches
  - Family Eleutherornithidae, *Eleutherornis* (fossil)
  - " Struthionidae, ostriches (old world)
- Order Rheiiormcs, rheas
  - Family Rheidae, rheas (South America)
- Order Casuariiiormes, cassowaries, emus
  - Family Casuariidae, cassowaries (Australian region)
  - " Dromiceidae, emus (Australian region)
  - " Dromornithidae, *Dromornis* (iossil)
- Order Aepyornithiformes, elephant birds
  - Family Aepyornithidae, *Aepyornis* (iossil and subfossil, Madagascar)
- Order Dinornithiiormes, moas
  - Family Dinornithidae, *Dinornis* (fossil and subiossil, New Zealand)
  - " Anomalopterygidae, *Anomalopteryx, Emeus* and allies (iossil and subfossil)
- Order Apterygiiormes, kiwis
  - Family Apterygidae, kiwis (New Zealand)
- Order Tinamiformes, tinamous
  - Family Tinamidae, tinamous (Mexico to South America)
- Order Gaviiformes, loons
  - Family Gaviidae, loons (northern hemisphere)
- Order Podicipediiormes, grebes
  - Family Podicipedidae, grebes (cosmopolitan)
- Order Procellariiiormes, albatrosses, shearwaters, petrels and allies
  - Family Diomedeidae, albatrosses (southern hemisphere and North Pacific)
  - " Procellariidae, shearwaters, fulmars (cosmopolitan)
  - " Hydrobatidae, storm petrels (cosmopolitan)
  - " Peiecanoididae, diving petrels (southern hemisphere)
- Order Pelecaniiormes, tropic birds, pelicans and irigate birds
  - Suborder Odontopteryges, *Odontopteryx* and allies (fossil)
    - Family Odontopterygidae, *Odontopteryx* (iossil)
    - " Pseudodontornithidae, *Pseudodorttornis, Osteodontornis* (iossil)
  - Suborder Phaëthontes, tropic birds
    - Family Phaëthontidae, tropic birds (tropical seas)
  - Suborder Pelecani, pelicans, boobies, cormorants, snakebirds

- Superfamily Pelecanoidea, pelicans and allies
  - Family Pelecanidae, pelicans (tropics to warm temperate)
  - " Cyphornithidae, *Cyphornis, Palaeochenöides* (iossil)
- Superiamily Suloidea, boobies, cormorants and allies
  - Family Pelagornithidae, *Pelagornis* (fossil)
  - " Sulidae, boobies, gannets (cosmopolitan)
  - " Elopterygidae, *Elopteryx, Eostega, Actiornis* (fossil)
  - " Phalacrocoracidae, cormorants (cosmopolitan)
  - " Anhingidae, snakebirds (tropics and subtropics)
- Suborder Fregatae, frigate birds
  - Family Fregatidae, frigate birds (tropics and subtropics)
- Suborder Cladornithes, *Cladornis* and allies (iossil)
  - Family Cladornithidae, *Cladornis, Cruschedula* (fossil)

Order Ciconiiiormes, herons, storks and allies
- Suborder Ardeae, herons, bitterns
  - Family Ardeidae, herons, bitterns (cosmopolitan)
  - " Cochleariidae, boat-billed herons (tropical America)
- Suborder Balaenicipites, whale-headed storks
  - Family Balaenicipitidae, whale-headed storks (Africa)
- Suborder Ciconiae, storks, ibises, spoonbills
  - Superfamily Scopoidea, hammerheads
    - Family Scopidae, hammerheads (Africa)
  - Superfamily Ciconioidea, storks
    - Family Ciconiidae, storks, jabirus (cosmopolitan)
  - Superfamily Threskiornithoidea, ibises
    - Family Threskiornithidae, ibises, spoonbills (cosmopolitan)
- Suborder Phoenicopteri, flamingos
  - Family Agnopteridae, *Agnopterus* (iossil)
  - " Scaniornithidae, *Scaniornis, Parascaniornis* (fossil)
  - " Phoenicopteridae, flamingos (temperate and tropical regions)
  - " Palaelodidae, *Palaelodus, Megapaloelodus, Telmabates* (fossil)

Order Anseriformes, screamers, ducks, geese, swans
- Suborder Anhimae, screamers
  - Family Anhimidae, screamers (South America)
- Suborder Anseres, ducks, geese, swans
  - Family l'aranyrocidae, *Paranyroca* (iossil)
  - " Anatidae, ducks, geese, swans (cosmopolitan)

Order Falconiformes, vultures, hawks, falcons
- Suborder Cathartae, new world vultures
  - Superfarnily Neocathartoidea, Neocathartes
    - Family Neocathartidae, *Neocathartes* (fossil)
  - Superfamily Cathartoidea, new world vultures
    - Family Cathartidae, new world vultures (the Americas)
    - " Teratornithidae, *Teratornis, Cathartornis* (fossil)
- Suborder Falcones, secretary birds, hawks, falcons
  - Superfamily Sagittarioidea, secretary birds
    - Family Sagittariidae, secretary birds (Africa)
  - Superfamily Fnlconoidea, hawks, falcons and allies
    - Family Accipitridae, hawks, old world vultures, harriers (cosmopolitan)
    - " Pandionidae, ospreys (cosmopolitan)
    - " Falconidae, ialcons, caracaras (cosmopolitan)

Order Galliformes, megapodes, curassows, pheasants, hoatzins
- Suborder Galli, megapodes, curassows, grouse, pheasants
  - Superfamily Cracoidea, megapodes, curassows
    - Family Megapodiidae, megapodes (Australian region)
    - " Gallinuloididae, *Gallinuloides* (fossil)
    - Cracidae, curassows, guans, chachalacas (Mexico to South America)
  - Superfamily Phasianoidea, grouse, pheasants, turkeys
    - Family Tetraonidae, grouse (northern hemisphere)
    - " Phasianidae, quails, pheasants, peacocks (cosmopolitan)
    - " Numididae, guinea fowl (Africa)
    - " Meleagrididae, turkeys (North America)
- Suborder Opisthocomi, hoatzins
  - Family Opisthocomidae, hoatzins (tropical South America)

Order Gruiformes, cranes, rails and allies
- Suborder Mesitornithides, roatelos, *Monias*
  - Family Jlesitornithidae, roatelos, *Monias* (Madagascar)
- Suborder Turnices, bustard quails, hemipodes
  - Family Turnicidae, bustard quails (old world)
  - " Pedionomidae, plain wanderers (Australia)
- Suborder Grues, cranes, limpkins, trumpeters, rails
  - Superfamily Gruoidea, cranes, limpkins, trumpeters
    - Family Geranoididae, *Geranoides* (fossil)
    - " Eogruidae, *Eogrus* (fossil)
    - " Gruidae, cranes (cosmopolitan, except South America)
    - " Aramidae, limpkins (tropical and subtropical America)
    - " Psophiidae, trumpeters (tropical South America)
  - Superiamily Ralloidea, rails
    - Family Orthocnemidae, *Orthocnemus, Elaphrocnelnur* (fossil)
    - " Rallidae, rails, coots, gallinules (cosmopolitan)
- Suborder Heliornithes, sun grebes
  - Family Heliornithidae, sun grebes (tropical Africa, southern Asia, tropical America)
- Suborder Rhynocheti, kagus
  - Family Rhynochetidae. kagus (New Caledonia)
- Suborder Eurypygae, sun bitterns
  - Family Eurypygidae, sun bitterns (Central and South America)
- Suborder Cariamae, seriemas and allies
  - Superfamily Phororhacoidea, *Phororhacos* and allies (fossil)
    - Family Phororhacidae, *Phororhacos* and allies (fossil)
    - Psilopteridae, *Psilopterus, Smiliornis* and allies (iossil)
    - " Brontornithidae, *Brontornis, Rostrornis* and allies (fossil)
    - " Cunampaiidae, *Cunampaia* (fossil)
  - Superfamily Cariamoidea, seriemas and allies
    - Family Bathornithidae, *Bathornis* (fossil)
    - " Hermosiornithidae, *Hermosiornis, Procariama* (iossil)
    - " Cariamidae, seriemas (South America)
- Suborder Otides, hustards
  - Family Otididae, bustards (old world)

Order Diatrymiformes, *Diatryma, Omorhamphus* and allies
- Family Diatrymidae, *Diatryma* (fossil)
- " Gastornithidae, *Gastornis, Remiornis* (fossil)

Order Charadriiiormes, shore birds, gulls, auks
- Suborder Charadrii, shore birds
  - Superfamily Jacanoidea, jaçanas
    - Family Jacanidae, jaçanas (tropics)
  - Superiamily Charadrioidea, plovers, sandpipers and allies
    - Family Rhegminornithidae, *Rhegminornis* (fossil)
    - " Kostratulidae, painted snipe (cosmopolitan, except North America and Europe)
    - " Haematopodidae, oyster catchers (cosmopolitan)
    - " Charadriidae, plovers, turnstoncs, surfhirds (cosmopolitan)
    - " Scolopacidae, snipe, woodcock, sandpipers (cosmopolitan)
    - " Recurvirostridae, avocets, stilts (cosmopolitan)
    - " Presbyornithidae, *Presbyornis* (fossil)
    - " Phalaropodidae, phalaropes (cosmopolitan, except Australia)
  - Superiamily Dromadoidea, crab plovers
