BALFOUR *TO* BOTH

BALFOUR, ARTHUR JAMES BALFOUR, 1ST EARL OF (1848–1930), British statesman, was a brilliant aristocratic intellectual who held a key position in the Conservative party (*q.v.*) after 1880 for nearly 50 years, and was prime minister from 1902 to 1905. He was born at Whittingehame, East Lothian, Scot., on July 25, 1845, the eldest son of James Maitland Balfour and of Lady Blanche Gascoyne-Cecil, a sister of the 3rd marquess of Salisbury. It was the great year of European revolution, but Balfour was to have little sympathy with the forces which that fateful year set in motion. If 82 years later militant democracy had still not succeeded in obliterating all the landmarks of the old English social order, the fact was due at least in part to the skilful, supple, yet steely leadership given by Balfour during the long rear guard action of the Conservative party. He was educated at Eton and Trinity college, Cambridge. His family background was highly intellectual and his mother, in particular, was a woman of much wit and intelligence. Balfour's father died in 1856 and Arthur succeeded to a large property and considerable wealth when he came of age. Although toward the end of his life his fortune became much impaired by surprisingly imprudent speculation, he was never personally worried about money matters.

When he first left Cambridge his serious interests were mainly philosophical, although his uncle Lord Salisbury persuaded him in 1874 to enter parliament as Conservative member for Hertford. In 1879 he published his *Defence of Philosophic Doubt* in which he endeavoured to show that scientific knowledge depends just as much as theology upon an act of faith. He regarded this as an argument in favour of theology. In the great Victorian struggle between science and religion, Balfour was on the side of religion. The majority of people, who failed to understand the book, or who read only its title, wrongly assumed that he was a skeptic. He continued to take a keen interest in scientific and philosophical problems throughout his life.

When he was 27, a romantic tragedy occurred which was to cast a shadow over the rest of his life. He was a close friend of Alfred Lyttelton, a nephew of Gladstone, and later a Conservative colonial secretary. In 1875 Balfour became unofficially engaged to Alfred's sister, May. A month later she died. Balfour never again seriously considered marriage.

In 1878 he became private secretary to his uncle, Lord Salisbury, who had recently been appointed foreign secretary, and whom he accompanied to the congress of Berlin. Two years later the general election resulted in a conclusive defeat for the Conservatives. Balfour retained his seat and became for a while a member of the so-called "Fourth party"—a group of four Conservative members of parliament, who, headed by Lord Randolph Churchill. made it their business and their pleasure to harry the official Conservative leadership with the cry of Tory Democracy. Balfour could agree with Lord Randolph in seeking to drive out Sir Stafford Northcote, the Conservative leader in the house of commons, but he had no intention of becoming involved in an attack on Lord Salisbury, who led in the house of lords. Balfour, in fact. kept closely in touch with his uncle about the activities of the rebels to whose ranks he ostensibly belonged. Throughout this period he seemed to most people a languid exquisite, rather than a man of action, an amusing and witty social figure no doubt, but one of the last people for whom political success could have been predicted. He moved in a circle of rich, clever and delightful men and women—'.The Souls"—a brilliant society of which he was a central figure. Few observers of this period were able to discern the toughness which lay behind all this glitter, that streak of "cool ruthlessness" which Winston Churchill described (in *Great Contemporaries*, 1937).

In June 1885 the Liberal government fell. Lord Salisbury became prime minister and appointed his nephew president of the local government board. In the general election later that year Balfour won the seat of East Manchester which he continued to represent until 1906. In the country as a whole, however, the Liberals were victorious, but Gladstone, by announcing a policy of Home Rule for Ireland, split his party and in the summer of 1886 was defeated first in the house of commons, then in the country. On the formation of Lord Salisbury's second administration (July 1886) Balfour held the post of secretary for Scotland. In March 1857 he was made chief secretary for Ireland with a seat in the cabinet. To the outside world the promotion of a dilettante man of fashion to the most difficult administration post appeared incredible. In fact it was very successful. Balfour was an implacable opponent of Home Rule and

he suppressed Irish insurrection with great efficiency, earning the soubriquet in Ireland of "Bloody Balfour." At the same time he strongly opposed the evils of absentee landlordism, and by his Light Railways, Congested Districts, and Land Purchase acts pursued a policy of "killing Home Rule by kindness," which, though failing in its ultimate purpose, did much to improve conditions in Ireland.

Balfour had made a name for himself as a formidable parliamentary debater and on the death of W. H. Smith in 1891, he became first lord of the treasury and leader of the house of commons. He was thus officially second-in-command to Salisbury who was prime minister and foreign secretary—a family combination of uncle and nephew unique in British history. Conservative fortunes were, however, on the wane, and in the general election of July 1892 Gladstone won a narrow majority. For three years Balfour led the opposition with much skill. In July 1895 the Conservatives were back in office and he resumed his old post. But his handling of the leadership of the house of commons did not go uncriticized—flippancy and a perhaps delusory impression of laziness being the main charges against him. As time went on he came to bear more and more of the burden of government, for Salisbury was ageing and his health declining. Balfour was critical privately of Joseph Chamberlain's conduct of the negotiations which ended in 1899 in the South African War, but once war had begun he was as resolute as anyone in its prosecution. He was the only minister in London when Sir Redvers Buller telegraphed asking permission to abandon the relief of Ladysmith. Balfour promptly told him to relieve it or resign. The ineptitude of the higher command made him a keen supporter of military reform, and one of his most important actions as prime minister was to lie in this field. The "khaki election" of 1900 gave the Conservatives a new lease of power. In July 1902 Salisbury resigned and Balfour succeeded him.

His premiership lasted more than three years. It ended in political disaster and an aura of failure has hung over it ever since. But this is not a fair verdict: the period saw many constructive reforms for which Balfour deserves much personal credit. The most important were the Education act (1902), the Irish Land Purchase act (1903), the Licensing act (1904), the creation of the Committee of Imperial Defence (1904). All four measures dealt with matters long bedeviled by complicated legal, technical and emotional considerations, and well illustrated Balfour's clarity of mind, absence of prejudice and readiness to grasp unpleasant nettles. The Education act put secondary education upon a rational basis; the Licensing act solved the problem of combining a reduction in the number of public houses with fair compensation for brewers; the Land Purchase act went far toward alleviating Irish agrarian poverty; the Committee of Imperial Defence was a notable contribution to the formation of a sound strategic policy. None, however, was a vote-winner and the first by appearing to subsidize Anglican teaching out of the rates was a notable vote-loser in Nonconformist quarters. Two other episodes contributed to the decline of the Conservative party. One which Balfour could and should have avoided was the decision to meet the shortage of workers in the Rand mines after the South African War by the mass importation of indentured Chinese coolie labour. This raised not only humanitarian objections, but also the less disinterested protest of organized labour in Britain which perceived a dangerous precedent. A prime minister less lacking than Balfour in the "common touch" would not have made such an error. The second difficulty, which was not Balfour's fault, arose from Chamberlain's espousal of the cause of tariff reform. This in the name of greater imperial unity involved abandoning the free trade tradition in favour of preferential treatment of colonial imports. It split the party and produced a cabinet crisis in 1903 which resulted in numerous resignations including Chamberlain's. Only Balfour's anxiety to see the finish of the negotiation of the Anglo-French entente (1904), a major, but to the general public scarcely noticed, revolution in British foreign policy, kept him in office.

The process of doing so involved him in much elaborate procrastination and the enunciation of many hair splitting formulas to preserve party unity, with resulting loss of prestige. At the end of 1905 he resigned. In the ensuing general election the Liberals won a crushing victory and Balfour lost his own seat. He was soon back in parliament, but his party leadership, although outwardly as confident as ever, came increasingly under challenge. Certainly he was no wiser than other Conservatives over the bill-wrecking policy pursued by the house of lords, and he did nothing to discourage the decision of the upper house to reject Lloyd George's budget in 1909. The two general elections of 1910 left the Liberals still in power though much reduced in strength, and the passage of the Parliament act of 1911 seemed to many Conservatives final condemnation of Balfour's policy. In Nov. 1911, stung by repeated criticisms, he resigned the leadership, his successor being Andrew Bonar Law.

Balfour was now 63 and his political career might well have seemed almost over, but World War I changed this. When H. H. Asquith was obliged to form a coalition in May 1915, Balfour succeeded Winston Churchill as first lord of the admiralty—not a position to which he was suited. When the second great political crisis of the war occurred in Dec. 1916 Balfour moved with impeccable correctitude but none the less surprisingly from support of Asquith who had always defended him to support Lloyd George who had been a severe critic. By accepting the foreign office in the new government he did as much as anyone to consolidate Lloyd George's position. The prime minister's dominant personality and the limitations imposed by war prevented Balfour from making any great mark on foreign policy, although his visit to the United States in April 1917 did much to smooth Anglo-American relations. The Versailles peace negotiations of 1919 were almost wholly conducted by Lloyd George and Balfour had little responsibility for the outcome. One important event during his tenure of the foreign office was his decision in favour of the Zionist aspirations for the creation of a Jewish national state in Palestine and its embodiment in the Balfour declaration of Nov. 1917 (see ZIONISM). In Oct. 1919 he became lord president of the council, and in the same year was elected chancellor of Cambridge university. In March 1922 he was made a knight of the Garter, and in May he accepted an earldom. He supported the Conservative coalitionists at the Carlton club meeting of Oct. 1922 and refused to join Bonar Law's or Stanley Baldwin's first administration. But in Baldwin's second cabinet, in 1925, he became lord president again. He was largely responsible for the negotiations which led to the definition of relations between Great Britain and the dominions which were to be expressed in the Statute of Westminster in 1931. He died at Woking on March 19, 1930.

BIBLIOGRAPHY.—*Chapters* of Autobiography, ed. by B. E. C. Dugdale (1930); Sir [illegible]Z. Malcolm, Lord Balfour (1930); B. E. C. Dugdale, Arthur James Balfour, 2 vol. (1936). (R. N. W. B.)

BALFOUR, FRANCIS MAITLAND (1851–1882), British animal morphologist who discovered fundamental facts concerning the development of the vertebrate nervous and urogenital systems, was born at Edinburgh on Nov. 10, 1851, the younger brother of Arthur James Balfour (1st earl). At Harrow school he was encouraged by George Griffith in natural history pursuits. Balfour entered Trinity college, Cambridge, in 1870 and studied natural sciences. Lectures on embryology by Michael (later Sir Michael) Foster attracted him to animal morphology, and after taking his tripos (honour examinations) in 1873 he occupied a research seat at the Naples zoological station. His work there afforded him material for a series of papers (published as a monograph in 1878) on the elasmobranch fishes, which threw new light on the development of the urogenital and nervous systems in the vertebrates. His treatise on *Comparative Embryology* was published in two volumes, the first (1880) dealing with the invertebrates, the second (1881) with the vertebrates. This work won wide recognition for its scientific validity and for the large amount of original research contained in it. It also formed an admirable digest of previous investigations. Although invited to succeed

George Rolleston at Oxford and Sir Wyville Thomson at Edinburgh. Balfour preferred to remain at Cambridge. and in 1882 a special professorship of animal morphology was instituted for him. Owing to an attack of typhoid fever he never delivered a professorial lecture. Going to the Alps to regain his health, he died, probably on July 19, 1882, attempting the ascent of the Aiguille Blanche, Mont Blanc. at that time unscaled. (J RM.)

BALFOUR, SIR JAMES (OF PITTENDREICH) *(c.* 1525–1583), Scottish judge, was pre-eminent among his political contemporaries through the adroitness and frequency with which he changed sides. A son of Sir Michael Balfour of Montquhanny, he was educated for the priesthood possibly at St. Andrews (1539 or 1540) and probably Wittenberg (1544). He was in St Andrens castle when it surrendered to the French (June 1547) and he subsequently became a galley slave. Released in 1549 by abjuring his Calvinism, and having been made official of Lothian *(c.* 1555) he then supported the party of Mary of Lorraine, rejoining the reformers in 1559 in order to spy on them. He was appointed parson of Flisk in 1560. After Mary Stuart's return to Scotland he was nominated an extraordinary lord of session (1561), an ordinary lord (1563) and chief commissary of Edinburgh (1564). He was made a privy councilor in 1565 and was knighted and made clerk register in 1566. Now a Lutheran, he was a prominent adviser of Mary and his death was planned along with that of David Rizzio (March 1566). An adherent of the earl of Bothwell, Balfour was principal counselor and deviser of Lord Darnley's assassination: at Craigmillar, he drew up and signed the murder band; he assisted the entry of the assassins to Kirk o' Field—a house which he had recently given to his brother; and he purchased gunpowder for the explosion. On the night of the deed he left Edinburgh in order to establish an alibi. Thereafter he was made captain of Edinburgh castle. When the lords rose against Bothwell in June 1567, Balfour not only changed sides and surrendered the castle to the earl of Moray in exchange for a pardon along with money and the priory of Pittenweem, but also betrayed Mary's military plans and surrendered the casket letters (*q.v.*) to the lords. Part of his reward was the lord presidency of the court of session (Dec. 1567).

Balfour fought against Mary at Langside in 1568. He was imprisoned briefly in 1569 for his part in Darnley's death but was released by bribery. However, when Darnley's father, the earl of Lennox, became regent in 1570, Balfour joined the armed supporters of Mary and was forfeited (Aug. 1571). He took an active part in the ensuing civil strife and had a hand in the death of Lennox (Sept. 1571). In 1573 after the earl of Morton became regent. Balfour was restored, paying for his remission with French money intended for the rebels. The same year he negotiated the pacification of Perth. Balfour's forfeiture of 1571 was renewed in 1579 and he fled to France, where he conferred with the Roman Catholic party but also offered his services to Elizabeth of England (to whom he professed a desire to hear Protestant preaching) and to Mary. He was recalled secretly to Scotland (Dec. 1580) to give evidence of Morton's complicity in Darnley's death. Balfour himself was acquitted of his part in this. He died between July 31 and Oct. 26. 1583.

Against Balfour's treachery must be set his judicial competence, his diplomatic skill and his legal nritings. His edition of statutes, *The Actis and Constitutiounis of the Realme of Scotland* (1566), received contemporary praise; and his *Practicks* (published 1754) have been judicially referred to as "of undoubted authority."

See P. G. B. McNeill, "Sir James Balfour of Pittendreich," *Juridical Review,* new series, vol. v (1960). (P. G B. McN.)

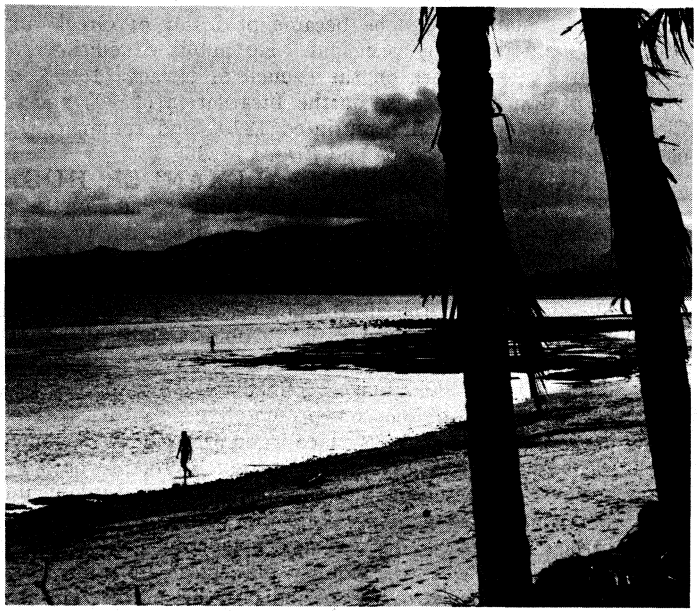
BALFOUR, ROBERT (in Latin ROBERTUS BALFOREUS; 1550?–after 1625), Scottish classical and patristic scholar, described by his compatriot Thomas Dempster as "the Phoenix of his age: a philosopher profoundly skilled in the Greek and Latin languages; and a mathematician worthy of comparison with the ancients," was born in Forfarshire and educated at St. Andrews. A convinced Catholic at the time of the Reformation in Scotland, he went to France, distinguished himself in disputations in the University of Paris and was invited to Bordeaux to teach in the Collège de Guienne, where he became professor of Greek and later (probably in 1586) principal. He published editions of Gelasius of Cyzicus' work on the council of Nicaea (1599), of Theodore of Raithu's treatise on the Incarnation (1599) and of Cleomedes' *Metsol-a* (1605; reprinted 1820) and commentaries on Aristotle's *Organon* (1616) and *Ethica* (1620).

BALFOUR OF BURLEIGH, ALEXANDER HUGH BRUCE, 6TH BARON (1849–1921), Scottish administrator chiefly remembered for his work as a committeeman, in which capacity he rendered considerable services to the state, especially in Scotland, was born at Kennet, Alloa, on Jan. 13, 1849. He was a descendant of Robert Balfour, 5th Baron Balfour of Burleigh, who had been attainted for Jacobite activities in 1716. The title was restored in 1869. Educated at Loretto, Eton, and Oriel college, Oxford, he plunged immediately into public life, becoming in 1876 one of the 16 representative peers of Scotland in the house of lords. But his place in politics lay not so much in the debating chamber as in the committee room where his sound business sense and calm, judicial turn of mind made him invaluable. For more than 40 years (he sat on his first commission when he was 26) he was in constant demand for royal commissions, committees of inquiry and courts of arbitration. Many of the blue books of the period bear his mark. He also played a part in the revival of Scottish Conservatism. becoming, in 1895, secretary for Scotland in Lord Salisbury's cabinet He discharged the duties of his office with great distinction. particularly in the sphere of administration, although he was also responsible for much useful legislation. In Sept. 1903 he left the government on the tariff reform issue at the same time as Joseph Chamberlain, but was deeply divided from him both as a confirmed free trader and in his belief in administration as the basis of government. Thereafter he played a diminishing part in politics, and his moderate views on the budget crisis of 1909 separated him further from the majority of his party. He devoted himself increasingly to the Church of Scotland, in the affairs of which he had always played a leading part. and wrote *An Historical Account of the Rise and Development of Presbyterianism in Scotland* (1911). It mas largely due to his patient advocacy that the union between the Church of Scotland and the United Free Church, which came soon after his death, was achieved. He died in London on July 6. 1921.

See Lady Frances Balfour, ***A Memoir*** of ***Lord Balfouv of Burleigh*** (1925). (M. SH.)

BALI, an island of the Lesser Sunda group. Indonesia, lies east of Java. Its area is 2.147 sq.mi., and its length 95 mi between the shallow Bali strait on the west and the deep Lombok strait on the east. the latter marking the edge of the Sunda platform *(see* MALAY ARCHIPELAGO). The extreme width is 50 mi. Bali is part of the province of Nusa Tengpara and is divided into eight districts. corresponding to the traditional princely states, each administered by a council of which the chairman is usually the reigning local *radja* or his heir apparent.

Geographical Characteristics. — Most of the island is mountainous and consists of volcanic formations. The narrow western section, Djembrana, is a wild, almost uninhabited upland. The central highland, of recent volcanic formation. rises to 7.775 ft. on Mt. Batukau, or Tabanan peak, and has three crater lakes, Bratan, Bujan and Tambelangan. The eastern highland has the majestic volcanic cone of Mt. Agung, or Bali peak (10.108 ft.), and to the northwest of it a grandiose *caldera,* having within its rim the crater lake Batur and the active volcano of that name. North of the mountains lies only a narrow lowland fringe, slightly indented; during the northwest monsoon shipping finds little protection from the strong winds, and the roadstead of Buleleng. the port of Singaradja, is often unsafe. The main lowland lies to the south of the central mountains. There numerous rivers emerge from the ravines they have cut in the soft volcanic rock, and flow across a composite plain of their own making. The rivers are unsuitable for navigation. Practically dry at one season, they become choked and are likely to flood during the period of heavy rainfall. The barren limestone peninsula of Tafelhoek is connected with this alluvial plain by



EWING GALLOWAY

VIEW ALONG ONE OF THE BEACHES OF BALI

a 1 mi.-wide isthmus. Southeast of Bali lies Nusa Penida, another limestone upland, an old convict settlement. Heavy seas run on the south coast during the southeast monsoon. The only safe anchorage is at Benua, the port for Denpasar, between the northward projecting spur of Tafelhoek and its isthmus, though only accessible to small ships because of the narrow and tortuous entrance between coral reefs. Bali's airport is on the isthmus. The southeast monsoon, from May to November, is the dry season, but more pronounced on the north than on the south side of the island. Singaradja has a mean rainfall of 45 in., Denpasar almost twice as much.

Bali belongs to Java in flora and fauna. It has a luxurious vegetation. Among the many palms is the palmyra or lontar palm, the leaves of which formerly were used as writing paper. There are many delicious tree fruits: some of them peculiar to the island. Teak occurs, though not in abundance. Giant waringin trees are held sacred by the Balinese. Tigers are known in the west, but not the rhinoceros or wild buffalo; deer and wild pig exist in considerable numbers and damage crops.

The People.—Since early times people from Java have migrated to Bali, bringing their Hindu-Javanese culture. The island was a part of successive Javanese empires. When Islam gained victory over Hinduism on Java (16th century), Bali became a refuge for many nobles, priests and other intellectuals. Since then the small island has remained the only stronghold of Hinduism in the archipelago and a repository of ancient Javanese civilization. Racially the Balinese resemble the people from east Java, although mixture with the indigenous folk has obviously taken place. In the interior there are a few walled villages, inhabited by descendants of the aboriginal, animisitic people (Bali-Aga). The Dutch made no serious attempts to control Bali until 1882, when the north coast was occupied, followed in 1908 by the conquest of the south; even thereafter the Dutch government interfered as little as possible with local customs. It is the Hindu-Javanese way of life, reminiscent of Java in pre-Islam days, combined with the natural beauty of the island, that has made Bali renowned as a treasure house of old Indonesian culture. As Bali is drawn into closer contact with the outside world, traditions are challenged by modernization and standardization, but beyond the towns the old way of life persists to a surprising degree. The Balinese are a handsome people, although the evidence is less obvious since pressure and example from the outside has induced many women to dress like their Muslim compatriots. The Balinese are frank though courteous in conduct, less servile than the Javanese, gay and witty, fond of music, poetry, dancing and festivals, extraordinarily able in arts and crafts, and passionately fond of games of chance, particularly betting at cockfights. By the 1960s there had been a decline in the number of festivals, partly because social attitudes were changing, partly because economic progress was not keeping up with the rising population.

Population.—Bali's population increased from about 1,101,000 in 1930 to an estimated 1,633,044 in 1956. Since few people live in the mountains, this means that the population density in the lowlands is more than 1,500 per sq.mi. Emigration to less populated islands might be a solution, but the Balinese are so deeply attached to the social-religious life of the community that leaving it is like going into exile. Since World War II, annual emigration may have averaged about 3,000.

Besides the Hindu Balinese, there is a small number of Muslims mostly on the northern and western sides. The towns have a number of Chinese business people. There are almost no Christians among the native population, and missionary activity is restricted. European and American artists have flocked to Bali in considerable numbers; Ubud in the foothills north of Denpasar became the centre of the colony.

Social Conditions.—Most Balinese children go to school at least for a few years and are taught the national Indonesian language. Public health projects, with the assistance of international agencies, work toward control of malaria, yaws and other diseases, but in the early 1960s there was a chronic shortage of doctors.

The Balinese village is laid out in a regular manner. Each family lives in its own compound, surrounded by earthen or stone walls. A narrow gateway leads into the shady courtyard which is usually divided into three sections, containing respectively the rice granaries and cattle sheds, the sleeping quarters and kitchen, and the house temple. The living quarters have walls of clay and roofs of thatch or palm leaves. All villages have temples and an assembly hall, usually located on a square which serves for festivals and markets. The larger ones have also residences (*puri*) of feudal overlords, which are elaborate variations on the basic home architecture. The larger towns, in addition to Singaradja and Denpasar (Badung), are Klungkung, centre of wood carving and gold and silver industries. Gianjar with a lively market and Ubud with a fine art museum.

Religion.—Balinese life centres upon religion: Hinduism, more especially Sivaism, fused with Malay ancestor cult and other animistic and magical beliefs and practices Places of worship are everywhere, from the "mother temples" at Besakih, half way up the slope of the holy mountain Agung, to family shrines in each courtyard. The Balinese firmly believed in reincarnation Cremation is the occasion of a joyous and most sacred duty to liberate the soul. Formerly it was common, at least among the higher classes, for the widows to be also burned with their husbands' corpses, but the Dutch government put an end to this custom. Caste is observed, though far less strictly than was the case in India. Since over nine-tenths of the population belong to the Sudra, or lowest caste, there is little formality among the villagers. The nobility is divided into priests (Brahmanas), the ruling royalty (Satrias) and the military class (Wesias). A man may not marry a woman of higher caste. There is elaborate etiquette concerning rank, including different modes of speech. The Balinese language is distinct from that of east Java, but the upper-class form contains many Javanese and Sanskrit words. There are numerous other social organizations besides caste. Each village (desa) is a self-contained community, bound together by veneration of common ancestors, and usually subdivided in co-operative ward societies (bandjars) whose members are bound to assist each other in temple maintenance, festivals and family rites. Each village or ward has its yearly commemoration for a temple. a magic ceremony to expel evil spirits, an anniversary for all the livestock, for food plants and so on. Each celebration requires either a banquet or a *gamelan* (orchestral) concert or dancing, if not all of these, and always carefully prepared offerings to the gods or spirits. The economic cost is high, but so is the social return in community spirit.

Arts and Crafts.—The Balinese orchestra is similar to that of Java, but has a richer sound and is more vigorous. It consists of

various percussion instruments, a two-string violin and a flute. Every village has its *gamelan* club, giving concerts or, more often, accompanying stage plays, shadow-plays and dances. The plays present parts of the ancient Hindu epics or are Balinized versions of Malay legends and love stories. Dancing is an equally integral part of Balinese life, serving magico-religious purposes or telling stories by pantomime. Modern influence has led to the addition of purely demonstrative dances and musical comedies, all, however, in genuine Balinese style. The artistic temperament is also evident in sculpture, painting, silver work, wood and bone carving, in the ephemeral beauty of votive offerings made of cut palm leaves and flower arrangements, and in the multifarious ritual accessories on the great bamboo towers and the animal-shaped wooden coffins in which corpses are carried to the cremation ground.

The Economy. — Balinese farmers are among the most skilful in Indonesia. Rice is the main crop; in order to flood the fields, the hills and sloping plains have been transformed into terraces wherever possible. Farmers are organized in co-operative water control boards (subak), which build and maintain the ingenious irrigation systems and supervise the equitable distribution of water. The average Balinese farm is 2.7 ac., of which 0.7 ac. is irrigated land, the remainder being used for dry crops such as yams, sweet potatoes, cassava and corn. Most farmers grow coconuts and fruits, and some have small oil palm and coffee plantings. In spite of intensive farming, the island has to import food for its growing population, and many people must eat starches other than rice, the preferred food. Land tenure problems aggravate the land shortage. Bali has a large cattle population, a handsome breed of deerlike animals, and also pigs, geese, ducks and chickens. There are several meat processing and canning plants. The typical Balinese dislikes the sea, and fishing is thus a minor occupation. Agricultural exports consist of beef and pork to Java and Singapore and small amounts of copra, coffee and palm oil. Important items in Bali's balance of trade are the sale of craft articles and the tourist business. The latter could be much larger than it is, were it not for the discouraging hotel facilities and the cumbersome controls by the central government. Bali has an extensive, though poorly maintained, road net.

Sieuwenkamp, *Zwerftochten op Bali* (1910); Beryl de Zoete and Walter Spies, *Dance and Drama in Bali*, new ed. (1952); R. Friederich, *Civilization and Culture of Bali* (1958). (J. O. M. B.)

BALIKESIR, a town of Turkey and capital of the *il* of the same name, is situated on rising ground above a fertile plain which drains to the Sea of Marmara. Pop. (1960) 61,012, having grown from 13,000 at the close of the 19th century. At or near Balikesir the Roman town of Hadrianutherae was founded, as its name commemorates, by the emperor Hadrian, but no trace of the ancient town remains. The older part of the present town, with the bazaar, occupies the upper slopes, while the lower part is well developed and has a modern appearance; it includes the administrative buildings, the railway station, a teachers' training school and residential areas. The town is linked by rail with Izmir and with Ankara via Kiitahya, and is well served by main roads. In comparison with the severe climate of inner Anatolia, Balikesir has a mild winter and early spring. These conditions; allied to the rich soils of the plain, have made the town the centre of an abundant agricultural area, with a varied production of cereals, vegetables, fruit, sesame, opium and even cotton. Its industries include cotton textiles, flour-milling and the making of rugs and leather products.

The *il* of Balikesir, the greater part of which lies in the basin of the Susurluk river (Simav Cayi), extends from the Kapidagi (Cyzicus) peninsula in the Marmara region to Edremit on the Aegean coast. Besides its agricultural wealth, it is rich in minerals: iron ore is worked at Edremit and boracite at Susurluk. Area 5,626 sq.mi. Population (1960) 671,218.

(N. Tu.; S. Er.; E. Tu.)

BALIKPAPAN, a bay and seaport in East Kalimantan (Indonesian Borneo). Pop. (1959 est.) 29,800. It is the site of a refinery (annual capacity 3,000,000 tons) owned and operated by Bataafse Petrolem Maatschappij, N.V. (Royal Dutch/Shell), which processes both imported and local crude oils. There are producing oilfields operated by the same company both at Balikpapan and in the coastal region stretching about 60 mi. toward the northeast. The first refinery on the site started operation in 1899 but the installations erected before World War II mere destroyed in Jan. 1942 in the face of the Japanese invasion. A new plant was erected after World War II.

BALKAN ENTENTE. The Balkan entente of Feb. 9, 1934, the statutes of which were adopted on Nov. 2, 1934, was established by Greece. Turkey. Rumania and Yugoslavia for the purpose of mutual defense against attack by another Balkan state and for other common purposes. Essentially the object was to guarantee the territorial integrity and the political independence of the signatory states against the improbable eventuality of an attack by either Bulgaria or Albania, not against the likelihood of aggression on the part of a major power such as Germany or Italy. Despite the professions of unity by members of the Balkan entente when the danger seemed somewhat afar. one by one the Balkan states became victims of axis aggression during World War II.

During the early war years. Rumania was brought under the domination of Nazi Germany (1940), and British attempts to reconstitute some form oi Balkan unity. with the participation especially of Greece, Turkey and Yugoslavia. failed to bring about material results. Similarly, a project ior Balkan union signed by the Greek and Yugoslav governments in exile on Jan. 15, 1942, which provided for political, economic and military co-operation, could not be implemented, partly because of Soviet opposition. Following World War II projects for Balkan union among the newly established Communist states of Bulgaria, Yugoslavia and Albania failed. largely because of Soviet opposition. although various bilateral treaties of alliance and co-operation were signed (1945–47). The latter ceased to be operative as regards Yugoslavia when the Yugoslav Communist party was expelled from the Cominform (1948).

A new Balkan entente. however, came into being on the basis of treaties signed on Feb. 28, 1953, and Aug. 9, 1954, among Yugoslavia, Turkey and Greece. These agreements provided for political. social and economic collaboration and for mutual defense. under article 51 of the United Nations charter. against possible aggression. The treaty of alliance was concluded for a period of 20 years. After 1954, however, there was considerable question as to the efficacy of the new entente. On the one hand, Greece and Turkey became members of the North Atlantic Treaty organization (1952), while Yugoslavia tended to pursue a more uncommitted policy. On the other hand, the controversy between Turkey and Greece over Cyprus rendered relations between those two countries difficult. Though projects for Balkan unity or entente were common, given the varying political and social systems. the conflict in national aspirations and the varying ethnic strains. a practicable entente remained a matter for future realization. *See* also BALKAN PENINSULA. (H. N. H.)

BALKAN PENINSULA. Since the early 19th century this name has been given to the most easterly of the three southern prolongations of the European continent. Balkan is a Turkish word meaning mountain, though in modern usage it is applied only to a particular mountain belt running east-west through Bulgaria. The countries comprising the peninsula are Albania, Bulgaria, Greece, Turkey in Europe and most of Yugoslavia. The area possesses certain basal resemblances to the Iberian and Italian peninsulas, particularly in its relation to the folded mountain chains of southern Europe and in its structural elements. But these resemblances depend upon iairly detailed points. mainly of interest to the physical geographer, and coexist with well-marked and obvious differences. The term Balkan peninsula would not have acquired its present familiarity to the general public if it had connoted only certain structural features. During the 19th century, when geographers and geologists were acquiring new knowledge of the interior of the region and were coming to regard it as an entity. not merely as a background to Greece and Byzantium, great political changes mere taking place within it. The people, submerged by the Turkish advance, began to organize themselves

into national states and, as the Turkish empire contracted, new names appeared on the map. The growth of the new states was accompanied by much turmoil, which had reflex effects outside the peninsula limits, however these be drawn; but the essential point is that it drew general attention to the region. It became increasingly clear that all the older European states, if in varying degree, were interested in the delimiting of Balkan boundaries, and thus the facts disclosed by detailed geographical study had more than purely technical importance.

No mountain barrier separates the peninsula from the continental mainland. There is thus no sharp break of continuity such as is experienced when the Alps are crossed and a new world is disclosed in Italy. A convenient northern limit (from east to west) is constituted by the line of the Danube, its tributary the Sava and the small feeder of the latter called the Kupa, from which an imaginary line is drawn to the port of Rijeka (formerly Fiume). This limit has a certain justification, if not a complete one. The Danube-Sava line, easily recognized on a map, served for a period as a boundary to the Turkish empire and thus as the frontier of Christendom. For a time also the Sava-Kupa-Rijeka section, which has a certain air of unreality, did at least approximate to the frontier between Austria and the Turk. However, a geographically satisfactory frontier in this northwestern section is difficult to draw. Even the Danube-Sava line, at least to the west of the Danube's Iron Gate, has never been a limit so far as people are concerned; it bears no relation to political frontiers, and the post-1918 state of Yugoslavia extends well beyond it into the Hungarian plain and the Alpine mountain belt. Historically and politically, Rumania. (not considered here geographically as part of the peninsula) north of the Danube is closely associated with the Balkan states. The first point about the Balkan peninsula is that on the north there is no real separation between it and central Europe. This physical continuity is accentuated by a notable increase in the width of the peninsula toward the north. Thus the distance in a straight line from the mouths of the Danube, to Rijeka is about 750 mi., whereas, by comparison, the line by which the Iberian peninsula is attached to the continent measures only about 250 mi. from sea to sea, the Pyrenees being continuous throughout and leaving but a small gap at either end.

The second outstanding feature is the peculiar structure that causes the peninsula to fall into two very unequal and very dissimilar parts. To the south is Greece, a secondary peninsula, with an average width of only about 125 mi. Although both sections are highly mountainous, not only is the Greek section much narrower but also it has a peculiarly dissected coast line that brings sea influences within easy reach of nearly every part. The broad; continental northern section, on the other hand, is largely removed from the surrounding seas because of its width, the nature of its shore lines and, in part, of the direction of its mountains. In climate. in vegetation and in possible crops, it differs profoundly from Greece. No less profound was the effect of the actual remoteness from the sea routes so freely open to the people of the south. It is this division into two parts--one sharing to the full the life of the Mediterranean peoples, the other cut oti from it—rather than the absence of a definite northern limit which made the European world so slow to recognize the existence of a Balkan peninsula. Until the peoples of the continental segment awoke, the whole northern area tended to be regarded only as a broader equivalent of the Alps or Pyrenees: the real peninsula was the Grecian one.

This article contains the following sections and subsections:

I. GEOGRAPHY

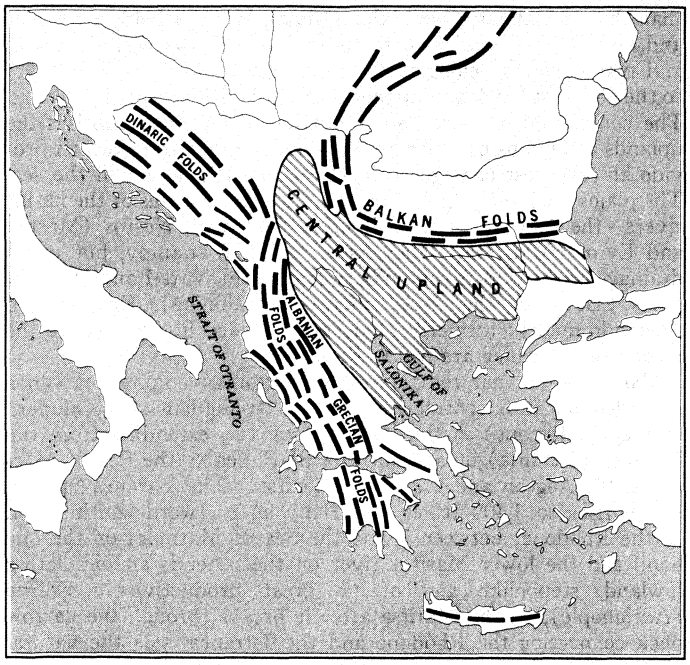
1. Structure **and** Relief.--It is the presence within the peninsula of young fold mountains that makes it essentially similar to the Iberian and Italian peninsulas. Two separate series of these can be recognized, one, of transverse direction, lying to the east, and the other, which is longitudinal, in the west. The Transylvanian Alps (*q.v.*) swing around in a great curve. the Danube breaking through at the Iron Gate at the western apex of the curve, and are continued in the Balkan mountains (Stara Planina), which have a roughly parallel direction. Fingering out eastward into several separate ranges and breaking off steeply on the shores of the Black sea, these rise to a maximum height of nearly 8,000 ft., and the most noted of their passes, the Shipka pass (*q.v.*) has a summit level well above 4,000 ft.

At first sight it might seem as if the crest of these mountains should be taken as the northern limit of the peninsula, rather than as the line of the Danube. But northward they sink gradually to a limestone tableland, presenting a marked contrast to the alluvial Walachian plain (Cimpia Romina) beyond the river, and the presence of this tableland means that the northern slopes as far as the passes, relatively high though these are, are gentle. The Balkans have indeed proved in practice much less of a barrier to human movement than would appear from a map.

Just as the Balkans are a continuation of the Carpathian branch of the Alpine chain. so the main chain itself bends down the western side of the peninsula. From the Julian Alps north of Trieste a series of mountains runs in a southeasterly direction close to the coast and parallel with it. These, to which the general name of Dinaric Alps may be given, rise to 8,274 ft. in the peak Bolotov Kuk of Durmitor; but their significance as a barrier does not depend upon their height. They are characterized by the great development of massive limestones. particularly extensive in the area lying behind the peninsula of Istria (*q.v.*). These limestone areas, called Karst (*q.v.*), display to a very marked extent certain peculiar relief features, dependent on the effect of rain water on their constituent rocks. Thus the surface soil is very thin, bare rock being frequently exposed; running water is usually absent at the surface, most of the rivers sinking, after a short course, into cavities of the rocks; caves and sinks are common, as well as elongated depressions called locally *polje,* or fields: because only in them as a rule is there sufficient depth of soil to permit cultivation.

The combination of these features makes the Karst areas difficult to cross, because continuous river valleys to serve as natural routes are generally absent and, where they occur, as in the case of the Neretva (Narenta) river, the stream tends to flow in steep-sided canyonlike gorges which form a great obstacle to transverse movement. Further, not only do these lands form a barrier between the sea and the interior but also they can as a rule support only a scanty and scattered population, for the local resources are small.

In places the limestone mountains rise steeply from the shore of the Adriatic, but a certain amount of subsidence has occurred, with the result that numerous islands fringe the coast. Because the mountain folds run parallel to the shore, the islands tend to be elongated in the direction of the coastline, and the straits and inlets tend to have the same direction. The islands are usually fertile and there is often a strip of productive land fringing the inlets. Water is also easy to obtain, for the streams which were lost on the heights above emerge as full-grown rivers where the rocky hills descend in cliffs to the sea margin, or springs even bubble up on the sea floor itself. In contrast with the dry and barren lands above! therefore, there is a possibility of cultivation and settlement on the shore. But the coastal areas are too narrow and the difficulties of communicating with the interior too great to



PHYSICAL STRUCTURE OF BALKAN PENINSULA

have allowed for the rise of indigenous civilizations there. The scattered towns on this Dalmatian coast represent islets of ancient but alien (Venetian) culture and, until relatively recent times, scarcely influenced the interior of the peninsula. They arose as offshoots of areas enjoying much greater advantages.

The Dinaric Alps may be said to extend to the neighbourhood of the mouth of the Drin in Albania. There the coast changes in direction, trending almost north-south, and the mountain belt thins out and draws back from the coast, so that the Albanian lowland intervenes between it and the sea. This triangular area. with its inland apex at Elbasan, extends southward to Vlore (formerly Valona); it shows another contrast with the Dalmatian area farther north in that several large and permanent rivers flow from the mountains across the lowland to the sea; there, then, access to the interior becomes at least relatively easy.

Another peculiarity is the proximity to southeastern Italy. Vlore is about Y0 mi. distant from Brindisi. the Strait of Otranto being about 50 mi. wide. The combination of this nearness to an area of old civilization and of natural routes to the hinterland was of great significance in the past, and, with Albania very much under Russian influence, it remains so at mid-20th century.

Vlore, with the adjacent sheltering peninsula ending in Cape Linguetta (Albanian Kep i Gjuhezes), marks the beginning of a new change. The coast reassumes a southeasterly direction. the fold mountains become more conspicuous as the Pindus (*q.v.*) range. which extends through peninsular Greece. Beyond the down-faulted Gulf of Corinth, in the Peloponnesus, the ranges diverge like fingers, leaving narrow triangular plains in between. In the eastern part of the Greek peninsula several ranges diverge eastward or southeastward from the Pindus, and between them lie the well-watered open plains which, like those of the Peloponnesus, nourished early centres of civilization.

The central core of the Balkan peninsula is an old crust block, roughly triangular in shape, with its apex pointing toward Belgrade and its broad base approaching the shore of the Aegean sea. That sea is believed to overlie a former extension of the crust block that has sunk beneath its waters. The numerous Greek islands represent fragments of the surface of this lost land which remained above sea level when the remainder sank. The narrow straits of the Bosporus and Dardanelles are also regarded as flooded parts of the courses of rivers which crossed the old land.

The central core of the peninsula, though it has retained a position above sea level, has been greatly modified as a result of the formation of the fold mountains on its margins. The narrowed northern region, constricted between the Dinaric Alps and the curve of the Balkans, is a broken hilly country traversed by a continuous longitudinal depression through which the Morava river flows on its way to the Danube. South of Nis (Nish), Yugoslavia, however, and extending to the Gulf of Salonika is a region of great structural complexity which seems to have received the full force of the thrust. Faults are innumerable, and closed basins alternate with short and steep highland belts. The basins tend to be elongated in a longitudinal direction: and the major river courses —for example the Vardar—consist of alternating basins and gorges. Many of the basins have formerly been lakes, and since they are floored with fertile soil, they are fitted to become centres of population: but their isolation from each other has had very important human effects.

In contrast with this fractured and much subdivided region, the southeastern part of the triangle. that lying between the Balkans and the Aegean, shows relative simplicity. There the core reaches its greatest height (9,596 ft. in the Rila mountains), and there also is the broadest unbroken mass of elevated ground. The general name of Rhodope (Rodopi) may be given to the whole block, though the separate parts have local names. The Rhodope upland is separated from the Balkan mountains by a considerable lowland, the Rumelian plain. watered by the Maritsa river. This is one of the most considerable tracts of lowland within the peninsula and is continued, beyond the Maritsa, into an undulating tract extending to the shores of the Sea of Marmara. There is also an interrupted belt of plain in Thrace, between the Rhodope and the Aegean, the total result being to make the southeastern part of the peninsula much less continuously hilly than the northwest, where lowlands are virtually absent.

2. The Bearing of Terrain on the Political Map.—In the above account emphasis was on the distinction between the fold mountains on the one hand and the central crust block on the other. The contrast is a geological one, based on the characters of the constituent rocks in the two cases, and is not readily apparent on a relief map, where land is classified on the basis of its height above sea level. The essentials of structure are worth note because the build of the peninsula has influenced the routes and the areas of settlement within and the zones of effective contact with adjacent lands outside. But it is the ordinary atlas map which affords the most familiar representation of the area, and it is necessary to correlate the facts shown there with those obtained from the survey of the broad structural features) and particularly to connect the political and administrative units with the general lie of the land.

Yugoslavia.—An orographical map shows an almost continuous area of high ground on the west, continued into the Grecian peninsula. which is mostly mountainous. In the northwest the way in which the high ground within the peninsula passes into the Alps proper means that the Danubian plains have no natural. easy exit to the Adriatic. But the mountain belt thins out in the Karst of the Slovenian Juliske (Julian) Alps, and beyond this narrowed section lies a tract of undulating country. mostly outside the peninsula as usually defined, for it extends beyond the Sava-Kupa line, but still within Yugoslavia, whose frontier with Hungary is the Drave river. This area is a continuation of the plains of the Danube and, where the Drave and Sava converge toward one another, in Slavonia, it includes a considerable area of true plain. Although the mountain belt that separates it from the Adriatic is neither wide nor lofty—it does not rise much above 5.000 ft.—yet because of its karstic nature it forms a very effective barrier. The chief elements of the belt are the Velika Kapela and Velebit mountains, both remarkably waterless and barren. This whole area of mountain and plain was once the kingdom of Croatia-Slavonia; from a physical standpoint it is a transition region between central Europe and the Balkan peninsula. Until the creation of Yugoslavia it had little direct relation to the Adriatic. though economic and political causes led to Hungary's making great efforts to develop Rijeka (Fiume) as a grain port during the later 19th century. In the past, Croatia-Slavonia was politically, economically and culturally attached to central Europe, but ethnically it belongs to the Balkan peninsula.

Northwest of Croatia-Slavonia, in the region where the Dinaric

Alps in the larger sense pass into the Julian Alps. lies the former Austrian crownland of Carniola, a Karst area, again lying outside the peninsula proper but having a considerable Balkan element in its population.

To the south of the Velebit mountains a narrow strip of coastline, with the mountain crest behind, forms Dalmatia. But the historic Dalmatia (*q.v.*) is really an interrupted series of maritime towns, Zadar, Sibenik, Trogir. Split and Dubrovnik (respectively the former Zara. Sebenico. Trau, Spalato and Ragusa) being among the most important. Until the creation of Yugoslavia these towns had little connection with the interior; their Roman antiquities, the Venetian lion which still decorates some of their old buildings, are visible indications that their position in relation to the peninsula had little effect on the life of their inhabitants.

The actual mountain belt, from the borders of Croatia-Slavonia to the confines of Greece, extends through the territories formerly known as Bosnia. Hercegovina and Montenegro (qq v.) to Albania. In Bosnia the limestone rocks of the coastal area give place to others, including sandstones, which at once allow for the development of deeper soils and of a more normal drainage system. Numerous rivers drain into the Sava. and Bosnia can be reached from that river. and thus from the Danubian plains, with relative ease. Other route lines connect it with the interior. Hercegovina is a karstic area with only one important river, the Neretva. which flows to the Adriatic. Montenegro is essentially a mountain aerie, a refuge that withstood invasion in the past as much perhaps because of its worthlessness as of the difficulty of conquest.

Access to the Adriatic coast from the Sava and Danube plains was much improved by the Yugoslav government between World Wars I and II. A new standard-gauge railway (the Lika line) was built to connect Zagreb and Split, and the narrow-gauge line from Brod via Sarajevo to Dubrovnik was connected to Belgrade.

Eastern Yugoslavia comprises the western part of the crust block. with its marked contrast between the northern section, draining into the Danube mainly by the Morava, and its complex southern section. draining into the Gulf of Salonika by the Vardar. West of the Morava the country is undulating and lowlands fringe the southern bank of the Sava. The Western Morava. a tributary entering the main stream from the west. also helps to define a block of land which affords possibilities of settlement. This was the nucleus of 19th-century Serbia, with Belgrade, at the junction of the Sava and Danube. as its capital. East of the Morava the surface is more elevated, the rocks of the crust block abutting upon those of the Balkan mountains. The complex southern region is Macedonia. with its jumble of people. its long history of turmoil and disorder. The western side of the crust block is much broken, and the relatively inhospitable mountain areas are interrupted by plains. once lake basins. which in turn are linked one to another by river gorges. Such are the Metohija basin and the plains of Kosovo, Tetovo. Skopje and Bitola (Monastir).

Albania.—Albania. with its coastal lowland, formerly malarial. and its mountainous hinterland, is a region of much interest. As already seen, it affords the possibilities of routes to the interior by the Drin. Shkumbin and Vijose valleys and might be supposed a prize worth having. But the inhabitants, who are mostly mountaineers with little interest in the sea or in sea traffic, have preserved a striking measure of individuality since very early times. The natural routeways that traverse their lands have never been of great value to them and their territory is not particularly productive. The strongly manifested individuality of the Albanians long prevented the growth of an indigenous political system and encouraged alien control. Twenty years of experiment in self-government. after liberation from the Turkish yoke. proved insufficient to develop a stable organization. and in 1939 the country came under foreign rule once more: this time Italian. The defeat of Italy in World War II allowed a Soviet-dominated Communist Albanian government to take over.

Greece.—Peninsular Greece comprises three relief elements: (1) the Pindus ranges in the centre and in the west, continuing southward beyond the Gulf of Corinth into the four-fingered Peloponnesus; (2) the western coastal belt, which is more broken than that of Dalmatia. while the off-lyingIonian islands are larger and exhibit less parallelism to the coast; (3) the eastern ranges and plains which belong in the north (Mt. Olympus, 9.570 ft) to the old crust block and farther south are offshoots of the Pindus. The continental or truly Balkan portion of Greece comprises the uplands and plains of southern Macedonia and Thrace, which provide an east-west passageway between the Rhodope and the sea. The plains are largely spread around the lower courses of the major rivers—the Axios (Vardar), Strimon (Struma). Nestos (Mesta) and Evros (Maritsa). They were formerly swampy. but many drainage works were executed between World Wars I and II The ports that serve them—Salonika (Thessalonike), Kavalla and Alexandroupolis (formerly Dedeagatch)—are in no case at the river mouths which are badly silted.

Turkey—All that remains of the Ottoman empire that once extended far into central Europe is a triangular area (modern Turkey in Europe) in the rear of Istanbul, extending from the Istranca (Istranja) upland and the Black sea to the Sea of Marmara, the Aegean and the lower Maritsa. The Istranca upland, nhich rises to 3,400 ft , is essentially an eastward continuation of the Rhodope; between it and the Sea of Marmara on the one hand and the lower Maritsa river on the other is an undulating lowland, steppelike and of no great productivity. Edirne (Adrianople), on the Maritsa after it breaks through the narrow neck connecting the Rhodope and the Istranca, nas the natural centre of that eastern part of Thrace, but its relative importance has been lessened by the proximity of the Greek and Bulgarian frontiers.

Bulgaria.—Bulgaria has as its northern frontier the Danube, except where the river takes its great bend to the north; there the frontier leaves it and runs slightly south of east to the Black sea, much of the steppelike Dobruja (*q.v.*) being included in Rumania Southward Bulgaria extends to the Rhodope crest, and is thus nearly bisected hy the Balkan mountains. Sofia, the capital, lies in a small basin between the Balkan mountains and a northwesterly prolongation of the Rhodope, the basin being drained by the Iskur river. which breaks through the Balkans to enter the Danube South of the range, and separated from it by a longitudinal depression, lies a parallel upland, the Sredna Gora ("middle forest"). The intervening depression (known, from its principal product, as the "Valley of Roses") is watered by the Tundzha (Tunja) river which seems to be making for the Black sea near the port of Burgas, but turns instead sharply southward, breaks through the western end of the Istranca and joins the Maritsa at Edirne

The upper Maritsa, on which stands Plovdiv (Philippopolis), flows through the wider depression which has been called the Rumelian plain These two fertile lonlands, with their bounding uplands form Eastern Rumelia, which was not united politically to north Bulgaria until 1885 Geographically the important point is that this region, with southern Macedonia. formed the granary of Turkey in Europe, as it did of the earlier Eastern empire. The Maritsa depression shows certain analogies to the valley of Andalusia in Spain both in its position between fold mountains and a crust block and in its value to an invader.

3. Routes and Lines of Communication.— Greece within its peninsula, Serbia in the Morava region, Bulgaria astride the Balkan mountains all became independent states while Turkey still held Thrace, Macedonia Albania and, at least nominally, a large part of the northwest. That the progressive contraction of Turkish territory led to such bitter and prolonged conflict was largely the result of the nature of the routes nithin the continental section of the peninsula and particularly of the difficult access of both Bulgaria and Scrhia to open water Thus the natural route lines demand careful consideration But the routeways nhich were important in the historic or even the recent past are not necessarily those of most value, for the political subdivision of the peninsula at mid-20th century and in particular the interposition of "iron curtain" frontiers across the routeways materially lessen their significance

On the northern, southern and eastern margins of the peninsula respectively are situated the three nodal points of Belgrade,

Salonika and Istanbul, all owing their importance to the land and water routes which converge upon them and all linked together by rail. That all are marginal and that, with the partial exception of Sofia, no focal point of similar importance exists within are highly significant facts.

Belgrade is situated at the junction of four great routes: from the north and the east, the Danube valley; from the south, the Vardar-Morava corridor; from the west, the Sava valley. The Danube is continuously navigable, despite the partial interruption of the Iron Gate, downstream to the Black sea as well as upstream. The Sava, though not a first-class waterway, can be used by steamers as far as the Kupa confluence at Sisak. Apart from the waterways, no less than seven railway routes converge on the city; the most important are the Orient Express routes from western and central Europe to the Aegean and the Bosporus — from France and Italy via Zagreb and the Sava valley, from Belgium and Germany via Budapest and the Danube plain; to Athens via the Morava and Vardar valleys, to Istanbul via the Morava valley and Sofia and to Bucharest via Vrsac. The last-named route lost its international significance after Rumania became a Soviet satellite. An important narrow-gauge railway leads southward across the mountains to the Adriatic coast at Dubrovnik.

Salonika is the only good port on the northern coast of the Aegean and is the best exit to open water for much of the interior. Three major land routes and some minor ones converge upon it. The first group consists of the meridional furrow indicated by the direction of the Morava and Vardar rivers, the route from Istanbul by the Thracian lowland and the route to Athens.

The Morava-Vardar furrow is followed by the railway from Belgrade to Salonika by way of Nis and Skopje. Although the headstreams of the two rivers, despite their contrary direction, actually interjoin in wet weather, it must not be assumed that a continuous valley line extends from the Danube to the Gulf of Salonika. The Morava, upstream from Nis, the Vardar, downstream from Skopje, both pass through gorges which offered considerable resistance to through communication in prerailway days. The Morava gorge at Vranje was actually the Serbian frontier at one stage in the development of that state and at the time the railway was built (1887) — a clear indication of the break in the furrow there. The Belgrade-Skopje section of this route was effectively duplicated in 1931 by construction of a railway which leaves the Morava valley at Lapovo and proceeds via Kragujevac, the Ibar valley and the Kosovo Polje.

The second major route entering Salonika runs through the Thracian plains and hills from Istanbul. It dates from 1895 and was essentially strategic in character — it was built at least 12 mi. from the coast to be beyond the then range of naval bombardment, and the two major ports which it served, Salonika and Dedeagatch, were both provided with bypass lines. It has had relatively little international significance, though it remains a possible route from central Europe to Istanbul, avoiding the crossing of the "iron curtain" frontier of Bulgaria. The third route is the southward continuation of the Orient Express route, from Salonika to Athens. This, sometimes called the Greek Longitudinal railway. was completed after the Balkan Wars, in 1916, but its functioning as an international route was delayed by World War I and its aftermath until 1920. It is a difficult route, alternately crossing plains and mountain ranges; its ruling gradient is 1:50.

The westward communications of Salonika are less important. A railway runs to the Florina basin and then turns north, crossing the Yugoslav frontier to Bitola and eventually linking with the Vardar valley line at Titov Veles. The road to the Adriatic, though of no significance at all in modern times, was an important Roman route — the Via Egnatia — leading from Bitola, Lake Ohrid (Ochrida) and the Shkumbin valley to Durres (Italian Durazzo, Roman Dyrrachium).

The fact that Salonika is politically Greek and not attached either to Yugoslavia, despite the presence of the Morava-Vardar furrow, or to Bulgaria, despite the relative nearness of Sofia, is explicable rather by the strength of a cultural and historical tradition than by purely physical facts. It is an Aegean port of much importance in the modern world, and to the Greeks the idea that control of Aegean trade is their national right is one that admits of no argument. Part of its basis is of course the geographical fact that their somewhat barren land could not support them unless supplemented by the sea trade for which they have always shown natural aptitude.

Istanbul, with a superb natural position where the waterway from the Black to the Aegean sea crosses the land route from Asia Minor to the Balkan peninsula, is connected to Belgrade by a diagonal furrow, certainly as important as the north-to-south one from Belgrade to Salonika. The route follows the Morava valley to Nis, ascends the Nisava tributary and crosses the Dragoman pass (2,550 ft.) to the basin of Sofia, then by another pass it reaches the Maritsa valley and follows this past Plovdiv and Edirne until the valley of the Ergene enables it to turn east toward Istanbul.

The main international railway routes through the Balkan peninsula were conceived in central Europe about 1869, when Turkey still held a large part of the peninsula. The wars of 1876–78, which materially altered the political map, upset the plans, but the main lines, Vienna-Belgrade-Sofia-Constantinople and Nis-Salonika, which in any case were to be international and not local avenues of transport, were opened in 1888. Subsequently, the political boundaries changed several times, more notably after the Balkan Wars of 1912–13 and after World War I, and the creation of a railway network thus responded to different national and local stimuli at different times. For its size and economic development, Bulgaria has a fair system, with important lines linking Sofia with the Danube and with the Black sea ports of Varna and Burgas, an important though difficult route across the Balkan mountains and many branch lines. After World War II the construction of a bridge across the Danube at Ruse made possible a through route to Moscow. Yugoslavia, assembled like a jigsaw from Serbia, parts of Austria-Hungary and what remained of Turkey, had to create a national railway system from a series of fragments — and largely succeeded in doing so between World Wars I and II. Its main needs were for better communication between the capital and the Adriatic ports of Split and Dubrovnik, for more railways in the south and for bridges across the Danube and Tisa (Tisza) rivers.

4. Climate. — Next to the relief and to the presence of the great highways, the factor which has most deeply influenced human life within the peninsula is the climate, acting mainly through its effect on natural vegetation and cultivated crops. The outstanding peculiarity is that the perfectly typical Mediterranean climate has a very limited extension, as compared with the central European type, which prevails through the greater part of the broad northern section of the peninsula and even extends into the centre of the northern part of the Greek section. While, therefore, five major climatic regions can be recognized, by far the largest of these is that which is in reality only an extension of the greater region lying to the north. In other words, no notable difference in climate separates the peninsula proper from the adjacent Danubian lands.

The Mediterranean climate is of peculiar interest because it is so closely linked to a particular type of culture showing a very delicate adaptation to local conditions. Three essential features differentiate the Mediterranean climate: the winters are warm in relation to latitude and the greater part of the rain falls during that period; the summers are hot and dry and one or more months may be practically rainless; throughout the year the skies are clear and there is abundant sunshine, for the winter rains come in heavy showers of short duration. Before these characteristic features can develop, there must be at once shelter from land influences and full exposure to sea ones. Further, there must be no great elevation above sea level, because with increasing height the winter temperatures become lower, the skies are cloudier and rains occur in summer as well as in winter. These conditions mean that the typical climate is best developed on coastal lowlands, particularly on islands and in narrow peninsulas penetrated by long sea inlets. Two regions within the peninsula show typical Mediterranean climate, but are regarded as distinct from one another because latitude and position bring about differences in the distribution of the rainfall throughout the year without affecting its

marked periodicity.

One of these is made up by the Greek islands, the Peloponnesus, the margins of the northern part of the Greek peninsula and a narrow strip on the coast of Albania. Even within the region so defined, however, elevation above sea level, as in the mountains, or an upland girdle, as in the plain of Thessaly, may produce local modifications. Athens and Corfu (Kerkyra) may be taken as representative places within this region. Athens. on the eastern side of a peninsula, largely sheltered from rain-bearing winds, has a much smaller total rainfall than the island of Corfu, which faces the wet winds of winter; but despite the difference in the amount of rain in the two places, its distribution is closely similar. At both places winter temperatures, as far as monthly averages are concerned. do not fall below 48°–50° F. Summer temperatures range from 78° to 81" F. (July averages), which permits the ripening of subtropical fruits. In Athens, July and August are practically rainless and only about 23% of the total fall occurs in the period April to September, so that more than three-quarters of the total falls in the cooler half of the year. More than one-third falls in the two rainy months of November and December. Corfu has a rainfall four times as great as that of Athens. and although only July can be described as practically rainless, only about 20% of the total rainfall occurs in the period April to September.

A narrow strip along the coast of Dalmatia is regarded as forming a second major region. Dubrovnik may be taken as typical, bearing in mind, however, that it is the most southerly of the important towns of Dalmatia. The winter temperatures there are closely similar to those experienced in the Greek region, much of Dalmatia being remarkable for its mild winter climate. The summers are not quite so hot as in Athens or Corfu, but the real distinguishing feature is the Iess-marked periodicity of the rainfall. There is now no rainless month. although July continues to be the driest period of the year. More than 30% of the total rainfall occurs during the period April to September, so that summer drought is far less marked. Oranges can he gronn without irrigation, and their coexistence with the olive is a distinguishing feature. Not only. however. is the strip with this typical Mediterranean climate very narrow, but changes occur with considerable rapidity toward the north. Except where, as in Split, the form of the coastline gives shelter, the more northerly places are often exposed to the blast of the bora, or cold northerly wind of winter, which is at once a danger to shipping and excludes the more delicate Mediterranean fruit trees When Trieste is reached on this eastern Adriatic coast, the somewhat cold winters (January average below 40° F) and the fact that the period April to September shows rather more than half the total amount of rain, with a rainfall maximum in October and a secondary one in June, mark the transition from the Mediterranean climate to the central European one. The northerly Dalmatian towns and the coast of Croatia show stages of the transition Usually it is easier to exaggerate than to underestimate the significance of this second, or Dalmatian, climatic region.

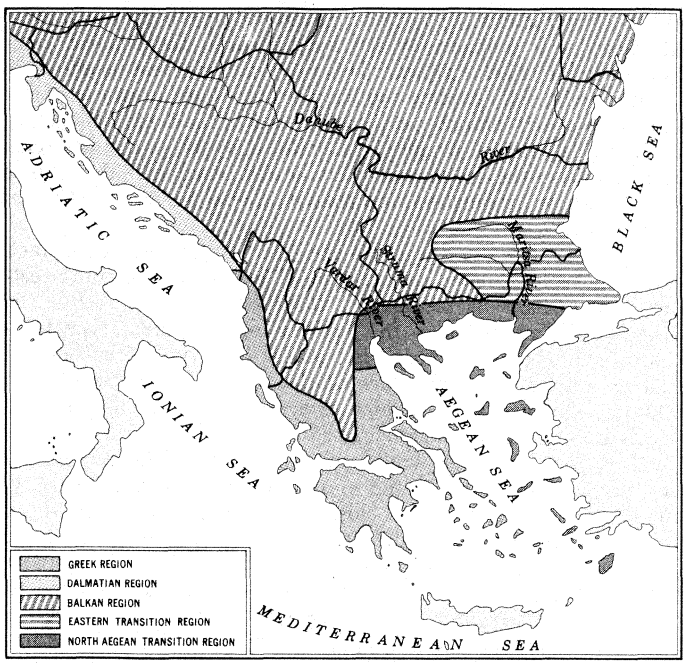
Southern and eastern Macedonia and western Thrace fall into a third region, characterized by notable modifications of the Mediterranean climate. Salonika may be selected as a representative locality. The winters are cold for the latitude (average January temperature 41° F.) because of the bitterly cold northerly winds which blow down the Vardar valley. and this feature is accentuated as the coast is left. But the summers are hot and the range of temperature between summer and winter is greater than at any of the places already discussed. There is no rainless month, and though July is still the driest period and November and December are the wettest months, there is a much more even distribution of rain throughout the year. the six colder months having very little more rain than the six warmer ones. The colder winters, especially where there is exposure to wind, again limit the distribution of the more delicate Mediterranean fruit trees, and growth even of hardy plants is checked during winter. On the other hand the high summer temperatures and the fairly heavy summer rainfall, with the possibility of irrigation from the mountain snows, make it possible to grow crops demanding both heat and moisture but being indifferent to winter cold because of their annual nature. Among such are cotton, rice, tobacco, maize (corn) and opium poppy.

Passing northward from Salonika into the interior of the peninsula, the change in this fourth region, from this modified Mediterranean to the true central European climate is rapid and is accentuated by the relief. The general features of that climate are the cold winters, the temperatures then showing little relation to latitude, the warm summers and a rainfall well distributed throughout the year, but with a tendency toward an early summer maximum. Skopje, in a latitude somewhat lower than that of Dubrovnik, though in a more elevated position, has mean January temperatures well below the freezing point and fully 18° lower than those of Dubrovnik. This means that there is a definite winter stoppage of agricultural activities, December, January and February all being too cold even for the growth of grass. On the other hand, despite its elevation, the summer temperatures at Skopje are not more than a few degrees lower than those of Dubrovnik. The rainfall is fairly well distributed throughout the year but May, June and October are the rainiest months, the maximum fall coming in May when temperatures are already fairly high (more than 62° F.). Belgrade, considerably farther north but less elevated than Skopje, has a very similar temperature range, but November is already a winter month. June instead of May is the rainiest month and the summer rainy period lasts for the three months of May, June and July, again with a second rainfall maximum in October. Broadly speaking, this climate, with summer heat and summer moisture coinciding, is one well suited to maize among cereals. With local variations caused by height above sea level and by degree of exposure, this type of climate prevails throughout the greater part of the interior of the peninsula, which thus falls into a fourth or central major climatic region. The total rainfall shows a tendency to increase toward the northwest, in Bosnia and northwestern Serbia; it diminishes toward the east.

As a fifth major region, eastern Thrace and the plains of Bulgaria may be included Over much of this region, especially in Thrace, the total rainfall is very small, giving the landscape a steppelike appearance, and the winters are very cold as a result of exposure to winds from the Russian plain. But the Maritsa valley allows Mediterranean influences to penetrate into southern Bulgaria, where also the Balkans give a certain amount of shelter from the cold winds of winter Parts of the valley plains of Bulgaria have in consequence much milder winters than northern Macedonia or Serbia, and as there is a tendency for the winters to be wetter than the summers, the climate is sometimes described as modified Mediterranean. The dry, sunny summers favour wheat rather than maize and the vine is grown in sheltered places. Cotton and rice are grown with irrigation.

To this general division of the whole area into five climatic regions, of which the central one covers by far the greatest area, it may be added that the fact that so much of the surface is elevated introduces numerous modifications in detail. Because of the cold winters of the central area, much of the ninter precipitation falls as snow. No mountain within the peninsula rises in the strict sense above the snow line, but the higher peaks of the Rhodope are only snow-free for about one month in the year, and even the Balkan mountains show some snow until July. This long persistence of parts of the winter snow cover has much influence on the flow of streams and thus on the possibility of the use of irrigation water. (M. I. N.; S. H BR.)

5. Vegetation. — The flora of the Balkan peninsula is one of the richest in Europe and consists of about 6,600 species of vascular plants. The largest families, on the basis of numbers of species, are the Compositae, Leguminosae, Caryophyllaceae, Labiatae, Gramineae and Cruciferae. The genera uith most species are *Centaurea* (knapweeds), *Silene* (campions), *Dianthus* (pinks), *Trifolium* (clovers). *Campanula* (bellflowers). *Carex* (srdges), *Verbascum* (mulleins) and *Thymus* (thymes). Floristically, Greece is the richest area. Apart from the actual number of genera and species the flora of the Balkan peninsula is botanically noteworthy for the number of its endemics (plants found nowhere else



FROM W. G. KENDREW, "CLIMATES OF THE CONTINEHTS," BY PERMISSION OF THE CLARENDON PRESS

FIVE MAJOR CLIMATIC REGIONS OF THE BALKAN PENINSULA

in the world). The central portion of the Balkan peninsula is geologically old and has been a land surface at least since the advent of the flowering plants. Moreover, the effects of the Ice Age were much less drastic than in northern and central Europe and many plants found a refuge in the peninsula. There are, therefore, a considerable number of old relict types in the flora. Examples are *Ramonda* and Haberlea of the Gesneriaceae, related to western Chinese genera, the Serbian spruce (Picea *omorika*), the Balkan yam (Dioscorea balcanica) and Forsythia *europaea,* the only native European species of this well-known garden genus. In contrast, there are many species that are most probably of relatively recent origin and may have partly originated by hybridization following the clearance of woody communities by man. Thus many of the pinks, campions, mulleins and thymes are closely related one to another and appear still to be evolving new microspecies.

Given the old Tertiary basis of the flora, the chief migration routes have been from the north and the east. From the north there was an extension of central European species, especially with the oncoming of the glacial period. The Aegean sea is of recent geological origin and plants from Asia Minor undoubtedly contributed to the floristic wealth of the Greek mainland and islands.

The vegetation of the Balkan peninsula clearly demonstrates the controlling influence of climate on plant life. In the northern and central parts the climax communities are deciduous forests up to about 1,500 m. (4,921 ft.), then coniferous forests to about 1,800 m. (5,905 ft.) and above these are high mountain scrub, herb and mat associations. In the southern and western coastal districts evergreen Mediterranean moods and brushwoods naturally dominate, with oak and conifer forests at the higher altitudes. Throughout the peninsula there has been great destruction of the woody vegetation by man. (W B. T.)

6. Animal Life.—The animals of the Balkan peninsula are a strange entanglement of three major elements. Mediterranean forms dominate along the southern and western borders of Greece, Albania and Yugoslavia; eastern steppe species in the lonlands of the east; and central European forms in the interior. Some of them are widely distributed in Europe, mainly in the mountains, whose peaks still have an Alpine element.

Among Mediterranean mammals are wild goat (bezoar), jackal, porcupine and several kinds of bat. Eastern elements include the ground squirrel (*Citellus*), some forms of hamster, the mole rat (*Spalax*), etc. The mole, lynx and wildcat. marten, wolf and fox, bear, hare, boar. red and roe deer are some of the central European mammals, while the chamois is an example of the Alpine element. The same types of distribution are found among the breeding birds. In the south and in Dalmatia, Mediterranean forms predominate, with the great cuckoo, the melodious warbler (*Hippolais*), etc.; and these also penetrate some of the great river valleys (*e.g.,* the Vardar) far to the north. Central European forms include chaffinch, creeper and some thrushes; among eastern types are the little bustard, the lesser gray shrike and the red-footed falcon; among Alpines are the mountain lark (*Eremophila alpestris*) and the Alpine ptarmigan. The big birds of prey include the golden imperial eagles and several kinds of vulture. The red-legged partridge (*Alectoris*) and the stork are common.

Among reptiles various forms of lizard are known, especially in seaside regions, and a certain number of species of gecko, turtle and snake among which are three kinds of poisonous viper. There are amphibians belonging to the Palearctic fauna, *e.g.,* the true toads, while central European fauna include true frogs, spade-foot toads and salamanders. There are also some Mediterranean forms. The fishes of lakes and rivers include carp, barbel, small salmon, wels or sheatfish (*Silurus*), etc.

The same zoogeographical entanglement is found in the invertebrates. Among harmful plant insects are tussock moths and Moroccan, Italian and migratory locusts After World War I the San José scale and the Colorado beetle were brought to Europe from America. The Colorado beetle, which did not reach the Balkans until after World War II, spread quickly.

In 10%-lying land near water, domestic buffaloes are not uncommon. The important meat animal is the pig and the chief milk and meat animals are cattle and sheep. Hens and turkeys are common among domestic birds.

Very special and peculiar faunas, not discussed here, live in the delta of the Danube, in the island of the Aegean sea and in Crete. See also the physical geography and economy sections of ALBANIA; BULGARIA; GREECE; YUGOSLAVIA. (AN. LU.)

II. ETHNOLOGY

The ethnology of the Balkan peninsula is more involved than that of either the Italian or the Iberian; first, because this peninsula has a more fragmented geography; second, because it is open to entry from more directions. On the northwest the plains of the middle Danube afford a way to central Europe; on the northeast there is a wide corridor through Moldavia from the steppes of the Ukraine; on the east, an easy passage is possible from Asia Minor across the Bosporus and through Thrace. while the coasts of Greece are accessible to all the eastern Mediterranean basin, and those of Dalmatia. though cut off by mountains from the interior. are easily approached by nater from across the Adriatic. People entered the Balkans from all these directions and left vestige. of racial types and customs derived not only from many parts of southern and central Europe but also from aide areas of central Asia and the near east

The main ethnic divisions of the Balkans are based on linguistic and religious differences rather than on true racial distinctions. Yet it is remarkable that in many cases the cultural group has clearly recognizable physical features which it may have acquired through long isolation and inbreeding bloreover, despite repeated immigrations into the peninsula from the heart of the continent, certain racial types have persisted there and absorbed the new blood from outside. Thus there is little doubt that the Slav-speaking folk nho poured into the Balkans from the 3rd century AD., and particularly after the 6th century. were predominantly of Nordic race; yet the present day Southern Slavs belong principally to the Dinaric race—tall, dark. and with high and broad head and prominent nose—a type that is probably very ancient there and that is also found farther west in a highland zone extending through northern Italy and southern Germany as far as Austria and Saitzerland.

In this section each ethnic group which is distinguished on cultural or political grounds will be considered in turn, and an account given of its historical origins, of the reasons for its separation from its neighbours in the Balkans and of its physical features.

1. The Southern Slavs.—These people, separated by the intru-

sive Magyars from their linguistic kinsfolk to the north, are united by ties of language and political allegiance. They are, however, subdivided by differences of religion, the Croats and Slovenes being Roman Catholics, the Serbs proper and Montenegrins mostly Greek Orthodox. Moreover, among the Dalmatians, Bosnians and Hercegovinians, who are normally classed with the Serbs, there are in addition to the Greek Orthodox Christians considerable Roman Catholic minorities, and in the last two cases also a fair proportion of Muslims.

The Slovenes of Carniola are physically very similar to their Austrian neighbours. They are of low height, with small round heads of Alpine type, and include a good number of fair individuals. Among the Croats to the south, however, there are on the average more tall individuals and more broad heads, dark colouring and prominent noses; and farther south still, among the Serbs, these Dinaric features become even more pronounced. Among the Serbs there is a preponderance of high broad heads, giving a mean cephalic index of about 85; the face tends to be long, the colouring of eyes and hair to be dark and the nose to be high-rooted and straight or convex, with a downward-turning tip.

The Bosnians and Hercegovinians are, like the Serbs, on the average tall and broad-headed; but there is an interesting physical difference between the Roman Catholic and Muslim communities, doubtless the result of protracted inbreeding within each group. The former includes a larger proportion of tall, fair and very broad-headed individuals.

Along the Dalmatian coast, the extreme broad-headedness of the population of the mountainous interior is not found, and among the inhabitants are more long-headed individuals of the Mediterranean race. Proceeding southeastward along the coast, from Istria to the borders of Albania, the population becomes on the average progressively taller and more dark in complexion.

In physique and culture, the Montenegrins, who live in rugged and isolated limestone mountains, are the most distinctive of the Southern Slavs. Although they speak a Slav Serbian language, they resemble the Albanians in their loyalty to their exogamous clans. They are probably the tallest people in Europe, the men averaging 178 cm. (about 5 ft. 10 in.) in height, and at the same time they are thickset and very heavily built. Their heads tend to be broad and high-backed and their noses large and beaked. In these respects they resemble the Dinaric type which seems to be very old-established in the western Balkans. But they differ from the standard Dinaric type in having broad rather than high faces, a high proportion of light eyes and, in particular, a preponderance of red hair, red beards and freckling.

2. Albanians. — This group numbers more than 2,000,000, of whom more. than half lives outside the boundaries of Albania: for the most part in Yugoslavia. They are distinguished from the Slavs by language in the first place, the Albanian tongue being a mixture of elements from Illyrian, Thracian, Latin, Slavonic and Turkic. They are also separated from their neighbours by religion and general culture: and there is no doubt that they represent the survivors of the native inhabitants of the Balkans in classical times, the Thracians, Macedonians and Illyrians, who were driven back into isolation by the invading Slavs. Later, the Albanians became even more alien to the Slavs by adopting Islam from their Turkish conquerors in the late 15th century. At mid-20th century nearly all the Albanians in Yugoslavia and 70% of those in Albania were Muslim.

There are two distinct groups of Albanians, each with its own dialect, costume and customs. These are the Tosks in the south and the Ghegs in the north and on the plain of Kosovo. The Ghegs comprise ten tribes, each of which is subdivided into political groups known as *bairaks*, and on a quite separate system into exogamous patrilineal clans or *fis*. This *fis* system often leads to inbreeding within small areas, through the institution of cross-cousin marriage, with the result that the physique of the Ghegs varies from district to district. In the north, near the borders of Montenegro, a tall thickset type, like the characteristic Montenegrin, is found, while to the east the population includes more individuals of the Atlanto-Mediterranean strain! tall but not very heavily built, with long head, dark hair and dark brown eyes. But the most characteristic physical type among the Ghegs, which there as elsewhere is probably by origin a hybrid, is the Dinaric, commonest in the tribe of Dibra. This type is of medium height, with a characteristically narrow and convex nose, light brown eyes and dark brown hair, and above all with a very broad and flat-backed head. This extreme occipital flattening may be partly artificial, resulting from the use of a hard cradle, but it appears that this is not the whole explanation and that it is also an inherited racial character.

The Tosks, like the Ghegs, are extremely broad-headed; in fact, the mean cephalic index measured in a Tosk district of southwestern Albania, 90.8, is the highest recorded in Europe. But the broad-headed character of the Tosks is of a different type from that of the Ghegs. The head is globular in shape, with high and bulbous forehead, and the back of the head is not flattened. In addition, the nose lacks the high bridge and depression of the tip which are often observed among the Ghegs. The Tosks, in other words, belong to the Alpine variety of the broad-headed people of Europe rather than to the more specialized Dinaric variety, and in this respect resemble closely the inhabitants of southern and central France. They are very given to emigration and have set up colonies in America.

3. Greeks. — These people also have long been accustomed to emigrate and although many exiled groups have returned since the beginning of the 20th century, particularly from Asia Minor, important sections of the Greek population are still to be found outside the political boundaries of Greece, not least in America. Furthermore, even inside Greece the population is by no means homogeneous. Whole districts, even as far south as Attica, still speak Albanian, and wide pastures on the Pindus mountains are still the preserve of Rumanian shepherds. The common loyalty of the modern Greeks, therefore, is linguistic and religious rather than territorial.

Among the Greek-speaking peoples can be traced a variety of communities of different physical types. These physical distinctions are doubtless the result of segregation and inbreeding within the various small compartments into which the territory of Greece is naturally divided, and it is likely that these distinctions were equally noticeable in classical times. Differences of head form from region to region afforda good illustration. In the high western slopes of the Pindus mountains or the district of Epirus, as well as in Macedonia, the Greek population, like their Tosk neighbours in Albania, is extremely broad-headed, with mean cephalic indexes of about 85–88. In the Peloponnesus, Attica and the Ionian Islands on the other hand. the populations have a mean cephalic index of 81 or 82, while in Thessaly the inhabitants are comparatively long-headed, with a mean cephalic index of 77. There is also a regional variation in the colouring of the complexion, the Macedonian Greeks, for example, being noticeably fairer than those of the Ionian Islands and the Peloponnesus.

Briefly, three main types can be traced within the Greek population. The first, with heavy and dark beard, strong brow ridges and eyebrows which run together, clearly belongs to the Alpine race. The second is taller, with a fairly long head, straight nose and dark brown hair and eyes, and represents a tall variety (Atlanto-Mediterranean) of the Mediterranean race. Third, much less common than the others, is a Dinaric element, with very dark hair, flat back to the head and narrow facial features. Very occasionally also a blond Nordic strain can be observed.

The Greek population, therefore, is of mixed ancestry. Yet to judge from measurements taken in a Greek community in Boston, Mass., there are certain special physical features which have become characteristic of these people and serve to distinguish them from their neighbours in the Balkans. Such are the broad jaws, high nasal bridge, wide cheeks and broad nose with a tendency to turn up rather than down at the tip.

4. Bulgarians. — These people were members of a heathen Ugrian tribe who entered the Balkans from eastern Russia in the wake of the Slavs and soon afterward adopted Greek Orthodox Christianity and abandoned their language in favour of the Slavic tongue of their predecessors. Later, the country fell under Turkish rule, and Tatar and Circassian settlers entered in considerable

numbers. Despite these repeated incursions, however, the bulk of the population of modern Bulgaria still belongs to the very ancient tali variety of the Mediterranean stock, usually known as the Atlanto-Mediterranean type. which inhabited the territory in Neolithic times. The chief characteristics of this type are dark colouring, moderate to tall stature. narrow face and. above all, a long head. The Bulgarians, on the average, are among the longest-headed folk of the Balkans, and only in the west, in the region of Macedonia where they come into contact with the Albanians. is there any significant broad-headed element in the population. The second chief racial constituent in the Bulgarian population is the Neo-Danubian, a moderately broad-headed race, generally of light complexion and with a characteristic concave snub-tipped nose. A slight flattening of the face suggests Mongoloid admixture. though the basic element of this type is undoubtedly Nordic. it is found also in central Finland and in the black earth region of Russia. and was probably introduced into Bulgaria during the Slavic and Ugrian invasions.

5. Rumanians. — These people, who are locally called Vlachs, are the most scattered of all the people of the Balkans. They have a common language. of Latin derivation. and a common pastoral nomadic economy, but their racial type varies widely from region to region. In Walachia, for example, the main element in the population resembles that of Bulgaria to the south. being of medium height, with dark hair and eyes: narrow forehead and nose and head of medium breadth. These features indicate a tall variety of the Mediterranean race. Farther north in Moldavia. where the Rumanian plain abuts on the black earth region, there is a higher proportion of individuals of the Neo-Danubian race, fairer and with flatter and broader faces and more snub noses. To the west. however, just over the crest of the Carpathians in Bukovina, the Vlach population belongs to the Dinaric race. Their heads are appreciably broader and larger than those of the plainsfolk. their stature taller, their faces longer and broader, their noses larger and more prominent and the backs of their heads much flatter. The Vlachs of Afacedonia and Istria appear also to belong substantially to the same tall, dark, prominent-nosed and broad-headed Dinaric race.

In short, the Vlachs have no racial uniformity but represent the descendants of the aborigines who, during the 150 years of Roman rule in the province of Dacia, in the 2nd and 3rd centuries A.D.. adopted something of the language and civilization of their rulers. After the withdrawal of Roman rule they were scattered by the various incursions of Goths. Slavs! Bulgars and Turkic peoples. but survived in isolated mountain districts in many parts of the Balkans, especially in Macedonia, northern Greece and southern Albania, where they took to a pastoral. seminomadic economy. Their physical features no doubt varied from one district to another at the time when they first came under Roman influence, and have since become even more localized as a result of intermixture of the various groups with their immediate neighbours.

The Slavic word *Vlach* means "foreigner," and it appears to be related to the terms Welsh and Walloon in western Europe.

Not only are the Vlachs or Rumanians proper, as defined by language and culture, widely scattered through the Balkans outside Rumania, but the inhabitants of Rumania itself are very mixed, and in the district of Dobruja, for example (a small plateau enclosed between the Black sea and the lower reaches of the Danube). E. Pittard remarked, besides the Vlachs, representatives of the following peoples: Bulgars, Ottoman Turks, Gaguz. Armenians, Kurds, Circassians, gypsies and Jews. These last two groups form important minorities throughout the Balkans, and since they are particularly concentrated in Rumania, it will be convenient to consider them at this point.

6. Balkan Jews. — The Jewish communities in the Balkans are predominantly made up of Spaniols or exiled Sephardim, that is, the descendants of those driven out of Spain in the persecution of 1492. They still speak a form of Spanish known as Ladino. and preserve a dress and various customs which recall their origins in Spain. Their number in the Balkans and in Turkey has been estimated at 300.000. Physically they must be classed. there as elsewhere in southern Europe and the near east. as a variety of the small Mediterranean race. The chief type is slender and delicately built and is of moderate stature with fairly long head. long narrow face, straight or convex nose and dark colouring. A second type has a shorter and broader face. well-developed chin. thicker lips, short and straighr nose, heavy eyebrows and deep-set eyes, and is altogether of coarser and more muscular build. From one district to another the physique of the Jewish communities naturally varies slightly as a result of intermarriage; in Bukovina, for example. a district of broad-headed folk. the mean cephalic index of the Jewish population is as high as 84. But generally the Jen-ish communities have preserved their racial characters. which are the outcome of a stable combination of several varieties of the brunette Mediterranean race. Although darker than most of the people of central Europe, they are fairer than their neighbours in Rumania. Among the Jews of Salonika. one-sixth are of blond colouring, although in other physical features they are no different from their coreligionists. Probably this blondness is an occasional tendency inherent in the Jewish stock.

7. Balkan Gypsies. — The gypsies (*q.v.*) of Europe are especially concentrated in the Balkans. and of the 1.000.000 or so in the world. more than half are estimated to live in Rumania and Hungary. and at least 150.000 in Bulgaria. Macedonia and Yugoslavia. A great many have now settled and have interbred to a varying extent with their neighbours. But wherever they retain their nomadic habit. the original racial type can still be traced. This type is of short stature: with long and low-vaulted head. small and fairly long face. narrow nose, straight black hair and very dark eyes and complexion. The Balkan gypsies are characteristic specimens of the dark-complexioned small Mediterranean racial type. which is at home in India, and this identification is confirmed by their language and traditions. Their speech is basically Indian, a derivative of Sanskrit, though it includes words borrowed from the languages of numerous countries. such as Iran, Armenia and Greece. across which they traveled on their way through the near east or during their wanderings in Europe. They appear to be the descendants of pariah tribes of northern India who moved to the west early in the present millennium and entered Europe about A.D. 1300. In the Balkan countries some of them were made landed serfs, while others were allowed to wander and to practise their traditional trades as tinkers. wood-carvers, gold panners. minstrels and sorceresses.

8. Turks. — The communities of Turkish-speaking Muslims in the Balkans, relics of the long period of Ottoman control. were being rapidly depleted at mid-20th century because of migration back to Turkey. There has been a particularly large exodus from Bulgaria. whence more than 50,000 departed in 1950 alone. Away from the small area of European Turkey, it is unlikely that many of these Balkan Turks are racially akin to the Ottoman conquerors. This is shown clearly by the range of physical types that is found among these European Turks. For example: those of Bosnia-Hercegovina belong to the local tall and very high- and broad-headed Dinaric race; while a series of measures taken in Sliven (Slivno) in central Rumelia showed. on the contrary, that the Turks there were long-headed and in this and other respects very akin to their Bulgarian neighbours. Manifestly. very many of the Balkan Turks are indigenous folk whose ancestors, from compulsion or self-interest. adopted the Turkish language and religion.

An exception must probably be made for the Yuruks or seminomadic shepherds. such as inhabit the southern slopes of Mt. Ograzden in Yugoslavia. There as in Turkey. these people preserve in a very pure form the language, economy and customs, and probably also the physical type, of the old Turks who emigrated from central Asia.

The Bektashi communities of Turks, however, are much more clearly of local origin, as is suggested by their doctrines and institutions, many of which are compromises with the practices of Greek Orthodox Christians. Such are their belief in the Trinity and their celebration of Christmas Eve. Since the dissolution of the dervish orders in Turkey in 1925. the Bektashi communities of the Balkans. in particular of Albania and parts or' Yugoslavia like the district of Strumica, have become the main survivors of this enigmatic sect. A colony was also established in New York

by immigrants. The true Bektashis are the members of an order of Muslim dervishes, who follow the rule of Haji Bektash, their 14th-century founder; but the villages which take instruction from these dervishes also adopted this name. The chief ways in which the Bektashis differ from orthodox Muslims—although they arrogate to themselves the title of Sunni—are in their devotion to Ali and to his children Hasan and Husain, in memory of whose martyrdom they fast for the first 12 days in the month of Moharram; in the privileges they accord to their women, who are even allowed to become dervishes; in their religious proceedings; in their custom of worshiping in tekkes (monasteries) and turbehs (mausoleums) rather than in mosques; and in their open compromises with the feasts and customs of their Christian neighbours.

9. **Ethnic** Survivals in **the** Balkans.— The Bektashi villages provide an example of the very mixed cultural traditions of the Balkans. In this peninsula people with varied customs and beliefs have come together, and though they often preserved their old racial and political differences and rivalries, they have at the same time interchanged ideas, beliefs, crafts and artistic symbols. These countries may indeed be regarded as a somewhat disorderly ethnological museum, in which traces of numerous people are haphazardly preserved. Mary Durham's studies of Balkan jewelry and tattoo patterns, for example, demonstrate how there are often retained side by side designs from Muslim and Christian sources, and even from ancient Illyrian and Mithraic sun cults. See also ALBANM; BULGARIA; GREECE; RUMANIA; YUGOSLAVIA.

(WM. C. B.)

III. POPULATION

Five major ethnic groups or races are to be found in the Balkan peninsula. These are the Albanians, the Greeks, the Bulgarians, the Southern Slavs (Serbs, Croats, Slovenes, Montenegrins) and the Turks. All of them, with the possible exception of the Southern Slavs, have at one time been spread over wider areas than those they now occupy. This is particularly true of the Turks, who for several centuries were primarily the governing occupiers of most of the peninsula. They also fairly effectively colonized certain parts of it, particularly in Thrace, Macedonia and in northeastern Bulgaria, and were finally ousted after World War II. This is also true of the Bulgarians, who at one time extended throughout much of Macedonia and Thrace. World Wars I and II, and the resultant frontier adjustments and population exchanges, have given the political map a much closer resemblance to the map of nationalities than it has ever had before. Except on the northwestern fringes of the peninsula, where some Rumanians, Hungarians, Austrians and Italians are included in Yugoslavia, the Albanians of the Kosovo-Metohija Autonomous Region are probably the only important minority left inside the territory of another country. The most mixed region is undoubtedly Macedonia —whose variety of people has given rise to the culinary term "macédoine" for a mixture of vegetables. There, ethnic differences have been confused by differences of religion, and adherents of the Greek Orthodox Church were long regarded as Greek, whatever their ethnic heritage; similarly, all Muslims were formerly regarded as Turks, whether they were of Bulgarian, Albanian or Southern Slav stock.

On the basis of censuses or projections therefrom, the population of the Balkan peninsula in 1960–61 was about 36,300,000, distributed as follows: Yugoslavia 18,500,000, Greece 8,358,000, Bulgaria 7,800,000, Albania 1,600,000. Substantial reductions in both birth rates and death rates have taken place during the 20th century, as the following table shows:

Country	Birth rate %			Death rate %		
	1906–10	1921–25	1959	1906–10	1921–25	1959
Yugoslavia	39	35	[illegible]	25	20	9
Bulgaria	42	39	[illegible]	24	21	9
Greece	—	[illegible]	19	—	15	7
Albania	—	—	41	—	—	9

These figures are largely the result of increased medical services, but are probably also in part due to the decreasing isolation of rural communities and to the rising standards of living, particularly among the ever-increasing proportion of the population which is urban-dwelling: In Bulgaria, for example, the proportion of the total population living in towns rose from 26% to 35% in the decade following World War II.

Population density within the four countries of the peninsula is relatively low, compared with most of central and western Europe: Yugoslavia 187 persons per square mile, Bulgaria 183, Greece 165, Albania 146 (compare Switzerland 341, Belgium 775). This is, of course, largely the result of the still essentially rural character of the population, the relative scarcity of really large towns and the complete absence of industrial conurbations. But such figures conceal wide differences within the countries, from region to region, which result from differences in altitude, relief and agricultural productivity. In most of the mountainous areas, but particularly in the Greek Pindus ranges, in northern Albania and in Montenegro, densities of much less than 100 per square mile prevail, while the greatest densities are reached in the plains of northern Yugoslavia (particularly the former Serbian area) and in the plains and basins of central Bulgaria. See also ALBANIA; BULGARIA; GREECE; YUGOSLAVIA. (S. H. BR.)

IV. HISTORY

The Balkans emerge from prehistory in classical times, with the history of Greece (*q.v.*) and with the Greek and Roman contacts with the various states and peoples of the central and northern regions of the peninsula. The northern hinterland of the Aegean was the kingdom of Macedonia (*q.v.*), with Thrace (*q.v.*) on its eastern frontier. For the Adriatic hinterland in ancient times see EPIRUS; ILLYRIA; for the inland area south of the Danube see MOESIA; also VLACHS. For the peripheral countries of the north see DACIA; PANNONIA. All these regions were eventually incorporated into the Roman empire.

The successive partitions of the Roman world ended with the Balkan provinces all in the Eastern half (see BYZANTINE EMPIRE). The period of the great migrations (see EUROPE: History) opened for the Balkans with the invasion of the Goths (*q.v.*) in the 4th century A.D. This, however, left no such permanent mark on the racial configuration of the peninsula as did the arrival of the Slavs (*q.v.*), who began to penetrate the peninsula at the end of the 5th century and continued to spread over it for the following 100 years. The Avars (*q.v.*), though their main seat of power was north of the middle Danube, also made incursions southward in the 6th century. Finally, in the 7th century, the Bulgars arrived from the Volga region. For the great new empires that emerged in the early middle ages from settlement of the invading people, see BULGARIA; SERBIA. For lesser states see BOSNIA-HERCEGOVINA; CROATIA. For the states formed by the remnants of indigenous people see ALBANIA; and for Walachia, RUMANIA.

The 11th century saw further invasions of the Balkans by people from the Volga region, namely the Pechenegs and the Kumans (*qq.v.*). At the beginning of the 13th century, however, Greek Byzantine rule over the south of the peninsula was replaced, except in Epirus, by Latin, through the diversion of the 4th crusade to Constantinople (see GREECE: History; also CRUSADES). For the Venetian occupation of the Adriatic coast see DALMATIA.

The Ottoman Turks (see TURKEY: History) began their onslaught on the Balkans in the 14th century and by the end of the 15th had occupied the whole peninsula with the exception of some coastal areas on the Adriatic and Montenegro (*q.v.*). Turkish power, however, began to decline in the 18th century, and schemes for the partition of its Balkan dominions between local states or between the great powers of Europe became the subject matter of the Eastern question (*q.v.*). Greece was recognized as independent in 1829 (see GREEK INDEPENDENCE, WAR OF), and the autonomy of Serbia was confirmed in 1830. Russian designs on the Balkans (see RUSSO-TURKISH WARS) culminated in the treaty of San Stefano (*q.v.*) in 1878, which created a greater Bulgaria extending from the Danube to the Aegean and from the Black sea to Albania, but at the congress of Berlin (*q.v.*) in the same year the other European powers, alarmed at this ex-

tension of Russian influence, redrew the map: Bulgaria was limited to the country between the Danube and the Balkan mountains; Serbia received Nis, Pirot and Vranje; the Dobruja (*q.v.*) was ceded to Rumania; and Austria-Hungary was accorded the right to occupy Bosnia-Hercegovina provisionally. Serbia and Rumania at the same time became independent principalities, while the independent status of Montenegro was recognized.

In 1881 Greece secured Thessaly and Arta (*qq.v.*) from Turkey. The Bulgarian occupation of Eastern Rumelia (recognized in 1578 as an autonomous Turkish province) in 1885 was followed by the Serbo-Bulgarian War (*q.v.*). The Greco-Turkish War of 1597 led to a rectification of the Thessalian frontier in Turkey's favour. In 1908 .Austria-Hungary formally annexed Bosnia-Hercegovina.

In 1912–13 the Balkan league of Greece, Serbia, Bulgaria and Montenegro attacked and defeated Turkey, this war being followed by a second between Bulgaria and its former allies (*see* BALKAN WARS). Greece received southern Macedonia with Salonika; Rumania the southern Dobruja; Bulgaria the Aegean coastline from Xanthi (Eskije) to Alexandroupolis (Dedeagatch); Serbia northern Macedonia. Serbia and Montenegro partitioned the sanjak of Kovi Pazar, and an independent Albania was created.

After World War I (*q.v.*) Bulgaria lost the coast of Thrace to Greece and a strip along its southeast frontier to Serbia (see NEUILLY, TREATY OF); Turkey was confined to the province of Eastern Thrace with Edirne (*see* SÈVRES, TREATY OF; LAUSANNE, CONFERENCES OF). A Serb-Croat-Slovene kingdom mas constituted, comprising Serbia, Montenegro, Bosnia-Hercegovina. Croatia and other Southern Slav regions taken from Austria-Hungary, together with northern Macedonia (see YUGOSLAVIA). Italy received the extreme northwest coast of the Balkan peninsula up to and including Rijeka and, in addition, certain of the Adriatic islands. Population exchanges on a large scale were carried out in order to stabilize the new frontiers. Eforts, encouraged by Great Britain and France, to preserve the independence and identity of the Balkan states were typified in the Balkan entente (*q.v.*) of 1934.

After World War II the Allied peace treaty with Italy, Rumania and Bulgaria concluded in Paris on Feb. 10, 1947, introduced the following changes'in the international frontiers: (1) the greater part of Venezia Giulia, as well as the enclave of Zadar and all the Adriatic islands were ceded by Italy to Yugoslavia; (2) a Free Territory of Trieste (*q.v.*), demilitarized and neutral, was formed; and (3) the transfer of southern Dobruja to Bulgaria, to which Rumania had agreed in 1940, was confirmed. At the same time British and French influence gave way largely to Russian in the formation of "people's republics" in Albania, Bulgaria. Rumania and Yugoslavia. Greece, however, after a civil war, became a member of the North Atlantic Treaty organization; and Yugoslavia, though Communist, broke with the Soviet bloc. In 1954 Trieste was partitioned between Italy and Yugoslavia. For later history see the articles on the independent Balkan states of the second half of the 20th century: ALBANIA; BULGARIA; GREECE; RUMANIA; YUGOSLAVIA; see also Index references under "Balkan Peninsula" in the Index volume.

BALKAN WARS. The Balkan Wars of 1912–13 deprived the Ottoman empire of almost all its territory in Europe, with the exception of part of Thrace and the city of Edirne (Adrianople). The Balkan allies, Serbia, Greece and Bulgaria, quarreled over the partitioning of their conquests, with the result that war broke out in 1913 between Bulgaria on the one hand and Serbia and Greece, joined by Rumania, on the other.

The Balkan Wars had their origin in the discontent produced in Serbia, Bulgaria and Greece by the disorders in Macedonia. The Young Turks' revolution of 1908 (*see* TURKEY: History) brought into power in Istanbul a ministry determined on reform but insisting on the principle oi centralized control. There were, therefore, no concessions to the Christian nationalities of Macedonia, which consisted not only of Macedonians but also of Serbs, Bulgars, Greeks and Vlachs. The Albanians, moreover, who had been the mainstay of Turkish rule in the Balkans, were likewise discontented with the Young Turk's centralist policy. The Internal Macedonian Revolutionary organization (I.M.R.O.; V.M.R.O. in Macedonia), founded in 1893, organized bands to resist the Turkish administration. Clashes not only exacerbated feeling within Macedonia but also roused public opinion within Bulgaria itself in favour of intervention. The I.M.R.O. became a powerful factor in Bulgarian politics. A similar development occurred in Serbia, where the patriotic society Narodna Odbrana ("National Defense"), invigorated by the infiltration of the "Union or Death" group (founded in May 1911 and better known as the Black Hand), was active not only within the Serbian administration but also in organizing Serbian resistance in Macedonia. The activity of the Bulgars in Macedonia had led, in Sept. 1903, to the formation of an armed band in defense of Greek interests, but the Greek government was equally determined to obtain extension of its territory in the Aegean islands and to secure union with Crete (*q.v.*). At first, Greeks, Serbs and Bulgars frequently acted in opposition to one another, but the events of 1911 brought them to realize that the main enemy was the Turk and that they could in the first instance achieve freedom only by a common understanding.

International circumstances were of considerable importance. Austria-Hungary had, in Oct. 1908, annexed Bosnia-Hercegovina, territory legally part of the Ottoman empire but under Austro-Hungarian occupation and administration after 1878 (see BERLIN, COKGRESS OF); the Austro-Hungarian government, moreover, had a treaty right to occupy the sanjak of Novi Pazar, which separated Montenegro from Serbia. Deeply resentful of Austria-Hungary's action, which excluded an eventual union of the inhabitants of Bosnia-Hercegovina with their fellow Serbs, the Serbian government nevertheless realized that it could not challenge one of the great powers and therefore turned its attention to Macedonia, where a weak power like Turkey could more easily be attacked, if an alliance could be achieved with Bulgaria. The Agadir crisis of 1911, moreover, revealed that the two great power groupings, the triple alliance and the triple entente, mere evenly balanced, so that the small powers might exercise some measure of individual initiative.

The **Balkan League, 1911–12.**—An opportunity for an effective alliance was presented when Italy declared war on Turkey on Sept. 29, 1911 (see ITALO-TURKISH WAR). While the Turks were preoccupied in Tiipolitania, the Balkan states could attack them in Macedonia and Thrace. With Russian encouragement Serbia and Bulgaria began to draw closer together in the autumn of 1911. Ivan E. Geshov, the prime minister of the pro-Russian government that had come to power as a result of the Bulgarian elections of June 1911, met the Serbian foreign minister Milovan Milovanovic, in great secrecy on Oct. 11, 1911, and discussed the principles of an alliance. After protracted negotiations a treaty of alliance, ostensibly against Austria but actually against Turkey, was concluded on March 13, 1912. The Russian foreign minister, S. D. Sazonov, intended this alliance to be a counterweight to Austro-Hungarian influence in the Balkans, for which reason in the secret annex it was stated that Russia should have the power to veto any action which the two powers proposed. The second article of the secret annex, however, provided for the partitioning

of Macedonia as the result of an offensive war. Serbia and Bulgaria were to divide Macedonia on the principle that Serbia should make no claim southeast of a line from Mt. Golema to Lake Ohrid, while between this line and the Sar mountains the Russian emperor was to act as an arbiter between the two parties.

This agreement was supplemented by an alliance between Greece and Bulgaria, concluded on May 29, 1912. Eleutherios Venizelos, who had become prime minister of Greece on Oct. 18, 1910, was a Cretan and saw that the liberation of Crete from Turkish suzerainty could best be achieved by military action in Macedonia in concert with Bulgaria and Serbia; it was, moreover, imperative that Greece should be a party to any partitioning of Macedonia in view of the extensive nature of Bulgarian claims.

The fourth state in the Balkan peninsula, Montenegro, concluded an alliance with Bulgaria on Oct. 6, 1912, and one with Serbia on Oct. 24. Secure from danger of early defeat in his mountain stronghold, King Nicholas I undertook to anticipate the three other powers' declaration of war on Turkey in order to provide a diversion.

The **First** Balkan War, **1912–13.**—The internal situation of Turkey was favourable for the action of the allies. Discontent had mounted against the administration of Said Halim Pasha (appointed on Oct. 4, 1911), with the result that the government dissolved the chamber of deputies on Jan. 18, 1912. Fresh elections gave an over helming majority to the Young Turks, but their methods caused further discontent, especially in the army. On July 23 a new ministry was formed under Ahmed Mukhtar Pasha, with only partial representation of the Young Turks. To achieve some political stability the war minister, Nazim Pasha, undertook a purge of unreliable elements in the army, which seriously reduced its efficiency.

The great powers realized, in the summer of 1912, that a crisis was imminent in the Balkans. The French prime minister Raymond Poincaré discovered the offensive nature of the Serbo-Bulgarian treaty during his visit to St. Petersburg (Aug. 9–16). Poincaré saw that hostilities in the Balkans might lead to a general European mar but was equally conscious that opposition to Russian policy might shake the Franco-Russian alliance. On Aug. 13 the Austro-Hungarian foreign minister, Leopold Berchtold, issued a circular to the powers, urging that they should concert to induce Turkey to adopt a policy of decentralization for the Christian nationalities of Macedonia—precisely that policy which was unacceptable to the Young Turks. On Sept. 22 Poincaré proposed to Great Britain and Russia that they and France should agree on a common policy and transmit their suggestions to the powers of the triple alliance, but Sazonov, then on a tour of western Europe, and Sir Edward Grey, the British foreign secretary, objected to this on the grounds that it would divide Europe into two camps and would prevent a real concert of the powers. On Sept. 28, therefore, Poincaré approached Germany for an understanding, to which Alfred von Kiderlen-Wachter, the foreign minister, agreed, provided that Austria-Hungary was associated with any steps the powers might take. The slowness of the powers' action and the recommendation which they were to make barely met the needs of the situation. They proposed that the *status* quo should be maintained and that Turkey should institute reforms, but this in effect meant that the Balkan powers were given a guarantee against loss of territory if they lost the war, while sentiment would be strongly against the restoration of Christian territory to Turkey if they won. Any reforms undertaken in European Turkey, moreover, could be carried out only on the basis of decentralization, which the Young Turks would not concede. On Sept. 21, 1912, Stoyan Danev, the Bulgarian foreign minister, had met Nikola Pasic, the Serbian prime minister, and the decision was taken to go to war.

The action of the powers was thus too late. On Oct. 8, 1912, Austria-Hungary and Russia made representations in the Balkan capitals and on Oct. 10 all the powers made a *démarche* in Istanbul, but on Oct. 8 Montenegro declared war on Turkey and opened hostilities. On Oct. 17 Turkey, to forestall declarations of war by Serbia and Bulgaria, broke off diplomatic relations; on Oct. 18 Greece declared war against Turkey and the three powers opened hostilities.

The Turks launched an offensive against the Bulgars with troops disorganized by Nazim Pasha's purge. Heavily defeated at Kirk-Kilise (Lozengrad or Kirklareli) on Oct. 22–23 and again at Lule Burgas (Liileburgaz) on 29–31, they were thrown back to the Chatalja (Catalca) lines. There they proved much stouter opponents when the Bulgars attacked them in their defensive positions on Nov. 17–18. The Bulgars failed to penetrate the Turkish lines and were repulsed with heavy casualties. In the meantime the Serbian army achieved a great victory at Kumanovo on Oct. 23–24, which enabled it to penetrate deep into Macedonia and to capture Monastir (Bitola) on Nov. 18. The Montenegrin militia advanced and laid siege to Scutari (Shkoder). An assembly of Albanian notables at Valona (Vlone) declared the independence of Albania on Nov. 28, but on that very day the Serbs occupied Durazzo (Durres). On Nov. 8 the Greeks entered Salonika, arriving only a few hours before the Bulgars. The Turkish collapse was so complete that all parties were willing to conclude an armistice on Dec. 3.

The London Conference.—While the fighting was in progress the great powers still sought for a settlement. It was Austro-Hungarian policy to prevent the aggrandizement of Serbia, because a strong Serbia would constitute a threat to the southern frontier of the Habsburg empire. The key to the situation, therefore, was what Austria-Hungary would accept. Berchtold, following his predecessor Aehrenthal's policy, decided not to exercise the treaty right to occupy the sanjak of Novi Pazar, which might have prevented Serbia and Montenegro from obtaining a common frontier. Instead he submitted to the powers on Nov. 4, 1912, the conditions that Albania should be erected as an independent state and that Serbia should not be allowed to reach the Adriatic. This proposal displeased Serbia, and both Austria-Hungary and Russia took military measures in view of the tension. On Dec. 12 Gen. Franz Conrad von Hotzendorf, well-known for his view that only offensive action could settle the Southern Slav question, resumed the duties of Austro-Hungarian chief of staff Russia avoided provocative action, but retained third-year conscripts with the colours for an additional period.

On Nov. 18, 1912, Kiderlen-Wachter proposed that the powers should meet to discuss a settlement on the basis that they reserved to themselves the settlement of Albania, the question of Adrianople (Edirne) and Istanbul, Mount Athos, the Aegean islands and Rumanian demands for compensation. It was agreed that the ambassadors of the powers should meet in London to work out the details of an agreement, but this disposition to seek a peaceful solution was accompanied by consultation in the two great alliance groups lest there should be a breakdown of international relations. On Nov. 4 Poincaré had made it clear to Russia that he would abide by the Franco-Russian alliance if the need arose. On Nov. 22–23 Sir Edward Grey and the French ambassador, Paul Cambon, exchanged letters defining the military commitments of France and Great Britain. The archduke Francis Ferdinand, heir to the Austrian throne, received assurances of German support during his visit to Berlin on Nov. 22–23 and these were made more definite by a public statement in the Reichstag by the chancellor Theobald von Bethmann Hollweg on Dec. 2.

The conference of ambassadors opened in London on Dec. 16 under Sir Edward Grey's chzirmanship. Agreement on the principle of Albanian independence was quickly reached, but Austria-Hungary favoured a larger Albania than Russia did. While negotiations were proceeding in London the Turkish government, on Jan. 22, 1913, submitted to an assembly of Ottoman notables the question whether or not Turkey should make peace. The council pronounced in favour of peace, but on Jan. 23 a coup *d'état* was carried out by a group of Young Turks under Enver Pasha to prevent the surrender of Adrianople to Bulgaria. On Feb. 3 the Balkan allies denounced the armistice and re-opened hostilities. The Bulgars did not, however, attempt again to force the Chatalja lines, but concentrated on the reduction of Adrianople, which did not capitulate until March 26. The Montenegrins likewise continued to besiege Scutari.

On March 21, 1913, Austria-Hungary agreed to a compromise solution on the northern frontier of Albania, but it nas difficult to force the Montenegrins to accept peace. Only a threat of military action by Austria-Hungary on May 4 compelled Montenegro to abandon Scutari, nhich had fallen on April 22. On April 21, the Balkan allies agreed with bad grace and with some reservations to negotiate on the principles established by the London conference, but only a sharp warning to their representatives in London on May 27 from Sir Edward Grey that they must either accept the powers' terms or go home brought about final agreement to the preliminaries of peace on May 30. The powers therefore reserved to themselves the Turkish European frontier question, the limits of Albanian territory and the disposition of the Aegean islands, leaving the Balkan powers to distribute among themselves the remainder of European Turkey. Albania was therefore established as an independent neutralized state on July 29. 1913. under international control and the sovereignty of Prince William of Wied.

The Second Balkan War, **1913.**—The territorial settlement produced discords among the Balkan allies, while Rumania laid claim to the town of Silistra and to an area of the Dobruja. Friction in Macedonia induced the Greeks to form an alliance with the Serbs on June 1, 1913, for the division of Macedonia on different lines from those agreed to by Serbia and Bulgaria in their alliance of March 13, 1912. At the same time Greece began negotiations for a definitive peace with Turkey in the hope of obtaining Turkish support against Bulgaria. Bulgaria had antagonized Greece by laying claims to Salonika. while the Serbs demanded that the towns of Prilep, Kichevo and Ohrid, which they had previously assigned to Bulgaria, should now be allotted them—on the flimsy grounds that Bulgaria had not honoured the letter of the military convention and that Serbia had originally expected an extension of territory to the Adriatic and ought now to receive compensation in Macedonia. Tension was so great that Geshov, the Bulgarian prime minister, resigned on May 30. 1913. rather than take further responsibility for the negotiations and his place was taken by the foreign minister Danev. The Russian government used its influence to obtain agreement, and the emperor himself sent telegrams to the kings of Serbia and Bulgaria asking for conciliation. Sazonov therefore, under the impression that they would accept Russian arbitration, on June 21 invited Serbia and Bulgaria to submit within four days their rival arguments. This demand produced a crisis in Bulgaria. The Bulgarian field commander, Mikhail Savov. declared that the army mould be satisfied with nothing less than the line of division agreed to in the original treaty of March 13. 1912. On June 22, 1913, a ministerial council in Sofia pronounced in favour of conciliation but on the same day a conference of Danev and Savov with King Ferdinand I at Vranje decided to ask Russia to arbitrate upon the basis of the original 1912 treaty. An award, moreover. was demanded within seven days. This demand, submitted on June 24. 1913, so annoyed Sazonov that he declared that he could not give Bulgaria further support. Ferdinand. probably expecting a quick victory and convinced that Austria-Hungary would support him, ordered Savov on June 28 to launch an attack upon the Serbs and the Greeks in Macedonia. The Bulgarian cabinet had not authorized this order and on July 1. countermanded it. Savov, though he had already begun the advance. now refused to act on his own interpretation of the situation and was accordingly on July 3 relieved of his command by Ferdinand for refusing to obey an order and replaced by the Russophil general Radko Dmitriev.

The consequences of Ferdinand's action were disastrous for Bulgaria. Austria-Hungary, anxious to favour Bulgaria as a counterneight to Serbia, might hdve offered support if Bulgaria had met Rumanian claims on the Dobruja. On June 27 the Rumanian government had given warning that it would mobilize in the event of war. A quick victory over the Serbs and Greeks would have enabled Bulgaria to face Rumania, but nithout support Bulgaria mas at the mercy of the Rumanian army, which began to advance into the country on July 11. Rumania was in the fortunate position of having both Austria-Hungary's friendship and the knowledge that Russia would refrain from hostile action in the hope of subsequently obtaining Rumania's allegiance to the triple entente. On July 12 the Turks violated their armistice with the Bulgars and began to advance into Thrace, recapturing Adrianople on July 22. The position was now hopeless for Bulgaria. Danev's pro-Russian ministry had resigned on July 15 and was replaced by the pro-Austrian cabinet of Vasil Radoslavov. On July 18 it was agreed that a conference should open at Bucharest to settle the terms of peace, though it was not until July 30 that the Bulgars obtained an armistice from the Serbs. Greeks and Rumanians.

The Treaty **of** Bucharest and the Turkish **Treaties.**—Under the treaty of Bucharest (Aug. 10, 1913) between Bulgaria on the one hand and Serbia, Greece and Rumania on the other, Bulgaria obtained a coastline of about 25 mi. on the Aegean, including Dedeagatch (Alexandroupolis), an extension of the southern frontier to include Petrich and Strumitsa and a small rayon of territory on the Black sea, but was compelled to cede to Rumania part of the Dobruja north of a line from Turtucaia to Balchik.

Bulgaria, moreover, failed to obtain the Enez-Midye (Enos-Midia) frontier in Thrace. Although this frontier had been awarded to Bulgaria by the London conference. the peace signed between Bulgaria and Turkey in Istanbul on Sept. 29. 1913. left Adrianople and a belt of territory on the right bank of the Maritsa river to Turks. Greece, which had enjoyed diplomatic support from Germany, obtained considerable extension of the northern frontier—which now ran from Cape Stylos (in the Corfu strait) northeastward to Lake Prespa and thence east to the lower Maritsa river to include Serrai, Drama and Kavalla—was also awarded the islands of Thasos, Samothrace, Lemnos, Lesbos. Chios. Samos, Icaria and Crete. Extensions of Serbian territory in Macedonia included the towns of Prizren. Uskub (Skopje) and Monastir (Bitola), while the sanjak of Novi Pazar was partitioned on Nov. 7 between Serbia and Montenegro. Greece concluded peace with Turkey in Athens on Nov. 14, 1913, and Serbia. with Turkey in Istanbul, on March 14, 1914. The territorial settlement was not. however, complete in every detail before the opening of World War I in 1914.

The Results **of the** Wars.—The political consequences of the Balkan Wars were considerable. Apart from Turkey. the real loser was Austria-Hungary. The partitioning of the sanjak of Novi Pazar between Serbia and Montenegro made it impossible in the subsequent crisis of June–July 1914 for Austria-Hungary to intervene in the Balkans by occupying the sanjak according to the Berlin treaty of 1878; the Austro-Hungarian ultimatum to Serbia on July 23. 1914, was thus made to appear naked aggression. The wars likewise altered the structure of alliances in the Balkans. Dissatisfied Bulgaria henceforth looked to Austria-Hungary for support, while Rumania tended to move out of the influence of the triple alliance toward the entente. The Turks. moreover, began to put their house in order and secured, in Nov. 1913, the services of the German general Liman von Sanders, with a group of technical advisers to strengthen the organization of their army. The most alarming aspect of the mar was the growth of tension between Austria-Hungary and Serbia. Serbia had extensive claims upon Albanian territory. Having obtained an assurance of German support, Austria-Hungary delivered an ultimatum on Oct. 17, 1913, to compel Serbia to withdraw from the Albanian borderlands. This however did not solve the Southern Slav question for Austria-Hungary, which emerged again in an acute form with the assassination of the archduke Francis Ferdinand (*q.v.*) on June 28, 1914, in Sarajevo, Bosnia. See WORLD WAR I; see also Index references under "Balkan Wars" in the Index volume.

BALKARIA: see KABARDINO-BALKAR AUTONOMOUS SOVIET SOCIALIST REPUBLIC.

BALKH (WAZIRABAD), a village of north Afghanistan, in the province of Mazar-i-Sharif, is about 14 mi. W. of Mazar-i-Sharif city. It is generally agreed to represent the ancient Bactra, capital of Bactria (*q.v.*). It is situated about 1,250 ft. above sea level, on the Balkh river, which formerly flowed into the Amu-Darya (Oxus), about 45 mi. to the north, but is now drawn off into 18 irrigation channels which water the surrounding lands. There are from 500 to 1,000 houses: the major elements of population are Usbeks and Tajiks, but there are also recently settled Pathans.

The modern town, Wazirabad, is situated amid extensive ruins. The outer walls, more than 7 mi. in circumference and in places built on great earth ramparts concealing older defenses, are probably Timurid. Slightly later (16th century) is the Sabz Masjid (Green mosque), which lies near the centre of the town and is now sadly depleted. North of the mosque is the Bala Hissar (citadel) and in its southern corner the *arg,* an imposing mound approximately 50 ft. in height. About 1 mi. E. of the mosque is another big mound, the Tepe Zargaran, lying just inside the defenses. About 1 mi. S. of the town are two large ruins, known as Top-i-Rustam and Takht-i-Rustam, which comprise a great Buddhist stupa and associated buildings, probably monasteries which may be identified with the *Nau Vihara* (new monastery) whose paintings excited the Arab travelers.

Lying on a once fertile plain, near the main routes from India to China and Central Asia, and within easy reach of the main routes from China to Iran and the Mediterranean, Balkh has had a stormy history. The earliest references are in the Avesta and the Achaemenid inscriptions. Odd finds of pottery of types known from Soviet Central Asia indicate the presence of a settlement c. 500 B.C. The city was captured by Alexander the Great and thereafter became the centre of the Bactrian Greek kingdom. It was also known as Zariaspa. About 125 B.C. Bactria succumbed to nomadic invaders from the north and the east (see YUE-CHI), from whom it derived its name Tokharistan. During the next centuries arose the Kushan power which invaded India but ruled, at least in the north, from Balkh; in the 5th century further invasions of Hephthalites (*q.v.*) occurred. Balkh was later held by the western Turks, although challenged by the Sassanids (*q.v.*) and in 653 raided for the first time by the Arabs. Constant fighting followed until the Muslim general Qutaybah took the city in 715. Balkh became the capital of Khurasan (*q.v.*), and under the Abbasids and Samanids its fame as a capital and centre of learning earned it the title "mother of cities." In the 11th century it was the scene of bitter fighting between the Seljuks and the Ghaznevids and in 1206, fell for a few years to the Khwarizm shah, only to suffer destruction in 1220 at the hands of Genghis (Jenghiz) Khan (*q.v.*). Thereafter Balkh lay ruined until, after its capture by Timur, it was rebuilt early in the 15th century and recovered its prosperity. But in 1480 the alleged miraculous discovery of the tomb of Ali in Mazar-i-Sharif heralded Balkh's decline. In the following century it passed into Usbek hands and later for a brief spell to the Moguls, finally falling to Ahmad Shah Durrani (*q.v.*) in 1752. Since 1841 it has been under Afghan control. See also AFGHANISTAN.

BALKHASH, a town in the Karaganda oblast (province) of the Kazakh Soviet Socialist Republic, U.S.S.R., lies on the northern shore of Lake Balkhash. Pop. (1959) 53,000. It is the second largest industrial centre of the oblast after Karaganda. It owes its existence to the large copper refining plant started in 1928 for the Kounradski mines (10 mi. N.). Apart from this it has ferrous metal rolling mills, fish canning, building materials and other plants. It was at first known as Bertys, and until 1937 as Pribalkhash. (G. E. WR.)

BALKHASH, LAKE (BALKHASH OZERO), a lake in the Karaganda and Alma-Ata *oblasts* of the Kazakh Soviet Socialist Republic, U.S.S.R., is located about 100 mi. W. of the Sinkiang-Uigur (China) border and 600 mi. E. of the Aral sea. It is 376 mi. in length and 46 mi. wide and the fourth largest inland sea in the U.S.S.R. with an area of 7,115 sq.mi. The lake is shallow (average depth 22 ft.) and its water though brackish can be used for irrigation and is potable. This relative freshness is due to the recent formation of the lake, but salinification is proceeding. From November to March the lake is frozen. During the rest of the year it is open to shipping and there are shipyards at the mouths of the Karatal, Lepsa and Ili rivers.

The fauna of the lake and of its feeder tributaries, which excludes the common frog, is more akin to the fauna of the Tarim (*q.v.*) basin rivers in Sinkiang-Uigur than to that of the Aral sea (*q.v.*). It seems probable that Lake Balkhash stood formerly in communication through Lakes Ebi Nuur and Telii Nuur with the lake that formerly filled the Lukchun, or Turfan, depression (in longitude 89° E. and latitude 42° N.), but researches show that any connection with the Aral sea, at least in recent times, was improbable.

The economic importance of the lake greatly increased during the Soviet regime. The Petropavlovsk-Karaganda-Balkhash railway line now reaches it from the north and the Turksib from the east. A large copper refining plant was built near the Kounradski copper mines. This necessitated the development, after 1933, of water transport on the lake and there is now a regular shipping service between Pristan Bertys and Balkhash. Fishing (carp and perch) is significant, especially at Burlyu-Tobe and Burubaital. (G. E. WR.)

BALL, ALBERT (1896–1917), outstanding British fighter ace of World War I who won 43 victories in air combat, was born on Aug. 21, 1896, at Nottingham. He was educated at Trent college, which he left in 1913. On the outbreak of World War I, he joined the army. During the summer of 1915 he learned to fly at his own expense at Hendon, Middlesex, obtaining his pilot's certificate in Oct. 1915, and transferred to the royal flying corps. Having served in France as an army co-operation pilot from Feb. 1916, he was posted in June to No. 11 fighter squadron (flying Nieuport Scouts) and later to No. 60 and 56 squadrons (flying S.E.5s). In spite of his skill and daring Captain Ball was shot down and killed over Annoeullin, near Lens, on May 7, 1917, in an encounter with a German fighter squadron led by Manfred von Richthofen. He won the Victoria cross, among many other honours. (D. CR.)

BALL, SIR ALEXANDER JOHN, BART. (1759–1809), British rear admiral, directed the naval blockade of Malta (1798–1800) and was civil commissioner there from 1802 to 1809. He entered the navy at an early age and was promoted lieutenant in 1778. From 1781 he served under Sir George Rodney and was present at his great victory of April 12, 1782, in the West Indies. Two days later Ball was promoted commander; in 1783 he became a captain. He then spent a year in France with the double purpose of learning the language and of living economically while on half pay. He did not receive a command until 1790, but thereafter he was continually employed. In 1798 he saved Nelson's flagship from running ashore after being dismasted, and the two became close friends. Ball served under Nelson at the battle of the Nile (Aug. 1798), and his ship, the "Alexander," was a particular opponent of Admiral de Brueys's flagship "L'Orient," which blew up. Two months later he was ordered to the blockade of Malta, which was kept up almost without a break for the next two years. After the fall of Malta (Sept. 1800), Admiral Ball did not return to naval service, in spite of Nelson's entreaty that he should continue afloat. In May 1801 he was made a baronet. As civil commissioner he endeared himself to the Maltese by his regard for their interests and by his opposition to the policy of treating the island as a conquered dependency. He died in Malta on Oct. 25, 1809. Ball befriended Samuel Taylor Coleridge, who was his secretary during 1804, and is highly praised by him in The Friend. (O. M. W. W.)

BALL, JOHN (d. 1381), one of the leaders of the Peasants' Revolt (1381) in England, was a priest at York and later at Colchester and was an agitator for about 20 years before the

uprising began. There is no evidence that Ball was influenced by the doctrines of John Wycliffe, but he gained notoriety by inflammatory sermons advocating a classless society. He was cited in 1366 to appear before Archbishop Langham of Canterburp and the faithful were forbidden to hear him preach. His arrest as an excommunicated person was ordered in 1376 and he was several times imprisoned. Shortly after the outbreak of the uprising in June 1381, Ball was rescued from prison at Maidstone by the Kentish rebels whom he accompanied to London, preaching at Blackheath from the already popular text "Whan Adam dalf and Eve span, Wo was thanne a gentilman?" According to the *Anonimalle Chronicle,* which incorporates an eyewitness account of events in London during the rebellion, he urged the killing of all the lords and prelates and members of the monastic orders. After the collapse of the uprising Ball was captured at Coventry. He was tried and hanged at St.. Albans on July 15, 1381. Knowledge of Ball's career is derived almost entirely from prejudiced chroniclers. Froissart calls him "the mad priest of Kent."

See G. R. Owst, *Literature and Pulpit in Medieval England (1933).* (T. B. P.)

BALL, THOMAS (1819–1911), U.S. sculptor whose best-known work is probably the equestrian statue of George Washington in the public gardens in Boston. Mass., was born at Charlestown, Mass., on June 3, 1819. After starting, self-taught, as a portrait painter he turned his attention in 1851 to sculpture, his earliest work being a bust of Jenny Lind.

At the age of 35 he went to Florence for study. There. with an interval of work in Boston (1857–65), he remained until 1897, when he returned to the United States and lived in Montclair, N.J., with a studio in New York city. His work includes many early cabinet busts of musicians (he was an accomplished musician himself). Josiah Quincy in City Hall square, Boston; Charles Sumner in the public gardens of Boston; Daniel Webster in Central park. New York city; the Lincoln "Emancipation" group at Washington, D.C.; Edwin Forrest as "Coriolanus," in the Actors' home, Philadelphia, Pa.; and the Washington monument in Methuen, Mass., are other examples which had a marked influence on monumental art in the U.S. and especially in New England. In 1891 he published an autobiographical volume, *My Three Score Years and Ten.* He died at Montclair on Dec. 11, 1911.

BALL. The ball is probably unrivaled in the long history of recreation. From prehistoric times the ball has been used, and ball play engaged in by young and old. The ball is mentioned in the earliest recorded literatures and finds a place in some of the oldest graphic representations. Homer and other early writers reported that the ancient Greeks found ball play particularly appealing and that it came to be much valued as a means of giving grace and elasticity to the figure. Homer was appealing to a sympathetic audience when he described, in the *Odyssey,* how the Princess Nausicaa and her maidens "fell to playing at ball" in Scheria (Corfu), that far-off land of the Phaeacians washed by the utmost tides of ocean; and again, when the wanderer reaches her father's palace, how Halios and Laodamas played a ball game, accompanied with dancing, before Alcinous and Odysseus. Though the Hebrews were the least athletic of races, Isaiah must have been sure of his simile being understood when he wrote: "He will surely turn and toss thee like a ball"; and some form of ball game is portrayed on early Egyptian monuments. Even among the Romans, who disliked participation sports, ball play was extremely popular. The Roman baths had an apartment set aside for ball play, and many gentlemen had ball courts in their private villas.

From early descriptions, both literary and graphic, and from models recovered in archaeological explorations, it is known that the ancient ball was usually made of leather strips sewn together and filled with various materials. The smallest, the *harpastum,* was a hard ball stuffed with feathers. The largest, the *follis,* was truly pneumatic in that it contained an air filled bladder and was quite similar to a modern soccer or basketball.

Many early games were merely variations of catch ball and required no fixed number of players. The ball was simply thrown back and forth among a group of individuals. Comparatively recent archaeological discoveries; however, have revealed the existence of genuine team games and competitions among the Greeks. Ball games were especially popular at Sparta, and the name "ball-player" was in use as a designation for youths who engaged in these games. A game popular among both Greeks and Romans was called *harpastum,* after the ball with which it was played. Basically, the game involved passing the ball from one player to another so as to avoid a third player between from gaining possession, but whether this was a true team game or merely a participation sport is uncertain. An analogy between this game and Rugby football has been claimed, but the resemblance is very slight.

Another early game known as *episkyros* is perhaps a truer anticipation of Rugby football, at least in the arrangement of the playing field. This game involved the use of two teams of equal numbers. In the centre ground between the two teams a white line was laid out, and at some distance behind each team another line was marked. The play consisted in throwing the ball back and forth until one team in the exchange was finally forced back over its rear line. One relief that has been recovered actually depicts this game.

There is no doubt that hall playing also was of great antiquity in western Europe. While it is difficult to discover the specific origin of various games played during the middle ages, it is known that a number of games, football, tennis and golf (*qq.v.*) for example, came to enjoy a high degree of popularity during the 15th and 16th centuries. Lacrosse (*q.v.*) was well established in the new world before Columbus sailed the Atlantic.

On examination, the early games are seen to be rather loosely defined, and accordingly the varieties of balls in use were few and comparatively simple. It is only through the development and refinement of skills required in games using the ball alone, and more particularly in games involving the use of various implements for striking it, that the specialization resulting in the modern multiplicity of ball types was reached.

The weight and circumference of various balls have been changed as the rules of the individual sports have been refined and developed over the years. Many sports have made certain changes in their ball specifications on advice from manufacturers, participants and spectators. Athletic officials have also agreed to changes in specifications in order to conform with alterations in other equipment used in a sport. A number of changes in ball construction have been made in order to increase the interest of the spectators. An example of this is the change made in the American football from the egg-shaped Rugby ball to a more elongated shape which was easier to throw with accuracy. This change increased the opportunity for diversification in the style of play and changed the sport from a rather dull and endless running game to one in which the forward pass played an exciting role.

A somewhat similar. change took place in baseball which. prior to World War I. was a tightly played game of defense which resulted in lower scores. A livelier ball was introduced about 1920 so that offensive play would be dominant.

In many sports the specifications of the ball have remained unchanged, except for minor adjustments, since the inception of the particular sport, the governing bodies of the various sports having adhered to the earlier ball specifications as much as possible in order to conform with the original playing areas and the original implement if one is used. There has been an increasing use of man-made in place of natural materials in the manufacture of balls.

For specifications of balls used in various sports *see* BASEBALL; BILLIARDS; BOWLING; FOOTBALL; TENNIS; etc.; *see* also Index references under "Ball" in the Index volume. (HY. W. J.)

BALLAARAT (BALLARAT), a city of Grenville and Grant counties, Victoria, Austr. It includes the borough of Sebastopol and portions of the shires of Ballaarat, Bungaree, Buninyoug and Grenville. It is situated at a height of 1.416 ft. in the central highlands of the state, astride the valley of the Yarrowee river! 70 mi. W.N.W. of Melbourne by road and 74 mi. by rnil. Pop. (1954) 39.945. Its name is derived from two aboriginal words meaning "resting place." The largest inland city of Australia Ballaarat has an Anglican and a Roman Catholic cathedral, a

school of mines and industries containing an art school, an art gallery, a historical museum and 1,787 ac. of reserves and recreation grounds, including Lake Wendouree near the heart of the city. The South Street eisteddfod takes place every year and the begonia festival is celebrated annually in March. Ballaarat is the centre of a rich agricultural and pastoral district whose chief crops are potatoes and oats and whose merino wools have always had a high reputation. It is also an industrial and commercial centre, producing woolens, agricultural and industrial machinery, flour, leather goods, bricks, chemicals, valves and art paper.

Gold was discovered in 1851 and Ballaarat quickly became one of the foremost mining towns of Australia. Its early history was marred by the incident of the "Eureka stockade" in 1854, when about 30 local miners, who were among those demanding the abolition of licences and political reform, were killed in a pitched battle with the military. Although the miners lost the day, they won their democratic rights within the state parliament. The "Welcome" nugget, weighing 2,217 oz., was found in shallow ground at Bakery Hill in 1858 and was only one of a number of large nuggets unearthed. However, the surface (alluvial) deposits were soon worked out and afterward reef mining, to depths of 2,000 ft. and more, prevailed until c. 1910 when the industry ceased. (H. R. MA.)

BALLAD. The name is given to a genre of narrative song perpetuated by oral tradition; the genre is characterized by certain features of style and treatment, being simple, concrete and unimpassioned in diction, fairly uniform in metre and rhythm, compressed in narrative scope, objective and impersonal in presentation, usually dramatic in structure and suggestive of the elemental and archetypal in its effect. The melody is repeated for each stanza, which is usually of four verses (*i.e.*, lines). This form of song is shared by most European peoples and has been carried to other areas such as the English, French and Spanish-speaking parts of the new world. Since ballads exist as orally transmitted songs, they have been preserved only by fortuitous noting down and printing, or in modern times by concerted efforts at collection. Much that we wish to know about them has been irretrievably lost.

Since they are handed down traditionally, we know them only as anonymous compositions. But their anonymity extends beyond the mere loss of the authors' names, for in successive performances many singers have worked their changes upon any one ballad. The fluidity of musical and textual substance is at the heart of the nature of a ballad. This fluidity operates within traditional restraints, for the changes made by the tradition-bearer are devoid of artful niceties and individualistic turns. Compare Browning's "The Glove," or the poems by Leigh Hunt and Schiller about the same incident, with the ballad "The Lady of Carlisle" for an illustration of the differences between traditional ballad and the poet's poem. Arnold's "Forsaken Merman" and Goethe's "Erlkonig" use themes from ballads—the poems owe their being to folk song—but they are unmistakably not ballads. Many an author has tried to imitate the ballad; his trade-mark is usually discernible. The marks of the ballad are the structural, rhetorical and stylistic necessities imposed by the process of oral transmission; although its origin may be obscure and it may tell a story, a song lacking the shaping effects of traditional rendering is not a true ballad.

Since the word "ballad" has at various times been applied to many kinds of popular verse, students of folk song frequently choose to qualify the term by the adjectives "popular" or "traditional." Ballads are a variety of folk song, but they are sufficiently a group in themselves to be classed separately. The distinction was first argued by William Shenstone in 1761 in letters to Bishop Thomas Percy, where he suggested use of the term ballad to distinguish the narrative of "action" from songs that were expressions of sentiment. Shenstone professed to be merely following "the ordinary opinion of the world, at last," and the distinction has been confirmed by later usage. Percy conceded the distinction, for "Ancient Songs and Ballads" appeared as the running title in his Reliques of Ancient English Poetry (1765), the first significant publication in British balladry. The word derives from late Latin *ballare,* "to dance," which has helped to confuse the history of the ballad with dance song. "Ballad" was used indiscriminately after the 15th century to refer to any kind of simple or popular song; before that it had been used in English to describe a poem of complex structure, French in origin (see BALLADE). Since the 18th century the word has been used increasingly in the particularized sense. Conversely, what we now call a ballad went by many names—song, tale, ditty—during earlier centuries. In other languages various names are used: in German, *Volkslied;* in Danish, Folkevise; in French, chanson *populaire,* or romance after the Spanish usage; in Russian, bylina.

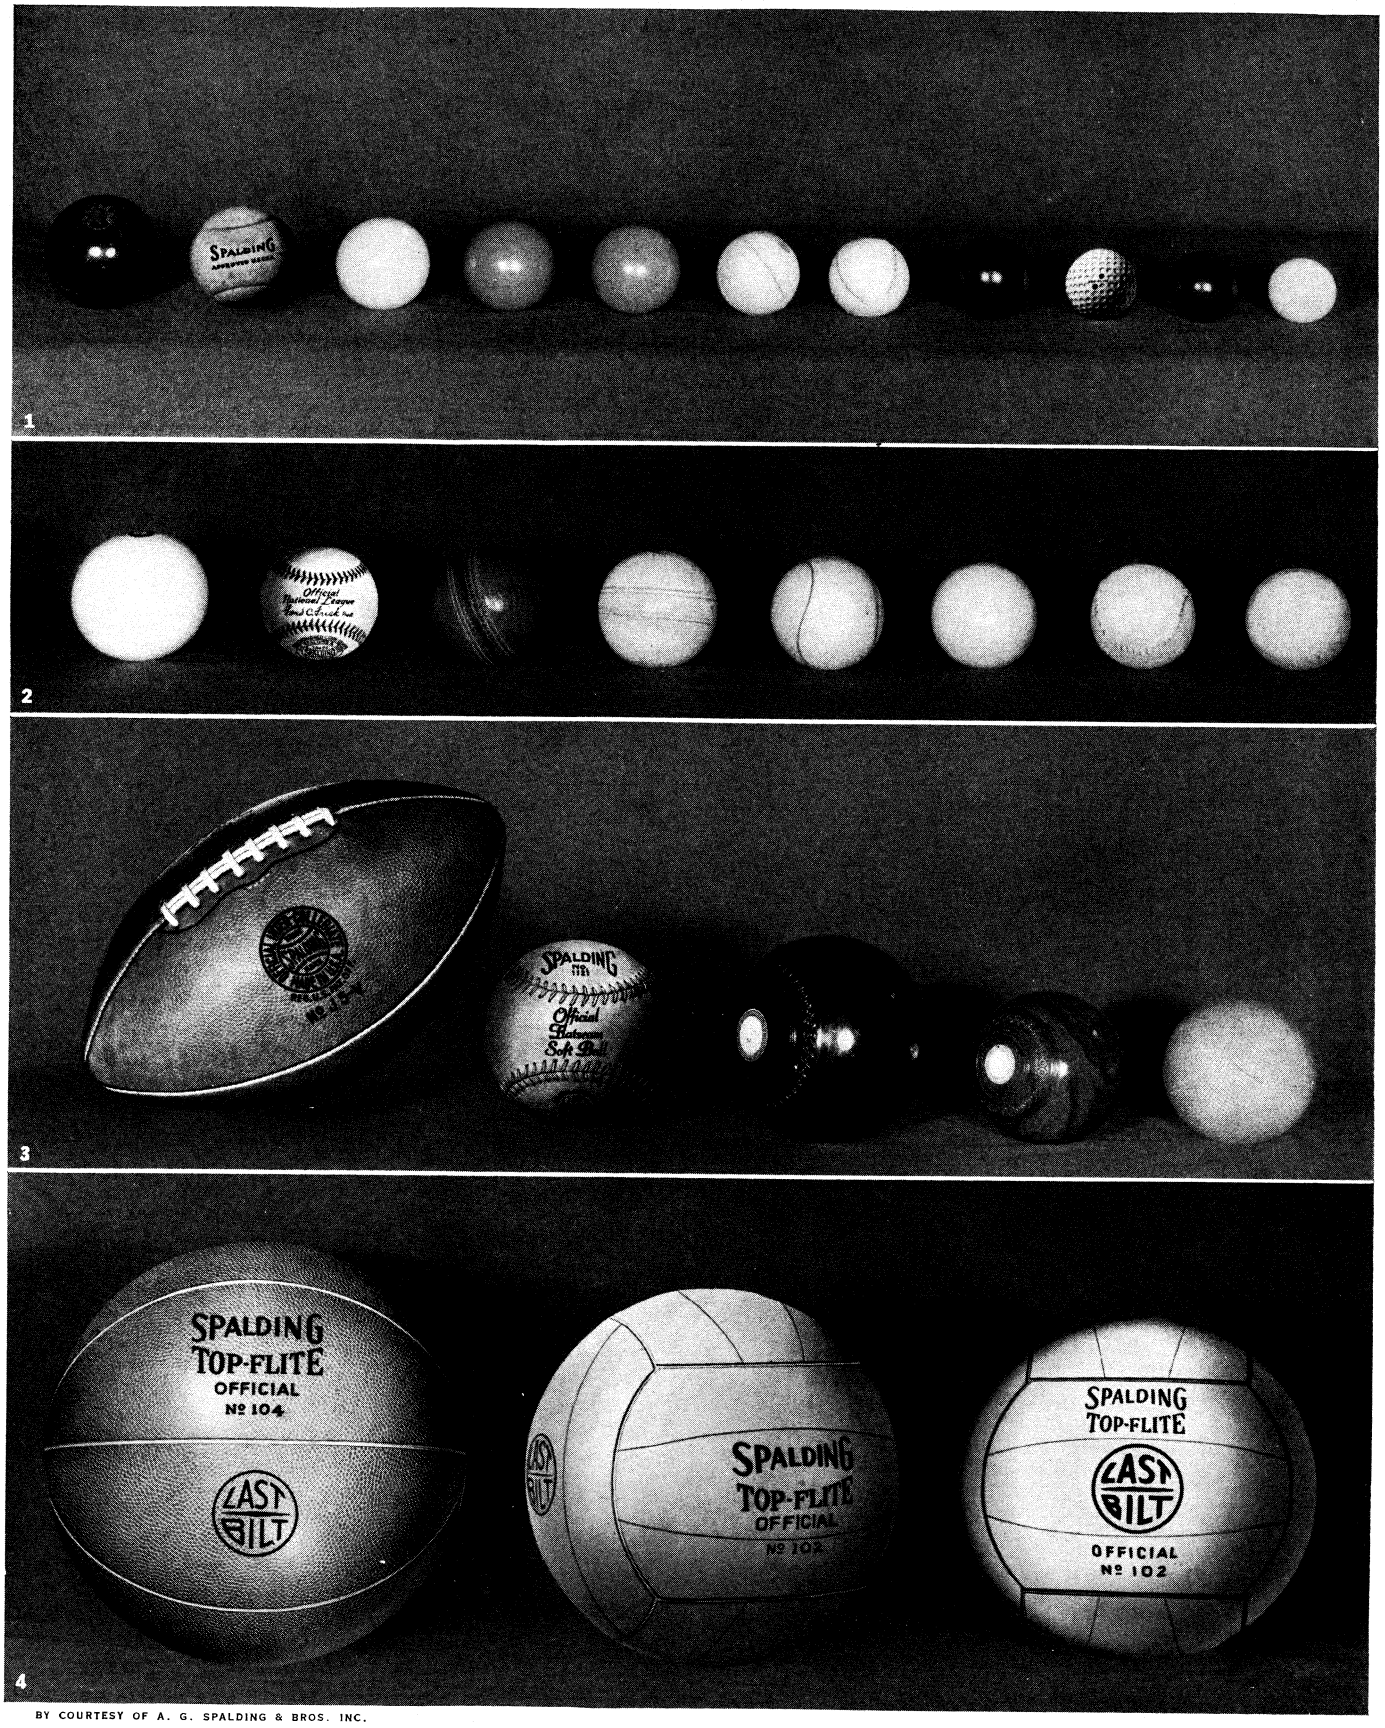
Critics hesitate to define the genre too narrowly, for by its very nature it is hard to circumscribe precisely. It differs in important respects from one linguistic area of Europe to another, and yet Spanish romances, Russian *byliny* and Scottish ballads belong to the same genre in spite of differences. Even within a single language community like the English-speaking one, there is considerable diversity in the body of narrative folk song comprehended by the term "ballad." Describing ballads by example, W. P. Ker said (in his lecture On the History of Ballads, 1100–1500, Proc. of the Brit. Acad. IV, O.U.P., 1910): "'What is a ballad?'—'A ballad is The Milldams of Binnorie and Sir Patrick *Spens* and The *Douglas* Tragedy and Lord Randal and Childe Maurice and things of that sort.' " These all appear early in the most important collection of ballads in English, Francis James Child's English and Scottish Popular Ballads, 5 vol. (1883–98). A ballad is also "Jesse James" and "John Henry" and "Frankie and Johnny" and "The Jam on Gerry's Rock" and "Springfield Mountain" and things of that sort, to name a few ballads native to America and unknown to Ker in 1910. A ballad is also "Ridderen i Fugleham" and "La belle dans la tour" and "Graf Friedrich" and "Donna Lombarda" and "Djuk Stepanovič" and things of that sort, if we choose to consider the term in its full import.

Chief Characteristics.—Narrative.—Ballads all tell stories. The narratives are usually concentrated (Thomas Gray remarked that "Childe Maurice" began in the fifth act of the play); episodic, leaping from one Iink to the next in the narrative chain ("Sir Patrick Spens"); suggestive rather than explanatory ("Edward"). They often proceed by dialogue interchange, which gives them a dramatic air ("The Maid Freed From the Gallows"). Usually the narrative is held back by the lyrical devices of repetition and refrain.

Ballads seem to take up any story, but certain themes appear frequently. By far the commonest subject is love, usually with tragic consequences—love requited ("Sweet William's Ghost"), unrequited ("Barbara Allen"), stolen ("Little Musgrave and Lady Barnard"), betrayed ("Lord Randal"), complicated by family entanglements ("The Twa Sisters"). Other favourite subjects are superstitions of shape shifting (*i.e.,* weird and monstrous changes in the appearance of a person under the spell of a supernatural being) ("Tam Lin," "Kemp Owyne") and ghosts ("The Wife of Usher's Well," "The Unquiet Grave"), fights and forays ("Kinmont Willie"), romance themes ("Sir Lionel," "The Marriage of Sir Gawain"), riddles and tricks ("Captain Wedderburn's Courtship"). broad and gross humour ("Our Goodman"), religious legends ("The Cherry Tree Carol"), adventures at sea ("Sir Andrew Barton") or in the greenwood ("Robin Hood and Guy of Gisborne") and accounts of history and policy ("The Death of Queen Jane," "Lord Derwentwater"). The romantic and tragic ballads and the ballads of magic are among those with international analogues; the more strictly national ballads are those revealing a background of minstrelsy or based on historical events.

Oral Transmission.—In spite of their diversity of subject, ballads have a family likeness, for both the language and the music reveal that they are spread and passed on by word of mouth. The treatment of subject, the narrative technique, the rhetorical devices of repetition and commonplace, the off rhymes, the use of dialect, these are all concomitants of oral tradition. Ballads are shaped by such tradition, like folk tales, except that the formal devices of song such as line length, stanza structure and rhyme hold the ballad's phrasing in check.

International Connections.—Ballads differ greatly in their geo-



BY COURTESY OF A. G. SPALDING & BROS. INC.

BALLS USED IN POPULAR SPORTS, VARYING GREATLY IN SIZE AND CHARACTER

1. Left to right: Lacrosse; tennis; billiard; snooker; bagatelle; Eton fives; Rugby fives; large squash rackets; golf; small squash rackets; table tennis
2. Left to right: No. 1 (equestrian) polo: baseball: cricket; hockey; lawn tennis; lawn bowls jack; rounders; rubber stoolball
3. Left to right: Football; softball; crown green bowl; crown green jack; croquet ball
4. Left to right: Basketball; soccer ball; volley ball

graphical spread. Some are confined to an area like the Scottish Border country; others are widely distributed throughout Europe and America. An example is "Lady Isabel and the Elf-Knight," also known as "The Outlandish Knight," the most widespread of ballads. About a quarter of the Child ballads, it is estimated, are international. In these, not only is the narrative shape maintained in versions of the same ballad from different countries but the similarities of verbal phrasing underscore the relationships.

Ballad Tunes.—Sir Walter Scott heard the tunes to the ballads that he recorded and later published in his Minstrelsy of the Scottish Border (1802–03). but he did not write them down. Attention to the melodic side of ballads came late. In Child's collection the "Airs" from manuscript sources number only 55 and are relegated to an appendix. The vast store of tunes that we now possess is the work in the 20th century of field collectors who have come to the understanding that ballads are half tune. The first collector to realize this fully was Cecil J. Sharp (*q.v.*), who collected about 5,000 oral records from singers in England and in the United States. Two others responsible for great collections of tunes were Gavin Greig in Scotland and Phillips Barry in New England. Sharp spurred collecting in other regions of America by his success in garnering melodies from the Southern Appalachians. The tunes of the British and the American ballad tradition have been painstakingly brought together, grouped and edited by B. H. Bronson in The Traditional Tunes of the Child *Ballads* (vol. 1, 1959).

The analysis of tunes and of the families into which they may be grouped is a new direction in ballad study. Tunes in tradition undergo changes just as do texts. The modality of a tune may change, the melodic contour also; phrases may be transposed, repeated or replaced; one tune may influence another; the tonal range may be altered and the rhythm shifted. The scales to which ballads are sung indicate a medieval musical heritage, for they correspond to the ecclesiastical modes named after Greek tribes by Glareanus in 1547 Ballad music does not derive from ecclesiastical music, a frequent misconception; folk music and church music alike used the only scales, the modes. that were known in the middle ages. The modality of a tune depends upon the position of semitones in a seven-toned scale; their absence makes for gapped six- and five-toned scales. Most tunes collected from tradition are in the Ionian mode, our major diatonic scale, but whether the Ionian mode was more prevalent than the Mixolydian, Dorian, Aeolian, etc., in former centuries is a matter for conjecture. It may be that the others have given way to the seven-toned major scale. The rhythm of ballad tunes is usually in double time, conforming with and dictating the dipodic verse rhythm. Tunes and texts have a close interdependence, formal features such as line length, stanza length and abcb rhyme all being held in check by the structure of the melody. Stressed tones in the melodic contour tend to coincide with the important words in the text, an aspect of the control that oral delivery has upon the ballad. The variants of a single ballad are by no means always sung to the same tune or tune family, and conversely a tune family will serve as the musical vehicle for many differing texts. One cannot speak of an original or right tune for any narrative. The tunes are not international in scope to the same degree as the texts.

The Age of the Ballads.—Considerable debate has taken place as to the dating of ballads and their place in the history of literature. The matter of dating involves three separate questions: "When did ballads make their first appearance in western Europe?" "What are the dates of the manuscripts and early printings that provide documentary evidence of ballads?" and "In what period did the ballads flourish?"

Some scholars at the turn of the 19th century, among them Francis B. Gummere, used the then new anthropological evidence to demonstrate that primitive peoples sang and danced to impromptu narrative verses suggestive of ballads. This school of thought equated ballads and the ballad dance with the beginnings of poetic expression in any society, and consequently the ballad in European languages was viewed as a retention of a primitive form that had its roots in prehistory (see F. B. Gummere, *The* Beginnings of Poetry, 1901). A less hypothetical approach to the evidence was bound in time to displace such a theory, and the tendency in accounts about ballads has been to assign a later date to the beginning of the genre. The oldest ballad recorded in any language exists in English, in a manuscript dating from the latter half of the 13th century. Some would deny that "Judas," in the Trinity college, Cambridge, manuscript is a true ballad; its way of treating a biblical story, its dialogue and repetitions, however, all suggest the ballad. The next record is two centuries younger, and by actual count fewer than 10 complete ballads are preserved in English in sources before 1600. The documentary evidence about balladry is then preponderantly from modern times. Early historians of poetry thought of the form as medieval, and in chronological surveys it became conventional to treat the ballads as if they belonged to the 15th century, the transition period between the middle ages and modern times. Such relegation of the ballads to a medieval limbo. treating them as "the literary debris of the middle ages," is not accepted by later scholars. Louise Pound demonstrated, for instance, that the historical materials in English and Scottish balladry are largely from the 16th and 17th centuries, and American ballads reveal the emergence of an entire ballad tradition in relatively modern times. Like a number of American ballads, "The Cowboy's Lament" or "The Streets of Laredo" dates from the era of western expansion; but it derives from earlier British songs with antecedents that have been traced to the 18th century. The vigorous "Sam Hall" has its roots in even earlier British song. It would be foolhardy to say arbitrarily that any one age is a ballad age.

In later centuries it is clear that ballads have been a living tradition in rural and backwoods communities. but at times they have also been perpetuated by upper levels of society. The beginnings of the ballad as we know it cannot be pushed back beyond the emergence of rhyme in English about 1100. Since actual ballads cannot be cited from a period earlier than the 13th century, it would seem unreasonable to date the inception of the genre before then. Tacitus mentioned the *cantilenae* of Germanic tribes. but there is little reason to believe that they resembled the ballads. The documentary evidence for British ballads increases the nearer one approaches modern times. Not until the late 18th century does the evidence become sizable, and not until the 19th does it become rich. In the 20th century the number of variants of ballads uncovered by assiduous collecting has increased tremendously; the collector does not find new ballads so much as add to the store of variants of known songs.

How many ballads are there in tradition? The question has been complicated by the shifting notions about ballads and by the classifications different editors and critics have employed. From the mass of popular verse that his predecessors had collected and published, Francis James Child for his standard edition chose 305 ballads with their variants. Issue is taken at times with his procedures of inclusion and exclusion, some arguing that he admitted too many. others that he admitted too few. Native American balladry has greatly increased the number of ballads in the English language, although no one has chosen to establish a count. Denmark's ballad account in *Danmarks gamle* Folkeviser (edited first by Svend Grundtvig. who issued vol. 1 in 1853) closes with the number 539, and the Danish collection purports to be almost entirely medieval song. The Danish ballad record is considerably earlier than the English (excepting "Judas"), for in the 16th and 17th centuries it mas the practice of the Danish gentry to write ballad texts into commonplace books. The ballads provided song accompaniment for the aristocratic long dance (in our own time a gesunkenes Kulturgut in the Faeroe Islands). The earliest of these books is known as the Karen Brahe manuscript; it contains 203 ballads written down about 1550. In 1591 Anders Vedel published his Hundredvisebog and Peder Syv in 1695 published an edition of 200 ballads. The manuscript and printing traditions for ballads in Denmark are thus comparatively early.

Printing and Ballads.—Ballads have entered the area of more formal literature in two ways: as material for the broadside press and as models for the literary or imitation ballad written by the poet. Broadsides (the printer's term for single, large sheets of paper) containing all forms of popular verse were issued by the

commercial presses almost from the time of the earliest printers. From the 16th to the 19th centuries there is a horde of such ephemeral verse, much of it of interest only to the historian and student of popular taste. The printing of traditional ballads on such broadsides preserved copies of songs or variants of songs that might otherwise have been lost. The poetasters on occasion reworked the substance of ballads for printing, and their handiwork can be recognized. Comparison of a traditional version of "Riddles Wisely Expounded" (no. 1 C in the Child collection, taken do n from recitation by William Rfotherwell early in the 19th century) with the 17th-century broadside copy in the collection made by Samuel Pepys (Child no. 1 A) reveals the false notes of supposed elegance and rectitude that the broadside poetaster is responsible for. The bathos of phrasing, the latinate vocabulary, the abstract terms, the moralizing conclusion, the intrusion of the "maker" into the song, all these are marks of an alien influence on traditional verse.

The widespread story of a revenant coming on horseback to seize and carry off his grieving love in a wild ride to his grave exists in English in a broadside form under the title "The Suffolk Miracle." Since it was such a fine ballad in other European tongues, Child included it in his collection in spite of thinking that it might "be classed with the vulgar prodigies printed for hawkers to sell and for Mopsa and Dorcas to buy." This ballad has since Child's time been collected from tradition in variants markedly superior to the earlier known broadside. Whether the oral texts are derived ultimately from the broadside printings of the 17th century is hard to say; Phillips Barry thought that the Scotch-Irish oral tradition of this ballad was independent of the broadside and doubtless older. "The Suffolk Miracle" demonstrates the relations of broadside printing and a tradition of song orally transmitted. Printing has crossed oral tradition, and probably few ballads are free of this helpful crutch to memory and the editing and "improving" that printing has usually entailed. The tale of "The Suffolk Miracle" was turned by Gottfried August Burger (*q.v.*) into the famous literary ballad "Lenore," thus illustrating the other contact between the popular ballad and literature. At the end of the 18th century men of letters developed a great interest in folk song. The term "ballad revival" is used to describe this interest, which ranged in time from Percy to Scott. The literary ballad became a fashion with the romantic school in Germany and Great Britain particularly. The language of the common man, the narratives of wonder and superstition, the four-lined stanza, these became hallmarks of a poetic tradition that Herder, Goethe, Scott, Coleridge, Keats and others derived from the ballads.

The Study of Ballads. — The main activity in ballad study since the beginning of the 19th century has been collecting and editing. Collecting may be a separate task, as in field collecting (often with phonograph or tape recorder). The fruits of such collecting increase the holdings of such repositories as the Folk Song archive of the Library of Congress, the libraries of the British Broadcasting corporation and of Cecil Sharp house in London, Das Deutsche Volksliedsarchiv in Freiburg, and Dansk Folkemindesarnling in Copenhagen, to name only a few. The editor is also a collector, however; Grundtvig and Child thought of themselves primarily as collectors, although the first great analytical contiibutions are also found in their editions. Collections are made in libraries as well as in the field. There have been three main phases in this era of collection. The first extends to the mid-19th century. It is characterized by the gentleman amateur preserving "reliques of antiquity" for a "polished age," atoning for rudeness of style and taking liberties with the text. The second period is the age of emergence of scrupulous editing and scientific scholarship; it is dominated by the work of Grundtvig and Child. In this period the significance of the variant is recognized. The third era results from Sharp's insistence on the music as of equal importance with the text. There has been a comparable scholarly development in other lands, although the Anglo-American, Danish and German ballads are more adequately edited and presented for scrutiny than those from elsewhere.

During the early part of the 20th century there took place a fierce scholarly debate, now only of historical interest, on the origin of ballads. The case for a communal origin of ballad poetry, championed by Gummere, was based on the assumption that ballads represent that variety of spontaneously created poetry that a throng might produce in co-operative dance and ritual observance. His ideas were compounded of too narrow an interpretation of German romantic asseverations like Uhland's *die Volker dichten*, (too literally read by Gummere as "the folk compose"), together with the application of the evolutionary principle to literature with the ballad regarded as the primal protoplasm. There were many attacks on the communalists, the most direct being that by Louise Pound in her *Poetic Origins and the Ballad* (1921). The "ballad war" proved of value primarily because of its by-products: scholars came to understand ballad style and language better, they perceived differences in narrative structure, they documented such stylistic devices as "incremental repetition" and they examined all the external historical evidence available. **A** balanced position between the communalists and the individualists is that taken by G. H. Gerould, summed up by the phrase "communal re-creation," by which is stressed the shaping effect of oral transmission.

Other major concerns of scholars include cataloguing and classifying of the materials collected and the preparation of bibliographic aids for further study; study of individual ballads and their changes through time; analysis of international connections and the dissemination of ballads. But ballads are not of interest only to the scholar; since the 1930s the general public has been receptive to a growing avalanche of recorded ballad music that bespeaks a 20th-century ballad revival. Discographies (lists of recordings) appear in most modern editions of ballads. The new and wide interest in ballads raises new questions of classification and judgment of performance and of the song performed—the authentic as opposed to the commercialized folk song, purism as opposed to eclecticism.

BALLADE, a fixed form of verse best exemplified in French literature, allowing considerable variation within precise limits and capable of great complication *(ballade laie; ballade triple; ballade balladant; ballade dquivoque, rdtrograde et léonine)*. Basically it consists of three stanzas and an envoy, the final lines of each stanza and of the envoy being identical (the refrain). The whole poem is constructed on three or four rhymes, masculine and feminine mixed, for preference, recurring in the same order in each stanza, the rhymes of the second part of the stanza being repeated in the envoy. These rules, gradually evolved from Guillaume de Machaut (*c.* 1300–1377) onward, are set out in Jean Molinet's *Art et Science de Rhe'torique* (printed in 1493), where it is further laid down that the length of the stanza is determined by the number of syllables in the refrain. An eight-syllable refrain, for example, requires eight-line stanzas; thus a possible four-rhyme pattern for a *huitain* would be *ababccdD* or *ababcdcD*. François Villon does not always observe this correspondence between syllables and lines (*e.g.*, in his "Ballade et

Oraison": "Père Noé . . ."). The envoy is sometimes omitted in both French and English ballades (as by Charles d'Orléans and Villon; Chaucer and many others); it may vary in length from four to seven lines, as in Villon's "Prière à Nostre-Dame" and "La grosse Margot" (cccdccD). Molinet required it to begin with *Prince,* or some similar form of address to a patron or literary judge. This is not the case with most of Charles d'Orléans' envoys nor always with Villon's *(see,,* for example, his "Ballade de bonne doctrine" and "La grosse Margot"). Among the most striking regular ballades ever written is. however, Villon's "Dames du temps jadis" of which the first stanza runs:

Dictes moy ou, n'en quel pays,	*a*
Est Flora, la belle Rommaine,	*b*
Archipiades, ne Thai's,	*a*
Qui fust sa cousine germaine,	b
Echo parlant quant bruyt on maine	*b*
Dessus riviere ou sus estan.	*c*
Qui beaulté ot trop plus qu'humaine?	*b*
Mais ou sont les neiges d'antan?	*C*

and the envoy:

Prince. n'enquerez, de sepmaine,	b
Ou elles sont, ne de cest an,	**c**
Qu'a ce reffrain ne vous remaine:	***b***
Mais ou sont les neiges d'antan?	*C*

The ballade had its origin in the Italian *canzone di ballo,* and developed toward its modern pattern through Provençal literature, to reach its most elaborate and highly polished form in the 14th and 15th centuries in France where, from the reign of Charles V, it flourished and became popular. Machaut and the *Livre des cent Ballades* occasionally offer heterometric stanzas (*i.e.*, with one shorter line). Eustache Deschamps and Georges Chastellain vary the number of lines up to 13 (with feminine alexandrine refrain); Charles d'Orléans favours the eight- or nine-line stanza (once with five-syllable lines). Jean Froissart, Alain Chartier. Christine de Pisan and Henri Baude were experts in the ballade, but the undoubted master of the genre was François Villon (*q.v.*). Clement Marot. Mme. Antoinette Deshoulikres. Jean François Sarrazin. Vincent Voiture and Jean de La Fontaine used it with skill. but, attacked by Molière and Nicolas Boileau-Despréaux, it fell into disfavour. It was revived, some 200 years later, by Théodore de Banville, whose *Trente-six ballades joyeuses* (1873) found many imitators.

In no other language except English has this typically French form found favour. In the 15th and 16th centuries many ballades were written, with more or less close attention to the French rules, by English poets. in particular by Chaucer. by John Gower (whose surviving ballades, however. are all in French) and by John Lydgate. After the 16th century original ballades were no more written in English until the end of the 19th century, when they were reintroduced successfully by Andrew Lang. whose *Lays and Lyrics of Old France* (1872) was the first published work to revive the ballade in its pure form: by Austin Dobson. whose "The Prodigals" (1876) is an example of a correct English specimen: by Swinburne and Rosetti. both notable for their translations from Villon; and by Edmund Gosse and W. E. Henley. At the same time ballades were being written in the United States, where they were even more popular than in England, by Oscar F. Adams, Brander Matthews and Clinton Scollard, among others. In the 20th century G. K. Chesterton wrote successful ballades.

See G. Lote, *Histoire du vers français,* vol. ii, pp. 270–285 (1949). (F. J. WE.)

BALLAD OPERA, a type of opera peculiar to England, where it originated in the 18th century. The plots were usually in the nature of a burlesque or extravaganza while the music, mainly confined to songs or interludes interspersed in the spoken dialogue, was based on popular tunes, at first ballads or folksongs to which new words were adapted, and later often tunes borrowed from the works of well-known composers. The most famous and one of the earliest ballad operas was *The Beggar's Opera* (1728), a satire on contemporary politicians and Italian opera, on a text by John Gay, with music adapted by John Pepusch (*qq.v.*). It had many imitators, and music for ballad operas was adapted or composed by Thomas Arne, Charles Dibdin, William Shield. Samuel Arnold, both Linleys, William Jackson, James Hook and Stephen Storace, among others. The ballad opera also had an influence abroad, and by its affinities with the French vaudeville, led to the development of *opéra comique* and of the German Singspiel. In England it developed into the light opera of Gilbert and Sullivan and, indirectly, through musical comedy (*q.v.*), into the modern "musical." In the 20th century there have been notable revivals of early ballad operas, and also, closely connected with the revival of folk song, attempts, both in England and in the United States, to revive the form itself, the most notable being Vaughan Williams' *Hugh the Drover.*

See E. Walter White, *The Rise of English Opera (3951).* (Cs. CH.)

BALLANCE, JOHN (1839–1893), New Zealand statesman, who, as prime minister (1891–93), initiated much progressive and enlightened legislation, was born at Glenavy, Antrim, Ire., on March 27. 1839. A farmer's son. he worked as an ironmonger in Birmingham, Eng., where he acquired political, economic and literary interests. He emigrated to New Zealand in 1865 and settled at Wanganui, where he founded the *Wanganui Herald.* He entered parliament in 1875 and supported the Liberal policy of leasing rather than selling crown lands. As colonial treasurer in Sir George Grey's cabinet (1877–79), he imposed a tax on unimproved land values. As minister of lands and native affairs. in the Stout-Vogel government (1884–87), Ballance promoted village settlements, putting poor men on farms of 20–50 ac. at low rents with small advances for initial expenses, but with limited success.

When the Liberals came to power with a sound majority in 1891, the country was ripe for substantial changes and, in particular, for the breaking up of large estates and for the closer development of the land. Organized labour, defeated in the maritime strike of 1890, turned to parliament to win security. Ballance, who became prime minister, had able men in his government: Pember Reeves as minister of education, justice and labour; R. J. Seddon as minister of mines and public works; and John Mackenzie as minister of lands and immigration. Despite heavy opposition from the legislative council much was effected. The property tax penalizing improvement was replaced by Ballance's graduated income and land taxes which pressed on large estates. The government gained the right to repurchase private lands to develop them effectively. On crown land perpetual leasing at low rents was favoured, while purchasing the freehold, though not prohibited, was discouraged. Reeves began his series of acts that in five years gave what was then the most progressive labour code in the world, by removing abuses in factories and shops and by prohibiting payment of wages except in money; coal mines were also regulated. The legislative council was made more docile by reducing life membership to seven years, and Ballance was also responsible for the introduction of female suffrage, though this was not brought about in his lifetime.

Ballance combined liberal fervour with a sense of detail, 'chose and handled his colleagues well, was tactful, courteous and humane. He was still in office when he died on April 27, 1893. (N. M. TA.)

BALLANCHE, PIERRE SIMON (1776–1847), made a distinctive contribution as a religious and social philosopher to French thought and literature during the first half of the 19th century. He was born at Lyons on Aug. 4, 1776. His outlook was fundamentally Catholic, but he also owed much to the views of J. Böhme, J. G. von Herder, G. B. Vico, C. Bonnet and the Illuminists *(see* ILLUMINATI) of Lyons. His *Du Sentiment considéré dans ses rapports avec la littérature et les arts* (1801) anticipates Chateaubriand's *Génie du Christianisme.* The problems of post-revolutionary France turned his thought to the origins and purpose of human society. *Essai sur les institutions sociales* (1818), like *Le Vieillard et le jeune homme* (1819, re-edited by R. Mauduit, 1929), reveals a mystical conception of the relation between tradition and progress, and reconciles the principle of Christian monarchy with liberal humanitarianism. Ballanche offered many of his quasi-prophetic works as "epics," usually amorphous compositions combining illuminism with speculations about comparative mythology. Such are the *Essais de palingénésie sociale* (1827–29), an ingenious interpretation of the Orpheus myth, and two incomplete works: *Formule générale de l'histoire de tous les peuples*

appliquée à l'histoire du peuple romain and *La Ville des expiations* (1832–35, re-edited by A. Rastoul, 1926). Ballanche's basic theme is the "rehabilitation" of fallen man through *"épreuve," "expiation"* and *"initiation." Antigone* (1814) and *L'Homme sans nom* (1820) had exemplified individual and collective expiations; "initiation" is mainly collective. He rejects Rousseau's doctrines. Society is the divinely appointed instrument whereby mankind is gradually released from "fatality" and educated for freedom—willing conformity to the designs of Providence. History is a succession of social rebirths or "palingeneses" by which closed societies open out until at last all classes achieve civic status. This is the work of great "initiators" from Orpheus to Jesus, in whose teaching all future initiations are implicit. *La Ville des expiations* applies this doctrine to criminal reform, and forecasts a theocratic organization of society. *La Vision d'Hébal* (1831) presents these views in apocalyptic guise. Ballanche's writings (partly collected, four volumes in 1830, six volumes in 1833) are diffuse and ill-organized, but their peculiar blend of poetry and prophecy appealed strongly to successive generations of romantic writers. Ballanche died in Paris on June 12, 1847.

S. Ballanche* (1945); J. Roos, *Aspects litteraires du mysticisme philosophique . . . au début du romantisme . . . Ballanche* (1951). (H. J. H.)

BALLANTYNE, ROBERT MICHAEL (1825–1894), Scottish author of stories which remain popular for their presentation of heroes whose self-reliance and moral uprightness lead to lively adventure, was born in Edinburgh on April 24, 1825. A clerk in the Hudson's Bay company (1841–48), he based his first book for boys, *The Young Fur-Traders* (1856), on his own experiences. In *Coral Island* (1857) he made a mistake through lack of firsthand knowledge and thereafter traveled widely, sharing the lives of lighthouse-keepers, lifeboatmen, tin miners and salvagemen to confirm his facts. Among the best known of over 80 books are *Martin Rattler* (1858); *Dog Crusoe* (1860); and *The Gorilla Hunters* (1862). He died in Rome on Feb. 8, 1894.

BALLARD, the name of a family of printers who from 1560 to 1750 virtually had a monopoly of music printing in France. The founder of the dynasty was Robert Ballard (d. 1588) who was brother-in-law to Adrian le Roy, the celebrated lutenist and composer. These two used movable type, cut in 1540 by Robert's father-in-law, Guillaume le BC (or du Gué), and printed much secular and sacred vocal music and volumes of lute tablature. Their first patent was granted in 1552 as sole music printers to Henry II. Robert's widow and son Pierre (d. 1639) continued the business and further patents were obtained from Henry IV and Louis XIII. Robert's grandson Robert II ran the firm from 1640 to 1679, and it was taken over successively by Christophe (d. 1715), Jean Baptiste Christophe (d. 1750), Christophe Jean François (d. 1765) and Pierre Robert Christophe (d. 1812), who carried on management until 1788. Throughout the history of the family the women were often as active in the business as the men.

Ballard publications, both those with the early movable type and the later ones engraved on copper plates, were noted for their beauty and care of presentation. Their title pages were frequently superb examples of decorative engraving. The music published by the family represented practically all the French composers of the period. The extensive list includes lute tablatures by Adrian le Roy, organ music by Jean Titelouze, vocal works by Clément Jannequin, Claude Goudimel and Orlando di Lasso, Marin Mersenne's *Harmonie Universelle*, works by André Campra, François Couperin, Michel de Lalande, Michel de Montéclair, François Philidor, and Jean Philippe Rameau, and Lully's operas and ballets. (B. P.)

BALL BEARINGS: *see* BEARINGS.

BALLET. A form of theatrical performance in which classical dancing is employed, usually in conjunction with music, pantomime and painting (in costumes and scenery), to tell a story or to express a theme. The term is also used to denote the technique of the classic dance, as when a child studies ballet. The word ballet derives from the Italian *ballare* ("to dance"). Originally a court spectacle, in which performers as well as audiences were drawn exclusively from the nobility, ballet became popular with the general public as early as the 18th century, when itinerant troupes of dancers gave performances all over Europe, and even in America. Until the 20th century, however, ballet developed most luxuriantly in the sheltered atmosphere of the court theatre or state opera house. The extensive world tours of the great ballerina Anna Pavlova, between 1910 and 1930, the widespread activities of organizations such as the Ballet Russe de Monte Carlo, Ballet Theatre (now the American Ballet Theatre), the New York City Ballet, the Royal Ballet and, after 1950, the inestimable influence of dancing seen in motion pictures and on television, all contributed to a tremendous growth of interest in ballet. In 1955 a televised performance of Petr Ilich Tchaikovsky's ballet *The Sleeping Beauty*, danced by the Sadler's Wells (now the Royal) Ballet, was seen by an estimated 30,000,000 viewers.

DEVELOPMENT OF THE ART

Court Ballet.—Ballet, like opera, is directly descended from the court festivals of the Italian Renaissance. In the days of the Medici it was customary to honour distinguished guests with elaborate banquets lasting five or six hours. The entertainment at these feasts often consisted of a series of entrees, or interludes of music, poetry (sung or declaimed), pantomime and dancing, loosely linked together by a central theme. Costumes were lavish, and the scenery, built up in three dimensions in the centre of the banquet hall, was often magnificent. Leonardo da Vinci designed the settings for several of these festivals at the court of Milan. One such fete, given in Tortona, Italy, in 1489, has been called the first actual ballet performance. Bergonzio di Botta, a wealthy gentleman addicted to extravagant entertaining, arranged a banquet in honour of Gian Galeazzo Sforza, duke of Milan, and his bride, Isabella of Aragon. Between the courses, the story of Jason and the Golden Fleece was enacted in music and dance. The participants were members of the nobility, and the dances they executed were based upon the formal, elegant court dances of the period.

When Catherine de Medicis became queen of France, she introduced there the banquet entertainments of her native Italy. Rumour said that she hoped through these diverting spectacles to distract the attention of her son, Henry III, from affairs of state. At any rate she made ballet history when, on Oct. 15, 1581, she presented the *Ballet comique de la reine*, celebrating the marriage of the duc de Joyeuse and Marguerite of Lorraine. This is the first ballet of which there is a complete printed account. Its author and choreographer was Baldassarino de Belgiojoso (Balthazar de Beaujoyeulx), an Italian violinist whom Catherine had appointed official director of court festivals.' The story concerned the legend of Circe and was enacted through music, poetry and allegorical dances by the queen, her ladies and the nobles of the court. The *Ballet comique* was a brilliant success, and Belgiojoso (or Beaujoyeulx, as he was known in France) published a description of it in a sumptuous volume that might be called the first ballet libretto. His definition of ballet as "a geometrical arrangement of many persons dancing together under a diverse harmony of instruments" would apply to many works danced in modern times. (*The Art* of *Ballet*, Mark *E*. Perugini, p. 57; Martin Secker & Warburg, Ltd., London.)

In England, the Italian custom of masquerading during balls had been introduced during the reign of Henry VIII. It grew in popularity and gradually evolved into the English masque, a form of spectacle very similar to French court ballet. Ben Jonson, author of delightful masques, owned a copy of the *Ballet comique da la reine*, which is now in the New York Public library. Court dances, during this period, were of two general types: the *basse danse*, of which the stately and dignified pavane was an example, and the lively *danse haute*, typified by the merry galliard, favourite dance of Queen Elizabeth I, with its quick running steps, jumps and capers. A remarkable book called *Orchésographie*, published in 1588 by a priest, Jehan Tabourot, using the pen name of Thoinot Arbeau, described these dances with such clarity that they can be reconstructed today. Later, French and Italian dancing

masters, such as Cesare Negri, who published treatises in 1602 and 1604, were to polish and elaborate upon the simple steps of these popular dances until they became the foundation of the classical ballet technique.

For another century, however, ballets continued to be performed by aristocratic amateurs. The dances remained simple, but a wide range of subject matter offered ample opportunity for resplendent display in costumes and décor. One early 17th-century ballet dealt with the regions of the upper air, and entrees represented hail, fog, lightning, clouds, a comet and a shooting star. Tobacco was the theme of a ballet given in Turin, Italy, in 1650. Its scenes represented the smoking and snuff-taking customs of various nations, as well as Indian cultivation of the plant. Other ballets ranged from Curiosity (in which Idleness ran about hunting for False Rumours) to the exotic Ballet of the Seven Kings of China. In 1632, for the first time, ballet performances were open to the general public on certain occasions, instead of only to invited court guests.

Ballet Under Louis XIV.—During the long reign of Louis XIV, ballet developed into a serious art form. Fond of dancing in his youth, Louis participated in many performances at court. His name of le Roi Soleil ("the Sun King") originated when he took the part of the sun in Ballet de la *nuit* in 1653, when he was 15. Louis gave up performing at 30 but throughout his lifetime remained an enlightened patron of ballet. Artists of genius were attracted to the French court, and such men as the dramatist Molière, the composer Jean Baptiste Lully, the poet Isaac de Benserade and the choreographer Charles Louis Beauchamp contributed to the development of the ballet. Their productions were conceived on a scale of unparalleled magnificence, but frequently they were hampered by a lack of trained performers. The form of Molière's comedy ballets, with the dance interludes spaced between spoken scenes, was actually dictated by the scarcity of skilled dancers. So few were available that Molière was obliged to allow time for them to change costumes and appear over and over again.

This shortage of dancers and the inability of the noble amateurs to keep pace with the increasing technical demands of professional dancing masters inspired Louis XIV to establish the Académie Royale de Danse in 1661. In the letters patent for its foundation, he declared that "Although the art of dancing has always been recognized as one of the most honorable, and the most necessary for the training of the body, . . . many ignorant people have tried to disfigure the dance and to spoil it . . . so that we see few among those of our Court and Suite who would be able to take part in our ballets, whatever scheme we drew up to attract them thereto. It being necessary, therefore, to provide for this, and wishing to establish the said art in its perfection, and to increase it as much as possible, we deemed it opportune to establish in our good town of Paris a Royal Academy of Dancing. . . ." (*The* Art of Ballet, Mark E. Perugini, p. 103; Martin Secker & Warburg, Ltd., London.)

The success of this academy, made up of the most experienced dancing masters of Paris, led Louis to found the Académie Royale de Musique in 1669 and to add a school of dancing, for the express purpose of training professional dancers, in 1672. These united organizations became the Académie Royale de Musique et de Danse, or Paris Opéra, which has remained for nearly three centuries a centre of ballet production.

Although court ladies frequently participated in royal divertissements, female roles on the public stage were played by young men until, in his ballet Le *Triomphe* de *l'amour,* in 1681, Lully introduced the first professional women dancers. A small ensemble was led by Mlle Lafontaine, the first *première* danseuse. The innovation was immensely successful; Lafontaine was called la reine de la danse. Elegance and dignity characterized the feminine dance of the time, for women's movements were hampered by their heavy costumes, similar to court dresses. Ballet was gracious and decorative but limited as a means of expression.

It mas Pierre Beauchamp, first choreographer of the Paris Opéra, who defined the five positions of the feet, on which classical ballet technique is based. He also invented one of the earliest forms of dance notation. There have been many attempts to formulate a script in which dances could be accurately recorded, just as musical compositions are written down. Beauchamp's system, which was partially successful, has come down to us through the publications of his pupils Raoul Ager Feuillet, whose Chore'graphie *où l'art décrire la* danse dates from 1699, and Louis Pécourt, who succeeded Beauchamp as choreographer at the Paris Opéra.

In the last years of the Sun King's reign, ballet sought new dramatic expressiveness. At a fete given by the duchess of Maine in 1708, Jean Balon (Ballon) and Françoise Prévost mimed the last act of Pierre Corneille's Les Horace. The musical accompaniment dispensed with explanatory words, but the dancers' pantomime was so lucid that the audience was moved to tears.

At about the same time, in England, John Weaver was making similar experiments in dramatic dancing. Probably influenced by the pantomimes of John Rich, the famous Harlequin, Weaver produced narrative ballets (advertised as consisting of "dancing, action, and motion only") such as The Cheats of Scapin, or, the Tavern Bilkers (1702) and The Loves of Mars *and* Venus (1716).

The Rise of the Virtuoso.—With the professional dancer firmly established, ballet technique developed rapidly. Women were still hampered by cumbersome costumes, but men were not so restricted, and soon began to explore the possibilities of pas *d'élévation,* or jumping steps. Jean Balon, who appeared at the Opéra from 1691 to 1710, danced with such remarkable lightness that this quality in dancing is still called *ballon.* He achieved extraordinary brilliance in spite of the fact that dancers habitually wore heeled shoes, which limited the flexibility of the foot. The traditional ballet costume for men, since the days when Louis XIV had danced the heroic roles of Greek gods and Roman warriors, had been the costume *à* la *Romaine,* or tonnelet, a stiff, bell-shaped, wired skirt of brocade or similar material, resembling in shape if not in lightness the tutus worn by ballerinas in modern times. Male dancers, and sometimes women, too, wore leather masks, comic or tragic in appearance, which represented the character portrayed and concealed all facial expression.

Marie Camargo, who made her Paris debut in 1726, was one of the first important innovators in the technique of the classic dance. Lacking in beauty and grace, she achieved great brilliance and virtuosity. Taught by David Dumoulin, she excelled in entrechats, jete's battus, cabrioles and other jumping steps formerly executed only by men. To show her twinkling feet, she shortened her skirts to the middle of the calf. She also adopted the *caleçon* de precaution, or close-fitting drawers, previously considered an unnecessary refinement. (Camargo is also credited with the invention of the heelless slipper.) Her favourite vehicle, a plotless divertissement typical of the period, was Les *Caractères* de la *danse,* a series of solo dances in contrasting styles, including the minuet, courante, saraband and *gigue.*

Camargo's rival, Marie Sallé, was noted for her extraordinary grace and expressive gesture. Probably influenced by her early appearances in London with John Rich, she rebelled against the formal construction of the *divertissements* presented at the Paris Opéra. In 1734, in London. she created a ballet called Pygmalion, which told the familiar story of the sculptor whose masterpiece came to life. As the statue, Sallé discarded the usual ballet costume, with its stiff panniers, and appeared in a simple muslin robe, her hair flowing. She attempted to unify the music, costume and style of dancing, thus anticipating the reforms of Jean Georges Noverre by a quarter of a century.

At the Paris Opéra, dancers concentrated on perfecting their technique, and such virtuosos as the brothers François, Pierre and David Dumoulin, Jean Barthélemy Lany and Louis Dupré continued to expand the vocabulary of ballet steps. The Paris appearances of Italian acrobatic and comic dancers, such as Pietro Sodi, Nicolini Grimaldi (father of the famous clown "Joey") and the spectacular Barberina Campanini, stimulated French emulation. Gaetan Vestris, the so-called "god of the dance," developed the broad, high leap or grand jete', still one of the most effective steps in classic ballet, and elaborated on the pirouette, or multiple turn on one foot, which was brought to Paris about 1770 by the German dancer Anne Heinel. Auguste Vestris, son of Gaetan, and his younger rival Louis Antoine Duport continued to experiment with

technique, until by 1800 men were able to execute incredibly high, sustained leaps and dazzling sequences of pirouettes.

Dramatic Ballet: The Ballet **d'Action** of **Noverre** and **Angiolini.**—Throughout ballet history, there has been an unending struggle between the exponents of the pure dance of formal, decorative beauty and virtuosity, and the advocates of dance as a means of dramatic expression. While technical advancement was making the classic ballet vocabulary a fluent language capable of expressing dramatic and emotional situations, theoreticians and choreographers were in bitter revolt against its use for purposes of mere acrobatic display. The most articulate and influential of the advocates of the *ballet d'action,* or drama in dance form, was Jean Georges Noverre, whose *Lettres sur la danse et sur les ballets,* published in 1760, is still considered the authoritative work on the subject. Nevertheless, the reforms advocated by Noverre were not so untried as he implied, for other choreographers had already achieved considerable success in this direction before he pointed the way.

The pantomimes of Rich and the early dramatic ballets of Weaver, as well as Sallé's *ballets d'action, Pygmalion* and *Bacchus and Ariadne,* were all staged in London. In Paris, in 1729, Sallé adapted the familiar solo work *Les Caractères de la danse* to duet form in order to give it a wider pantomimic range, and in it both she and her partner, Antoine Bandieri de Laval, discarded the traditional mask so that their expressions might be seen.

From about 1737 Jean Baptiste de Hesse, ballet master of the Théâtre Italien, Paris, staged a series of pantomimic ballets deriving from the commedia dell'arte. In 1753 he choreographed a tragedy in dance mime, *Acis et Galatde,* which seems to have been a genuine forerunner of the ballets of Noverre. Many of De Hesse's pupils, whom he trained as dance actors, later became stars of the Paris Opéra. Nevertheless his innovations seem to have had little influence on that stronghold of conservatism, and his name and works passed into oblivion.

In Vienna, about 1740, the choreographer Franz Hilverding was producing dramatic ballets such as *Britannicus,* based on Racine's tragedy, and *Alzire,* after Voltaire. For other themes he drew on Greek mythology, as in *Venus and Adonis* (1753), *Diane et Endymion* (1754) and *Ulisse et Circe* (1756).

Hilverding's pupil, Gasparo Angiolini, continued his work in Vienna and went still further in the development of the danced drama. In the preface to his ballet *Le Festin de Pierre, ou Don Juan* (1761). Angiolini stated: "If we can stir up every passion by a mute play, why should we be forbidden to attempt this? If the public does not wish to deprive itself of the greatest beauties of our art, it must accustom itself to be moved by our ballets and brought to tears . . . ."

Angiolini endeavoured to revive the ancient ballet pantomimes of the Romans, as he explained in the preface to his ballet *Semiramide* (1765). In both of these works, as well as in the original production of the opera *Orfeo ed Euridice,* he collaborated with the composer Christoph Gluck.

Although the work of his predecessors and contemporaries should not be minimized, it was Noverre who forcefully called attention to the decadent state of ballet in Paris and brought about extensive reforms. When he wrote his revolutionary *Lettres,* he was only 33 and ballet master of a provincial theatre in Lyons. Nevertheless he dared to challenge the potent authorities at the Paris Opéra. "A well-composed ballet . . . must be expressive in all its detail and speak to the soul through the eyes; . . ." he wrote, ". . . Steps, the ease and brilliancy of their combination, equilibrium, stability, speed, lightness, precision, the opposition of the arms and legs—these form what I term the mechanism of the dance. When all these movements are not directed by genius, and when feeling and expression do not contribute their powers sufficiently to affect and interest me, I admire the skill of the human machine, I render justice to the strength and ease of movement, but it leaves me unmoved . . . ." "Dancing," he continued, "is possessed of all the advantages of a beautiful language, yet it is not sufficient to know the alphabet alone. When a man of genius arranges the letters to form words, and the words to form sentences, it will cease to be dumb; it will speak with both strength and energy; and then ballets will share with the best plays the merit of affecting and moving, and of making the tears flow, and, in their less serious styles, of being able to amuse, captivate and please . . . ." (J. G. Noverre, *Letters on Dancing and Ballets,* trans. by C. W. Beaumont, pp. 16, 19–20, C. W. Beaumont, London, 1930.)

Noverre's theories shocked dancers who had spent all their lives mastering technical feats designed to entertain without stirring the emotions. His ideas were not welcomed at the Paris Opéra. In Stuttgart, Ger., London, Vienna and Milan, Italy, however. he carried out his theories in nearly 100 ballets, such as *Fêtes Chinoises* (about 1751), *Les Caprices* de *Galathde* (about 1758), *Psyche' et l'Amour* (1762), *Adele de Ponthieu* (1773) and *Les Horaces* (1774). Drawn by curiosity, Gaetan Vestris went to Stuttgart to observe Noverre's work and was so impressed that he returned each summer to dance in Noverre's ballets. In 1770 Vestris arranged for the production at the Paris Opéra of an abbreviated version of Noverre's *Mede'e et Jason.* The leather mask, which Noverre had attacked in his book, was still used by male dancers in Paris. Now, in the role of Jason, Vestris discarded it, revealing an unsuspected talent for acting. A little later Maximilien Gardel followed his example, and the mask fell into disuse. A trace of its influence remains in the chalk-white make-up of Pierrot.

In 1776 Noverre was finally called to the Paris Opéra. There, in the ballerina Marie Madeleine Guimard, he found the ideal interpreter of his *ballets d'action.* Her mime was as convincing as her technique was skilful. Two of his own pupils, Jean Dauberval and Charles Le Picq, carried out his theories in the ballets they produced in Italy, England. France and Russia. At the Grand theatre, Bordeaux, France, in 1789, Dauberval staged *La Fille mal gardée,* which shares with Vincenzo Galeotti's *The Whims of Cupid and the Ballet Master* (in the repertoire of the Royal Danish Ballet) the distinction of being the oldest ballets still performed in the early 1960s.

Noverre's theories were followed and amplified by the Italian choreographer Salvatore Vigano, a pupil of Dauberval. Long active in Vienna, he staged Beethoven's only ballet, *Prometheus,* in 1801 Whereas Noverre had been content to carry forward the dramatic action in long mimed scenes that alternated with formal dances, Vigano sought to achieve a synthesis of dancing and pantomime. In 1811 he became choreographer at La Scala, Milan, where, during the next ten years, he produced such heroic works as *Mirra, La Vestale, I Titani* and *Otello.* Vigano'assigned definite individual characteristics to each of his dancers and built up the roles of his ballets like those in a play. He was skilful in handling great masses of people and liked to work on a grandiose scale. The effectiveness of his method is attested by Stendhal, who wrote that the tragedian Edmund Kean in *Otello* and *Richard III* had not moved him as much as Vigano's ballets.

Le Picq, Dauberval, Vigano and a few later followers such as Gaetano Gioja and Louis Henry constructively developed the theories of Noverre. In Paris, however, Pierre Gardel and other Paris Opéra choreographers continued to stage conventional ballets, patterned after a routine formula, on subjects that had been popular a century earlier: gods and goddesses, nymphs and fauns, shepherds and shepherdesses. The advent of the romantic period was to bring new themes, new techniques and a new style of dancing.

The Romantic Ballet.— The spirit that infused the arts in the early years of the 19th century and that was expressed in the novels of Sir Walter Scott and Victor Hugo, in the music of Frédéric Chopin and Louis Hector Berlioz, and in the painting of Eugene Delacroix, found its perfect symbol in the dancingof Marie Taglioni. Fragile, delicate, lighter than air, she danced as though she were a disembodied spirit.

The innovations of Auguste Vestris and Duport, with their vigorous leaps and vertiginous pirouettes, had brought ballet technique to a high state of advancement by the time Taglioni began her training. Shortly after 1800—the exact date has never been established—women had begun to dance on the extreme tips, or points, of the toes. The possibilities of this new technical device had not yet been thoroughly explored, however, and it remained for

Taglioni to make such imaginative use of points that their introduction has often been erroneously credited to her. She used them so that she was able to achieve the actual illusion of flight. Trained chiefly by her father, Filippo Taglioni, Marie made her debut in Vienna in 1822. Ten years later, with the creation of her father's ballet *La Sylphide* at the Paris Opéra, March 12, 1832, she inaugurated a new era in the history of ballet.

"The old dancing did not appeal to the mind, but spoke only to the eyes," wrote Charles de Boigne, in his *Petits mkmoires de l'Opéra,* ". . . the dance was merely a profession, the profession of jumping as high as possible, and pirouetting like a top . . . ." Operatic ballets were still based chiefly on Greek legends, interpreted according to rigid balletic convention. Taglioni discarded ancient subjects for more romantic themes.

"After *La Sylphide,"* wrote Théophile Gautier, ". . . the Opera was given over to gnomes, undines, salamanders, nixes, wilis, peris —to all that strange and mysterious folk who lend themselves so marvellously to the fantasies of the *maître de ballet* . . . . The Greek cothurnus was exchanged for satin shoes . . . ."

The diaphanous dress worn by Taglioni in La *Sylphide,* with its fitted bodice and airy, bell-like skirt, was the prototype of the tutu, or full, light skirt which, in various lengths, has remained the accepted uniform of the classical dancer for more than a century. Ballet costume had undergone sweeping reforms at the time of the French Revolution, when the panniers and hoop skirts abhorred by Noverre were finally discarded in favour of clinging tunics inspired by Greek robes. Taglioni, noted for the modesty and purity of her dancing, had adopted a long, full skirt of the Sylphide type for *Flore et Zéphire,* two years before the creation of her most famous role. This was the costume she always preferred. It is still used in Michel Fokine's *Les Sylphides* (inspired by the earlier ballet) and, in adapted form, in modern works like George Balanchine's *Bourre'e fantasque.*

As the Sylphide, a forest sprite loved by a Scottish youth who abandons his fiancée for her, Taglioni created a whole new style of dancing marked by floating leaps, miraculously balanced poses (such as the *arabesque)* and a delicate, restrained use of the points. She followed her success in *La Sylphide* by other works similar in theme and likewise created by her father, *La Fille du Danube* (1836) and *L'Ombre* (1839).

In the meantime, a rival had appeared in the shape of Fanny Elssler, a Viennese dancer who epitomized the earthly aspects of romanticism and was at her best in the fiery Spanish *Cachucha* and the spirited Polish *Cracovienne.* Elssler conquered Paris in 1836, when she was 26. with the creation of the role of Florinda in *Le Diable boiteux.* This she followed with *La Gypsy* (1839) and *La Tarentule* (1839), both of which displayed to full advantage her warmth and vitality in *pas de caractère,* or theatricalized folk dances. In 1840 Elssler came to the United States. where for two years she danced with a success unprecedented in American theatrical history. Her popularity attained fantastic proportions, and she returned to Europe with a fortune estimated at $500,000. Elssler outstayed her leave of absence from the Paris Opéra by a year and a half, and on her return found its doors closed to her. She went to London and Italy, where during the next decade she found ample outlet for her varied gifts in the dramatic ballets of Jules Perrot.

The spectacular interest added to women's dancing by their recent conquest of a new plane, in dancing on the points of the toes, combined with the rare phenomenon of two contemporary but contrasted ballerinas of genius, Taglioni, daughter of the air, and Elssler, child of the earth, detracted from the importance of the male dancer and nearly caused the disappearance, in France at least, of male virtuosity in ballet. Perrot turned his attention to choreography and achieved renown for his excellent *ballets d'action,* in which all the rich resources of the ethnic dance were brilliantly adapted for the theatre. His finest works included *Ondine* (1843), *Esnzeralda* (1844) and *Catarina* (1846), all created in London, which he made an important ballet centre.

While Elssler was touring America, Taglioni was in Russia, and the post of leading ballerina at the Paris Opéra fell to a young Italian dancer, Carlotta Grisi, who combined the ethereal lightness of Taglioni with the appealing warmth of Elssler. For Grisi, Gautier wrote the ballet *Giselle,* produced at the Paris Opéra June 28, 1841. Combining as it does the two principal facets of the romantic ballet, through the colourful peasant scenes of the first act and the unearthly, haunting atmosphere of the second, *Giselle* has not only survived but has increased in popularity until it has become an indispensable feature of the repertoire of almost every ballet company. Its original choreography was by Jean Coralli, but the role of Giselle, still considered the touchstone of the ballerina's art, is said to have been staged by Grisi's husband, Perrot.

Rich in great executants, the romantic period also produced Fanny Cerrito, a vivacious, undisciplined, captivating little Neapolitan, and Lucile Grahn, a Danish ballerina whose style resembled that of Taglioni. In 1845 Benjamin Lumley, an astute London theatre manager, united Taglioni, Grisi, Cerrito and Grahn in one fabulous *Pas de quatre.* Expertly staged by Perrot, this *divertissement* marked the pinnacle of the romantic ballet. Its success led to the presentation, in 1846, of *Le Jugement de Paris,* in which Taglioni, Grahn and Cerrito were supported by Perrot and Arthur Saint-Léon, a young man whose extraordinary abilities as both dancer and violinist had succeeded in overcoming the current prejudice against male dancers. Saint-Léon, like Perrot, turned to choreography, creating numerous works for Cerrito, who became his wife. His last ballet was *Coppélia,* produced at the Paris Opéra on May 25, 1870, a few months before his death.

In both Paris and London, after 1850, the leading ballerinas, including Amalia Ferraris and Carolina Rosati, concentrated on strength and virtuosity rather than on the poetic qualities that had made Taglioni's dancing appeal to the imagination and touch the heart. Choreographers exploited the physical prowess of their stars and were content to depend upon spectacular scenic effect and impressive masses of ensemble dancers rather than to cultivate the art itself, either in its dramatic aspects or as pure beauty of movement. A hint of the forgotten artistry of Taglioni was glimpsed during the brief career of Emma Livry, who made her debut in 1858. When *La Sylphide* was revived for her, Taglioni emerged from retirement to coach her in the role and to create for her, in 1860, the only choreographic work of Taglioni's career, *Le Papillon.* Just three years later Livry died, aged 21, from the effect of burns received when her ballet skirt caught fire from an open gas jet during a stage rehearsal. Her tragic death heralded the general decline of western European ballet.

The Italian School.—The technique of the classic ballet, very much as it is practised today, was codified by the Italian dancer Carlo Blasis in his *Traîté klkmentaire, thkorique et pratique de l'art de la danse,* published in Milan in 1820. An experienced dancer and a prolific writer, Blasis issued several versions of this treatise, as well as books on such allied subjects as music, history, drama and pantomime. His indomitable energy found its principal expression, however, in his work as head of the ballet school at La Scala, Milan, a post he assumed in 1837.

The advice to young dancers that Blasis propounded in his *Code of Terpsichore* (1830) is applicable today. "Dancing," he wrote, ". . . cannot be acquired and retained without the utmost study and assiduity. Remain not, therefore, twenty-four hours without practicing . . . Particularly attend to the carriage of your body and arms. Let their motions be easy, graceful, and always in accordance with those of the legs . . . Take especial care to acquire perpendicularity and an exact equilibrium. In your performance be correct. and very precise; in your steps, brilliant and light; in every attitude, natural and elegant. A good dancer ought always to serve for a model to a sculptor or painter . . . Let your countenance be animated and expressive . . . Be vigorous, but avoid stiffness; seek to acquire a facility of spring. . . Rapidity is very pleasing in a dancer; lightness still more so . . . ."

The teaching methods of Blasis and his wife, Annunciata Ramaccini, were strict and demanding. During his long directorship of the Scala school, it became the principal source of supply for solo dancers for the entire theatrical world. Established stars, like Cerrito and Grisi, came to Milan to study with him. He developed Ferraris, Sophia Fuoco, Flora Fabbri and Marietta

Baderna, who later danced in the opera houses of Paris, London and St. Petersburg. His pupil Giovanni Lepri was the teacher of Enrico Cecchetti, one of the greatest dance pedagogues of the 20th century who became in turn director of the Scala academy and who in his turn taught Pavlova, Vaslav Nijinsky, Cia Fornaroli, and Ninette de Valois, director of England's Royal Ballet. The traditions of Blasis have been handed down directly and without interruption. These traditions include a number of Blasis' own discoveries and innovations. A statue of Mercury by Giovanni da Bologna inspired the *attitude,* which he invented. He probably discovered the snapping movement of the head that makes it possible for dancers to turn indefinitely, without dizziness. He enlarged the scope of dancing on the points. The invention of the reinforced or blocked toe-shoe, unknown to Taglioni and Elssler, who danced in soft satin slippers, enabled dancers to execute multiple pirouettes on the point instead of the demi-point, as before. It was Pierina Legnani, a graduate of the Scala academy, who first executed 32 *fouettks,* the whipping turns on one toe featured in the third act of *Swan Lake.*

Late in the 19th century there emerged from La Scala such ballerinas as Maria Bonfanti, Giuseppina Morlacchi and Malvina Cavalazzi, all celebrated in the U.S., Caterina Beretta and Rita Sangalli, stars of the Paris Opéra, and Virginia Zucchi and Carlotta Brianza, who won their greatest fame in Russia. The dazzling technique of these brilliant soloists, combined with a prevailing laxity in the training of ensemble dancers, led choreographers to concentrate on the presentation of the prima ballerina, to the detriment of ballet as a whole. This led to the degeneration and ultimate stagnation of the ballet, which by 1900 had reached a low level in most of Europe and the U.S. The exception was Russia, where the genius of Marius Petipa had fused the French and Italian schools into the form indelibly labeled Russian ballet.

Ballet in Russia Before 1900.—Ballet was firmly established in Russia by the time of Catherine the Great. Angiolini produced some of his finest works in St. Petersburg, as did Noverre's pupil Le Picq. In 1801 the French-Swedish dancer Charles Louis Didelot was appointed choreographer, principal dancer and director of the ballet school. Before his retirement in 1829, he had produced dozens of ballets, reorganized the school, imported guest artists (including Duport) and developed such native Russian dancers as Marie Danilova and Avdotia Istomina, who won the admiration of the poet Aleksandr Pushkin. From 1837 to 1842 Taglioni danced in Russia, where her father staged some of his most typical ballets, including *La Sylphide, L'Ombre* and *La Fille du Danube.* Elssler, Grisi, Cerrito and Grahn also appeared in St. Petersburg. The inspiration provided by such distinguished visitors helped produce the Russian ballerinas Elena Andreyanova, who later danced in Paris and Milan, and Nadezhda Bogdanova, whose successful appearances at the Paris Opéra were interrupted by the Crimean War.

The major force in the development of Russian ballet was a Frenchman, Petipa, who reached St. Petersburg in 1847 after a brief, adventurous career that had already included appearances in France, Spain and the United States. His brother Lucien was *premier danseur* of the Paris Opéra, while his father, Jean Petipa, had been ballet master in Brussels before going to Russia to teach in the Imperial Academy of Dancing. Marius Petipa served as leading dancer until 1858, when he was allowed to produce his first ballet, *Un Mariage sous la rkgence,* at the Imperial theatre. *La Fille du Pharaon,* a magnificent three-act spectacle that he staged in 1861, established him as an important choreographer. Although Perrot and Saint-Leon, who were frequent visitors to Russia, left their mark on its ballet, Petipa molded it into its distinctive national form. Appointed choreographer in 1862, he was the virtual dictator of the Russian ballet until his death in 1910.

Christian Johannsen, a Swedish pupil of August Bournonville, who in turn had studied with Auguste Vestris, was the principal teacher at the Imperial school. He developed the Russian method of teaching, with its varied exercises and its emphasis on versatility, softness and purity of line. He formed a long line of accomplished ballerinas, including Eugenia Sokolova, Ekaterina Vazem, Varvara Nikitina and Johannsen's daughter Anna, later one of the teachers of Tamara Karsavina.

Late in the century Petipa, always an admirer of virtuosity, began importing Italian stars to enhance his ballets with their glittering technique. Zucchi, Legnani and Cecchetti dazzled the Russian dancers with their brilliant tours de force. It was not long, however, before Mathilde Kchessinska and Olga Preobrajenska were emulating their most effective steps. Cecchetti remained to teach in Russia and helped to form Pavlova, Nijinsky and the other artists who burst upon the western world with such splendour during the first Paris season of the Diaghilev ballet in 1909. Petipa collaborated extensively with the composer Tchaikovsky. Although Mozart and Beethoven had written ballet music, throughout most of the 19th century it had been written to order by light, facile composers like Adolphe Adam, Cesare Pugni, Léon (Aloisius Ludwig) Minkus and Léo Delibes. Tchaikovsky's splendid scores for *The Sleeping Beauty, Swan Lake* and *The Nutcracker* remain outstanding examples of ballet composition, although Aleksandr Glazunov composed three fine ballet scores, and in the 20th century Sergei Prokofiev attempted similar things in his *Romeo and Juliet, Cinderella* and *The Stone Flower.*

Petipa and his assistant, Lev Ivanov, shared in the choreography for *Swan Lake,* still unsurpassed in the classic style. Ivanov staged *The Nutcracker,* following Petipa's preliminary notes. *The Sleeping Beauty,* probably Petipa's masterpiece, was revived in its entirety by Diaghilev, and is well known in England and America through performances given by the Royal Ballet and on television.

Petipa combined the smoothly flowing elegance of the French school with the virtuosity of the Italians. He perfected the elaborate, full-evening ballet in which set dances, emphasizing the spectacular art of the prima ballerina, alternated with static mimed scenes in which the story unfolded through stylized gestures. In the early years of the 20th century the young choreographer Michel Fokine led a revolt against this rigid balletic formula, inaugurating the great contemporary renaissance of ballet.

The Diaghilev Ballet.—Sergei Diaghilev first stimulated western interest in Russian art by presenting, in Paris, an exhibition of paintings and a series of concerts of Russian music. These attracted such wide attention that in 1909 he organized a troupe of dancers, artists on vacation from the Maryinsky theatre, and presented a season of ballet at the Théâtre du Chbtelet.

As choreographer of the enterprise, Diaghilev chose Fokine, a 29-year-old dancer who had already demonstrated his reluctance to follow blindly the choreographic traditions of his predecessors. As early as 1904, he had declared his belief that ballets should no longer be broken up into separate dances but should flow without interruption (as in Wagnerian opera), the whole story or theme being expressed through dance movement, which should not be exclusively classical but should vary in style according to the theme expressed. This was, of course, simply a return to the forgotten principles of Noverre. The officials of the imperial theatres showed little sympathy for Fokine's revolutionary ideas, but he was able to put them into practice in his *Acis et Galathée,* staged for a pupils' performance; *The Vine,* given for charity; and the miniature masterpiece immortalized by Pavlova, *The Dying Swan. Chopiniana,* which we know as *Les Sylphides,* was created for a charity performance in 1908.

For his first Paris season (1909), Diaghilev chose Fokine's ballets *Les Sylphides, Le Pavillon d'Armide* and *Cléopâtre,* all of which had already been given in Russia. Fokine also put together a *divertissement* called *Le Festin,* which included dances by Petipa and other choreographers, and staged a new work of major importance, the magnificently barbaric *Prince Igor.* This ballet represented glorious departure from the pretty and innocuous trifles to which Parisian audiences were accustomed and was a triumph for Fokine and Diaghilev. The original Diaghilev company included Pavlova and Mikhail Mordkin (both of whom departed after the first season), Karsavina, Nijinsky, Adolph Bolm, Vera Fokina, Alexandra Fedorova, Bronislava Nijinska and other dancers who were to spread the fame of Russian ballet around the world.

The early Diaghilev seasons coincided with the richest period of

Fokine's creative activity. In rapid succession he choreographed *Scheherazade, The Firebird, Petrouckka* and *Le Spectre de la rose,* each work showing a new facet of his genius. Diaghilev meanwhile had discovered the composer Igor Stravinsky and commissioned his first ballet scores. He had secured the collaboration of painters like Alexandre Benois and Leon Bakst, whose contribution to the initial impact of the Russian ballet upon the world of art can scarcely be overestimated.

The dancing of Nijinsky came as a revelation to audiences in western Europe, who had long forgotten what male dancing could be. At the Paris Opéra, the unpleasant custom of *travesti* prevailed, and girls frequently played men's roles. Nijinsky, the supreme male dancer of modern times, had a phenomenal *elevation,* made more spectacular by his seeming ability to remain suspended in air. His strange, exotic personality transformed him into the creature of another world when he entered the magic circle of the stage. Scarcely less impressive was Karsavina, a superb actress-dancer and the ideal interpreter of Fokine's ballets. Diaghilev encouraged Nijinsky to attempt choreography. He staged *L'Aprés-midi d'un faune* (1912), *Jeux* (1913) and Stravinsky's *Le Sacre du printemps* (1913). All three of these works were marked by radical departures from accepted choreographic practice, utilizing angular, stylized movement far ahead of its time. Each of Nijinsky's ballets precipitated a scandal, and the furor attending the première of *Sacre du printemps* attained monumental proportions. Nijinsky created only one other ballet, *Till Eulenspiegel* (given in New York in 1916), before his tragic insanity cut short a phenomenal career.

In 1914 Diaghilev discovered the young Leonide Massine, whom he groomed to replace Nijinsky, presenting him first in Richard Strauss' *The Legend of Joseph.* Massine's first ballet, *The Midnight Sun* (1915), proved him a gifted choreographer. For Diaghilev he created such works as *The Three-Cornered Hat, La Boutique fantasque* and *Pulcinella,* collaborating with the painters André Derain and Pablo Picasso.

By this time Diaghilev had broken his ties with Russia. His company toured constantly in Europe, South America and the United States, where it appeared in 1916–17. At first, Diaghilev worked only with Russians: Stravinsky, Bakst, Benois and Fokine. Later his company became international in many respects. He commissioned scores from Erik Satie, Georges Auric, Francis Poulenc, Manuel de Falla and Darius Milhaud. Décors were designed by Maurice Utrillo, Georges Braque, Giorgio de Chirico and André Bauchant. Russian dancers, including Lydia Lopokova (Lopoukhova), Felia Dubrovska, Vera Nemtchinova, Olga Spessivtzeva (Spessiva), Alexandra Danilova. Pierre Vladimiroff, Anatole Vilzak and Serge Lifar, were joined by Poles such as Leon Woicikowski and Stanislas Idzikowski, and eventually by the English dancers Lydia Sokolova (Hilda Munnings), Anton Dolin and the 14-year-old Alicia Markova (Alice Marks).

In 1921 Diaghilev revived *The Sleeping Beauty* in London, but as usual the impresario was ahead of his time. Petipa classics became generally popular only a quarter of a century later.

Diaghilev's last choreographer was George Balanchine, an artist of marked originality as well as an ardent disciple of Petipa. Trained in the U.S.S.R., he left it in 1924 and joined Diaghilev. For Diaghilev he created about ten ballets, including *Apollo, The Prodigal Son, La Chatte* and *Le Bal.* After Diaghilev's death in 1929, Balanchine was to exert a tremendous personal influence on the whole course of contemporary classic ballet.

Pavlova.—Anna Pavlova, trained in the Russian Imperial school in St. Petersburg, was already one of the finest dancers of the Maryinsky theatre when, in 1907, she made the first of her foreign tours, to Stockholm, Copenhagen, Prague and Berlin. In 1909 she danced in Paris with the Diaghilev company, leaving it to accept a contract at the Metropolitan Opera with her partner, Mordkin, in Jan. 1910. Although from 1910 to 1913 she returned to Russia intermittently for limited engagements, from this period she devoted herself more and more intensively to the tours that absorbed the remainder of her life. First with a single partner, later with her own company, Pavlova danced tirelessly and unremittently, on stages large and small, good and bad, in villages and capitals all over the world. which she circled more than once. A superb artist, completely and selflessly dedicated to the dance, she brought ballet to people who had never suspected its existence Through her personal genius and her courageous example she inspired a whole generation of dancers, from Australia to Finland. Her service to ballet and her influence on the artists who followed were inestimable.

Ballet in **America,** 1735–1932.—Since colonial days, American audiences have shown warm and discriminating appreciation of ballet as an entertainment and as an art, but neither official nor private enterprise has ever given it a permanent home in the United States. Consequently it has never been consistently cultivated; its progress has been sporadic, and it has gone through long periods of eclipse as well as cycles of healthy evolution.

Ballet was probably introduced to the colonies by Henry Holt, a dancer from London, who in 1735 presented *The Adventures of Harlequin and Scaramouch, with the Burgo'master Trick'd,* in Charleston, S.C. Harlequinades and pantomimes were often seen on colonial stages, and the hornpipe ranked high in popularity. However, ballets were not given in America with any frequency until after the French Revolution, which uprooted artists in great numbers. As early as 1791 Stephen Sicard, a pupil of Maximilien Gardel, presented his Philadelphia pupils in a timely work called *The Congress' Return.* Alexander Placide and his wife produced a "dancing ballot" *(sic)* called *The Bird Catcher* in New York in 1792. Later the Placides moved on to Charleston, where in association with the choreographer Jean Baptiste Francisqui they gave such well-known works as Noverre's *Les Caprices de Galathée* and Gardel's *La Chercheuse d'esprit.* Their ballet company included Jean Baptiste Val and his wife, and the youthful prodigy Louis Duport. In 1794 Anna Gardie made her American debut in *La Forêt noire.* Until she was tragically murdered by her husband, four years later, Mme Gardie brightened the American stage with her vivid mimic artistry. James Byrne, noted English dance mime who revolutionized the traditional presentation of Harlequin, spent several years in the United States (1796–1800). His most ambitious productions were the "grand serious pantomimes" *The Death of Captain Cook* and *Oscar and Malvina.* Mrs. Byrne's debut was marred by the hisses of an audience that disapproved her scanty costume; she was obliged to add a pair of pantalettes.

The ballet traditions introduced by French refugees had all but died out when, in 1821, New York's Park theatre engaged a new ballet master, Claude Labassé, who had danced under Pietro Angiolini's direction in Milan. In 1827 Mme Francisque Hutin made a sensational debut. She excelled in multiple *pirouettes* and in dancing on points, then fairly new even in Europe.

Charles and Marietta Ronzi Vestris, relatives of the great *dieu de la danse,* toured in America in 1828–29. During the following quarter of a century the United States enjoyed a steady stream of dancers from Europe and even developed a few native artists of considerable distinction. Mary Ann Lee and Augusta Maywood, both trained in Philadelphia, Pa., by a former Paris Opéra dancer, Philip Hazard, made their debuts together in 1837. Maywood soon went to Paris, appeared with astonishing success at the Paris Opéra and enjoyed a flourishing career in Portugal, Austria and Italy, attaining the rank of prima ballerina at La Scala, Milan. Mary Ann Lee also studied in Paris but soon returned to America, where she was the first to dance *Giselle* (in Boston, Mass., Jan. 1, 1846).

Jean and Marius Petipa danced briefly in New York in 1839, as did Paul Taglioni, brother of the great Marie. and his wife Amelie. The Taglionis presented *La Sylphide,* already well known in the United States through productions by Mme Celeste (Celeste Keppler) and other touring ballerinas, who led their itinerant troupes as far west as the Mississippi river.

The romantic ballet in America reached its peak with the visit of Fanny Elssler, 1840–42. The great Austrian dancer created a furor comparable only to that which greeted the singer Jenny Lind a decade later. When Elssler danced in Washington, D.C., congress was obliged to recess because it could not obtain a quorum. In Baltimore, Md., young admirers unhitched the horses from her carriage and pulled her from the theatre to her hotel, then sere-

naded her until early morning. In such ballets as *La Tarentule, La Sylphide, Nathalie* and *La Gypsy*, her mature artistry captivated intellectuals like Ralph Waldo Emerson, Margaret Fuller and Fanny Appleton Longfellow. Her *Cachucha* and *La Cracovienne* swept the country and were imitated by everyone from aspiring American ballerinas to children in dancing school. Elssler encouraged American dancers, engaging Julia Turnbull, Henrietta Vallée and George Washington Smith for her company. Her partner, James Sylvain (born Sullivan), had several American pupils but did not remain in the country long enough to establish a permanent school.

Ballet continued to enjoy enormous popularity for a decade after Elssler's departure. Hermine Blangy, from the Paris Opéra, was able to dance *Giselle* ten times in a fortnight in Mobile, Ala. In New York, in 1848, the Monplaisir Ballet gave *Esmeralda* every night for more than a month. This troupe, which featured the great comic dancer Leon Espinosa, traveled as far as California. Even the colourful Lola Montez, more noted for her influence on King Louis I of Bavaria than for her dance talent, profited from the vogue for ballet in the United States. In 1866 *The Black Crook*, called the first musical comedy, featured an elaborate dance sequence, but by this time ballet had lost much of its poetic beauty. A handful of distinguished dancers, including Bonfanti, Sangalli and Morlacchi (who earned the admiration of Brander Matthews and Philip Hale), maintained high standards of individual artistry in the face of a general vulgarization of the ballet.

With the opening of the Metropolitan Opera house in 1883, one might have expected the steady encouragement of American dancers and choreographers. Such was not the case. The Metropolitan imported its dancers until 1909, when Malvina Cavalazzi, who had been its first ballerina, returned to open the company's first ballet school. Its first American-born choreographer, Zachary Solov, was not engaged until 1951.

During its brief existence, 1885–1887, the American Opera company made a genuine effort to present fine ballet and even tried to establish a school. It introduced Delibes' *Coppélia* and *Sylvia*, and starred first-rate dancers like Maria Giuri.

It was the depressing sterility of the ballet, around 1900, that caused creative artists like Isadora Duncan, Loie Fuller and Ruth St. Denis to turn to other forms of dance expression. A glimpse of hope for the traditional art came with the debut of the Danish dancer Adeline Genée. In a musical comedy, *The Soul Kiss* (1908), and later as guest artist at the Metropolitan, Genée, with her precise technique and delicate charm, did much to reawaken American interest in ballet. Cia Fornaroli, the Metropolitan's ballerina from 1910 to 1913, also rose far above the prevalent level of mediocrity.

The Russian renaissance of the dance was announced in the United States by the debut of Pavlova and Mordkin in *Coppélia* at the Metropolitan Opera early in 1910. Their sensational success was followed by the appearance of several more or less Russian ballet companies and, in 1916, by the arrival of the full Diaghilev Ballet. American artists and critics were profoundly impressed by Fokine's masterpieces in their original settings by Bakst and Benois, but the general public was not yet ready to give wholehearted support. Not even the belated appearance of Nijinsky, delayed by wartime internment in Hungary, was able to save the tour from financial collapse. In 1918 Adolph Bolm staged Fokine's version of the opera-ballet *Le Coq d'or* for the Metropolitan, with Rosina Galli as the queen of Shemakha. In 1919 he staged and danced *Petrouchka*. Two American works, Henry Gilbert's *The Dance in the Place Congo* (1917) and John Alden Carpenter's *Skyscrapers* (1926), completed the list of independent ballets given at the Metropolitan until Balanchine's appointment as choreographer in 1935.

Pavlova, meannhile, toured the length and breadth of the country, bringing her inspiring art to thousands who had never seen ballet and awakening the desire to be ballerinas in hundreds of little girls. Her last appearance in the United States was in 1925.

During the 1920s there were sporadic attempts at ballet production by the Neighborhood Playhouse and the League of Composers in New York, while in Chicago, Ill., Bolm's company flourished briefly, and Ruth Page began her first attempt at choreography on an American theme with the production of *Oak Street Beach* in 1929. St. Denis, Ted Shawn and the Denishawn company toured regularly, doing much to cultivate audience interest and to develop an understanding and appreciation of dance, but their repertoire did not include classic ballet.

Although great artists in other fields of dance, such as the Spaniards Vicente Escudero and La Argentina (Antonia Mercé) and the Indian Uday Shan-Kar, made frequent U.S. appearances, very little ballet was seen in the United States between the departure of Pavlova in 1925 and the arrival of Col. W. de Basil's Ballet Russe de Monte Carlo in 1933.

Ballet in England. — The British Isles have produced good dancers since Shakespeare's day, when William Kempe earned notoriety by dancing a jig from London to Norwich. An Irishman named Simon Slingsby held his own as a soloist in Noverre's London company of 1781. The Byrnes and the Degvilles competed successfully with imported stars in the London of 1800. England might have claimed one of the great ballerinas of the romantic period if the promising young Clara Webster had not been burned to death in 1844.

During the last years of the 19th century, when ballet was on the decline elsewhere, it was solidly established on an entertainment level in two of London's most popular theatres, the Alhambra and the Empire. Cavalazzi, Legnani and Cecchetti all danced at the Alhambra. Katti Lanner, daughter of the famed composer of waltzes, was ballet mistress at the Empire, where she established a school for training English dancers. Espinosa also taught in London, and after his death in 1903 his school was continued by his son Edouard. Prima ballerina of the Empire theatre, 1897–1907, was the exquisite Adeline Genée, noted for meticulous technique and sparkling style. The Empire featured elaborate, rather tasteless productions such as *The Milliner Duchess* and *The Bugle Call*, but it also gave the Delibes classics, *Coppélia* and *Sylvia*. Genée was succeeded by Lydia Kyasht, of the Russian Imperial ballet, and then by Phyllis Bedells, the first English girl in nearly a century to attain recognition as a classic ballerina.

Pavlova exerted a profound influence on ballet in Great Britain, dancing frequently in London from 1908 until her last public appearance, at Golder's Green Hippodrome, Dec. 1930. The Diaghilev Ballet danced annually in London. Both Pavlova and Diaghilev engaged British dancers, some of them (including Markova and Patrick Healey-Kay, who became Anton Dolin) trained by the exiled Russian dancer Seraphima Astafieva.

During the 1930s the De Basil Ballet Russe de Monte Carlo, with Massine, Danilova, Irina Baronova, Tamara Toumanova and David Lichine, made annual visits to London. The Royal Danish Ballet made a deep impression on its first visit to England, in 1953, while the Covent Garden Opera house season of the Bolshoi Theatre Ballet of Moscow with its almost legendary ballerina, Galina Ulanova, in 1956, was sensational. Nevertheless two women, the Irish-born Ninette de Valois (Edris Stannus) and the Polish Marie Rambert (Miriam Rambach), were chiefly responsible for the high status attained by British ballet in the 20th century.

Rambert was a student of Émile Jaques-Dalcroze when Diaghilev invited her to teach eurythmics to his company. Her lessons influenced Nijinsky's choreography for *L'Aprés-midi d'un faune* and *Sacre du printemps*. Rambert, in turn, learned the value of classic ballet technique. She studied under Cecchetti, following his methods when she opened her own school in London in 1920. She had a decided flair for discovering choreographic talent. She encouraged Frederick Ashton in the creation of his first ballet, *A Tragedy of Fashion*, in 1926. Among her other protégés were Antony Tudor, Walter Gore, Norman Morrice, Frank Staff and Andrée Hoaard. In 1930 she founded the Ballet Club, devoted to developing English choreographers and dancers. Later known as the Ballet Rambert, this enterprising and progressive company was still active after more than 30 years. Dancers uho worked intensively under Rambert include Agnes de Mille, Maude Lloyd, Peggy van Praagh, Celia Franca (director of the National Ballet of Canada), Sally Gilmour, Hugh Laing, Harold Turner and John Gilpin. Tudor's first works, *Cross Gartered* (1931), *Lysistrata*

(1932), *Dark Elegies* (1937), and the work that many consider his masterpiece, *Lilac Garden* (1936), were created for the Ballet Club under Rambert's supervision.

A short-lived but important influence on British ballet was the Camargo society, first projected in 1929 by Philip J. S. Richardson, editor of *The Dancing Times,* and the critic Arnold Haskell. Devoted to the advancement of ballet through professional productions of classic and modern works for subscription audiences, it commissioned ballets by Ashton, De Valois and Tudor, and presented Spessivtzeva in *Giselle* and *Swan Lake* before its dissolution in 1933.

By this time the Vic-Wells Ballet, later to become England's Royal Ballet, was firmly established. De Valois, its director and guiding spirit, had danced in pantomime, Italian opera and in the Diaghilev Ballet before establishing a school in London in 1926. She also had valuable experience in play production for the Abbey theatre. Dublin, and the Festival theatre, Cambridge. That same year Lilian Baylis, director of the Old Vic theatre, engaged her to stage incidental dances for operas and plays. When Miss Baylis reopened Sadler's Wells theatre in 1931, the Vic-Wells Ballet was officially organized with six dancers. Soon Markova, Dolin, Lopokova and Idzikowski made guest appearances. The company was gradually enlarged, and in 1933 Markova became its ballerina. *Giselle, The Nutcracker* and *Swan Lake* were produced for her. In the years that followed, De Valois' ballets *Job, The Rake's Progress* and *Checkmate* were added to the repertoire. Through such works as *Façade, Les Patineurs* and *A Wedding Bouquet,* Ashton was recognized as a major choreographer. Robert Helpmann, who joined the company in 1933, soon became its principal male dancer, pre-eminent in dramatic roles. When Markova left the Vic-Wells in 1935, many of her roles were inherited by 16-year-old Margot Fonteyn, who later matured into one of the great ballerinas of the century. Noted for her musicality, sensitivity and perfection of line, Fonteyn is unsurpassed in *The Sleeping Beauty* and incomparable in the many roles Ashton has created for her. During World War II the Vic-Wells Ballet made frequent excursions to the continent to entertain troops. Helpmann choreographed several dramatic ballets, such as *Hamlet, Adam Zero* and *Miracle in the Gorbals.* Beryl Grey and Xloira Shearer, gifted ballerinas, emerged from the ensemble. Violetta (Prokhorova) Elvin, newly arrived from Moscow, joined the company.

In 1946 the Sadler's Wells Ballet, as it was then known, was invited to reopen Covent Garden Opera house. *The Sleeping Beauty* was revived for the occasion, and in that same year Massine revived *The Three-Cornered Hat* and *La Boutique fantasque,* especially for the company, dancing in these ballets himself. In 1948 he revived *Mamzelle Angot* and in 1951 he produced a new ballet, *Donald of the Burthens,* based on Scottish rhythms and dances. Ashton choreographed Prokofiev's *Cinderella* (1948), Delibes' *Sylvia* (1952), Hans Werner Henze's *Ondine* (1958) and a new version of one 'of the oldest ballets extant, Dauberval's creation of 1789. *La Fille mal gardée* (1960).

In 1949 Sadler's Wells Ballet made its first triumphant American tour; increasing its prestige at home. An organization of gigantic proportions, it had its own school, providing general education in addition to ballet training, as well as a sister company, Sadler's Wells Theatre Ballet, founded in 1946 and functioning as a separate entity. In 1957 Sadler's Wells received a royal charter and was renamed the Royal Ballet. Its two companies began a gradual amalgamation that was completed in 1959, with control placed under the Royal Opera house, Covent Garden. From that year its peerless ballerina, Fonteyn, appeared as guest artist, while its accomplished dancers included Svetlana Beriosova. Nadia Nerina, Lynn Seymour, Michael Somes, David Blair and Alexander Grant.

Technical standards were maintained in England through a number of schools, individual teachers of ballet and examining bodies such as the Royal Academy of Dancing and the Cecchetti society.

In 1949 Markova and Dolin formed a small group and went on tour. By the following year their performances had become so popular that a company was founded on a permanent basis under the title of Festival Ballet. Julian Braunsweg became the administrator, with Dolin as artistic director. The first London season of this company lasted for three months, from Oct. 1950 to Jan. 1951. In addition to the famous founder-leaders, John Gilpin, Natalie Krassovska and several other highly accomplished dancers have appeared with the company, both as guests and on its permanent strength, Gilpin having become assistant artistic director under Dolin. In 1951 Festival Ballet became the first English company to be invited to Monte Carlo, where they made a great impression, with David Lichine and Tatiana Riabouchinska as guest artists. Subsequently the company made extensive tours throughout Europe and North and South America. In its repertory are *Swan Lake, The Nutcracker,* various Fokine ballets *(Les Sylphides, Prtrouchka, Scheherezade* and *Prince Igor*) and a number of works produced especially for the company by Lichine, Harald Lander. Michael Charnley and Jack Carter.

Another company that did a great deal to promote interest in ballet during and after World War II, especially in provincial England, was the International Ballet founded by Mona Inglesby in 1941. Miss Inglesby was the company's prima ballerina, and at the outset the repertory included several one-act ballets. Later Miss Inglesby, with the assistance of the distinguished Russian *régisseur* Nicolai Sergueeff, arranged *Swan Lake, The Sleeping Beauty, Coppélia* and *Giselle.* International Ballet was the first company in Great Britain to appear for special seasons in super cinemas and in arenas such as those employed for ice hockey; and for a time this group enjoyed tremendous success. In 1953, however, through increasing costs, chiefly those of travel and orchestral salaries, the company. which had been substantially subsidized by Miss Inglesby's father, was compelled to disband

France After 1920.—The somnolence of the Paris Opéra Ballet, stagnant since the death of Saint-Léon in 1870, was interrupted in 1924 by the revival of *Giselle* for the great Russian ballerina Spessivtzeva and finally dispelled in 1930 with the appointment of Serge Lifar. Diaghilev's last *premier danseur,* as ballet master.

Lifar cleared the Opéra Ballet of deadwood, raised its tecnnical standards and greatly enlarged its repertoire. His ballets included *Promethée, Icare* (danced to a percussion accompaniment of his own devising), *Joan de Zarissa, Le Chevalier et la damoiselle,* and dozens of others. Except for an interlude following World War II, he continued as director of the Opéra Ballet until 1958, when he was replaced by George Skibine. Yvette Chauviré, noted for her feminine elegance, and Nina Vyroubova, trained by Russian teachers outside the Opéra, and the American ballerina Marjorie Tallchief achieved distinction among its stars. Harald Lander choreographed several successful works. In 1960 Gene Kelly became the first American to produce a ballet for the Opéra when he staged *Pas des dieux* to music by George Gershwin. Many gifted dancers educated at the Opéra, such as Janine Charrat, Renée Jeanmaire, Colette Marchand, Jean Babilée and Roland Petit, revolted against its rigid hierarchy and left to form their own companies or to dance in revues and films. Petit, an imaginative young man with a flair for the theatrical, formed Les Ballets des Champs Élysées in 1945. Later he headed Les Ballets de Paris, which toured the United States in 1949 and 1950.

The Marquis de Cuevas' Grand Ballet de Monte Carlo made its headquarters in Paris and Monte Carlo after its foundation in 1947. With two American dancers, Rosella Hightower and Marjorie Tallchief, as its principal ballerinas, it presented an extensive repertoire of classic and modern ballets.

Ballet in Denmark.— After the Royal Danish Ballet held its first festival in 1951, attention was increasingly focused on this company, which has enjoyed an uninterrupted existence since the mid-18th century. Its early masters, Antonio Sacco and Vincenzo Galeotti, were strongly influenced by Noverre and Angiolini. They established dramatic ballet on the Danish stage before the close of the 18th century. The principal architect of the Danish ballet was August Bournonville, born in Copenhagen in 1805. He studied under Auguste Vestris, danced at the Paris Opéra and returned to Copenhagen in 1829 to guide its ballet for nearly half a century. The Danish style, with its emphasis on masculine virtuosity and expressive mime, is actually the pre-romantic style of Vestris and Duport, which Bournonville brought from Paris and meticulously preserved. The Bournonville ballets *La Sylphide,*

h7apoli and *Konservatoriet,* with Galeotti's *Tlze Whims* of *Cupid and the Ballet Master* (the oldest ballet still performed in its original choreography, dating from 1786), still maintained a key position in the Danish repertoire early in the sixth decade of the 20th century. Lander, who served the company as dancer and principal choreographer between 1925 and 1951, broadened its scope and gave it a more international character. Alexandre Volinine produced *Ciselle,* and Massine staged his *Le Beau Danube.*

After Lander's departure, the noted Russian teacher Vera Volkova was appointed artistic adviser of the Royal Danish Ballet and head of its school. Her influence was observed in the superimposition of the Russian style. with its emphasis on elegance and length of line, on the strongly Danish technical foundation of the dancers.

Several Balanchine ballets were added to the repertoire. In 1955 Ashton produced Prokofiev's *Romeo and Juliet,* and in 1957 Peggy van Praagh and Ninette de Valois staged the Petipa version of *The Sleeping Beauty.* Birgit Cullberg's *Tlze Moon Reindeer* was *a* stirring ballet on a Scandinavian theme. The company visited London in 1953 and the United States in 1956 and 1960. Preeminent among the classic dancers of the time were Erik Bruhn (who appeared as *premier danseur* of the American Ballet Theatre between engagements in his native Copenhagen), Henning Kronstam and Flemming Flindt.

Soviet Union.—Ballet in the U.S.S.R. has followed the traditions established by Marius Petipa in the 19th century. Many Petipa classics remain in the repertoire. although they are sometimes restaged. Ballet technique was developed to an extraordinarily high level of proficiency, sometimes approaching the acrobatic, through the work of such fine teachers as Vasili Tikhomirov (1876–1956) in Moscow and Agrippina Vaganova (1879–1951) in Leningrad. Vaganova's textbook, *Fundamentals of the Classic Dance* (1934), was translated into many languages. Ekaterina Geltzer, a contemporary of Pavlova, continued to dance in the 1930s, when Vaganova's pupil Marina Semenova attained her greatest fame. Vakhtang Chabukiani and Constantin Sergeev combined prodigious technique with forceful dramatic conviction.

Three- or four-act ballets remained the rule rather than the exception. In the active repertoire during the early 1960s were the Tchaikovsky ballets *Swan Lake* and *The Sleeping Beauty,* Petipa's versions of *Giselle* and *Don Quixote,* and the more recent works *Red Sails, Shurale, Laurencia, Tlze Bronze Horseman* and *The Fountain of Bakhchisarai.* Prokofiev's *Romeo and Juliet,* choreographed by Leonid Lavrovsky, enjoyed particular favour.

Soviet choreography in general tended to conventionality, although much imagination was shown in devising unusual lifts, and in the careful delineation of each ballet's story. Principal centres of ballet production were the Bolshoi theatre, Moscow, and the Kirov theatre, Leningrad, although ballet companies functioned even in remote sections of the Soviet Union. Chief glory of the Soviet ballet in the early 1960s was its extraordinary ballerina, Galina Ulanova. a lyrical dancer with a phenomenal ability to sustain a role. Forty-seven years old at the time of her London dehut in 1956 and nearing 50 when she first appeared in the United States, she won critical acclaim that recognized not the slightest diminution of her technical or interpretive resources. Her contemporaries Olga Lepeshinskaya and Natalia Dudinskaya remained popular favourites. while among her younger colleagues. Maya Plisetskaya, Raissa Struchkova, Yuri Zhdanov and Nikolai Fadeyechev earned high praise. Character dancing was developed to an extraordinary degree by Vladimir Levashev ancl Georgi Farmanyantz.

Tremendous excitement attended the American debut. of the Bolshoi Ballet in 1959. The company's lavish productions arid magnificent dancers aroused intense enthusiasm, although there was some controversy over the choreographic merits of individual ballets. Especially memorable were Ulanova's characterizations of Giselle and Juliet.

Beginning in 1958 foreign ballet companies and guest stars were invited to the U.S.S.R. for the first time in many years. The Paris Opéra Ballet, with Marjorie Tallchief, was one of the earliest visitor.;. Tn 1960 the American Ballet Theatre: headed by Marjorie's sister. Maria Tallchief, and Erik Bruhn, became the first U.S. dance company to appear in the Soviet Union.

Ballet in America After 1932.—After the death of Diaghilev, a number of his associates formed the Ballet Russe de Monte Carlo with Col. Wassily de Basil as its head. Balanchine and Massine mere the principal choreographers, with Danilova, Baronova, Tounianova. Riabouchinska and Lichine as leading dancers. The company made its U.S. debut late in 1933. Although it returned to Europe each year before the war, its activities soon centred in the United States. In addition to many works originally produced by Diaghilev, the repertoire included new ballets by Balanchine *(Cotillon, La Concurrence)* and Massine *(Jeux d'enfants, Scuola di Ballo).* During the 1930s Massine's controversial experiments in the use of symphonic music produced several important productions. *Les Présages* used Tchaikovsky's Fifth Symphony, *Choreartium,* Brahms' Fourth, and *Seventh Symphony,* Beethoven's score. Discord within the company caused a split in its ranks in 1938. De Basil led a group called the Original Ballet Russe, which spent most of the war years in South America and had little influence in the United States. Massine reorganized the Ballet Russe de Monte Carlo and brought it back to the United States with new ballets (*Gaîté Parisienne, St. Francis,* a revival of *Giselle)* and a galaxy of dancers new to this country, including Markova, Mia Slavenska, Frederic Franklin and Igor Youskevitch.

During the war years the Ballet Russe became, in everything but name, a U.S. company. As European dancers dropped out they were replaced by Americans (Maria Tallchief, Mary Ellen Moylan, Leon Danielian) until its personnel was almost entirely American born. The company presented American ballets, De Mille's *Rodeo* and Ruth Page's *Frankie and Johnny.* After Massine's departure Balanchine was for a time the principal choreographer, creating *Night Shadow* and *Le Bourgeois gentilhomme.* After he left in 1916, no firm hand guided the artistic policies of the Ballet Russe, and its productions became haphazard although it frequently offered excellent dancing. Danilova and Franklin. its stars for more than a decade, earned a tremendous personal following, and their indefatigable efforts to take good ballet to remote corners of America rivaled those of Pavlova herself.

Ballet Theatre, established in 1940, united some of the most distinguished dance artists of England and America: Tudor, De Mille, Dolin, Laing, Bolm and Fokine, who prepared *Les Sylphides* for the opening performance. The dancers, almost exclusively American, demonstrated conclusively that permanent schools with good teachers had produced technicians able to compete with the best of the Europeans. From the ranks of Ballet Theatre came Nora Kaye, acknowledged the finest dramatic dancer of her time, Alicia Alonso, versatile classicist, Melissa Hayden, Diana Adams, Janet Reed, Rosella Hightower, Jerome Robbins, Michael Kidd, John Kriza and a score of others who helped raise the standards of American ballet. Ballet Theatre's first program included Tudor's wonderful *Lilac Garden,* which disclosed unexplored possibilities in the expressive power of the classic vocabulary. Tudor. a follower of Fokine's dictum that each new theme demands its own style of movement, proved his versatility in such contrasted works as the hilarious comedy *Gala Performance,* the tragic *Dark Elegies,* the hitter satire *The Judgment of Paris,* and the poetic *Romeo and Juliet.* One of the major contributions of Ballet Theatre mas the production of Tudor's memorable *Pillar of Fire,* which first revealed Kaye's capacities as a dance actress. Ballet Theatre also encouraged American choreographers and composers, and the use of American themes. producing Jerome Robbins' *Fancy Free,* score by Leonard Bernstein; Kidd's *On Stage,* music by Norman dello Joio: and De Mille's *Fall River Legend,* composed by Morton Gould. In 1958 Cullberg's *Miss Julie* revealed the impressive dramatic ability of classic dancer Erik Bruhn.

After 1946 Ballet Theatre toured extensively in Europe and South America, admirably furthering cultural exchange. Its first visit to the U.S.S.R. in 1960 mas the subject of considerable controversy. Inactive during most of 1059, the company reassembled for a brief, unsatisfactory New York season before beginning a European tour. By the time it reached the Soviet Union, however, the company had regained much of its former brilliance and prestige. Its performances there were well received, and, although

profound differences in taste in choreography mere discernible between Soviet audiences and those in the west, individual artists won enthusiastic acclaim. Particularly successful were Bruhn (recognized as one of the world's great dancers), Maria Tallchief, Lupe Serrano (especially in William Dollar's *The Duel),* Scott Douglas and Royes Fernandez.

The youngest of the great American companies, the New York City Ballet. is in a sense the oldest. At the invitation of Lincoln Kirstein, Balanchine came to the United States in 1933 to found the School of American Ballet. The first company to grow out of the school was the American Ballet, which made its debut in Hartford, Conn , in 1934, had a brief New York season early in 1935 and became the official ballet of the Metropolitan Opera that autumn The repertoire, entirely by Balanchine, included *Serenade,* which has since become a classic, and one work on an American theme, the college satire *Alma Mater.* Dancers included William Dollar. Gisella Caccialanza, Annabelle Lyon, Harold and Lew Christensen and Eugene Loring. Balanchine's progressive classicism did not mix with the Metropolitan's old-fashioned operatic traditions. and the American Ballet disbanded after three years, but not before it had presented three works by Stravinsky, *Apollo, The Card Party* and *Le Baiser de la fée.*

Meanwhile, several of the dancers had banded together under Kirstein's leadership to form the Ballet Caravan, which rapidly became the incubator for a generation of American choreographers: Loring, who created *Yankee Clipper* and *Billy the Kid;* Lew Christensen, with *Filling Station* and *Pocahontas;* and Dollar, with *Promenade* and *Airs and Variations.* Here. and especially in the work of Loring, the influence of the modern dance on American ballet choreography first became strongly apparent. The reaction against stilted ballet convention, which had motivated dance revolutionaries like Duncan, Graham and Doris Humphrey, had borne fruit in a whole new vocabulary of movement that ballet choreographers began to absorb, adapt and incorporate into their own works.

Although the American Ballet mas reactivated for a good-will tour of South America in 1941, it was not until 1946 that Kirstein and Balanchine again joined forces in the creation of a company. This was the Ballet society, a subscription organization dedicated to the production of works for the lyric theatre, including both ballet and opera. Attracting dancers of the calibre of Maria Tallchief, Tanaquil LeClercq, Nicolas Magallanes, Todd Bolender and Francisco Moncion, the Ballet society during its two years of existence produced nine new works by Balanchine and ballets by six young Americans : Bolender, Dollar. John Taras, Lew Christensen, Merce Cunningham and Fred Danieli. In 1948 the New York City Center of Music and Drama invited the young company to join it with the title of the New York City Ballet. It thus achieved the unique advantage of a permanent home theatre, something no American ballet company had previously enjoyed. In its first decade of existence, the New York City Ballet gave nearly 75 ballets, most of them original works by Balanchine or his associate artistic director, Robbins.

Working for his own company, Balanchine reached the full flowering of his genius. He has been largely responsible for the American classic style (splendidly exemplified in his *Symphony in* C), based on the pure classic technique as transmitted through the Russians, but incorporating certain American qualities of clean. cool, buoyant athleticism. The unusual gifts of Robbins, most versatile of choreographers, provided the New York City Ballet with a wealth of works ranging from the exhilarating *Pied Piper* to the thoughtful *Age of Anxiety.* Works by Tudor, Dollar, Bolender and Christensen added depth and variety to the repertoire, which was enriched in 1957 by Moncion's touching *Pastorale,* and by a stimulating excursion into the realm of lyric theatre, John Butler's staging of Gian-Carlo Menotti's "madrigal fable," *The Unicorn, the Gorgon and the Manticore.* Balanchine explored new paths in his provocative and fascinating *Agon* (1957) and pursued them still further in the equally unorthodox *Epzsodes,* in which he collaborated with Martha Graham. using music by Anton Webern (1959).

In 1960 the stars of the New York City Ballet included Melissa Hayden, Patricia Wilde, French ballerina Violette Verdy, Jacques d'Amboise and three highly promising young dancers, Allegra Kent, Edward Villella and Jonathan Watts. Maria Tallchief had withdrawn to join the American Ballet Theatre. The career of gifted Tanaquil LeClercq was tragically interrupted by polio in 1956.

Ballet activity in the United States was not confined to the major companies. In the 1930s Catherine and Dorothie Littlefield built the Philadelphia Ballet into an admirable ensemble, the first American company to visit Europe (in 1937). Ruth Page, Bentley Stone and Walter Camryn, in Chicago, made valuable experiments nith American thematic material The San Francisco Ballet. developed by Willam Christensen and directed after 1952 by his brother Lew, consistently produced fresh and original works, in addition to staging classics like *The Nutcracker, Swan Lake* and *Coppélia.* It undertook government-sponsored tours of South America, the orient and the near east with notable success.

After Balanchine staged the dances for *On Your Toes* in 1938, ballet played an important part in the Broadway theatre. The greatest impetus was derived from the impact of De Mille's stunning dances for *Oklahoma!* in 1943. Robbins, Kidd and Loring, as well as the modern dancers Hanya Holm, Helen Tamiris and John Butler, contributed memorable dance scenes for the musical comedy stage.

In the early 1960s a tendency toward the establishment of regional ballet companies was increasingly evident As teaching standards were gradually raised all over the country, professional and semiprofessional groups were established in such widely scattered centres as Atlanta, Ga.; Detroit, Mich.; Houston. Tex.; Miami, Fla.; Neu Orleans, La.; Seattle, Wash.; and the University of Utah, Salt Lake City. A young company of solid accomplishment and exceptional promise was the Washington Ballet, directed by Frederic Franklin and Mary Day, in the U S. capital.

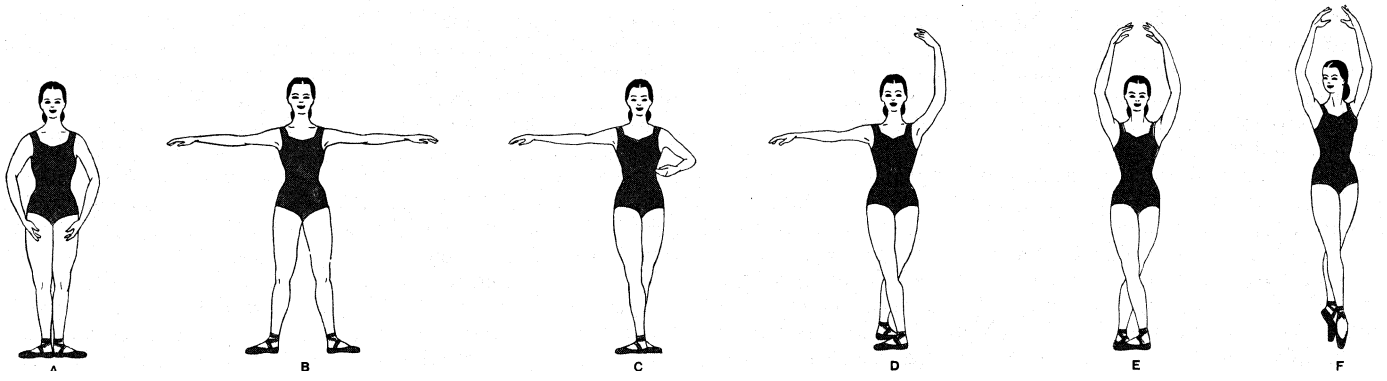
Trends.— After 1950 there was an impressive increase of interest in ballet all over the world. Greater facility of travel enabled artists like Markova, Danilova, Fonteyn, Kaye, Alonso, Tudor and Dolin to visit far corners of the world. The favourable influence of ballet films such as *The Red Shoes, Invitation to the Dance* and *Romeo and Juliet* should not be underestimated Neither should the dissemination of knowledge about ballet through increased publication of books and magazines on the subject. and through constructive criticism by dance specialists such as John Martin of the *New York Times,* Walter Terry of the *New York Herald Tribune,* Cyril *W*. Beaumont of the London *Times* and Alexander Bland of the London *Observer.*

In the early 1960s there were ballet companies in Australia, South Africa, Iran, South America, Japan and the Philippines. Turkey organized its own ballet, with the help of Ninette de Valois. Poul Gnatt of the Royal Danish Ballet headed a company in Ne Zealand. Alicia Alonso headed the state-sponsored Ballet de Cuba; Canada had its Royal Winnipeg Ballet, founded in 1940, and the younger National Ballet of Canada. Countries where ballet had long been established but which had not felt the full effect of the 20th-century renaissance (Austria, Germany, Sweden) turned to other lands where it was in a healthier state (notably, to England) for help in its rehabilitation.

The United States, after centuries of dependence on the resources of the old world, began to play a prominent part in the international exchange of art and artists. Its dancers and choreographers, recognizing no barriers of language, were not the least of its cultural ambassadors. *See* also DANCE; PANTOMIME; CHOREOGRAPHY.

BALLET TECHNIQUES AND TERMS

Classical ballet technique is acquired through an arduous system of physical training, evolved over three centuries of experimentation, and designed to enable the human body to move with the greatest possible agility, control, speed, lightness and grace. It is based upon the turned-out position of the legs, which greatly increases the range of movement through added mobility in the hip joint, and also imparts a more pleasing line to the extended leg, as in the classic *arabesque.* Modern advances in choreography have caused ballet masters to demand ever-higher standards of proficiency and versatility in their executants Ensemble dancers of the early 1960s could easily execute steps (such as the *fouetté en tournant*) considered difficult *by* the star



DRAWN ESPECIALLY FOR "ENCYCLOPEDIA BRITANNICA" BY ARLINE K. THOMSON

FIG. I.— THE FIVE BASIC POSITIONS OF THE FEET. THESE MAY BE EXECUTED WITH THE FEET FLAT (A–E) OR ON POINT (F, IN THE FIFTH POSITION). POSITIONS OF THE ARMS, WHILE FOLLOWING GENERALLY ACCEPTED RULES. HAVE NEVER BEEN DEFINITIVELY NUMBERED OR STANDARDIZED. AND VARIOUS ARM POSITIONS ARE USED WITH EACH OF THE POSITIONS OF THE FEET

performers of the 1890s.

The ideal age for commencing the serious study of ballet is eight or nine, although the child should not dance on point (toe-dancing) until two or three years later, when the bones of the foot are more fully developed. Boys often start dance training later than girls. Daily classes are needed to acquire real proficiency. Once a dancer has acquired facility, virtuosity and polish, daily practice is required to maintain it.

The vocabulary of the ballet is extensive, and its steps can be varied in an infinite number of ways. Only a few fundamentals can be described here.

All ballet steps are based on the five fundamental positions of the feet, codified by Beauchamp about 1680 (see fig. 1[A–E]):

First position.—The heels are together, toes turned out until feet are in a straight line.

Second position.—The feet are in a parallel line, separated by a distance of about 12 in., and both turned outward, with the weight equally divided between them. In second position *en l'air* ("in the air"), the weight is supported by one foot while the other is raised at the side. (Fig. 3[A] shows the raised leg in second position en *l'air,* at the conclusion of the whipping movement of a *fouetté en* tournant.)

Third position.—The heel of one foot rests against the instep of the other. Both are firmly turned out and the weight is divided between them. Used extensively in 18th-century social dances such as the minuet and gavotte, this position has almost disappeared from theatrical usage.

Fourth position.—One foot rests about 12 in. in advance of the other, both are turned out and the weight is divided between them. Like the second position, fourth has its equivalent en *l'air.* The weight is supported on one leg while the other is raised in front of the body.

Fifth position.—The feet are turned out and pressed closely together, the heel of the right foot against the toe of the left, and vice versa.

Ballet training includes basic exercises performed each day, with a wooden rail or *barre* for support. These movements are designed to give strength and flexibility to the entire body while helping the dancer acquire perfect posture or "placement," with the weight lightly balanced over the centre of gravity and the legs turned out from the hip sockets. The movements include:

Plié.—A bend of the knees.

Battement.—An extension of the leg. In a *battement tendu* one leg is extended (in front, side or back) until the point of the stretched foot barely touches the ground. In a grand battement the working leg is raised to hip level or higher.

Rond de jambe.—A circular movement of the leg, accomplished either with the toe on the floor or with the working leg raised.

Développé.—A smooth gradual unfolding of the leg, toward the front, side or back.

Classroom exercises are seldom seen on the stage, although ballet choreography derives from them. In almost every classic ballet, however, the spectator will he able to discern certain positions of the body and typical steps.

Arabesque.—One of the most beautiful of ballet positions. The weight of the body is supported on one leg, while the other is extended in back, with the knee straight. The arabesque may be varied in many ways, by changing the position of the arms, the angle of the body and the height of the leg in the air. (See figs. 2[A], 2[B] and 2[C].)

Attitude.—A classic position similar to the arabesque, except that the knee of the raised leg is bent. In an attitude en avant, the raised leg is in front of the body, with knee bent. In an attitude *allongée,* the raised leg is elongated, or nearly straight. Like the arabesque, the attitude is capable of infinite variation. (See fig. 2[D–E].)

The most spectacular steps of the ballet are the pas *d'élévation,* or jumping and leaping steps, and the various tours ("turns"). Pas *d'élévation* include:

Cabriole.—A jump in which the dancer beats the calves of the legs together in the air, with a scissorslike movement. When the beat takes place the legs are extended at an angle to the body, at the front, side or back.

Entrechat.—A jump, beginning and ending in the fifth position. While the body is in the air the feet are rapidly crossed. Every trained classic dancer can execute the entrechat-quatre and *entrechat-six,* which consist of four and six crossings respectively. Nijinsky, Eglevsky, Bruhn and a few other dancers have accomplished the entrechat-dix (ten crossings).

Jete'.—A jump in which the weight is transferred from one foot to the other. In a jete' hattu the legs are crossed in the air before the descent. One of the most effective forms is the grand jete', a broad leap with one leg stretched forward and the other ,back, like a "split" in the air (see fig. 3[C]). In a grand jete' en *tournant* (sometimes abbreviated to *tour jeté*), the body turns in the air as the transfer of weight is made.

A dancer who excels in jumping steps and attains considerable height from the floor in his leaps is said to have good elevation; if he has lightness and elasticity, rebounding without effort, he has good *ballon.* The ballerina usually executes turns on the point (the extreme tip of the toe); the male dancer often leaves the ground entirely, to revolve in the air. Of the many varieties of ballet turns, those frequently seen include:

FIG. 2.— VARIOUS TYPES OF ARABESQUE AND ATTITUDE: (A) FIRST ARABESQUE, ON POINT: (B) ARABESQUE PENCHE, ON POINT; (C) THIRD ARABESQUE (CECCHETTI SYSTEM). ON POINT; (D) ATTITUDE CROISÉE, ON POINT: (E) ATTITUDE ALLONGÉE, ON POINT

DRAWN ESPECIALLY FOR "ENCYCLOPÆDIA BRITANNICA" BY ARLINE K. THOMSON

FIG. 3.—(A AND B) TWO POSITIONS USED IN THE FOUETTÉ EN TOURNANT, (A) THE WHIP, OR ACTUAL FOUETTÉ, CONCLUDING IN SECOND POSITION EN L'AIR; (B) THE TURN. THE BODY REVOLVES IN THIS POSITION IN ANY SIMPLE PIROUETTE ON POINT; (C) GRAND JETÉ, A SPECTACULAR BROAD LEAP OFTEN USED BY MALE DANCERS

Chaîné, or *deboulé.*—A series of turns, executed either in a line or in a circle, in which the feet remain close to the floor and the weight is transferred rapidly and almost imperceptibly from one to the other as the body revolves.

Fouetté en tournant.—One of the most brilliant steps in ballet. The dancer turns on one foot (usually, on point) while at each revolution the working leg whips sharply to second position *en l'air* and then in to the supporting leg (*see* figs. 3[A] and 3[B]). In a *rond de jambe fouetté en tournant,* the working leg whips front to fourth position *en l'air* and then to second before being pulled in for the turn.

Pirouette.—A turn in place, on one foot. A good dancer can execute four or five continuous revolutions; a virtuoso, as many as a dozen. In a *pirouette sur le coup de pied,* the raised foot rests on the supporting ankle; in a *pirouette à la seconde,* it is extended in the second position. Pirouettes can also be executed in *arabesque,* in *attitude,* etc.

Tour en l'air.—A complete single, double or triple turn in the air, usually beginning from and ending in the fifth position. It is almost always executed by male dancers. The more brilliant display steps are linked by softer, less spectacular movements, which require great style and control for their proper execution.

Chassé.—A slide, in which the weight is transferred from two feet to one, or from one to another.

Glissade.—A sliding step, beginning and ending in fifth position.

Bourrée, or *bourrée couru.*—A rapid run, like a trill on the points of the toes, with the feet in fifth position (*see* fig. 1[F]). The feet move so quickly that the transfer of weight is almost imperceptible, and the ballerina seems to skim across the stage. There are many other *pas de bourrée,* or variations on this step.

(LN. ME.)

BALLETT, a type of vocal composition that enjoyed a brief vogue in England at the end of the 16th century. Both the word and the music it designates were directly imitated from the five-part *balletti* of G. G. Gastoldi (Venice, 1591). These pieces were distinguished by homophonic texture, strongly marked dancelike rhythms and refrains in which the voices sing such syllables as "fa la la" in imitation of instruments. Thomas Morley published his *First Booke of Balletts to Five Voyces* (1595) in both English and Italian editions, which suggests that Italian pieces of this kind had already achieved popularity in England; a further edition of the same collection, with German words, was printed at Nürnberg in 1609. Morley himself, the most Italianate composer of his generation, did not return to the genre, but Thomas Weelkes published a collection of *Balletts and Madrigals,* again for five voices, in 1598. Though it would have been possible to dance to these balletts they should really be regarded as a form of idealized dance music; *i.e.,* dance music translated from the ballroom into the sphere of the madrigal. Both Morley's and Weelkes's collections were reprinted in *The English Madrigal School,* ed. by E. H. Fellowes, vol. iv and x (1913–24). (J. J. N.)

BALL GAMES: *see* BASEBALL; BASKETBALL; etc. *See* also SPORTS. ARTICLES ON.

BALLIA, a town in the Varanasi (Benares) division of Uttar Pradesh, India? the headquarters of Ballia district, is near the confluence of the Lesser Sarju river with the Ganges, 75 mi. N.E. of Varanasi city. Pop. (1951) 30,638, (1959 est.) 38,000. Ballia is an ancient settlement, but because of changes in the course of the Ganges there were withdrawals of settlement northward in 1873–77 and around 1894; and the civil lines, or administrative quarter, across the railway from Ballia proper, were occupied only in 1900. Ballia proper is a rectangular area,, with the Chauk, an open space around a masonry well, as its central market square. The town contains two colleges of Gorakhpur university. It is a junction on the North Eastern railway, with metre-gauge lines running to Varanasi, Mau and Monghyr. It is mainly an administrative and business centre, with some oil-crushing, flour-milling and cottage industry. River fish are exported to Calcutta. An annual cattle fair is held in October–November.

BALLIA DISTRICT, the easternmost section of Uttar Pradesh, is a wedge of alluvial plain in the angle of the Ganges-Gogra confluence. Pop. (1961) 1,326.817. Area 1,182 sq.mi. It is highly fertile but subject to frequent flooding. Three-quarters of the population depends on agriculture, though there are some hand-loom and other cottage industries. The main crops are rice, barley, gram. millets, pulses, oilseeds and sugar cane. (R. L. SI.)

BALLINA (BÉAL ÁTHA AN FHEADHA), an urban district in County Mayo, Republic of Ireland, on the river Moy. Pop. (1961) 6,028. In the suburb of Ardnaree is the Roman Catholic cathedral (diocese of Killala), with an east window of Munich glass, and adjoining it are the ruins of an Augustinian abbey (1427). It was the first town to be captured by the French invaders after they landed at Killala bay in 1798. The salmon fishery is notable.

BALLIOL, the name of a family that played an important part in the history of Scotland and came originally to England from Bailleul (Somme) in Normandy. GUY DE BALLIOL already possessed Bywell on the river Tyne, Marwood on the river Tees and perhaps Stokesley in Yorkshire, during the reign of William II (1087–1100). Guy's nephew and successor, BERNARD (d. c. 1167), built Barnard castle and was the first of his family to receive lands in Scotland. He fought against David I of Scotland at Northallerton in 1138, and with King Stephen was captured by Matilda at Lincoln in 1141. His son BERNARD (d. *c.* 1190) was present at the capture of King William of Scotland at Alnwick in 1174. Bernard and his son and successor EUSTACE (d. c. 1210) occur frequently in English records. HUGH (d. 1228), who succeeded his father Eustace, supported King John against the baronial party in England in 1215–16.

Hugh's son and successor JOHN (d. 1268) married in 1233 Dervorguilla, daughter of Alan, the last "Celtic" lord of Galloway, and also a co-heiress of David: earl of Huntingdon, younger brother of King William of Scotland. John was from 1251 to 1255 a guardian of the young Scottish king Alexander III. His loyalty to Henry III of England in the Barons' War led to the loss of his lands in 1263 and to his capture at the battle of Lewes in 1264; but by 1265 he had recovered lands and liberty. John was the founder of Balliol college, Oxford. He had quarreled with the bishop of Durham in c. 1255 and apparently in penance for this he was supporting several scholars at the university by 1266. After his death in 1268, his wife completed his endowment of scholars, giving their house a charter in 1282. John was succeeded in turn by his three sons. HUGH (d. 1271), ALEXANDER (d. 1278) and JOHN DE BALLIOL (*q.v.;* d. 1314).

EDWARD (d. 1364), John's son, inherited only the 'family lands in France and his father's claim to Scotland. He was kept in England from 1296 to 1315, after which he lived mainly in France. With the connivance of Edward III of England he attacked Scotland in Aug. 1332. He defeated Donald, earl of Mar, regent for the young David II, took Perth and was crowned at Scone in September. He acknowledged Edward III as suzerain over Scotland in Novemher. promising him £2,000 worth of land, but was defeated in Dec. 1332 by a Scottish coalition. Edward III then came openly to Balliol's aid and, after winning the battle of Halidon Hill near Berwick in July 1333, received from him Lothian and the counties of Berwick, Selkirk, Peebles and Dumfries in fulfillment of the £2,000 agreement. Balliol's hold on parts of Scotland was precarious and by 1339 he lost Perth. He resigned his kingdom, title and personal lands to Edward III in 1356. and died in Jan. 1364 a childless pensioner of the English king. SIR ALEXANDER DE BALLIOL (d. c. 1310). chamberlain of Scotland from c. 1287 to c. 1296, belonged to a cadet branch of the family which held the lordship of Cavers (Roxburghshire) until 1368. (A. A. M. D.)

BALLIOL, JOHN DE (c. 1250–1314), king of Scotland from 1292 to 1296, was the youngest son of John de Balliol of Barnard castle. Durham. and his wife Dervorguilla, daughter and heiress of Alan, lord of Galloway. His brothers dying childless, he inherited the Balliol lands in England and France in 1278 and succeeded to Galloway in 1290. In that year, when the heiress to the kingdom of Scotland. Margaret? "the maid of Norway," died, Balliol became one of 13 competitors for the crown. He at once designated himself "heir of the kingdom of Scotland," clearly anticipating the vindication of his claim. which was derived from his mother, daughter of Margaret, eldest daughter of David, earl of Huntingdon, brother to kings Malcolm IV and William. His chief rival was Robert de Bruce (grandfather of King Robert I) whose claim was as son of Earl David's second daughter.

The English king Edward I met the Scottish baronage at Norham in Northumberland and insisted that as adjudicator between the claimants he should be recognized as overlord of Scotland. His court of 104 persons discussed the rival titles for more than a year, hut Balliol's simple claim bv primogeniture ultimately prevailed. Edward I confirmed the decision on Nor. 17, 1292, and Balliol was enthroned at Scone on Nov. 30, doing homage to Edward at Newcastle on Dec. 26. Edward had agreed that appeals should not lie from Scotland to his court hut he summoned King John in March 1293 for failure to do justice to Macduff, son of the earl of Fife. John did not attend until Oct. 1293. when he refused to answer without his barons' advice and mas judged contumacious. When in June 1294 Edward demanded military aid from Scotland for his projected war in Gascony, the Scottish reaction was in effect to transfer King John's power to an elected council; and at Paris on Oct. 23, 1295, Scottish commissioners concluded a treaty of mutual aid with the French. When Edward I sent an army to Gascony in Jan. 1296, the Scots raided northern England. Edward reacted quickly; he took Berwick on March 30. Castle after castle fell to the English king, and at Kincardine (Mearns) on July 2, at Stracathro (July 7), at Brechin (July 10) and again at Montrose, John resigned his kingdom to Edward I. He was stripped of his arms and knightly dignity in a ceremony which later earned him the nickname "Toom (empty) 'Tabard." John mas a prisoner in the Tower of London until July 1299 when papal intervention secured his release. Thereafter, he lived obscurely at Bailleul (Somme) in Normandy, where he died in 1314.

Probably the Wallace rising of 1297 was in his favour, but the movement of 1297–1300 does not seem to have committed itself to the name of the king (if any) for whom it fought. After 1300 the party under John de Soulis openly supported King John; but they abandoned the struggle in 1304 and the independence of Scotland was later won by the Bruces who never recognized the validity of John's acts. *See* also SCOTLAKD: *History.* (A. A. M. D.)

BALLISTIC GALVANOMETER, a galvanometer with a small damping factor and therefore a long period of oscillation. *See* INSTRUMENTS, ELECTRICAL MEASURING.

BALLISTIC MISSILES: *see* MISSILES; ROCKETS.

BALLISTICS. Ballistics is that branch of applied physics concerned with missile weapons and their propulsion, motion and effect at the target. Included among missile weapons are small-arms bullets, artillery projectiles, aircraft bombs, rockets, guided missiles and ballistic missiles.

The subject is conveniently divided into three branches: interior (or internal) hallistics, which treats of the propulsion of the missile; exterior (or external) ballistics, which treats of the motion of the missile along its trajectory through the circumambient medium, which may be air, water or space; and terminal baliistics,

which treats of the effects that the missile produces at the target through blast, heat. nuclear radiation, etc. Information related to the general subject of ballistics can be found in the articles AMMUNITION. ARTILLERY; SPACE EXPLORATION; ROCKETS; and SMALL ARMS, MILITARY.

INTERIOR BALLISTICS

Interior ballistics is usually considered to exclude the treatment of propulsion engines employing atmospheric oxygen to burn their fuel. even though such "air-breathing" engines may a-ell be capable of the high performance required for weapon propulsion. With this exclusion, the propulsion engines of interest to interior ballistics are the gun and the rocket. These have in common the employment of a propellant as a source of energy for a heat engine, which usually operates by controlled and directed expansion of hot gases.

Propellants.— A propellant is a substance, or a mixture of substances. which upon suitable ignition releases a large amount of chemical energy at a high, though controllable, rate. The effect of the energy liberation is to convert the propellant substance into a high-temperature gas. Propellants may be gaseous. liquid or solid. or combinations of these three, although gaseous propellants have been little used because of the difficulty of storing and transporting them. Combinations have also been little used. Propellants of practical interest are either liquid or solid. *(See* also PROPELLANTS.)

Liquid propellants may be monopropellants, consisting of a single substance stable under conditions of storage but decomposing exothermically at increased temperature and pressure (for example, hydrogen peroxide or hydrazinej, or bipropellants. consisting of two substances stored separately and mixed only in the combustion chamber. Most successful liquid propellants have been bipropellants. the two liquids usually being distinguished by the terms fuel and oxidizer. A very large number of combinations have been used or suggested, the fuels including liquid hydrogen, hydrocarbons. alcohols, ammonia. hydrazine and aniline. and the oxidizers including liquid oxygen. nitric acid, hydrogen peroxide and fluorine. Liquid propellants may also contain a catalyst to promote the desired chemical reaction or inert material to increase the propellant mass. The German V-2 missile. as an example. employed a three-to-one mixture of ethyl alcohol and water. burned with liquid oxygen.

Solid propellants are always monopropellants, and are of two principal types. Composite propellants consist of a physical mixture of fuel and oxidizer. Black powder, made from charcoal. sulfur and potassium nitrate, belongs to this class and was the only propellant in use from the invention of gunpowder until the 19th century. More advanced composite propellants consist characteristically of a finely ground crystalline oxidizer. usually an inorganic nitrate or perchlorate. mixed intimately with a synthetic plastic or rubber which not only serves as fuel but also gives the propellant the required mechanical strength. The other class of solid propellant. like the liquid monopropellant, relies on the existence of chemical compounds capable of burning without the addition of any other material. Such compounds are explosives, and their formulation into propellants must be such as to permit control of their burning rate. with no danger of detonation. which would liberate energy too rapidly for its successful control. While many explosives are capable of use in propellants, the only ones of any practical importance are nitrocellulose and mixtures of nitrocellulose and nitroglycerin. colloided to control burning rate. Those with a nitrocellulose base. called single-base propellants. were the first "smokeless powders" to be developed and are widely used as gun propellants. Double-base propellants have a nitrocellulose-nitroglycerin base and are used in rockets as well as guns. since their process of manufacture permits the fabrication of larger grains than are feasible with single-base compositions. Solid propellants also include small amounts of additives for such purposes as retarding chemical processes of deterioration during storage. improving physical strength or ease of processing. influencing burning rate or decreasing hygroscopicity.

Control of the rate of burning of liquid propellants is achieved by means of auxiliary machinery which governs the rate of admission of material to the combustion chamber. This method is obviously not suitable for solid propellants, the whole charge of which is contained in the combustion chamber at the start of burning. Their burning is controlled by the geometrical design of the propellant grain. with consideration of the characteristics of the weapon in which it is to be used. Upon ignition of a solid propellant charge. burning takes place on all the exposed surfaces, at a rate which does not vary from point to point. Thus all surfaces recede at the same rate, and it is possible to derive a purely geometrical relation between the amount of propellant burned at any time and the corresponding value of some thickness parameter characteristic of the grain. such as the unburned diameter of a cylindrical grain. The rate at which the thickness parameter decreases (the rate of burning) increases with increasing pressure, and is also afiected by the temperature of the grain before burning, as well as by the composition of the propellant. The rate of burning is frequently taken to be proportional to a power of the pressure, as low as 0.1 or as high as 1.0 for different propellants. If a more precise relationship is required, data derived directly from experiment are used. It is clear from the foregoing that a considerable degree of control of burning may be produced by proper shaping of the grain, including the provision of perforations, and much ingenuity has been expended on the design of grains for various purposes. In rocket grain design. it is common practice to attain further control of burning by the use of inhibitors. which are pieces of inert material cemented or otherwise applied to part of the surface. The inhibited surface takes no part in the burning. A grain design is termed repressive if its surface decreases during burning (as for a long solid cylinder i. neutral if it remains relatively constant (as for a hollow tube) or progressive if it increases (as for a hollow tube whose outside surface is inhibited).

The relationship between the mass of propellant burned and the thickness parameter and the relationship between rate of burning and pressure are two of the systems of equations which it is the task of the interior ballistician to solve. Other quantities of interest determined by the propellant are the energy liberated by combustion. the equation of state of the propellant gases and their specific heats. all of which are calculable from thermochemical data *(see* THERMODYNAMICS).

It is easy to prepare a list of the desirable characteristics of a propellant. A large energy release gives high performance (although it also entails a high temperature of the combustion gases, and so creates problems in the design of parts of the engine that must withstand them). A low molecular weight of the combustion products improves efficiency. Uniformity of performance of the propellant, its stability and inertness to its environment during manufacture. storage and handling. its freedom from toxicity, its ease and low cost of manufacture are all obviously to be desired. Absence of smoke or flame in the exhaust is a frequent military requirement. No propellant combines all these features to a high degree.

Interior Ballistics of Rockets.—: rocket engine. or motor. consists essentially of a chamber in which coinbustion takes place and the high-temperature, high-pressure gases are confined, and as outlet to the chamber one or more De Laval nozzles. The De Laval nozzle, a device of basic importance in the operation of turbines and ram jets as well as rockets, is characterized by an internal cross-sectional area which decreases smoothly from the entry to a minimum at a position called the throat, and then increases smoothly to the exit. Corners or abrupt changes in cross section must be avoided, particularly in the diverging portion; otherwise the gas flow through the nozzle will be disturbed to the detriment of efficiency.

The gas evolved from the burning of propellant in the chamber moves, relatively slowly, toward the afterend of the chamber and enters the nozzle. In the converging portion the gas gains velocity at the expense of its thermal energy. If the throat of the nozzle is not overly large, the gas flow velocity reaches the local velocity of sound at that point. It now enters the diverging portion of the nozzle, and since its flow has become sonic, expansion of the

cross section produces further increase in velocity, so that at the nozzle exit the flow is supersonic by a considerable margin. In this fashion the rocket motor produces a jet of high-velocity gas whose reaction on the motor produces the thrust or force that drives the rocket forward. In accordance with Newton's third law of motion, the thrust is equal to the mass rate of discharge of the gas multiplied by its exit velocity, plus a small term depending on the difference between exit pressure and atmospheric pressure.

A simplified calculation of the performance of a rocket motor may be made by assuming a steady-state, one-dimensional flow of the gas. with no friction or heat loss to the walls. The lams of fluid dynamics, essentially the laws of conservation of mass, momentum and energy, and knowledge of the thermodynamic properties of the gas then permit calculation of the details of the flow for an assigned chamber pressure. It is found that the thrust of the motor is proportional to the product of the throat area and the chamber pressure, with a factor of proportionality between one and two, depending on the thermodynamic properties of the propellant and on the expansion ratio. This is true provided that the nozzle throat has not been made so large that the flow does not become supersonic. and that the expansion ratio has not been chosen to be so high or so low that efficiency is lost, neither of which conditions is very restrictive in practice. For the fixed chamber pressure assumed and the rate of mass flow determined, the laws of burning permit the calculation of the required flow rate of liquid propellant or the geometry of the grain of solid propellant. as indicated in the discussion of propellants above.

Minor effects which must be taken into account in a more precise treatment of the rocket motor include nonaxiality of the flow, heat transfer to the walls and nonuniformity of burning of the propellant. Actual rocket design uses a combination of calculation from theory and empirical determination from test.

Experimental methods in rocket interior ballistics rely heavily on the static test, in which the rocket motor is operated while held in a fixed stand. Under these circumstances measuring instruments may be used freely. without the concern for weight and space limitations and the difficulties of recording the data that a flight test entails. Thrust of the motor is measured by allowing a slight forward motion against a force-sensing element, which may operate on mechanical, hydraulic or pneumatic principles. Pressures are measured by Bourdon gauges or manometers if response to rapid fluctuations is not desired; if it is, piezoelectric. capacitance or other types of pressure gauges with good high-frequency response are used. Temperatures of metal parts and other components are usually measured hy thermocouples. Temperature measurements in the propellant gas are very difficult to make, since the gas not only is very hot but also may be moving very rapidly: radiation methods have been used with some success. Measurements of other quantities, such as time, stress or vibration. are performed in much the same manner as in other Gelds of experiment.

Both liquid- and solid-propellant rockets are widely used, and a comparison of the merits of the two types is in order. A greater variety of substances can meet the requirements for a liquid propellant, and higher available energies and lower temperature sensitivities are therefore available. Production of liquid propellants is often simpler, since no fabrication of the substance is required. The thrust of a liquid-propellant rocket is much easier to vary or turn on and off during flight. A liquid-propellant rocket may have a weight advantage, since its propellant can be contained in tanks of relatively light construction and the combustion chamber. with its heavy walls to withstand the gas pressure, need not be very large; the chamber must be large enough to contain the whole propellant mass if a solid is used. This advantage tends to be offset by the weight of the machinery required to produce and control the flow of liquid fuel and oxidizer, the complicated nature of which is a disadvantage in itself. The net effect is that liquid propellants offer a weight advantage only for large thrust or long duration of thrust; that is, for large rockets. Solid-propellant rockets. in addition to being simpler in construction. require less maintenance. are more reliable and stand rough handling better. They are especially preferable where the handling of quantities of inflammable and toxic liquids in close quarters would otherwise be involved. as on shipboard.

Interior Ballistics of Guns. — From the viewpoint of interior ballistics, a gun consists of a chamber in which the propellant is ignited and a bore down which the projectile travels. The bore is almost always rifled. Characteristics of importance include the chamber volume, the length of the bore or distance the projectile travels in the barrel and the mass and diameter of the projectile. Of somewhat lesser importance are the shape of the chamber, the weight of the gun. the rifling design. the design of the rotating or driving band of the projectile and the strength of the barrel at each point along it, which provides an upper bound for the pressure which can be applied after the projectile passes that point.

When the propellant charge is ignited, the pressure in the chamber begins to rise rapidly and soon reaches a value high enough to move the projectile ("shot-start" pressure). The principal resistance to motion of the projectile at this stage is the force required to deform the rotating band to fit the rifling of the barrel. As the projectile moves. the propellant gas expands into the space behind it, the rate of pressure rise is reduced and the temperature of the gas begins to decrease. With increasing projectile velocity, the expansion becomes rapid enough to cause the pressure to begin to drop. When the burning of the charge is complete. and the evolution of propellant gas ceases, which usually occurs when the projectile is from one-third to two-thirds of the way down the barrel, the pressure drop becomes more rapid. When the projectile leaves the bore with its full velocity. a few hundredths of a second after ignition, the remaining pressure vents the propellant gas to the atmosphere.

Since a gun, as compared with a rocket. must burn its propellant in a very short time. and a large surface area is therefore required. a gun charge characteristically consists of a large number of identical solid grains. {Liquid propellants are not used in guns to any important extent.) Each of the grains is considered as burning simultaneously with the others and in accordance with the laws of burning described above.

In addition to the laws of burning, a complete system of interior ballistic equations for the gun includes three other major members. The equation of state of the propellant gas relates the pressure, volume and temperature of the gas. The law of conservation of energy is formulated to express the balance between the thermal energy of the gas and the kinetic energy of the projectile and the gas. Newton's second law of motion gives the acceleration of the projectile in terms of the pressure on its base. Numerous small effects must also be taken into account, such as those arising from resistance to projectile motion, heat loss to the walls and pressure gradient in the barrel. The resulting system of differential equations is too complex for direct solution. and before the rise of the modern large-scale computing machine much effort was devoted to approximate solutions which were either analytic or capable of being summarized in relatively brief tables. After World War II it became possihle to produce quickly a numerical solution for any set of parameters, and interest in analytical solutions tended to diminish.

The quantities of major interest in the ballistic solution are pressure and projectile velocity, and these are also the quantities most frequently measured in experimental firings. The crusher gauge is an inexpensive and reliable instrument for routine measurement of pressure. A piston exposed to the gas compresses a copper cylinder longitudinally, and the permanent deformation is a measure of the peak pressure attained. The gauge is best calibrated by direct comparison with a piezoelectric or strain pressure gauge. The latter gauges are also used directly, mounted in the gun wall or in the chamber, when a more accurate measurement of peak pressure or a measurement of the pressure as a function of time throughout the firing is desired. Velocity of the projectile as it leaves the gun is determined most accurately by radar devices. A widely used method employs a pair of photoelectric devices. placed a known distance apart and producing an electrical pulse when the projectile passes each device. The time

between the two pulses is measured accurately by an electric counter. Coils are frequently substituted for the photoelectric devices. in which case the projectile is magnetized before firing. The ballistic pendulum. the oldest device for measuring projectile velocity. is still in use and is capable of very good accuracy. The projectile is caught by a massive pendulum whose subsequent swing measures the momentum and hence the striking velocity of the projectile. Position of the projectile in the barrel may be determined by a short-duration burst of X-rays or by probes which the projectile shorts in passing.

Recoil of the gun is measured by photography or by a mechanical indicator. Temperatures in the wall of the gun may be found by drilling the wall and inserting thermocouples. A useful auxiliary piece of apparatus is the explosion vessel or closed bomb, a strong container in which a charge of propellant may be ignited and burned at constant volume. with means for measuring pressure as a function of time. The maximum pressure obtained is related to the energy liberated. and the course of pressure with time gives information on the rate of burning.

Small arms are a special case for interior ballistics because of the different bore resistance resulting from the soft metal sheath and the large relative magnitude of the heat loss to the walls. Recoilless guns, in which recoil is counteracted by venting a portion of the gas through a nozzle to the rear, and smooth-bore muzzle-loading mortars also require special formulations of theory, but also present no grave difficulties.

EXTERIOR BALLISTICS

The problem of exterior ballistics may be stated very succinctly: to predict the entire trajectory of a missile. As long as the only case of practical interest was that of a gun firing at a surface target, the position of the point of fall of the projectile as governed by the aim of the gun was the desired end product. and the other details of the trajectory. including the time of flight of the projectile. were of secondary interest. The introduction of the airplane into warfare quickly gave rise to the new problems of aircraft gunnery. antiaircraft gunnery and bombing. Here either the weapon platform or the target or both are in relatively rapid motion, and any point on a trajectory may represent the position of the target. Accordingly, more precise prediction of the details of the trajectory became a requirement. During World War II the great improvement in the determination of target position brought about by radar made it necessary to provide more accurate ballistic information. and rocket problems became important. After the war still different problems were generated by the advent of guided and ballistic missiles.

The end result of an exterior ballistic calculation is usually a firing table. summarizing the trajectory information essential to the user of the weapon in determining how to release the missile so as to hit the target. In the simplest case. that of surface-to-surface gunfire. the primary information contained in the table is a listing of the angles of elevation corresponding to various ranges. The principal information in bombing tables, for another example. is range and time of flight for various altitudes of the bomber above the target. In many cases the firing table is built into a machine called a director. which accepts observations of target position and computes the release conditions. A radar, a director and a pomer-aimed gun can thus form a fully automatic system for antiaircraft fire.

The time-honoured method of observing the results of firing and correcting the aim of succeeding rounds is of only limited application. At best. against a fixed target which cannot return fire. the spotting rounds are expended to produce no effect on the target. Under most conditions of modern warfare the opportunity to fire is evanescent and the conditions are continually changing. Observation of bomb impact error is of no value in releasing the next bomb. since the aircraft cannot again assume the same position with respect to the target. An accurate firing table is thus of the first importance.

It would seem at first glance that the construction of a firing table would be a simple matter of observing weapon trajectories under controlled conditions and tabulating the results. The attainment of an acceptable degree of accuracy, however, requires that a number of minor variables be taken into account, including wind. temperature and density of the atmosphere; temperature of the weapon propellant and others. A set of simple empirical observations for one weapon would therefore require firing under so many conditions as to be prohibitively costly in time and effort. Furthermore, each weapon would then be a separate case, and it would not be possible to bring to bear on a new problem the accumulated experience gained from old ones. The only practicable alternative is to assign to theory the role which it usually plays in the physical sciences. that of furnishing a unifying framework for the results of experiments and permitting accurate prediction of the results of experiments not actually carried out. In exterior ballistics as in any other field. of course. experiment is the court of last resort. and it is still necessary to obtain information on a limited number of trajectories to permit simplification of the theory to a manageable degree of complexity. The principles involved in the formulation of a mathematical theory of exterior ballistics. and the methods used in applying it, are the subject of this discussion.

The Equations of Motion of a Missile.—Clearly a missile in flight is a mechanical system, and accordingly is governed by the dynamical equations for the motion of a rigid body (see MECHANICS). Since these equations state that the product of mass by acceleration. for the missile as a whole, is equal to the resultant of the applied forces. and that the time rate of change of angular momentum is equal to the resultant of the moments of the applied forces, they form a set of six second-order differential equations: once the force resultants are set down in concrete terms of missile position and velocity (and perhaps time), the problem is definite and. is susceptible of solution by the methods to be indicated below. A solution consists of finding the three coordinates of the missile's centre of mass and three angles defining its orientation in space at any desired time.

Although this set of equations. with the most accurate available account of the complete force system. is soluble. it is formidably complex. and the solution a lengthy process not to be undertaken unless absolutely necessary. It is at this point that the skill of the exterior ballistician is exercised in the choice of a mathematical model of the motion. The mathematical model is a simplification of the general differential equations, whose solution predicts the motion of the particular missile under consideration to the degree of accuracy required for practical purposes. The ballistician examines the general equations term by term: primarily the expressions for the forces. dropping some entirely as insignificant and approximating others by simpler and more tractable forms. He is guided in this by consideration of the dispersion of the missile, the errors in its fire control, the errors to be expected in field determination of environmental conditions affecting the trajectory and other circumstances limiting the useful accuracy of the solution to be obtained.

The Forces Acting on a Missile.—The most obvious and universal force to be taken into account is that of gravity. This is usually considered as a constant force acting along the vertical, although for long-range trajectories it may be necessary to allow for its variation with distance from the centre of the earth or for its variation in different parts of the globe. If the frame of reference is fixed in the earth, centrifugal force and Coriolis force are present. These result from the rotation of the earth; the former is usually combined with gravity, and the latter has a small effect noticeable only for long-range trajectories. If the missile is rocket powered, the propulsive force, or thrust, is important while the rocket is burning. The thrust is usually taken to be directed axially with a magnitude derived from static firings and given as a function of time; in some cases it is necessary to consider lateral forces arising from thrust asymmetries. (Since the motion of a projectile before it leaves the gun is calculated by the methods of interior ballistics, propulsive forces are not considered in gun exterior ballistics.) Guidance forces occur for guided missiles. or for the propulsion phase of ballistic missiles. They may arise from the action of control surfaces in the air stream around the missile, or from lateral thrust produced by deflection

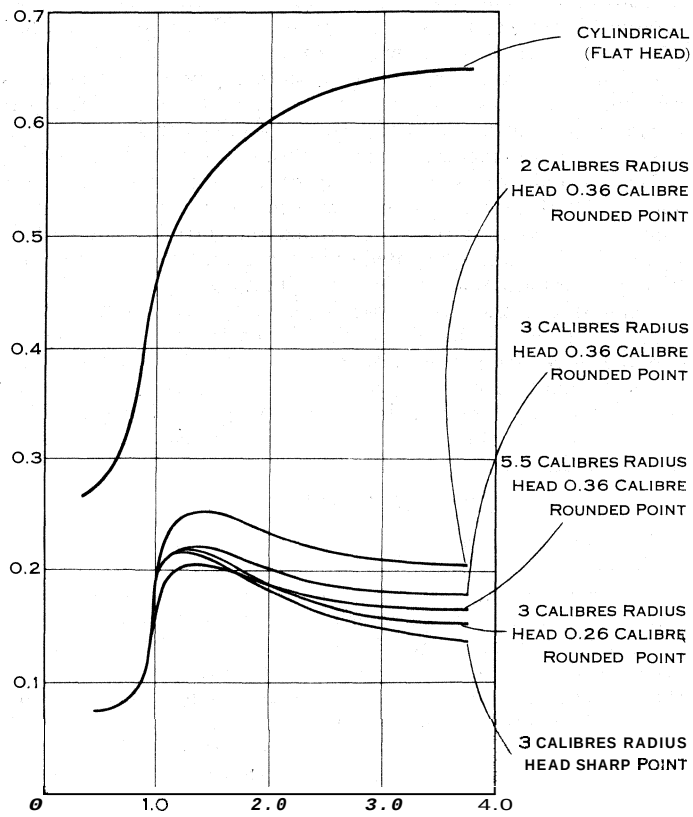
of the rocket jet by means of vanes or by rotation of the rocket motor within the missile.

The most complex contribution to the force system comes from the aerodynamic forces, produced by the resistance of the atmosphere to the missile motion. In order to arrive at suitable expressions for them, it is necessary to consider some of the characteristics common to all missiles. The usual shape of a missile is an elongated cylinder with a more or less pointed nose Even when this shape is varied. the missile is still elongated and has rotational symmetry about its longitudinal axis. The reasons for this shape lie partly in design considerations not of concern here and partly in the reduction of the effects of air resistance that it entails, but if this reduction is to be realized, with its advantages of increased range and decreased dispersion, the missile must be made to travel nose on. If this is accomplished, the missile is said to be stabilized. Stabilization is brought about in one of three ways. Bombs, most mortar shells and most rockets are fin stabilized, having fixed guiding surfaces attached to them, much like the feathers on an arrow. Most projectiles and some rockets are spin stabilized; the projectile spins about its axis because the gun bore is rifled. and the rocket because its several small nozzles are inclined slightly to its axis. If the spin is properly chosen, the missile is stabilized in much the same way as an ordinary top. The third method of stabilization is by rocket thrust control, mentioned as a guidance force above. Perfect stabilization is never achieved If the angle between the missile axis and its direction of motion. called the angle of yaw, is always small, the stability is good; if the yaw remains large for any length of time (for example, after an accidental disturbance to the trajectory), stability is poor The simplest approximation to the aerodynamic force system. which is adequate for some purposes, can be obtained on the assumption that the yaw is zero. Since the missile is rotationally symmetrical with its spin (if any) around its axis, the symmetry implies that the only aerodynamic force acts along the missile axis. This force is called the drag, and experiment shows that it depends on the shape of the missile. on its maximum diameter d, on its velocity through the air v, on the density of the air ρ, and on the local velocity of sound a. This being the case, it may be shown by dimensional analysis (*q.v.*) that the drag must be of the form

$$\text{drag} = \rho v^2 d^2 K_D$$

where K_D is a dimensionless quantity called the drag coefficient and is dependent on the missile shape and on the Mach number, which is the ratio v/a. The manner of this dependence is illustrated in the figure. The various drag coefficients shown there for different nose shapes are based on the Krupp experiments of 1912. One particular drag coefficient, known as the Gâvre function, dominated ballistic practice for many years. It resembles rather closely the curve in the figure for a two-calibres radius head. (This expression means that the nose of the missile is of ogival shape, with the radius of the ogive twice the diameter of the missile.) The Gâvre function was formulated in 1898 by the French. and was based on a study of previous firings in many countries. Since nearly all of these firings had been done with projectiles approximating the shape just mentioned. the Gâvre function was strictly applicable to this shape. but ballisticians used it for a long period for projectiles of all shapes.

If the assumption of zero yaw is not made. the drag remains the principal aerodynamic force, but by no means the only one. A closer approximation to the general aerodynamic force and moment system, which is sufficiently accurate for most purposes, is obtained by assuming that the yaw is small and that the component of the missile angular velocity perpendicular to its axis is small. The forces and moments are then written as a power series in the small cross-velocity and cross-spin components and powers higher than the first are neglected. Arguments from symmetry then lead to the conclusion that ten aerodynamic coefficients (including K_D) suffice to describe the force system; these coefficients are also dependent on Mach number and shape, and are determinable from experiment. As a further refinement the important coefficients are sometimes taken to be functions of the yaw angle. In another refinement, the departure from cylindrical symmetry of a finned missile due to the fins is taken into account, with the small changes in the coefficients which this implies. As stated before, it is the responsibility of the ballistician to examine the force system for each type of problem and decide which terms must be included in the mathematical model for the best compromise between simplicity and accuracy for that problem.



FROM DRYSDALE, "MECHANICAL PROPERTIES OF FLUIDS" (BLACKIE & SON)

THE DRAG COEFFICIENT FOR 10-CM. PROJECTILES

Showing how it varies with velocity. The effect of small changes in the shape of head can be seen in the curves. Note the effect at high velocity

The Computation **of** Trajectories. — The methods used to solve the equations of motion derived as indicated above will be illustrated by the zero-yaw mathematical model with additional simplifying assumptions. It will be assumed that the only forces acting in an earth-fixed co-ordinate system are those of gravity and drag, and that the gravitational field is constant. It will also be assumed that atmospheric conditions are standard; that is, that there is no wind, that the surface temperature of the atmosphere is 59° F and that the surface density a standard value, and that the temperature and density change with height in accordance with standard laws designed to reflect average conditions. (Temperature and density will of course vary with weather, and the effects of the departure from the standard atmosphere as well as the effects of wind will be considered later.) Under these circumstances. the motion of the missile is confined to a plane, and the two co-ordinates of its centre of mass describe its position at any time. If the x-axis is horizontal and the y-axis vertically upward, the equations of motion are:

$$\frac{d^2x}{dt^2} = \frac{\rho v K_D}{C}\frac{dx}{dt} \qquad \frac{d^2y}{dt^2} = \frac{\rho v K_D}{C}\frac{dy}{dt} - g$$

The ballistic coefficient C is equal to m/id^2, where i is a dimensionless constant called the form factor customarily introduced into the zero-yaw drag force to permit a certain degree of correction for the neglected aerodynamic effects without increasing the difficulty of the solution The density of the standard atmosphere decreases approximately exponentially, and the temperature linearly, with increasing y. (Temperature changes alter the

velocity of sound! and hence K_D.)

The computation of a standard trajectory for the mathematical model assumed consists of finding a solution of the equations above. Prior to 1914 the usual purpose was to reduce the equations to a form soluble in terms of elementary functions, or at worst quadratures. No such method of genera1 applicability was found. although the Siacci method is still in use for very flat trajectories. such as forward fire from aircraft guns. From 1917 the principal method of solution of the equations has been some form of numerical integration. In essence, the time interval during which the trajectory is described is divided into a large number of small steps. The values of x, y, dx/dt and dy/dt being known at the beginning of the first step (initial position and velocity of the missile), the equations permit exact calculation of d^2x/dt^2 and d^2y/dt^2 at the beginning of the first step. Over a small enough step, the second derivatives can be treated as constants, and simple integrations give the values of the first derivatives and the co-ordinates at the end of the first step. The computation is then repeated for the second step. and so on. The accuracy of the results obtained is clearly greater the smaller the step. but once an acceptable accuracy has been attained. further decrease of the size of step increases the labour of the computation without significant improvement in the results. It should be remarked that the use of numerical integration is by no means peculiar to ballistics. It is, as a matter of fact, the only method available for the accurate solution of most differential equations. and hence of a very large class of scientific and engineering problems. Its use in ballistics is essentially an outgrowth of the development of numerical methods in astronomy. In view of the importance of numerical integration, much attention has been given to refinements and the development of efficient techniques for special problems. as well as to methods for the prediction of the error of approximation.

Once the problem has been formulated, the actual work of performing a numerical integration is simple, involving only the operations of arithmetic. It can therefore be done by relatively unskilled labour. and until the period after World War II the standard procedure was to engage a large staff of computers who did the arithmetical operations, perhaps with the aid of small desk calculators. Because of the large number of repetitive steps required for each trajectory, and the large number of trajectories required for each weapon, this was an extremely expensive procedure. and the solution of problems involving a mathematical model much more realistic (and hence more complex) than the simple example above was economically impossible. Simple and repetitious operations are those which can best be mechanized. and it is not surprising that the development of the large-scale electronic calculator revolutionized exterior ballistics. nor that a great part of the support for its development came from military sources interested in better firing tables. Following the pioneer days of 1947, increasingly rapid and powerful calculators. such as the ENIAC. EDVXC and ORDVAC at the army's Ballistic Research laboratories at Aberdeen. Md., and the Mark II. Mark III and NORC at the naval proving ground. Dahlgren. Va., were applied to the problems of exterior ballistics. These calculators also furnished opportunities for corresponding advances in computation in other fields. Thus no great difficulty is offered by mathematical models of the most complex aerodynaniic force systems measurable, and trajectories are computed in vast numbers.

Differential **Corrections.**—A collection of standard trajectories. even though based on the most precise mathematical model. would form an utterly inadequate firing table. The standard atmosphere used in their computation makes no allowance for variations of temperature and density with the weather. Wind. which acts by changing the missile velocity with respect to the air, has been ignored. The muzzle velocity of a projectile decreases as the gun barrel wears, and propellant temperature changes affect both projectiles and rockets. Corrections for these and other minor variables are required, in such form that the user can apply them in the field. The older way of calculating these differential corrections was to calculate the perturbation of a standard trajectory when a standard disturbance was applied: for example. for a 10% change in air density. The newer method. more suited to machine calculation. is to calculate another complete trajectory for the disturbed condition. In either case, the estimate obtained of the effect of the standard disturbance is tabulated in the firing table. and the user allow for an effect proportional to the disturbance he observes.

Experimental Measurements.— The determination of the aerodynamic coefficients needed for the most accurate calculations is not an easy matter. The expense of determining them from actual firings of the missiles would be prohibitive. even if it were physically possible to obtain all the data required, Measurements of the aerodynamic forces and moments can be made on a scale model in an aerodynamic wind tunnel or similar models can be fired down an aeroballistic range. This consists of a series of stations past which the model travels in free flight. As it passes each station it triggers a brief flash of light, and photographic records are made showing its position and orientation at the time of the flash. which is also recorded. From precise data on the successive positions. orientations and times, the aerodynamic coefficients may be determined. Some ranges include provision for pressurization. to permit enhancement of the aerodynamic effects.' or for firing the missile model through gases in which sound travels less rapidly than in air. to permit a greater variation of Mach number than would otherwise be possible. An older method of obtaining the drag coefficient alone is by means of a resistance firing. This consists essentially of measuring the times at which the missile in free flight passes three successive points in space. Distance traveled is plotted against time. and the curvature of the arc through the three plotted points is a measure of the deceleration and hence of the force on the missile. The principal difficulty with this method is that it is not easy to launch a missile with no initial yaw. A better technique is to employ a radar device to measure the velocity continuously as the missile describes a substantial portion of its trajectory.

In addition to the determination of aerodynamic coefficients, some actual firing of the full-rcale missile is required. Scale-model tests cannot quite duplicate full-scale phenomena. both because the aerodynamic coefficients depend to some extent on scnle and because a fully accurate scale model is impossible. (Even a small change of the machine finish on the nose of a missile can affect its trajectory to an observable extent.) The basic physical data collected during the full-scale range firing of a projectile or a rocket include measurements of missile weight. centre of mass and moments of inertia. and its initial velocity and initial direction of motion. In addition. the air density and temperature are determined by sounding techniques. as are the direction and speed of the wind. for the n-hole range of altitudes covered by the trajectory. Measurements of the position of the missile as it describes its trajectory are obtained by radar methods or by triangulation from photographic or theodolite observations. and these measurements are accurately timed. The position of the termination of the trajectory. whether by impact on the surface or by sir burst, and the corresponding time of flight are determined with special care. A better sample of the conditions of use of the missile is acquired by conducting the firings on several days. using different lots of ammunition. and in the case of projectiles using both new and old guns. In range bombing. or bomb calibration, bombs are dropped from a number of altitudes and at different aircraft speeds. A series of position and time measurements for aircraft and bomb. bomb yaw and meteorological data are recorded. The position measurements are usually made by photographic instrumentation. Much the same methods are used for aircraft-dropped mines.

Construction of Tables.—For a projectile, two trajectories are computed for each round. from the mathematical model chosen. using the actual conditions under which that round was fired: muzzle velocity. meteorological conditions and so on. These are called weather trajectories. and the two computed differ only in the value of the form factor used. The best form factor is determined by comparison of the weather trajectories with the range firing data for the round. Marked variation of the form factor from round to round is generally a sign that the assumed

drag function is a poor one. When the best value of the form factor for all the firings has been found. standard trajectories and differential corrections may be computed and the firing table composed. The procedure is similar for rockets, although the thrust must be included as another force, and special attention must be given to the burning period. during which a small yaw may produce a considerable effect because the thrust acts along the rocket axis and not along the trajectory. For this reason, a more complex mathematical model is usually employed for the period of burning than after burning.

For a bomb. a rather simple model is used, and two form factors are determined, one giving best fit with the observed range and another best fit with the observed time of flight. The table entries of range and time of flight are computed with the two separate form factors. The form factors are different because the mathematical model is not fully adequate; it ignores the disturbance of, the bomb's motion by the air flow about the aircraft at release. As aircraft speeds continue to increase, it may be necessary to develop a more sophisticated model.

Other Problems. — Problems of the stability of rockets and bombs may be attacked by the methods which have been outlined. The basic difficulty with both types is that substantial yaw may be induced early in the trajectory while the missile is still moving relatively slowly. This occurs when a rocket is fired into a cross wind and when a bomb is released from a high-speed aircraft. Once the yaw exists. there is a complex interaction of the effects of the various aerodynamic forces which may produce instability and bad flight. The circumstances under which this will occur have been investigated using advanced mathematical models, with good results. There are also approximate theories available which aid in understanding these phenomena. A similar but more difficult problem is that of projectiles fired from supersonic aircraft in any direction except ahead. The difficulty is due to the large disturbances induced in the projectile path by the supersonic air flow across it.

The role of exterior ballistics in the field of guided missiles may be considered as secondary. There is little interest in launching them precisely toward the target, since their flight is controlled throughout the trajectory. There are thus no firing tables for guided missiles, and exterior ballistic computations are made only for proposed designs. to determine their stability in flight and response to control forces.

Ballistic missiles are in a different category. A ballistic missile is guided from launching until the end of burning, at which point guidance and propulsion both cease. The missile then completes its trajectory in free flight. At the end of burning, therefore. it must be aimed for the target. as a projectile at the gun muzzle must be. The entries in the firing table are the data which must be set into the missile guidance system before launching. so that during the burning period it can steer the missile to the desired aiming conditions. The mathematical model for the trajectory calculations during burning includes the given thrust of the motor and a simulation of the modes of action of the control and guidance systems. During free flight these are inactive, and a simpler model is adequate. Over the major portion of its free flight, a long-range ballistic missile is at such a high altitude that aerodynamic forces are of little consequence; when the missile begins to descend toward its target, they become predominant. The problem of expense of firing is most serious; it is impossible to fire enough rounds to determine empirically all the quantities of interest, and ballistic computation plays an important part in providing answers to the design questions which must be resolved during development, as well as providing firing tables for the completed missile. Satellite trajectory calculations, from launching to orbit, are very similar to those for ballistic missiles.

The theory of the exterior ballistics of a missile traveling through water is not as highly developed as the theory for air travel. The density of the medium. and hence its resistance. is so much greater that what would be small, easily approximated effects in air must be considered in all their complexity. Experiment with scale models or full-scale missiles still dominates this field, although the theory is making substantial progress along much the same lines developed in air ballistics.

TERMINAL BALLISTICS

Terminal ballistics takes up where exterior ballistics leaves off — when the missile reaches the target or otherwise ends its flight. The portion of the missile active in producing target damage is referred to under the general name of warhead, although this usage is somewhat anomalous. since essentially the whole bomb or the whole projectile is the warhead, while rockets, guided missiles and ballistic missiles have warheads which are separate, identifiable components. Warheads produce their effects on the target by one or more of several means, which will be discussed briefly.

Blast is produced by the detonation of a charge of high explosive carried in the warhead. It produces its effects by means of a shock wave, whose propagation is calculable by fluid dynamics and whose properties are determinable by means of pressure measurements. Calculation of the effects produced is more difficult, particularly if the target is a complicated structure or is in motion. Detonation of the explosive also converts the metal case in which it is carried into high-velocity fragments, which are also capable of producing damage. Their numbers. directions of flight, velocities and masses are the parameters of interest, and description, prediction and control of these properties have been undertaken. Penetration. by the warhead or its fragments, may produce the desired damage directly, as in the perforation of a boiler or an aircraft fuel cell. Penetration of an armoured structure may also be a necessary preliminary to the infliction of other damage, as in the case of an explosive-loaded warhead fuzed to detonate after it enters the protected space behind the armour. Much study has been given to the penetration of earth, wood, concrete, rock, steel and flesh. The results depend upon a variety of factors, including the warhead (or fragment) mass. cross section, velocity and angle of impact and the strength of the target material. Observation of the process of penetration is very difficult because of the short times and large forces involved, and theoretical treatments have generally been semiempirical. The study of penetration damage to human or animal bodies is sometimes called wound ballistics. Incendiary mixtures (*q.v.*) are sometimes used to inflict damage by fire. Nuclear warheads produce not only blast but also intense thermal radiation and nuclear radiation, both immediate and lingering.

(RL. H. L.)

BALLOON, a bag or envelope of impermeable material which, when inflated with a gas lighter than air, rises from the ground. The complex of envelope with equipment, load, etc., is also called a balloon or an aerostat. Balloons have been important in sport, war and scientific research.

Legends of all time show that man desires to get his feet off the ground and soar into the unknown regions of the sky. but the methods described in the legends always copied nature and used heavier-than-air devices. (*See* AERODYNAMICS.) Neither in the vegetable nor animal kingdom does nature make use of lighter-than-air devices; *i.e.,* aerostatics. Balloons, therefore, did not result, as did airplanes, from man's ability to adapt nature's methods to his own use. Balloons resulted from man's creative genius.

Invention and Early History. — The Montgolfier brothers. Jacques Etienne and Joseph, French paper manufacturers. on June 15, 1783. at Annonay near Lyons, filled a bag 33 ft. in diameter with smoke from a straw fire and saw it rise to a height of 1,000 ft. Soon it was realized that not the gas resulting from the straw combustion but the heat made the balloon go up. Air expands when heated so that a given volume weighs less than the

same volume of cold air.

The impression created by the Montgolfiers' experiment was tremendous, and in August of the same year J. A. C. Charles. a French proiessor of physics, released a hydrogen-filled balloon irom Paris. It had long been known that hydrogen was lighter than air. but only the year before. in 1782, had Tiberius Cavallo made soap bubbles with hydrogen and seen them rise to the ceiling of the room. an easy and still fascinating experiment. In Great Britain a number of miniature hot-air and hydrogen balloons were sent up in 1783 and 1784. and in Aug. 1784 abortive attempts were made to fly in hot-air balloons by James Tytler (editor of the second edition of the *Encyclopædia Britannica*) at Edinburgh. and by Moret and Keegan at London. The first aerial voyage in Britain was made by the Tuscan Vincenzo Lunardi on Sept. 15, 1784, when he flew in a hydrogen balloon from London (Moorfields) to Standon in Hertfordshire.

A very interesting and quite fundamental law of physics states that the weight per cubic foot of any gas is strictly proportional to its molecular weight: *i.e.*, the sum of the weights of all the atoms forming the molecules of that gas. The average molecular weight of air is 29. and 1 cu.ft. of air at standard conditions (32° F. and 29.92 in. mercury) weighs 0.0807 lb. Any gas that is appreciably lighter than this can be used to inflate a balloon. The lightest of all known gases is hydrogen, the molecular weight being 2; the weight of 1 cu.ft. of hydrogen is only 0.0055 lb., and the lifting force of 1 cu.ft. is equal to the weight of 1 cu.ft. of air minus 0.0055 lb., that is 0.0752 lb. It is certain that there is no "missing link" among the light elements. and that no lighter gas will ever be discovered. Even if a weightless gas should ever be found, the difference between its lifting force and that of hydrogen would be so small that such a weightless gas would not have any great advantage from a lifting point of view.

Next to hydrogen, helium, with a molecular weight of 4, is the lightest gas and has the advantage over hydrogen of being noncombustible. Mixed with air, it does not explode. Formerly a very rare and expensive gas. helium was isolated in the 20th century irom some American natural gases. The United States armed forces rarely use anything but helium for inflating balloons.

The density of methane (molecular weight 16), the main constituent of natural gas, is too great to make it attractive. Ammonia, molecular weight 17, has the advantage of being easily compressed and transported in relatively thin cylinders, but pure ammonia is very dangerous to men. It can, however, be transformed chemically into a much lighter gas mixture of 75% hydrogen and 25% nitrogen.

The first experimental flights with animals as well as the first manned flights. however. were made with the Montgolfiers' hot-air balloons. Jean Pilâtre de Rozier (1756–85) went up several times in a captive balloon and proved it was possible to keep the fire burning while the balloon was aloft. On Nov. 21, 1783, Pilâtre de Rozier and the marquis d'Arlandes made the first manned free-balloon flight over Paris for 5½ mi. in about 25 minutes,

On Dec. 1, 1783, Charles. accompanied by one of the Robert brothers who had manufactured the balloon, ascended in a hydrogen-filled. rubberized silk balloon to 2.000 ft. and flew 27 mi. Most of the features of the classic free balloon (fig. 1) were introduced at this time. The only important later additions were: (1) the rip panel invented by the U.S. aeronaut John Wise (1808–79); and (2) the drag, or guide (trail), rope invented by the Englishman Charles Green (1785–1870). The rip panel is an elongated section of the balloon that is only lightly fixed in place and can be quickly pulled or ripped open at the moment of landing. It adds greatly to the safety of ballooning by making quick deflation possible and preventing the balloon from dragging along the ground, throwing the passengers against trees! houses or other obstacles. The drag rope, a heavy manila rope attached to the load ring, reduces vertical and horizontal speeds before landing, gives the aerostat a "front" and "back" and automatically replaces ballast release when flying very low over flat country.

Balloon Flight. — The control of a balloon is neither difficult nor complicated but requires intelligence and the ability to meet changing conditions. Before launching, the balloon is "weighed-off" by the release or addition. of ballast until it just barely stays on the ground. Then a certain amount of ballast is jettisoned, depending on conditions, and the aerostat is air-borne. The chief of the ground crew shouts, reminding the pilot to open the neck (or appendix), the opening at the bottom of the balloon. If the appendix is not opened, the expanding gas of a fully inflated balloon will burst the bag during ascent.

Once the balloon is air-borne. it becomes a part of the air. The balloon goes where the wind blows. There is no bumping, no noise. The sounds of the ground fade away. One loses the sense of earthliness and gains a feeling of being part of infinite space, almost a part of eternity Man, however, is man — and the time comes when one must return to earth. This too is a simple procedure. A line, or cord, leads from the basket up through the balloon to a valve, one to three feet in diameter. The pilot pulls this valve line, gas escapes and the balloon starts down. Once started, the balloon often descends with increasing speed, and the pilot must drop ballast discreetly to slow the descent. Instruments on board show the altitude and the rate of ascent or descent. A balloon that rises too rapidly usually "overshoots" its position of equilibrium, and it takes skilful maneuvering, valving and ballasting by the pilot

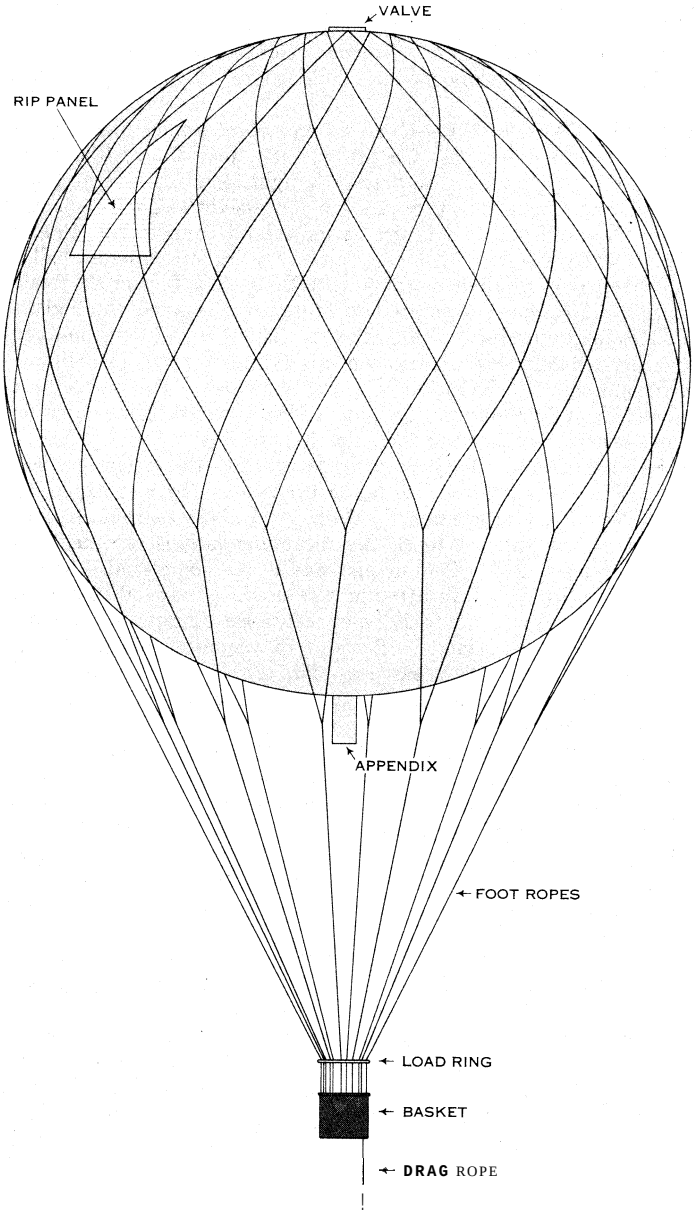

FIG. 1.—CLASSIC FREE BALLOON

to make the balloon level off. At different altitudes the winds blow in different directions, so that it is often possible for a smart pilot with knowledge of weather conditions to choose his direction of travel. Races have often been run to see who, starting from a given place, could land nearest to a specified point. Pilots frequently landed squarely on a bed sheet marking the desired spot

Other 19th-Century Flights. — In 1821, at the coronation of George IV, Charles Green made the first ascent with a balloon inflated with coal gas. Coal gas is much heavier than hydrogen and the fire hazard is greater, but its cheapness and its former easy availability offered great advantages. Green also, on Nov. 7, 1836, accompanied by Robert Hollond, M.P., and Monck Mason, flew in the "Vauxhall" balloon, later called the "Great Nassau" balloon, from London to Weilburg in the duchy of Nassau, Ger., a distance of 480 mi., in 18 hr., a brief time compared to the time such a trip would have taken by sailboat and horse-drawn coach.

The Alps were first crossed from Marseilles to Turin in Sept. 1849 by François Arban. Count Henri de la Vaulx flew over the Mediterranean in 1901 from Toulon to Algeria. One of the amazing early long-distance balloon flights was that of Wise, who in 1859 flew from St. Louis, Mo., to Henderson, N.Y., a distance of 800 mi. The distance record is held by H. Berliner who in Feb. 1914 flew 1,890 mi. from Bitterfeld, Ger., to Kirgishan (Urals). H. Kaulen had already made a duration record by staying aloft 87 hr in Dec 1913.

Flight Over Water. — Crossing important bodies of water has always been a challenge. On Jan. 7, 1785, Jean Pierre Blanchard, who later was to make the first U S flight, Jan. 9, 1793, at Philadelphia. and J. Jeffries, U S. physician, crossed the English channel from Dover, Eng , to a forest 12 mi. inland from Calais, France. They barely made it, throwing out every bit of available ballast and even part of their clothing. In June 1785 Pilâtre de Rozier and P. A. Romain attempted to cross from France to England. Pilâtre introduced a new idea that he hoped would help him control his altitude. the use of a hot-air cylinder. 10 ft. in diameter, attached beneath the gas bag of 37 ft. diameter. The device functioned for only about half an hour. Then the hydrogen caught fire and both men plunged to their death.

Several attempts have been made to cross the Atlantic ocean. john Wise was involved with the preparation of one expedition from New York city, using the *New* York *Daily* Graphic balloon, but withdrew when he found his recommendations repeatedly ignored or overruled. The voyage was never completed. Shortly before World War I an attempt was made with a 500,000-cu ft balloon, the "Suchard," to fly from east to west across the Atlantic, utilizing the trade winds Because of technical difficulties the flight was canceled at the last moment. After World War II new balloon designs and new materials made the project seem more feasible. and on Dec. 12, 1958, four Englishmen (three men and a woman) made another attempt to cross the Atlantic, leaving from the Canary Islands. The take-off was very rough, and unfortunately their barograph failed to function so that there was no objective record of the altitudes reached, the length of time in the air or of the distance traveled. They had wisely provided the balloon with a seaworthy basket and eventually completed a large part of their transatlantic journey by sailing on the ocean after cutting the balloon loose.

Ballooning as a Sport. — Interest in ballooning as a sport was greatly increased by James Gordon Bennett (1841–1918) nho offered a grandiose trophy and a substantial money prize to the winner of an annual long-distance race. The winning country was to be the host of the succeeding race. The trophy, after having been won three successive times (1922–24) by Belgium, came to rest permanently with the winner. The Belgians promptly offered a new prize and the races continued. The Belgian pilot Ernest Demuyter also won the races in 1920, 1936 and 1937, a total of six times. thereby demonstrating that winning a free-balloon race is not a matter of luck but one of skill. Poland won in 1938, and the races were not revived after World War II.

Reasons for the decrease of interest in ballooning as a sport lie in the widespread increase of electric-power lines, making landing operations dangerous, and in the great increase of airplanes. The horrifying catastrophe of the "Hindenburg" (see AIRSHIP: *Germany*) produced a terrific fear, not wholly justified, of hydrogen Helium is not only extremely expensive but not easily accessible to civilians. Coal gas is manufactured less and less.

Balloons in War. — The possibility of using balloons in war was envisioned from the beginning. Benjamin Franklin, in Paris at the time of the first ascents of the Montgolfier balloons, prophetically wrote: "This Method of filling the Balloon with hot Air is cheap and expeditious, and it is supposed. may be sufficient for certain purposes. such as elevating an Engineer to take a View of an Enemy's Army, Works, Etc. conveying Intelligence into, or out of a besieged Town, giving Signals to distant Places, or the like."

Military observation balloons (captive balloons; i e., balloons fastened to the ground by long cables) were actually used as early as 1794, and again during the American Civil War (1861–65) by both the Federal and Confederate armies. A city was first

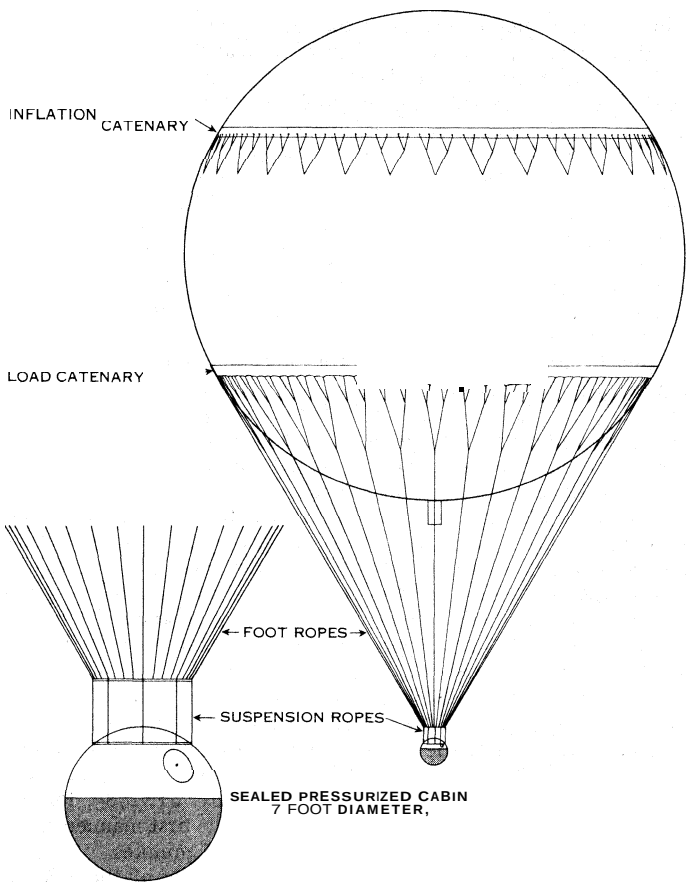

FIG. 2 — PICCARD STRATOSPHERE BALLOON

bombed from the air in 1849 when the Austrians used pilotless hot-air balloons to bomb Venice. In the War of 1870–71, during the siege of Paris, balloons had strategic importance They not only took out tons of mail but also carrier pigeons, which in turn brought news back into Paris Furthermore the balloons flew out the members of the French government into unoccupied parts of France.

The captive balloon used as an observation platform was the most common type of military balloon. The spherical captive balloon. however, is a very unsatisfactory instrument for such use. Even a wind of 20 m p.h. is too much for a captive spherical balloon. The aerostat bounces violently about. The envelope of the balloon has been known to come between the observer in the basket and the ground under observation. During the latter decade of the 19th century the spherical balloon was modified to make better captive balloons by elongation. addition of fins etc , resulting in an aerostat that combined the properties of the kite and

the balloon. Gradually a better streamlined body was developed largely by the Germans so that it could withstand winds of 50 m.p.h. The Caquot balloons designed bv the French in 1916 became the best captive balloons used in World War I for the observation of troops and the detection of submarines. It is claimed that they could stand a gale of 70 m.p.h. and rise to 6.000 ft. The invention of the airplane eventually eliminated the value of observation balloons. In World War II, however, captive balloons effectively raised steel-cable barrages over many cities and over ships at sea—forcing attacking planes to altitudes where precision bombing became difficult and strafing impossible.

Free unmanned balloons were also used in World War II by the Japanese to bomb the United States. Security measures and the co-operation of the press and radio prevented the enemy from learning how many of their balloons, nearly 1,000, actually reached some part of the North American continent. Believing that only a few had landed in America, the Japanese abandoned the weapon as ineffectual.

Scientific Use of Balloons.—The most important modern aspect of the free balloon lies in its contribution to meteorology and other sciences, notably the study of cosmic rays. The first aerial photographs were taken from balloons. The free-balloon pilot Captain Spelterini (real name Eduard Schweizer, 1852–1931) was the first to see and photograph the pyramids from above (1890).

Salomon August Andrée (1854–97) attempted to fly over the north pole in 1897 and actually came to within 500 mi. of it. but the information he uncovered on this tragic voyage was not found until 1930 when a Norwegian surveying party found the bodies of Andrée and his two companions 200 mi. from Spitsbergen, their starting point. The detailed boardbook, the diaries and letters found with the bodies were still largely decipherable. The photographs, even after 33 years, were developed and gave extraordinarily good prints.

Balloons opened the atmosphere to investigation, and scientists immediately made use of them for measurement of temperature, winds, humidity and so on. Long before men could climb Mt. Everest, its altitude was not only reached but surpassed by manned free balloons. Men strove for greater and greater heights. The use of oxygen became indispensable. but at high altitudes even with oxygen many balloonists died from suffocation.

Superficial consideration seems to show that men breathing pure oxygen could stay alive at a pressure of $\frac{1}{10}$ atm. (about 50,000 ft.). Mountaineers, without additional oxygen, in fact do go beyond an altitude where the pressure is $\frac{1}{2}$ atrn. (approximately 17.000 ft.). Since air is by volume $\frac{1}{5}$ oxygen, it would appear reasonable to assume that, breathing pure oxygen. man would not be worse off at $\frac{1}{10}$ atrn. than he would be when breathing air at $\frac{1}{2}$ atm. This hypothesis neglects, however. the fact that man emits carbon dioxide and water vapour at constant partial pressure. so that the little gas he would still get into his lungs at 50,000 ft. would be largely carbon dioxide and water vapour. In addition to oxygen deficiency at high altitudes there is the danger of "bends" (caisson disease). very small nitrogen bubbles developing in body tissue under decreasing pressure. In order to avoid "bends" one must breathe oxygen for some time before a high-altitude ascent as well as during the ascent—and one must ascend slowly. In a pressurized cabin these precautions are not necessary, but the pressurized cabin did not exist until after 1930.

Investigation of the upper atmosphere by unmanned balloons also eliminates this danger. The first small pilot balloon. a small unmanned balloon. came into use in 1893. The pilot balloon is usually made of latex and carries no load. It is sealed and rises at approximately constant speeds till it bursts. It is watched from below for observation of wind speeds and direction at different altitudes.

The pilot balloon was the forerunner of the sounding balloon, an unmanned balloon which carries scientific equipment and recording devices. Such balloons (both closed latex and open-neck plastic balloons) are in constant use for meteorological and cosmic-ray study and classified government projects.

The French meteorologist Leon Teisserenc de Bort (1855–1913) actually discovered the stratosphere by means of sounding balloons. He found that in the temperate zones, at and above an altitude of about 35,000 ft., the air temperature is nearly constant (−70° F.). From this discovery he concluded, a little too hastily, that above this altitude no vertical winds existed, and clouds had no reason to be formed. Eric Regener. (1881–1955). Robert Millikan (1868–1953) and others made intensive studies of cosmic rays during the 1920s and early 1930s by means of sounding balloons that had to be recovered after flight. Later radio balloons were used, but for years manned flights gave more reliable results. Manned flight. however, was restricted to low altitude.

Piccard Balloons.—Auguste Piccard, a Swiss scientist and professor of physics in Belgium, was also a balloon pilot and had used the free balloon in 1926 to perform the hfichelson-Morley experiment (*q.v.*) on light speed in different directions. When he became interested in cosmic ray study, he decided to modify the balloon (see fig. 2 and 3) and construct a pressurized cabin, so that he could ascend safely to the stratosphere with an effective physics laboratory. Sponsored by the Belgian Fonds National de la Recherche Scientifique (F.N.R.S.), he had little difficulty arranging for the manufacture of the balloon, which differed from the classical balloon chiefly by elimination of the net. The net was replaced by two catenary belts: the upper one for handling during inflation and the lower one for carrying the load during flight.

He had difficulty arranging for the construction of the cabin (gondola) and was repeatedly told it could not be done. Finally he asked a manufacturer to build him a spherical beer barrel with windows, so that he could look *into* the sphere to check on its contents, and a large hatch, so that a man could get inside to clean it. This the engineer said could be done.

The first cabins for the stratosphere balloons were built either of soft aluminum or magnesium by welding two "polar plates" and one centre belt together to form a sphere. In addition to several 4-in. windows looking out. both up and down, at a 45° angle, there was one window on top looking up, so that the pilot could check on the balloon, and one window looking down for purposes of terrestrial navigation. There were two hatches. This design has one drawback. A weld that terminates in a "dead end" creates, beyond the extremity of the weld, undue stresses in any sphere,

be it a balloon or a pressurized cabin. A fatal accident in Belgium and the destruction of a balloon during inflation in the Black hills of South Dakota drew attention to this basic fact. Jean Piccard, twin brother of A. Piccard, in designing the cabin for project Helios (*see* below) therefore designed a cabin using eight spherical triangles (fig. 3[A]) producing a spherical octahedron, so that no weld terminated in a "dead end." but each formed a portion of a "great circle" around the sphere. This cabin has been used three times by the U.S. armed forces for project Strato Lab (see Table II). Each time certain modifications have been made (fig. 3), the number of windows increasing from one 9-in. window to four. The number of hatches increased from one to two, and these are larger than the original hatch in order to allow the men to slide through them wearing pressure suits? parachutes and equipment.

The hatches of the early cabins each had double hatch covers, one inside and one outside, held together by a heavy screw. J. Piccard made a radical break in design by utilizing the inside pressure, and only the inside pressure. of the cabin to hold the single hatch cover in place: thus ensuring easy opening of the hatch when the balloon redescended to the air pressure at which the hatch had originally been closed or, during flight, after equalization of the inside and outside pressures.

Air regeneration in a pressurized cabin is a problem that must be solved. In a 7-ft. cabin occupied by two people the oxygen content. 21% by volume at the start, goes down about 1% of the total air volume per hour. After four to five hours fresh oxygen must be added. Carbon dioxide (0.03% at the start) goes up 1% of the total air volume per hour. After about one hour absorption of the excess should be started. using sodium or potassium hydroxide, which can be put into gauze bags hanging from the walls of the cabin. Even before the end of the first hour it is important to absorb "anthropotoxines," by-products of human metabolism, which very soon reduce human efficiency and easily produce nausea and other bad effects. While the above-named hydroxides absorb some of the anthropotoxines, activated charcoal is added for others. Water is best absorbed by magnesium perchlorate or by silica gel. The temperature of the cabin at altitudes between 35,000 and 85,000 ft. can be held within very agreeable limits (60°–70° F.) by the method described by A. Piccard. The last gondola designed by him and used by Comdr. T. G. W. Settle, U.S. navy, and by Jean and Jeannette Piccard (see Table I) was painted with a heat-reflecting white paint on its upper portion and black on its lower portion up to 4 in. above its equator. Later cabins, designed to go to 100,000 ft., have been kept unpainted in order to reflect a maximum of solar radiation.

Stratosphere Flights.—When everything was ready for A. Piccard's first stratosphere flight, starting from Augsburg. Bavaria, the German authorities tried to prevent the flight because the aerostat was not "conventional." It is difficult to realize that as late as 1933 the Piccard stratosphere gondola was the only pressurized aircraft cabin in existence, and that, even after A. Piccard's successful flights. the industry still believed that it was impossible to build pressurized cabins for high-altitude airplanes.

With his assistant, Paul Kipfer. Piccard in 1931 made the first manned flight to the stratosphere (51,775 ft.) and lived to tell the tale. In 1927 the barograph of a balloon manned by Capt. H. C. Gray of the U.S. army had shown that he had reached an altitude of 42,470 ft., but Captain Gray was dead at the landing. In 1932, with Max Cosyns. Piccard made the second flight. this time to an altitude of more than ten miles. There followed several other stratosphere flights (see Table I), and the record went to the United States in 1933. In 1935 Capt. A. Stevens and Capt. O. Anderson reached an altitude of 72,377 ft. in a flight sponsored by the U.S. army and the National Geographic society. This was a record both with respect to altitude and the amount and importance of cosmic-ray data obtained. The cosmic-ray instruments for this flight, as well as for the 1934 flight of J. and Jeannette Piccard, were built by the Bartol Research foundation of the Franklin institute under the direction of W. F. G. Swann.

The manned stratosphere flights made in the 1930s (Table I) were, in every instance, made with pressurized cabins that were copies of A. Piccard's original cabin with slight modifications, some of which were good, some of which were disastrous. The U.S. army-National Geographic society cabin was considerably larger than Piccard's. contributing to the efficiency of the crew. J. Piccard's method for rapid release of outside ballast not only assured the safe landing of his balloon through a heavy cloud layer but also saved the U.S. army-National Geographic society flight at the start when high winds blew the balloon to the edge of the Stratobowl before the cabin had wholly cleared it. One of the Russian cabins had hatch covers held by numerous bolts (instead of one central screw or, as in J. Piccard's later design, none at all), each of which had to be opened by a wrench. This arrangement resulted in the death of the Russian crew, who could not bail out in an emergency. The balloons themselves were made successively larger but were still constructed according to Piccard's design, and one used the same general inflation technique. Stratosphere balloons: manned or unmanned, are only partially inflated before start. The material was rubberized cotton but was thinner than standard balloon fabric.

Later Design and Material Developments.— The ultimate seemed to have been reached. It seemed impossible to build larger balloons of light enough material. It was time for another break with convention. In 1935 Thomas H. Johnson, then assistant director of the Bartol Research foundation, suggested to J. Piccard the possibility of making sounding balloons from a new material, a plastic film called cellophane. Johnson and others had customarily used sealed latex balloons singly or, for heavier loads, in small clusters. Johnson wanted a single balloon capable of carrying radio-equipped cosmic-ray instruments to high altitudes. Piccard immediately went to work designing the new balloons and built the first on the floor of the attic of the Bartol Research

TABLE I.—*Early High-Altitude, Manned Free-Balloon Flights 1931-36*

Date	Crew	Launching site	Landing site	Balloon volume	Altitude	Remarks
May 27, 1931	A. Piccard P. Kipfer (engineer)	Augsburg, Ger.	Ober Gurgl glacier, Aus.	500,000 cu.ft.	51,775 it.*	First use of pressurized cabin for manned flight. Altitude record. Duration 16 hr. Valve rope broke, but crew and scientific equipment landed safely
Aug. 18, 1932	A. Piccard M. Cosyns	Zürich, Switz.	Volta Mantuana, Garda, Italy	500,000 cu.ft.	53,153 ft.*	New altitude record. Fully controlled flight with scientific equipment functioning well. First daytime landing from the stratosphere
Sept. 30, 1933	G. Profkoviet F. N. Birnbaum K. D. Godunow	Moscow, U.S.S.R.	Near Moscow, U.S.S.R.	860,000 cu.ft.	60,680 ft.	Claimed altitude not verified by Fédération Aéronautique Internationale but accepted through courtesy. No information about scientific work
Nov. 20, 1933	T. G. W. Settle, U.S. navy Maj. C. Fordney, U.S. marines	Akron, O.	Blayside, N.J.	600,000 cu.ft.	61,221 ft.*	New altitude record. Valve rope escaped from cabin during flight. Much equipment, even doors, jettisoned. Safe landing at southern tip of New Jersey
Aug. 18, 1934	M. Cosyns N. Van der Elst	Hour Havenne, Belg.	Morska Sobota, Yugo.	500,000 cu.ft.	50,840 ft.	Balloon traveled approximately 1,000 mi., a distance record for stratosphere flights
Oct. 23, 1934	Jeannette Piccard Jean Piccard	Dearborn, Mich.	Cadiz, O.	600,000 cu.ft.	57,579 ft.*	Take off and landing through thick cloud layer. Fully controlled flight. Heavy load of scientific equipment gave good cosmic-ray data
June 26, 1935	Warigo Christofil Priluchi	U.S.S.R.	U.S.S.R.	883,000 cu.ft.	52,800 ft.	During uncontrolled descent the crew parachuted to safety
Nov. 11, 1935	Capt. A. Stevens Capt. O. Anderson, U.S. army	Rapid City, S.D.	White Lake, S.D.	3,700,000 cu.ft.	72,377 ft.*	New altitude record. Heavy load of scientific equipment gave rich cosmic-ray data and photographs. Fully controlled flight

*Altitude verified by the Federation Adronautique Internationale (F.A.I.).

TABLE II —*Notable Plastic Balloon Ascents*

Flight and balloon capacity	Date	Crew	Launching site	Landing site	Altitude	Load carried	Duration	Cabin	Remarks
Bartol Research foundation (cellophane), 2,578 cu.ft.	Spring-summer 1936	None	Swarthmore, Pa.	About 30 mi. distant	About 58,000 ft.	4 kg.	?	None	First plastic balloon. Appendix apparently failed to open. Balloon tore at top altitude
University of Minnesota (cellophane), 2,578 cu.ft.	June 24, 1936	None	Minneapolis, Minn.	Arkansas, distance 6 0 0	About 50,000 ft.	7 lb plus ballast	10 hr.	None	First plastic balloon to level off and carry scientific instruments over constant level course for considerable period
1—G.M.I.,* 144 cu.ft.	July 11, 1947	None	St. Cloud, Minn	North of Anoka, Minn.	28,000 ft.	4 lb.	About 3 hr.	None	First plastic balloon released after lifting of security regulations
36 and 37 Naval Research laboratory 27,000 cu.ft.	Feb. 14-20, 1956 Feb. 18-23, 1956	/None None	Oppama, Jap.	Precise locations not known	About 30,000 ft.	/Radiosonde weight not given	128 hr. 98 hr.	None None	Flight 36 traveled 15,400 mi. Flight 37 traveled 12,4001 mi. and was picked up in Strait of Gibraltar by a Dutch vessel at 36°58′ N., 00°16′ W. about one week after termination
University of Minn. 314-G.T.S.,* 1,000,000 cu.ft.	Sept. 7, 1956	None	Anoka, Minn.	Georgetown, Ky.	144,000 ft.	22 lb. plus 43-lb. ballast	About 3 days	None	Altitude record. Mylar Tetroon designed by W. F. Huch and K. B. Thorness, University of Minnesota
1856—G.M.I.,* 125,000 cu.ft.	Aug. 10, 1956	M. D. Ross Lee Lewis U.S. navy	Anoka, Minn	Stevens Point, Wis.	40,100 ft.	1,422 lb.	3 hr. 48 min.	Open	Crew used oxygen A Strato Lab flight
1948—G M I,* 202,000 cu ft	Sept 26, 1956	H. Froehlich K. Lang General Mills, Inc.	Anoka, Minn.	Cresco, Ia.	42,300 ft.	2,075 lb.	/About 6 hr.	/Open	Highest manned open-basket Bight
2000—G M I,* 803,000 cu ft.	Nov 8, 1956	M. D. Ross Lee Lewis U.S. navy	Rapid City, S.D.	Valentine, Neb.	75,800 ft.	1,772 lb.	3 hr. 52 min.	Piccard-type sealed aluminum sphere	New unofficial altitude record. A Strato Lab/ flight
Manhigh I—W.R.,* 2,000,000 cu.ft.	June 2, 1957	Capt. J. W Kittinger	South St. Paul, Minn.	Weaver, Minn.	96,000 ft.	1,213 lb.	6 hr. 32 min.	Winzen-type sealed aluminum capsule	New unofficial altitude record
Manhigh II—W.R.,* 3,000,000 cu.ft.	Aug. 19-20, 1957	Maj. D. G. Simons	Crosby, Minn.	Frederick, S.D.	101,500 ft.†	1,710 lb.	32 hr. 10 min.	Winzen-type sealed aluminum capsule	New official F.A.I. altitude record for manned flight
"Pleiades II" 30,000 cu.ft.	Sept. 18, 1957	Don Piccard	Valley Forge, Pa.	Spring Garden, Pa.	About 3,000 ft.	1355 lb.	2 hr.	Open aluminum	First multiple-plastic-balloon flight
Strato Lab II—W.R.,* 2,000,0	Oct. 18, 1957	M. D. Ross /LeeLewis U.S. navy	Crosby, Minn.	Hermansville, Mich.	86,000 ft.	12,395 lh.	9 hr. 20 min.	Piccard-type sealed aluminum sphere	Unofficial altitude record for two-man flight
98—R.I.,* 3,000,000 cu.ft.	Oct. 27, 1957	None	Brownwood, Tex.	Louisiana	137,750 ft.	510 lb.	10 hr. 30 min.	None	Altitude record for unmanned polyethylene/ balloons
2288—G.M.I.,* 3,755,544 cu.ft.	Oct. 4, 1958	None	Eniwetok, Marshall Islands	...	88,700 it.	2,412 lb.	3 hr. 15 min.	None	Balloon destroyed by rocket fired by radio. Heaviest load for unmanned balloon
2385—G.M.I.,* 3,814,000 cu.ft.	Sept. 9, 1958	None	Anoka, Minn.	St. Charles, Minn.	1105,350 ft.	1,538 lb.	18 hr. 57 min.	None	Largest Skyhook balloon
Strato Lab III—W.R.,* 2,000,000 cu.ft.	July 26-27, 1958	M. D. Ross Lee Lewis U.S. navy	Crosby, Minn.	Jamestown, N.D.	82,000 ft.	13,529 lb.	33 hr. 41 min.	Piccard-type sealed aluminum sphere	Heaviest load and dura-
Naval Research laboratory 10,000,000 cu.ft.	May 4, 1961	M. D. Ross Victor Prather U.S. navy	Aircraft carrier "Antietam," off Louisiana	Gulf of Mexico	113,500 ft.*		...	Open aluminum	Crew wore space suits. V. Prather killed in retrieval operations

*G.M.I. refers to General Mills, Inc.; W.R. to Winzen Research Inc.; G.T.S. to G. T. Schjeldahl Co.; and R.I. to Raven Industries, Iuc. These organizations manufactured the various balloons.

†Altitude verified by the Federation Aéronautique Internationale (F.A.I.).

foundation in Swarthmore, Pa.

These open-neck balloons were made from gores ("orange peelings") of the new film, attached to each other by vertical seams with cellophane tape which carried the main part of the load. Only the upper half of the balloon, measured vertically, was spherical. The lower half was conical. Both Johnson and Piccard built balloons of this design and flew them successfully in 1936 (see Table II). The one built and launched by Piccard (fig. 4), with the help of his students in the department of aeronautical engineering at the University of Minnesota, traveled a distance of 600 mi. carrying an automatic ballast-releasing device and radio equipment for reporting temperature, humidity and altitude during flight.

Confident in his plastic film balloons, Piccard went ahead with plans for manned flight and propounded a new theory. While it is true that the single sphere is the system with the smallest surface per unit volume, it is not the shape of the lightest possible aerostat. The stresses in an open-neck balloon at any location are proportional to the radius of curvature and proportional to the inside pressure difference, which in turn is proportional to the height above the appendix. This relation makes the stresses, and consequently the necessary thickness of the fabric (or film), proportional to the square of the diameter. The replacement of one large bag by eight small ones of the same total volume (fig. j) multiplies the surface by two but cuts down the stresses to one-quarter, so that the total weight of the eight small balloons is only half the weight of the large balloon of equal volume. More generally speaking, if one single balloon is replaced by n smaller balloons of the same total volume, the necessary weight is reduced by a factor equal to the third root of n.

The theory cannot be contested, but the maneuverability of a multiple-balloon aerostat was vigorously questioned. Sponsored by the Kiwanis club of Rochester, Minn., Piccard made a solo open-basket ascent to 10,000 ft. in a multiple-balloon aerostat. the "Pleiades," using 98 Deney and Almy latex sounding balloons (1937). When it was necessary to stop the ascent and bring the aerostat back to earth. Piccard simply eliminated one balloon, or more according to need, by cutting the string that held it to the load ring or by pulling the balloon down within reach and stabbing it with his knife. When. just before the landing, it became necessary to release several balloons in rapid succession, he shot them quickly with his revolver. He replaced the pulling of the rip panel of the conventional balloon by blasting off a large cluster of the balloons with a small charge of TNT.

After World War II new plastics were at hand, so that very large and efficient balloons could be built, and Piccard had plans ready for a flight to 100,000 ft. He was quietly seeking sponsorship when he met 0. C. Winzen and fired him with enthusiasm for the plan. Winzen successfully approached both the U.S. navy and General Mills, Inc.. and project Helios was started in 1946. It called for the construction of an aerostat employing 80 plastic

balloons of 250,000 cu.ft. each. The manufacture of the large plastic balloons was begun in 1947. These balloons were like the 1936 cellophane balloons, but larger, and like them, each balloon could be used only once. After experimentation with different films! polyethylene (0.001 in. thick) was chosen. The seams of the cellophane balloons had simply been taped because cellophane cannot be heat welded. For the seams of the polyethylene balloons Piccard combined heat welding and taping.

A corollary of the multiballoon theory explained earlier (fig. j) is simple: if one balloon carrying 70 lb. will rise to 100.000 ft., then 80 balloons will lift over 5,000 lb. to the same altitude. The new balloons required the development of new methods of inflation and the training of special teams to handle each balloon. The new, lightweight pressurized cabin (fig. 3) mentioned above was under construction in the early summer of 1947 when project Helios was. unfortunately, terminated. The feasibility of.putting a multiple-plastic-balloon aerostat into the air was declared impossible by the sponsors. Before the termination, however, J. and Jeannette Piccard were the first to launch one of the new 250,000-cu.ft. plastic film balloons successfully. Their method of inflation involved the use of an outer casing, or sleeve: which keeps the uninflated part of the balloon tightly together, preventing the wind from turning it into a huge sail. At the moment of release the inflation sleeve is ripped off. The project was still "classified," so that the balloon which carried no load was automatically ripped as soon as it was a few hundred feet off the ground.

The importance and usefulness of these balloons, now frequently called Skyhook balloons, was amply demonstrated after 1947. They were manufactured from polyethylene film by two firms in Minnesota and one in South Dakota. Another plastic balloon made from polyester film (Mylar), using a different design, was manufactured by still another firm in Minnesota.

Polyester films are stronger than polyethylene. Though for many years they were rarely used because they could not be heat welded satisfactorily (they still require a special adhesive for sealing the seams). they hold the altitude record for sounding balloons. (See Table II.)

Constant-level balloons are also built of polyester films. This constant-level balloon is a closed-neck pressure balloon, the gas volume of which is not affected by variation of temperature. If it is heated by the sun, the inside pressure increases without changing the volume of the displaced air. Its lifting force is, therefore, nearly constant, and the balloon has no primary reason to change altitude. The possibility of such balloons was long discussed in textbooks on ballooning, but the conclusion had always been that no balloon material was strong enough to withstand the increase of pressure produced by solar radiation. Normally balloons superheat in the morning sun and, as they rise, loose the expanding gas through the appendix. In order to maintain altitude, therefore, they are obliged to release ballast when they cool in the evening. Since plastic balloons are transparent, they are less heated by the sun. This fact in itself would not be sufficient to allow the building of constant-level balloons. By the late 1950s, however, there were plastic films which, weight for weight, were very much stronger than older balloon fabrics, and constant-level balloons could be. and were, built. launched and successfully flown by G. T. Schjeldahl Co.. maintaining a constant level over a period of several days.

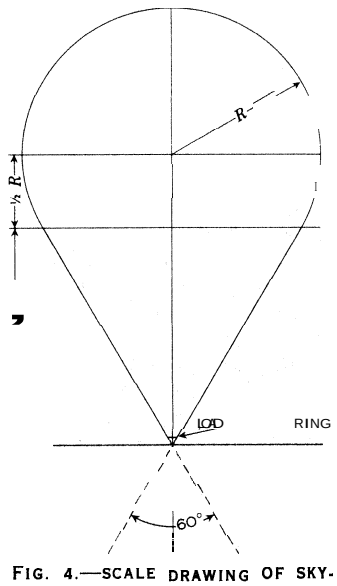

FIG. 4.—SCALE DRAWING OF SKYHOOK, THE PICCARD PLASTIC BALLOON

Further developments also took place in the shape of plastic balloons. Ralph Upson, professor emeritus of the University of Minnesota, proposed the "natural" shape (fig. 6) which takes the stresses off the film and transfers them to the tapes (now made of fibreglass) to a greater extent than occurs in the Piccard design. The disadvantage of the "natural" shape from the manufacturer's point of view comes from the fact that each time there is a need to change the size of the balloon or the load it is designed to carry, gores must be retailored. and the complicated calculation must be done by analogue computer. No two balloons of different size have exactly the same "natural" shape.

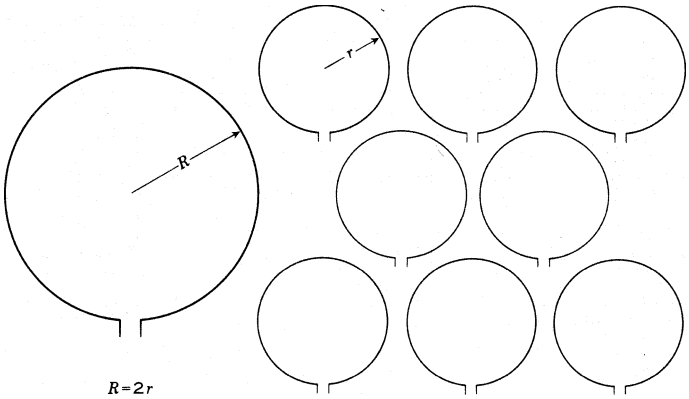

FIG. 5.— PRINCIPLEOF THE MULTIPLE VERSUS THE SINGLE BALLOON
For equal strength the material of the large balloon must be four times as strong and weigh four times as much per square inch as that of the small balloons

Three other shapes have been developed for the sake of economy rather than efficiency. Athelstan Spilhaus of the University of Minnesota introduced the "pillow" balloon. "Endless" plastic tube. as produced by the industry, is quickly formed into "pillows" by one straight transverse weld and one cut per balloon. These balloons were used in great numbers to send information behind the "iron curtain."

The Tetroon, a balloon shaped like a tetrahedron, designed by W. F. Huch. research fellow, and R. B. Thorness. engineer. at the University of Minnesota and first manufactured in Northfield, Minn. (Table II), requires only straight-line cuts and taping of flat film. The shape of the tetrahedron when inflated comes surprisingly close to that of a sphere, although the stresses are not uniform. In this manner, balloons, nearly as efficient mechanically as spherical balloons. are more simply and economically manufactured than the Skyhook.

Another economical balloon is the "milk-bottle" designed by Don Piccard. son of J. Piccard. It is made simply by tying off one end of a length of plastic tubing and binding the other end around a ring to which the load is suspended. D. Piccard used a complex of 12 of these to form a multiple-plastic-balloon aerostat, the "Pleiades II." In order to bring any manned aerostat back to earth. it is necessary to release gas in determined amounts. With a small number of balloons, cutting a balloon loose, as was done in the original "Pleiades" flight, would cause the loss of too great an increment of lifting power at any one time. "Valving" became necessary. Piccard accomplished this by pulling the top of a balloon down with a cord leading through the balloon until gas spilled out of the appendix, a much safer method from the fire hazard point of view than the historic method of valving. On his flight in Sept. 1957 Piccard proved the feasibility of his father's project—a multiple-plastic-balloon aerostat.

Manned Scientific Flights. — Many scientific experiments can now be handled by radio-sounding balloons. Manned flights, however, are still necessary for such experiments as photographing the spectrum of Mars. Automation has advanced very far in the past years, but man is still, as W. F. G. Swann said: "the best automaton yet created." For this reason manned flights to greater and greater altitudes are desirable: and science asks for them. The balloon has the advantage not only of being able to reach altitudes where the earth's atmosphere is very thin (approximately 0.001 atm.) hut of maintaining an essentially stable platform there for hours, even days on end, while traveling very great distances.

As has been seen, however, single balloons of too great a volume are inefficient. although with better quality of plastic films and tapes extremely large balloons of good efficiency can be made. (Table II.) A Skyhook balloon of 3,000,000 cu.ft. has carried a load (unmanned) of 510 lb. to an altitude of 137,750 ft., while one of the same volume carried 1,710 lb. (manned) to only 101,500 ft. (Table II.) A single balloon of seven times this volume, however, would not be able to carry a sevenfold load to the higher altitude (137,750 ft.). On the other hand, a cluster of seven balloons, each of 3.000.000 cu.ft. capacity, would carry a 3,500-lb. manned laboratory to this great altitude.

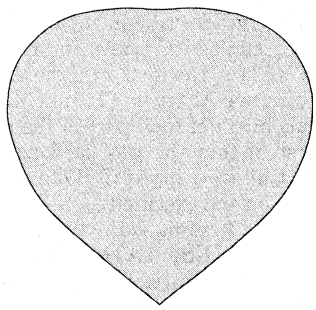

FIG. 6.—OUTLINE OF THE "NATURAL" SHAPE OF THE UPSON PLASTIC BALLOON

Compared to the Piccard balloon (Fig. 4), the horizontal circumference has been expanded and the vertical axis shortened. The meridian lines remain the same

The future of high-altitude manned ballooning lies therefore in the multiple-plastic-balloon aerostat.

(J. F. PD.; JE. P.)

BALLOONFLOWER *(Platycodon grandiflorum)*, a Eurasian. showy perennial of the bellflower family (Campanulaceae) that is widely grown for ornament. It is an erect herb. from 18 to 30 in. high, with usually solitary, terminal inflated buds (whence the common name), which open to bell-shaped or deeply saucer-shaped, dark blue (pale blue, lilac or white in some varieties), 2–3 in. wide flowers. Dwarf and double and semidouble flowering forms exist. They are handsome, easy to grow, border plants.

(J. M. BL.; X.)

BALLOT, in modern times a sheet of paper that a voter uses to indicate his choice of candidates in an election. Ballots are customarily deposited in a ballot box until the polls are closed and are then taken out and counted. The Australian ballot, so-called because of its origin, is a form of official balloting that affords the voter the chance to vote secretly. See ELECTORAL SYSTEMS; VOTING MACHINES.

BALLOU, HOSEA (1771–1852), U.S. Uni ersalist theologian, for over 50 years the most influential leader of the Universalist Church. was born at Richmond. N.H., on April 30, 1771, the son of a Calvinistic Baptist minister. He was converted to belief in universal salvation in 1789 and began preaching the doctrine on a Calvinistic basis, substituting for the elect all mankind. He re-examined Calvinistic tenets, however, under the influence of Ethan Allen's deistic work *Reason the Only Oracle of Man.* The result of his rethinking of Universalist theology was forcefully presented in his most important book, *A Tvcntisc on Atonement* (1805). Ballou placed great stress on the use of reason in religion, transferred Universalism from a trinitarian to a unitarian base and discarded the doctrines of original sin and vicarious atonement:. Christ died not to reconcile God to man but rather as a demonstration of God's unchanging love for man. Between 1795 and 1805 Ballou's forceful preaching converted the greater number of Universalist clergymen to the new liberal approach. From 1817 he took the position that punishment for sin is limited to this life; at death the soul is immediately purified by divine love and enters the state of immortality. The controversy which ensued resulted in the secession of the "Restorationists," who insisted on belief in a limited period of punishment in the afterlife. Ballou set forth his position in *An Examination of the Doctrine of Future Retribution* (1834).

After circuit riding for several years. Ballou served churches in Portsmouth, N.H., Salem, Mass., and Boston (1817–52). He died at Boston on June 7, 1852. *See* also UNIVERSALIST CHURCH.

See the biography by O. F. Safford (1889) and Ernest Cassara, *Hosea Ballou and the Rise of American Religious Liberalism* (1958).

(ET. CA.)

BALLYCASTLE, an urban district of County Antrim, N.Ire., 55 mi. N.N.W. of Belfast, on a bay of the same name opposite Rathlin Island, where Robert Bruce is said to have hidden in a cave. Pop. (1961) 2,643. At the foot of Glenshesk and close to Knocklayd (1,687 ft.), it has a pleasant strand. Cliffs run east, to reach their highest at Fair Head (626 ft.), and west past Carrick-a-rede Island, known for its rope bridge. Near the town are the ruins of Bonamargy Franciscan friary. Ballycastle became a market centre, fishing harbour and holiday town.

BALLYMENA, a municipal borough in County Antrim, N.Ire., on the river Braid. Pop. (1961) 14,740. It is 28 mi. N.N.W. of Belfast and is close to the fine desolate scenery of the Xntrim plateau and the Glens of Antrim. A market town, it serves a wide countryside and its industries include the spinning, weaving, finishing and bleaching of linen and the manufacture of carpets and tobacco. Harryville Mote overlooking the Braid is an Anglo-Norman motte and bailey castle.

BALLYSHANNON (BÁILE ÁTHA SEANAIGH), a seaside town in County Donegal, Republic of Ireland, at the mouth of the Erne, 139 mi. N.W. of Dublin by road. Pop. (1956) 2,434. The town is built up the steep banks of the river and is crossed by a bridge connecting it with the suburb of The Port. O'Donnell castle, built in 1423, once stood north of the market yard. It was successfully defended by Hugh Roe O'Donnell against the English under Sir Conyers Clifford in 1597. demolished in 1602, rebuilt in 1610, again demolished and finally built over. The poet William Allingham was born in Ballyshannon. One mile northwest are the ruins of the once-famous Cistercian abbey of Assaroe.

The Erne river hydroelectric development scheme comprises two power stations, the Cathaleen's Fall power station at Ballyshannon and the Cliff power station near Belleek.

BALM, name applied to several plants of the mint family, especially *Melissa officinalis,* also called balm gentle or lemon balm, and cultivated for its fragrant leaves. which are used in flavouring. The term also is applied to *Melittis melissophyllum,* bastard balm; *Monarda didyma,* bee balm or Oswego tea; *Collinsonia canadensis,* horse balm; *Glecoma hederacea* and *Satureja (Calamintha) nepeta,* field balm; and *Molucella laevis,* Molucca balm or bells of Ireland. Aromatic exudations from species of *Commiphora* (trees and shrubs of the incense-tree family [*see* BURSERACEAE]) also may be referred to as balm. Balm of Gilead or balm of Mecca is the myrrhlike resin from *C. opobalsamum* of Arabia. The balsam fir *(Abies balsamea)* is sometimes called balm fir or balm of Gilead fir. The balm of Gilead poplar is *Populus gileadensis.* Balm of heaven is the California laurel *(Umbellularia californica).*

(J. W. TT.)

BALMACEDA, JOSÉ MANUEL (1840–1891), Chilean liberal reformer and president, whose struggle to strengthen the presidency led to a major civil war, was born in Santiago on July 19, 1840. A scion of a wealthy family, he studied first for the church. but his trip to the Lima congress of 1864 as an aide to former Pres. Manuel Montt (*q.v.*) decided him on a political career. In 1870 he was elected to congress, where he soon showed qualities of leadership. From 1878 to 1881 he was minister to Argentina, in which post he succeeded in keeping Argentina from joining Peru and Bolivia against Chile in the War of the Pacific (*q.v.*). He returned to Chile to serve in the cabinet of Pres. Domingo Santa Maria (1881–86), where he energetically pushed anticlerical measures and promoted public works with the ever-growing public revenues derived from nitrates.

Balmaceda was elected president in 1886. During his regime public education mas advanced and major achievements were made in several technical areas, including railroad construction. The president, however, was caught up in the legislative revolt against the executive, begun in the 1860s, which was aggravated by bitterness in certain sectors over the religious reforms. Balmaceda fought valiantly to prevent congressional erosion of the powers of the president, but his relations with congress deteriorated to the point where he was obliged to dissolve that body. This precipitated the Chilean civil ar (*q.v.*). Congressional forces, supported by the navy, rose in revolt. After a hard-fought struggle that lasted eight months, Balmaceda's forces were finally defeated. He sought asylum in the Argentine legation where he committed suicide on Sept. 19, 1891. Balmaceda's defeat and death left conservative parliamentary government entrenched until the mid-1920s. *See* CHILE: *History*. (J. J. J.)

BALMER, JOHANN JAKOB (1825–1898), Swiss mathematician and physicist, discovered a formula basic to the development of atomic theory. He was born May 1, 1825, in Lausen, Basel-Land canton, Switz. A secondary-school teacher in Basel from 1859 until his death, he also was a part-time lecturer on geometry at the University of Basel from 1865 to 1890. In 1884 Balmer developed a formula representing the wave lengths of the spectral lines characteristic of hydrogen. This formula, although containing only one constant, represents all the lines of atomic hydrogen in the visible and near ultraviolet regions with perfect accuracy. The series is generally known as the Balmer series.

The Balmer formula was derived in 1913 from two simple postulates by Niels Bohr. As had already been suggested by Balmer, Bohr predicted other line series of hydrogen, and such series were subsequently found by others. The Balmer formula has served as a model for the formulas of other spectral series and is therefore fundamental to the field of atomic spectroscopy. For a description of the position of the Balmer formula in atomic theory, *see* QUANTUM MECHANICS: *The Bohr Atom*. (G. HG.)

BALMERINO, JAMES ELPHINSTONE, 1ST BARON (*c.* 1553–1612), Scottish favourite of King James (James VI of Scotland, later James I of Great Britain and Ireland), chiefly remembered for his zeal in the Roman Catholic cause, was the third son of Robert, 3rd Baron Elphinstone (d. 1602). He was made secretary of state in Scotland in 1598, accompanied James to England in 1603 and the following year was made Baron Balmerino. In 1605 he became president of the court of session. Balmerino's downfall was occasioned by his attachment to his religion. In 1599 a copy of a letter to Pope Clement VIII, ostensibly from James and addressing the pope in very cordial terms, was seen by Elizabeth I. The English queen asked James for an explanation, whereupon both the king and his secretary of state declared the letter a forgery. There the matter rested until 1608, when the existence of the letter was again referred to during some controversy between James and Cardinal Bellarmine. Interrogated afresh Balmerino admitted that he had written the compromising letter, that he had surreptitiously obtained the king's signature and that afterward he had added the full titles of the pope. In March 1609 he was tried, attainted and sentenced to death, but after a brief imprisonment he was released. He retired to his estates, where he died in July 1612.

Balmerino's elder son JOHN (d. 1649), 2nd baron, was restored to his father's title in 1613. He was prominent in opposing Charles I's ecclesiastical policy in Scotland and for this he was imprisoned in 1634. He died at Edinburgh on Feb. 28, 1649. His great-grandson ARTHUR (1688–1746), 6th baron, was a distinguished Jacobite and took part in the risings of 1715 and 1745. After the first of these he was pardoned (1733), but following his capture at Culloden in April 1746, he was tried, found guilty of high treason and executed (Aug. 18, 1746). On his death the Balmerino peerage became extinct.

BALMES, JAIME LUCIANO (1810–1848), Spanish ecclesiastic, political writer and philosopher, whose liberal ideas found strong opposition in Roman Catholic conservative circles, was born in Vich, Cátalonia, on Aug. 28, 1810, and died there on July 9, 1848. Balmes was founder and editor of *El Pensamiento de la Nación*, a Catholic weekly, but he is best known for his *El protestantismo comparado con el catolicismo en sus relaciones con la civilización europea* (1842–44; Eng. trans., 1849), an able defense of Catholicism against the accusation of not sympathizing with the spirit of progress. His philosophical works are El *criterio* (1845), called Balmes' logic; *Filosofia fundamental* (1846; Eng. trans. by H. F. Brownson, 1856) and *Curso de filosofía elemental* (1847). *A* critical edition of his *Obras completas* by I. Casanovas was published in 33 vol. at Madrid (1948–50).

BIBLIOGRAPHY.—I. Casanovas, *Balmes; su vida, sus obras y su tiempo* (1942); *R.* Sencourt, "Jaime Balmes," *Dublin Review*, 221:29–43 (autumn 1948); B. Menczer, "Order and Liberty," *Tablet*, 192:36–37 (1948). (A. GA.)

BALMONT, KONSTANTIN DMITRIEVICH (1867–1943), was the leader of the Russian Symbolist poets of the late 19th century. He was born at Gumishche, in the province of Vladimir, in central Russia, on June 3, 1867. A student of Elizabethan drama and the works of Calderón, Poe and Shelley, he first became known as the translator of Shelley and apostle of his ideas. His extensive travels in South Africa, Mexico, New Zealand and Spain account for the exotic vein in his poetry. He produced his best work during the 1890s and the early years of the 20th century. The titles of the collections published during this period—Pod *severnym nebom* (1894; "Under the Northern Sky"), V *bezbrezhnosti* (1895; "In Boundless Space"), *Tishina* (1898; "Silence"), *Goryashchie zdanya* (1900; "The Burning Buildings"), *Budem, kak solntse* (1903; "Let Us Be Like the Sun")—indicate the stages of his development from pure aestheticism to an aggressive and partly anarchical Nietzschean poetry, which brcught him immense popularity. He also wrote several volumes of prose. In 1918, following the outbreak of the Russian Revolution, he went to live in Paris. He died there in 1943.

BALMORAL CASTLE, a private residence of the British sovereign, is situated in the parish of Crathie and Braemar, Aberdeenshire, Scot., on the right bank of the Dee (there spanned by a fine bridge), 8 mi. W. of Ballater and 926 ft. above sea level. Anciently belonging to the Farquharsons of the Inverey branch, but forfeited by them after the Jacobite rising of 1745, the estate was acquired subsequently by the earl of Fife. By his trustees it was leased to Sir Robert Gordon, brother of the prime minister, the earl of Aberdeen. On Sir Robert's death in 1847 Albert, prince consort, acquired the reversion of the lease and later became the owner of the property, which he bequeathed to Queen Victoria. The royal family arrived at Balmoral on Sept. 8, 1848. The small castle of the Farquharsons, although much added to in modern times, soon proved itself inadequate and the present castle was begun in 1853 and completed three years later. The site of the old castle is marked by an inscribed tablet on the lawn in front of the present building. The architect of the new castle was William Smith of Aberdeen, but the prince consort exerted considerable influence on the external design. Built in a light gray local granite, the castle is a contemporary version of the Scottish baronial style, the principal feature being a 100-ft. tower. Many memorials to the royal family were erected in the grounds, with some fine trees planted by Prince Albert. The parish church of Crathie (1903), replacing the kirk of 1806, is 1½ mi. E. Farther down the river stands Abergeldie castle, an ancient keep of the Gordons, with modern additions, which after 1848 was leased by

the sovereign, It was inhabiied by King Edward VII when prince of Wales. (W. D. S.)

BALNAVES, HENRY (1512?–1570), Scottish diplomatist, was one of the chief promoters of the Reformation in-Scotland. Educated at the universities of St. Andrews (1527) and Cologne, where he became a Protestant, he was appointed clerk to the treasury in 1537 and an ordinary lord of session in 1538. In 1543, during the Protestant period of the earl of Arran's regency, he became secretary of state and was a commissioner for the proposed marriage of Mary Stuart and Prince Edward (afterward Edward VI of England). but after Arran's reconciliation with Cardinal Beaton (Sept. 1543) he was imprisoned in Blackness castle. On his release (1544) by English forces under the earl of Hertford he became a paid agent of England and during the seige of St. Andrews castle he acted as emissary of the rebels. Following the surrender of the castle (June 1547) he was imprisoned at Rouen, where he wrote *The Confession* of *Faith* (1584). Balnaves returned to Scotland and was restored in Feb. 1557. He took an active part in the religious rising of 1559 and was a commissioner for the treaty of Berwick (1560). He was again appointed an ordinary lord of session in 1564. On the fall of Mary he sided with the Protestant lords and was one of the earl of Moray's commissioners at the York proceedings in 1568, by which time he was a privy councilor. He died in Edinburgh in Feb. 1570.

(P. G. B. McN.)

BALOCHI (BALUCHI). The term Balochi is used in its widest sense to describe all the populations inhabiting Baluchistan (Balochistan) in West Pakistan. but is more properly applied only to the tribes who speak the Balochi language. It should therefore exclude the Brahui-speaking tribes. The Balochi proper are divided into two groups, the Sulaimani and the Makrani, and these are separated from each other by a compact block of Brahui tribes. Branches of the Balochi tribe found in Sind and the Punjab belong to the Sulaimani group, while those of Seistan are Makrani.

The Balochi speak an Aryan language related to modern Persian and their original homeland lay probably on the Iranian plateau. There is little reliable information on their early history. though the tribe is mentioned already in Arabic chronicles of the 10th century A.D. The old tribal organization is best preserved among those inhabiting the Sulaiman mountains. Each tribe (*tuman*) consists of several clans and acknowledges one chief, even though in some *tuman* there are clans that stand in habitual opposition to the chief.

The Balochi are traditionally nomads with a preference for a pastoral style of life. but cultivation is becoming more and more common and every chief has a fixed residence. The villages are collections of mud or stone huts; on the hills enclosures of rough stone walls are covered with roofs of matting and so turned into temporary habitations. The Balochi raise camels, cattle. sheep and goats. and practise carpetmaking and embroidery. Their agricultural methods are primitive. They now profess Islam, but do not observe all the orthodox fasts and prayers, and among the tribesmen of the hills there are hardly any religious leaders (mullahs). They have the reputation of being singularly free from religious fanaticism and intolerance.

BIBLIOGRAPHY. — *Sf.* Longworth Dames, *The Baloch Race* . . . (1904); H. A. Rose, *A Glossary of the Tribes and Castes of the Punjab and North-West Frontier Province* . . . , 3 vol. (1911–14); H. Field, *Anthropological Reconnaissance in West Pakistan, 1955* (1959).

(C. v. F.–H.)

BALOCHI LANGUAGE, spoken by the Balochi (*q.v.*) in Baluchistan and Sind in West Pakistan, in Persian Baluchistan and the eastern border districts of Iran, and in the Merv region in the Turkmen Soviet Socialist Republic, overlapping also into southern Afghanistan. The number of speakers in 1954 may have been about 1,000,000. Although it closely resembles modern Persian in structure and has borrowed words from Persian, Arabic and Indo-Aryan languages. Balochi is an independent branch of Iranian, retaining some very archaic features (*see* IRANIAN LANGUAGES). It belongs to the "northwestern" group of Iranian, having been brought into its present home during the middle ages, and it has no special affinity to its nearest east Iranian neighbour, Pashto. Brahui (*see* BRAHUI LANGUAGE) has borrowed freely from Balochi. The language is divided into two dialect groups: the eastern (east of Quetta) and the western (in Makran. Iran. etc.).

Western Balochi is the more archaic. It has a very simple phonemic system. Thus. in western Balochi *brāt*, "brother." *āp*, "water," *gōk*, "cow," *rōch*, "day." *pād*, "foot," *drāj*, "long"; eastern Balochi *brāth*, *āf*, *gōkh*, *rōsh*, *phādh*, *drāzh*.

Characteristic of Balochi is the change of w- to *gw-*, as in *gwāt*, "wind," and of hw- to *w(h)*, as in *wāb*, eastern *whāv*, "sleep." Nasalized vowels are frequent. Balochi is written, but not to any great extent, in the Persian characters.

The grammar is simple, and there is no distinction of gender. The ancient case inflection is retained in a varying degree. There is an oblique case in *-a* or *-ā*, arid a genitive singular in western Balochi, *-äi*, etc. (*aspäi*, "the horse's"). But in some dialects the genitive is identical with the nominative or the oblique. Thus the western Balochi, *tai pissaī gisā* or *faii pita lōgā*, "in your father's house." corresponds to the eastern dialects, *thaī phith* (or *phisā*) *lōgh* (*ā*). The dative suffix is *-ār*, *-ārā*, and the oblique plural ends in *-āṅ*, genitive plural *-āna*, or *-ānī*. Attributive adjectives precede the noun and add the suffix *-ēn*. Thus, *sharrēṅ āp*, "good water." The comparative suffix is *-tir*.

The personal pronouns are in the western: *man*, "I," genitive *manī*, *amā*, *mā*, "we," *tau*, "thou," genitive *taī*, *shumā* (eastern *shawā*), "you." The numerals follow the Persian except in the case of *sai*, "three," *chiār* (eastern), "four."

The verb has two bases: the present or simple root, from which the infinitive is formed by adding *-ag*, *-agh*; and the past, formed as in other Iranian languages by adding *t*, in many cases with changes in the final root consonant. Thus, *kushag*, "to kill." *kushta*, etc.. "killed"; *rudag*, "to grow," *rusta*, "grew." Indefinite present first singular *kushāṅ*, *kushīn*; definite present *kushagāyān*; imperfect *kushagāyatān*; past *man kushta(g)*, intransitive past *man rasit(ag)āṅ*, "I arrived."

The so-called "passive" construction of transitive verbs in past tenses was no doubt the original one, and still prevails in some western dialects. Thus, *ē mardā ā mard jat*, "this man struck that man"; *ē mardā hamā mard kushtagant*, "this man has killed these very men." In some dialects, however. the object is put in the accusative/dative: *mardā apsārā kushta*, "the man killed the horse"; or the construction has been completely changed into the ordinary Persian one.

Literature.—Balochi possesses much simple and vivid popular poetry. The most original part is the epic ballads dealing with the early wars and settlements of the Balochi and recited in the assemblies of the clans by professional minstrels, who were, however, not poets themselves.

BALODIS, JANIS (1881–?), Latvian army officer, commander in chief of the army in his country's war of independence, was born on Feb. 20, 1881, at Trikate in the province of Vidzeme. He graduated from the military academy in Vilnius (Vilna) in 1902. was commissioned an officer in the Russian army and was wounded both in the Russo-Japanese War and in World War I. In Kov. 1918 he returned to Latvia and from the beginning participated in Latvia's war of liberation. For personal bravery, integrity and devotion to his troops Balodis became a legendary figure of that period. On Oct. 16, 1919, he was appointed commander in chief of the Latvian national army: and under his command the newly founded state saw its liberation. Subsequently General Balodis left the army and in 1925 was elected to the Latvian *saeima* (parliament). In Dec. 1931 he became minister of war. On hfay 15, 1934, he was appointed deputy prime minister in the cabinet of Karlis Ulmanis (*q.v.*). When on April 11, 1936, Ulmanis assumed the duties of the presidency, Balodis became the vice-president. Shortly after the Soviet army's occupation of Latvia. Balodis was arrested (July 21, 1940) and deported to the U.S.S.R. (A. SP.)

BALQA (AL BALQA'), a liwa (district) of the Hashemite Kingdom of Jordan, includes the subdistrict of Salt. Pop. (1959 est.) 79.532. Area about 432 sq.mi. One of the most fertile areas of the country, it produces cereals, grapes and fruit of many kinds. It adjoins the district of Amman on the east and extends as far as the edge of the Jordan valley on the west.

(G. W. L. H.)

BALQUHIDDER (Gaelic, "the farm in the back-lying country"), a village of Perthshire, Scot., best known as the burial place of Rob Roy (*q.v.*), lies near the eastern end of Loch Voil, about 2 mi. W. of Balquhidder station and 28 mi. N.W. of Stirling by road. Population of civil parish (1951) 671. The Braes of Balquhidder, a lofty ridge, rise along the northern bank of the loch. The Maclaurins held the district from the 9th century until their Macgregor neighbours slew the chief and ousted the clan in 1558. Robert Macgregor, known as Rob Roy, died in a house beyond the west end of Loch Voil in 1734. His grave and those of some of his family are said to be marked by three tombstones in the old churchyard, although the rude carving on the stones indicates that these date from several centuries before the time of Rob Roy. The old kirk is a ruin and stands in front of the new one.

BALSA, the name given to a tree (Ochroma pyramidale) of the bombax family (Bombacaceae), called also corkwood, native to tropical South America and noted for its exceedingly light wood (Spanish balsa, a "raft" or "float"). The wood resembles clear white pine or basswood. Well-seasoned commercial balsa wood. which weighs only 6 to 8 lb. per cubic foot (although it may weigh as much as 2½ lb. per cubic foot from very slow-growing trees). is the lightest commercial wood. Because of its buoyancy, about twice that of cork, it is admirably adapted for making floats for lifelines and life preservers. Its resiliency makes it an excellent shock-absorbing material for packing furniture and similar articles, and also for foundation pads for machinery. Because of its insulating properties, it is used for lining incubators, refrigerators and cold-storage rooms. Its lightness combined with high insulating power renders it extremely valuable as a material for constructing the various containers used in dry-ice transportation. It is also employed in the construction of passenger compartments for airplanes and in making model airplanes and boats.

BALSAM, a term properly limited to such resins or oleoresins as contain benzoic acid or cinnamic acid or both. Those balsams which conform to this definition make up a distinct class, allied by their composition, properties and uses. Those found in commerce are the balsam of Peru. balsam of Tolu, liquid storax and liquidambar. Balsam of Peru is the produce of a lofty leguminous tree, *Myroxylon* pereirae, growing within a limited area in El Salvador and introduced into Ceylon. It is a thick, deep brown or black, viscid oleoresin having a fragrant balsamic odour. It is used in perfumery. Though mentioned in the pharmacopoeias it has no medicinal value. Balsam of Tolu is produced from M. *balsamvm*. It is brown, thicker than Peru balsam and becomes solid on keeping. It also is a product of equatorial America. It is used in perfumery and as a constituent in cough sirups and lozenges. Liquid storax is a balsam yielded by *Liquidambar* orientalis, a native of Asia Minor. It is a soft resinous substance with a pleasing balsamic odour, especially after it has been kept for some time. It is used in medicine as an external application in some parasitic skin diseases. and internally as an expectorant. An analogous substance is derived from *Altingia* excelsa in Java. Liquidambar balsam is derived from Liquidambar *styraciflua,* a tree found in the United States and Mexico. It contains cinnamic acid but not benzoic acid.

Of so-called balsams, entirely destitute of cinnamic and benzoic constituents, the following are found in commerce: Mecca balsam or balm of Gilead, from *Commiphora* opobalsamum, a tree growing in Arabia and Ethiopia. When fresh it is a viscid fluid with a penetrating odour, but it solidifies with age. For balsam of copaiba *see* COPAIBA. Under the name of wood oil, or Gurjun balsam. an oleoresin is procured in India and Indonesia from several species of *Dipterocarpus,* chiefly D. *turbinatus,* which has the odour and properties of copaiba and has been used for the same purposes. Wood oil is also used as a varnish in India and forms an effective protection against the attacks of white ants. Canada balsam or Canada turpentine is an oleoresin yielded by the balsam fir, *Abies* balsamea, a tree that grows in Canada and the northern part of the United States (see CANADA BALSAM).

The garden balsam is an annual plant, Impatiens *balsamina,* family Balsaminaceae, and the balsam apple is the fruit of *Momordica balsamina,* family Cucurbitaceae.

BALSHAM, HUGH DE (d. 1286), English Benedictine monk, was bishop of Ely and one of the founders of the collegiate system at Cambridge university. After having been subprior of the monastery of Ely, he was elected by his brethren bishop of Ely in 1256. King Henry III. however, chose another man for the bishopric, and it was only after much trouble that the pope confirmed his election in 1257. In 1280 Hugh provided lodging for scholars at the Augustinian hospital of St. John in the nascent university at Cambridge, but, the arrangement proving unsuccessful, the bishop separated the students from the hospital and used some of the revenue of the church of St. Peter to establish in 1284 a hall for the students which came to be known as Peterhouse.

(E McD)

BALTIC, THE. The Baltic exchange, or Baltic Mercantile and Shipping Exchange, Ltd., originated in London in the 17th century, when ships' captains and merchants met to do business in various coffeehouses, from 1744 at one called the Baltic. The exchange is unique today as a world market for fixing cargoes for tramp ships, and has other markets for the sale and purchase of grain in bulk, for dealing in oilseeds and for chartering aircraft. Its 2,500 members represent shipowners and merchants, and negotiations are verbal; hence the importance of the Baltic motto: "Our Word our Bond." The exchange—in St. Mary Axe since 1903—is in the midst of London's shipping community. In 1956 Queen Elizabeth II opened a new wing to the exchange, containing a spacious banqueting suite.

BALTIC LANGUAGES. A branch of the Indo-European (*q.v.*) linguistic family spoken on the southeastern shores of the Baltic sea, the Baltic languages (B.L.) include modern Lithuanian (Lith.) and Lettish (Let.), or Latvian, and now extinct Old Prussian (O.Prus.) as well as the dialects of the Curonian (C.), Semigallian (Sm.) and Selonian (Se.) tribes. (See also LITHUANIAN LANGUAGE; LETTISH [LATVIAN] LANGUAGE.)

Lacking, a common genuine name, the designation B.L. (*Baltische* Sprachen), first suggested by F. Nesselmann in 1845, has replaced from the end of the 19th century the misleading terms of Lettic or Lettish, Lithuanian and Letto-Lithuanian. The Lithuanian philologist K. Buga, utilizing Tacitus' (*De Germania*) *Aestiorum* gentes, proposed a term Aistian (*aisčių kalbos*) which, however, has not been generally accepted in linguistic literature. Within Indo-European (I.E.), Baltic belongs to the satem group which also includes Slavonic, Indo-Iranian, Armenian and Albanian and is characterized by the change of the primitive I.E. palatals $*k̂$, $*ĝ$ to sibilants in contrast with a mere dispalatalization in the centum group (Italic. Greek, Teutonic, Celtic, Tocharian and Hittite). Thus, corresponding to the primitive I.E. word $*km̥tóm$ "hundred" on one side are Lith. *šimtas,* Let. *simts,* Old Church Slavonic (O.Ch.S.) *sŭto,* Sanskrit (Sans.) *çatám,* Avestan *satəm* and on the other. Latin (Lat.) *centum,* Greek (Gr.) hekatdn, Gothic (Goth.) *hund.*

Baltic and **Slavonic.**—Baltic in its primitive form is more closely related to Slavonic than to any other branch of I.E. Both have a number of common features in phonology and morphology as well as in vocabulary and syntax. This led many scholars in the 19th century to the assumption of a Balto-Slavonic linguistic unity, placed (T. Milewski, 1948) between 2000 and 1500 B.C., a concept never disproved though often attacked. (See SLAVONIC LANGUAGES.)

Most of the earlier scholars working on this problem based their conclusions on a bare enumeration of actual similarities between Baltic and Slavonic. They neglected to take into consideration the possibilities of a dialectal I.E. inheritance, parallel developmen; due to close vicinity, late origin and borrowing.

Among the exclusively Balto-Slavonic innovations may he mentioned: (1! a dual representation of *I.E.* syllabic *r̥*, **l̥*, **m̥*, *n̥* by *ir, il, im, in* and *ur, ul, um, un* (*cf.* Lith. *vil̃kas* "wolf" = proto-Slavonic [Pr.S.] **vĭlkŭ* and Lith. *tul̃žti* "to soak" = Pr.S. **tŭlstŭ* "thick": (2) certain accent shifts (Lith. *dū́mai* "smoke" = Russian (Rus.) *dým*, genitive *dýma* in oppoiition to Sans. *dhūmàh*. Lith. *rankà* "hand." accusative singular *rañką* = Rus. *ruká, rúku*) and tone correspondences (Lith. *várna* "crow," *var̃nas* "raven" paralleled by Serbo-Croatian *vrȁna, vrân*); (3) dative plural in *-mus* (Old Lithuanian [O.Lith.] *vilkamus* = Pr.S. **vĭlkomŭ* in contrast with Sans. *vr̥bébhyah*); and (4) genitive plural **nōs(s)ōn* "of us" (*cf.* O.Prus. *nuson*, Lith. *mū́sų*, O.Ch.S. *nasŭ*). On the other hand, the innovation in the genitive singular Lith. *vil̃ko*, Let. *vilka* = Pr.S. **vĭlka* (originally an ablative iorm) is not shared by O.Prus. And the formation of the definite adjective by adding the pronoun **jo-* (*cf.* Lith. *basàsis* from *bãsas* + *jìs* and Pr.S. **bosŭjĭ* from *bosŭ* + *jĭ* "the barefoot one"), frequently quoted as exclusively Balto-Slavonic. occurs also in Xvestan and is rather a comparatively late parallel development. *If* this feature were old. one would expect in Slavonic **bosošĭ* or at least **bosŭšĭ* (from **bosos+jĭs*). The Baltic forms show also enough discrepancy (standard Lith. *baltàsis*, dialectal *baltàjis* and *baltùjis*, Let. *baltaîs* "the white one." O.Prus. *pirmoys* "the first one." O.Lith. genitive singular *pajoprasto* for modern *pãprastojo* "the simple one") to be considered pre-Baltic.

In the vocabulary there are actually only about 100 words exclusively Balto-Slavonic in form and meaning (Endzelin); *e.g.*, Lith. *kárvė* "cow," *kiáunė* "marten." *péntis* "heel, butt-end," *rankà* "hand," *pirtìs* "kiln" = Pr.S. **korva*, **kuna*, **pęta*, **rǫka*, **pĭrtĭ*.

On the other hand, one must take into account the numerous differences which separate Baltic and Slavonic not only in vocabulary (*cf.* Lith, *diẽvas* "god," *výras* "man." *kẽlias* "road," *rãtas* "wheel," *lãbas* "good" as against Pr.S. **bogŭ*, **mǫžĭ*, **dorga*, **kolo*, **dobrŭ* in the same meanings) but also in phonology (*cf.* Lith. *o*, Let. ū and both *uo* from I.E. **ā*, **ō* fused in Slavonic into a; also Pr.S. **vĭrchŭ* "top," **sŭchŭ* "dry." locative *trĭchŭ* "three": Lith. *viršùs* but *saũsas, trisù*) and in morphology (especially in the verbal systems). The migration of the pre-Balts to the northeast, probably around 2000 B.C., severed the contact with the pre-Slavs and thus led to a separate linguistic development on both sides. A new contact: as late as the 6th century A.D. in the east. but much earlier in the southwest. was established again by the Slavonic expansion. This is reflected in a number of correspondences between Old Prussian and Slavonic unknown to East Baltic (*cf.* the consonant groups *fl,dl*, dialectally preserved in Old Prussian as in West Slavonic. but changed to *kl, gl* in East Baltic; pronominal forms *tebbei, mien, wans, mais* equaled by O.Ch.S. *tebě, mę, vy, mojĭ* in opposition to Lith. *tãvie>táu, manè, jùs, mãnas;* in vocabulary *assanis* "autumn," *dalptan* "chisel." nominative plural *maldai* "young." *waisei* "you know"=Pr.S. *(*j*)*esenĭ*, **dolto*, **moldŭ*, **vęsi* but Lith. *ruduõ, káltas, jáunas, žinaĩ*=Let. *rudens, kaẽts, jaûns, zini*).

Besides Slavonic, Baltic may have had some contact with only one other member of the I.E. family—Germanic (*cf.* Lith. *vienúolika* "eleven." *dvýlika* "twelve," O.Prus. *ains* "one." dative singular *nautei* "need" = Goth. *áinlif, twalif, ains, naups*).

Proto-Baltic.—The earliest form in the development of the Baltic languages may be called proto-Baltic (Pr.B.). Its constitution as an independent linguistic group. to judge from archaeological data. may have taken place not later than the end of the 2nd millennium B.C. Because of its peripheral and isolated position Baltic from the very beginning was less affected by changes. characteristic of central I.E. languages. The later great migrations had also no apparent impact which might have stimulated linguistic change. Persecution. short of extinction, also tends to drive a language underground and so preserves it from rapid internal change. Because of this retarded development. Baltic duly claims the title of the most archaic of all living I.E. languages. The original phonological system. especially vocalism (practically all short and long vowels excepting **o*, **a* and **ə* which fused into *a*; diphthongs; pitch accent; also final *s, r, n*) and numerous morphological features (seven of the eight. *I.E.* cases inclutling vocative. dual, three genders. supine). has been preserved n-ith such a fidelity that modern Lithuanian plays in the comparative grammar of Indo-European a role equal to that of classical Greek. Sanskrit. Italic and Gothic. In many instances Baltic presents forms which are much closer to Indo-European than those of other languages recorded 2,000-2.500 years ago. For instance. Lith. *sūnùs* "son" is identical with the reconstructed I.E. **sūnus*, while the other languages show newer developments (*i.e.*, Sans. *sūnúḥ*, Goth. *sunus*, Old English *sunu*, O.Ch.S. *synŭ*, Russian and Polish *syn*). And I.E. **gʷīwos* "alive" survives in Lithuanian with slight change as *gývas* but not so in others: Pr.S. and O.Ch.S. *živŭ*, Sans. *jīváḥ*, Lat. *vīvus*, Goth. *qius*, Old English *cwicu* "living." Old Irish *biu*, *beo*, Gr. *bíos* "life." The richness of inherited forms has even been expanded by special Baltic innovations. For instance. to the old I.E. locative singular in **-oy*/*-ey* surviving in adverhial function (*cf.* O.Prus. *obītai* "in the morning." Lith. *namiẽ<*namei* paralleled by Gr. *oĩkoi, oĩkei* "at home") have been added four new forms (*cf.* modern Lith. *kalnè* "in. on the mountain," *kalnañ* "into, onto the mountain" anti O.Lith. and dialectal *kalníep* "by the mountain." *kalnóp* "to the mountain" from *kálnas* related to Lat. *collis<*kolnis* and English *hill<*hulni-*). This practice of treating additional case forms by adding postpositions map well be due to West Finnish influence. The close contact between the Balts and the ancestors of the modern Finns. dating hack to pre-Christian times, is attested to by several hundred Baltic loanwords present in all West Finnish languages including the faraway Mordvin. For instance. Estonian *tugijas* "thistle." Finnish *taivas* "sky" and *hanhi* "goose" point to Pr.B. **dagijas*, **deivas* and **žansis*, the protoforms of modern Lith. *dagỹs*, *diẽvas* "god" (O.Prus. still *deiws*) and *žąsis* (O.Prus. *sansy* and dialectal Lith. *žansis*), and Let. *dadzis, dìevs* and *zùoss*. The borrowed Finnish *seinä* "wall" and *heinä* "hay." *tarha* "enclosure" confronted with Lith. *síena* and *šiẽnas*, *dar̃žas* "garden" prove beyond doubt that Lith. *š, ž* originating from I.E. **k̑*, **g̑* represent the proto-Baltic phonetic state and a very early stage of palatalization preserved also in Sanskrit (*cf.* above *šim̃tas=çatám*), another peripheral language. The rest of the satem languages underwent a second palatalization resulting in *s, z*. On the other hand. the conservatism of Baltic is not absolute. The proto-Baltic consonantism. intact in Old Prussian and slightly changed in Lithuanian. shows no trace of I.E. aspiration or labiovelar stops. The verbal system has been simplified in a sweeping way. Only the old present and future tenses were retained while the imperfect. aorist and perfect were replaced already in proto-Baltic by a newly created preterit characterized by the stem vowel *ā* or *ē* (cf. Lith. *vẽdė-me* "we led." *sė́jo-me* "we sowed" = Let. *vedēm*, *sējā-m* against present tense Lith. *vẽda-me*, *sė́ja-me* = Let. *veda-m*, *sēja-m*).

The early dialectal differentiation of Baltic led at, first to a split into West Baltic (W.B.) and East Baltic (E.B.). This, to judge from certain archaeologic and linguistic data (emergence of tribal cultures. common designations for iron and steel: Lith. *geležìs*, *pliẽnas*, Let. *dzèlzs*, *pliens*, O.Prus. *gelso*, *playnis*), may have occurred not later than 500–300 B.C. The Greek geographer Ptolemy of the 2nd century already knew about the existence of separate Old Prussian tribes (*Galíndai kaì Soudinoí*).

West Baltic.—This group is represented solely by Old Prussian and a closely related dialect of Suduvians. or Jatvingians, both decimated through early wars and finally germanized in the 17th century. Old Prussian is even more archaic than Lithuanian. For instance, it preserves Pr.B. **ei* (*cf.* examples. above) and **tj*, **dj* (*median* "forest" = Lith. dialectal *mẽdžias* = Let. *mežs*), neutral nouns (*assaran<*ezeran*=Pr.S. *[*j*]*ezero* and masculine Lith. *ẽžeras*), many inflectional forms and vocabulary items unknown to East Baltic (*cf.* genitive singular *deiwas<*I.E.**-oso*, like Old English *dómæs*, genitive singular *stessei* "this"=Sans. *tasya*, dative singular *kasmu* "who"=Sans. *kasmāi; emmens<*enmens* "name" =Pr.S. **ime:* Lat. *nōmen; panno* "fire"=Goth. *fōn*, *aglo* "rain"= Gr. *achlús* "mist." *dadan* "milk"=Sans. *dádhi* against Lith. *var̃das*, *ugnìs*, *lietùs*, *píenas* = Let. *vàrds*, *uguns*, *liêtus*, *piẽns*). Old Prussian shows closer ties to both Slavonic (*see* above) and Germanic than either Lithuanian or Lettish. For instance! 33 vocabulary

items common only to Slavonic and 19 to Germanic have been counted (Endzelin). All this reflects prehistoric contacts (cf. also the change of Pr.B. *s, š* into *s, z*, as in Slavonic). *(See* examples, above.) The independent character of Old Prussian points to deep dialectal differences in proto-Baltic which, most likely, never was so uniform as, for instance, proto-Slavonic. A 16th-century report relates that a Lithuanian could understand Old Prussian "only very little," which is not quite true in respect to Lithuanian and Lettish even four centuries later.

East Baltic.—East Baltic includes modern Lithuanian and Lettish, also Curonian or Kurish, Semigallian and Selonian, the dialects of minor Baltic tribes. After the initial split of proto-Baltic into two groups the larger East Baltic continued as a uniform linguistic entity for quite a long time. Historical records of the individual existence of East Baltic people date from the 9th (for Curonians) to the 13th (for Selonians) centuries. But linguistic data allow a more precise and detailed determination of the emergence of separate languages from primitive East Baltic. The oldest Russian loanwords in Lettish *(cf. sùoģis* "judge," *kūkes* "Christmas meal," *žerbińš* "sort" from Old Russian [O.Rus.] *sudjá, kutjá, žerebej)* and differences between Lettish, Lithuanian and Old Russian forms of some place and river names *(cf.* Let. *Rucava, Seseve, Rīga* = Lith. *Rùkiava, Šešėvė,* dialectal *Ringà;* Let. *Cēsis, *Rēzīte* = O.Rus. *Kěsi, Rěžica;* Let. *Pededze* < **Pedeģe:* Estonian *jõgi* "river") demonstrate that the most characteristic phonetic innovations of Lettish are comparatively young. The slow process of its individualization began after A.D. 700 and ended around 1100 with the monophthongization of nasal combinations *(cf.* Let. *mūks* "monk" borrowed from Old Norse *munkr* around A.D. 1000).

The emancipation of Semigallian and Selonian, to a large part because of their geographical position, apparently coincides in time with that of Lettish. But peripheral Curonian may have assumed its shape already around A.D. 400–600. This is confirmed by the development of a rich Curonian prehistoric civilization after A.D. 100. The main reason for the disintegration of primitive East Baltic is to be seen in population shifts and early migrations leading to occupation and baltization of previously West Finnish (Livonian) territories. The ancestors of the Latvians, properly Latgallians, Selonians, Semigallians and Curonians moving in successive and overlapping waves, took possession of the larger part of Latvia as late as A.D. 100–700. The Curonian expansion beyond the Venta and Abava rivers proceeded only after 1000. And latvianization of the Livonians has continued into the 20th century.

Lithuanian, thanks to its stable central—or rather rear-guard—position, was saved from superseding and assimilating non-Baltic languages with the exception of some Slavonic influx from the southeast. This explains its conservative character as against Lettish. A later north and west expansion of Lithuanian (1400–1700) to depopulated territories, formerly held by other East Baltic and also by Old Prussian (beyond the Nemunas [Neman] river) tribes, brought no change, except dialectally, in this respect. Lettish is much more advanced and simpler both phonetically and morphologically. Its younger forms in most cases can be traced back to the older ones still current in standard Lithuanian. Marked simplification has been achieved in Lettish by dropping *(a, e, i)* and shortening *(ā, ē,* i, *ū* > *a, e,* i, *u)* vowels in final position, by extensive monophthongization *(an, en, in, un* > *uo, ie, ī, ū,* finally *ai, ei, au* > i, *u)* and by morphological analogies and generalizations (same endings for accusative and instrumental in singular and plural, pronominal inflection of nouns, no inflection for conditional). The former affricates were eliminated (Pr.B. **tj, *dj* > *E, dž* > *š, ž;* cf. examples, above) and new ones developed (cf. Let. *acs* "eye," *cers* "stump," *cìeš* "suffers," *dzīvs* "alive," *dzęguze* "cuckoo" as compared with Lith. *akis, kẽras, keñčia, gjvas, gegužė),* a process which parallels Slavonic palatalizations. Several characteristic innovations, such as *s, z* for Pr.B. *S, š* (cf. examples, above), fixed accent on the first syllable and abandoning of grammatical gender in the Livonian dialect, are due to the influence of the Finnish substratum.

From the three extinct East Baltic dialects there are no written records, except proper names from the 13th to 15th centuries and phonetic and vocabulary dialectisms in Lettish and Lithuanian dialects. Curonian. spoken as late as 1600 (in Latvia), presents a typically transitional dialect between Lettish and Lithuanian. It preserved the combinations *an, en, in, un* like Lithuanian and Old Prussian, but, on the other hand, had *s, z* for *š, ž* and c, *dz* from *k, g* under the same condition as Lettish *(cf.* medieval *Sentatze, Zintere, Swente* = Lith. *Santakh, Giñtaras, Sventdji;* Let. dialectal *dziñtars* for *dzītars* = Lith. *giñtaras,* O.Prus. *gentars* "amber"). There are also some links to Old Prussian (palatal *t',* d' from **tj, *dj;* Let. dialectal *du-cele* "two-wheeled cart" = O.Prus. *kelan* "wheel"). And this is quite obviously due to their prehistoric contact along the lower course of the Nemunas river.

The Semigallians and Selonians merged with the neighbouring Latvians and partially with the Lithuanians already around 1400. To judge from the scarce name material in contemporary sources and modern dialectisms, Semigallian must have been very close to Lettish! if not a dialectal variant of it. Selonian was rather more independent as evident from the partial preservation of the groups *an, en, in, un.* The same is testified by the accent shift of North Lithuanian in former Curonian and Semigallian but not Selonian territory.

Galindian.—The Russian chronicles mention fighting in the 11th-12th centuries a warlike tribe of Golyad (O.Rus. *Goljadĭ* < **Golędĭ* = Pr.B. **Galindā:* Lith. *gãlas* "end"; cf. also O.Prus. *Galindo,* a tribal district), settled above the Protva river (near Mozhaisk). The tribal name survives in eight different place and river names in the former governments of Moscow and Orel. Further detailed place-name studies. conducted by K. Buga and M. Vasmer, established that all White Russia and bordering areas as far as Kalinin (Tver) and Tula were inhabited by Balts prior to the East Slavonic expansion covering those lands around A.D. 500–600. The Baltic roots preserved in the name material speak rather for the very ancient character of Galindian. One notes Pr.B. *S, i* and several vocabulary items older in form than those used in Lithuanian *(cf. Žukopa,* a river name: **žukas* + *apē* paralleled by O.Prus. *suckis* "fish" and *ape* "creek," Lith. *žuksparnis* "osprey" but only *žuvìs* "fish" and *ùpė* "river").

Documents.—Written records of the Baltic languages are of late date. An undated minute German-Old Prussian vocabulary, compiled around 1400, is followed solely by three catechisms (1543 and 1561). The quite abundant and philologically very valuable Lithuanian religious literature begins in 1547. The first Lettish writings, unfortunately in corrupt language, appear beginning 1585. The beginnings of the standard languages of both Lithuanian and Lettish dated from the time of their national revival in the 19th century followed by vigorous development after the gaining of national independence subsequent to World War I, now once more extinguished (1939).

*(A*Y. S.; J. WH.)

BALTIC **SEA** (Ger. OSTSEE; Swed. ÖSTERSJÖ; Russ. BALTISKOYE MORE; Fin. ITÄMERI), a sea extending between latitude 54° and 66° N. and longitude 9° and 30° E., surrounded by Sweden, Denmark, Germany, Poland, the republics of Lithuania, Latvia and Estonia (incorporated into the U.S.S.R. in 1940), the U.S.S.R. and Finland.

The main axis runs approximately southwest to northeast, and the length from Kiel to Haparanda is 1,700 km. (1,056 mi.). The average width is about 200 km. (124 mi.). The Baltic connects with the North sea by a channel between Denmark and the south of Sweden. The boundary between the two seas is commonly taken to be along a line from the Skaw to the Swedish coast. The North sea section of this channel is called the Skagerrak (*q.v.*), the Baltic section the Kattegat. At its southern end the Kattegat is split by the Danish islands into three sections—Öresund (the

Sound), the Lille Baelt (Great Belt) and the Store Baelt (Little Belt)—which lead to the Baltic sea proper. The total area of the sea is 422,300 sq.km. (163.050 sq.mi.).

Formation.— -The Baltic consists of two sections of geologically different origin. North of the Ahvenanmaa Islands the Gulf of Bothnia is a sunken trough in the heart of the Fennoscandian shield; *i.e.,* the area of Xrchean rocks forming the surface of Finland and most of Sweden. The trough was prohably formed by faulting and later deepened by ice action. 'The true Baltic. south of the Ahvenanmaa Islands, occupies a basin created by subaerial denudation during the long interval from Late Paleozoic to Tertiary times. Its surface was further modified by river action during the Tertiary period and again later when it became the main channel for ice streams during the Ice Age. The Paleozoic shales and limestones. such as are now exposed in Gotland, Gland and Bornholm. were more easily weathered than the older rocks of the Bothnian area.

Four phases are identified in the postglacial evolution. An enlarged Baltic sea with a probable outlet by way of Lakes Hjalmaren, Vänern and Vättern. and known as Yoldia sea, succeeded the northward retreat of the ice. Its limits, reaching a maximum *c.* 7500 B.C., are recognized by the distribution of shells of a salt-water mollusk *Yoldia arctica.* Minor uplift in the southwest. severing tlie North sea connection. converted the Baltic basin into a fresh-water lake, which occupied an area larger than the present Baltic area. The extent of this so-called Ancylus lake, which reached a maximum *c.* 6500 B.C., is identified by the distribution of the shells of the fresh-water snail of the same name. The third phase. associated with the opening of the Danish outlets and uplift around the coasts of Sweden and Finland, is named after *Litorina,* o salt-water snail. It. reached its msximum extent *c.* 4500 B.C. The effects of the present phase of continuing, though differential, emergence are especially evident around the Gulf of Bothnia. The local detail of land emergence is well illustrated in the successive Land Survey maps of Vaasa province in Ostrobothnia.

Depths.— The narrow Danish straits appear to be the drowned volleys of streams that cut their way back across the low harrier which hemmed in the Ancylus lake. All three. and especially the Lille Baelt. are too shallow for easy navigation by big modern ships. The deep channel of the Store Baelt is both narrow and winding and even Öresund (23 ft.) is hot deep enough for the larger ocean liners. East of the Danish archipelago the sea deepens slowly to more than 164 it. between the Swedish coast and the islands of Kugen and Bornholm. Within the Baltic proper there are four basins or deeps separated from one another by sills, the latter generally marked by the occurrence of islands. The first. east of Bornholm, reaches a depth of 344 ft. The large central basin surrounds Gotland and shows soundings oi 1,539 ft. to the west oif Landsort, and of 820 ft. to the east of the island. A minor extension in the Gulf of Danzig (Zatoka Gdańska) is more than 200 m. (656 ft.). 'Ihe main Bothnian basin between the Ahvenanmaa and Kvarken Islands reaches 294 m. (965 it.) in its western part. and the inner basin north of the Kvarkens 128 m. (420 it). A central channel 50 m. (164 ft.) deep reaches almost to the head of the Gulf of Finland.

Salinity.— The outlets of the Baltic are so narrow and shallow that it is virtually a lake. This is further emphasized by the facr that the sea receives the drainage of a land area more than four times as great as its own area: *i.e.,* 1,603,000 sq.km. (642,084 sq.mi.) to 422.300 sq.km. (163,050 sq.mi.), including such large river basins as those of the Vistula and Oder, as well as that of the Neva bringing the overflow of the great Russian lakes. In addition. all this region receives at least a moderate rainfall on lands whose soils are already saturated after the spring thaw. Salinity is therefore low in all parts. In the Kattegat, freely connected with the North sea, it is 30‰ (30 per mille or 3%): but falls to 15°/₀₀ in the belts and 8°/₀₀ east of Moen. In the Gulf of Finland it has dropped to 6°/₀₀ and in the Bothnian aren to 2°/₀₀. Off Haparanda the water is no more than slightly brackish. Westerly storm winds sometimes force salt water through the entrance channels but this quickly spreads in a thin layer over the deepest parts of the sea bed.

Results of Freshness.—The low salinity and freshness of the Baltic waters has two important results. It is responsible for the long winter freeze-up of the ports and also for the poverty of its marine life. Even Stralsund. just within the Baltic proper, is closed by ice on an average of about one month s year. All the ports of the Gulf of Finland and the Gulf of Bothnia are closed for shorter or longer periods, as long as three to lour months in the inner reaches. Icebreakers are commonly employed to prolong the open period of ports which are always subject to closure, and to battle with the ice of ports which are more marginal; *e.g.,* Helsinki.

Marine life in the Baltic offers a remarkable contrast with the abundance in the North sea, the number of species present being less than one-tenth of those found in the latter area. Species present in both are markedly diminished in size; *e.g.,* the Baltic herring (strömming) is no bigger than a sardine arid the cod only about one-fifth the weight of those found on the Norway coasts.

Movements.— The great inflow of land water, but slightly reduced by evaporation, also raises the level of the Baltic above that of the North sea and the open ocean. Even in the Kattegat there is a difference of 10 cm. (3.9 in.) and this rises, as the distance from the outlets increases. to 22 cm. (8.65 in.) off Bornholm. 31 cm. (12 in.) off Stockholm and 38 cm. (15 in.) near the heads of the Gulfs of Bothnia'and Finland. Because of the lower density of the Baltic waters some difference of level would be necessary to maintain equilibrium. but the inflow of river water is more than sufficient to secure this. Levels are lowest in spring, when rainfall is usually slight and the main thaw in the northern and higher regions has hardly begun. Highest levels art reached in August. often a rainy month. or in early September. Northeasterly gales. because of their long fetch. cause high waves and a piling of water along the Polish and German coasts which often cause much flooding and damage, Southeasterly winds in spring drive floating ice toward the Danish archipelago and may delay the opening of the ports after the winter freeze.

Because of the surplus water accumulating in the Baltic there is usually art outflow through the channels to the North sea. This is mainly concentrated on Öresund. because tlie main stream hugs the Swedish coast, and it may create there a current of three to four miles an hour. Westerly gales drive the saltier North sea water chiefly through the Store Baelt. Though this denser water quickly sinks to the floor of the deeper basins the surface movement, backed by the prevailing southwesterly winds. continues along the German coast and helps to produce the characteristic features of spit (*nehrung*) and lagoon (*haff*). Tidal movements are almost completely absent from the Baltic.

Coasts.— The Baltic coasts show great variety. In the Archean area the shores are fringed by Innumerable rocky islets (skerry guard) along tlie edge of an upliited coastal plain. The plain is largely composed of resorted morainic materials but its surface is broken by rocky hummocks. obviously coastal skerries when the sea level was higher than in modern times. In central and southern Sweden the coasts are generally lower except where outcrops of older rock emerge above the marine clays and sands of postglacial age. In the southwest. low cliffs, reguiar coastal outlines and few islands are the dominant features.

The southern and southeastern shores of the sea are almost everywhere low and smooth in outline, carved for the most part from morainic materials by tlie action of the eastward-flowing current and the westerly winds which give rise to it. The Danish coasts have many short stretches of cliff and little bays offering easy access to the land. From the Danish frontier to Lübeck bay is found the *förden* type oi coast. clearly produced by submergence. which is still in progress there and in the southwestern islands of the archipelago. The *förden* are long. straight-sided and deep inlets believed to have originated as the valleys of streams flowing beneath the ice sheets. They provided excellent harbours for such ports as Flensburg and Kiel when ships were of smaller size than those of modern limes. The *bodden* coast fronn Luheck bay to and including the Oder estuary is extremely irregular and also a product of submergence. In their irregular form and shallowness the *bodden* offer a marked contrast to the *förden.* En-

trance to them is partially blocked by islands of morainic material or, as in the case of Riigen, of chalk. Many of them have been linked together by sandspits which partially explains their odd forms.

East of the Oder (Odra) mouth coastal outlines are smooth. Great sandspits (*nehrungen*), capped by dunes, have been formed by the eastward drift and the local wind and wave action; *e.g.*, Frische Nehrung and Kurische Nehrung. These spits have converted into lagoons the depressed areas along the old shore lines; *e.g.*, the Vistula lagoon or Frisches Haff (Zalew Wislany). The mouths of the Oder, Vistula and Neman (Memel) and the Gulf of Riga have been partly molded by glacial action. Each of them occupies a "tongue basin" formed by a lobe of the retreating Scandinavian ice sheet.

Climate. — The modifying effect of the North Atlantic drift is scarcely felt in the Baltic region, nor has the sea itself more than a slight effect on temperatures, for the air over it seldom differs by more than 2°–3° F. from that over the neighbouring land. Its main influence is of a somewhat unusual kind and results from the freezing of the surface waters. The long period of thaw in the spring slows the advance of that season and the slow spread of surface freezing similarly prolongs the autumn. The presence of open water away from the coasts during the whole winter in the central and southern areas has some little effect in checking the rigour of the winter cold.

BIBLIOGRAPHY.—A succession of authoritative papers on the Baltic have been contributed to *Fennia*. *See* especially *M*. Sauramo, *Fennia* 2 (1939) ; E. Kääriäinen, *Fennia* 2 (1953) ; *Atlas* of *Sweden*, sheets 19–20.

(T. HER.; W. R. ME.)

BALTIMORE, GEORGE CALVERT, 1ST BARON (d. 1632), English statesman, whose name is associated with the foundation of Maryland, son of Leonard Calvert and Alice, daughter of John Crosland of Crosland, was born in 1578 or 1579 at Kipling in Yorkshire and educated at Trinity college, Oxford. After traveling on the continent, he became secretary to Robert Cecil, afterward earl of Salisbury. In 1606 he was appointed clerk of the crown in Connaught and Clare, in 1608 a clerk of the council, and he was returned to parliament for Bossiney in 1609. He assisted James I in his discourse against Vorstius, the Arminian (Remonstrant) theology professor of Leiden, and in 1613 took charge of the Spanish and Italian correspondence. The same year he was sent on a mission to Ireland to investigate grievances. He was appointed clerk to the privy council in 1605; was employed in missions to France (1611) and the Palatinate (1615); was knighted in 1617; became a secretary of state in 1619; and was given a pension of £1,000 a year in 1620.

He represented successively Yorkshire (1621) and Oxford university (1624) in the house of commons, where it fell to him in his official capacity to communicate the king's policy and to obtain supplies. He was distrusted by the parliament and was in favour of the unpopular alliance with Spain and the Spanish marriage. On Feb. 12, 1625, after he had declared himself a Roman Catholic. he gave up his office, was created Baron Baltimore of Baltimore in the Irish peerage and received a grant of large estates in Ireland. Henceforth he was seen little in public life, and his attention was directed to colonial enterprise.

In 1621 he sent Capt. Edward Wynne to Newfoundland and established a small settlement named Ferryland, and in 1623 he procured a charter for the colony under the name of Avalon. In 1627 Baltimore visited the colony for a short period and a year later returned with his family to take up residence there. In the course of this extended visit conflict arose over his Catholic practices, the saying of Masses and the priests who accompanied him to Avalon. In addition, the severe climate took its toll in death and illness among the company so that Lady Baltimore left the colony for Virginia in the autumn of 1628. Baltimore therefore petitioned the king for a land grant in a more temperate climate and without waiting for the reply sailed for Jamestown to join Lady Baltimore.

But Baltimore was forbidden to settle there unless he took the oaths of allegiance and supremacy. He returned home and died on April 15, 1632, before a new concession was secured, the charter of Maryland passing the great seal on June 20, 1632, in favour of his son CECILIUS (CECIL) CALVERT, 2nd baron Baltimore (1605–75), who founded the colony.

Baltimore wrote *Carmen funebre* in D. Hen. Untonum (1596); The Answer to Tom Tell-Troth . . . (1612) is also attributed to him, and Anthony Wood mentions Baltimore as having composed "something concerning Maryland." He married Anne, daughter of George Mynne of Hertingfordbury, Hertfordshire; after her death in 1622 he remarried, and it was the 2nd Lady Baltimore who accompanied him to America in 1628. His second son, LEONARD, became first governor of Maryland in 1634.

George Calvert's grandson; CHARLES CALVERT (1637–1715), 3rd baron Baltimore, was the son of Cecilius Calvert and Anne Arundell, daughter of Lord Arundell of Wardour. He was commissioned governor of Maryland in 1661 and succeeded as proprietor of the colony when his father died in 1675. Like his grandfather, Calvert was a Catholic, and since those of his faith were a decided minority in the colony, antipopish feeling proved a serious handicap. Matters were further aggravated by the hostility of the Susquehanna Indians, and by the need to defend his territorial jurisdiction against claims by William Penn. Antagonism in the assembly led Calvert, in 1670, to restrict suffrage by property qualifications and sometimes to set aside acts passed by the assembly. Finally, after the English Revolution of 1688, he was deprived of the province. He returned to England and was later accused of taking part in two popish plots but was never arrested. He died in London on Feb. 21, 1715. His son, BENEDICT LEONARD, had conformed to the established church in 1713 and thereupon had Maryland restored to him.

See William Hand Browne, ***George*** and *Cecilius Calvert* (1890).

BALTIMORE, chief city of Maryland and seventh in size in the United States. lies at the head of tidewater upon the Patapsco river, one of the many deepwater estuaries of the Chesapeake bay. The commercial and industrial life of the city developed around the tributaries of the Patapsco.

Baltimore is situated not only on deep water! but also at the fall line of the Piedmont region. Within a few miles of the water the land rises to 200–300 ft. above sea level. The valleys of the streams which flow through deep ravines toward the Patapsco and its branches are mostly parks, while surrounding heights are sites of residential developments.

The city covers an area of 91.93 sq.mi., of which 78.72 sq.mi. is land and 13.21 sq.mi. water surface.

HISTORY

Early History. — The founders of Baltimore, which is named after the family of the Barons Baltimore who established Maryland in the early 17th century, sought only to provide an outlet for the tobacco grown locally. Half a dozen such "tobacco ports" were chartered in the same year (1729). There was no appreciable development until about 20 years later when it was found that flour had an immediate market in Ireland and Scotland. Surrounding landowners began to abandon tobacco culture for wheat and to build flour mills along their little streams. The city's real growth began at that time.

Generally speaking, the wheat growers and the merchants who profited by their labour came to dominate the city in the economic sense, while the tobacco-growing aristocracy determined the city's social life.

The Revolution. — At the outbreak of the American Revolution, Baltimore was a bustling port of about 6.700, whose trade, despite British restrictions, extended to the Caribbean, over northern Europe and far into the Mediterranean. The merchants were in the ascendancy and carried the city and the colony into the patriots' column.

During the Revolution, the town grew rapidly in importance. It had developed a hardy breed of seafaring men and its own type of sailing vessel, the Baltimore clipper. Numerous privateers were fitted out and preyed upon British shipping. On the land, too. the citizens of Baltimore made their mark; the "Maryland line." for example, held against the British in the battle of Long Island while George Washington was making his escape across

the East river.

The continental congress held its sessions in Baltimore in 1776.

The 19th Century. — Ballitnore boomed more spectacularly after the war when the assumption of the state debt by the federal government suddenly gave the merchants access to new credit with which to exploit the markets freed from British restrictions. Tobacco and flour buyers from Bremen. Ger., and other Hanseatic towns moved in and became a significant element in the community life. The iron industry increased while copper smelting became a new industry. By 1797 Baltimore obtained from the general assembly the right to dissociate itself from the surrounding countryside and call itself a city.

The War of 1812 saw Baltimore privateers put to sea again. The British, following the sack of Washington, attempted the reduction of Baltimore. The British land forces were repulsed and the fleet, after vainly attempting to silence Fort McHenry, finally sailed away. The fort's flag. which survived the 30-hour bombardment and is now preserved in the Smithsonian institution. inspired Francis Scott Key to write "The Star Spangled Banner."

Meanwhile. Baltimore merchants sent their buyers westward in search of wheat for their mills and ships. They met the competition of the Erie canal by beginning the construction (1827) of the Baltimore and Ohio railroad, determined to reach the Ohio river with this new means of transportation.

Political struggles of the 1850s cast a blight over the city. The Know-Yothing party gained control. and riots and confusion were the order of the day. Lincoln's election in 1860 and the outbreak of the American Civil War brought the troubles to a climax. A period of disorder was followed by military occupation. Every established routine of life and trade was interrupted or broken. The effects lingered for decades.

The 20th Century. — Up to the time of the great fire of 1904. the physical aspect of the city had changed little since the Civil War. The usual residence was red brick, with white marble steps. There were miles of streets lined with these little Georgian edifices. Business was largely individual. While it manufactured a wide range of products. Baltimore was essentially a commercial rather than an industrial ton-n. Its chief business was jobbing and the south was its chief customer.

The great fire broke out on Feb. 7, 1904, and spared but few buildings in the business district. Most of the changes in the city date from the fire. Streets were widened, sewers installed and modern paving laid. A few years later a modern system for the purification of water was provided. The old red-brick Georgian houses were outmoded and with them went much of the old charm. Baltimore became a more bustling, more efficient. more strident city than ever before.

The changes thus begun were accelerated by World War I and the impetus it gave to trade, particularly the export of coal and wheat. Imports. too. were stimulated by the opening of new iron mines and oil wells in the Caribbean area. The existing steelworks were enlarged many times, and modern oil refineries constructed. Industries tributary to these basic ones were attracted to the city.

In a relatively short time, the economic basis of Baltimore changed. It became a heavy-industry town as well as a commercial and small-industry one.

The shift brought changes, also, in the character and appearance of the inhabitants. Industrial workers. both white and Negro, poured in, chiefly from the south and southwest. For the first time the city learned that it had real slums.

The process of change continued through the depression of the 1930s and was accelerated again by the onset of World War II. Streets became noisy traffic arteries. Hundreds of blocks of old row houses were demolished in the name of slum clearance. and subsidized housing projects erected in their places. The Georgian tradition of beautiful brickn-ork was not lost in the suburbs. however. and some of the sections such as Guilford. Roland Park. Homeland. Ten Hills and others are quiet. dignified and, in a modest way, beautiful.

During World War II war industries and steel plants greatly expanded. Sixteen new industries and expansions in 90 plants were announced in the first year after Pearl Harbor. and the boom continued throughout the remainder of the war. In addition to being an important shipbuilding, steel and aircraft manufacturing area, Baltimore became a major production centre of high-octane gasoline. In 1944 a large plant for the production of extruded magnesium shapes was completed.

The end of World War II brought a decrease in shipbuilding and ship-repair work. However, the port of Baltimore flourished. (See *Commerce* below.)

After World War II Baltimore pioneered in attacking urban blight and in the eradication oi slum conditions by stepping up law enforcement implemented by a minimum standard housing code and a housing court, the first of its kind in the United States. An Urban Renewal and Housing agency, which in the late 1950s embarked upon a 20-year $900,000,000 program, was designed to integrate the city's antiblight and slum efforts.

Historic Sites. — Among the best-known historical sites in Baltimore are the Washington nionument. completed in 1829, and the Battle monument (1827) dedicated to the defenders of the city in 1814. Among many others are the Francis Scott Key monument and the double equestrian memorial to Generals Lee and Jackson. Throughout the city are numerous statues honouring famous men.

Fort McHenry and Flag house; where the fort's famous flag was made, are popular sites. as are the 234-ft. Shot tower, once used in the manufacture of shot; the Mount Clare station (1830). the first passenger and freight station in the U.S.; the grave of Edgar Allan Poe; and many old homes. By law, the U.S. flag may fly both night and day at Fort McHenry and Flag house.

POPULATION

Baltimore's population in 1960 was 939.024. making it the nation's seventh largest city. The city is surrounded by a ring of suburban communities. The city of Baltimore together with Baltimore, Anne Arundel, Carroll and Howard counties comprise the Baltimore standard metropolitan statistical area, with a total population of 1,727,023 in 1960. Baltimore county. on the east, north and west of the city, had a population of 492,428 in 1960, and Anne Arundel county to the south had 206,634 persons. (For comparative population figures see table in MARYLAND: Population.)

ADMINISTRATION AND FINANCE

Baltimore operated under a charter granted by the state of Maryland until 1918 when the city was allowed to adopt a charter which was not a part of the state law. This charter was replaced by another independent charter in 1946. Nevertheless the city must obtain the approval of the state legislature in order to borrow money, except for emergency purposes; the city acknowledges the authority of the legislature to enact measures of local concern.

The city's chief elective officers are the mayor! the president of the city council and the comptroller. 'The city solicitor and the director of public works are appointed by the mayor. The unicameral city council possesses important legislative powers. Many fiscal powers, however, are granted to the director of public works and the board of estimates. The mayor possesses an item veto on appropriation measures.

The chief source of income is the property tax which yields about 30% of the city's total revenue. The city receives considerable income from state-collected, locally shared revenue, state and federal aid and revenue from public service enterprises. The city's leading expenditures are: education, public works, welfare, police, debt service and fire protection. The city's net funded debt was more than $300,000.000 by the end of the first decade after mid-20th century.

COMMERCE, INDUSTRY, AND TRANSPORTATION

Transportation and Commerce. — Baltimore, the eastern terminal of one of the principal and historic trade routes between the east coast and the middle west through the Appalachian mountain passes. is one of the busiest ports in the United States, handling about 40.0G0.000 short tons of cargo annually. The value of

foreign trade handled annually was approximately $1,000,000,000 and more after mid-20th century.

The port has many advantages. It comprises approximately 40 mi. of developed water front and is subject to only minor tide variations. The port is not disturbed by severe storms, heavy seas, currents or tidal disturbances; and it is virtually free of ice. The port provides access to the sea through both the Chesapeake bay and the Chesapeake and Delaware canal. Closer than other eastern ports to several inland centres, the port makes possible loner overland freight rates to shipping.

The principal north-south highway and railroad arteries of the east coast pass through the city, and trunk line and short line railroads with important terminal facilities serve the port. The railroads own and operate most of the piers accommodating ships in overseas trade. Facilittes include about 270 piers, wharves and docks. Specialized piers handle bulk cargoes such as coal, grain, ores and fertilizers.

Baltimore's shipbuilding and repair facilities are among the world's finest. The port is served by more than 90 steamship lines providing more than 260 regularly scheduled sailings each month to more than 250 foreign ports.

Excellent highways stem from Baltimore in all directions and motor-truck accommodations have been added to the port's facilities. More than 150 interstate truck lines connect the city with the north, south and west. The 6,300-ft.-long Patapsco river vehicular tunnel (1958) provides a by-pass for through traffic.

International and domestic air trade are handled at the two municipal airfields. Friendship International airport, the facilities of which rank with the most modern in the country, is equipped to handle all types of air traffic. Harbor airport has facilities for both land and sea aircraft.

Industry.— By 1960 there were more than 1.900 industrial establishments in the Balttmore metropolitan area which employed more than 200,000 persons and paid over $1,000,000,000 annually in wages and salaries. Manufacturing establishments in the Baltimore area include the Bethlehem Steel corporation which has an annual ingot capacity of 8,200,000 net tons; a spice, tea and extract company; and producers of sulfuric acid, bichromate, portable electric tools, bottle closures, high-tension electrical insulators, men's straw hats, and venetian blinds and parts. The area also leads in fertilizer production and basic refractories. Other industries include copper refining, sugar refining and the production of aluminum, stainless steel, aircraft, telephone cable, electronic equipment and tin containers.

Leading industry groups, with their approximate percentages of the total number of manufacturing employees in the 1950s, were: primary metal industries, about 20%; transportation equipment, more than 15%; food and kindred products, more than 10%; apparel and other fabric products, about 7.5%; fabricated metal products, printing and publishing, and chemicals and allied products, more than 5% each; electrical machinery, nonelectrical machinery, and paper and allied products, less than 5% each.

EDUCATION AND CULTURAL ACTIVITIES

Public education in Baltimore is under the direction of a nine-member board which appoints the superintendent and other members of the department of education. The school system enjoys more independence from state control than do county units. The integration of schools for white and Negro students was carried into effect in Sept. 1954.

The major institution of higher learning located in Baltimore is the Johns Hopkins university (*q.v.*). Its college of arts and sciences, school of engineering and school of business are at Homewood, in the northern part of the city. Across town are the medical school and the school of hygiene and public health (in connection with the Johns Hopkins hospital) and McCoy college which offers special courses for part-time adult study.

Johns Hopkins university's special undertakings include a laboratory of applied physics at Silver Spring, Md.; the School of Advanced International Study, Washington, D.C.; the Arctic Research laboratory, Point Barrow, Alaska; the Institute for Cooperative Research: the Thomas C. Jenkins Laboratory of Biophysics; the McCollum-Pratt institute for the study of "trace" elements; the Isaiah Bowman School of Geography and several others.

Goucher college, formerly called the Woman's College of Baltimore, was established by the Methodist Church in 1885. The official connection with the church was dissolved in 1914. In 1941 the college, formerly located in the city, began the construction of new buildings at Towson, a suburb, and formally began moving there in 1950. The college had disposed of the last building on the old campus by 1953. Enrollment by the end of the 1950s exceeded 700.

Loyola college, founded in 1852 and conducted by the Society of Jesus, had a full-time enrollment of about 700.

For girls the Roman Catholic Church operates the College of Notre Dame of Maryland, with an enrollment of about 750 full- and ~art-timestudents.

Morgan State college was organized originally by the Methodist Episcopal Church for the higher education of Negroes. Taken over by the state in 1939, it was provided with an extensive campus inside the city limits of Baltimore. Enrollment included about 2,000 students annually.

The undergraduate department of the University of Maryland is at College Park, closer to Washington than to Baltimore. But the professional schools of law, medicine, pharmacology and dentistry, as well as the nursing school and the hospital, are all in Baltimore.

The state owns and operates, in Baltimore, the Maryland institute, a day and night school for training architects and mechanical draftsmen as well as giving instruction in the fine arts. The Rinehart School of Sculpture is a particularly successful part of this academy.

The Peabody institute, established by endowment from George Peabody, the Massachusetts-born banker who made much of his fortune in Baltimore, was originally made up of a library, an art gallery and a conservatory of music (endowed in 1868, the first school of its kind in the United States). As other galleries came into being, the art gallery was abandoned. The library contains a large collection of specialized works and periodicals of great value to the scholar. The conservatory ranks as one of the major schools of music in the country.

Baltimore has two major art galleries. The municipally owned Walters Art gallery was the gift of Henry A. Walters whose father, William T. Walters, assembled the original collection. The collection includes examples of the works of most of the Italian, French and English classicists, both painters and sculptors, and is especially rich in Byzantine craftsmanship and medieval manuscripts. Since 1929 the Baltimore Museum of Art has been largely municipally owned and maintained. Its original building was successively enlarged to house a long series of bequests from private collectors. Some of the notable gifts were the Epstein collection, mostly of Renaissance painting and sculpture; the Jacobs collection, largely English and French of the 18th and 19th centuries; and the Cone collection, chiefly French moderns, especially Henri Matisse and Pablo Picasso. There is also a Maryland wing for rooms from typical houses of the colonial period and the Sadie **A.** May young people's art centre. The Enoch Pratt Free library (opened in 1884), originally endowed but later mostly supported by taxes, is Baltimore's chief public library. The Peale museum, built in 1814 by Rembrandt Peale, is a municipal museum of local history. The Maryland Historical society has, in addition to the usual collection of portraits and memorabilia, large numbers of manuscripts, including the logs of some of the famous merchantmen and privateers of the 18th and 19th centuries.

Baltimore has its own symphony orchestra, and an opera and theatre season.

PARKS AND RECREATION

Baltimore's department of recreation and parks maintains about 60 parks, athletic fields, swimming pools, golf courses and similar facilities. The city is the home of the professional football team, the Baltimore Colts; the Baltimore Orioles of the American Baseball league; Pimlico Race track; and has complete water recreation facilities. School and college athletics are well attended and Balti-

BALTISK (BALTIYISK or BALTIISK), a town and port of Kaliningrad oblast of the Russian Soviet Federated Socialist Republic, U.S.S.R., formerly the German Pillau in the province of East Prussia, stands at the tip of the narrow peninsula between the Vislinski gulf (Frisches Haff) and the Baltic sea, on the northern side of the entrance to the gulf. The town is chiefly an outport for Kaliningrad (formerly Ronigsberg), with which it is linked by rail and ship channel. There are metalworking and light engineering industries and ship repairing. (R. A. F.)

BALTS, a group of nations belonging to the Indo-European linguistic family (see BALTIC LANGUAGES) and living on the southeastern shores of the Baltic sea. To it are ascribed not only the Lithuanians and the Letts (Latvians) but also several nations now extinct, namely the Prussians (Germanized at the beginning of the 18th century); the Curonians (Lettonized in the 16th century); the Semigallians and the Selonians (extinct in the 14th century). The eastern Baltic tribes, spread in Belorussia and western Russia, were Slavonized after the northward expansion of the Slavs (7th–13th centuries).

The name Balts is derived from the Baltic sea; it is a neologism, used since the middle of the 19th century. An older name applied to the Balts is Aistians, also not a real national name of the Balts but taken from *Aestiorum gentes,* mentioned by Tacitus in A.D. 98. Tacitus located the *Aestiorum gentes* on the right shore of the Baltic sea and described them as collectors of amber and energetic cultivators of crops and fruits. The Gothic writer Jordanes of the 6th century A.D. wrote that the Aestii lived to the east of the mouth of the Vistula and occupied the longest stretch of the Baltic coast.

The Anglo-Saxon traveler Wulfstan, who visited present East Prussia in the 9th century, mentioned that the land of the Balts (Estum or Estland, not to be confused with Estland, the German name for Estonia) was very big, had many cities and a surplus of honey and fish. Designations of the separate Baltic tribes in historic records appear as early as the 2nd century A.D.; *e.g.,* Ptolemy mentioned "Galindai" and "Soudinoi" (later also called Jatvingai), the tribal names of the western Balts (Prussians). The chronicles of the 13th century mention 11 separate Prussian tribes.

The Curonians, who once lived in western Lithuania and western Latvia, are mentioned in Scandinavian records from the 7th century. Alongside these early historic records, archaeological material also shows that the Baltic group was differentiated into small tribes as early as the 1st millennium B.C., but a fully documented picture of the distribution of the Baltic tribes can be established only on the basis of the written history of the 12th–13th centuries A.D.

Origin, Distribution **and** Prehistory. — As the archaeological material suggests, the northeastern Indo-Europeans, from which the Baltic linguistic group developed, went to the eastern Baltic area and what later became western central Russia during the expansion period of the Indo-Europeans before and about 2000 B.C. They took to the forested zone of northeastern Europe knowledge of agriculture and cattle raising. The newcomers occupied a large territory reaching northward to southwestern Finland and eastward to the upper Volga basin. However, in the northern Baltic area and along the upper Volga these food producers did not survive and were amalgamated with the local hunters and fishermen during the second half of the 2nd millennium B.C.

In the southeastern Baltic area between the Oder (Odra) and Dvina (Daugava) rivers, in Belorussia and western Russia, this culture persisted throughout the Bronze and Iron Ages to c. A.D. 500. The wide extent of the Baltis in the east is witnessed not only by a continuous archaeologically reconstructed culture, but also

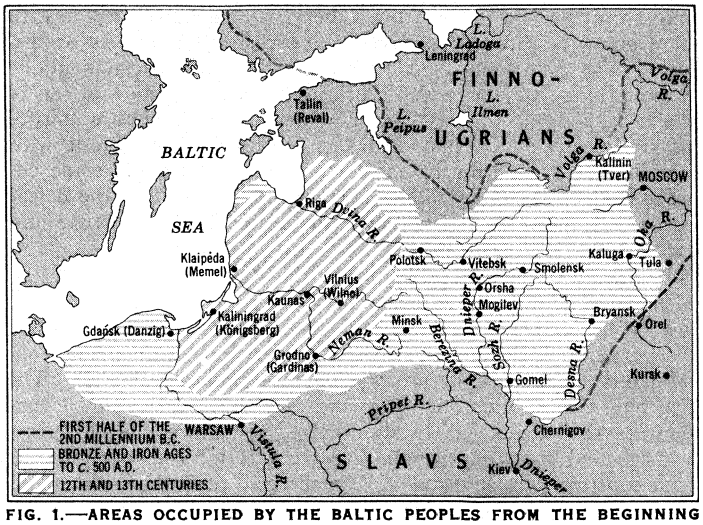

FIG. 1.—AREAS OCCUPIED BY THE BALTIC PEOPLES FROM THE BEGINNING OF THE 2ND MILLENNIUM B.C. THROUGH THE 13TH CENTURY

by the distribution of river and place names of Baltic origin in the upper Dnieper, upper Dvina, upper Volga and upper Oka basins. Also, hundreds of Baltic loanwords in the Finno-Ugrian languages indicate an affinity between the Finns and Balts. The many loanwords in the Volga Finnic languages must have been borrowed directly from the eastern Balts when they were settled in central Russia, as early as the 2nd millennium B.C. The name of the Volga river is explained as Baltic, connected with the Lithuanian *ilgas,* "long." Finally, the extension of the Balts to the Moscow-Kaluga-Tula line is best witnessed by the existence of the easternmost Balts, the Galindians (the "Golyad" of the Russian chronicles), until the 12th century or later and by numerous Baltic "islands" preserved until the 19th and even 20th centuries around Smolensk, Vitebsk and Minsk. The Baltic character of finds in graves and hill forts is maintained in central Russia until the 6th and 7th centuries AD. Ornaments and tools were of the same style as those found in eastern Lithuania. Hill forts in Belorussia are still called "Lithuanian hill forts." The south-north expansion of the Slavs between the 6th and 8th centuries cut off the eastern Balts from their western core. About the 8th century the Slavs had already reached the Minsk-Polotsk-Lake Ilmen line.

In the west the Balts were confronted with the Germanic expansion. In the last centuries B.C., Goths and other eastern Germanic tribes took possession of Pomerania and the lower Vistula area. In the beginning of the 13th century the Teutonic Order of the Cross founded its castles on the Vistula mouth and, after unceasing wars between 1231 and 1288, conquered the Prussians. The Teutonic Order of the Sword, established in 1201 in Riga, caused the disintegration of the Curonians and Semigallians.

The individual prehistoric culture assigned to the proto-Balts and early Balts developed in the course of the first half of the 2nd millennium B.C. The culture along the Baltic seacoasts bears the name "Baltic seashore culture" (*Hafküstenkultur*); the eastern branch in central Russia is labeled the "Fatianovo culture." Both groups were in a transitional stage from the Stone Age to the Metal Age. Baltic amber, being an item of transcontinental trade, played an extraordinary role in the evolution of civilization along the Baltic coasts. The growth of the Bronze Age culture was largely influenced by impulses from central Europe, the Unetice and Lusatian civilizations. In the second half of the 2nd millennium B.C., there existed between the Oder and Dvina rivers a classical Baltic Bronze Age culture distinctive in its locally produced metal types, pottery and burial rites in barrows surrounded by stone rings.

During the period of Scythian, Celtic and Germanic migrations, the Baltic culture maintained its individual features. The continental branch, distributed between eastern Lithuania and Latvia and the upper Volga-Desna river! lived a rather secluded and peaceful life. The western Balts were considerably influenced by Germanic and Celtic cultures. The most prosperous centuries

were from the 2nd to the 5th A.D. because of extensive trade with the Roman empire. Thousands of graves and hill forts of this period have been found to contain typically Baltic artifacts unique in their form and geometric decoration. From the cultural centre in the Neman (Nemunas) basin influences of the Baltic culture radiated to Estonia, Finland and to central Russia. Trade with Scandinavia started during the Bronze Age. Wars and trade between the Scandinavian vikings (Danes and Swedes) and the Balto-Curonians and coastal Prussians started in the 7th century and lasted to the 12th century.

History.—The written history of the Balts begins in the 12th–13th centuries A.D. To face the threat from the Russians and from the Teutonic Order (*q.v.*), established in the 13th century along the borders of the Balto-Prussian territory, the Lithuanians consolidated themselves into a powerful state (see LITHUANIA). The Teutonic Order, intending to expand over the Prussian and Lithuanian territory. met with well-organize: resistance. Nevertheless it succeeded in conquering the Prussians during the course of the 13th century (see PRUSSIA). The struggle with the Lithuanians lasted about 150 years until allied Polish and Lithuanian armies dealt a decisive blow to the order at Grünwald (Tannenberg) in 1410. Thus. German expansion to the east was checked, and the Germans were unable to annex the lands between Prussia and their Livonian colony. established as early as 1158 (see LIVONIA).

The growth of the Lithuanian state coincides with the 14th and 15th centuries. when Lithuania was ruled by the Gediminas (1316–41) dynasty. During the reign of Algirdas (1345–77) the eastern borders of Lithuania reached the same areas that in prehistoric times were occupied by the Baltic Galindians, west of Moscow, and to the Black sea in the south. The same territory was maintained during the reign of Vytautas (1392–1430). This extent of the Lithuanian empire in the east, covering about 350,000 sq.mi., protected western Europe as well as part of Russia and the Ukraine from Tatar rule.

After the union between Lithuania and Poland in 1569, the Lithuanian idea of statehood gradually receded. In 1503 Lithuania began to lose some of its eastern provinces to the Russians. Because of the danger of Muscovite invasion, the duchy of Livonia concluded a union with Lithuania in 1561. The Baltic areas of the Lithuanian-Polish federal state as well as the Latvian provinces were divided between Russia and the German kingdom of Prussia in the partitions of Poland in 1772, 1793 and 1795. The major part of Lithuania and all Latvia (*q.v.*) was under Russian rule until 1918; after World War 1 the independence of Lithuania and Latvia was restored. In June 1940 both states were occupied by the U.S.S.R. Between 1941 and 1944 the Soviet occupation was temporarily interrupted by the German invasion in World War II, but in 1944 the Russians returned.

Religion and Mythology.—The pre-Christian Baltic religion was a typical farmer's religion, closely related to the other Indo-European religions. Sky was considered the male aspect of nature, with its phenomena—light, fire, sound and the separate sky bodies, the sun, the moon and stars. Earth represented the female aspect of nature, with its plants, hills, stones and waters. The interaction of these two stimulated and protected the power of life. The ancient meaning of dievas ("god") was inseparable from the meaning of "sky." The sky deity was conceived as thunder and called Perkunas (Lithuanian), Perkunis (Prussian), Perkons (Latvian). His functions were to fertilize the earth and protect human and animal life.

The sun and the moon had a particular influence on the well-being and regeneration of earth life. In songs, the sun and moon frequently appear as personified beings. The personified earth deity was called by the Lithuanians Zemyna, by the Latvians Zemes Mate ("earth mother"). There were also protecting demi-goddesses of the forests, fields! stones, waters, animals, crops and homesteads. They were called by the general name deive and also had individual names. The 13th-century Volhynian chronicle preserves several mythological names, though in distorted form. More reliable are, those of the Lithuanian Medeine, the goddess of forests; Zverine, the goddess of animals; Angis (Andij), the snake god; and Kalvelis, the smith.

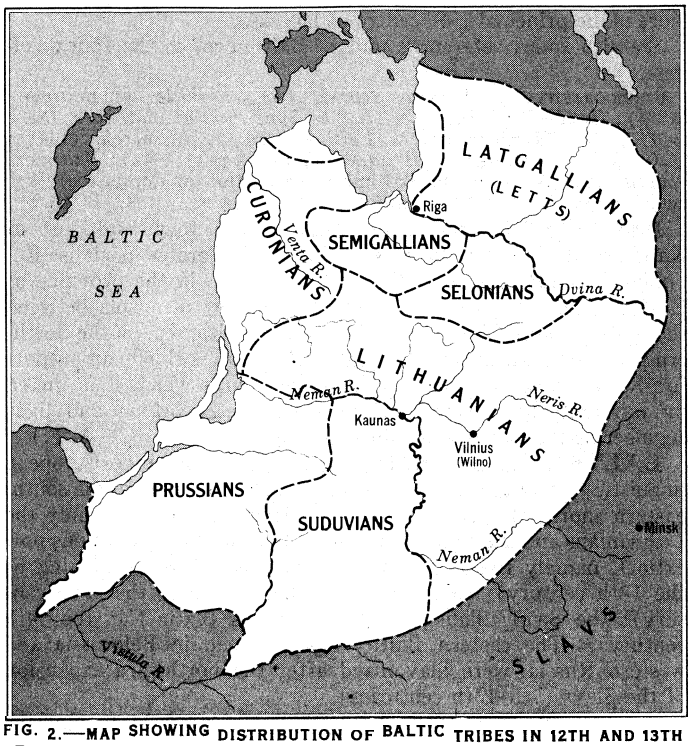

FIG. 2.—MAP SHOWING DISTRIBUTION OF BALTIC TRIBES IN 12TH AND 13TH CENTURIES

All Balts had a goddess of fate, Laima. She leads the human life from birth to grave and man is unable to change her decisions. In songs Laima is closely connected with the sun. In Latvian beliefs three other demigoddesses with analogous functions are preserved—Mara, Dekla and Karta. In Lithuanian and Latvian folklore, fairies (*laumes*) are clever and beautiful women with long blond hair and long breasts, perfect spinners and weavers, good, motherly and helpful until they are angered. The 16th-century sources mention the gods of the Old Prussians—Pikulas, Autrimpas, Patrimpas, Okopirmas and Suaxtix (Zvaigzdikis ?)—but their exact functions are not recorded. The most developed cults were those of forests, trees, fire, sun and snakes and that of the dead. Fire in ritual use was called *gabija*. Cult places were on *alka*-hills or other sacred places having names with the roots *ram-* or *rom-*. All religious ritual was based on the belief in the eternity of cosmic life. The human spirit was conceived of as a dynamic force which did not perish with the body but migrated into another living body, plant or animal.

As Christians, Lithuanians are Roman Catholic, Latvians either Lutheran or Roman Catholic. During the 12th and 13th centuries German missionaries converted the Latvians and their kindred tribes. Christianity was officially brought to Lithuania in 1387, after the grand prince Jogaila (Jagiello) married Queen Jadwiga of Poland and was baptized in 1386.

BALUCHISTAN, the southwestern part of the province of West Pakistan, derives its name from its chief inhabitants, the Baloch or Balochi (Baluchi). It extends from the Gomal river in the northeast to the Arabian sea in the south and from the borders of Iran and Afghanistan in the west and northwest to the Sulaiman mountains and Kirthar hills in the east. Its coastal section is known as Makran (*q.v.*), which continues into Iran.

Politically it includes the Quetta and Kalat divisions. The former consists of the districts of Quetta-Pishin, Sibi, Loralai. Chagai and Zhob, with attached leased areas, agency territories and tribal areas (Mari and Bugti). The latter includes the former states of Kalat, Kharan and Makran (now constituted as districts). Area 132.909 sq.mi. (including Las Bela). The former state of Las Bela. though a part of Baluchistan, is now a district in the new Karachi division formed in 1961. In its continuity to the west lies the Irani Baluchistan.

PHYSICAL GEOGRAPHY

Geology. — The mountain ranges of Baluchistan are formed of Cretaceous and Tertiary beds, forming part of an extensive system of Tertiary (Alpine-Himalayan) times arranged as if in a festoon hanging southward between the Pamirs and Mount Ararat. The outer edge is looped up at Sibi to form the subsidiary festoon of the Mari and Bugti hills to the east. Outside (*i.e.*, south of) the folds lie the horizontal deposits of Makran and within them the stony desert of northwestern Baluchistan. Besides the Cretaceous and Tertiary beds, Jurassic rocks occupy considerable areas of Baluchistan. Triassic beds lie along the south side of the upper Zhob, and limestone bearing fossils of fusuline Foraminifera have also been found there. With the exception of the Upper Cretaceous and Lower Tertiary, especially in northwestern Baluchistan, there is an extensive development of volcanic tuffs and conglomerates probably contemporaneous with the Deccan traps of India. Great masses of syenite and diorite were intruded during the Tertiary period, and within the curve of the folded belt a line of recent volcanic cones stretches from western Baluchistan into eastern Iran. The sharp bends of the hill ranges around the Kachhi plain have contributed to the instability of this area and have made it seismically important; Quetta was subjected to violent earthquakes in 1931 and 1935, that of the latter year being a major disaster (see QUETTA).

Relief and Drainage. — The great break in the mountains about Sibi, and the line of the Bolan and Khojak passes followed by the railway from Sukkur on the Indus to Chaman on the Afghan frontier, divide Baluchistan into two distinct parts. To the northeast. hedged in between Afghanistan and the Indus plains. stretch long ridges of rough highlands. The average breadth of this highland lobe is 150 mi., but in the north it narrows to less than 100 mi. along the Gomal river. It is mainly inhabited by Pathans. Southwest of the railway is a square block of territory measuring about 300 mi. by 300 mi., primarily the home of the Brahui and the Balochi, but with a great variety of physical conditions and inhabitants. Between southwestern Baluchistan and the northeastern lobe is the wedge-shaped Kachhi plain.

Northeastern Lobe. — This area is bounded by the Sulaiman range on the east and the Toba-Kakar range in the northwest. The main central range of the Sulaiman, decreasing in height from north to south, forms the dominant geographical feature of northeast Baluchistan. Toward the north of the range is a group of peaks forming an oblong massif known as Kaisargarh (Kasi-Garh) or, more generally, as the Takht-i-Sulaiman ("Solomon's throne") from a celebrated shrine or *ziarat* of that name near its southern abutment. The highest point in the range is 11,290 ft. In the northern part extremely narrow gorges constitute a striking feature. These clefts provide means of communications through the mountains.

From the main Sulaiman range a number of hills curve away westward to merge in the broad mountain core which abuts the uplands of Quetta-Pishin, where are found some of the grandest peaks in Baluchistan: Khalifat (11.434 ft.), south of Ziarat; Takatu to the north of Quetta; Chehiltan (Chiltan) to the southwest; and the great square-headed Murdar to the south. The highest peak is Zarghun (11.738 ft.), northeast of Quetta, which lies in the midst of the mountains. on an open plain formed by the high-level tributaries of the Pishin Lora river, 5,500 ft. above the sea.

Kachhi Plain. — The curved recession of the Sulaiman ranges to the northwest leaves a flat alluvial plain, Kachhi, to the south, striking deep into the Baluchistan mountain system. Kachhi is a land of dust storms and violent winds, where the temperature does not fall below 100° F. in summer and drops below freezing point in winter.

Bolan-Khojak Gap. — The Bolan-Khojak gap provides an important line of communication across the central Brahui range and, to the north, across the Khwaja Amran mountains. It connects Sibi with Chaman, via Quetta. With many a detour the direction remains roughly from southeast to northwest. The route has three sections: (1) the Bolan pass (*q.v.*); (2) the middle part between Darwaza and Kila Abdullah; and (3) the Khojak pass. This latter pass, in the north, runs across the Khwaja Amran range and connects Kila Abdullah with Chaman.

Southwestern Quadrangle.—The square block of southwestern Baluchistan, with its mountain folds opening fanwise from the Kalat plateau in the northeast, naturally drains south and west, either to the Arabian sea or to the swamps of Lora and Mashkel. The Hab river between the Pab and the Kirthar ranges, the Purali, or Porali (the ancient Arabis or Arabius), draining the low-lying flats of Las Bela, the Hingol (the ancient Tomerus) and the Dasht in Makran are all considerable streams, draining into the Arabian sea and forming important arteries in the network of internal communications. An exception to this pattern is the Mula, which carries the floods of the Kalat highlands eastward through magnificent[b]gorges into the Kachhi plains and forms one of the most important of the ancient highways from the lower Indus plains to Kandahar. To the north are the long lines of the Sarawan ridges, enclosing narrow fertile valleys and passing southwest to the edge of the Kharan desert. Some streams, like the Kuar. drain northward to the Pishin Lora, which itself flows westward into the Hamun-i-Lora marsh and desert. To the northwest of the plateau lies the Kharan desert, with intermittent river channels often lost in the sand waves before they reach the Mashkel swamps on the borders of Iran. The principal ranges are the Ras Koh in the north; the Siahan range (separating Makran and Kharan) and the central Makran range, running northeast and southwest, in the centre; and the Talar-i-Band or Makran coast range (Bahr-i-Garr) in the south. To the southwest are the long sweeping valleys of Rakhshan and Panjgur which, curving northward. likewise discharge into the Mashkel. The mountainous seaboard of Makran south of the Panjgur and west of the Hingol is poorly watered by the long lateral Dasht (Kech or Kej) river and several smaller mountain streams. The eastern frontier of southern Baluchistan follows the foot of the Kirthar range, whose limestone walls rise sheer for thousands of feet.

Climate. — Excluding the coastal strip in the south, Baluchistan has a subtropical continental climate marked by extremes of temperature and aridity. Kachhi and the Chagai-Kharan area are two of the hottest and driest regions of the Indo-Pakistan subcontinent. In the Zhob-Loralai and Quetta-Sarawan regions in the northeast, though the winter is very cold, the summer is cool and pleasant. The annual rainfall on the whole is less than 8 in.. increasing to about 15 in. at Shahrig in the northeast and falling in the northwest to under 3 in. Most of the rain occurs in winter as a result of western disturbances. Summer rains from the monsoons are important only in the northeast. The coast has moderate temperatures and low rainfall and is dominated by a steady inflow of sea breeze in summer.

Extensive changes have taken place in the climatic conditions, as is shown by the remains of forests now entirely desiccated. Wanton destruction of forests may have been a factor in the widespread desiccation of large areas of the Baloch highlands, where evidence of ancient irrigation works and of cultivation attests to a once flourishing civilization and suggests slow but persistent climatic variations.

Vegetation. — Generally speaking, the country is scantily clothed with vegetation and most of the hills are bare of forest growth. On the plains and lower highlands trees and herbs are conspicuously absent, and the bare stony soil supports a desolate jungle of stunted scrub. the individual plants of which are almost all armed with spines, hooks and prickles of diverse appearance. In the upper highlands the vegetation is extremely varied according to local conditions. There are extensive fruit gardens in the

northeast highlands, and wild olives are also found. There are numerous groves of date palms in Makran where the date is the staple food.

Animal Life. — Transport is almost entirely by camels. Donkeys are also owned by every nomadic family. Sheep (of the fat-tailed variety) and goats are numerous and constitute much of the agricultural wealth. The quality of the wool is coarse. The goats are generally small and not very hardy. Thickly built bullocks are bred in the hills. An excellent breed of cattle comes from Nari in Kachhi. The Sarawan and Kachhi produce the best horses in Baluchistan. The question of fodder is one of the most difficult in Baluchistan since there is not much grass in the greater part of the country, and horses and bullocks chiefly subsist on the straw of cereals. The waters off the coast swarm with fish and mollusks, the former including sharks, perch, catfish, herrings and pomfrets.

HISTORY

The earliest trace of human occupation goes back probably to the end of the 4th millennium B.C., when the climate was better and rainfall heavier. The whole area abounds in *dhambs* or mounds, the sites of prehistoric settlements, dating mainly from the Chalcolithic period (Bronze Age), and in part contemporary with the Indus valley civilization. The settlements were in the valleys and at the foot of the hills. The complex relationships of these sites have yet to be established, but their chief centres are the Quetta (Bolan pass) and Zhob valleys, and Kalat (Nal valley) in the northeast and the Makran (Kulli) in the south. There is evidence of trade from the Makran coast reaching Mesopotamia and southern Persia, and of an Indus valley trading station at Sutkagen Dor.

In addition to a reference in the Avesta (*q.v.*) to Vara Peshin-Anha, which has been identified as the Pishin valley. Herodotus states that Mykians—the Maka of the Bisotun (Behistun) inscription—were included in the 14th satrapy of the Persian empire as organized by Darius in the 6th century B.C. Makran, the name of the southwestern coastal area of Baluchistan and the neighbouring Iranian territory, has been taken to mean "the land of the Maka." But nothing is known of the area until the time of Alexander (*q.v.*) the Great. After his victories in India, he crossed Las Bela and Llakran (*qq.v.*) from east to west in 325 B.C., with the main body of his troops, while his admiral, Nearchus, coasted along their shores to the Persian gulf and kept such an accurate log that many of the ports and headlands mentioned can be identified. Craterus, in charge of the invalids and elephants, left Alexander in the Indus delta, marched through the Mula pass and northern Baluchistan, and rejoined him in the Halil Rud valley (Iran). Thereafter little more is known of Baluchistan, which probably passed under the control of the Parthians (see PARTHIA) and later of the Kushan dynasty. About this time Buddhism flourished in Baluchistan. In the 7th century the Arabs overthrew the Persian empire and gradually annexed its outlying provinces. In 707 Mohammed bin Kasim captured various strongholds in Makran, advanced into Sind and established the Muslim power in the Indus valley. The Arabs ruled Baluchistan from Khuzdar in Jhalawan until the 10th century.

When Persia regained its independence upon the gradual weakening of the caliphate, Baluchistan was included in the empire, but its chiefs were practically independent, so long as they furnished military contingents when called upon. From 1595 to 1638 the province formed part of the Mogul empire. The Balochi, who gave their name to the country, are comparatively recent arrivals. They apparently entered Baluchistan in the 11th and 12th centuries, being driven out of Persia by the Seljuks. They conquered western Makran but failed to seize the uplands of Kalat. Their rivals, the Brahuis, who occupy the highlands of Saraman and Jhalawan in Kalat, are of Dravidian stock. They rose to power in the 17th century under their chief Kambar, who overthrew a dynasty of Hindu rajahs, and since this period Muslims have been dominant throughout Baluchistan. Kambar's descendant. Abdulla Khan, conquered the fertile district of Kachhi. After Nadir Shah of Persia avenged the Afghan invasion of his country and captured Kandahar, he appointed Abdulla's successor Nasir Khan I as *beglerbegi* or "chief beg" (modern Turkish bey) of Baluchistan in 1739. Upon the assassination of Nadir Shah in 1747, Ahmad Shah Durrani (*q.v.*) founded the kingdom of Afghanistan. Nasir Khan at first acknowledged his overlordship but in 1758 rebelled. He was defeated by Ahmad Shah in the field, but the Afghan was unable to capture Kalat and a treaty was negotiated.

British Control. — The political connection of the British government with Baluchistan commenced with the outbreak of the first Afghan War in 1839 when it was traversed by the army of the Indus and was afterward occupied to protect the British lines of communication through the Bolan pass to Kandahar. In the attack on Kalat. the khan Mir Mehrab Khan was killed. His son Mir Nasir Khan II later regained Kalat. The first British treaty with Kalat state was negotiated in 1854. From 1856 to 1876 its history was a chronicle of anarchy, revolt and outrage. By the treaty of 1876 the independence of Kalat was recognized, the khan agreeing to co-operate with the British governor general. In furtherance of the defense of India, the position at the head of the Bolan pass, which included Quetta and the surrounding country, was occupied; in 1879, as a result of the second Afghan War, by the treaty of Gandamak, Sibi and Pishin were annexed. In 1891 Sir Robert Sandeman extended British authority over the Zhob valley. between Pishin and the old frontier of India. In 1899 Nushki, and in 1901 the area now known as Nasirabad subdivision, were acquired from Kalat on perpetual lease. Thus the province of British Baluchistan came into being. The khans of Kalat continued to rule until 1955 when the state was merged in West Pakistan.

In the wake of World War I came the famine and influenza which took a heavy toll of life. The earthquake of May 31, 1935, caused great destruction at Quetta, hlastung and Kalat. In Quetta between 22.000 and 25.000 persons perished and property worth hundreds of millions of rupees was destroyed. In 1947, when the province became a part of Pakistan, its alien (as distinguished from indigenous) Hindu and Sikh population, numbering about 48,000 (1941 census), mainly employed in trade. defense and civil service, almost all returned to India and about 30,000 Muslim refugees found their way into the province from India.

The States. — Before 1947, the whole centre and south of Baluchistan was either in practice or nominally feudatory to the khan of Kalat, but during British rule the independence of three other leading chiefs was asserted or recognized. Las Bela's obligation to Kalat had for many years been confined to a formal duty to supply military aid; Kharan emerged as a separate state in 1940; and Makran became independent of Kalat in 1948, when all three acceded to the new dominion of Pakistan. Kalat itself joined shortly after. In 1952 the four states formed an entity called the Baluchistan States union, and in 1955 they were merged in the newly integrated province of West Pakistan, forming part of the Kalat division.

Jirga System. — An important feature of the administration of the region is the jirga (assembly) system which dates back to the days of, Nasir Khan I who sought to consolidate the warring tribes by associating them with the administration. It was revived by Sir Robert Sandeman in 1877. In essence the system retained the rule of tribal chiefs through tribal custom, but under British supervision. Petty matters were settled by the village jirga. Intertribal disputes and differences were referred for final settlement to a provincial jirga, held annually at Sibi. These jirgas were known as shahi *darbars* until the inception of Pakistan. The jirga still continues as a recognized system. It is both a judicial and executive body dealing with day-to-day problems of tribesmen. The *sardar* ("headman"), *motabars* and elders constitute a jirga. Membership is almost hereditary. Internal and intertribal matters are decided on the basis of age-old conventions, customs and traditions.

When the jirga meets a "Sibi week" is celebrated. Several hundred members of the jirga are awarded sanads ("certificates") and *khalats* ("prizes") by the governor for meritorious services. An industrial exhibition, horse and cattle show, sports and races are also popular events.

THE PEOPLE

Baluchistan has an average density of only ten persons per square mile but in the Kalat division the average is only seven, falling to two in the districts of Chagai and Kharan. The total population in 1961 was 1.384.000 (including Las Bela). Almost all the people are Muslim; the largest Hindu minorities are in the Sibi (9%) and Kalat (2%) districts. They are chiefly agricultural and pastoral and transhumance is practised in the hilly areas. Because of isolation illiteracy is widespread.

The Meds. the Pathans and the Jats appear to have been the inhabitants of Baluchistan at the time of the Arab invasion. The Meds now. as then, live along the coast of Las Bela and Makran and are fishermen. They are the Med of the Arab chroniclers and may well be the Ichthyophagi of Alexander's time. The general habitat of the Pathans is the compact block of highland country in the northeast of the province, comprising the districts of Quetta-Pishin, part of Sibi and Loralai and the whole of Zhob. The chief indigenous Pathan tribes in Baluchistan are Kakars, Tarins and Shiranis, the Kakars being the most numerous. The Pathans are tall, robust and well-built. The Jats, less numerous, are cultivators in Kachhi and Las Bela. (See PATHAN; JAT.)

Beside Pathans the chief indigenous races are the Balochi and Brahui. The word Baloch means nomads or wanderers. Baloch legends suggest that they derived from Arabia or Aleppo, but more probably they are Iranian. They entered Baluchistan from Kirman and Seistan throueh Makran and slowly spread through the province in two main divisions, western and eastern. Many moved eastward to Kachhi, Sind and Punjab. They tend to be shorter than the Pathan and wear their hair long. They are expert riders. The western Baloch predominate in Chagai district and Makran and their important tribes include Nausherwani, Rakhshani, Boledi and Gichki. The Nausherwani, an Iranian group, appear to be identical with the Tahuki or Tahukani of Iranian Baluchistan. The Boledi were once the ruling race of southern Baluchistan. The Gichki are the dominant race in Panjgur and Kej in Makran where they ousted the Boledi. Tradition suggests that they were originally Hindus who made their way to Makran from the east in the 16th or 17th century. The Rind are the main tribes of the eastern Baloch. Of them, the Mari and Bugti tribes. who occupy the southern buttresses of the Sulaimans, are the most numerous. They are almost certainly of Arab extraction and claim to be Kurdish, They came to Sind either with the Arab conquerors or later and remained there mixed with the original Hindu inhabitants. (See BALOCHI.)

The Brahuis are a confederacy of tribes occupying the highland country of Sarawan and Jhalawan in the Kalat division. They are also found westward in Chagai and Kharan and even in Makran. In view of their Dravidian language their origin has been a subject of great speculation. Their own explanation is that the word Brahui is derived from an eponymous ancestor. Braho (a modification of Brahim or Ibrahim), who was a descendant of Mohammed's uncle Mir Hamza. (See BRAHUI.)

Languages. — The chief indigenous languages spoken are Balochi, Pashto, Brahui and Jatki (or Jagdali). Balochi is spoken by nearly one-third of the population and in more than half of Baluchistan (see BALOCHI LANGUAGE). Pashto, the language of the Pathan tribes, is spoken in the northeastern districts. Brahui is found in the centre of the country around Sarawan and Jhalawan (*see* BRAHGI LANGUAGE). The term Jatki includes a number of local languages, which fall into two main groups resembling Sindhi on one side and western Punjabi (Lahnda) on the other (see SINDHI LANGUAGE; LAHNDA LANGUAGE). Jatki is more scattered and is spoken in Kachhi, Las Bela, Sibi and Barkhan (west of the Punjab border). (K. S. AD.)

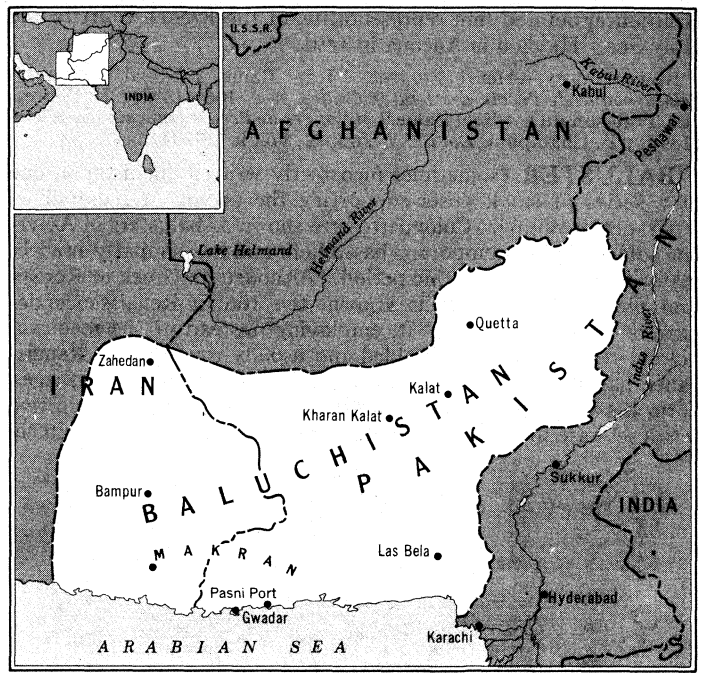
BALUCHISTAN (BALUCHESTAN), a region in the southeast of Iran, previously within the province of Kerman but from 1959 united with Seistan (*q.v.*) in one province (*ostan*) with the capital at Zahedan. The province has an area of 69,487 sq.mi. and a total population in 1956 of 428.600. Baluchistan is the least developed of all Iranian regions partly because of the singularly harsh environment and partly because of the prevailing social conditions. Precipitations are scarce and mostly fall in a few violent rainstorms causing foods and heavy erosion. The region consists largely of broken uplands. or lowlands submerged in oppressive heat for eight months of the year. The nomadic element, Balochis and Brahui (*qq.v.*) with many admixtures. was dominant to the detriment of cultivation, which obviously much receded during historic times. Sedentary groups include descendants of old Iranian stock. Indians (Jat) and some remnants of an old primitive stratum. Camelback raiding and internal warfare was common. Besides tribal areas there existed a number of petty principalities, partly paying allegiance to the khanate of Kalat.



REGION OF BALUCHISTAN. DIVIDED BETWEEN PAKISTAN AND IRAN

Frequently claimed by the more potent rulers of Persia, this western part,of Baluchistan in its wider sense was conquered by Persia piecemeal during the 19th century, and its boundary was fixed by an international boundary commission in 1872. The government has striven for final pacification and economic rehabilitation. Settlement was assisted by the construction of dams (Bampur-Iranshahr). A motorable road was opened from Zahedan to the minor port of Chah Bahar. Zahedan (pop.. 1956, 17,490) and Zabol (in Seistan) are the only towns of importance. Zahedan is connected by rail to Quetta, West Pakistan; it is a road junction for the roads from Pakistan to western Iran and from the U.S.S.R. through Meshed to the Gulf of Oman, and has an airport.

The coastal region, which extends into Pakistani Baluchistan, is known as Makran (*q.v.*). (H. BO.)

BALUE, JEAN (c. 1421–1491), French cardinal, the treacherous minister of Louis XI, was born at Angles-sur-l'Anglin, in Poitou, of obscure parentage. He became almoner to Louis XI, bishop of Evreux in 1465 and cardinal in 1467. About that time Balûe was compromised in the king's humiliation by Charles the Bold. duke of Burgundy, at Péronne and excluded from the council. He then intrigued with Charles against his master; their secret correspondence was intercepted. and on April 23, 1469. Balue was thrown into prison—but not, as has been alleged, in an iron cage. In 1480. through the intervention of Pope Sixtus IV. he was set at liberty and went to live in Rome. He received the bishopric of Albano and afterward that of Palestrina. In 1484 he was even sent to France as legate a *latere*. The government of Anne de

Beaujeu appointed him representative of the French court to the Holy See. He died in Ancona in 1491.

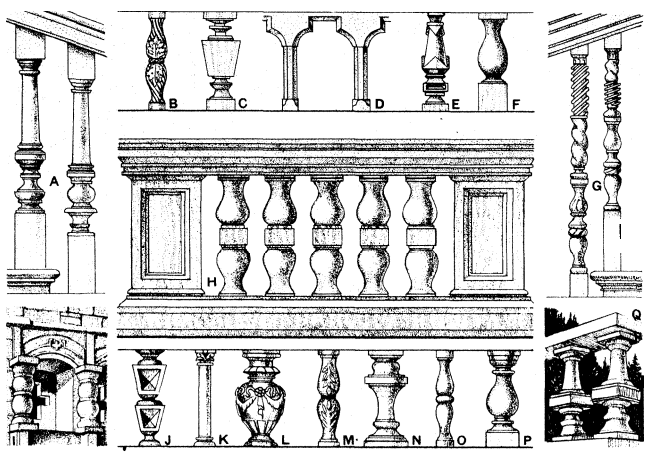
BALUSTER (sometimes incorrectly written "banister"), one of a series of small posts supporting the coping or handrail of a parapet or railing. Colonnettes are shown as balusters in Assyrian palaces by contemporary bas-reliefs and are similarly used in many railings of the Gothic period. Although no Greek or Roman example of the baluster is known, the Italian Renaissance designers made great use of it, employing, instead of the medieval colonnette, forms richly molded and usually round. The Renaissance balusters generally had a capital, a base and a vase-shaped form between. In early Renaissance work a form similar to two vases set base to base is frequent. The later Renaissance architects



EXAMPLES OF BALUSTERS

(A, G) Georgian Colonial (G: Hancock house, Boston, 1737); (B, F, H, K, M, O, P) Italian Renaissance (H, Library of St. Mark's, Venice, c. 1550); (C, E, N) modern baroque variations: (D) French Gothic, Chartres cathedral, 13th century; (I) Saxon romanesque; (J, L) Italian baroque: (Q) modern French

codified balusters into orders like columns, and those of the baroque went to the other extreme of fantasy in baluster form. The term "baluster shaft" is used of any similar vertical shaft such as those found dividing the windows in Saxon work.

BALUZE, ÉTIENNE (1630–1718), French scholar, notable both as the author of historical works and as the collector and publisher of documents and manuscripts, was born at Tulle, near Limoges. on Nov. 24, 1630. He was educated at the Collège St. Martial at Toulouse, where he studied chiefly ecclesiastical history and canon law, becoming in 1654 secretary to the archbishop of Toulouse, a historian of note. Just before the archbishop's death in 1662 he entrusted Baluze—who had already brought out several works of his own—with the task of publishing all his papers.

After five years as secretary to the bishop of Auch, in 1667 Baluze entered the service of Colbert as his librarian, a post he was to hold for more than 30 years. In 1670 he received the additional appointment of professor of canon law at the Collège Royal. He published his *Concilia Galliae Narbonensis* in 1668, following this with other important works, including *Capitularia regum Francorum* (1677), *Miscellanea* (1678–83), *Nova collectio Conciliorum,* (1683, only one vol. published) and *Vitae Paparum Avenionensium* (1693). He also edited the works of many ecclesiastical writers. During this period he was in correspondence with other scholars and readily put at their disposal what his own researches revealed. In 1700 he relinquished his position as librarian, having enormously enriched Colbert's collection of books, and in 1707 was appointed director of the CollPge Royal. In 1708 appeared his *Histoire généalogique de la maison d'Auvergne,* undertaken at the request of the cardinal de Bouillon. In this, which purported to trace the cardinal's descent from the counts of Auvergne in the 9th century, Baluze made use of documents already proved to have been forged. De Bouillon fled abroad, and Baluze, having been deprived of all his offices, was banished for some years from Paris. While in exile he completed his *Historia Tutelensis* (1717).

Baluze died in Paris on July 28, 1718.

BALZAC, HONORÉ DE (1799–1850), French novelist, one of the greatest writers of fiction of all time, was born in Tours on May 20, 1799. His parents, by whom he was much influenced, were strongly individual characters. His father, whose surname was originally Balssa, was a self-made man of southern peasant stock who had obtained a legal training for himself and held responsible administrative posts for 43 years under Louis XVI and Napoleon. From him Balzac derived his enthusiasm for Laurence Sterne and Rabelais. Balzac's mother, who belonged to a well-to-do family of Paris cloth merchants, was 32 years younger than his father. She was overrigid in her treatment of children, and Balzac later deplored what he felt to be a lack of maternal affection. It was this which he sought in some of his personal relationships in subsequent life. Several of his stories contain reflections of his childhood and growth to manhood in conditions often far from happy. He saw little of family life during his early years; he was sent to school at Vendôme from the age of 8 to nearly 14 and did not return home during this period. He was particularly close to his sister Laure, 16 months younger than himself. To her he poured out his youthful convictions about the high destiny which he was sure awaited him.

Although his relations with his mother, were often strained, Balzac was to turn to her for help on many occasions, especially during periods of financial stress. She was preoccupied with occultism and mesmerism and with the mystical philosophy of Swedenborg. This started Balzac's own interest in these and similar topics. He was greatly fascinated by hypnotism and magnetism and by all that he could discover concerning the fantastic or supernatural. He eagerly adopted J. K. Lavater's theories of the supposed connections between physical appearance and character or destiny and was equally attracted by F. J. Gall's system of phrenological deductions. The more solidly based ideas of the scientists Geoffroy Saint-Hilaire and Cuvier also held a compelling interest for him.

All this marked his work profoundly. He not only looked for the spiritual or mystical truths underlying outward realities but was also convinced that an inescapable relationship existed between external circumstances and the ways in which individual lives might be expected to develop. A man's antecedents, environment, upbringing and proiession would all shape his destiny. New conditions or some apparently insignificant turn of events might bring out latent possibilities in his character and set him on a different route. For these reasons Balzac gave much space in his novels to a minute description of all the physical factors by which his characters found themselves surrounded—the towns and streets in which they lived, the houses which both expressed and formed their personality, the clothes which were so much a part of themselves, the signs and gestures by which they gave themselves away.

To describe and interpret the age in which he lived was Balzac's greatest aim. He was well qualified for such a task. He was a close and accurate observer, with great powers of assimilation and an amazingly retentive mind. He was also an omnivorous reader who took all knowledge for his province, a man of intense imagination and creative power and a visionary with an intuitive understanding of human nature which he himself compared to second sight.

Far-reaching changes were taking place in France in Balzac's lifetime. The echoes of the Revolution of 1789 were still reverberating, and the structure of French society was being transformed. Balzac grew up under the regime of Napoleon I, whose name held a particular magic for him, as for many of his contemporaries. It was partly a desire to be a Napoleon of the pen that fired his own ambitions. He wrote about the Napoleonic era in several works, notably *Une Ténébreuse Affaire* (serialized 1841;

authorized ed. in book form, 1842),[1] a story of conspiracy which anticipates the modern detective novel. He chiefly concentrated, however, on the quarter century following Napoleon's defeat in 1815. and this period provides the setting for more than two-thirds of his stories, with particular emphasis on the years of the Restoration, 1815–30. Unlike some authors of the romantic generation, Balzac had no desire to escape from his own times. To others, the period often seemed a colourless anticlimax after the excitements of Sapoleonic days. To Balzac, it represented adventure and achievement,. One of his great gifts was for seeing possibilities for the storyteller in material that might have appeared commonplace.

Literary **Beginnings.**—Balzac was first intended for the legal profession. He was registered as a student in the law faculty of Paris university from 1816 to 1819; during this period, he was also a clerk in the office first of a solicitor, then of a notary; He was to utilize his experiences and his knowledge of judicial procedure in many stories, for instance *Le Colonel Chabert, Le Contrat de mariage* and *César Birotteau.* From the first, however, he was convinced that his true bent was for literature. In 1819, his parents agreed to let him try his hand as a writer. He established himself in a garret near the Arsenal in Paris, with an allowance of 1,500 fr. per annum. To prove himself. he wrote a verse tragedy, *Cromwell,* which he read to an unenthusiastic family audience in 1820. An opinion was sought from François Andrieux. the future secretary of the Académie Française, whose verdict was that Balzac might employ his time better than by composing tragedies or comedies. A more colourful version of this episode is given by Balzac's sister Laure in her informative but not always accurate reminiscences (Laure Surville. *Balzac, sa vie et ses oeuvres, d'après sa correspondance,* 1858), where Andrieux is reported as saying that Balzac should occupy himself with anything but literature. Balzac. sure that he had only to persevere to establish himself as a genius, resolutely disregarded Andrieux's advice. He constantly tried to launch himself as a dramatist and, toward the end of his life. cherished the notion of adapting all his novels for the stage so as to earn better financial rewards. His plays were almost invariably unfortunate. (*Src* D. Z. Milatchitch. *Le Théâtre d'Honoré de Balzac* and *Le Théâtre inédit d'Honoré de Balzac,* 1930).

From 1819 to 1825. Balzac was chiefly occupied with experiments in fiction. and irom 182 j to 1828 with various ill-fated business ventures. From the early 1830s onward. he also produced many journalistic writings on a variety of topics, from theories of government to questions of elegance. With his awareness of new developments. he was among the first to recognize the growing power of the press. Many of his novels first appeared as serials in newspapers, a fashion which became popular in the middle 1830s. He founded various short-lived periodicals—the first of them. the *Feuilleton des journaux politiques,* in 1830—which he hoped would serve him in his ambitions for a political career. This, however, never materialized. His political convictions shifted in various directions, but in the main he favoured a benevolent autocracy. Similarly, after alternating between mysticism and irreverence, he eventually proclaimed his support for the Catholic Church.

Balzac's first attempts at fiction are represented by a fragment entitled *Falthurne* (probably late 1820; ed. by P. G. Castex, 1950) and by a longer unfinished work entitled *Sténie, ou les erreurs philosophiques* (attributed to 1820–21; ed. by A. Prioult, 1936). Both remained unpublished until the 20th century. They show his interest in philosophical speculation and metaphysical inquiry and also his determination from the outset to establish himself not merely as a novelist but as an intellectual leader. He felt too that it was the function of the modern novelist to do what epic poets had done for earlier generations.

After *Falthurne* and *Sténie,* from 1821 to 1825, Balzac wrote a number of unsigned or pseudonymous stories, either in collaboration with various second-rate authors or on his own. The full extent of this activity remains uncertain, but he is known to have been partly or wholly responsible for at least eight of these stories. He had no illusions about their merits and never admitted them to his collected works. They were potboilers, but they were also deliberate exercises in different forms of writing, parodies or imitations of elements then fashionable in literature. Balzac drew from many sources: popular thrillers, melodrama, the English tale of terror. the works of Rousseau, Diderot, Richardson. Scott, Byron, Goethe. Chateaubriand and James Fenimore Cooper. Long neglected, these youthful productions have been much studied since. They show him anticipating themes and character studies typical of his later works. (*See* A. Prioult, *Balzac avant la Comédie humaine, 1818–29,* 1936).

Literary efforts not proving sufficiently remunerative: Balzac became a publisher in 1825 and a printer in 1826. In 1827, he bought a type-foundry as well, but disaster soon followed. In 1828, he was narrowly saved from bankruptcy and left with liabilities of at least 60,000 fr. From now on his life was to be one of mounting debt and almost incessant toil.

Balzac spent far more than he could afford on luxuries of every. kind: personal adornment. furnishings, paintings. *objets d'art,* exquisite coiiee. His passion for collecting grew to resemble that of his hero in *Le Cousin Pons.* He paid off obligations by incurring others. promised work that he could not complete in time and had interminable arguments nith publishers over broken contracts. Long spells of seclusion, when he \\-orked for 1; or 18 hours a day, alternated nith brief excursions into the fashionable world and periods of recuperation in the country. He was for ever conjuring up wonderful schemes to provide a short cut to fortune and. however often they came to naught; always believed that his nest venture would bring riches beyond compare. It was partly this ability to live in a realm of make-believe that enabled him to write so convincingly.

In his financial difficulties. Balzac received substantial advances from his mother and from Madame de Berny (Laure Hinner; 1777–1836), whom he first met in 1821. Madame de Berny was a goddaughter of Louis XVI and Marie Antoinette; her father had been a court musician, and her mother a lady's maid to the queen. She was 22 years older than Balzac. and the mother of a large family; she gave him a warmth of affection which he had never previously known, and her death in 1836 n-as one of his deepest griefs.

Balzac also owed much to Madame Carraud (Zulma Tourangin; 1796–1889), whom he first met in 1819. The wife of an instructor at the military academy of Saint Cyr, she represented all that n-as best in the liberal *bourgeoisie* of the period. She was a wise and loyal friend for many years. (See *Honoré de Balzac: Correspondance avec Zulma Carraud,* revised ed. by M. Bouteron. 1951.)

Balzac's relationship with the duchesse d'Abrantès (Laure Junot [*q.v.*], the widow of one of Sapoleon's marshals), whom he probably met in 1825, was of a different character. She enlisted his help in writing her memoirs, fascinated him with reminiscences of the Sapoleonic period and helped him to gain a foothold in the fashionable world—to which he sought admission partly because of *amour-propre,* partly for self-advancement, partly in order to study a mode of life that could never be adequately imagined from outside.

Themes and Ideas. — During the 1820s, Balzac was working his way toward the road which he was to follow as a novelist. One of his first intentions: in emulation of Scott, was to write a sequence of stories depicting the history of France from the earliest days. Only subsequently did he decide to become the historian of his own times and to give his works the cohesion of a vast chronicle in which every novel would be like but one chapter in the whole.

The first novel that Balzac signed with his own name. *Le Dernier Chouan* (1829; entitled *Les Chouans* in 1834) ranks as a historical novel in so far as it deals with a royalist insurrection of 1799. It points decisively, however, toward that representation of contemporary life which was henceforth to be his main concern, though he never lost his interest in the past or in the lessons to be learned from it. At intervals up to 1841. he wrote over a dozen more works of fiction dealing with events prior to 1800. from the time

[1]The dates given in this article for first publication in book form are those of the French editions authorized by Balzac. They were sometimes preceded by Belgian editions pirated from the serial publications.

of Dante (*Les Proscrits,* 1831) to the French Revolution (Un *Épisode sous la terreur,* 1831).

Balzac's opportunities for observing the contemporary scene were increased by constant journeys in France and different parts of Europe. His wide circle of friends and acquaintances brought him into contact with many walks of life. He knew both provincial and metropolitan life as few writers have done. No French novelist has drawn material from such a diversity of regions, but Paris provided the background for many of his stories, and it was there, in a variety of districts, that he chiefly lived from 1814 onward. His home in what is now the Rue Raynouard — with a trapdoor enabling him to escape from his creditors into the street behind—was later transformed into the Balzac museum.

The contrast between the provinces and the capital became his constant theme. No theme is more typically Balzacian than that of the ambitious young provincial fighting for advancement in the competitive world of Paris. Here, Balzac believed, the effects of modern civilization could be seen in their most extreme and demoralizing form. He admired those who were ruthless, astute and, above all, successful in thrusting their way ahead and was attracted by the theme of the individual in conflict with society: the adventurer. rebel or criminal. He was reproached for making his villains more vigorous and interesting than his virtuous characters. Nevertheless, he strongly condemned a social system in which moral principles were being replaced by money values.

These topics providetl material largely unknown. or unexplored. by earlier writers of French fiction. The individual in Balzac's stories does not live in a world remote from material difticulties, but is continually affected by the pressure of outward circumstances. Conversely. his own actions are represented as spreading out in widening circles. bringing their consequences to bear, not upon hitnself alone, hut upon many others too. This is particularly the case with some of the central characters in the novels. They are the victims and the embodiment of some ruling passion: avarice. excessive paternal aiiection. feminine jealousy. vindictiveness. the mania of the collector. the curiosity of the scientist. the artist's desire for perfection. Once such an obsession has gained a hold. Balzac shows it growing irresistibly in power and blinding the person concerned to all other considerations, The typical structure of his novels from the early 1830s onward is determined by this approach: there i n long period of preparation and exposition. then tension mounts swiftly to an inevitable climax. as in classical tragedy

Literary and Social Success, 1830–32.—In 1830 Balzac sud denly acquired celebrity with a skittish and cynical essay, the *Physiologie du mariage.* The six stories in his *Scènes de la vie privée,* 2 vol. (also 1830), increased his reputation. He began to frequent some of the best-known salons of the day and redoubled his efforts to set himself up as a dazzling figure in society. His resplendent waistcoats, his turquoise-studded cane, his tilbur and two horses made him the talk of the town, as he intended. He adapted for his own use the armorial bearings of an ancient noble family with which he had no connection and assumed the honorific particle "de." The first publication in which he used this particle nas *La Peau de chagrin,* 2 vol. (1831j, a story of the fantastic symbolizing one of his most constant themes, viz., the nay that vital energy might be dissipated by the satisfaction of desires.

This work gained him many new readers. In particular it brought him. in Sept. 1831, an admiring but pseudonymous letter from a lady who in Feb. 1832 revealed herself to be the marquise de Castries (Henriette de Maillé, duchesse de Castries in 1842). Balzac n-as captivated by her beauty and by the fact of her belonging to one of the oldest noble families of France. She introduced him to her circle and, in 1832, invited him to join her on a trip to Italy. They parted company, however, in Geneva, in circumstances never fully explained. Balzac's pride was deeply wounded, but he did not break with her completely; they corresponded, and sometimes met. almost to the end of his liie.

Madame **Hanska.**—Meanwhile Balzac had received a letter from another lady admirer which altered his whole existence. Written. it is thought, on Feb. 28. 1832 (the day of Balzac's first letter to Madame de Castries), and posted from Odessa, it was signed "l'Étrangère" and told him he would never know the writer in any other way. Balzac acknowledged this by a personal advertisement in the *Gazette de France* of April 2. The lady wrote again on Tov. 7, and this time he replied by an advertisement in *La Quotidienne* of Dec. 9. Her identity was soon revealed. She was Éveline Hanska (née Ewelina Rzewuska; 1800–82), a Polish countess, the wife of an immensely wealthy landowner 22 years older than herself. She and Balzac first met at Neuchâtel late in Sept. 1833 and agreed to marry when she was free. They met again in Geneva from Dec. 1833 to Feb. 1834 and in Vienna between May 16 and June 4, 1835. Balzac traveled there in great style. aided by an advance from Edmond Werdet, his long-suffering publisher; he was introduced to Metternich and other leading members of Austrian society. He did not see Madame Hanska again until 1843, 20 months after her husband died in Tov. 1841.

Balzac's courtship was mainly conducted through a voluminous correspondence, later published as *Lettres à l'Étrangère* (vol. 1–2 ed. by the vicomte C. de Spoelberch de Lovenjoul. 1899–1906; vol. 3–4 ed. by Marcel Bouteron, 1933–50). Here he poured out his hopes and anxieties and gave Madame Hanska a constant progress sheet recording the efforts he was making to realize his ambitions. Of her letters to him only those of Nov. 7, 1832, and Jan. 8, 1833, have survived: the rest were destroyed at her wish.

Projects and Achievements, From 1832.—To put himself in a position to marry Madame Hanska became Balzac's great incentive. He was now at the peak of his creative power. In the period 1832–35, he produced more than 20 works, including *Louis Lambert* (first published as *Notice biographique sur Louis Lambert,* 1832), *Le Médecin de campagne* (1833), *Eugénie Grandet* (1833), *La Recherche de l'absolu* (1834), *Le Père Goriot* (serialized 1834–35; in book form 1835), his masterpiece, and *Le Lys dans la vallée* (part serialized 1835; in book form, 2 vol., 1836). Among the shorter stories were *Le Colonel Chabert* (1832), *Le Cure' de Tours* (1832), *La Femme abandonnée* (1832), the trilogy entitled *Histoire des treize* (1833–35) and *Sdraphita,* a highly mystical work which he dedicated to Madame Hanska (1834–35). Between 1836 and 1839, he wrote *Le Cabinet des antiques* (in periodicals. 1836–38; in book form 1839), the first two parts of *Illusions perdues* (1837, 1839), *Les Employés* (serialized as *La Femme supérieure,* 1837; in book form. retitled, 1838), *Histoire de la grandeur et de la décadence de César Birotteau* (1837 but dated "1838"), *La Maison Nucingen* (1838), *Le Curé de village* (fragments 1839; in book form 1840) and parts i and ii of *Béatrix* (1839). Between 1832 and 1837, he also published three sets of *Contes drolatiqucs.* These stories, Rabelaisian in theme, are written with great verve and gusto in an ingenious pastiche of 16th-century language.

That the *Contes drolatiques* should have been written by the author of *Sdraphita* reflects part of Balzac's many-sided personality. To most people he seemed full of exuberant vitality, talkative, jovial and robustious, egoistic. credulous and boastful. George Sand was among the few to see a deeper aspect of his nature. but even she did not know the Balzac who perhaps resembles his hero Louis Lambert, detached from the workaday world and searching out mysterious regions of abstract thought.

It is hard to imagine how Balzac combined this literary work with his many other activities. In spite of frequent assurances to Madame Hanska, he formed other attachments. In 1834, he met an Englishwoman, Sarah Lowell, Countess Guidoboni-Visconti, who meant much to him for several years. He went twice to Italy on business for her husband and her, and they often helped him financially, especially over his purchase in 1837 of a property called Les Jardies at Ville-d'Avray (Seine-et-Oise). There he built a house and, among other projects, thought of growing 100.000 pineapples at a price defying all competition, but everything went calamitously wrong and he eventually sold the property at enormous loss. In 1838, he visited Sardinia, in search of silver mines left by the Romans. to find that someone had already obtained the concession. In 1839, with Gavarni the artist, he vainly tried to save from execution a notary and writer called Sébastien Peytel, in his view wrongly accused of murder. He also became president of the Socidte des Gens de Lettres, founded to protect the rights of authors. ior which he had been vigorously campaigning. In 1835

Balzac had bought a major interest in the *Chronique de Paris,* but he gave it up after six months, with a debt of 45,000 fr. In 1840 he made his last attempt to launch a periodical, the *Revue parisienne.* This ran to three issues. mainly written by himself, and included his famous tribute to Stendhal, then unrecognized.

Balzac produced several notable works in the years 1841–42. These included *Une Ténébreuse Affaire (see* above), *La Rabouilleuse* (serialized as *Les Deux Frères* and *Un Ménage de garçon en province,* 1841–42; in book form as *Les Deux Frères,* 2 vol.. 1843. but dated "1842"), *Ursule Mirouët* and *Albert Savarus.* After this the rate slowed up appreciably. Increasing ill-health made him anxious about completing a task whose limits he was constantly extending. He was beset by financial cares and troubled by Madame Hanska's continual postponements of their marriage. Her reasons have been much debated, but she had many legal difficulties to overcome and some cause for hesitation before marrying a debt-encumbered foreign author.

In 1844. using a subject which Madame Hanska had suggested: Balzac produced *Modeste Mignon.* He also began *Les Paysans* (13 ch. serialized 1844; completed by his widow, 1855). In 1846 and 1847 he published the last two parts of *Splendeurs et misères des courtisanes,* the first two having appeared in 1843–44. His last two masterpieces were *La Cousine Bette* and *Le Cousin Pons* (serialized 1846 and 1847 respectively as parts i and ii of *Histoire des parents pauvres;* in book form as *Les Parents pauvres,* 2 pt.. 1847–48). With *La Rabouilleuse,* they constitute his most sombre pictures of human depravity, but they also emphasize loyalty and self-sacrificing devotion. After 1847, Balzac began no work which he lived to complete.

La **Comédie humaine.**—Throughout his career, Balzac's general plan for his fiction grew more ambitious. He explained his intentions, as they developed, in various letters and prefaces. In 1830. in his *Scènes de la vie privée,* he had begun the process of grouping his stories together. This was carried iurther in *Études de moeurs au XIXe siècle,* 12 vol. (1834–37), which prepared the nay for the publication of his collected works under the title *La Comédie humaine* (probably inspired by that of Dante's *Divine Comedy*).

This edition. illustrated by Gavarni. Daumier. H. Monnier and other leading artists. began to appear in 1842. By 1848. 1; volumes had been published. In 1855, after Balzac's death, it was reprinted, with the addition of three further volumes: vol. xviii concluded the *Comédie humaine,* while vol. xix contained Balzac's plays and vol. xx his *Contes drolatiques.*

The sales of the *Comédie humaine* proved disappointing. and in 1845 Balzac drew up a catalogue for a second and enlarged edition of 26 volumes. This gave the titles of 51 new works which he proposed to include. but only one of these was eventually completed. This was *Les Frères de la consolation,* entitled *L'Envers de l'histoire contemporaine* when finally published in book form (1855). He subsequently wrote five more works whose titles had not appeared in his 1845 list, namely: *Gaudissart II, Un Homme d'affaires, Petites ntiskres de la vie conjugale, La Cousine Bette* and *Lc Cousin Pons.* These brought the total of works comprised in the *Comédie humaine* to 91, the three component parts of *Sur Catherine de Médicis* being regarded as one work.

Balzac divided *La Comédie humaine* into three main compartments: *Études de moeurs, Études philosophiques* and *Etudes analytiques.* The first: 14 volumes of the edition of 1842–48, is subdivided into scenes of private life. provincial life. Parisian life, political life, military life and country life. Balzac. however, rated some of the stories in his *Études philosophiques* above the more realistic novels by which he was mainly known in his lifetime.

These divisions were somewhat artificial, and Balzac often regrouped them without finding an entirely satisfactory arrangement. It became increasingly difficult as his design grew more far-reaching and its ramifications more intricate. His achievement, he told Madame Hanska in 1843. would consist in having carried a whole society in his head. This reaffirmed ambitions expressed to her in a letter of Oct. 26, 1834. His "human comedy," as he explained in his famous preface oi 1842, was intended to include 2.000 to 3.000 outstanding characters. This number, he believed, would serve to represent contemporary life in all its complexity. (In his letter to Hippolyte Castille of Oct. 11, 1846, he gave the figure as 4,000 to 5,000.) In the end, the total number of named characters in the *Comédie humaine* is estimated to have reached 2,472, with a further j66 unnamed characters. In addition, a number of historical personages appear under their real names.

Balzac did not quite realize his tremendous aim of making his novels comprehend the whole of society at that time. His projected scenes of military and political life were only partially completed, and there were certain other gaps, for instance in regard to the new class of industrial artisans. Severtheless, no novelist has thronged his pages with men and women drawn from so many different spheres, nor with characters so widely representative of human passions and frailties, projected with dynamic and convincing force. Their salient features are heightened and sometimes exaggerated to caricatural proportions: they are both types and individuals. Together they make up the picture of an age, but they belong, in many cases. to all humanity.

It was a picture not merely of diversity, but also of interdependence. Balzac saw society as a unit, a great drama with endless links and relationships. He conveyed this by a technique which he first applied systematically in *Le Pbre Goriot* in 1834, after experimenting with it earlier, viz., by making the same characters reappear in one story after another. His previous works were rewritten to bring them into line, and henceforward Balzac used this method more and more extensively.

Many of Balzac's difficulties arose from his striving for perfection. He would not allow anything to be published before he was fully satisfied, and some of his works were rewritten a dozen or more times. These strenuous revisions were not limited to stylistic details. He often began with a relatively simple subject, but let fresh ideas come crowding in during composition, until finally the story went far beyond his first intention. Even when it was in print he would frequently introduce new variations on his theme, as successive editions appeared. His characters too lived on in his mind, sometimes changing considerably before acquiring their final shape.

Balzac's method was almost invariably to reinforce, to emphasize and amplify. There are lengthy digressions in which he aired his knowledge or expounded his views, but at its best his expression is remarkably graphic and sometimes tersely epigrammatic. His command of the French language was probably unrivaled, and, although unsuccessful as a playwright, he was a master of dialogue. His sardonic humour saves even his more pessimistic stories from being uniformly dark, and he had a real gift for comedy. He gave the French novel new dimensions and helped to make it a major form of literature.

Last Years.—During Balzac's last years, the strain of work became excessive. though at times he was still buoyed up with thoughts of achievement. After many disappointments, he met Madame Hanska in Germany in 1845, and they traveled with some happiness in Belgium. Holland and France. He visited her at her estate of Wierzchownia in Volhynia in 1847 and went there again in Sept. 1848 for a longer period, his health by now gravely impaired. On Jan. 11 and 18, 1849, he was a candidate for the Académie Française, but was twice defeated. receiving only two votes each time. He married Madame Hanska at Berdichev on March 14, 1850. In May they journeyed to the house in the Rue Fortunée in Paris, which he had partly furnished with her money. From then on Balzac was ill most of the time until his death, Aug. 18, 1850. His funeral took place Aug. 21, in the cemetery of Père Lachaise; Victor Hugo pronounced the funeral oration.

Manuscripts and **Editions.**—After Balzac's death, many of his manuscripts were destroyed. The vicomte Charles de Spoelberch de Lovenjoul, a Belgian scholar, devoted much of his life to collecting Balzac items of every kind. He left them. after his death in 1907. to the Institut de .France. They now are in the Lovenjoul collecton at the Château de Chantilly. Marcel Bouteron was curator for over 30 years; Jean Pommier succeeded him.

For Balzac's complete works *see* the edition by M. Bouteron and H. Longnon. 40 vol. (1912–40), and *L'Oeuvre de Balzac,* ed. by

A. Béguin and J. A. Ducourneau, 16 vol. (1949–53). *La Comédie humaine* is also published in the Plkiade series, ed. by M. Bouteron. 11 vol. (1935–60). A further important edition of Balzac's *Oeuvres complètes,* by La Société des Études Balzaciennes, began to appear in 1956. *See* also, in addition to the editions mentioned in the text. *Les Cahiers balzaciens,* ed. by M. Bouteron, 8 vol. (1923–28), and *Honor6 de Balzac: Letters to His Family 1809–1850,* ed. by W. Scott Hastings (1934; Fr. ed. 1950). There are valuable editions of separate works by S. de Lovenjoul, M. Bouteron. M. Allem, B. Guyon, M. Bardèche. P. Bertault, P. G. Castex, G. Robert and G. Matoré (conjointly), M. Regard, A. Adam and J. Pommier. *See* also the excellent anthology edited by J. Merlant: *Honoré de Balzac, morceaux choisis* (1912).

BALZAC, JEAN LOUIS GUEZ DE (*c.* 1597–1654), French man of letters, one of the original members of the Académie Franqaise and a critic who exercised an important influence on the development of classical French prose. He belonged to a family called Guez (who had a house at Balzac near Angoulême) and was baptized on June 1, 1597. After studies at the University of Leiden (1615), some youthful adventures and a period in Rome (1620–22), he hoped for a political career and wrote in defense of Richelieu's administration. When he saw, however, that Richelieu would never satisfy him, he retired to his country house, to maintain relations with Parisian literary circles chiefly by correspondence. Elected to the Académie Franqaise in 1634, he rarely attended its sessions. He died at Balzac on Feb. 18, 1654.

Balzac's publications include *Le Prince* (1631), a political treatise which shows a remarkable understanding of politics despite its pompous style: and Le *Socrate chrétien* (1652), which gives the conclusion of his ethical thinking, a synthesis of Stoicism and Christianity. Far more influential, however. were the *Lettres* (actually short political: moral and literary dissertations) in numerous editions, continually being expanded, from 1624.

Superficially. Balzac can be described as a baroque writer. He was strongly influenced by the moral philosophy of ancient Rome and so, inevitably, by Seneca's style, and he modeled his work on the collections of letters, in the baroque manner! which were then being published in Italy. The affectation and the subtleties of his style were deliberately contrived to take the reader by surprise, and he did in fact achieve by this means some unusual and remarkable eifects. On the other hand, he fought against the influence of the 16th-century writers, recommended logical exactness and the precise use of terms and upheld the same linguistic principles as did his friends Chapelain and Vaugelas. His reputation was high in his lifetime. but declined quickly after his death. His friend Valentin Conrart edited his complete works (1665).

See A. Adam, *Histoire de la littérature française au XVII^e siècle,* vol. i and ii (1948–51). (AE. A.)

BAMAKO, the capital of Mali, is situated on the west bank of the Siger, between the river and the steep flank of the Mandingo plateau. It is one of the most picturesque towns of west Africa and an important commercial centre. Pop. (1955 est.) 68.197 including 3,197 Europeans. When occupied in 1880 by Capt. Joseph Gallieni. Bamako was a settlement of a few hundred inhabitants grouped in villages. It became the capital of the former French colony in 1908 and then assumed its present general layout. It is now a large town. with a huge market, a botanical and zoological park, institutions for research: many schools and an active artisan community. Its decorative gardens give it an air of freshness. The government headquarters is about 3 km. (1.9 mi.) distant on the Koulouba spur, the hospital on another spur and the European town between the railway station and the Siger. Of the old African quarters only that of Bozola remains. a "village" with winding lanes where fishers' nets are dried. New African quarters surround the town to east and west. with mud huts built on plots in chessboard or star formation, often surrounded by a wall enclosing a courtyard.

Bamako stands where the Dakar-Siger railway meets the river, which is navigable upstream as far as Kouroussa in Guinea but interrupted downstream by the Sotuba rapids. A bridge over the river was completed there in 1960. The town is also on international air routes. (J. D.)

BAMBARA, a Negro people who live in the upper Niger region of the Republic of Mali and speak a language of the Mandingo group. They number somewhat less than 1.000.000 and are sedentary agriculturalists who also own cattle. Those Bambara who are not cultivators are organized into endogamous castes of craftsmen. They live to a great extent intermingled with other tribes, and there is no centralized organization. Small districts made up of a number of villages are each under a dominant family which provides a chief. or *fama.* The succession is patrilineal. passing from senior to junior first through one. then through the next generation. The *fama* has considerable powers derived from his role as a representative of the original inhabitants of the district, and is involved mystically in aericultural operations. The Bambarn are distinguished by their indigenous method of writing and they also have a remarkable system of metaphysics and cosmology, to which French anthropologists have paid much attention. The associated cults. prayers and myths play an important part in the life of the people. Sculpture in wood and metal is well developed and has religious bearings. Mid-20th-century changes include the introduction of peanuts, rice and cotton as cash crops, and migration to larger towns of French origin. *See* also MAXDINGO and AFRICA: *Ethnography (Anthropology), West Africa.*

See H. Paques, *Les Bambara* (1954). (I. C.)

BAMBARA KINGDOMS. The historical Bambara kingdoms of Segu (Segou) and Beledugu, on the upper Niger river in west Africa. were evolved under the direction of ruling lineages of mixed Fulani (*q.v.*) origin during the 17th century. Little is known of the origins of the Bambara but their homeland appears to have been in the country between the towns of Bougouni and Sikasso from which they expanded in a northeasterly direction. By the 12th century they were occupying the banks of the Niger between Bamako and Macina where they constituted the bulk of the peasantry under the then flourishing Mali empire.

Of the Bambara kingdoms Segu, always the more important, attained considerable power under Kaladian Kulubali (reigned *c.* 1652–82) who was able to assert his independence of the Moorish governor of Jenné (Djenné) and is even said to have conducted a successful attack upon Tombouctoo. After a decline the state was virtually recreated by a great warrior chief Mamari Kulubali (reigned *c.* 1712–55). He based an efficient military autocracy upon a large slave army, destroyed Sounsana (near blourdiah), the

capital of Beledugu, and imposed his suzerainty upon the Fulani of Macina. N'Golo Diara (reigned 1766–90). the founder of a new dynasty at Segu, extended his authority over Jenné and Tombouctoo. Meanwhile the Massasi, the defeated ruling family of Beledugu, had withdrawn westward and established a relatively stable kingdom in Kaarta. In 1796 Mungo Park (*q.v.*), the first European to explore the country, found his advance impeded by a war then in progress between Kaarta and Segu.

The Bambara kingdoms were finally overthrown by the *jehad* of the Tukulor Marabout al-Hadj Omar who seized Kaarta in 1854 and Segu in 1861. Occupied by the French during their campaigns on the upper Niger (1876–90), the area was included in French West Africa until 1958 and thereafter formed successively part of the Republic of the Sudan within the Mali federation and part of the Republic of Mali (1960).

The Bambara, who call themselves Banmana, number about 1,000,000. They form an important tribal group in the Republic of Mali and are dominant in the administrative circles of Bamako, Segu and Bougouni. The Bambara language is to be classified as a member of the widespread Mande group and is closely related to Mandinka. The mass of the Bambara agriculturalists have always been strongly attached to their traditional religion, a typically Sudanese animism in which hierarchical associations of initiates play an important role. Some confusion of tribal nomenclature arises from the fact that in local Muslim usage the term Bambara is often used to mean "pagan" and loosely applied to any non-Muslim community.

(D. H. J.)

BAMBERG, a town in the *Land* of Bavaria, Germany, the chief town of the administrative district of upper Franconia, is built on seven hills in the wide valley of the Regnitz river, 2 mi. above its confluence with the Main, and 39 mi. N. of Nürnberg. Bamberg is also an archiepiscopal province. Pop. (1959 est.) 73,547. It is first mentioned in 902, and the Babenberg family derives its name from it. A see was founded there in 1007 by the emperor Henry II, and from the middle of the 13th century the bishops were princes of the empire. In the Domplatz ("Cathedral square") is the medieval Imperial cathedral, containing many notable statues, the tomb of Henry II and his wife Kunigunde and a wooden altar carved by Veit Stoss. The bishop's palace: built between 1571 and 1576, lies to the west of the cathedral and houses a local history museum. To the north is the New palace, built between 1695 and 1704 and containing the splendid apartments of the prince-bishops and a collection of pictures; there is a beautiful rococo rose garden in the courtyard. On the hill above is the former Benedictine abbey with the baroque St. Michaelskirche and in the southern part of the town, on the Kaulberg, is the Carmelite church with Romanesque cloisters and the Gothic upper parish church. On the Altenberg to the southwest of the town is the chapel of the ancient *Schloss* ("castle") which contains the memorials to the counts of Babenberg and some interesting stained glass windows. Opposite the civic theatre is the Ernst Hoffmann house where the poet and composer lived from 1808–13. Industries include textiles and other clothing, shoes, fine porcelain, electrical equipment and beer. There is extensive market gardening.

BAMBERGER, LUDWIG (1823–1899), German economist and publicist and a leading authority on currency matters in Germany, was born of Jewish parents in Mainz on July 22, 1823. The Revolution of 1848 interrupted his studies in French law and he became a republican radical and a newspaper editor. He took part in the republican rising in the Palatinate in 1849, escaped to Switzerland and was in France when condemned to death *in absentia* in 1852. He worked as manager of the Paris branch of a London bank until 1866 when the amnesty enabled him to return to Germany. He had become an admirer of Bismarckian policy and dissociated himself from all democratic groups. In 1868 he was returned by Mainz to the *Zollparlament*. In 1870, at Bismarck's request, he participated in the Franco-German peace negotiations and in 1871 he became a member of the *Reichstag* as a National Liberal.

Bamberger obtained the standardization of the German coinage, the adoption of the gold standard and the establishment of the Reichsbank. An ardent free trader, he refused to follow Bismarck in his policy of protection, state socialism and colonial development after 1878, though he had supported him in his attempts to nationalize the railways and in his outlawing the Socialist party. In 1880 he left the National Liberal party and with his followers formed the so-called *Sezession*.

Thenceforth Bamberger belonged to the circle of the crown prince Frederick and his wife Victoria, being for years the trusted adviser of the princess. He left politics in 1892 but remained the recognized authority on currency, his most important disciple being Karl Helfferich. He died in Berlin on March 14. 1899. A five-volume edition of his works appeared between 1894 and 1898, *Bismarck Posthumus* in 1899, *Ausgewählte Reden und Aufsätze uber Geld- und Bankwesen* in 1900 and his private diary, under the title *Bismarcks grosser* Spiel, in 1932.

Bussmann, "Zwischen Revolution und Reichsbegriindung: die politische Vorstellungswelt von Ludwig Bamberger," *Festschrift fur S. A. Kaehler* (1950).

BAMBOO, any member of the Bambusoideae, a subfamily of the grasses (*q.v.*). The bamboos have age-old connections with fishing. papermaking, landscape gardening, handicrafts, the fine arts and even poetry.

General Importance and Use.—Bamboos minister to many material needs of oriental peoples, having long been creatively exploited in handcrafts. In heavily populated areas, bamboo is the one suitable material that is cheap and plentiful enough to supply the need for economical housing. Besides this, it provides the ram material for hundreds of objects in daily use in the home and in the pursuit of a livelihood. The young shoots are eaten as a vegetable everywhere in the orient; the living plants provide a decorative or protective hedge about homes or villages. Scholars. artists and epicures have celebrated the admirable qualities of bamboo in paintings and verse.

The suitability of bamboo tools and bamboo fibres for making paper was demonstrated many centuries ago by Chinese artisans. Fine papers of many varieties and adaptations can be made from bamboo pulps. *Bambusa vulgaris* and *Melocanna baccifera* rank high in performance, both in the mill and in the field: though most of the pulp manufactured from bamboo comes from other species —principally *Dendrocalamus strictus* and *Bumbusa arundinacea*— because larger and more accessible natural stands of these species are available. Most of the bamboo pulp made in India is used for blending with weak (short-fibred) pulps from other sources to make wrappings and stationery. High-grade bamboo pulps can be used in the pure state for coated or uncoated book and magazine papers. Fibre with a high length-to-diameter ratio gives many bamboo pulps a special versatility.

Modern Uses.—New uses for bamboo products have been developed. and new significance found in old uses. Tabasheer, found within the culm (hollow aerial stem) internodes of many tropical bamboos, consists almost entirely of amorphous silica in a microscopically fine-grained state: it has excellent properties as a catalyst for certain chemical reactions. From the white powder abundantly produced on the outer surface of young culms of a Chinese bamboo, many substances have been isolated, among these being a crystalline compound related in chemical composition to the female sex hormone. Liquid diesel fuel has been prepared from bamboo culms by distillation. The enzymes nuclease and deaminase, in addition to an enzyme that dissolves fibrin and another capable of hydrolizing salicin. have been extracted from bamboo shoots. Glucuronic acid and L-xylose have been isolated in a crystalline state from the juice of bamboo shoots. An aqueous extract of bamboo shoots showed superiority over conventional media for the culture of certain pathogenic bacteria; this extract, when added to tuberculin, increased the intensity of responses to the skin test.

Dried mature bamboo leaves may be used for deodorizing fish oils. and in both the eastern and western hemispheres the foliage of many bamboos has long been used for forage. Improvement of the management of grazing range in the coastal plain of North Carolina. where a native bamboo is the principal source of browse for beef cattle. was the objective of a 14-year project in which three state agencies and three agencies of the U.S. department of agriculture collaborated with fruitful results.

Young shoots of many tropical species of bamboo contain lethal amounts of cyanogens. The digestive processes of herbivores destroy the poison, but in India cattle sometimes die when they are allowed to eat too freely of the toxic young shoots, of which they are very fond. Boiling readily drives off the volatile cyanogens, so there is no risk involved for man in eating the cooked shoots.

Morphological and Growth **Characteristics.**—Bamboos are set off from other grasses by the predominance of certain structural characters, many oi which are considered to be "primitive." The most easily recornizable vegetative features of the bamboos are the woodiness and strong branching of the stems. the stalked leaf blades, and the marked dimorphism between the sheaths clothing young culm shoots and those borne on the leafy twigs. To these may be added such floral characters as well-developed scales at the base of the flower, usually three in number, and a pistil consisting of a more or less well-developed column, bearing one. two or three (rarely more) stigmas. No single character is diagnostic. however, and the boundary between bamboos and other grasses is not sharp.

COURTESY OF U.S. DEPARTMENT OF AGRICULTURE

Moso bamboo (*Phyllostachys pubescens*), a hardy Chinese bamboo introduced at an early date in Japan, where it is cultivated extensively for its edible shoots and its useful culms. It is cultivated in Europe and the United States

Bamboos may be propagated by seed (though because of the rare occurrence of fruit, this method is seldom applicable), by division and by cuttings. They are described as hungry plants which well repay generous treatment. They will flourish in a rich, not too stiff loam, and for the first year or two should be well mulched. They should be sheltered from winds and well watered during the growing period. When being transplanted, the roots should be disturbed as little as possible.

Bamboos range in size from dwarfs a few inches high to giants with stems reaching 8 in. in diameter and 120 ft. in height: some are slender climbers with stems about an inch in diameter that oiten exceed 200 ft. in length. Most bamboos are thornless. but a few kinds have sharp spines consisting of specialized twigs or modified aerial roots.

Range.—Of uneven geographical distribution, bamboos appear more or less prominently in the natural vegetation of many parts of the tropical. subtropical and mild-temperate regions of the world, from sea level to the snow line. They are found in the greatest abundance and variety on the southeastern borders of Asia, from India to China and Japan. No native bamboos have been found in the vast Eurasian continent north and northwest of Tibet and China. The island of Madagascar is particularly rich in endemic species, having more known kinds than all of Africa. Two endemic species have been described from Australia. In the western hemisphere, the natural distribution of bamboos extends from southern United States to the southern end of Argentina and Chile. The geographical distribution has been greatly modified by human intervention, many natural stands having been more or less completely destroyed in clearing land ior agriculture The canebrakes of the United States have become extremely reduced in number and extent *Guadua aculeata,* a giant species once abundant locally in several countries of Central America, has been almost completely eliminated by excessive harvesting of the culms for building purposes. On the other hand, an introduced species, *Bambusa vulgaris,* has been naturalized in large areas on the island of Jamaica, in the wake of a sort of migratory agriculture in which stakes freshly cut from culms of this bamboo, used to support yam vines, take root and produce thriving colonies. *Sinobambusa tootsik,* a Chinese bamboo once highly prized as'a garden ornamental in Honolulu, has come to be regarded as a dangerous weed there, because it escaped from cultivation and now dominates many acres of once pure native vegetation. In Africa. Europe. the British Isles and the United States, introduced bamboos have found an important place as ornamentals and as a source of fishing poles, garden stakes and fencing. and materials for handicrafts and for interior trim and home decoration. Bamboo forests are effective stabilizers of soil and run-off. Many little-kno n but promising exotic species are confined to introductory gardens, where basic studies are performed to determine their usefulness in the local economy as potential sources of food, paper pulp, e t ~ . (F. A. McC.)

COMMON BAMBOO (BAMBUSA VULGARIS) SHOWING THE VEGETATIVE AND FLOWERING PARTS TAKEN FROM THE VISIBLE PART OF THE PLANT (A) Leafy twig, (B) flowering branch, (C) section of young shoot, (D) section of young culm showing internodes, nodes and branch buds

BAMBURGH, a coastal village of Northumberland, Eng., (pop. [1951] 407) lies 50 mi. N. of Newcastle upon Tyne by road. It has coast guard and lifeboat stations and is the head of one of the ancient "shires" of the county. The principal feature is the ancient castle, built above a 150-ft. cliff, formed by the Whin sill which there, as in the Farne Islands to the northeast, outcrops boldly. The fortress was founded in the 6th century by Ida (*q.v.*), the first king of the Bernicians, and is associated with St. Oswald of Northumbria (*q.v.*), "the fair-handed." It remained the principal fortress of the kings of Northumbria and later of the earls of Xorthumberland. Rebuilt after the Conquest, its Norman keep, surrounded by magnificent later walls and buildings, now much altered and restored, still dominates the scene. Defended by Henry VI and his tragic Queen Margaret, it became, heroically, the "last stay oi the Red Rose in the North," and withstood a ruinous siege in 1464. The parish church is dedicated to St. Aidan (*q.v.*), who founded the original building and died in a small shelter attached to its west end in 651. In 1121 it became a monastery of Austin canons. dependent on Nostell priory; part of a fortified tower remains of this establishment. The village also had a leper hospital (1256–1376) and a Dominican priory (1265–1539) of which traces remain. Attempts were made in 1255 and 1332 to build up the village as a borough and considerable privileges were granted by royal patrons; but the lack of any commercial harbour and the ruin caused by Scottish raids and civil war brought these to nothing. The place is now chiefly remembered as the birth and burial place of Grace Darling (*q.v.*) and has a museum, belonging to the Royal National Lifeboat institution, with relics of her famous rescue. (MI. G. C.)

BAMBUTI, the commonest name for the 35,000 pygmies of the Ituri forest, in the northeast Republic of the Congo (formerly the Belgian Congo). Also known as Twides, Aka (northern Ituri) or Efe (eastern), they are the purest race of pygmies in Africa, averaging under 4 ft. 6 in. Much lighter in colour than their Bantu and Sudanic neighbours, they also differ in blood type and other

physical characteristics, and are probably the earliest inhabitants of the area. Various pygmoid groups are found in other parts of the equatorial forests (see BATWA).

The Bambuti are nomadic hunters and gatherers living in small bands that vary in composition and size throughout the year, but which are generally patrilineal groups of from 10 to 25 individual families. The tropical rain forest provides all their basic needs; food. fresh water from innumerable streams and springs, firewood and clothing. Huts are made simply by forming a beehive-shaped frame of sticks covered with phrynium leaves. A camp is lived in for about a month and then abandoned.

Technology is limited to the necessities of a hunting and gathering economy. The Efe hunt with bow and arrow; elsewhere nets and spears are used.

There are no chiefs, not even any formal councils of elders; problems and disputes are settled by general discussion. The Bambuti believe in a benevolent forest deity, and important occasions, including the maturity of boys and girls, marriage and death, are marked by special songs designed "to rejoice the forest." The music is complex in rhythm and harmony, but visual art is virtually nonexistent. Music, dance and mime provide a means of reinforcing accepted values and form the basis of religious expression.

Marriage is by sister exchange. Few pygmies are polygynous, and family bonds are strong and lasting. The Bambuti show little concern with afterlife; the dead are buried in or near their hut and the camp is then abandoned.

There is a loose exchange relationship with neighbouring Bantu tribes, and an apparent adoption of some of their customs. Such acculturation is superficial, however, in spite of the use of a common language.

Archaeological evidence is lacking, but early Egyptian records show that the Bambuti were living in the same area 4,500 years ago.

BAMFORD, SAMUEL (1788–1872), English radical reformer. who was the author of several widely popular poems (principally in the Lancashire dialect) showing sympathy with the condition of the working class. was born at Miston, near Middleton, Lancashire, on Feb. 28, 1788. He became a working weaver and earned great respect in northern radical circles as a reformer; but he was moderate in policy and jealous of rivals. He formed a Hampden club in Middleton in 1817 and met William Cobbett, Henry Hunt, William Benbow and Sir Francis Burdett. The same year, although he was an opponent of violence, he was arrested and imprisoned. In 1819 he was arrested again as a result of attending and speaking at the Manchester meeting known as Peterloo (*q.v.*) and was sentenced to 12 months imprisonment. Bamford lost some of his popularity when he left his trade and became a journalist in London (c. 1826). He was also disliked for his work as a special constable during the Chartist riots. But he continued to press for reform of working-class conditions, on which his Passages *in the Life* of *a Radicul* (1840–44) and Early Days (1839) are very illuminating, although marred sometimes by personal prejudices. He died at Harpurhey. Lancashire, on April 13, 1872, and was accorded a public funeral, attended by thousands. (A. BRI.)

BAMIAN, a town in the Parwan province of Afghanistan. The town lies about 80 mi. W.N.W. of Kabul in a valley of the Hazara country near the main road link between Kabul and the northern provinces of Mazar-i-Sharif, Kataghan. Badakhshan and Maimana. The valley is that of the Bamian river, lower known as Surkhab. which flows northward via Runduz toward the Amu-Darya (Oxus). It lies north of the main ranges of the Koh-i-Baba, the western extensions of the Hindu Kush. The main road connection with Kabul is via the Shibar pass (9.800 ft.) and the town of Bamian is at 8,480 ft. Pop. (1960 est.) 10,000. It has a government hotel.

The early history of Bamian is obscure. It first appears in Chinese sources of the 6th century A.D., and was visited by the Chinese pilgrim Hsiian Tsang (*q.v.*) in the 7th century. In those days it was a great centre of Buddhism with more than 1,000 monks. The language, script and coinage differed but little from those of Turkistan. Then as now its chief glory lay in the hundreds of man-made caves cut into the cliffs north of the town, and the two great Buddha figures which have since excited the wonder of both Arab and European travelers. They too are carved from the living rock and finished with fine plaster. They probably date from the 6th–7th centuries, although formerly they were thought to be somewhat earlier. The larger figure is 175 ft. high, the lesser is 120 ft. In style they recall the Gandharan school of northwest India and north Indian work of the 5th–6th centuries generally. When Hsüan Tsang saw them they were glistening with gold and jewels. The caves are of various forms and many bear traces of fine fresco painting which links them with contemporary caves in Sinkiang. The modern town lies below the caves. To the south is the Muslim fortress of Shahr-i-Gulgula, largely dating from the 9th–12th centuries and destroyed by the Mongols. About 11 mi. E. of Bamian is the pre-Muslim fort of Shahr-i-Zohak. In the 7th century Bamian was ruled by princes probably of Hephthalite extraction (see HEPHTHALITES) but subject to the western Turks. Its princes first accepted Islam in the 8th century. It was invaded by the Saffarid ruler Yakub ibn Layth in 871, and its Buddhist idols were carried off to Baghdad. Later Bamian became subject to the Ghaznevids (*see* GHAZNI), and in the 12th century a branch of the Ghorid dynasty ruled there (see GHOR). In 1221 the town was sacked by Genghis (Jenghiz) Khan (*q.v.*) and its inhabitants exterminated. Since that time it has never regained its former glory.

BAMILEKE, a name of uncertain origin for 90 west African peoples in the Bamileke region of the Republic of Cameroun. who share a common culture, which resembles that of the Tikar people. Their origin is uncertain, but it has been suggested that under pressure from the Fulani in the 17th century they moved southward in a series of migrations from the region now occupied by the Tikar proper. They number 500,000, of whom 455,000 inhabit the small, independent kingdoms within the Bamileke region. They do not refer to themselves as Bamileke, but use the names of the 90 kingdoms to which they belong.

Each of these states was ruled by a king (Fon, *Fong*, Fo, Foeh) whose position was hereditary within a localized patrilineal lineage. At least in Bafoussam subdivision, he was assisted by his queen mother (*Mafo*).

The Bamileke practise sedentary farming, with fallowing. Their staple crops are maize. taro and peanuts. Men clear the fields, build houses and engage in crafts, and women do most of the farming. They have a few livestock! but these and hunting play minor roles in their economy.

Their square houses have conical thatched roofs surmounting latticework walls made of raffia poles with the interstices filled with mud. Chiefs' houses are decorated with carved door frames and house posts. Brass casting is not reported, but in other respects their art resembles that of Tikar in content as well as style.

Ancestor worship is the dominant form of religion. The lineage head preserves the ancestral skulls and offers sacrifices to them. Charms and medicines are prepared by doctors *(nganga)* who also practise divination by interpreting the earth spider's manipulation of marked blades of grass. Some Bamileke have been converted to Islam, mainly in the north, and others to Christianity.

The Bamileke are enterprising people who have played an important role in the econoinic development of Cameroun. Since 1910

an estimated 45.000 have left their homes and settled as farm labourers, farmers and traders in areas toward the coast. and among the Bamum, Nyokon and Banen to the east and southeast.

See R. LeCoq, *Les Bamileke* (1953); *F.* C. Egerton, *African Majesty* (1939). (WI. .

BAMPTON, JOHN (1690?–1751), English divine who gave his name to one of Protestant Christendom's most distinguished lectureships, was educated at Trinity college, Oxford, M.A. in 1712 and became canon of Salisbury. He died on June 2, 1751. His will directs that eight lectures shall be delivered annually at Oxford in the university church on Sunday mornings in full term. "between the commencement of the last month in Lent term and the end of the third week in Act term." Since 1895 the Bampton lectures have been given every second year. Their importance may be gauged by the amount of controversy that has arisen over the Bampton lectures of various theologians—*e.g.,* Charles Gore's (*q.v.*) of 1891 on the incarnation, William R. Inge's of 1899 on mysticism. Hastings Rashdall's of 1919 on the atonement and R. H. Lightfoot's of 1934 on History and Interpretation in the Gospels. The "Sarum lectures" have been established to enable other than Anglican theologians to lecture; these are also supported by the Bampton fund. (J. J. PN.)

BAMUM (known also as **MUM** or MOM), a west African people numbering 75,000 who claim a common origin with the Tikar. Their kingdom. with its capital at Foumban in Cameroun, lies between the Bamileke on the south, the Tikar on the east and the many Tikar peoples of the Bamenda province on the west. It is ruled by the king (*Mfon*), whose position is hereditary within one of the exogamous patrilineal lineages, with the help of his queen mother (*Na*).

The first *Mfon*, Nchare, and his followers are believed to have come from Tikar territory over 250 years ago. Settling among the Bamileke and other Tikar. Nchare proclaimed himself king and established his palace at Foumban. The 11th *Mfon,* Mbuembue, was the first to enlarge the kingdom and, following an attack by the Fulani at the beginning of the 19th century. he fortified Foumban with a surrounding wall and ditch. The 17th *Mfon,* Njoya (1895–1923). became the most celebrated.

Familiar with writing in Arabic script from contact with Fulani and Hausa, Njoya invented a system of writing with 510 pictographic characters about 1895. This he revised six times, the seventh system being a syllabary of 73 characters plus 10 numerals. With the help of his scribes Njoya prepared a book on the history and customs of the Bamum which has been published in a French translation, a map of his country, a religious book and a book on medicine and local pharmacopoeia. In 1912 he established the first of 47 schools to teach reading and writing in his sixth script and in 1913 he commissioned a member of his court to prepare a printing press for it. In 1920, annoyed by his troubles with the French administration. which deposed him in 1923, Njoya destroyed the type, which had been cast by the lost-wax method. and closed his schools. Njoya was converted to Islam in 1918, and it is estimated that more than half of the Bamum are Muslims.

Njoya built a beautiful new palace. established what was really a museum. and was a patron of beadworkers. brass casters. weavers, dyers and other craftsmen. His palace contained 300 looms and six dye pits with different colours, some of which Njoya himself discovered. The arts for which the Tikar in general are noted flourished under his royal patronage.

Men do embroidery, weaving, leatherwork, wood carving, ivory carving, metalwork and blacksmithing, and women make pottery. Both men and women work the land. The Bamum are sedentary farmers who do some fishing but little hunting. Their principal crops are maize, millet, cassava and sweet potatoes.

They believe in a supreme god (*Njinyi, Nnui* or *Yorubang*) who creates children. and they practise ancestor worship. Bamum diviners interpret the manipulation of marked leaves by the earth spider (*ngame*).

BAN, a title formerly used in Hungary to denote the governors of military districts known as banats and later used to designate the local representative of the Hungarian king in outlying possessions; *e.g.,* Bosnia (see BOSNIA-HERCEGOVINA) and Croatia (*q.v.*). (See also BANAT for the province specifically so named.) Ban is a Persian word meaning "lord" or "master" and was first introduced into Europe by the Avars (*q.v.*). The office and title were revived in the kingdom of Yugoslavia in Oct. 1929 when the country was divided in *banovine,* or provinces, but the German-Italian invasion of April 1941 did away with them.

BANANA. One of the world's most important fruits, the banana is consumed extensively throughout the tropics, where it is grown, and in the temperate zone, where it is popular because of its flavour, its food value and its availability at all times of the year.

Botany.—The plant is a gigantic herb, springing from an underground stem, or rhizome. to form a false trunk 10 to 20 ft. high, composed of the leaf sheaths and crowned with a rosette of 10 to 20 oblong to elliptic leaves which sometimes attain a length of 10 to 12 ft. and a breadth of 2 ft. The large flower spike, carrying numerous yellowish flowers in half-whorllike clusters, emerges at the top of the false trunk and bends downward to become the bunch of 50 to 150 individual fruits, or fingers. which are grouped in clusters, or hands, of 10 to 20. Once the plants have fruited they die. and are replaced by others (suckers) which arise from the underground stem. The life of one stool or clump thus continues for many years.

Bananas belong to the genus *Musa,* of the family Musaceae (*q.v.*), but the botany of the cultivated forms is confused. Tall-growing varieties of which the fruit is eaten uncooked are commonly listed as forms of *M. sapientum;* the dwarf or Cavendish variety as *M. cavendishii;* and the plantains or forms eaten only when cooked as *M. paradisiaca.* However, *M. paradisiaca* is viewed by some botanists as a subspecies of M. *sapientum,* while others hold the opposite to be the case. There has further been a tendency on the part of modern investigators to consider that many commercial bananas. including the all-important Gros Rlichel. are not derived from either of these. but wholly or in part from the species *M. acuminata.*

BY COURTESY OF UNITED FRUIT CO.

BANANAS (VARIETY GROS MICHEL) READY FOR HARVEST

There are 100 or more varieties of the banana in cultivation; confusion exists because of diverse names applied to one and the same variety in different parts of the world. As regards the origin and early history of this fruit. Alphonse de Candolle wrote (*Origin of Cultivated Plants* [1883]):

> The antiquity and wild character of the banana in Asia are incontestable facts. There are several Sanskrit names. The Greeks, Latins, and Arabs have mentioned it as a remarkable iruit tree. Pliny speaks of it distinctly. He says the Greeks of the expedition of Alexander saw it in India and he quotes the name *pala* which still persists in Malabar. Sages reposed beneath its shade and ate of its fruit. Hence the botanical name *Musa sapientum.* Musa is from the Arabic *mouz* or *mawoz,* which we find as early as the 13th century in Eba Baithar. . . . There is an immense number of varieties of the banana in the south of Asia, both on the islands and on the continent; the cultivation of these varieties dates in India. in China, and in the Archipelago from an epoch impossible to realize; it even spread formerly into the Islands of the Pacific and to the west coast of Africa; lastly, the varieties bore distinct names in the most separate Asiatic languages, such as Chinese, Sanskrit, anti Malay. All this indicates great antiquity of culture, consequently a primitive existence in Asia, and a diffusion contemporary with or even anterior to that of the human race.

Cultivation.— Shortly after the discovery of America, the banana (an African name) was brought from the Canary Islands to the new world. where it was first established in Hispaniola, soon spreading to other islands and the mainland. Its cultiva-

tion increased until it became one of the staple foodstuffs in many regions; then in the 19th century it began to appear in the markets of the United States. Between 1870 and 1880 the present-day banana industry began to develop, mainly through the efforts of two men, Capt. Lorenzo D. Baker and Minor C. Keith.

Bananas thrive naturally on deep, loose, well-drained soils in humid tropical climates, but are grown successfully under irrigation in semiarid regions such as the south side of Jamaica. For the export trade they cannot profitably be cultivated where temperatures often fall below 50° F.; such temperatures result in "chilling" of the fruit, preventing its proper ripening; but for home use they are grown successfully in cooler regions, including the southernmost part of Florida. Suckers and divisions of the pseudobulb are used as planting material; the first crop ripens within 10 to 15 months. and thereafter production is more or less continuous. Frequent pruning is required to remove surplus growth and prevent crowding in the clump, or mat. Mechanical tillage is customary in semiarid regions. but in many countries this is not practised; weedy growth is controlled instead by the shade of the banana plants and through occasional cleaning with the machete. Nitrogenous fertilizers are often used to increase quantity and quality of production.

A good commercial bunch of bananas consists of nine hands or more and weighs from 50 to 125 lb. Three hundred or more such bunches may be produced annually on an acre of land, if the soil is good and cultural attention adequate. When ripe, the fruit contains as much as 22% of carbohydrate. mainly sugar; it is high in ash and a good source of several vitamins. Thus it is an unusually valuable source of human food.

Cooking varieties (plantains). which differ from other bananas in that the ripe fruit is starchy rather than sweet, are extensively cultivated and used in tropical regions, but rarely appear in the markets of the temperate zone.

Interesting features of the banana industry are the sudden and great changes that take place in production as the result of the opening up of new regions. the havoc wrought by floods and windstorms (to which the plant is peculiarly susceptible! and the ravages of Panama disease and of a few other pests.

The industry in the Caribbean is based largely on Gros Michel, which in terms of quantity and cash value of the crop is one of the world's most important fruit varieties. Its origin is almost certainly Asian; it is saicl to have been brought to the attention of horticulturists in tropical America by Jean Pouyat of Martinique. Jamaica was the first country to undertake its cultivation on an extensive scale; Costa Rica and Panamá were not far behind. In the Canary Islands. on the west coast of Africa and in Brazil the dwarf or Cavendish variety has been of greater commercial importance.

Beginning about 1925, great changes began to take place in banana agriculture, or horticulture as it should more properly be called, through the application of modern cultural practices in the Caribbean area. Careful examination of lands to eliminate unsuitable soils before planting, efficient drainage practices. the selection of proper planting material, overhead irrigation and. especially, the use of fungicides to control the Sigatoka disease (*Cercospora musae*) and other developments put the industry on an intensive basis.

The so-called Panama disease, caused by a fungus of the genus *Fusarium* (which lives in the soil), made necessary the abandonment of large areas from time to time. so far as the cultivation of the Gros Michel banana is concerned. This disease, however, does not affect the value of the land for the production of other crops.

Production.——After mid-20th century annual world exports of bananas were usually in excess of 3,000.000 tons. In 1958. for example, about 3,900.000 tons were exported. While the United States generally imports more bananas than any other country, large quantities also go to Great Britain and continental Europe, especially from the West Indies and the west coast of Africa.

Even for local consumption bananas are not left on the plant until fully ripe. For exportation. the degree of maturity they are allowed to attain before harvesting depends upon distance from market and type of transportation.

Specially designed refrigerated ships operate between numerous tropical countries and centres of consumption in North America and Europe.

Chief sources of production in Middle America include Costa Rica, Honduras, Guatemala. Mexico. Panamá and the Canal Zone, Dominican Republic, Guadeloupe, Jamaica and Martinique; in South America: Brazil. Colombia and Ecuador; in Africa: Canary Islands, Eritrea, the Cameroons region, Guinea and Nigeria and in Asia. Formosa. (W. Po.)

BANAS, the name of four rivers in India: (1) a river of Rajasthan which rises in the Aravalli range about 25 mi. N.W. of Udaipur and after a 330-mi. eastward course flows into the Chambal and so into the Jumna and eventually the Ganges; (2) another river, sometimes called the West Banas, rising in the Aravallis about 35 mi. W.N.W. of Udaipur on the opposite side of the watershed to (1) and flowing southwest across northern Bombay for 170 mi. to the Little Runn of Cutch; (3) a small river in Shahabad district, Bihar, forming the drainage channel between the Arrah canal and the Son canals system and finally falling into the Ganginadi; (4) a small river in Baghelkhancl rising in northwestern Surguja district, Madhya Pradesh, and flowing northward to the Son, 15 mi. S.E. of Rewa city. (L. D. S.)

BANASKANTHA, the northernmost district of Gujarat state, India, is named after the Banas river which crosses it. Following Indian independence the district was formed from petty Muslim and Rajput principalities and *jagirs* ("feudal estates"). After boundary adjustments its area is 4.039 sq.mi.; pop. (1961) 995,980. Extending from the Runn of Cutch eastward to the Aravalli range, it is a sandy plain on the south of the Thar desert. One-sixth is barren, but parts are afforested and there are good pastures: millets and wheat are staple crops; maize, potatoes. timber! wool and handwoven cloth are produced for export from the district. There are also quarries for building stone. Communications are in general restricted to unimproved roads: but the district headquarters, Palanpur, the market town of Deesa (pop., 1951, 10.616) and a few other townships are on the Western railway. Palanpur (pop. 22,629) is 80 mi. N.N.W. of Ahmedabad. It is an ancient settlement, mentioned by Gujarat chroniclers as the home of Vanaraja, founder (A.D. 746) of the Chavada dynasty. (V. A. M. J.)

BANAT, a region of Europe lying across the modern frontiers of Hungary, Rumania and Yugoslavia, being bounded by Transylvania and Walachia in the east, by the Tisa river in the west, by the Mureş river in the north and by the Danube in the south. The name means frontier province or province governed by a ban (*q.v.*).

Largely an area of rolling plains, Banat is mountainous in the east with summits reaching from 4.000 to 7,500 ft. Its main rivers are the Timiş (Tamis), the Bega (Begej), the Caraş (Karas) and the Nera. Cattle, horses, sheep and pigs are reared. The main crops are wheat, maize, sugar beet and tobacco. There are also flourishing vineyards and some mineral deposits (coal at Anina, iron ore. zinc and petroleum at Kikinda). The main railway line Belgrade-Timişoara-Bucharest crosses the province.

Banat has been inhabited since prehistoric times and there are Paleolithic remains near Vrsac. The most important discoveries of the Neolithic period are at Starcevo. Srpski Krstur, Novi Knezevac and Crna Bara. Cemeteries with urns have been discovered at Vrsac and Ilandza. There are findings of the Bronze Age at Vatin and Dubovac (Dubova). Under the Romans Banat was either in Moesia Superior or in Dacia. Later the Goths invaded the province and after them there came the Gepidae, the Huns and the Avars. The Slavs began to establish themselves there in the 5th century.

Banat was occupied by the Magyars at the end of the 9th century. In 1233 the Hungarian king Andrew II created the Banat of Severin (Terra de Zevrino) and entrusted its defense to the knights of the Order of St. John of Jerusalem. After the battle of Kosovo (1389) and especially after the occupation of Serbia by the Turks (1459) a large number of Serbs immigrated into Banat. At the beginning of the 16th century four Serb bishoprics were

organized in Banat, and the Serb monasteries Bezdin, Mesic and Hodos were built.

Led by the grand vizier Mohammed Pasha Sokollu (Sokolovic), the Turks conquered the greater part of Banat in autumn 1551. The following summer they took Timişoara (Temesvár), which became the seat of the *il.* In 1594 the Serbs revolted against the Turks, but were suppressed with much bloodshed.

By the peace of Passarowitz (1718) Austria gained Banat and formed the Temeser Banat or Banat of Temesvár under a *Generalkommandant* with his seat at Timişoara. Later the military government in northern Banat was replaced by a civil administration. Maria Theresa and Joseph II brought colonists from the Rhineland, from Lorraine and from Luxembourg into Banat. In 1779 Banat was incorporated into Hungary. After the Hungarian revolution of 1848 Banat was in 1849 detached from Hungary and joined with Srem and Backa to form a "Serbian Vojvodina" (still under Austria), but this unit was abolished in 1860, and under the .lustra-Hungarian compromise of 1867 Banat was again incorporated into Hungary. , By this time the population of the province had become ethnically mixed. In 1919 its estimated total of 1,582,000 was 40% Rumanian, 20% Serb, 23% German and 14% Hungarian.

At the Paris peace conference of 1919, Rumania claimed the whole Banat, as promised to Rumania by the Allies during World War I in the secret treaty of Aug. 17, 1916. This clashed with Serbian ethnic and historic aspirations, and the treaty of Trianon (June 4. 1920) between Hungary and the Allies divided Banat into three unequal parts. Rumania obtained the eastern area (7,113 sq. mi.); the kingdom of Serbs, Croats and Slovenes, later to be called Yugoslavia, obtained the western part (3,591 sq.mi.); and the district of Szeged was left to Hungary.

(M. A. P.)

BANBRIDGE, an urban district and market town on the Bann river! County Down, N.Ire., 24 mi. S.W. of Belfast by road. Pop. (1961) 6,115. Area 1.2 sq.mi. To flatten the summit of a steep hill in the main street, the roadway was brought through a cutting 200 yd. long and 15 ft. deep, the terraces on either side being connected by a bridge. All branches of the linen industry are carried on in Banbridge; there is also a considerable manufacture of lighter types of footwear. Banbridge serves as market centre for a wide area of agricultural countryside. (Hu. S.)

BANBURY, a municipal borough in Oxfordshire, Eng.. lies on the river Cherwell, 23 mi. N. of Oxford by road or rail. Pop. (1961) 20,996. Area 8 sq.mi. Banbury is the centre of a rich agricultural district and its cattle market is one of the biggest in England, about 420.000 animals being sold annually. Besides a large aluminum works there are factories for agricultural machinery, electrical apparatus, furniture, fabricated and constructional steelwork and surgical supports. A big new industrial estate was developed during the early 1960s. Commerce markets are still held biweekly in the open, and a fair in October. For centuries Banbury was noted for its ale, cheese and cakes. Although beer is still brewed locally, it is the Banbury cakes—a spiced currant pastry—for which the town is chiefly noted. Part of the original cake shop dates from the 16th century and there are some fine timbered and stone houses. The present church replaces a magnificent Gothic one destroyed as unsafe in 1790.

A great battle is said to have been fought at Banbury in 556 between Cynric and Ceawlin and the Britons. Banbury was in the hands of the bishop of Dorchester for about four centuries and then belonged to the bishop of Lincoln from 1073 until the Reformation. Its first charter was granted in 1554 and the offices of high steward and recorder established by the charter of 1608 are still in existence. The original Banbury cross, celebrated in the nursery rhyme beginning "Ride a cockhorse to Banbury cross," was destroyed in 1602 by the zealous Puritans who were frequently satirized by contemporary dramatists, but was replaced in 1859. Banhury castle, built in 1125, was twice besieged by parliamentarians during the Civil War and afterward demolished. Broughton castle (14th–16th century), 2½ mi. S.W., the present seat of Lord Saye and Sele, was used by the parliamentary party, and the battle of Edgehill (1642) was fought 8 mi. N.W. of Banbury. Sulgrave manor, the early home of George Washington's ancestors, lies 8 mi. N.E. (see SULGRAVE MANOR). (F. G. E. B.)

BANCA D'ITALIA, the sole bank of issue of the republic of Italy. It was established in 1893 as a joint-stock company by the merging of two Tuscan banks with the National Bank of the Kingdom. The Banca d'Italia became the sole note-issuing bank in 1926, after the right of issue had been taken from the Bank of Naples (Banco di Napoli) and the Bank of Sicily (Banco di Sicilia). In 1936 it was made a public credit institution.

The statute of the bank is approved by decree of the president of the republic. Its capital may be held only by credit and by insurance bodies. Its powers are exercised (1) by an assembly of the shareholders; (2) by its supreme council; (3) by a committee of this council; and (4) by the governor, the director-general and the vice-director-general. Supervision of the bank's work lies with the treasury, in conjunction with a commission of supervision comprising members of parliament and government officials under the presidency of the head of the treasury.

The bank's business is principally with discounting bills up to four months (for the account only of credit concerns) and with advances up to six months. It accepts interest-free deposits from private persons and interest-bearing deposits from the credit and insurance institutions. The rate of interest is fixed by ministerial decree.

Until 1928 there was a ceiling for the issue of bank notes and a compulsory minimum for the reserve in gold or the equivalent amounting to 40% of the circulation; but in that year the limit on the issue was abolished, and in 1935 the reserve of 40% was suspended. The note circulation is therefore not limited, nor is it linked to a definite reserve; but the quantity, the design, the denominations and the particular features of the notes to be printed are laid down by ministerial decree. In Jan. 1960, the money possessed by the Banca d'Italia and estimated on the same basis as 1936 was revalued at the new value of the lira; the resulting balance of 627,000,000,000 lire was, as on preceding occasions, assigned to the state treasury and allotted to the paying-off of part of its debt to the Banca d'Italia. For the lira, see ITALY: *Finance.* In order to regulate the volume of credit, the bank exercises control over the work of credit institutions and authorizes the issue of negotiable securities, under the direction of an interministerial committee for credit and saving. Authorization must be obtained from the bank before credit institutions can be established and before they can open branches; permission must also be obtained if loans are made exceeding one-fifth of the resources of the banks concerned. Their accounts are subject to scrutiny, and periodical inspections are made. The credit institutions (other than the savings banks and the rural banks) must place reserves with the Banca d'Italia either in treasury bonds or in cash amounting to 25% of their deposits. Beginning in Sept. 1958, even the savings banks were obliged to form a reserve equal to 20% of the increments from their deposits. Interest is paid on these reserves. The chief instruments of enforcement of the credit policy of the bank are: the compulsory reserves brought into force in Sept. 1947; the submission to the bank of applications for authority to grant credits for all amounts in excess of a prescribed figure; and the power to accept or refuse bills for rediscount, and advances.

As far as the market is concerned, credit institutions must obtain the bank's authorization before increasing their capital. Its permission must also be obtained by the special credit bodies before issuing medium- and long-term bonds (except those secured against land). Also, all issues of negotiable securities, whether to be placed with credit concerns or to be quoted on the stock exchange, require the bank's authorization. The authority of the Banca d'Italia is separate from that of the treasury for the floating of companies, for the increase of cash capital and for the issue of debentures whenever the amount exceeds 500,000,000 lire.

The control of exchange is effected through the banks by the Italian Exchange Control bureau, over which the governor of the Banca d'Italia presides. The bank not only endowed this bureau

with funds but also provides it with the means for its operations.

Finally, the bank administers the clearinghouses and acts as treasurer for the account of the state. In this latter capacity it may make advances to the treasury of up to 15% of the expenditure provided for in the budget. (LA. R.)

BANCHIERI, ADRIANO (1567–1634), Italian composer of much sacred and secular music, most famous for his madrigal-comedies. He was also an organist, musical theorist and poet. Born at Bologna in 1567, he spent almost his whole life at the monastery of S. Michele in Bosco near Bologna, becoming abbot in 1620. He was also prominent in Bolognese academies. His numerous madrigal-comedies are second in importance only to those of Orazio Vecchi. *Il festino nella sera del giovedì grasso acanti cena* (1608; mod. Eng. ed.. *The Animals Improvise Counterpoint,* 1937) contains some delightful characterization. Although he used the *basso continuo (see* THOROUGH BASS). the style of his music is on the whole backward looking. He died at Bologna in 1634. (N. Fo.)

BANCROFT, GEORGE (1800–1891), **U.S.** historian, politician and diplomat who wrote a ten-volume *History of tlze United States,* was born in Worcester. Mass.. on Oct. 3, 1800. His father, Aaron Bancroft, was a distinguished Congregational clergyman, author of a *Life of Washington* and one of the founders of the American Unitarian association. George Bancroft was educated at Phillips Exeter academy, Exeter, N.H., and at Harvard university, where he prepared for the ministry. In 1818 he gained a Harvard scholarship to the universities of Gottingen, Heidelberg and Berlin in Germany. He received the Ph.D. degree in history from Gottingen in 1820, and on his return to Harvard in 1822 became tutor in Greek. In 1823 he joined Joseph Green Cogswell in establishing Round Hill school for boys at Northampton, Mass. At Round Hill he became increasingly interested in German poetry and philosophy, writing articles and translations for the *North American Review* and the *Anterican Quarterly Review.*

Bancroft severed connections with Round Hill in 1831. Although a member of a Federalist-Whig family, he began his political activities in the Workingmen's and Anti-Masonic parties in Xlassachusetts, running unsuccessfully in 1834 as Anti-Masonic candidate for general court. After this he joined the Democratic party and became an influential figure in its inner circles. After Martin Van Buren's election as president of the U.S in 1836, Bancroft was appointed collector of the port of Boston. an important patronage post. Two of his appointees were Orestes Brownson and Nathaniel Hawthorne. He lost his collectorship in the Whig victory of 1840 and with it much of his influence in the Massachusetts Democratic party. In 1845, with the assistance of Van Buren, he entered Polk's cabinet as secretary of the navy, serving until late 1846. During his brief period in the cabinet he favoured the extension of the Naval academy at Annapolis, Md.; issued the directive that led to the occupation of California; and as acting secretary of war, sent Gen. Zachary Taylor into the disputed territory between Texas and Mexico, thus precipitating the Mexican War. Bancroft in 1846 asked for and received appointment as minister to England, where he remained until 1849.

On his return to the U.S. Bancroft took up residence in New York city and resumed work on his *History oj tlze United States,* the first volume of which had. appeared in 1834. the second in 1837 and the third in 1840. In evolving his theory of history, Bancroft derived much from the nationalistic German school of historians. In his view the office of the historian was twofold: first, to examine the past as a record of man's attempts to perceive and act upon divinely inspired concepts of truth, morality, beauty, justice and freedom; second, to find in the past evidences of man's progress, and to recognize and explain the significance of God's plan for the liberation of the human race. He believed the political and social system of the U.S. represented the highest point yet reached in mankind's quest for the perfect state. Bancroft placed great emphasis on the use of original sources? building a vast personal collection of documents and hiring copyists to transcribe materials from archives in Great Britain, France. Spain and the Netherlands. Only in his failure to make full use of newspapers, periodicals and journals did he fail to approximate modern research methods.

Though one critic complained that the early volumes of the history "voted for Jackson." they sold well and Bancroft's reputation as the leading U.S. historian was firmly established by 1850. Volumes iv and v appeared in 1852, vi in 1854 and vii and viii in 1858 and 1860, carrying his narrative to 1776. With the rise of the slavery and secession controversy and the outbreak of the American Civil War, he gave less time to historical writing and more to support of the Republican party and Lincoln, although he never entered actively into the antislavery or other reform movements. During the war he spoke and wrote for the Union cause, and published volume ix of the history in 1866. Bancroft supported Andrew Johnson, and was appointed minister to Prussia in 1867. During the Franco-German War he followed a consistently pro-German policy, and in 1871, on its conclusion, became minister to the German empire. He was responsible for the successful settlement of the Oregon boundary dispute between the U.S. and Great Britain, which was arbitrated before the emperor of Germany in 1872, and he negotiated important naturalization and trade treaties with Germany.

The tenth and final volume of the history, covering the last year of the American Revolution, appeared shortly after his return to the United States in 1874, and Bancroft immediately began preparing a revision for the centenary edition, which appeared in 1876. By removing digressions and pruning his style. he reduced the original ten volumes to six. although his approach to American history remained unchanged. A two-volume study, *The History of the Formation of the Federal Constitution,* was published in 1882. and in 1886 he combined it with the centenary edition to form the author's last revision in six volumes. He also published a pamphlet on the paper money controversy in congress in 1884 and a life of Martin Van Buren in 1889, and he contributed several historical sketches to the *New York Ledger.* He died in Washington. D.C.. on Jan. 17. 1891.

Though Bancroft's career as politician and diplomat deserves recognition, it was as the pioneer historian of the *C.S.* that he wished to be judged. With a few exceptions, historians before him had been collectors or annalists, concerned chiefly with state or Revolutionary War histories. Bancroft was the first to plan a comprehensive study of C.S. history from its beginning. a tack that eventually required 40 years to complete. He approached history as a philosopher. molding it to fit his preconceived thesis, which rested on a deeply held. intuitive faith in mankind's perfectibility. He neglected economic and social factors in historical development in favour of political, military and religious viewpoints. However, he was one of the first to recognize the importance of the colonial period, of foreign relations and of the frontier as factors in C.S. history.

BANCROFT, HUBERT HOWE (1832–1918), U.S. historian of western North America, was born in Granville. 0.. May 5, 1832. He arrived in California in 1852 and in 1856 opened a bookstore in San Francisco which became the largest bookselling and publishing house west of Chicago. In 1859 he began to collect California materials, soon expanding his interest to include all of western America from Panamá to Alaska. This was the nucleus of the 60.000 volume library he sold and in part gave to the University of California in 1905.

In the 1860s utilizing his own holdings, he began a comprehensive and exhaustive history of the area of his collecting. His *Native Races of the Pacific States* (5 vol., 1874–75) was followed by 34 volumes of history (1882–90). including *Chronicles of the Builders* (8 vol., 1891–92), *Book of the Fair* (5 vol., 1893), *Book of Wealth* (10 vol., 1896–1908), and half a dozen miscellaneous volumes (1887–1917). Acting as his own publisher he sold his books by subscription. marketing about 250.000.

For his ambitious task as historian Bancroft employed numerous assistants, all but one of them as inexperienced as he was in research and writing. He put them to work indexing his library, taking notes! writing drafts, and whenever possible producing copy

for the printer. His own writing, revising and supervising gave the volumes essential unity of design and execution. But he made the great mistake of not explicitly identifying his helpers and their contributions. His works took and held rank as the basic reference on the history of the United States and his library as its principal research centre. He died in Walnut Creek, Calif., March 2, 1918.

See his own *Literary Industries* (1890) and *Retrospection, Political and Personal* (1912); W. A. Morris, "The Origin and Authorship of the Bancroft Pacific States Publications," *Oregon Historical Quarterly,* vol. iv, pp. 287–364 (1903); John W. Caughey, "Hubert Howe Bancroft," *American Historical Review,* 1:461–470 (1945), *Hubert Howe Bancroft, Historian of the West* (1946). (J. W. CA.)

BANCROFT, RICHARD (1544–1610), archbishop of Canterbury, noted for his anti-Puritan zeal, was born in Sept. 1544 at Farnworth, Lancashire, and educated at Christ's college, Cambridge. He received important preferments—his great-uncle was archbishop of Dublin—and was chaplain successively to the vice-chamberlain Christopher Hatton and Archbishop Whitgift. He was appointed in 1587 as a member of the high commission, and among the more noteworthy cases which he directed were proceedings against "Martin Marprelate" *(see* MARPRELATE CONTROVERSY), Thomas Cartwright and his friends and John Penry. Bancroft's scathing sermon against the Puritans preached at Paul's Cross on Feb. 9, 1589, brought him into prominence. In June 1597 he was consecrated bishop of London, and in consequence of the advanced age of Whitgift was virtually invested with the power of primate. In 1600 he headed a diplomatic mission to Denmark. He took a prominent part in the famous conference of prelates and Presbyterian leaders held at Hampton Court in 1604, and in the framing and passing by convocation of the canons of that year. By his orders Puritan ministers were required to conform to these canons or suffer deprivation. In March 1604 Bancroft, on Whitgift's death, was appointed president of convocation, and in Nov. 1604 he was elected to the see of Canterbury. In 1608 he became chancellor of Oxford university. Bancroft was "chief overseer" of the Authorized Version of the Bible. One of his last acts was to assist in the re-establishment of episcopacy in Scotland. He died in London on Nov. 2, 1610.

See R. G. Usher, *The Reconstruction of the English Church,* 2 vol. (1910); A. Peel (ed.), *Tracts Ascribed to Richard Bancroft* (1953). (G. HU.)

BANCROFT, SIR SQUIRE (1841–1926), English actor and manager, who did much to build the tradition of the modern theatre, was born in London on May 14, 1841. He first appeared in Birmingham in 1861 and played in the provinces for several years. His first London appearance was in 1865, in *A Winning Hazard* at the Prince of Wales's theatre under the management of Marie Effie Wilton (b. 1840) whom he married in 1867. At the old Prince of Wales's theatre (now Scala) the Bancrofts produced all the better-known comedies of Thomas William Robertson—*Society* (1865), *Ours* (1866), *Caste* (1867), *Play* (1868), *School* (1869), *M.P.* (1870)—and caused a revolution in theatrical production, sweeping away the old crude methods of writing and staging. Later, at the same theatre, they produced new plays and revivals: such as Edward Lytton's *Money,* Dion Boucicault's *London Assurance* and an adaptation of V. Sardou's *Théodora,* entitled *Diplomacy.* In 1880 they moved to the Haymarket theatre and continued a brilliant career until their retirement in 1885. Bancroft joined Henry Irving in 1889 to play Latour in a revival of *The Dead Heart.* Lady Bancroft died in 1921, Sir Squire Bancroft (he was knighted in 1897) in London on April 19, 1926. Bancroft was a good, polished actor but never a great one, his wife being the more talented. But their management was outstanding, and it was his policy and judgment which directed it. The Bancrofts also gave a start to many actors and actresses who subsequently became famous.

See Mr. *and Mrs. Bancroft, on and off the Stage* (1888) and *The Bancrofts: Recollections of Sixty Years* (1909), by themselves; also *Empty Chairs* (1925), a volume of reminiscences, by Sir Squire Bancroft. (W. J. M.-P.)

BAND, a term used in music to describe a group of instruments played together. The instruments are generally of one family or type and in the United States the term has been restricted more specifically to groups of wind instruments. Colloquially it may be synonymous with orchestra.

Derived from the French *bande* ("group"), the term was first applied in England to the "king's band" of 24 violins at the court of Charles II. This was modeled on Louis XIV's group of violins, a development of the practice of employing musicians at court and in noble households that was widespread throughout Europe in the 16th and 17th centuries. The string band remained popular, and composers from Bach and Handel to Benjamin Britten wrote music for small groups of stringed instruments. The string band is also a feature of 20th-century musical life.

The term has also been more generally applied to mind bands, especially military bands and brass and silver bands, and to jazz bands and percussion bands.

The formation of wind bands began in Germany, where military bands, later consisting chiefly of oboes and bassoons, developed from the 15th century onward. German musicians joined foreign groups and the wind bands spread to England via France. In the 18th century a variety of percussion instruments, known as "Turkish music" (cymbals, triangles, the military glockenspiel and the crescent), was introduced, and at this period, too, Negro drummers appeared in European bands, brandishing their drumsticks in the manner of the later drum major. By the end of the 19th century the number of wind instruments had greatly increased, and the marches of Haydn written for the Derbyshire yeomanry were scored for trumpet, two horns, two clarinets, two bassoons and serpent. In Berlin. in 1838. 1,000 wind instruments and 200 drummers were assembled by the organizer of Prussian military music to perform in honour of the Russian emperor. In England the standard of playing was raised when instruction was begun in military music at Kneller hall, Hounslow. Middlesex, in 1857. In the United States both P. S. Gilmore (*q.v.*), bandmaster during the Civil War, and J. P. Sousa (*q.v.*), leader of the U.S. marine band, developed the standard of military bands to a virtuoso level and undertook tours in Europe.

Wind band is the name given to a small group of brass and woodwind instruments used by composers in works destined for concert performance. Serenades for wind band were written by Mozart and, in modern times, by Hindemith and Schonberg. The Italian word *banda* signifies the brass band on the stage or, in opera, behind the scenes, notably in Berlioz' *Requiem* and in Verdi's *Rigoletto* and *La Traviata.*

In England the brass band, sometimes called silver band when the instruments are made of an alloy, began to replace the earlier bands of the town "waits" and of the village churches at the end of the 18th century, when their formation was encouraged particularly by employers in industrial areas. The development of the cornopean, a predecessor of the cornet, and of a family of brass instruments, invented by Adolphe Sax (*q.v.*), on all of which the fingering was similar: made the adoption of these instruments by amateurs a possibility. Among the earliest of these bands was the Stalybridge Old band (1814) and the famous Besses o' the Barn, an all-brass band by 1853. The movement attained national popularity with the institution of contests, notably at Bellevue, Manchester and the Alexandra palace, London. After the first National Brass Band festival (1900), a high standard of playing by bands representing towns. factories; the Salvation army and numerous other religious and social bodies was maintained and composers such as Sullivan, Ireland, Elgar and Holst wrote works for brass band, usually scored for cornets, flugelhorns, horns, baritones in B flat, euphoniums and basses. The brass band also has a wide popularity in the United States.

In schools the percussion band is a term used for a children's orchestra of percussion instruments, its purpose being to develop a sense of rhythm. Britten introduced a children's percussion band in his setting of the Chester miracle play *Noye's Fludde.* Dance bands or jazz bands originated in the U.S. at the end of the 19th century and assumed a large variety of forms *(see* JAZZ).

See J. F. Russell and J. H. Elliot, *The Brass Band Movement* (1936).

BANDA, a town and headquarters of a district of the same name in Uttar Pradesh, India. The town (pop. 1951, 30,327) is

situated 95 mi. W. of Allahabad on the right bank of the Ken river, a tributary of the Jumna. It is accessible by road from Allahabad and is a market town and cotton mart. and well known for its moss agates. which are exported throughout the world.

BANDA DISTRICT (pop. [1961] 954.632) has an area of 2.950 sq.mi. and lies between the Jumna on the north and the escarpment of the Vindhya hills on the south, Most of the population is engaged in agriculture, cultivating the richer alluvial soil of the plains, and pasturing cattle and other animals on the hills. The crops grown include cotton, oilseeds. millet. rice, pulses and other food grains.

Banda and the neighbouring fort of Kalinjar (*q.v.*) changed hands many times in the wars between the Muslims. Marathas. French and British, as they command the northern end of one of the main routes from the Ganges-Jumna Doab across the hills of central India to the Deccan. The road leading south from Banda is no longer maintained, and Banda has declined as a centre of trade. Chitrakuta hill, 35 mi. E. of Banda, near the town of Karwi. is a famous place of pilgrimage connected with the Ramayana story. The district is also rich in remains of the Stone Age.

(M. N. K.)

BANDAGES AND BANDAGING. A bandage is a strip or piece of woven material used to bind up wounds. Its general use is to retain dressings or splints in position; to give support to a part of the body; and to exert pressure to stop or prevent bleeding.

FIG. I.— TRIANGULARBANDAGE AS ARM SLING

Triangle is tied behind neck at side of spine and pinned at elbow. In injury of forearm, the hand is elevated slightly above level of elbow

There are four kinds of bandages: the triangle. roller or pleated gauze. four-tailed and many-tailed. In medical usage each method of bandage application is given a distinctive name. For example. a roller bandage applied in spiral form to cover each finger and the hand is called a gauntlet.

The triangle is the most useful bandage for emergencies as it fulfills every need in bandaging: it is easily made, is easy to apply, will stay on, will cover any part of the body. and little danger of injury to flesh or blood vessels results from its application. The triangle bandage is usually made by cutting diagonally muslin or gauze 36 to **40** in. square. As an open triangle it is used as a sling for the arm, as a bandage to cover the head. the hand or the foot. It is folded to make various widths in order to adapt it best for use on the various parts of the body. When folded repeatedly it becomes a cravat bandage. in which form it may be used for a sling or to cover the palm of the hand. the eyes or the ears. Wlien made of surgical gauze and kept sterile it is suitable to use directly on a wound the same as any surgical dressing: either with or without the addition of solutions or ointments. The cotton or muslin bandage is stronger than the gauze and therefore more suitable for the application of pressure or to give support.

Another common type of bandage is the roller bandage, from 1 to 3 in. or more in width, averaging 10 yd. in length and rolled longitudinally. It is usually applied spirally. The material of this bandage is usually muslin, flannel. gauze or cheesecloth, gauze or cheesecloth being preferred for elasticity. The iour-tailed bandage. for which 5 to 8 in. wide by 2 to 3 ft. long is a representa-

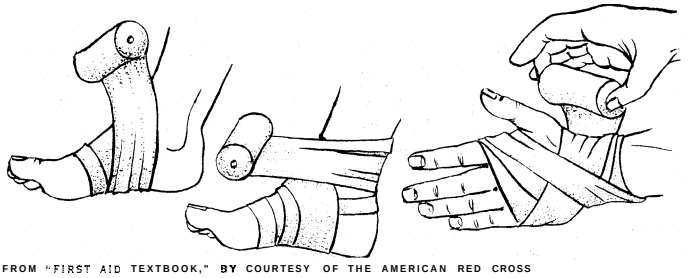
FIG 5 — ROLLEROR SPIRAL BANDAGES

(A) Spiral is begun on small part of injured limb and wrapped as far up as needed. (B) End of gauze is anchored at wrist and spiral wrapped down finger, back to wrist and tied

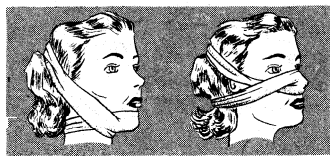


FROM "FIRST AID TEXTBOOK," BY COURTESY OF THE AMERICAN RED CROSS

FIG. 6.—FIGURE-EIGHT BANDAGE FOR ANKLE OR WRIST

Bandage is anchored with several turns around instep (or palm), carried diagonally upward around ankle (or wrist), and downward around foot (or hand)

tive size, is useful for injuries of the lower jaw and head, elbow and knee. The many-tailed bandage is an elaboration of the four-tailed bandage and its uses are similar.



FROM "FIRST AID TEXTBOOK." BY COURTESY OF THE AMERICAN RED CROSS

FIG. 7.— FOUR-TAILED BANDAGE FOR WOUNDS OF CHIN OR NOSE

Bandage is centred over dressing and upper tails carried downward, lower tails upward

Bandages applied to meet various needs and positions of the body have special names. Among them are: Johannes Esmarch's figure-eight bandage, in which the turns cross each other like a figure 8; the circular bandage applied to a part in circular turns; the gauntlet and demigauntlet hand bandages; Desault's bandage for a fractured clavicle; the oblique, pressure, suspensory, reversed, spiral and spiral reverse bandages; the T-bandage; the Spica, which is a spiral folded regularly on itself like the letter V for use at the junction of a limb to the body.

Some bandages are made of special materials to meet specific needs; *e.g.*, the roller bandage of crinoline filled with plaster of Paris or splints; starch, silica and dextrin bandages for stiff and immobile dressings; the rubber bandage for flexible support as in varicose veins; and numerous other highly specialized bandages. (W. R. R.)

BANDA ISLANDS, in the Banda sea, Indon., lie 130 mi. S.E. of Amboina and 66 mi. S. of Ceram. The ten islands cover only 72 sq.mi. Pop. (1956 est.) 13,686. The three largest are Bandalontar or Great Banda (6 mi. long), Bandanaira and Gunungapi, grouped around an inland sea which forms Banda harbour; Bandalontar, sickle-shaped, lies south and east, Bandanaira to the north, with Gunungapi to the west. Undoubtedly these three islands form part of the rim of a crater.

West and southwest of Gunungapi are Ai and Run, and north and northwest, Pisang and Suwangi. Channels on either side in the south of Banda harbour enable vessels to enter with safety during either monsoon, while a northern passage, between Gunungapi and Bandanaira, is navigable for small vessels. Bandalontar has coral rock to a height of 400 ft., with lava and basalt above, and is certainly volcanic, while Gunungapi (2,152 ft.) is an active volcano which caused destruction in 1820 and 1852. It is covered with bushes to within 700 ft. of the summit, which exhibits various shallow and extinct crater basins and a hot, smoking plain, sending forth sulfurous vapours and covered with split lava blocks. The volcanic soil, however, is admirably adapted to the growth of the nutmeg, which is indigenous. Other products are cloves, coconuts, tapioca and various tropical fruits and vegetables. The population of the islands is 10,000 of whom 6.000 live in Bandanaira, the capital, on the island of that name, the port for the group.

The people are a mixed race, mostly descendants of Javanese, Macassarese and people from neighbouring islands brought in by the Dutch as slaves to work the nutmeg plantations in the place of the Bandanese, who refused to do so and were either killed or banished. A colony of exiled Bandanese continued to exist on one of the neighbouring islands of the Kai group. They, alone, use the old Bandanese language. On Gunungapi there is a small colony of Butonese. On Bandanaira there are many Arab and Chinese traders and some Malays, with a few Europeans and Eurasians, officials and persons engaged in business. Agriculture and fishing are the occupations of the inhabitants, many of whom are Christians.

Trade is in Chinese and Arab hands. Regular ship service connects Bandanaira with Amboina. There are roads sufficient for the needs of the population, and a radio station. The approach, especially from the north, is beautiful, as is the scenery about the inland sea. The marine gardens beneath this sea are probably unrivaled.

The Banda Islands were discovered and annexed by the Portuguese Antonio d'Abreu in 1512, but early in the 17th century the Dutch expelled the Portuguese and established themselves, in spite of native opposition, on Bandanaira and built a fort there. The Dutch East India company allotted the nutmeg plantations (Dutch *perken*) to deserving former servants, the so-called "perkeniers," but kept the monopoly on the nutmeg trade. For 300 years the perkeniers, who gradually became of mixed blood, were the aristocracy of the islands. The English tried to establish themselves in the islands at the same time as the Dutch. After some unsuccessful attempts — among them that of Capt. David Middleton — English influence made headway on Bandalontar, Run and Ai, and in 1621 the Dutch, anxious to make an end of native rule, proposed a joint Anglo-Dutch conquest of the islands. The English declined to co-operate, whereupon the Dutch crushed Bandanese resistance and ruled the islands under a governor, soon eliminating the English element. Alleged English participation against the Dutch in a native revolt on the island of Run led to the Amboina massacre (see AMBOINA). As a result, in 1654, under pressure from Cromwell, Run was awarded to the descendants of those who perished in Amboina. It was held until 1664, when the Dutch captured it. In 1796 the islands were taken by a British naval force, restored to the Dutch in 1800, retaken during the Napoleonic War and restored finally by the treaty of Paris of 1814. Japan occupied the islands in World War II. (J. O. M. B.)

BANDAR ABBAS, a port of Iran on the strait of Hormuz, seat of the governor of the Persian gulf ports subdivision of the ostan (province) of Kerman, and the main maritime outlet for a large part of southern Iran, stands on the barren northern beach of Hormuz bay opposite the islands of Qeshm (Qishm, *q.v.*), Larak and Hormuz (Hormoz). Pop. (1956) 17,690, mainly Arabs and Negroes; in 1900 it was less than 10,000. The climate is oppressive by reason of heat and humidity in summer, but pleasant from October to April. Many inhabitants leave the town in summer for the villages at the foot of the mountains, especially Minab where some of them own date palm gardens. The roadstead is shallow and not well sheltered from the southeastern winds. Large vessels have to lie as much as four miles out. Port facilities are very poor; the port served as a base for British-Indian troops in World War I but was completely neglected during World War II. Water supply is good and plentiful from a rich source 12 mi. distant. Annual trade averages about 20,000 to 30.000 tons, exclusive of the oil products from Abadan. Imports (mainly sugar) are greater than exports, which include Kerman rugs and raw wool, dried fruits, pistachios and dates. Exchanges with the Arabian coast are small. The town has a cotton mill and a fish canning plant. Development plans after 1960 included the construction of a new harbour to the west of the town and road improvement to open an immense hinterland to this port at the entrance of the Persian gulf. There are also large agricultural possibilities in the district and valuable iron deposits on the islands of Hormuz and Qeshm.

Bandar Abbas (Persian for "port of Abbas") was established in 1623 by Shah Abbas I at the site of the village of Gumrun, or Gombrun, to replace the ancient and famous city of Hormuz (*q.v.*) which had fallen into the hands of the Portuguese (1507). The English were permitted to build a factory there (as later were the Dutch and French) and assisted in the seizure of Hormuz which was destroyed and completely abandoned. During the 17th century Bandar Abbas was the chief maritime city of Persia, claiming a population of 40,000. In the 18th century the rival port of Bushire (*q.v.*), founded by Nadir Shah, obtained commercial supremacy in the gulf when, after the destruction of the English factory by the French in 1759, the East India company transferred its activities to Bushire. From about 1780 Bandar Abbas and its surrounding district were in the hands of the rulers of Muscat (Masqat), but in 1868 the Persian government regained possession of the area. (H. Bo.)

BANDARANAIKE, SOLOMON WEST RIDGEWAY DIAS (1899–1959), Ceylonese statesman whose electoral victory in 1956 was revolutionary in its effect, was born in Colombo on Jan. 8, 1899. the son of a rich landowner. Educated at Christ Church, Oxford, Eng., he was called to the bar at the Inner Temple in 1925. Soon afterward he returned home. Entering politics, he renounced Christianity to become a Buddhist. In 1931 he entered the newly formed state council. In 1947, as a prominent member of the United National party (U.N.P.), he was elected to the new house of representatives and appointed minister

of health and local government. Having resigned from the government and from the U.N.P. in 1951, he was returned in 1952 as founder of the Sri Lanka (Blessed Ceylon) Freedom party. He became the leader of the opposition. Four years later he formed the People's United front (P.U.F.), a political alliance of four leftist parties which swept the election, and he was sworn in as prime minister on April 12, 1956. The P.U.F. advocated a neutralist foreign policy and a Sinhalese Buddhist nationalism at home. By amicable agreement the British bases on the island were relinquished in 1957 and Ceylon remained a realm of the Commonwealth of Nations. The attempt to introduce Sinhalese as the country's official language led to serious riots. In 1959 the country's economy began to falter and in May a split occurred in the P.U.F., depriving Bandaranaike of a parliamentary majority. Steering a complicated course to retain power, he alienated some of his former supporters. A Buddhist monk, Talduwe Somarama Thero, shot him on Sept. 25 and Bandaranaike died the following day.

BANDELIER, ADOLPH FRANCIS ALPHONSE (1840–1914). U.S. archaeologist and anthropologist. a pioneer student of Indian cultures of the southwestern United States, Mexico and Peru-Bolivia, was born in Bern. Switz., on Aug. 6, 1840. When eight years old he emigrated with his family to the United States. Originally forced to pursue an uncongenial business career, he found solace in historical-ethnographic library studies, his "life's life." Between 1873 and 1879, under the intellectual dominance of Lewis H. Morgan (*q.v.*), he endeavoured to prove, in support of the latter's evolutionary theories, that Aztec sociopolitical structure had been entirely kin-based, democratic and substantially similar to the Iroquois system. The results of his investigations were published in three classic studies: *On the Art of War . . . of the Ancient Mexicans* (1877), *On the Distribution and Tenure of Lands. . . Among the Ancient Mexicans* (1878) and *On the Social Organization . . . of the Ancient Mexicans* (1879).

After 1880 Bandelier was able to devote full time to research and during the next decade undertook archaeological, ethnographic and documentary studies in the southwest and Mexico. His best-known works on the former area are *Final Report of Investigations Among the Indians of the Southwestern United States . . .* (1890–92) and a fictionized Pueblo ethnography, *The Delight Makers* (1890). After 1892 he turned to Peru and Bolivia; the most important publication resulting was *The Islands of Titicaca and Koati* (1910). Returning to the United States in 1903. he held various museum, teaching and research posts until 1913, when he embarked for Spain to pursue archival investigations. He died on March 18, 1911.

Bandelier's works, particularly those relating to the southwest and Peru-Bolivia, are still of considerable value. His Mexican studies suffer seriously from his constant forcing of the facts to fit Morgan's scheme, which he had adopted with enthusiasm. Recent scholarship has largely rejected Bandelier's principal conclusions regarding the fundamental nature of Aztec society and government.

Bandelier*, Instituto Nacional de Antropologia e Historia, Serie Historia, IV (1960). (H. B. NI.)

BANDELLO, MATTEO (1485–1561), Italian novelist who had a wide influence in England, France and Spain, was born in 1485 at Castelnuovo Scrivia in Tortona, Lombardy. Bandello, who was a monk; a diplomat and a soldier as well as a writer, was educated at Milan and the University of Pavia. He frequented the courts of Ferrara and Mantua and knew Niccolò Machiavelli.

At the age of 50 he was entrusted with the education of Lucrezia Gonzaga to whom he was greatly attracted and to whom he dedicated a long poem. After the battle of Pavia he fled to France with his protector, Gen. Cesare Fregoso, and later lived at Bassens near Bordeaux. In 1550 he was made bishop of Agen and spent the remainder of his life in France writing the stories on which his reputation rests Bandello died at Agen in 1561

Bandello's *Novelle* (4 vol 1554–73) are frequently daring in the manner of Boccaccio's *Decameron*, and provide a valuable insight into the social intrigues of the Italian Renaissance They were translated into French under the title *Histoires tragiques* (1559), and in Spain they were greatly admired by Lope de Vega. Shakespeare's *Ronteo and Juliet* derives from a tale of Bandello In France his influence persisted until the 19th century

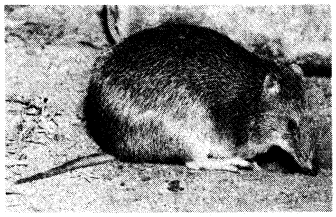
BANDEROLE, a small flag or streamer carried on the lance of a knight or flying from the masthead of a ship. In architecture, it is a sculptured band for bearing an inscription, etc.

BANDICOOT, any of about 20 species of 7 genera of the marsupial family Peramelidae, occurring in Australia and neighbouring islands. They resemble mouse- to cat-sized kangaroos. Some species are uniformly grayish or buffy; others have conspicuous dark bars across the lower back and hips. Most bandicoots are omnivorous, eating a wide variety of plant and animal foods; a few are strictly vegetarian. They are most active at night. digging characteristic conical pits in search of food. Only the bilbies (*Thylacomys*) expertly dig burrows for dens: the daytime retreat of the others is an artfullv concealed shallow pit or hollow log. Bandicoots are intolerant of each other and prone to fight. They do so by leaping at each other, striking out with the hind feet and, if successful, tearing out hair and sometimes flesh with the strong claws. Two to eight young comprise a litter, according to the species. They are usually considered pests.



JOHN WARHAM

SHORT-NOSED BANDICOOT (THYLACIS FOROSUS)

See MARSUPIALIA: *The Australian Bandicoots.* (K. R. KN.)

BANDICOOT RAT, a large ratlike rodent *(Bandzcota indica)* of India and Ceylon, with a body 12 to 15 in. long and a tail an additional 11 to 13 in.; it weighs 2½ to 3 lb. The colour is variable but generally blackish-brown above, grayish-brown below. It has a short head, a broad muzzle and a scaly and almost hairless tail. The bandicoot, a burrower inhabiting forest, cultivated land, villages and towns, is destructive to crops, grain and poultry. The litter number is probably large, for the female has 12 teats. The lesser bandicoot rat or Indian mole rat and the short-tailed bandicoot rat or mole rat are smaller allied species. The animal is said to grunt like a pig and a native (Telegu) name *Pandi-koku* (meaning "pig-rat") has been corrupted into "bandicoot." The name has since been applied to a family (Peramelidae) of Australian marsupial mammals zoologically very distant from the original bandicoot of India. *See* also RODENT. (L. H. M.)

BANDIERA, ATTILIO (1810–1844) and **EMILIO** (1819–1844), Italian patriots, who lost their lives in an abortive revolt against Austrian rule. The sons of Baron Francesco Bandiera, an admiral in the Austrian navy, they were born in Venice, Attilio on May 24, 1810, and Emilio on June 20, 1819. They themselves entered the Austrian navy, but were won over to the cause of Italian independence and unity and corresponded with Giuseppe Mazzini and members of the revolutionary organization Giovine Italia

("Young Italy"). They planned to foment a rebellion in the navy, which was largely composed of Italians, but were betrayed and fled to Corfu early in 1844. They then resolved to undertake an expedition to Calabria, where groups of insurgents were believed to be holding out against the Neapolitan government at Cosenza. With a small band of adherents they set sail on June 12, 1844, landing on the Calabrian coast four days later. Through the treachery of one of their followers they were captured, and on July 25 the Bandiera brothers and seven of their companions were executed. The moral effect of the execution was considerable. The action of the authorities was widely condemned, and the brothers were regarded as martyrs of the Risorgimento.

BIBLIOGRAPHY.—G. Ricciardi and P. Lattari, *Storia dei fratelli Bandiera e consorti* (1863); C. Causa, *Vita dei fratelli Bandiera* (1888); C. R. Barbiera, *I fratelli Bandiera* (1923)

BANDINELLI, BACCIO (1493?–1560), Italian sculptor, was born in Florence, probably on Nov. 12. 1493. and died there on Feb. 7, 1560. The son of Michele di Viviano de' Brandini, he assumed the surname Bandinelli in 1530. Trained as a goldsmith, Bandinelli later worked under the sculptor Giovanni Francesco Rustici, and became one of the principal artists at the court of Cosimo I de' Medici, grand duke of Tuscany. Accounts of Bandinelli and his work given in Giorgio Vasari's *Lives* and in the *Autobiography* of Benvenuto Cellini represent him as jealous, malignant and untalented.

Bandinelli's surviving works prove him to have been a more distinguished sculptor than his contemporaries allowed, and his copy of the Laocoon (commissioned by Pope Clement VII for Francis I of France and now in the Uffizi, Florence), his statue of Hercules and Cacus (completed in 1534 for a position outside the Palazzo Vecchio, Florence. and carved from a block of marble destined for a group of this subject by Michelangelo) and his reliefs on the choir screen of Florence cathedral explain the vogue which his austere, rather arid work enjoyed at the Medici court. In later life he was supplanted in favour by Cellini and Bartolomeo Ammanati, but shortly before his death he secured the grant of a site for his own tomb in the church of the SS. Annunziata, Florence, where he set up his last work, a group of "The Lamentation Over the Dead Christ," executed jointly with his son Clemente. (J. W. P.-H.)

BANDIRMA (formerly PANDERMA), a town and seaport of northwestern Turkey, lies on the southern shore of the Sea of Marmara within the *il* of Balikesir, of which it is administratively a *kaza*. Pop. (1960) 28.858. It is an active transit port on the shortest route between Istanbul and Izmir and is linked by rail with the latter. There are regular shipping services to and from Istanbul. It is connected by road with both the above cities and with Balikesir, Eskişehir and Ankara. The town is also a trading centre for the rich agricultural plains which border it on the south. (S. ER.; N. Tu.; E. Tu.)

BANDITRY. The bandit is a robber who generally disdains the commoner forms of theft such as the picking of locks or pockets in favour of face-to-face contact with his victim. By ambush, skirmish, kidnapping or false pretense the bandit secures control over the hapless traveler on the highway or trail. The isolated farm or lonely village may also attract his attention. He is the pirate of the dry land, preying on solitary rider, express coachman or truck driver. After robbing his victim, the bandit may hold him for ransom and all too often commits murder to preserve his anonymity or to gratify an antisocial obsession.

Most bandits appear to have chosen the vocation more as a means of revenge for some real or imaginary wrong done by society than for the promise of booty. Yet the bandit is not without social fame, even grudging admiration. The very daring of a Jesse James, the good-natured roguishness and camaraderie of a Robin Hood, the genius of a John A. Murrel and the operettalike colourfulness of a Ned Kelly must always strike a responsive chord even when applied in the most reprehensible of pursuits.

Thus, in India the villagers have devised a whole lore of songs celebrating the exploits of the dacoit. Generations of English children are reared on the legends of the Merry Men of Sherwood forest. The peasants of Macedonia and Albania still cherish the Horatio Algerlike image of success afforded by the tales of their brigand kings. In Italy the bandits are the subject of popular verse.

To those of a romantic proclivity, the bandit or brigand is the dashing. devil-may-care lover portrayed in Alfred Noyes' celebrated poem "The Highwayman" who defies the noose to court the maid. Or he may be Benedetto Mangone, the 16th-century Italian bandit whose delicate sensibilities compelled him to give safe conduct to Torquato Tasso, because he could not bring himself to rob a poet.

To people suffering from oppression, the bandit, however selfish and shoddy his motives. may become a heroic symbol of revolt. The Sicilian mafia (*q.v.*) was originally such a symbol of protest against Neapolitan misrule. This phenomenon was very apparent in the attitude of many California Mexicans toward Joaquin Murrieta who from 1850 to 1853 robbed and killed the hated gringos and defied their law. Murrieta, who was only 23 years old when he was decapitated! became something of an avenging angel to his people.

It is. moreover, sometimes difficult to distinguish between the bandit and the patriot. Even in the worst of bandits there may be a spark or façade of idealism. John A. Murrel linked his fantastic plan for a pirate empire in the southern United States to an uprising and freeing of the slaves, and many a northern abolitionist unwittingly gave aid to Murrel's bandits before the plot was uncovered in 1834. Conversely, genuinely patriotic or chauvinistic movements may, perforce, resort to tactics indistinguishable from those of the bandits. In 1901 a Bulgarian band fighting Turkish persecution captured a U.S. missionary, Ellen Marie Stone, and used the ransom of $72,000 to purchase arms and ammunition. In the 20th century, the Sinn Feiners in Ireland, the Haganah in Israel, the *maquis* in France, the partisans of World War II and the EOKA in Cyprus sometimes resorted to bandit means to achieve other ends. The Mau Mau in Kenya represented a particularly striking merger of banditry and nationalism in the 1950s.

Sometimes the line between banditry and nationalism is deliberately obscured by those fighting to suppress a popular uprising. The so-called Brigands War of 1795–1803 in the Caribbean was nothing less than a war fought by the slaves of the British and French West Indies to secure the freedom promised them by the French Revolution. Yet. because Great Britain and later Napoleon chose to regard the Negroes as bandits rather than as insurgents they were not, technically, compelled by international law to accord to captured slave-soldiers the humane status of prisoners, and hundreds were executed. The last thousand of Gen. Louis Delgres's Negro army retreated into Matouba fortress on Guadeloupe, set fire to the arsenal and blew themselves up.

Banditry flourishes almost as a by-product of dissolute public behaviour in wars and in times of grave economic, political and administrative injustice. The medieval *écorcheurs* ("skinners") of the Hundred Years' War roamed. robbed and terrorized France after being discharged from the armies. The *chauffeurs* ("stokers") of the French post-revolutionary period forced their victims to secure ransom by holding their feet in fires. Banditry flourished in the north of Spain when government was weak and after foreign invasion and civil wars. It reached its climax in 18th-century Catalonia. where it began in the strife of the peasants against the feudal landlords. Yet it has always been put down readily by a just and capable administration.

In the United States, the Civil War bred Frank and Jesse James (*q.v.*), Cole Younger and the "border bandits," men trained to guerrilla warfare for service as Confederate irregulars in Kansas and Missouri. Under the leadership of William C. Quantrill, Bill Anderson and Arch Clements and in the service of the "Black Flag" brigade, these irregulars developed a taste for the violent life. On Aug. 21, 1863, Frank James and Cole Younger participated in a Quantrill raid on Lawrence. Kan., during which some 150 to 182 residents were put to death and much of the town was burned. Before commencing his career as a Confederate irregular leader. Quantrill himself is alleged to have been a horse thief, professional gambler and murderer.

After the war, the freebooters of the border states continued their new way of life. The James gang was hunted by sheriffs. posses and Pinkerton detectives in over 100 counties of 12 states for bank. train, railway and stagecoach robberies as well as for incidental murders. The assassination of Jesse James in 1882. the growth of law and order exemplified by "hanging judges" such as Isaac C. Parker of the Fort Smith, Ark., federal bench, and the fading of the war memory finally brought about the demise of middle western brigandage.

Banditry has traditionally flourished in the isolated rough terrain and rougher morality of the frontier. Indeed, the term maquis, applied to French refugees from German labour conscription who formed the nucleus of French partisan resistance to the German occupation in World War II, refers to the bush of Corsica. Together with the equally favourable terrain of southern Italy, Spain and Greece. this wild terrain affords the European bandits their best hiding places.

The term bushranger similarly describes such Australian bandits as Ben Hall! Frank Gardiner and Ned and Dan Kelly who. in the latter half of the 19th century, held sway in the badlands of New South Wales and Victoria. Ned Kelly was perhaps the most colourful of frontier brigands, dressed in a suit of homemade armour like a mock-medieval knight, riding down the main streets of terrorized villages brandishing revolvers and howling outlandish songs. He was shot in the leg—the chink in his armour—on June 28, 1880, and hanged on Nov. 11.

The greatest frontier bandits, however. were the products of the American south and west. River pirates fattening on the Mississippi migrant and commercial trade benefited by the divided jurisdiction that made one bank of the lower river Spanish and the other American.

Diamond Island on the southern border of Illinois became a nest of brigands, and from headquarters on nearby Cave-in-Rock on the Ohio river Philip Aston, dressed in ruffles and lace, went about scuttling river boats and murdering their crews. A few miles down the river. James Ford rounded out his career as justice of peace with the avocation of ferryman and bandit chieftain. His ferry carried the traders, his bandits robbed them and his court protected the offenders: a memorable example of pioneering self-sufficiency.

The great land trails into the south. Daniel Boone's Wilderness road and the Natchez trace, ran through ideal bandit country of dense thicket, wilderness and dark swamp. There such men as Joseph Thompson Hare. Samuel Mason and Murrel had their domain. Micajah and Wiley Harpe, who first plundered the trace in 1797, were unquestionably mad; they dismembered their victims' corpses. Micajah ("Big Harpe") killed Maj. John Love "because he snored so.!' and thought nothing of murdering women and infants. At the end, the anguished husband of one of his victims cut off Micajah's head and nailed it to a tree on the trace.

Banditry is by no means unique to Europe and America. Indeed, it appears to have found its last sanctuary in parts of Africa and Asia. Early in the 20th century kidnappings of British subjects and U.S. citizens by the Moroccan Ahmed ibn Muhammed Raisuli led to several international incidents. Raisuli's kidnapping in 1904 of the American Ion Perdicaris led to Pres. Theodore Roosevelt's famous demand. "Perdicaris alive or Raisuli dead." On Oct. 8, 1927, two French children were kidnapped and their parents murdered by Moroccan brigands. In India, the proud and wealthy chieftain Mansingh was the law's most brilliant and successful antagonist until. on Aug. 2j. 1935, he was killed nesr Agra by a specially trained company of Gurkha police. The equally famous Bhupat was in the second half of the 20th century still at large. presumably in Pakistan. In Iran, the murder by Dadshah's bandits on March 24, 1957, of three Americans, Kevin Carroll and his wife and Brewster A. Wilson, who were touring southeastern Iran on behalf of the U.S. government, led to the fall of the Hussein Ala government and the suspension of United States aid activity in the area.

Bandits may be hunted either by militia or by the population at large. To arouse the citizenry, a reward for a bandit's capture may be offered or he may be declared an outlaw—that is, a man deprived of all legal protection, who may be hunted and even killed with impunity by anyone. The common law of England and the constitution of the United States forbid the outlawing of persons except by judicial process. See also GUERRILLA WARFARE; INSURGENCY.

BIBLIOGRAPHY.—McFarlane's *Lives and Exploits of Banditti and Robbers* (1837) is a useful introduction to the subject. A good survey of some American banditry is found in Robert M. Coates, *The Outlaw Years* (1930). For additional background *see* Henry F. Lutz, *The Alleged Robbers' Guild in Ancient Egypt* (1937). (T. M. FK.)

BANDJERMASIN (BANJERMASIN), a town of Indonesia, the centre of a district of the same name and capital of South Kalimantan province, is situated on the south coast of Borneo. Pop. (1956 est.) 172,304. The town lies among the swampy mouths of deep, swift-flowing rivers which drain the largest plain in Kalimantan; during the rainy season torrential waters pour down from the mountains of the interior flooding the surrounding plains and the swamps. To the east a mountain range sweeps down from the north, but the hills are not easily accessible because of the lack of roads. Bandjermasin is built on an island between the Barito and Martapura rivers, both of which are navigable well beyond the town by large vessels. The houses are raised on piles; gardens are walled and drained; and rivers and streams are used in place of roads. There is a good harbour and Bandjermasin port carries most of the import and export trade for the extensive valley region. Exports from the port include rubber, pepper, timber, rattan, cordage fibres, gold and diamonds. In the vicinity are sawmills at Alalak and Tjerutjuk; kilns for bricks and earthenware goods are at Sungri Tabok. Coal comes from Pengaron, about 40 mi. away. Bandjermasin district had an estimated population in 1950 of 415,007.

A sultanate was formerly centred on Bandjermasin, covering the entire southerly region of the Barito basin. In the 18th century a treaty was made with the Dutch East India company. There followed a long period of conflict between various claimants to the sultanate until the area was finally brought under the direct control of the Dutch. This led to a revolt in 1859, which smouldered as guerrilla warfare in the hills for about 30 years and was never finally extinguished.

BANDON (DROICHEAD NA BANNDAN), a town of County Cork, Republic of Ireland, 17 mi. S.W. of Cork by road and situated in a broad, open valley on both sides of the Bandon river. Pop. (1956) 2.434. It is an agricultural centre and there are distilleries, breweries and flour mills. There are many archaeological remains in the district. Bandon was founded about 1608 by the earl of Cork. who planted English and Scottish settlers.

Kilbrogan church (1610), the first Protestant church built in Ireland, contains the town stocks. Fragments remain of the old town wall which was destroyed by the Irish in 1688–89. after which there was a long resistance against the admission of Roman Catholic inhabitants.

There is good salmon and trout fishing in the Bandon; two miles down-river is Inishannon, the head of navigation.

BAND SAW: see MACHINE TOOLS; WOODWORKING MACHIKERY.

BANDUNG (BANDOENG), the capital of the province of West Java. Indon. It is situated on the northern edge of a plateau nearly 2,400 ft. above sea level, surrounded by beautiful mountain scenery, with several waterfalls, terraced rice fields and heights rising to nearly 7,000 ft. The climate is mild and pleasant with cool nights. Pop. (1956 est.) 870.346.

Bandung is a modern city with wide tree-lined streets and shops, banks and private residences, many of them built in European style. The chief shopping centre is Braga, and there are several street markets, the best being Pasar Baru. Entertainment is provided by motion picture houses, a theatre and a racecourse. There are several churches and a large mosque. Xmong notable public buildings are the Merdeka and the Dwiwarna, where the Asian-African conference. attended by representatives of more than 20 Asian and African countries, was held in April 1955. *(See* BANDUNG CONFERENCE.) Bandung has three large parks, the finest of which is the Taman Sari, ,or Jubilee park, adjoining the zoological garden.

WAAGENAAR-PIX FPOM PUBLIX

MATHEMATICS AND PHYSICS BUILDING OF THE UNIVERSITY OF INDONESIA AT BANDUNG

The town is the acknowledged centre of Sundanese cultural life and learning. Music, usually of flutes or bamboo instruments. and the puppet theatre are popular. The faculties of pure and technical science of the University of Indonesia are in Bandung. A teachers training college was opened in 1954 and there are academies for plastic art, physical education and military affairs. The geological museum contains an interesting collection of minerals and fossils. There is a Pasteur institute, and in the Lembang highlands, to the north, is the Bosscha astronomical observatory. The Tangkubanprahu volcano; 8 mi. beyond, is reached by way of a large area devoted to the experimental cultivation of vegetables and flowers, especially roses.

Improved communications are making Bandung increasingly a commercial city. The chief industry is the manufacture of textiles and there are many factories and weaving mills in the town. most of them owned by Chinese. The government-administered 'Textile institute supplies advice on the industry and facilities for research in the technical field of yarn analysis and the use of dyes and chemicals.

There is a large quinine factory that produced 80% of the world's quinine before World War II. A ceramic institute is maintained by the ministry of economic affairs to promote research into ceramic raw materials and to provide technical information and assistance to the ceramic industry. Manufactures include rubber goods and machinery. Bandung is connected with the chief towns on the island by the state railway. There is an airport at Andir, 5 mi. W. of the city.

Bandung was founded by Marshal H. W. Daendels, Dutch governor general, in 1810, but was little more than a village until, in 1884. the government railway was brought to it from Bogor. It was then regarded as the capital of the whole of the Sundanese country and as a health resort for the coastal people.

The town was of great strategic value during the Japanese invasion of World War II, and its fall on March 7, 1942, practically sealed the fate of Java.

BANDUNG CONFERENCE, known officially as the Asian-African conference and held April 18–24. 19jj. at Bandung, Indon.. was organized on the initiative of Indonesia supported by Burma, Ceylon, India and Pakistan. 'They and 24 other Asian and African countries sent delegations. The conference reflected the five sponsors' dissatisfaction with what they regarded as a reluctance of the rrestcrn powers to consult with them sufficiently on decisions affecting Asia; their concern over tension between China and the United States; their desire to lay firmer foundations for China's peaceful relations both with the west and themselves; their opposition to continuance of colonialism — especially France's in north Africa; and Indonesia's desire to promote its case in the dispute with the Netherlands over western New Guinea.

Major debate centred around the question of whether Soviet policies in eastern Europe and central Asia should be censured along with western colonialism. A consensus was reached wherein "colonialism in all of its manifestations" was condemned, implicitly censuring the U.S.S.R. as well as the west. Communist China's prime minister. Chou En-lai, displayed an unexpectedly moderate and conciliatory attitude which tended to quiet fears of some anti-Communist delegates concerning China's possible aggressive intentions. He was applauded for his statement that China wished to avoid war with the United States and was "willing to sit down and enter into negotiations with the United States government to discuss the question of relaxing tension in the Far East and especially the question of relaxing tension in the Taiwan area."

A ten-point "declaration on the promotion of world peace and co-operation," incorporating the principles of the UN charter and the Indian punch *shila* (Nehru's five principlesj was unanimously adopted. Agreements concerning economic and cultural co-operation lacked real substance and led to little.

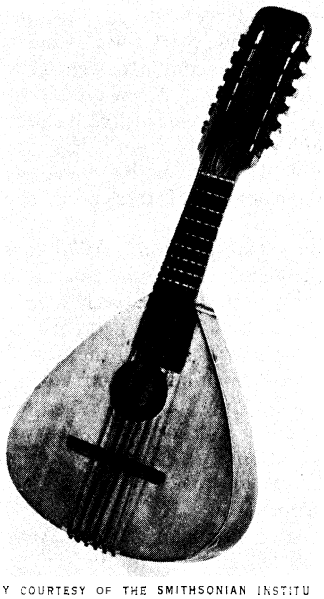
BANDURRIA, a short-necked, pear-shaped stringed instrument nith a flat hack. peculiar to Spain. where it is often used for the performance of outdoor music. It is strung with six paired courses of strings of gut and metal-spun silk, tuned in fourths as follows: G sharp (below middle C), C sharp. F sharp. B. E. A. There are 12 fixed metal frets on the finger board, and the instrument is played with a short, hard plectrum. The regular tuning in fourths throughout gives great facility and uniformity of lingering in chromatic passages.

(E. HA.)



BY COURTESY OF THE SMITHSONIAN INSTITU T N

SPANISH BANDURRIA. ABOUT 18TH CENTURY

BANEBERRY (HERB CHRISTOPHER). popular name for *Actaea spicata* (family Ranunculaceae: *q.v.*), an herb with long-stalked compound leaves, small white flowers and black berries, found wild in thickets in limestone districts in the north of England. It is widely distributed in the north temperature zone. *Actaea alba,* with white fruits, and *A. rubra,* with red fruits, are common in eastern and midwestern North America. The rootstocks and berries of baneberry contain irritant resins that have a cathartic action and produce vomiting.

BANÉR, JOHAN (1596–1643). Swedish field marshal. was born at Djursholm castle on July 3 (new style; June 23. old style), 1596. of an old Swedish noble family. His father. Gustaf Banér, a member of the king's council. was executed in 1600 after the defeat of Sigismund III of Poland (*see* CHARLES IX. king of Sweden). Entering the Swedish army in 1615, Johan Banér was greatly influenced by the military ideas of the young king Gustavus Adolphus: he served with distinction in Russia, in Livonia and in Poland and early attained the rank of general.

In Germany from 1630 (*see* THIRTY YEARS' WAR), he led the victorious right wing of Swedish horse at the first battle of Breitenfeld (*q.v.*) in 1631. 'Thereaiter he served as the king's

chief of staff at headquarters. In 1632, wounded in the fighting around Nürnberg, he did not take part in the battle of Ldtzen, where Gustavus Adolphus was killed. In 1634 he was appointed field marshal, with command of an army corps in Silesia and Bohemia; and when the main Swedish army had been crushed at Nordlingen he was asked to take command of the whole Swedish army in Germany. Having restored discipline by forceful action against mutineers, he resolved on an offensive strategy, despite the enemy's numerical superiority.

In 1636 his great victory at Wittstock restored for some time Sweden's paramount influence in central Germany. In 1637, hard pressed by the enemy's armies and almost surrounded, he made a strategic retreat into northern Germany that provoked the contemporary comment that "the enemy had put him in the sack but had forgotten to tie it." By the end of 1638, however, Banér had collected reinforcements, with which he began a new offensive toward central and southern Germany. At Chemnitz (April 1639), he defeated the emperor's army. Reinforced by French troops under the comte de Guébriant, he advanced toward southern Germany during the summer and autumn of 1640, but could not force the enemy to a battle. After a dangerous march through Bohemia in the winter, when Banér for the last time gave proofs of his courage and ability, he died at Halberstadt, Gcr., on May 20 (N.S.; 10, O.S.), 1641, of a pulmonary disease contracted during the winter campaign.

Banér's lucid intellect and military genius made. him one of the foremost soldiers of the Thirty Years' War. His strategy was characterized by great mobility, by readiness to take the initiative and by the swiftness of his advances. His tactics were distinguished by his daring and unconventional methods and by rude energy. The battle of Wittstock is a classic example of masterly leadership. A tall man with a commanding glance, he enjoyed the complete confidence of his troops despite his stringent rule ("he carried lightning and thunder on his tongue"). He was a generous host to the officers in his staff. His letters to Axel Oxenstierna were published in 1893.

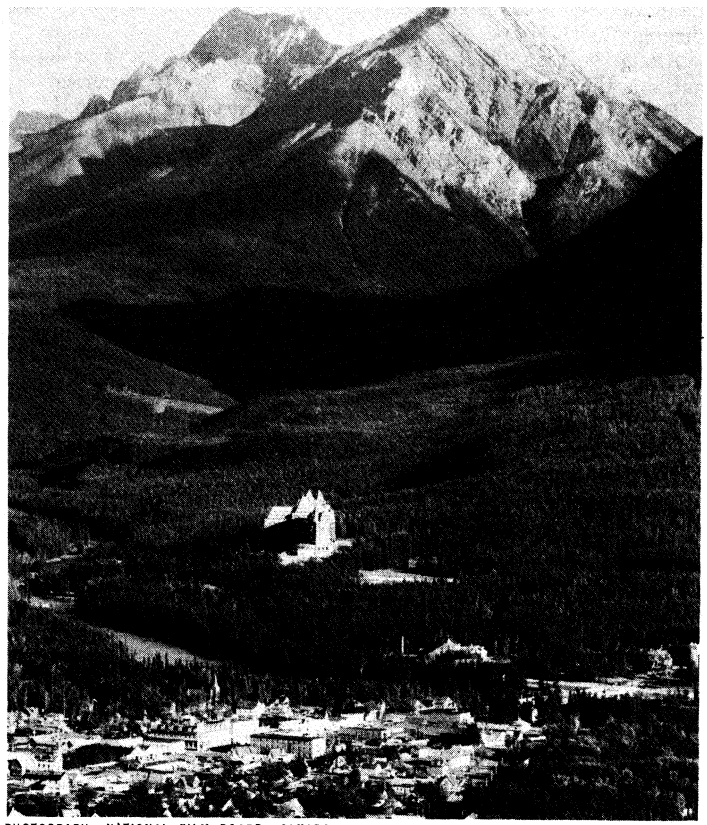
BANERJEA, SIR SURENDRANATH (1848–1925), Indian nationalist leader. was born in Calcutta, of a distinguished Kulin Brahman family, on Nov. 10, 1848. Educated at Doveton college, Calcutta. he passed the examination for the Indian civil service (1869). When the civil service commissioners tried to exclude him on the ground that at Calcutta university he had wrongly stated his age (which he had reckoned from the date of conception, in accordance with Hindu custom), he successfully appealed to the court of queen's bench against their decision. He was posted to Sylhet but in 1874 was found guilty of procedural irregularities and dismissed (he considered himself a victim of racial discrimination). He turned to teaching and journalism and took a leading part in the foundation of the Indian association in 1876. As editor of the Bengalee and as an effective speaker at the annual sessions of the Indian national congress. which first met in 1885, he exercised a powerful influence over Indian nationalist opinion. He was a firm believer in representative government and in the efficacy of "constitutional" methods of agitation for it—such as the making of speeches at political meetings and the drawing up of petitions. He opposed the extreme methods advocated by B. G. Tilak and the non-co-operation advocated by M. K. Gandhi. He welcomed the Montagu-Chelmsford reforms (1919) as a step toward responsible government, accepted office as minister for local self-government in Bengal and was knighted (1921). He held office from 1921 to 1924, but was bitterly attacked by extreme nationalists as a turncoat and was defeated at the polls by a Swarajist (Independence) candidate. In his autobiography, ***A** Nation in **Making*** (1925), he criticized non-co-operation as a sterile policy. He died at Barrackpore on Aug. 6. 1925. (KE. A. B)

BANFF, a popular resort in the Rocky mountains of Alberta, Canada. Pop. 2.518 (1956). On the main line of the Canadian Pacific railway and on the Trans-Canada highway, it is the principal centre for the Banff National park of Canada, which has an



PHOTOGRAPH, NATIONAL FILM BOARD, CANADA

THE VILLAGE OF BANFF. BEHIND THE LARGE RESORT HOTEL RISES GOAT MOUNTAIN

area of 2,585 sq.mi. The town stands at an altitude of 4.538 ft. It is 84 mi. W. of Calgary and 40 mi. E. of Lake Louise. with which it shares a large tourist patronage. Besides the scenic beauty of the region the town's chief attractions are its two government-controlled hot sulfur springs. Its annual winter sports carnival and ski tournament draw visitors and competitors from other parts of Canada and from the United States. In summer the Banff School of Fine Arts. operated by the extension department of the University of Alberta, conducts its classes there. (JN. H. W.)

BANFF, royal and small burgh, seaport and czpital of Banffshire. Scotland. Pop. (1961) 3,329. It is a seaside resort situated on rising ground on the west bank of the mouth of the river Deveron, about 46 mi. N.W. of Aberdeen by road. A road bridge connects it with the town of Macduff on the east bank. The fishing trade is important and local industries include a distillery, a brewery, an iron foundry and boatbuilding.

The first charter was granted to Banff by Malcolm IV in 1163 and further privileges were conferred by Robert Bruce in 1324 and Robert II in 1372. On a hill near the sea a castle was built (1750) on the site of an old one which had been a royal residence and where, in 1613, James Sharp (*q.v.*), the archbishop, was born. Duff house, immediately adjoining the town, was a seat of the duke of Fife. It was built in 1740–45 after designs by Robert Adam. In 1906 the duke presented the whole estate to the towns of Banff and Macduff.

BANFF NATIONAL PARK, in southwestern Alberta. Canada. was established as that country's first national park in 1885 when an area of 10 sq.mi. surrounding the newly discovered hot mineral springs at Banff (*q.v.*) was set apart for public use.

The park. which includes some of the finest alpine scenery in the Canadian rockies. has been enlarged to more than 2,500 sq.mi. It is noted for its wildlife; game animals protected there include bighorn sheep. Rocky mountain goats, elk, moose, deer, and black and grizzly bears.

More than '750,000 tourists visit Banff park annually, and ac-

commodations for them range from luxury hotels at Banff and Lake Louise to camp grounds and trailer parks at various points throughout the park.

Along the scenic highway connecting Banff and Jasper national parks is the Columbia ice field, the largest in North America.

BANFFSHIRE, a county of northeastern Scotland, is bounded on the north by Moray firth, on the east and south by Aberdeenshire and on the west by Moray and Inverness-shire. Its land area is 630 sq.mi.

Physical Features.— The county forms a long, narrow triangle, based in the north on the 30 mi. of coast and tapering southwestward to a point near Cairngorm (4,084 ft.). The southern, Highland half of Banffshire is roughly the basin of the Avon, along with part of the catchment area of the upper Deveron. The northern half is broadly the rolling lowland between the lower Spey and the lower Deveron rivers.

In the extreme south is part of the granitic Cairngorm plateau reaching more than 4,000 ft., with an annual rainfall exceeding 60 in. and distinctive arctic-alpine vegetation. Great ice-carved corries, with cliffs of more than 1,000 ft., cut into the mountain sides, which drop within a mile from 4,000 ft. to the glaciated ribbon lake of Loch Avon at 2,400 ft. The granite runs east into the Ben Avon massif at 3,600–3,800 ft. The steep face of these high tablelands look across a series of lower, dissected plateaus planed mainly across rocks tightly folded and metamorphosed in the Caledonian orogenesis. Very marked belts of quartzite and limestone strata run northeast-southwest among the slates, phyllites and mica schists of the Moine and Dalradian formations. There are further granite intrusions, and also younger, unaltered sediments of Old Red Sandstone in the northeastern and northwestern corners and in pockets inland around Cabrach and Tomintoul (the highest village in the Highlands at 1,160 ft).

The lower plateau surfaces form very broadly a series of east to west steps descending toward the firth and dissected by southwest-northeast longitudinal valleys like Glenrinnes and Glenfiddich, though there are also transverse valleys. The hills, with summit planes of 2,000 to 2,400 ft., have a mean annual rainfall of about 40–45 in. and are dominated by heather moorland. Intermediate, upland plateau surfaces give green rolling hills with summit planes at about 800 ft and 1,500 ft. The lowest and most recent surfaces are the post-glacial raised beaches, giving important stretches of well-drained, readily warmed and easily cultivated soils. Mean annual rainfall is about 30 in. The spring tends to be dry with cold easterly winds, and sea fogs are not uncommon; from July the rainfall increases; sunshine remains adequate (August mean more than 4 hours) and harvests are usually successful. There are cliffs at Troup Head, in schists amid an Old Red Sandstone belt. Fulmar petrels breed there, while in the Cairngorms there are red deer, wildcats, golden eagles, snow buntings and dotterels. (A. T. A. L.)

History.—Banffshire has many relics of early man. In several parishes are remains of stone circles; stone cists and urns, sometimes ornamented, have been found. Stone axes, three of which are reputed the finest of their kind in Scotland, have been unearthed, also flint arrowheads, scrapers, saws and borers.

There were many conflicts with the Danes. A sculptured stone near St. Moluogs' church, Mortlach, is believed to mark the site of Malcolm II's victory in 1010. Malcolm III established a bishop's see at Mortlach about 1063, whence it was translated to Aberdeen by David I.

Of medieval relics, the ruined castles of Findlater, Auchindown and Balvenie are noteworthy. both in setting and story. The ruined churches of Gamrie, which dates from the 12th century, and of Deskford, with its large sacrament house, deserve mention. The most impressive ecclesiastical structure in Banffshire is Cullen church. which is still used; it was made collegiate about 1543 by Alexander Ogilvy of Deskford and Findlater, whose monument is in the church. Robert Bruce's second queen died at Cullen in 1327; he gave five pounds annually "for the support of a chaplain for ever to serve in the parish church of the Blessed Mary of our burgh of Cullen, for the weal of the soul of the whilom most august Princess Elizabeth." Of the Carmelite friars, established in the royal burgh of Banff by Bruce, only slender documentary records remain.

After the Reformation parts of Banffshire clung to their Catholic traditions. The Enzie, with its centre at Preshome, mas long the stronghold of Scottish Catholicism. In Glenlivet was established at Scalan in 1717 a seminary which until its removal to Aberdeenshire in 1799 trained more than 100 priests during the penal times. Scalan was purchased in 1946 by Scots Catholics for preservation as a valued memorial.

In 1594 the "Popish earls" Huntly and Errol defeated a royal force under the earl of Argyll in Glenlivet. Viscount Dundee maneuvered in Banffshire before the battle of Killiecrankie (1689), receiving valuable aid from John Grant of Ballindalloch. The shire was strongly Jacobite; many lairds who rebelled in 1715 had sons who supported Prince Charles Edward in 1745. (W. R. Hu.)

Population and Administration.— In 1961 the population was 46,400. The chief burghs, all small ones. are Banff (3,357), the county town, Buckie (7.666). Keith (4,208) and Macduff (3,479), the others being Cullen, Dufftown (*qq.v.*), Aberchirder, Aberlour, Findochty, Portknockie and Portsoy. Banff and Cullen are royal burghs. Banffshire together with the shires of Aberdeen and Kincardine, forms a sheriffdom, and there is a resident sheriff substitute at Banff who sits also at Keith. The county returns one member to parliament.

Industries and Communications.— Farming, fishing, boatbuilding. distilling and limestone quarrying are the main industries of Banffshire. Breeding and fattening of cattle, particularly of the Aberdeen Angus variety, is carried on throughout the county and there is extensive dairy farming. The earls of Fife and the earls of Findlater, afterward earls of Seafield, did much to reclaim lands for farming. It was a Seafield who, in 1846, received the honorary gold medal of the Highland and Agricultural Society of Scotland for his great plantations of useful trees in this and neighbouring counties.

The cod and herring fisheries are important at Buckie, while fishing is also carried on from the harbours of Macduff, Gardenstown and Whitehills. There are valuable salmon fisheries along the coast and on the Spey and Deveron, while trout fishing in most of the streams is among the tourist attractions. Distilleries are numerous throughout the county; the one at Glenlivet is particularly well known. Near Keith there are woolen mills reputed for quality hut there was need in the early 1960s for more light industries to absorb labour released by the mechanization of farming and the decline in fishing. Limestone is extensively quarried for crushing, while slates (for roofing) and granite have also been worked in the past. A variety of veined serpentine is known as Portsoy marble.

Bus and restricted rail services connect the chief towns and villages and provide communication with Aberdeen, Elgin, Nairn and Inverness. (R. J. Cu.)

BANG, BERNKARD LAURITS FREDERIK (1848–1932), Danish veterinarian, whose most noted work was the discovery in 1897 of *Brucella abortus,* the germ responsible for contagious abortion in cattle, was born at Soro. Sjaelland, on June 7, 1848. He studied at the University of Copenhagen and at the Royal Veterinary and Agricultural college there, graduating from the latter in 1873. Having obtained his M.D. in 1880, he began teaching in the same year at the Royal Veterinary school, of which he eventually became director. He was also for many years veterinary adviser to the Danish government.

Bang brought to veterinary medicine a wide knowledge of general pathology and bacteriology, and he and his pupils made the Danish school a model for the whole world. By his own researches he probably contributed more than any of his contemporaries to the advancement of veterinary science, and much of his work was

of the highest importance for preventive medicine. Bang's discovery of *Brucella abortus* (Bang's bacillus) assumed even greater importance when it became known that the organism was a not uncommon cause of brucellosis (*q.v.*) in man. Equally important were Bang's work on bovine tuberculosis and his method of control of the disease by isolating affected cows and removing their newborn calves and feeding them milk of healthy animals. His name is also associated with important researches on smallpox vaccination, actinomycosis, bacillary necrosis, swine fever and swine erysipelas, and Johne's disease. He died at Copenhagen on June 22, 1932. (W. J. Bp.)

BANG, NINA HENRIETTE WENDELINE (1866–1928). Danish economist and political writer, the first woman cabinet minister; was born in Copenhagen on Oct. 6, 1866. Graduating M.A. at Copenhagen in 1894. she married, in 1895, an outstanding Danish Socialist. Gustav Bang (d. 1915). Devoting herself not only to Social Democratic politics and journalism but also to economic studies, she began, with the support of Danish and foreign scientific funds. to produce a comprehensive work on dues in the Sound, finally published as *Tables of Shipping and Goods Transport on the Sound, 1497–1660,* 3 vol. (1906–33). She became. a member of the *landsting* (upper house) in 1918. In 1924. when Thorvald Stauning formed the first Danish Social Democratic government. she was appointed minister of education. Nina Bang died in Copenhagen on March 25, 1928.

BANGALORE, the capital city of Mysore state. India. and headquarters of Bangalore district, lies 3,113 ft. above sea level. 183 mi. W. of Madras (219 mi. by rail). Pop. (1961) 907,627. It consists of the closely built old town, with modern suburbs laid out on a gridiron pattern north and south, and to the east a sprawl of military cantonments, the largest in India south of the Krishna river.

Bnngalore is one of the two centres of the University of Mysore and the seat of 17 of its constituent and affiliated colleges. conducting the work of the science, medical, engineering, veterinary, agriculture and commerce faculties. There also are the Indian Institute of Science (1911). the Raman Research institute (1943; named after the Indian Nobel prize physicist), the National Aeronautical Research laboratory (1960) and a division of the National Power Research institute (1960). Among other prominent buildings are the Vidhana Soudha or legislature (1956), the maharaja of Mysore's palace and the museum. The city is well provided with open spaces, among them a botanical garden, the Lalbagh.

Bangalore is at the focus of south India's road system: it lies on the Varanasi-Cape Comorin national highway and is connected by main roads with Bombay and Madras; and with Kerala via Mysore city. the Nilgiris and Palghat gap. It is a busy junction on the Southern railway, linking the broad-gauge line from Madras with an extensive metre-gauge system to the north and west. Hindustan airport, 5 mi. E. of the city centre, is served by scheduled flights to and from Bombay, Madras, Mangalore and Colombo.

Beside the large aircraft, railway coach and machine tool installations run by the central government. Bangalore has state-owned electrical! telephone, porcelain and soap factories; and commercially operated concerns producing pharmaceuticals, tex-. tiles. radio parts, glassware, leather and footwear, agricultural implements and paper.

Bangalore's warm, subhumid climate, giving pleasant winters and tolerable summers. make it a popular place of residence. But water supply for its increasing industrial and domestic needs presents a problem, as its 36 in. annual average rainfall is inadequate and there are no rivers nearby.

The nucleus of modern Bangalore was "hele Bangaluru" (old Bangalore), the settlement around a mud fort built in 1537 by a petty chief, Kempe Gowda. Early in the 17th century it was captured by Shahji (Sahu) Bhonsla. father of Sivaji (*q.v.*), founder of the Maratha dynasty. Sivaji sold it to the Hindu rajah of hlysore in 1687. In 1758 it was granted as a *jagir* or fief to Hyder Ali (*q.v.*), afterward usurper of Mysore. During his reign the fort was rebuilt in stone. It was captured in 1791 by the British under Lord Cornwallis, but restored the next year to Hyder's son Tipu Sahib (*q.v.*). He dismantled the fort; but following his final defeat in 1799 and the restoration of the old Hindu dynasty, it was rebuilt by Purnaiya, the state minister. Bangalore was the headquarters of the British caretaker administration from 1831 to 1881; and from 1881, when the rajah was again restored, to 1947, when India became independent, the British retained the city's administrative and military quarters.

BANGALORE DISTRICT abuts the southwestern (Madras) border of Mysore state. Pop. (1961) 2,505,598. Area 3,081 sq.mi. The main crops are millets and oilseeds. (G. K. GH.)

BANGKA (BANKA), an island of Indonesia off the east coast of Sumatra across Bangka strait which is only 9 mi. wide at its narrowest point. On the east, Gaspar strait. wider and island-studded, separates Bangka from the island of Billiton. Bangka. with its dependencies, is a division of the province of south Sumatra. It is 136 mi. long and 69 mi. wide and its area, with a few adjacent islands, is 4,611 sq.mi. The soil is somewhat dry and stony, but the greater part of the surface is covered with tropical vegetation. The virgin forest has almost disappeared because of mining and agricultural operations. The hills, of which Maras in the north is the highest (2,293 ft.), are covered with vegetation to their summits. Bangka resembles the Malay peninsula geologically, with formations of granite, Silurian and Devonian slate, frequently covered with sandstone, laterite (of small fertility) and alluvium. The granite runs from west-northwest to south-southeast in short, irregular hill chains. These are generally near the east coast; hence the rivers of the west coast are longer. There are no volcanoes and the number of anchorages along the coast is small. The rivers run in deep valleys; in their upper courses, and some in their lower courses, the rivers form extensive marshes. Nevertheless, many are navigable for nearly 20 mi. because they were once inlets of the sea, and are tidal for some distance. The Selan and the Jarin rivers are the largest. The climate is hot, especially from May to August (southeast monsoon), but at night in the hills it is quite cool. The mean annual rainfall is 118 in. and the average number of rainy days is 159. The wet and cooler season is from Xovember to February (northwest monsoon).

Bangka is one of the chief tin-producing centres of the world. Tin mining is a government monopoly. The ore is found in many river alluvial deposits and in the alluvial strata on the slopes of small hills; it is worked in open cuts and by dredgers that work in the sea just off the coast. The labour ordinarily is supplied by about 15,000 contract coolies, mainly Chinese, who work under government supervision, and electrical power is used extensively. The tin for consumption in Indonesia is smelted on Bangka and the remainder in the U.S. and the Netherlands.

The population was (1956 est.) 279.597 including foreign Asians, mostly Chinese. The inhabitants (Muslims) are mainly immigrant Malayan peoples. The aborigines are represented by only a few primitive hill tribes, probably of mixed Malay origin and akin to the Bataks of Sumatra, who live by hunting, fishing and the collection of forest products. Rice, pepper (grown by Chinese), gambier (for dyeing and tanning), coffee and coconut palms are cultivated. There are more than 1,000 mi. of roads fit for wheeled traffic, but no railways. The island has radio connection with Java and frequent air and steamship communication nith Java and Sumatra and with Singapore and Penang. The chief town is Pangkalpinang (pop. [1957 est.] 43,322), on the east coast, and the chief port is Muntok (pop. [1956 est.] 25,430), at the northern end of Bangka strait. The sultan of Palembang. in Sumatra. ceded Bangka to the British in 1812, but in 1814 it was exchanged with the Dutch for Cochin in India. Japan occupied Bangka in 1942; it was reoccupied by the Dutch in March 1946 and became part of the independent Republic of Indonesia in 1949. (J O. M. B.)

BANGKOK (KRUNGTHEP), the capital, sole metropolis and chief port of Thailand (Siam), is situated on the banks of the Maenam Chao Phraya. 25 mi upriver from the Gulf of Siam. Bangkok proper, the municipality of Krungthep, lies on the east bank of the river, in the province of Phra-nakhorn. Pop. (1957

est.) 1,204,894. The municipality of Thonburi (*q.v.*), across the river on the west bank and connected with Krungthep by three modern bridges, is in effect part of metropolitan Bangkok.

The climate of Bangkok is hot throughout the year, the average temperature being 83.8" F. during the hot, dry months of March and April, and 79.3" F. during the cool season from November through February. Most of the annual rainfall, averaging about 60 in., occurs during the rainy season from May through October. Monthly mean relative humidity seldom falls below 60%.

Prior to 1767, Bangkok was merely a fortified outpost guarding the approaches to Ayutthaya (*q.v.*). In that year the old capital was destroyed by Burmese invaders, and Taksin, a popular general of Chinese extraction who became king after driving out the Burmese, established the national capital at Thonburi. During his reign (1767–82), a large Chinese settlement and market serving the capital grew up on the east bank of the river. When Taksin was succeeded as king by Rama I, the founder of the Chakkri dynasty, the present royal city was established on the site of the Chinese trading centre, which was removed to Sampheng, a quarter which is still the Chinese centre of Bangkok. The position of the new royal city in a loop of the river afforded natural protection on three sides, and a wall and moat were constructed on the exposed eastern flank.

Throughout the 19th century, Bangkok was an eastern Venice, for most of the populace lived in houses on stilts at the edges of canals and the river, and trade mas carried on in sampans, floating shop houses, and junks anchored in the river. The first major street outside the royal city, New road, was built in 1864 to connect the palace with the foreign consulates down the river. From 1880 to 1910 most of the city's population gradually shifted from the waterways to live by newly planned roads. Several of the remaining canals still carry considerable commercial traffic.

The Chinese, whose immigration was deliberately encouraged by the 19th-century Thai kings, formed at least half of Bangkok's population until the late 1930s. In the late 1950s approximately 40% of the population of Krungthep was of immediate Chinese descent, 20% being China born, and the corresponding proportions for Thonburi municipality were 28% and 16%. Ethnic Chinese dominate both commerce and industry.

Bangkok is the communications hub of Thailand. All railways radiate from the capital, and most roads either begin there or start irom one of the rail lines beginning there. The city lies at the centre of the extensive canal network linking the three main rivers of the central plain, and much of the rice produced there is milled in the Bangkok area prior to shipment. Teak logs from the forests of northern Thailand are floated down-river to the city for milling and export. About 50 rice mills and 130 sawmills line the river and the larger canals of metropolitan Bangkok, which is also Thailand's chief centre for light manufacturing industry. Bangkok handles most of the nation's foreign trade, and dredging operations completed in 1954 make the city docks directly accessible to large ocean-going vessels. The government-owned port of Bangkok has modern installations which can handle ten 10,000-ton vessels simultaneously. Don Muang airport, 12½ mi. N. of the city, is the starting point of all internal routes, and its international traffic is the heaviest in southeast Asia.

One of the most colourful cities of the east, Bangkok attracts about 10,000 tourists annually, and offers television, night clubs, air-conditioned theatres and several excellent hotels, There are three big parks where the many fairs and festivals are held, and where kite fighting, one of Thailand's national sports, takes place. Bangkok's national theatre, the Silpakorn, presents traditional Thai dancing, drama and music. The exhibits of the national museum nearby include archaeological finds from earlier civilizations in Thailand, ***objets d'art*** of all kinds and historical lore.

Overshadowing Bangkok's other attractions are the several hundred Buddhist temples, with their glittering tile roofs and flashing spires. Among the finest are Wat Pho, which houses a huge gilded reclining Buddha and, along the gallery around the inner sanctuary, a fabulous array of early bronze Buddhas; Wat Suthat, noted for its carved and inlaid doors, early frescoes, and the giant swing, a survival of Brahmanic state ceremonies; and Wat Benchamabopit, an exquisitely detailed marble temple, whose central Buddha is a reproduction of the famous Phitsanulok image. The Grand palace, covering more than a square mile, provides an architectural feast, with its castellated walls and profusion of halls built at different periods. It includes the Dusit throne hall and Wat Phra Kaeo, both built by Rama I. The former ranks among the finest examples of traditional architecture, while the latter serves as the king's chapel and contains a sacred jasper image of the Buddha.

Thailand's facilities for higher education are almost all centred in Bangkok. University instruction is offered in liberal arts at Chulalongkorn university; in law and applied social science at Thammasat university; in agriculture, forestry and fisheries at Kasetsart university; and in medicine at the University of Medical Sciences. The capital also has a college of education, a modern technical institute, an academy of fine arts with university status, and the national service academies. Bangkok is the home of the Siam society, founded in 1904 for the study of Thai culture, history and science. Over 25 daily newspapers are published in the city, including several in Chinese and English.

Bangkok is the permanent home of the United Nations Economic Commission for Asia and the Far East (ECAFE), regional headquarters of several UN specialized agencies, and a centre for international conferences. In 1955 it became headquarters of the Southeast Asia Treaty organization (SEATO). In addition to the Chinese, the foreign community includes about 10,000 Indians and Pakistanis, approximately 2,000 Europeans, over 1,500 Americans, and representatives of every east Asian country. If not the most cosmopolitan city of Asia, it is at least an uncommonly diverse meeting ground of east and west. (G. W. SK.)

BANGOR, a municipal borough in County Down, N.Ire., lies on the southern side of Belfast lough, 12 mi. E.N.E. of Belfast by road or rail. Pop. (1961) 23,865. Area 3.7 sq.mi. Bangor is a seaside resort with a small harbour and rapidly expanding light industries. It is the headquarters of the Royal Ulster Yacht club. Its history began about 555 when St. Comgall founded a monastery. This was to become the most celebrated seat of learning of its time and two of Comgall's pupils, St. Columban and St. Gall, between them founded a number of monasteries on the continent of Europe. (St. Gall gave his name to one of the cantons of Switzerland.) Repeated incursions by Danes from the 9th century laid waste the settlement. It was partially rebuilt by St. Malachy in the 12th century and part of his stone church still stands. David Bailie Warden, a native of Bangor, fled after the rebellion of 1798 and later became U.S. ambassador to France and a member of the French Academy. (T. B. G.)

BANGOR, cathedral city and municipal borough (1883) of Caernarvonshire, Wales, is located at the northern entrance to the Menai strait, at the junction of the coast road with that from Capel Curig and Bettws-y-Coed. Pop. (1961) 13,977. Area 2.5 sq.mi. It is a notable educational centre. The University College of North Wales, founded there in 1884, became a constituent college of the University of Wales in 1893. Other educational facilities include a North Wales Counties' Training college which had an unusually distinguished succession of students in its early days, Church of England training college and a school for divinity, an Independent college and a Baptist college and a museum of Welsh antiquities. The boys' county school was founded in 1557 as the Friars' grammar school.

A depression running northeast-southwest divides the town into

two parts, Upper and Lower Bangor. Upper Bangor, on the northwest ridge, contains the buildings of the University college (1911, with later additions) and the residential quarter. On the southeast side of the valley, in Lower Bangor, are the chief shopping centre and the cathedral. small and lon. inheriting traditions dating from the days of Celtic Christianity. St Deiniol—to nhom the cathedral is dedicated—founded a religious house there in the early 6th century. Successive structures were restored or rebuilt after destruction by Normans, by King John and by Owain Glyn Dwr (Owen Glendower, *q.v.*). In 1866 Sir George Gilber Scott undertook the reitoration of the cathedral The building, cruciform in design, comprises an aisleless choir, transepts and nave nith aisles. A central tower projected by Scott was abandonrd because of the danger of overloading the foundations. Early settlement in the neighbourhood is indicated by a British camp supposedly of Roman date on a height overlooking the tonn. Slight traces of a Norman moat and bailey castle can be found on a rock near the Friars' school. Bangor showed markedly conservative tendencies during the civil wars and nas the centre of the Bangorian controversy (*q v.*) in the early 18th century. The Congregationalist influence of the slate quarry workers of the neighbourhood during the 19th century made the town a centre of religious and educational movements.

Port Penrhyn nearby exports slates from the Penrhyn quarries near Bethesda. Penrhyn castle. the seat of Lord Penrhyn, stands in a large park northeast of Bangor. It is a modern copy, in Penmon marble, of a Norman castle.

BANGOR, a city of Maine, U.S., 76 mi. N E. of Augusta; port of entry situated on the Penobscot river, 60 mi from the ocean. and seat of Penobscot county. (For comparative population figures *see* table in MAINE: *Population*) In 1604 Samuel de Champlain, the French explorer, was the first nhite man in the Bangor vicinity. The first permanent settler. Jacob Buswell, came from Massachusetts in 1769. Originally called Kenduskeag Plantation (1776) and later Sunbury (1787) the place was incorporated as a town in 1791; and was probably narned Bangor by the Rev Seth Noble after the tune name for one of his favourite hymns. Bangor received a city charter in 1834 and adopted a council-manager form of government under a charter of 1931.

The town was captured and briefly occupied by the British in the War of 1812 and made its greatest economic strides after the treaty of Ghent. which ended that war. Lumberinn and shipping were the main industries. and the city became one of the leading lumber ports in the world before the American Civil War. In the last half of the 19th century, Bangor became an important commercial. manufacturing and trade centre. The city's varied manufactures include pulp and paper, lumber products, footnear. tools, extracts, cashets, canoes and sporting goods.

Bangor supports a symphony orchestra and a community concert association. The Bangor Theological seminary (Congregational, incorporated 1811) was established there in 1819. At Orono nine miles up the river, is the University of Maine (founded 1865). (G. A. BI.)

BANGORIAN CONTROVERSY, a theological-political dispute in the Church of England arising from the publication in 1717 of *A Preservative Against the Principles and Practices of the Non-Jurors* by Benjamin Hoadly, bishop of Bangor. Hoadly contended that the civil government had jurisdiction over ecclesiastical affairs only when these endangered national peace, as when it deposed clergymen who refused allegiance to William and hlary. Later, in a sermon. he identified the church with the Kingdom of Christ. which is not of this world, and denied that officers of the earthly institution act literally with Christ's authority.

The lower house of convocation. already antagonistic to Hoadly's latitudinarian principles, received its committee report on the *Preservative* and sermon charging that the bishop had subverted all government and discipline in the church and had impugned the authority of the government in church affairs. But before further action could be taken, the government prorogued the convocation, which was not to meet again for over a century (*see* also CONVOCATIONS OF CANTERBURY AND YORK).

Over 60 writers, including the later famous William Law, joined in the controversy that raged for three years over such issues as permitting religious dissent, excluding thousands of English Christians from the national church, and using the sacraments as a test for political office.

BIBLIOGRAPHY.—*The Works* of *Benjamin Hoadly, D D.* (1773) contains a bibliography of the pamphlets of the controversy *See* also John Overton and Frederic Relton, *The English Church From the Accession of George I lo the End of the Eighteenth Century (1906)*; John Stoughton, *Religion in England Under Queen Anne and the Georges* (1878); Norman Sykes, *Church and State in England in the Eighteenth Century* (1934). BANG'S DISEASE: *see* BRUCELLOSIS.

BANGUI, the capital tonn of the Central African Republic, lies on the west hank of the Ubangi river at its bend southward nhere the Chad routes enter the Congo basin. Pop (1959 est) 79 634 of whom 2 740 were Europeans The town is built below wooded hills nhich extend from the dense forest where the river widens below the Mission rapids In its new African quarters, to the nest in the marshy plain, the inhabitants are grouped by race and religion The European town began among the mango trees on the hank but has spread up the slopes Development has been in three directions. along the river, where are the port and industrial quarter; westward along the Mbaiki road. where European plantations were established; and at the junction of hill and plain, where are the administrative buildings, modern residences, mission, hospital and civil aviation quarters. Industries include soap making. breweries and norkshops. but the tonn is mainly commercia The river port developments include a quay 1 300 ft. long and an oil port downstream. Exports include cotton, timber, coffee. sisal and cabbage palm *(Oreodoxa)*; imports are building and industrial materials. Bangui is a hub of communications being connected to the naternay and the roads to Cameroun, Chad and upper Ubangi After 1960 these were supplemented by a railway to Chad and an airport. (J. D)

BANGWEULU, the African name. meaning "large water," for a lake and extensive swamps in Northern Rhodesia which are part of the Congo river system. They lie at an altitude of 3 760 ft. above sea level and cover a triangular shaped area of about 3,800 sq mi The lake, at the northwest corner is 45 mi long by 24 mi broad It is shallow and has two inhabited islands. Chisi and Mbabala. A much larger island Chilubi, at the edge of the swamp, has 6,000 inhabitants of the Babisa tribe.

The swamp is the result of excessive vegetation growth over a section of low gradient along the course of the Chambezi river, n-here it acts as a check to the annual flooding, releasing the flood waters slowly through a myriad of channels and lagoons, to issue as the Luapula river where the slope increases again.

There are many low islands in the swamp and a very large area knonn as the Lunga bank which used to support about 5,000 of the Unga tribe until they were flooded out about 1940. A survey showed that the disaster was the result of the choking of a main channel and a new channel, now known as the Debenham cut. was dug in 1949 and has resulted in the emergence of the Lunga bank once more and improved facilities for navigation by power launches.

For a long time. fishing in the lagoons of the swamp has been a native industry. and dried fish (valued at more than £100.000 or $280.000 annually) is exported to the industrial centre of the copper belt about 100 mi. to the nest.

The vegetation responsible for the swamp consists of a high *Phragmites* reed growing just above mean water level, a zone of the well-known papyrus at water level and a floating grass, known as hippo-grass, in deeper water.

David Livingstone was the first white man to visit the lake in 1868 and he died on its southern border in 1873. Since then its history has been a peaceful one and the swamps are still rarely visited except by government officials and missionaries.

See F Debenham, *Study of an African Swamp (1952) and The Way to Ilala* (1955). (F. DE)

BANHA (BENHA), a market town of lower Egypt and capital of Al Qalyubiyah governorate, lies 29 mi. N. of Cairo by rail. Pop. (1957) 46.834. It has profited by its position at the bridging point of the Damietta branch of the Nile on the direct route from Cairo to Alexandria through the central delta

provinces, and has become an important road and railway junction, with rail connections to Az Zaqaziq and the canal zone, Zifta, Tanta and the northern delta, Minuf and Shibin al Kawm in the west. It stands between the Nile and the Tawfiqi canal in the heart of a highly fertile cotton-growing region. Unlike many other provincial capitals in the delta it has not attracted industries and those established relate to the surrounding agricultural produce: cotton ginning, some small cotton and flax mills, vegetable dehydrating and canning. Close by are mounds indicating the site of the ancient town of Athribis. (A. B. M.)

BANIA (Sans. *vanijya*, "trade") is an Indian caste designation generally used for any Indian moneylender or trader throughout northern and western India though, strictly speaking, many trading communities are not banias and, conversely, some banias are not traders.

Banias are supposedly descended from the twice-born "clean" Vaisyas of the fourfold division of Vedic society, with Brahmans and Kshatriyas above them and Sudras below The innumerable bania subcastes are based on place of origin, special customs, ancestral claims and local gods.

In religion banias are Vaishnavas or Jains. They are strict vegetarians, teetotalers and orthodox in observing ceremonial purity. They are noted for ostentatious display. Trained as small boys in the family business to be skilful calculators of compound interest, they early acquire the acquisitive personality—hoarding, multiplying money by charging high rates on distress loans to the ignorant and impecunious, and worshiping their account ledgers. Gujarat has produced many famous bania bankers (seths), as has Rajasthan, original home of the omnipresent Marwari businessmen. India's great leader Mohandas Gandhi belonged to a Gujarati bania caste.

See D. R. Gadgil, *Origins of the Modern Indian Business Class*, an Interim Report, Institute of Pacific Relations (1959); H. B. Lamb, "Business Organization and Leadership in India Today," *Leadership and Political Institutions in India*, ed. by R. Park and I. Tinker, pp. 251–265 (1939). (H. B. L.)

BANIM, JOHN (1798–1842) and **MICHAEL** (1796–1874), two brothers, Irish novelists of peasant life. Sons of a small trader and farmer. both were born in Kilkenny, John on April 3, 1795, Michael on Aug. 5, 1796. John studied drawing in Dublin for a while and subsequently taught it in Kilkenny. Shortly afterward he went to Dublin where he earned a living by journalism. In 1821 his blank verse tragedy, *Damon and Pythias*, was produced at Covent Garden; John married, moved to London, and continued to live by journalism. In 1825 there appeared *Tales, by the O'Hara Family*, written in collaboration with Michael, who had studied for the bar but had had to take over his father's business. All three *Tales*—*two* by John, *The Fetches* and *John Doe*, and one by Michael, *Crohoore of the Bill* Hook—are remarkable for their intensity of imagination and melodramatic invention and were immediately successful, John being dubbed "the Scott of Ireland." He followed them with *The Boyne Water* (1826), a novel about the Jacobite wars in Ireland, and in 1826 a second series of *Tales* appeared, containing *The Nowlans*, a story of passion, guilt and religious fervour displaying a degree of insight which makes it possibly John's best novel. *The Croppy* (1828) is mainly by Michael, then an active supporter of Roman Catholic emancipation. The plot is conventional melodrama but the background, the Wexford rebellion of 1798, is memorably handled. Despite an intensely painful spinal malady, John continued to produce novels, including *The Denounced* (1830), *The Mayor of Windgap* (1835) and *The Smuggler* (1831), in which he attempted an English theme with some success. 111-health eventually led to poverty, however, and in 1833 subscriptions were opened for him in England and Ireland. He returned to Kilkenny in 1835, was awarded a civil list pension, and died on Aug. 13, 1842. *Father Connell*, the Banims' happiest book, published the same year, was almost entirely by Michael, who continued to write but in 1873 retired to Bootèrstown, near Dublin, where he died, Aug. 30, 1874.

The Banims, primarily storytellers. delighted in complication, mystery. coincidence and dramatic confrontation. Their plots are often lurid to a degree and their dialogue preposterous, but in spite of this the romantic imagination that informs their work is sombre and powerful. As delineators of Irish life in their time they cannot compare. however, with William Carleton (*q.v.*).

See P. J. Murray, *The Life of John Banim* (1857). (A. CR.)

BANISTER, JOHN (*c.* 1630–1679), English violinist and composer, the first organizer of public concerts in England, was born in London, *c.* 1630. He learned the violin from his father, and in 1660 joined the king's band of 24 violinists. After further training in France he became leader of a select group of 12 court violinists, and. later, of the 24. In Dec. 1666 he was ordered to submit to instruction from Louis Grabu, the French musician, who had become master of the king's music, and in March 1667 Grabu replaced him as leader of the king's band. Pepys records Banister's fury at this eclipse by foreign musicians, from which he never completely recovered, although he continued in the royal service.

Banister made musical history on Dec. 30, 1672, when he gave at his own home the first public concert for which admission was charged (one shilling). His reputation as a composer rests on his songs for plays by Dryden, Wycherley, Shadwell and other Restoration dramatists and especially on his settings of four of Ariel's songs for Shadwell's adaptation of *The Tempest* (1673). He died in London, Oct. 3, 1679, and was succeeded at court by his son John (d 1735), who continued in the service of James II, William and Mary and Queen Anne, and was also principal violinist at the Italian Opera in Drury lane. (B. P.)

BANI SUWAYF (BENI SUEF), a town of upper Egypt 77 mi. S. of Cairo by rail and capital of a governorate of the same name, stands on the west bank of the Nile, which there hugs the bluffs marking the edge of the Eastern desert. West of the town the valley is nearly 12 mi. wide and intensively cultivated. Pop. (1957) 70,100. The town is connected by a branch line with Al Fayyum to the northwest. Ten miles to the south is the site of ancient Heracleopolis Magna. The principal industry is cotton weaving.

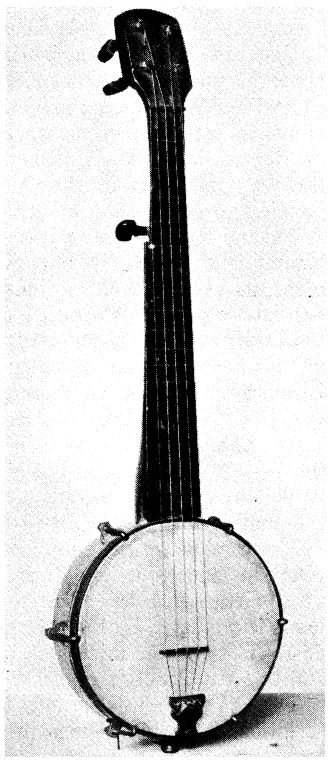
BANI SUWAYF GOVERNORATE consists of the flood plain of the Nile and extends about 45 mi. north to south in the Nile valley and averages 12 mi. in width, most of this being west of the Nile. To the east, between the Nile embankment and the foothills are stretches of barren gravel. It is bounded north by Giza governorate and south by Al Minya governorate, with the desert edge of the valley to the east and west. Pop. (1960) 859,000. Area 510 sq.mi. Famous antiquities include the 4th-dynasty pyramid of Seneferu at Maydum, 12th-dynasty pyramids of El Lahun and Hawara (Senusret II and Amenemhet III) and the ruins of Heracleopolis Magna, capital of middle Egypt during the 22nd dynasty. The river flood plain there is densely settled and among the most effectively irrigated parts of the Nile valley. About 67% of the occupied population is engaged in agriculture and the principal crops grown (in order of importance) are: cotton. maize (corn), wheat, millet, onions and dates. Perennial irrigation water is supplied from the Al Ibrahimiyah canal, Egypt's largest irrigation canal which parallels the Nile between Asyut and Giza. Industrial activities are limited to the processing of agricultural commodities, principally flour milling and cotton ginning. Alabaster is quarried near Bani Suwayf, the capital, which is the only large town. (A. B. M.)

BANJAK ISLANDS (BANYAK ISLANDS), a group of more than 60 small isles north of Nias and west of Sumatra, Indon. The largest island is Great Banjak, or Pulau Tuangku (meaning "chief's residence"), about 20 mi. long. The population is a mixture of settlers from north and central Sumatra (Achinese and Menangkabau) and from Nias. Most of them are Muslims. Agriculture (rice and root crops) is largely for subsistence, but copra is exported. (J. O. M. B.)

BANJA LUKA, a town in the people's republic of Bosnia-Hercegovina, Yugos., lies on the Vrbas. river, a tributary of the Sava. Pop. (1961) 50,463. A railway line links the town with Belgrade, Zagreb and Sarajevo and a good road connects it with the Trieste-Ljubljana-Zagreb-Belgrade highway. The name is derived from ban, the title of the head of the Bosnian medieval state, and from the fact that the town is built at the head of a valley. The town was first mentioned by this name in connection with the Bosnian Ban Radislav (1295). Under the Turks Banja

Luka was an important military centre. They built many mosques, of which Ferhadiya is the most beautiful. The town is the seat of a Roman Catholic and also an Orthodox bishop. There is an important annual stock and produce fair, at which horse racing is a popular feature. In the town there exist the remains of Roman forts as well as of the Roman baths. In the 19th century Banja Luka played an important part in the uprisings of the Bosnian feudal lords against Istanbul as well as in the rebellions of the Serbs against the Turks (see BOSNIA-HERCEGOVINA: History). In 1941 Banja Luka—the town and the province—were made a part of the axis-created kingdom of Croatia, and during the course of World War II partisans liberated Banja Luka three times. The town, which has an industrial section built after World War II, has a machine tool factory, a steel mill, a power station, cloth, cereal and tobacco factories, a brewery and corn mills. (V. DE.)

BANJO, a stringed instrument originating in North America, apparently associated in the first place with the Negro population, who may have given it its name from the bandju of the Congo region. It is the only modern stringed instrument of western origin that employs a stretched skin membrane as the soundboard or belly, The circular body consisted originally of a wooden drumlike shell, open at the back, to which the skin, or vellum, was nailed. Later a "flesh-hoop" was introduced, with screw stretchers for varying the tension of the "head." The long neck, or handle. is "stepped in" to the body, its shank fitting into mortices at the top and bottom. Here again, the banjo is unique among western instruments in using this primitive stick-and-resonator construction, where all resistance to the pull of the strings is taken by this central member.



BY COURTESY OF THE METROPOLITAN MUSEUM OF ART, THE CROSBY BROWN COLLECTION OF MUSICAL INSTRUMENTS, 1889

AMERICAN BANJO, 19TH CENTURY

The first banjos had either nine or seven strings; six of the full-speaking length of the neck (about 24 in.), and from one to three shorter strings, about 16 in. long, the tuning pegs and nut being mounted on a thickening of the neck on the bass, or thumb, side nearest the player. These short high-pitched strings were played only by the thumb and were intended to complete the contour of melodies or upper parts of chords without awkward shifting of the hand. The strings were of gut, and passed from the pegs over a pressure bridge to a violin-type tailpiece or string holder at the bottom end. The neck was unfretted, like a violin finger board.

The popularity of the banjo among English-speaking peoples reached a climax in the last two decades of the 19th century, when the number of strings became more or less standardized at five, four of the ordinary length plus the short chanterelle or thumb string, tuned thus:

but sounding an octave lower than the written notes. Of these, the fourth (C) string was of silk, covered with fine copper wire, and the others usually of gut (later sometimes replaced by silk, with an occasional first string of steel). Tuning was by means of violin-type pegs mounted in the flat head. Later a screw adjustment was used to keep the pegs bearing properly without either jamming or slipping.

About 1890 the more sophisticated zither-banjo was introduced. The chief difference was in the body, the vellum being of smaller diameter and mounted in a frame suspended within a hollow-box resonator with a closed back, which threw the sound forward. The finger board was fitted with fixed metal frets, like the guitar, the number eventually reaching as many as 24. Metal frets began to be used on the ordinary banjo at about the same time. Since zithers use steel wire for strings 1, 2 and 5, they were fitted with "machine heads"; *i.e.*, scre -and-wheel adjusters for the pegs. A peculiarity of these machines was that they included a sixth peg for symmetry, although it was permanently useless. The *chanterelle* was tuned from the head, the unused part of the string passing beneath the finger board, to emerge at the fifth fret. This enabled the old excrescence and peg to be done away with, and the neck became streamlined for greater technical facility.

Other sizes of the banjo have included at various times the piccolo banjo, tuned an octave higher, the hanjeaurine, a fifth higher, and bass and contrabass instruments. Banjo-type instruments have also been adapted to the pitch and tuning of the mandolin, with four pairs of steel strings; and, in miniature form. to the ukulele (*q.v.*), with four single gut strings. The tenor banjo is common. It is rather shorter than the standard instrument, with four strings only, tuned in fifths at viola pitch. The traditional technique is plucking with the fingers, but with modern instruments the plectrum is also used. (E. HA.)

BANK, SAVINGS: see SAVINGS BANK.

BANKER MARKS (MASONS' MARKS) cut upon the dressed stones of a building (though rarely seen on tracery or carved work), were apparently the personal trade-marks of masons working the stone at the banker (Ital. *banco*), or stonecutters' bench. They are to be seen widely in Europe from Roman times to the present, but most frequently on medieval work: when they were cut on the exposed face; since then they have been cut on the bed to avoid disfigurement. In Germany the same marks were also used by important masons as personal badges. These personal marks were often passed from father to son. From the 16th century, when others besides working masons were admitted to masonic guild lodges, they too were allocated banker marks, which were entered in the lodge register.

Davis, "Masons' Marks as a Guide to Architectural History," *Journal of the British Archaeological Association,* vol. xvii (1954); L. F. Salzman, *Building in England Down to 1540 (1952).* (E. M.J.)

BANK FOR INTERNATIONAL SETTLEMENTS. The Bank for International Settlements (B.I.S.) at Basel, Switz., was created with two purposes in mind: (1) to provide an agency to handle the payment of reparations by Germany after World War I (see REPARATIONS); and (2) to establish an institution for co-operation among the central banks of different countries (see CENTRAL BANK). The objects of the bank were stated as follows in its statutes:

> to promote the co-operation of central banks and to provide additional facilities for international financial operations; and to act as trustee or agent in regard to international financial settlements entrusted to it under agreements with the parties concerned.

A committee drew up the basic documents creating the bank in 1929; the Hague conference of 1930 confirmed them, and the bank started business on May 17, 1930. The bank's capital was fixed at 500,000,000 gold francs, but of this amount only 25% had been paid up by 1961. Subscription of the capital was originally guaranteed in equal parts by the central banks of Belgium, France, Germany, Great Britain and Italy and by two banking groups, one Japanese and the other from the United States. The shares issued to the Japanese banking group were repurchased in 1952 by those of the European central banks which originally guaranteed the subscription of the bank's capital, the Japanese government having renounced in 1951 all its rights concerning the bank. In the early 1960s most of the U.S. shares were in European hands and

the membership of the *B.I.S.* extended to all European central banks except that of the U.S.S.R.

At the outset the bank was to receive reparations payments from Germany and allocate the proper share to each creditor nation. Under the impact of financial crisis, however. Germany's payments of the reparations provided for in the Young plan (see YOUNG, OWEN D.) were suspended by the Hoover moratorium of July 1931. The bank was active in attempts to counteract the crisis and participated in the granting of international credits. Within the framework of the Young plan, it had made certain investments in Germany the total of which has remained, from 1932, unchanged at about 300,000,000 gold francs. An agreement was concluded in 1953 with the Federal Republic of Germany for the settlement of these investments.

Excluding the amount of long-term government deposits of 228,909,375 gold francs and corresponding investments under the Hague agreements of 1930, the total of the bank's balance sheet on March 31,1961, was 3,973,433,539 gold francs. The bank's own funds, consisting principally of the paid-up capital, the reserves and the major part of the provisions for contingencies, amounted to about 342,000,000 gold francs. These funds were held in gold, both to provide the high degree of liquidity necessary for an institution in receipt of central-bank funds and as a basis for the bank's manifold transactions in terms of gold. Under its statutes the bank may undertake only operations that are in conformity with the monetary policy of the countries concerned. Its operations have been short term, both as regards its granting of credits and its purchases and sales of gold and foreign exchange. The bank showed a profit every year, except for 1945. Dividend payments were suspended in that year but resumed in 1951.

In 1947 the bank was appointed agent for the execution of the first intra-European compensation agreement initiated under the Marshall plan (*q.v.*), and in 1950 it became agent for the Organization for European Economic Cooperation in respect of the European Payments Union (*q.v.*). After the liquidation of the latter at the end of 1958, the bank was appointed agent of the Organization for European Economic Cooperation (later of the Organization for Economic Cooperation and Development) in respect of the European monetary agreement.

In 1954 the bank was invited to undertake certain functions as depositary under the terms of an act of pledge concluded with the high authority of the European Coal and Steel Community (*q.v.*).

The monetary and economic department of the bank is responsible for the preparation of the bank's annual report. It has also made special studies, at the request of the central bank concerned, of the economic and financial position of a number of special areas, including Austria, France, Italy and the sterling area.

The B.I.S. is thus an international bank which makes its services available to the European central banks, a centre for economic and monetary research and consultation and a technical agent for the execution of certain specific agreements. The founders of the bank attached great importance to the permanent contacts which the bank would make possible between officials of different central banks. Apart from the war years, the central-bank governors who are members of the board of directors have held regular monthly meetings in Basel, and the governors of other central banks have attended annual meetings and made other occasional visits. See also INTERNATIONAL PAYMENTS; MONETARY AGREEMENT.

(P. J.)

BANK FOR RECONSTRUCTION AND DEVELOPMENT. INTERNATIONAL. This bank was established as an international organization, designed to help finance sound projects for reconstruction and development — reconstruction in war-devastated countries and development of world economic resources, particularly in underdeveloped regions. Commonly known as the World bank, it had its origin in preparations for postwar international financial and economic co-operation which culminated in the United Nations Monetary and Financial conference held in July 1944 at Bretton Woods, N.H. Out of this conference, at which 44 nations were represented, grew two complementary, but separate, organizations: the International bank and the International Monetary fund.

The principal purposes of the bank, set forth in its articles of agreement (charter), may be summarized as follows:

1. To assist in the reconstruction and development of its member countries by facilitating the investment of capital for productive purposes, thereby promoting the long-range growth of international trade and improvement of standards of living.
2. To promote private foreign investment by guarantees of and participations in loans and other investments made by private investors.
3. When private capital is not available on reasonable terms, to make loans for productive purposes out of its own resources or funds borrowed by it.

The bank came into existence on Dec. 27, 1945, when its articles of agreement were signed by 29 governments. The bank officially began operations at its headquarters in Washington, D.C., in June 1946. By June 30, 1961, the bank had 68 member countries. The largest of these, in terms of capital subscribed, were the United States, the United Kingdom, France, Germany, India, Japan, Canada, China (Formosa) and the Netherlands. Also among the bank's members were many smaller or less wealthy countries such as Iceland, Israel, Lebanon, Luxembourg, Afghanistan, Libya, Denmark, Ghana, Yugoslavia and the Latin American republics.

The bank's charter authorized it to engage in the following types of financing: it may lend funds directly, either from its capital funds or from funds which it borrows in private investment markets; it may guarantee loans made by others; or it may participate in such loans. Loans may be made to member countries directly, or to any of their political subdivisions, or to private business or agricultural enterprises in the territories of members. When the member government in whose territory the project is located is not itself the borrower, however, this member government, its central bank or some comparable agency acceptable to the International bank must guarantee the loan.

Lending Operations **and** Policies. — The first loans by the bank were made for urgently needed reconstruction in several European countries whose economies had been damaged by the war. By 1949, however, emphasis in the bank's lending had shifted to developing productive facilities and resources, particularly of the bank's economically less developed member countries. The bank became an important source of long-term capital for this economic development. By June 30, 1961, the bank had granted 292 loans totaling the equivalent of $15,790,000,000 (net of cancellations and refundings through subsequent loan operations) to 57 countries and dependent territories. The distribution of the loans is indicated by the fact that 35 loans were made to Africa, 85 to Asia and the middle east, 6 to Australia, 60 to Europe and 106 to Latin America.

The bank obtains its funds for loans from paid-in capital subscription, from borrowings in the capital markets of the world and from net earnings. Sales to investors of portions of the bank's loan portfolio and repayments of loans to the bank, while representing only a recovery of funds originally derived from one of the above sources, have the same effect as new capital in that they reduce the amount the bank would otherwise have to obtain from other sources. The capital markets of the world provide the largest amount of funds for loans. By June 30, 1961, the bank's outstanding funded debt amounted to $2,228,500,000. On the same date loan funds available from other sources were $1,651,000,000 from capital subscriptions; $379,000,000 from operations; $1,451,500,000 from repayments and sales of loans.

Since the bank is primarily a source of long-term loan capital, its resources have been used largely to assist in the financing of investments for which large amounts of long-term loan capital are required and for which this method of financing is appropriate. For this reason, a large part of the bank's portfolio consists of loans to publicly and privately owned utilities, such as undertakings for the generation and distribution of electric power, railroads, ports and inland waterways, airlines and airports, telecommunications, and pipelines.

The bank has also assisted in the financing of highways and roads. It has made loans to industrial enterprises, to development banks which in turn finance industrial activities, for the expansion of agricultural production through farm mechanization. irrigation and flood control, and land clearance and improvement, crop

processing and storage, livestock development and forestry.

Loan Procedure. — Among the conditions that must be met before the bank can consider a loan are the following, derived from the articles of agreement: (1) the projeet for which the loan is sought must be for a productive purpose; (2) the borrower must be unable to obtain the loan elsewhere on reasonable terms; (3) there must be a reasonable prospect that the borrower, and the guarantor also, if there is one, will be able to meet the obligations contracted under the loan; (4) if a member government is not the borrower, the loan must be guaranteed by the member in whose territory the project is located. The bank established the procedure, before making a loan, of sending bank representatives to the prospective borrowing country to make an investigation on the spot. This investigation ordinarily covers the country's economic and financial position generally, as well as the specific project for uhich the loan is sought.

As a matter of general policy the bank lends only for specific projects, and only for the cost of imported material and equipment and services obtained from abroad. Disbursements are usually made directly to the supplier. But, if special circumstances warrant, it departs from this general policy and makes loans to finance the foreign exchange expenditures of a broad general development program, or, alternatively, it agrees to the use of loan proceeds to cover investment expenditures incurred in the borrowing country itself.

As contemplated in its charter, one of the important aspects of the bank's lending operations is that in general the proceeds of its loans can be used for purchases in all member countries and certain other countries and not only in the country whose currency is used in a particular loan operation.

In the early years of its operations, bank loans were used almost exclusively for purchases in the United States because other countries did not have available significant amounts of capital goods for export. As productive capacity recovered throughout the world, this situation changed radically and borrowers from the bank obtained a great deal more of the goods they needed from sources outside the United States. The bank obtains the particular currency needed by the borrower either out of its own holdings in that currency or by purchasing it with other currency that it holds. In the first case the loan is repayable in the currency provided to the borrower; in the second case the loan is repayable in the currency used by the bank to buy the currency furnished to the borrower. By June 30. 1961, total disbursements amounted to the equivalent of $4,319,500,000, of which $2,709,500,000 was repayable in U.S. dollars and the remainder in 31 other currencies.

Technical Assistance. — In addition to financial assistance, the bank, as a service to its member countries, furnishes them with technical assistance, partly in connection with its loan operations and partly independently of them.

Between 1949 and 1961 the bank organized 20 survey missions to 8 countries in the western hemisphere, 6 countries in Asia, 5 countries in Africa and 1 European country. The purposes of these missions were to survey the development potentialities and problems of the countries and to make recommendations designed to assist the governments in formulating long-term development programs. The reports of these missions were published by the bank and, in most instances, by the government of the country that had invited the mission.

The bank also provides technical assistance to its member countries in different forms and with more limited objectives. It has stationed special representatives in several countries in Latin America and Asia to assist the authorities in the preparation of development or public investment programs. It has organized, in co-operation with the Food and Agriculture Organization of the United Nations, missions to survey the possibilities of agricultural development in four countries, and co-operated with the governments of member countries in the preparation of special surveys.

Economic Development Institute. — As a further extension of its technical assistance activities, the bank established, in 1955, the Economic Development institute, a training centre for government officials of underdeveloped countries and territories concerned with the formulation and execution of development policies and programs. The institute offers an intensive six-months seminar course in which economic problems of underdeveloped countries are analyzed, to a large extent on the basis of the bank's experience with its member countries, and in which the participating officials who come from government departments, central banks and public development institutions have an opportunity to exchange their own views and experiences.

International Development Association. — In Sept. 1960 the bank established the International Development association (IDA) as an affiliate. Its purpose is to provide loans to less-developed countries on more flexible terms than those of conventional loans. IDA and the bank are administered jointly to assure effective co-ordinatiop.

Capital Structure. — The bank's capital is derived from subscriptions by its member countries to shares of capital stock. Members' subscriptions in general are in proportion to their economic resources. When the bank was established, its authorized capital was $10,000,000,000. Of this amount, only 20% was paid in by member countries, partly in gold and partly in their national currencies; 80% remained on call and served to support the bank in its borrowing operations in the money markets of the world. By mid-1959, with the funded debt of the bank approaching $2,-000,000,000, it was clear that the continued high rate of demand on the bank for development loans meant that it would frequently be in the market to borrow funds for its operations. Therefore on Sept. 15, 1959, as a result of action by the bank's board of governors, the authorized capital was increased to $21,000,000,000, and each member was asked to double its subscription, the additional capital to remaiq on call. The effect was to provide massive additional guarantee resources to serve as backing for the bank's sales of bonds and notes to investors. In addition, several members of the bank made further increases in their capital subscriptions and 10% of these increases were paid in cash. As a result, subscribed capital rose from $9,500,000,000 to $20,093,000,000 by June 30, 1961. Of this amount, roughly $1,651,000,000 was available to the bank for its operations.

Marketing Operations. — The bank began its borrowing operations in 1947 when two bond issues totaling $250,000,000 were publicly sold in the United States. In the bank's earlier years, the U.S. investment market was the principal source of borrowed funds. Progressively, however, the bank succeeded in broadening the market for its issues on an international scale. There were 46 issues of bonds and notes outstanding by June 30, 1961, aggregating $2,228,500,000; they were held by investors in about 40 countries. The outstanding bonds and notes were denominated in U.S. dollars, Belgian francs, Canadian dollars, deutschemarks, Netherlands guldens, pounds sterling and Swiss francs. In the United States the bulk of trading in the bank's bonds is on the over-the-counter market, but they are also quoted on the New York Stock exchange and on all major exchanges in Europe. The maturities and other terms affecting the bank's issues are determined by market conditions and the requirements of the bank.

In addition to direct borrowing, the bank sells to financial institutions securities it receives from borrowers in connection with its loans. In this way, as well as by its own borrowings, the bank acts as a channel for the flow of private capital into international investment. By June 30, 1961, the bank had sold or had agreed to sell to investors the equivalent of $1,013,000,000 from its loan portfolio.

Interest Charges and Financial Results. — Interest and other charges are on a nondiscriminatory basis without distinction among borrowers. The total interest rate charged on loans consists of three components: the estimated cost of borrowing to the bank; a 1% commission which the bank levies for the purpose of creating a special reserve against losses; and a small fraction out of which administrative costs are met. Between 1953 and 1960 the interest rate varied between 4% and 6¼%.

In the fiscal year 1960–61, the bank's net income amounted to $63,000,000. This income was placed in the supplemental reserve against losses on loans and guarantees bringing that reserve to $408,000,000; loan commissions were credited to the bank's special reserve, increasing that reserve to $193,500,000. By June 30,

1961, the total of their reserves had risen to $601,500,000.

Administrative Organization. — The bank's charter provided for an administration composed of a board of governors, executive directors, a president and staff. All powers of the bank are vested in the board of governors consisting of a representative appointed by each member. This board meets normally once a year.

The board of governors delegated most of its powers to a board of 18 executive directors. Five executive directors are appointed by the five largest stockholders. The other executive directors are elected by the governors of the remaining member nations for two-year terms. Each executive director is entitled to cast the number of votes of the member or members by which he was appointed or elected. Each member country is entitled to 250 votes plus 1 vote for each share of capital stock held.

The president of the bank is ex officio chairman of the executive directors. He is selected by the executive directors. and is the chief executive officer of the bank. Subject to their general direction on questions of policy, he is responsible for the conduct of the business of the bank and for the organization of its staff. In June 1961 the bank's operating staff consisted of approximately 700 persons representing about 50 different nationalities.

The first president of the bank was Eugene Meyer, who held office from June to Dec. 1946. He was succeeded by John J. McCloy, who took office in March 1947 and held the presidency until June 1949. Eugene R. Black became president of the bank on July 1, 1949.

(JN. H. A.; X.)

BANK HOLIDAYS, in the United Kingdom, are those days which by the Bank Holidays act of 1871 and by a supplementary act of 1875 are observed as holidays in all banks in England, Wales, Northern Ireland and Scotland. They are not statutory public holidays; their observance, however, is no longer limited to banks. Before 1830, the Bank of England closed on approximately 40 saints' days and anniversaries, but in that year the number was reduced to 18 days. In 1834 they were further reduced to four—Good Friday, May 1, Nov. 1 and Christmas day. By the act of 1871, the following were constituted bank holidays in England, Wales and Ireland: Easter Monday, the Monday in Whitweek, the first Monday of August, Dec. 26 if a weekday and, by the act of 1875, Dec. 27 when Dec. 26 falls on a Sunday; and by the Bank Holiday (Ireland) act. 1903, March 17, St. Patrick's day (or, if that is a Sunday, the next following day) as a bank holiday for Ireland. In England, Wales and Northern Ireland. Christmas day and Good Friday are bank holidays under common law. In Scotland. New Pear's day, Christmas day, Good Friday, the first Monday of May, the first Monday of August or, if Christmas day and New Year's day fall on a Sunday, the next Monday following are bank holidays under the act of 1871. By the same act it was made lawful for the sovereign to appoint by proclamation, any day to be observed as a bank holiday throughout the United Kingdom or any part of it, or to substitute another day. These powers rnay be exercised in Northern Ireland by the governor in council and it has become customary for July 12 (the anniversary of the battle of the Boyne, 1690) to be appointed a bank holiday in Northern Ireland. Bank holidays are observed in customs and excise establishments under the Customs and Excise act, 1952.

BANKING. In this general survey of banking several aspects of the subject are examined in separate sections, as the following outline indicates:

I. History of Banking
  A. Ancient and Medieval World
  B. Modern Europe
  C. Great Britain and the Commonwealth of Nations
  D. The United States
II. Principles of Banking
  A. Creation of Deposits
  B. Reserves and the Limitation of Deposit Creation
  C. Central Banking in Relation to Commercial Bank Reserves
  D. Theory of the Banking Firm
  E. Development of Banking Principles
III. Practice of Banking
  A. Deposits
  B. Lending Operations
  C. Investment Practices
  D. Relations With Other Financial Institutions

In a discussion of banking it is essential at the outset to distinguish between commercial banks and central banks. Central banks may be viewed as "bankers' banks." They are lenders of last resort to the commercial banks; they regulate the monetary and credit conditions of the countries in which they operate; they act as banks and fiscal agents to governments; and, usually, they have a monopoly of the note issue. In the exercise of their function as lenders to banks and to governments, they create credit and thus fulfill the essential function of a bank. In many countries they serve both as central banks and as commercial banks. *(See* also CENTRAL BAKK.)

A modern commercial bank provides a wide variety of services to its customers. It usually accepts savings deposits. It may maintain a vault with individual safe-deposit boxes available to its customers on a rental basis, and it may serve as an administrator of trust funds. A commercial bank may also offer a broad range of other services such as the purchase of travel tickets, the disbursement of dividend payments for corporations and the payment of amounts due on behalf of its customers. These activities impose great re'sponsibilities on banks and require highly developed skills; but they involve relatively little theoretical analysis.

The commercial bank, in its characteristic role, makes loans, accepts deposits and provides a means of payment by the transfer of deposits from one account to another. Its most distinctive feature, however, is its power to create credit and thus add to the money supply by lending sums larger than the sums deposited with it in actual cash. To describe and define a commercial bank as a bank that has the distinctive power to create money and credit excludes from this category a number of institutions frequently referred to as banks. Such a definition excludes savings banks (*q.v.*), investment banks *(see* INVESTMENT BANKING), trust companies *(see* TRUST COMPANY) and other institutions in the financial field that lack the power to create credit. Institutions of this latter type are not discussed here apart from incidental reference.

I. HISTORY OF BANKING

There exists little historical evidence as to the nature of banking operations before the 13th century. For the earlier period, the distinction between commercial banks and other types of banks is difficult to make with certainty. As A. P. Usher points out, it is very difficult in this early period to differentiate between the activities of dealers in coin and in bullion from the activities of banks. Money-changers and bankers were often viewed as one and the same. Although there are very early records of loans and of deposits it does not follow that they constitute evidence of banking activity in the sense in which we have defined it. Such early transactions may not have involved the creation of credit but may well have been limited to the acceptance of deposits and the making of loans. Thus what follows must be read in the light of these views and in the light of the commonly held opinion that commercial banking evolved only in the later medieval period from the much older functions of moneylending and money-changing. Central banking, of course, is of comparatively recent origin and development.

A. ANCIENT AND MEDIEVAL WORLD

There are records of loans by the temples of Babylon as early as 2000 B.C. As temples were considered sacred places under the special protection of the gods, they were not likely to be robbed, and thus were considered safe depositories. Companies of traders

also carried on banking functions connected with the buying and selling of goods. A notable example in ancient Babylon was the Igibi bank that flourished in the 6th century B.C. In Greece by the 4th century B.C financial activities were being performed by the temples, by public bodies and by private firms. The latter accepted deposits, made loans, tested and changed coins and arranged credit transactions between cities to avoid the movement of specie. The Greek system was imported into Hellenistic Egypt and also influenced Rome. Roman law recognized payment in bank in discharge of a debt, and in the 2nd century A.D. public notaries were appointed to register such transactions.

The decline of trade after the breakup of the Roman empire made banking facilities less necessary, and at the same time usury laws imposed restraints on lending. Records from Genoa and other Italian cities go back to the 12th century. but it is not until the 14th century that a large volume of evidence is available. By this time the trade of Europe had developed along two main lines. (I) the Italian cities and, later. Bruges, Antwerp and the towns of the Hanseatic league became centres of warehouse trade and developed local banking systems; and (2) at certain centres of communications there grew up the great international fairs, of which those of Champagne (an ancient province of France) are the most famous, with their own system of finance through ambulatory bankers and also their function as centres for international clearings. Distinct from both these systems were the international financiers who were concerned, among other things, with the finance of the international wool trade, the collection and transmission of papal revenues and making loans to kings and princes.

When deposit banking re-emerged in medieval Europe, the only way of transferring bank credit was through oral instruction by the debtor and acceptance by the creditor in the presence of witnesses. Holograph documents (written in the hand of the principal) came into use in the 13th and 14th centuries, and by the second half of the 14th the nonnegotiable bill of exchange (*q.v.*) was firmly established. But the use of any document serving the purpose of the modern check was only occasional before 1500, and the legal doctrine of negotiability evolved only gradually from the 16th to the 18th centuries.

At the Champagne fairs the value of purchases appears to have been recorded in the books of a fair banker as they were made. At the end of the fair the various book debts were offset. so far as possible, against one another, and balances settled either in cash or by drawing a bill payable at the next fair. By the 15th century the fairs were also serving as clearinghouses for payments arising in other forms of trade; for example, the Cely family in England was taking bills payable at the fairs in payment for wool exported through the Calais staple; and similar methods seem to have been used at the other important fairs. The system, though ingenious and highly important in its day, involved neither deposits nor credit creation, so that it did not contribute much to the evolution of modern banking.

The same might be said of the great merchant bankers who dominated high finance during the middle ages and the Renaissance. The men of Piacenza were the first Christian bankers to challenge the monopoly of the Jews in this field. They were soon displaced by others from Siena, Lucca and Florence, but the name of Lombard clung to them all and was adopted for the street in London where money-lenders carried on their business. The Bardi and Peruzzi of Florence and the Frescobaldi of Lucca played a big part in the state finances both of England and France. but their power was broken by Edward III's repudiation of his debts in 1339 followed by the confiscation of their property in France and by a revolution in Florence. Native financiers such as William de la Pole in England and Jacques Coeur in France were unable for long to meet the growing needs of their governments, and the 15th century saw a second period of Florentine financial power. This time the outstanding family was that of the Medici, who laid the foundations of their immense fortune as financial agents for the papacy. The Florentines suffered again from defaults and confiscations and gradually lost ground to Genoese and Germans One other name must be mentioned, that of Fugger, the family who were the greatest moneylenders of the 16th century: they played a vital part in the election of Charles V as emperor and supported him through all the vicissitudes of his reign and also had extensive dealings in Germany, Italy, Hungary, Spain, the Netherlands and England. However, they too suffered the common fate of their kind. meeting their ruin in the crash of the Spanish state finances at the end of the 16th century. These and other smaller firms dealt to some extent in borrowed money, though they relied largely upon their own capital; they had little interest in ordinary commercial finance and were agents for the raising of government loans and the management of the resulting exchange transactions rdther than bankers in the modern sense.

The sedentary bankers of the Mediterranean cities, especially Venice. Genoa and Barcelona, were, the direct ancestors of modern commercial bankers. They accepted deposits which mere regularly transferred from one account to another in payment for commercial debts; the normal method of transfer was by an entry inscribed by the banker in his books in the presence of both debtor and creditor. In the 14th and 15th centuries Venetian bankers allowed customers to overdraw their accounts, but this was regarded as an abuse. Failures among them were common, and as early as 1356 there were proposals for the establishment of a public bank. It was not until 1587, however, that the Banco della Piazza di Rialto was founded in Venice. It was to receive deposits in coin, to transfer them from one account to another and to pay bills of exchange, but it was not to make loans nor, since it had no legal source of revenue, did it pay interest on deposits. Its services were performed free: expenses being a charge to the state. The constitution was not strictly observed, and the bank did make loans, especially to the government, and got into difficulties as a result. It was to meet the difficulties of the state that the Banco Giro was formed in Venice in 1619, the creditors of the government agreeing to accept payment in the form of credits with the new bank. The two public banks were fused in 1638 and continued to operate until 1806. Other important public banks dating from the middle ages were the Casa di San Giorgio in Genoa (1107) and the Bank of Deposit in Barcelona (1401).

The Bank of Amsterdam, founded in 1609, was similar in constitution to the Banco della Piazza di Rialto. Its original functions were to accept and transfer deposits, to exchange coins. to purchase specie and uncurrent coin for the mint and to act as a clearinghouse for bills of exchange. All bills of more than 600 florins were to be made payable at the bank. but this law was not strictly enforced. The overdrawing of accounts was prohibited, but the bank did give credit to certain institutions, including the city of Amsterdam and the Dutch East India company. By the beginning of the 18th century bank deposits had become inconvertible. but for many years they circulated freely and the bank maintained their value by prudent management. However, it suffered severely in the French wars at the end of the 18th century and was liquidated in 1819. Similar banks were founded in other Dutch cities and, in 1619, at Hamburg.

B. Modern Europe

France. — At the beginning of the 18th century. when banking in England was making rapid progress, France suffered from the failure of the financial system of John Law (*q.v.*). The Banque Générale was founded in 1716 as a bank of deposit and also of note issue, but its constitution provided that notes were to be issued only against the deposit of coin and that no credit was to be given to private customers. However, the bank soon became involved with the rest of the system and these principles were disregarded. In 1717 the Compagnie d'Occident was formed to trade with Louisiana, and two years later it was transformed into the Compagnie des Indes. with a monopoly of foreign trade and the right to farm the customs. Law now proposed to repay the public debt by making the creditors of the state shareholders in the company. In 1718 the bank. then known as the Banque Royale, had its notes made legal tender. It became more and more involved with the company. issuing a great volume of notes in order to support the value of the company's shares in the market. These reckless issues helped to produce a violent inflation and to bring

about the collapse of the system in 1720. The holders of Law's notes lost heavily and the idea of a note-issuing bank was discredited in France for many years to come.

A number of banks doing discount and deposit business were founded during the 18th century, but there was no bank of issue until 1776. Then Blanchaud (a Swiss) and Clouard (a Scot) formed the Caisse d'Escompte, which made overgenerous advances to the government and was liquidated in 1793. In 1796 a syndicate of private bankers in Paris founded the Caisse des Comptes Courants, and shortly afterward the Caisse d'Escompte de Commerce was formed by a commercial group. Both were taken over by the Bank of France in 1800 and 1803, respectively. *(See* BANQUE DE FRANCE.)

The Bank of France was founded in 1800 and received its basic constitution in laws of 1800, 1803, 1806 and 1808. The management was entrusted to a governor and 2 deputy governors appointed by the head of the state and a council of 15 regents and 3 auditors elected by the general assembly of the 200 largest shareholders. The business of the bank was to be note issue, receipt of deposits on current account, collection and discount of bills of exchange and dealing in precious metals. It also acted as banker to state and was at times called upon to make large advances to the government. In 1803 the bank was given a monopoly of note issue in Paris. A number of provincial banks of issue were founded under the July monarchy, but all their notes were discredited during the 1848 revolution, and the Bank of France arranged amalgamations with them. Thenceforward (apart from a brief interval in which other notes circulated in Savoy after its cession to France) the Bank of France was the sole issuing body. There was no legal requirement of a reserve. A maximum issue was fixed by law, but the restriction had little meaning: in times of difficulty the bank always asked for and obtained an increased issue. Notes were made legal tender and inconvertible in 1870, but full convertibility was restored in 1878. The law of 1808 empowered the bank to establish branches, and several were set up between 1830 and 1840. Under a law of 1857 the bank could be compelled to set up at least one branch in each *département,* and at the end of the century about 120 branches had been established.

For many years the Bank of France was practically the only institution offering facilities for the transfer of current-account balances. The check was little used and was not fully recognized in French law until 1865. Hence, the circulation both of notes and of bills of exchange was much greater than in England. The bank discounted very small bills, but normally insisted on three signatures and so remained predominantly a bankers' bank. It always maintained a very large reserve. The law of 1803 placed France on a bimetallic standard, and the bank commonly cashed its notes in silver. After 1875, however, gold was the only metal suitable for export, and the bank strove to build up its gold reserve, which, by 1907, accounted for about four-fifths of the total reserves.

The Bank of France always came freely to the assistance of other banks in time of crisis but appears to have made little effort toward credit control during the first half of the 19th century. The private banks and later the joint-stock banks did chiefly a discount business and, in the absence of an organized discount market, rediscounted directly with the central bank. The Bank of France had neither the powers nor the opportunities for open-market operations of the type being developed by the Bank of England, and it was not until 1857 that its discount rate was freed from the restriction of the usury laws. Under these circumstances the bank could vary only the time allowed for payment of the bills which it would discount, and this was done on occasions. Aiter 1857 discount rate was used as an instrument of policy, but only sparingly. In an effort to minimize fluctuations the bank bought gold at a premium. sold at a premium (until 1897) or availed itself of the bimetallic law to refuse gold for export when it thought such action expedient. On the other hand the bank gave assistance to foreign institutions on a number of occasions when it appeared that this course would minimize the ultimate pressure on France; the transactions with the Bank of England in 1839, 1890 and 1907 are outstanding examples of this practice.

The only other banking development before 1848 was the foundation of a large number of small banks doing discount (lending) and deposit business. These banks remained numerous throughout the century, but their importance declined greatly in face of competition from the big joint-stock banks. The first of these, the Comptoir National d'Escompte de Paris, was founded as an emergency measure in 1848 and was followed by the Crédit Industriel et Commercial (1859), the Crédit Lyonnais (1863) and the Société Générale de Crédit (1864). These banks set out to develop the check system and attracted deposits by opening a nationwide network of branches and offering attractive rates of interest. They participated to some extent in the issue of industrial shares, but their advances to industry were very limited; by far the most important part of their business with industry and commerce was in the form of discounts.

A few institutions on the periphery of the banking world deserve mention. The Crédit Foncier and the Crédit Mobilier were both formed in 1852; both did a limited deposit business, but the former was chiefly an agricultural mortgage company and the latter an investment bank. The Crédit Mobilier, after a spectacular career, was liquidated in 1867, but the Crédit Foncier remained an important part of the French financial system. The successors of the Crédit Mobilier were the *banques d'affaires,* or business banks, of which the first was the Banque de Paris et des Pays Bas (1872). These firms were chiefly concerned with the marketing of industrial securities and, although they accepted deposits from firms with which they had dealings, they did not seek deposits from the general public.

Germany. — There were few banks of any significance in Germany before the middle of the 19th century. The Bank of Prussia, forerunner of the Reichsbank, did only a small and old-fashioned business until 1846, when it received a new constitution and began to grow rapidly. The old Hamburg *Giro* bank continued its business until absorbed by the Reichsbank in 1875. The Seehandlung, formed as a state-owned trading company by Frederick the Great, acted as banker to the Prussian government and did a limited general business. There were wealthy merchant bankers engaged in international finance, and the Rothschilds were extending their activities from Frankfurt am Main over the whole of Europe; but the local private banker was still doing only a small and primitive business. Banks of issue were subject to regulation by the various states; the first was formed in Bavaria in 1834, and there were 33 in existence in 1875.

The Bank of Prussia was transformed into the Reichsbank in 1875. The capital was privately owned, but the representatives of the shareholders had mainly advisory functions; the bank was managed by a president, vice-president and directorate appointed by the emperor on the nomination of the Bundesrat and was subject to the supervision of a state-appointed curatorium.

The act of 1875 regulated the issue of bank notes. Each bank received an "indirect contingent" of notes not covered by cash (the Reichsbank received 250,000,000 marks out of a total of 360,000,000), and there was a tax of 5% on uncovered issues in excess of this. It was further provided that all notes must be covered by a reserve of one-third in gold, current coin or imperial notes (an issue fixed in 1874 at 120,000,000 marks). By 1905 only four banks besides the Reichsbank retained their issues, and these accounted for only 6% of the total bank-note circulation. Reichsbank notes were made legal tender in 1909.

The Reichsbank was required to provide banking facilities for the whole empire, and no other central bank used the branch system so extensively. Within 30 years from its foundation the bank established about 100 main branches and more than 4,000 sub-offices. With the development of the branches went that of the transfer system. Even persons without an account might, for a small fee, pay money in for transfer to anyone holding an account anywhere in Germany and this service was very widely used.

The Reichsbank was obliged by its charter to act as banker to the empire and the states free of charge. Most of its private lending was by way of discount. The official rate was usually

higher than that of the other banks, but in 1880 the Reichsbank began to make discounts at a lower "private" rate in times of easy money; it handled a much larger proportion of the total discount business of the country than did most central banks.

The bank, like the Bank of England, was obliged to buy gold at a fixed minimum price and to pay its notes in gold; and it acted from the first as keeper of the central gold reserve and lender of last resort. These obligations of a central bank imply a general regulation of credit; and the chief instrument for thii was discount policy, involving both variations in the official rate and in the bank's readiness to discount at the "private" rate. At times the bank also tried to protect its reserve by making interest-free advances to importers of gold and by buying gold at more than the statutory price.

The first great German joint-stock bank was A. Schaaffhausenscher Bankverein, founded in Cologne in 1848. The Discontogesellschaft was founded in 1851; the Bank fur Handel und Industrie (Darmstadter und Nationalbank), in 1853; the Berliner Handelsgessellschaft and the Mitteldeutsche Kreditbank, in 1856. Another spate of promotions from 1870 to 1872 produced, among others, the Deutsche bank, the Dresdner bank and the Commerz- und Discontobank. The expansion of industry after 1870 was accompanied by rapid development in banking The large provincial banks established offices in Berlin and opened branches, though they did not try to penetrate directly into the smaller towns. There were some amalgamations, but the chief way in which the big banks both extended and consolidated their influence was by obtaining a share in the capital and representation on the boards of provincial banks. By these means nine large Berlin banks, those already mentioned together xith the Nationalbank für Deutschland, came to dominate the banking system.

The main differences in the business of the English and German joint-stock banks were the lower cash ratio and larger bill holdings of the German banks and their closer association with industry Contrary to a widely held opinion, the German banks did not deliberately hold long-term industrial stock; but they did take a very big part in the issue of such stock and. when an issue miscarried, might be left with substantial holdings which they would have to retain for some time. The banks were frequently represented on the boards of firms which they assisted in this way, and their control over industry was increased by the widespread practice of voting stock deposited with them by customers. The banks were also most energetic in forming subsidiaries and establishing agencies abroad, and their activities in this way were conspicuous in Italy, Rumania and Bulgaria, in the near and far east and in South America.

Other European Countries.— The other countries of Europe showed wide variety in their banking systems. In general, those of northwestern Europe were the most mature; those of southeastern Europe. the least. In most countries savings banks and mortgage companies were important parts of the financial system, and in the Austrian empire, Italy and Poland it is difficult to draw a line between them and the commercial banks. The commercial banks of Scandinavia and the Netherlands tended to confine themselves to deposit banking on the English model; those of Austria. Italy, Sxitzerland and, to a lesser extent, Belgium followed the German pattern in associating closely with industry; and those of eastern Europe were chiefly concerned with agricultural finance. All the major countries set up central banks, sometimes in private hands, sometimes with state participation; in some there was no special commercial banking legislation, while in others the powers of the banks were carefully regulated.

The oldest joint-stock commercial bank in Europe, the Société Générale pour favoriser l'Industrie Nationale (later Société Générale de Belgique) of Belgium, was founded in 1822. In 1850 the National Bank of Belgium was formed, taking over the note issues of the older joint-stock banks and acting as fiscal agent for the state. Other banks were formed during the second half of the 19th century, and by 1913 there were 70 of them. but the Société Générale was by far the most important. In the Netherlands the Bank of the Netherlands was founded in 1814. There was a flourishing private banking system; but joint-stock banking did not begin until after 1860, and growth was comparatively slow.

In Scandinavia the Bank of Sweden (oldest surviving bank in the world at mid-20th century) dates from 1668, but Swedish private banking did not begin until about 1830 and joint-stock commercial banking until 1864. Joint-stock banks were not allowed to issue notes, but private banks could do so until 1897, when all issues were centralized with the Bank of Sweden. Thereafter no new private banks were formed; altogether there were about 80 banks in 1913. The system in Finland closely resembled that of Sweden, private banking beginning in the 1860s and joint-stock banking in the 1880s. The first Norwegian bank, other than the Bank of Norway (1814), was not founded until 1848; thereafter progress was gradual, and the system remained highly decentralized with many small local banks. In Denmark joint-stock banking began in 1846, and there mere no less than 144 banks in 1913, though 7 of them accounted for two-thirds of total deposits.

The Austro-Hungarian system comprised three parts, centred on Vienna, Budapest and Prague, of which the last was the least important. The Austrian section was dominated. in 1913, by ten big Viennese banks, which had grown up on the German model with extraordinarily close relations with industry and trade, while in Hungary there were a few large and very many small banks concerned largely with agricultural finance.

Switzerland had a tradition of private banking, and Swiss joint-stock banking began with the local "discount banks" formed between 1820 and 1840. Several bigger banks were founded after 1860 to finance railway and industrial development, and these grew into the most important element in the system. The cantonal banks were formed in the third quarter of the 19th century, primarily to assist agriculture, but some also did a general banking business. The central bank, the Swiss National bank, was not founded until 1905.

In Italy a number of note-issuing banks were formed in the separate states during the 1840s, and there was a rapid development of the banks closely associated with industry after the unification of the country. The National Bank of the Sardinian States, formed in 1849 by merging two banks of Genoa (1844) and Turin (1847), became the National Bank of the Kingdom of Italy. A crisis in 1893 provided the opportunity for a syndicate headed by the Discontogesellschaft and other big German banks to form the Banca Commerciale Italiana (1894), which grew into one of the most important banks in the country. In 1913 five large banks controlled two-thirds of all deposits; of these the Credito Italiano as well as the Banca Commerciale had some German participation.

Modern Spanish banking began with the formation of the Bank of St. Charles in 1782. In 1844 the Bank of Isabella II was formed; and in 1847 the two banks merged. In 1856 the combined bank was reorganized as the Bank of Spain with a monopoly of banking activity throughout the country. The bank issued notes, operated current accounts and did some discount business but mas heavily involved in the unsatisfactory Spanish state finances and was in difficulties throughout the century.

Banking in Russia dates from 1768, when Catherine II set up two banks of issue in Moscow. The Russian State bank was founded in 1860, and the first joint-stock commercial bank in 1865. The banking system was not, however, highly developed and depended considerably on French and German capital. The immature banking systems of other eastern European countries also relied largely on foreign capital, German in Rumania and Bulgaria, French and British in Greece.

The 20th Century.—World A'ar I brought a general increase in bank deposits and involved most banks in large purchases of government securities. Its aftermath included great territorial and political changes in many countries and currency disturbances in almost all. The period 1919–29 was mainly occupied with these problems.

Central banks were set up in the new countries (Poland, Czechoslovakia. Hungary, Yugoslavia, Estonia, Latvia and Lithuania); and the Bank of Spain was reorganized as a true central bank in 1921. The new countries all endeavoured to build national banking systems. In the former Austro-Hungarian empire, the Hun-

garian system grew up from the big Budapest banks. A central corporation of banking companies was formed in 1916 and remained after the war, with powers of inspection over member banks. Branches of Austrian banks in Czechoslovakia were either liquidated. taken over by Prague banks or formed into new Czech companies, while Yugoslavia made some progress in building a national system on the much more primitive foundations existing there. The sphere of influence of the Austrian banks was thus greatly restricted, and there were several amalgamations, as a result of which the big Viennese banks were reduced to four by 1929. In former Russian Poland there had been eight Polish commercial banks and three state institutions doing some banking business. These continued after liberation and a number of new banks were formed.

The timing of inflation and deflation varied considerably between countries. In the inflationary period new banks were formed and the nominal though not the real value of deposits increased, while deflation and stabilization brought liquidations and further concentration in banking systems. Deflation was first felt in Scandinavia in 1921; both in Norway and Sweden the state gave emergency assistance, and there were a large number of closures. In France, Belgium and the Netherlands there was less change in banking structure, but some concentration took place in France through the big banks extending their branches and, in Belgium and the Netherlands, gaining control of smaller provincial banks. The German system underwent great change. In 1924 the Reichsbank was reconstituted under a general council (half of which was foreign), with its discount policy restricted and without the power to buy long-term securities. A subsidiary, the Gold Discount bank, was established to assist foreign trade and was later used for a wide variety of purposes. The big commercial banks suffered heavy losses in the inflation and had to face competition from new banks formed for particular industrial groups and from public institutions (one of which, the Reichskreditgesellschaft, formed in 1922, was a full-fledged commercial bank). A series of amalgamations between 1914 and 1929 reduced the big Berlin banks from nine to five.

In Italy the Banco di Sconto was in difficulties in 1921 and was replaced by the Banca Nazionale di Credito, which amalgamated with the Credito Italiano in 1930. A comprehensive banking law of 1926 provided for registration of all banks, state approval for all new banks or branches and inspection by the Bank of Italy; and in 1930 all note issues mere placed in the hands of the Bank of Italy. (See BANCA D'ITALIA.)

The depression which began at the end of 1929 hit the banks of many countries. The failure of the Austrian Credit-Anstalt in May 1931 had repercussions throughout central Europe, and before the depression was ended the state had to take special measures in Austria, Germany, Hungary, Czechoslovakia, Sweden, Italy and Belgium. The German crisis was the most acute: the Deutsche, Commerz-, Dresdner and Darmstadter banks were all assisted by the state; the two last were amalgamated, and at one time the Gold Discount bank held 90% of the capital of the combined bank. Later. however, the special advances were repaid and the capital returned to private hands.

The crisis was followed by legal changes affecting both central and commercial banks. Central banks were given more freedom of action in Austria, Poland, Czechoslovakia, Sweden, Hungary, Denmark and Yugoslavia by reducing the amount of reserve required by law and in Germany, France, Poland, the Netherlands, Hungary and Lithuania by extending their powers in respect of open-market dealings. The constitution of the Reichsbank was changed in 1933, when the general council was abolished and the appointment of the president placed in the h'ands of the chancellor. In 1936 the Bank of Denmark was nationalized and the Bank of Italy was reorganized.

In commercial banking the tendency was toward more stringent control. The German law of 1934 set up the office of banking commissioner with the power to fix cash ratios and to limit the amount of credit that might be given to a single customer. The Italian law of 1936 gave the governmental office of inspection wide powers over the type of credit that a bank might give and over the direction of lending; and laws creating or strengthening controls were also passed in Sweden, Switzerland, Belgium and Rumania.

The Russian banking system developed on distinctive lines as part of the machinery of central economic planning. All banks were nationalized in Dec. 1917, but they practically ceased to operate in the chaos which followed. The new system began with the foundation of the State Bank of the Russian Soviet Federated Socialist Republic, later the State Bank of the Union of Soviet Socialist Republics (U.S.S.R.) (Gosbank), in 1921. Several other banks were set up and, under the New Economic Policy, received deposits and discounted bills both for state institutions and private firms. By decrees of 1927 and 1928, however, Gosbank became the sole source of short-term credit. Five other banks provide long-term credit for different sections of the economy, but only one, the Savings bank, accepts deposits from individuals; this bank will transfer deposits from one account to another, but its main function is to mobilize personal savings for investment in state loans. With the abolition of private trade and the introduction of the five-year plans, Gosbank assumed the responsibility of seeing that state enterprises kept within the "ration" of credit allocated to them in the plan. Each enterprise was compelled to keep its spare funds with Gosbank (which had opened a large number of branches); bills of exchange were no longer discounted and, instead, the bank gave credit to the purchaser, which was then transferred to the account of the seller on delivery of the goods, thus greatly easing the problem of supervision.

World War II produced new inflationary pressures everywhere, besides leading to great territorial and political changes. The German banks had penetrated deeply into the financial systems of the occupied countries, but the Allies declared all share purchases by Germans to be void, and foreign affiliates of German banks were liquidated. Currency reform was necessary in many countries after the war. Belgium, Yugoslavia, Denmark, France, the Netherlands, Czechoslovakia, Austria and Finland made new note issues, and in some of those countries part of the holding of old notes was placed in blocked bank accounts. In the U.S.S.R., at the beginning of 1948, old rubles were exchanged for new at the rate of one new for ten old, and bank deposits and the value of government bonds were also scaled down. German currency reform of June 1948 also involved drastic cancellations of the old currency.

The banking systems of Estonia, Latvia and Lithuania were incorporated with that of the U.S.S.R. when those states lost their independence; and those of the countries which passed under Communist control (Poland, Hungary, Czechoslovakia, Bulgaria, Rumania and Yugoslavia) were nationalized. In eastern Germany the old banks were abolished and a new system, resembling that of the U.S.S.R., was created. In the western zones the three large commercial banks (Deutsche, Dresdner and Commerz-) were divided in 1945–46 into 30 small units, each of which was allowed to operate in only one of the 11 Lander. New central banks were set up for each state and, as part of the currency reform, there was created the Bank of the German States (Bank Deutscher Lander) at Frankfurt am Main with a monopoly of note issue and limited powers over the state central banks. The 30 commercial banks created in 1945–46 proved too small for efficient operation and, in 1952, the law was amended. The country was divided into three banking regions and the banks consolidated into nine new firms, each of which could operate throughout the whole of one region. To prevent any further concentration, interlocking shareholdings and directorates were prohibited. The central banks of Norway and the Netherlands were nationalized and that of Belgium was brought under state control.

In France the nationalization movement went much further; the law of Dec. 1945 nationalized the Rank of France and the four largest commercial banks; in 1946 the two principal *banques d'affaires* were nationalized; and the smaller banks, of both kinds, were brought under stringent control. In the late 1950s various policies looking to economic and financial rehabilitation were made effective with the result that the substantial inflationary pressures were abated. On Jan. 1, 1960, the French franc was

revalued at .18 gram of fine gold or 20.25 U.S. cents per franc.

The war in Korea in 1950 aggravated the inflation which had been a chronic feature of the European economy since World War II, and caused most western European countries to abandon the low and stable interest rates which had survived from the 1930s and to adopt more orthodox monetary policies. There was a general rise in interest rates in 1950–51 and, thereafter. central banks varied their rates according to the economic circumstances of their respective countries. In most cases the new policy involved only the more active use of powers already possessed by central banks, but in some countries (*e.g.,* the Netherlands in 1954) central banking powers were substantially increased.

C. Great Britain and the Commonwealth of Nations

England. — In the middle ages, English finance was not as fully developed as that of the great commercial centres on the continent and much of it was in the hands of foreigners. Financiers were mainly concerned with loans to the crown, with the collection and transmission of papal revenues, and with the finance of foreign trade. Bills of exchange were widely used but did not circulate as money and bank notes were unknown. The type of loan that might be made was severely restricted by the usury laws, though the Reformation substantially altered prevailing views on this point and after 1545 the state confined itself to the establishment of a maximum rate of interest.

The Tudor period was one of expanding trade, capital accumulation and increasing need for financial agencies and instruments. Merchants like Sir Thomas Gresham (*q.v.*) played a growing role in the financing of foreign trade and London scriveners began to lend money, both their own and that which they had borrowed for the purpose. It is generally held, however, that the direct ancestors of modern banks were neither the merchants nor the scriveners but the goldsmiths. At first the goldsmiths accepted deposits for safekeeping only; but early in the 17th century their deposit receipts were circulating as money and thus became the prototypes of the first English bank notes. Soon the goldsmiths began to issue notes not only against the deposit of coin or of bullion but also by way of loan. This may be viewed as the beginning of fractional reserve banking in England. Some of the goldsmiths lost heavily on their loans to the crown in the reign of Charles II. Some went into bankruptcy but others survived and came to be leaders among the London private banks in the 18th and 19th centuries. Two notable examples of the latter group are Child's and Hoare's.

The financial difficulties of the crown continued after the revolution of 1689 and led to the foundation of the Bank of England (*q.v.*) in 1694. Establishment of the Bank of England marked the beginning, in a sense: of the development of a banking system consisting of a central bank and of a number of private banking firms. At the time of its founding the Bank of England made an initial loan to the government of £1,200,000 in return for a charter of incorporation. In 1697 it was granted a monopoly of joint-stock banking in England and Wales. In 1707 it became the principal agent for the circulation of exchequer bills and in 1715 it acted for the first time as agent for the issue and management of a government loan. Gradually, during the next 40 years, it became banker to the exchequer and the principal government departments, holding their deposits and paying their drafts as any bank does for its customers.

The Bank of England also did ordinary banking business, issuing notes, receiving deposits and discounting bills of exchange. But its role as banker to the state and its monopoly of joint-stock banking placed it in a unique position; and in its relations with the private banks it soon became much more than just a privileged competitor. About 1770 the London private bankers (survivors of the old goldsmith bankers reinforced by a number of new firms) practically ceased to issue their own notes and used Bank of England notes instead. Most of them opened drawing accounts with the Bank of England, as also did the Royal Bank of Scotland. The country banks managed their business in the capital through a correspondent, generally one of the private bankers. The Bank of England's reserve of gold could thus be drawn upon in time of crisis by these London banks and, through them, by all the multitude of small banks which were springing up all over England in the second half of the 18th century. To meet this obligation the Bank of England had to accumulate a large reierve, and most of the country's gold stock not in actual circulation came to be concentrated in its vaults.

Thus by the end of the 18th century the Bank of England was performing, though not yet fully, several of the recognized functions of a central bank; it acted as banker to the government, manager of the public debt. bankers' bank and custodian of most of the country's gold reserve. It did not yet. however, recognize the responsibility of acting as "lender of last resort" or accept the supreme duty of a central bank; namely, that of exercising a general direction and control over monetary affairs.

There were very few private banks outside London until after 1750, but subsequent development was rapid; there were about 150 in 1776, 350 in 1800 and 430 in 1833. They enjoyed, of course, no corporate status and could not comprise more than six partners. They varied greatly in size and stability from wealthy and well-managed firms, such as Gurney's of Norwich and Stuckey's of Somerset, to tiny and evanescent enterprises started by small tradesmen in market towns. Many failed in the commercial crises of the period: their activities often embarrassed the Bank of England: and they were blamed for many of the monetary troubles of the time, Nevertheless, they played a vital part in the finance of the Industrial Revolution. At first nearly all these banks issued notes, and the country bank note was the chief form of paper currency in circulation outside London and Lancashire. By 1830 the bank deposit transferred by check was becoming important; and the banks made an increasing proportion of their loans by means of overdrafts, rather than by issuing notes. Indeed one of the distinguishing characteristics of the history of banking in Great Britain and the commonwealth is the early development and use of the check. The treatment of the check in England, where under the common law it was defined as a bill of exchange and hence at all times negotiable, greatly facilitated the circulation of deposit credit. This stood in sharp contrast to developments on the continent where the limitations of the nonnegotiable check made extensive use of deposit credit impossible until well into the 19th century.

Cash reserves of the private banks which varied greatly in size, were held partly in gold but chiefly in Bank of England notes. The more prudent bankers invested some of their assets in government securities, and loans were made on mortgage — to farmers on the security of stock, to businessmen often on personal security only. The most important and general means of lending was, however, by the discounting of bills of exchange; banks in country districts often had difficulty in getting as many bills as they wanted, whereas those in expanding manufacturing areas were under constant pressure for loans and therefore began to sell bills to those in agricultural districts through agents in London, who thus constituted, in the early 19th century, the origin of the London discount market.

Central Banking, 1793–1844. — The wars with France of 1793–1815 imposed a great strain on the English monetary system, and in 1797 the government, by order in council, forbade the Bank of England to pay its notes in gold, a restriction that was confirmed by parliament and continued in force until 1821. Freed from the necessity of cash payment, both the Bank of England and the country banks thereupon increased the amount of their note issues and the volume of their lending. The government continued its inflationary methods of mar finance with the result that prices rose; the foreign-exchange rates fell; and gold bullion was sold in the market at a premium over its mint price.

These events led to much controversy and to a parliamentary inquiry which produced the famous Bullion report (*Report of the Select Committee on the High Price of Gold Bullion,* 1810). The policy of the Bank of England's directors was to meet what they called "the legitimate needs of commerce" by discounting all good bills brought to them at a rate of 5%, the maximum allowed by the usury laws; they maintained that the resulting increase in their note issue had no influence upon prices or the foreign ex-

changes. The directors' critics, including such great economists as David Ricardo, Thomas Robert Malthus and Henry Thornton, though they disagreed over details, all maintained that there was a close connection between the volume of Bank of England notes and the level of prices and further that the level of prices affected the foreign-exchange rates and thus the inflow or outflow of gold and the reserve of the bank. Once this chain of reasoning was accepted it followed that the bank, as custodian of the central gold reserve of the country, must shape its lending policy according to general economic conditions and exercise a general control over money and credit. This critical period was thus of the highest importance in the development of central banking theory.

Only four years after the resumption of cash payments there occurred, in *1825,* one of the most violent financial crises of the century. The course of events was one which became familiar, with slight variations, in later years; a rise in domestic prices and the value of imports caused the exchanges to fall and the Bank of England's reserve to be depleted; then a few big business failures precipitated a run on the banks and a further drain on the reserve, not for export but for domestic circulation. The remedy, which became classical, was for the bank to raise its discount rate to protect its reserve against the foreign drain and then to lend freely at the high rate in order to maintain confidence at home (the function of "lender of last resort"). In *1825* the bank allowed its reserve to fall dangerously low before taking protective action; nevertheless, at the height of the panic, it discounted all eligible bills and even relaxed its rules of eligibility.

The crisis caused the bank directors to take a broader view of their responsibilities both as lender of last resort and as regulator of the monetary system. In an attempt to build up a more stable banking system, the government persuaded the bank to open branches in a number of provincial towns; and, in *1826,* parliament sanctioned the opening of joint-stock banks outside a radius of *65* mi. from London and prohibited the issue of notes of less than £*5.*

The act renewing the bank's charter in *1833* made three more important changes in the law: (1) Bank of England notes were made legal tender; (2) the usury laws were repealed as far as they affected bills of exchange, setting the bank free to raise its discount rate above 5% and paving the way for the use of variations in bank rate as an instrument of policy; and *(3)* joint-stock banks were declared to be legal even within the limit of *65* mi. provided that they did not issue notes.

Public dissatisfaction with the Bank of England was aggravated by further crises in *1836* and *1839,* and criticism developed into a controversy between what are usually known as the Currency school and the Banking school. The Currency school, led by Samuel Jones Loyd (Baron Overstone), Robert Torrens and George Warde Norman, laid great stress on the close connection between the amount of money and prices; they defined money as gold and bank notes and from that deduced their main proposition, that the total of notes and coin in circulation ought to be made to vary in exactly the same way as would a purely metallic currency. The Banking school, led by Thomas Tooke and John Fullarton, pointed out the importance of other instruments of credit and argued that a varying amount of credit could be built up on a given cash base; they were no less critical of the policy of the bank than their opponents but did not wish to see it fettered by any rigid legal restrictions.

The Bank Charter act of *1844* embodied the views of the Currency school. The bank was divided into an issue department and a banking department. It was allowed a fiduciary issue (backed by government securities) of *£14,000,000* beyond which amount all notes had to be covered by gold or silver (the silver not to exceed one-fifth of the whole); and mas obliged to buy gold at £*3* 17*s.* 9*d.* a standard ounce and to pay its notes in gold coin, which was equivalent to selling gold at £*3 17s.* 10½*d.* an ounce. 'The note issue served both for the use of the public and as a reserve for the banking department. No new banks of issue were to be allowed; existing ones were limited to their average circulation in the three months prior to the introduction of the bill; and any bank which ceased to issue, stopped payment or amalgamated so as to give itself more than six partners was to forfeit its rights, whereupon the Bank of England was authorized to raise its own fiduciary issue by two-thirds of the permitted issue of the forfeiting bank. The Iast country bank to issue notes did not cease until *1921,* but country banks' issues had become insignificant long before this.

Developments, 1844–1914.—The first provincial joint-stock banks were formed at Huddersfield and Bradford in *1827.* The act of *1833* was followed the next year by the foundation of the London and Westminster bank, with a great banker, J. W. Gilbart, as manager. Gilbart had to fight both the Bank of England, which refused him a drawing account, and the London private bankers, who refused him admission to their clearinghouse; but his bank prospered and was soon followed by others. By *1841* there were 115 joint-stock banks in England and Wales, and the number of private banks had fallen to *321.* After this boom, however, promotion of joint-stock banks diminished, and the structure of the system remained fairly stable until the great amalgamations at the end of the century; in *1886* there were *117* joint-stock banks but more than *250* private ones still in existence, the chief change since *1841* having been the extension of the branch system by the joint-stock banks.

Under the act of *1826* joint-stock banks still retained unlimited liability and had no corporate existence. These disabilities were removed by a series of acts from *1844* onward, and in *1862* banks were brought within the general law of limited liability. However, the established banks were reluctant to take advantage of the new law, and it was not until after the failure of the City of Glasgow bank, with heavy loss to the shareholders, in 1878 that limited liability became general.

The critics of the act of *1844* had feared that it would result in an undue restriction of credit; this was avoided by the rapid growth of the check system. The sponsors of the act had hoped that it would remove the need for any discretionary action by the bank; but they, too, were proved wrong. When gold was withdrawn from the Bank of England, notes had to be canceled and the reserve of the banking department mas reduced; the size of the fiduciary issue was so fixed that, when a drain of gold occurred, the reserve of the banking department was threatened with exhaustion long before the gold in the issue department. The bank was thus obliged to develop and refine the same techniques to meet the new emergency as it had used, in a more primitive form, against the old.

The *50* years before *1844* had seen the evolution of central banking theory; the next *50* saw the Bank of England experimenting with its techniques of credit control and gaining steadily in power and experience, although in *1847, 1857* and *1866* it had to obtain from the government permission to exceed its legal issue with the promise of a bill of indemnity if it broke the law. The Bank of England allowed its private business to dwindle and concentrated on central banking; the commercial banks increased their balances with the Bank of England; and the system was developed whereby those balances were replenished, when necessary, by calling in loans from the discount market, the bill brokers then trying to borrow elsewhere and going to the Bank of England only in the last resort.

The international financial business of London was growing very rapidly at this time. The acceptance and discounting of foreign bills had begun as early as *1830* and, during the second half of the 19th century, the foreign bill largely displaced the domestic bill {which was being driven out of use by the check) in the London market. London became a short-term lender to the world and a clearinghouse for international payments. Foreigners deposited money with British firms, especially the merchant bankers who accepted bills, dealt in foreign exchange and floated foreign loans in London; British banks were formed to operate in the empire and in foreign countries; and foreign banks established offices in London. This business nas not in the same hands as was domestic banking, but it was of vital concern to the Bank of England. The bank's reserve became much more sensitive to foreign influences although, since the discount of foreign bills far exceeded the holding of foreign deposits in London, a sufficient rise in bank rate

could always be relied upon to check discounts and so produce an inflow of gold as old bills matured and were paid off.

The main methods of credit control were bank rate and open-market operators. Bank rate, used experimentally before 1844, was used regularly soon afterward and became more important toward the end of the century, when other banks came to fix their rates for loans and deposits in relation to it. Open-market operations were a means of making bank rate "effective"; *i.e.,* of preventing other short-term interest rates from falling too far below bank rate. The Bank of England would sell securities, thus taking money out of the market, when it wished to raise rates and buy them when it wished to ease credit.

After the Baring crisis of 1890, in which the Bank of England took the lead in averting a panic by raising a guarantee fund for Barings. there mas closer co-operation between it and the other banks. This was made easier by the rapid spread of amalgamation. The Bank of England could now communicate informal hints on policy to the other banks; and in 1911 a more formal arrangement was reached, whereby the Clearing Bankers committee met once a quarter at the bank.

It was only between 1890 and 1918 that English banking came to consist of a few very large banks operating a nationwide system of branches. The increasing scale of industry was the main reason for the series of amalgamations which brought this about; a subsidiary reason was the public demand for larger reserves that followed the Baring crisis. By 1914 there were only 16 members of the London clearinghouse, 13 of these being great joint-stock banks, and the small local bank was nearly extinct. The Birmingham and Midland bank (forerunner of the Midland bank) absorbed the Central Bank of London in 1891 and the City bank in 1898 to become the London, City and Midland; and in 1897 E. H. Holden, the person most responsible for the subsequent pace of amalgamation, had become manager. In 1896 Barclays bank had been formed by the fusion of 15 private banks, mostly of Quaker origin. In 1902 the Union of London and Smiths was formed by the combination of a London joint-stock bank (the Union), a London private bank (Smith, Payne and Smith) and a number of north midland banks linked with the private bank by family ties. The climax came during a few months in 1917–18; the Midland absorbed the London Joint Stock bank; the National Provincial absorbed the Union of London and Smiths; the Westminster absorbed Parr's; and Barclays absorbed the London and Provincial and London and South Western, which had themselves amalgamated less than a year before.

This spate of amalgamation gave rise to fears, of a "money trust." A treasury committee reporting in 1918 suggested legislation making government approval necessary for further amalgamations; no such law was passed, but the banks entered into an informal understanding not to arrange further mergers without treasury approval. Since then, amalgamations have been very few.

History From 1914.—The gold standard was inoperative during World War I and formally suspended from 1919 to 1925. Gold coin was replaced in ordinary circulation by treasury notes. which circulated concurrently with those of the Bank of England until the issue was transferred to the bank in 1928. From 1925 to 1931 gold bullion was freely obtainable at the bank, though gold coin never came back into use; but in 1931 the gold standard was again ahandoned, and in 1939 the bank's gold stock was transferred to the exchange equalization account. Thereafter, though the separation of departments established in 1841 was preserved, the bank held practically no gold. the note issue being wholly fiduciary with its arnount fixed by the treasury.

The "cheap money" policy which followed the abandonment of the gold standard caused bank rate to fall into abeyance and led to a relaxation of the central bank's control over credit. Such control as it still had was of a qualitative rather than a quantitative nature and exercised through informal contacts and persuasion. Throughout this period the bank worked in close and increasingly harmonious contact with the government.

The Bank of England was nationalized by an act that came into force on March 1, 1946. Under nationalization the directors were appointed by the crown; the treasury might issue directions to the bank; and the bank could make recommendations and, if necessary, give directions to the commercial banks. The act might seem only to have given formal expression to a relationship that had grown up, by mutual consent, between the three parties; but any government so inclined could use the wide and rather vague powers of direction conferred by it to exercise a much more stringent control over the commercial banks than was at first attempted.

For the commercial banks World War I and the postwar inflation brought a great increase in deposits. As these banks were also large subscribers to war loans, war conditions brought them into much closer contact with the Bank of England than before. After the war cash ratios were more stable and the conventional 10% (reduced to 8% in 1947) became established. The banks also entered more into acceptance, discount and foreign-exchange business; and some of them formed subsidiaries to operate abroad. During the depression in the early 1930s banks were faced with a falling demand for commercial loans and increased the proportion of government securities in their assets, and this tendency continued during the great increase in deposits which took place during World War II.

The Labour government. elected in 1945, intensified the drive for cheap money in an effort. to bring the yield of long-term government bonds down to 2½%. Bank rate was retained at 2%; the Bank of England kept the commercial banks liberally supplied with cash, and there was a further rapid growth of deposits. This policy was modified in 1947 and drastically changed, with a change of government, in 1951. Bank rate was raised to 2½% in Nov. 1951 and to 4% in March 1952, and the liquidity of the banking system was reduced by the funding of £1,000,000,000 of treasury bills. Thereafter the Bank of England, like the central banks of most other European countries, adopted a flexible policy, reducing bank rate in 1953–54 and raising it again to counteract inflation and a loss of gold reserves in 1955–56. A vigorous use of bank rate to control inflation was still evident at the beginning of the 1960s. During this period there were a number of technical changes designed to restore to the Bank of England the control over the financial system which it had largely abandoned between 1931 and 1951.

Scotland and Ireland.—Scotland differed from England in having no law against the formation of joint-stock banks and in the early development of branch banking. The core of the system was constituted by the three chartered banks. the Bank of Scotland (1695), the Royal Bank of Scotland (1727) and the British Linen company (1744). These firms began to found branches in the middle of the 18th century and were joined later by a number of unchartered joint-stock banks. By 1826 there were 36 banks in Scotland. all the most important being joint-stock. In 1845 Sir Robert Peel's government followed up the Bank Charter act by regulating Scottish note issues—no new note-issuing banks were to be allowed; and the 19 issuing banks in existence were restricted to a fixed fiduciary issue, further issues to be covered wholly by gold or silver. The privilege of note issue was more significant in Scotland than in England, and no important banks were founded after 1845. Concentration proceeded gradually, and the number of banks was reduced to eight by 1914. Toward the end of the 19th century connections with England grew closer; and in the final stages of the amalgamation movement Barclays acquired control of the British Linen bank; Lloyds, of the National Bank of Scotland; and the Midland, of the Clydesdale bank and the North of Scotland bank (amalgamated in 1949). The Royal Bank of Scotland, however, gained control of Glyn, Mills and Company and of Williams Deacon's. Contrary to the practice in English amalgamations, however, the Scottish banks retained their separate identities.

In Ireland there were many small and weak private banks and a few strong ones founded during the 18th century. The most important was David La Touche and Son, founded by a Huguenot poplin manufacturer around 1700. In 1783 the Bank of Ireland was given a charter that was closely modeled on that of the Bank of England. The Bank of Ireland originally had a monopoly of joint-stock banking. but this was modified in 1821 and finally abolished in 1845. The bank acted as government banker and

manager of the national debt in Ireland and later as banker and lender of last resort to the Irish commercial banks, but never attained the full stature of a central bank since it relied in time of strain upon the Bank of England, which was the ultimate holder of cash reserves for both countries. Also, the Bank of Ireland, unlike the Bank of England, continued to play an important part in ordinary commercial banking. After 1821 a number of joint-stock banks were formed; and these in 1845 were given their own fiduciary note issues as in Scotland. In the second half of the 19th century the remaining private banks were absorbed by the joint-stock banks, and in 1914 there were nine such banks operating more than 800 branches. One of them, the National, was also a member of the London clearinghouse. As in Scotland, there was some fusion with English banks. the Midland gaining control of the Belfast Banking company, the Westminster of the Ulster bank. The formation of the Irish Free State was followed by the issue of Irish notes under the control of a currency commission (1927) and the establishment of the Central Bank of Ireland (1942), but it did little to disturb the close banking connection between Great Britain and Ireland.

Commonwealth **of** Nations. — Banks were established in the countries which later formed the British Commonwealth at an early stage in their development. Control over banking varied with the degree of independence attained by the new settlements; initially it was exercised from London, then by the various state and provincial legislatures, finally by the dominion governments. Private banks played little part in this field and all the important banks were joint-stock companies. They naturally had close connections with London, kept reserves in London and formed an important element in the London money market. None of the dominions had a central bank until after World War I.

Canado. — The banks doing ordinary commercial business in Canada are the chartered banks; the oldest is the Bank of Montreal. founded in 1917 and chartered in 1822. Its charter was similar to that of the first Bank of the United States (see below) Until 1867 charters were issued by the provinces of Upper Canada and Quebec; subsequently. the regulation of banking was in the hands of the federal government, which granted charters under a series of decennial banking acts. beginning in 1871. Law regulated banking in much more detail in Canada than in most other countries. Characteristic features were the fixing of a minimum paid-up capital ($100.000 in 1871 and $250,000 since 1890); the limiting of interest on loans and of dividends; the liability of shareholders for double the nominal value of their shares; the prohibition of loans on real estate (modified in 1944 and 1954); and the rigid control of amalgamations On the other hand, there was no control over the amount of reserves and the only stipulation in this field before 1934 was that 40% of reserves (whatever they might be) should be held in Canadian notes (1881).

There were 28 Canadian chartered banks in 1867 and 20 more were formed between 1867 and 1881; but the number was reduced by amalgamations to 10 in 1931. Branch banking developed early and by 1931 there were more than 3.000 branches. The chartered banks issued their own notes, which formed the main currency of the country until displaced by those of the Bank of Canada after 1934. They also did all ordinary banking business and participated, unlike the English joint-stock banks, in the making of long-term capital issues for industry.

The Canadian central bank, the Bank of Canada, was set up by an act of 1934. It acts as banker to the government and to the chartered banks, which nere bound to keep a reserve of 5% of their liabilities with it. The Bank of Canada gradually took over the note issue of the chartered banks and also their gold reserves and those of the central note reserve. Before 1940 the Bank of Canada was required to keep a gold reserve of 25% of its notes and deposits. In the decennial revisions of the banking lam of 1944 and 1954, the banks were allowed to make mortgage loans, and in 1954 the Bank of Canada was empowered to vary the commercial banks' cash ratio. In 1944 the Industrial Development bank was set up to provide long-term finance for industry. and in 1954 the first steps were taken toward the building up of a call-loan market.

Australia. — In Australia the pioneer undertaking was the Bank of New South Wales, founded in 1817 and followed during the next 25 years by 18 other banks. These banks, unlike those of Canada, made loans on land and played a big part in the building-up of the large "squatter" estates. The discovery of gold in 1851 led to a further boom in bank formations; and when the search for gold subsided, the banks began to play an increasing part in the finance of secondary industry. Connections with England were very close and many banks drew a large part both of capital and of deposits from London at this time. In 1893 a severe financial crisis left some banks with liabilities mhich they took several years to discharge. Altogether more than 50 banks were formed in the 19th century, but the number was reduced by failures and amalgamations to 16, of which 3 have their head offices and the great part of their shares in England. Up to 1910 the banks had issued their own notes, but in that year a treasury-note issue was established and a tax imposed on bank notes. The Commonwealth Bank of Australia, formed in 1911, held the federal account and the accounts of some of the states and was intended to compete with the ordinary trading banks. By acts of 1920 and 1924 the note issue was transferred to it and, especially after 1929, it came to operate more and more as a central bank.

The Bank act of 1945 added to the central banking powers of the Commonwealth bank in several ways, including giving it the right of requiring commercial banks to deposit a variable amount of their assets in special accounts with it. At the same time the act provided that, in case of difference of opinion between the Commonwealth bank and the government, the federal treasurer might issue directions to the bank. This power was somewhat modified in 1950 by the setting up of a bank board with half its members drawn from circles outside both the Commonwealth bank and the government. The 1945 act also created a new industrial finance department of the bank, and encouraged it to develop its ordinary banking business, so that Australia is one of the few countries in which the central bank and the commercial banks are in active competition with one another.

New Zealand. — Of the five trading banks in New Zealand in the mid-1950s three were Australian, namely, the Bank of New South Wales, the Commercial Bank of Australia and the Australia and New Zealand bank (the last formed by a merger of the Bank of Australasia and the Union Bank of Australia in 1951). The first of their branches was opened by the Union in 1840. The Bank of New Zealand was chartered in 1861, but in 1894 it was in trouble and the government came to its support. From then on the government appointed part of the directorate until it was wholly taken over by the state in 1945. The National Bank of New Zealand was founded in 1872 with two-thirds of its capital in London. All these banks enjoyed the right of note issue until 1934, when this function was taken over by the newly created central bank, the Reserve Bank of New Zealand. The Reserve bank was nationalized in 1935 and the Bank of New Zealand in 1945.

India, Pakistan and *Ceylon*. — In India a banking system of the European type was superimposed upon an indigenous banking system of great antiquity. Besides small local bankers and moneylenders there are the joint-stock banks, the Imperial Bank of India, the exchange banks and the Reserve Bank of India. The first joint-stock bank, the Bank of Hindustan, was founded as early as 1770; development was slow during the 19th century but more rapid after 1900, and there was never the process of concentration which took place in Britain and the other countries of the commonwealth. In 1940 there were 180 banks, operating nearly 1.200 branches. The exchange banks, of which the oldest is the Chartered Bank of India. Australia and China, are mainly concerned with international transactions. The Imperial bank was formed in 1921 by the merger of the three presidency banks (Bengal, 1808, Bombay, 1840, and Madras, 1833). The presidency banks had originally possessed the right of note issue, but this was taken over by the government in 1862. The Imperial bank held government balances and acted as a clearinghouse, but never as a true central hank. The Reserve Bank of India was created as a central bank by an act of 1934 and commenced operations in 1935, taking over the note issue from the government.

The creation of the Republic of India and of the new dominions of Pakistan and Ceylon led to further changes. In 1948 the State Bank of Pakistan was established as a central bank. nith the state owning a controlling interest in its capital On Jan. 1, 1919, the Reserve Bank of India was nationalized and given increased powers o er the commercial banks. In 1954 the Industrial Credit and Finance Corporation of India was formed with the co-operation of the International Bank for Reconstruction and Development. In the following year the Indian government took over the Imperial bank with the intention of merging it with a number of small local banks to form a state bank with a nationwide branch network. Pakistan set up a new central bank in 1948 and Ceylon in 1950.

The British Colonies.—The monetary history of the colonies has been varied, but they have certain fundamental features in common. There was no development of central banking; instead, currency boards were set up to issue local currency against reserves held in sterling and maintain an automatic convertibility at fixed rates. Commercial banking is not highly developed and is concerned largely with the finance of foreign trade; financial assistance to agriculture and industry varies with the economic development of the colonies, but in general is limited by the difficulty of obtaining adequate security from native cultivators. The most important banks are British companies. including the Bank of British West Africa, Barclays (Dominion, Colonial and Overseas), operating in east and west Africa and the West Indies, and the Chartered Bank of India, operating in Malaya. Some of the dominion banks also have colonial branches: three Canadian banks operate branches in the West Indies, several Indian banks in east Africa and Malaya and the Bank of New South Wales in the Pacific colonies. There are few local banks in the British colonies, though one, the Hong Kong and Shanghai bank. plays an important part in far eastern banking.

(E. V. MN.; FK. L. K.)

D. THE UNITED STATES

Banking in the United States had its origins, apart from its rudimentary beginnings in certain colonial institutions, with the grant of a charter (1781) to the Bank of North America. Doubts concerning the legal power of the continental congress to grant a charter to a banking institution led the bank successfully to seek a charter from the state of Pennsylvania in 1782, and later from New York, Massachusetts and Delaware. The establishment of the Bank of North America was a response, in part, to the needs of the continental congress, associated with the financing of the American Revolution, although the government had no voice in the management of the bank.

The Bank of North America was a very successful institution. It made substantial loans to the government, provided credit facilities for private business and issued a currency redeemable in specie on demand. The bank's success (it continued under renewed charters from the state of Pennsylvania until 1863 when it became a national bank, *see* below) provided encouragement to others. The Bank of Massachusetts was chartered in 1784 and the Bank of New York in 1791. These early institutions were the forerunners of a large number of state banks One estimate indicates that there were 28 such banks by 1800 and 88 by 1811. This development, implying as it did the need for credit institutions. established the precedent for the far-ranging state banking systems which. apart from the first and second Bank of the United States, constituted the whole of the banking system of the nation until the establishment of the national banks pursuant to the National Bank act of 1863 as amended.

First Bank of the United States (1791–1811).—Establishment of a national bank to be the creature and the agency of the national government under the new federal constitution was one of the important measures urged by Alexander Hamilton (*q.v.*), first secretary of the treasury, in developing the powers of the new government. The proposal aroused an important and lasting controversy. for it directly involved certain basic issues upon which Jefferson and Hamilton were to remain divided. There was opposition not only on the general ground that a banking monopoly mas incompatible with U.S. ideals, but also on the particular ground that the federal congress had no authority under the constitution to issue corporate charters. The Federalist majority in congress followed Hamilton's proposal, and a charter was enacted. The bank began business in 1791, with a capital of $10,000,000, of which the government owned one-fifth and was the largest stockholder. The bank's charter ran for 20 years. but political opposition and the ineffective organization of the bank's supporters prevented its renewal.

Experience meanwhile had developed a function for the bank that had not been foreseen. namely, its regulation of the private banks. At this time note issue continued to be a more important, or at least a more conspicuous feature of banking than were deposits. Bank notes, which entered circulation as the money that banks lent to their borrowers, comprised much the greater part of the total amount of currency in circulation. Since the country was growing fast, there was a powerful demand for loans which tended to produce an overextension of credit. Consequently it was to the general interest that expansion be restrained from proceeding to extremes from which recovery mas bound to be costly and painful. The Bank of the United States imposed such restraint automatically. As depository of the government, with offices in the chief seaports and commercial centres, it constantly received from collectors of revenue the notes of private banks with which dues to the government were paid. As fast as it received these notes, it called for their redemption in gold and silver by the banks of issue, automatically restricting thereby the overextension of credit and protecting the economy from inflation Conversely, in periods of panic and deflation, the bank could ease the pressure. Essentially, it was engaged in what was subsequently called central banking.

The first Bank of the United States was successful as a banking institution. Political opposition supported by those who objected to the restraints with which the growing number of state banks were faced as a consequence of the bank's practice of presenting state bank notes for redemption led to the lapse of its charter in 1811. The officers of the bank successfully sought a state charter in New York and continued to operate as a state bank.

Second Bank of the United States (1816–36).—Shortly after discontinuance of the first Bank of the United States, economic conditions made it evident that re-establishment was necessary, and congress in 1816 chartered a new institution with wider powers than before and with closer links to the government. Although the new bank made a good start, it was for a time grossly mismanaged, and did not really prosper until after 1823, when Nicholas Biddle (*q.v.*) of Philadelphia became its president.

Under Biddle its central banking responsibilities seem to have been as consciously recognized and developed as were those of the Bank of England at the same time—perhaps more so. But since these responsibilities had usually to be exercised as restraints, private banks resented them and complained of oppression. It was a period when developments in industry and transportation were enhancing the richness of U.S. resources, and when the idea of democracy was beginning to connote free enterprise and *laissez faire*. Hence the very conditions that made restraint upon credit advisable made it objectionable.

This opposition to the Bank of the United States on the part of the more speculative and impatient men of business united incongruously with the traditional agrarian opposition to it. The agrarians disliked all banks, associating them with privilege, wealth and aristocracy; and they disliked the Bank of the United States because it was the biggest and because it was a creature of the federal government, the growth of which they had always feared. Opposition to the bank centred behind the leadership of Andrew Jackson (q v.), who had become president in 1829; his attack and the bank's unsuccessful defense are matters of political history, the bank war being one of the most bitterly controverted episodes in U S. history. Again the constitutional issue was raised; nor did a leading decision of the U.S. supreme court (*McCulloch* v. *Maryland*, 1819) upholding the constitutionality of the bank prevent the constant reiteration of this theme. Again, too, it was alleged that the bank was a monopoly antithetical to the ideals of

the U.S. Clearly the restraining influence which the bank exercised resulted in the pressures which led President Jackson to prevent the renewal of its charter. In 1832 congress renewed the bank's charter, which was to expire in 1836; Jackson vetoed the act and arranged to have the government's funds deposited in banks incorporated under state law. Practically speaking, this cut the bank's operating contact with the government and ended its performance of the central banking function. *(See* also UNITED STATES [OF AMERICA]: History.)

During the period of the bank war and of Jackson's second term, 1833–37, economic activity was intense, prices were rising and speculation was feverish. The bank made some attempt at restraint, but its effectiveness was gone. Moreover, in expectation that it mould not continue, there was a general move to set up new local banks. In May 1837 the boom burst with a disastrous flood of bankruptcies and slackening of business, and all the banks of the country stopped paying out specie. A year later payments were resumed under the leadership of New York bankers, the primacy of New York as the country's financial centre being thereby established.

There was still a long aftermath of banking trouble, however. In effect, the federal government in ending the Bank of the United States without alternative, abandoned responsibility for the monetary system. The constitution plainly intended to take all such responsibility from the individual states and lodge it in the federal government, and since bank liabilities in the form of circulating notes constituted the principal part of the circulating medium, the federal government's responsibility included regulation of bank notes. That responsibility was not resumed until 1863.

The State Banks (1816–63).—The lapse of the charter of the first Bank of the United States in 1811 encouraged the establishment of additional state banks which increased from 88 in 1811 to 246 by 1816. The growth in the number of state banks continued even after the establishment of the second Bank of the United States in 1816, approximating 330 by 1829 and 788 by 1837. It is generally agreed that while the regulations of the several states with respect to banking varied enormously, they were directed—even in the best of circumstdnces—primarily toward the control of the note liabilities of banks, ignoring essentially the bank's liability to depositors. A large number of the newly established banks followed banking practices generally thought to be unsound, particularly with respect to note issue and to appropriate provision for the redemption of notes. During this period legislative attitudes in the several states respecting banking ranged from a prohibition thereof to a nearly complete abdication of public responsibility for banking practices. As one might expect, this range of attitudes led to quite sound banking practices in certain areas and to the most serious abuses of financial responsibility in others. In the early years of this period, charters were issued to banks by the several states by special legislative enactment. This practice allegedly, and the evidence in numerous cases bears out the allegation, led to corruption and bribery associated with bills to grant corporate charters to banks and, in turn, led to the establishment in many states of "free" banking, a system which provided that banks, like other business enterprises, were to be viewed as "associations," not "corporations." In Ne York it was provided that notes issued by such associations be secured by pledges of state bonds.

The laws of the several states respecting free banking varied greatly and produced both good results and bad. The results in Alabama, Florida, Illinois, Kentucky, Mississippi, Michigan, North Carolina and many other states were very unfavourable, whereas Indiana. Louisiana, Missouri, Ohio and Virginia established sound and successful banking systems each having a central bank with branches. In general, however, and taking the country as a whole into account, the banking system, consisting as it did of many separate state systems, was chaotic. This situation was particularly bad with respect to the issue of bank notes, which constituted a much larger part of the circulating medium than is true in the 20th century (because of the comparative growth of demand deposits); several early efforts at control, both private and public, centred around note issue.

The Suffolk System (1818–58).—This system, created by the Suffolk bank of Boston, provides an illustration of private control of bank-note issue by bankers. It was a common thing throughout the country for notes to turn up in cities far from the banks that had issued them, and because of the difficulty and expense of getting such notes redeemed they circulated at a discount. Some brokers and bankers specialized in the collection of notes if they could reduce the expense of collection to less than the discount. The Suffolk bank arranged to redeem the notes of New England banks which would maintain balances with it, and to make the plan effective it systematically called on other banks for payment of their notes. The Suffolk, in fact, paralleled the function of the Bank of the United States and was itself in a rudimentary way engaged in central banking. In one important respect, it was more advanced than the Bank of the United States, for other banks maintained with it balances to which their notes were debited, whereas the Bank of the United States, as it received the notes of other banks, demanded payment accordingly. The Bank of the United States, in other words, regulated banks as their creditor; the Suffolk regulated them as their debtor. The latter relation became typical of modern central banking. Although the Suffolk bank was an efficient regulator, it was peremptory and severe toward other banks, whose hostility had greatly modified its operations by 1858, shortly before the National Bank act ended state bank-note issue.

A public attempt to the same purpose was represented by the New York Safety Fund established by legislative enactment in 1829. The provisions of the act required the maintenance by the banks of a general fund—administered by the state—for the redemption of the notes of banks that failed. This was in a real sense a forerunner of the Federal Deposit Insurance corporation. The fund was made proportional to the assets of the several banks instead of to their note issues, which would have been more reasonable. When the fund was held to be, in essence, a guarantee of bank deposits as well as notes, difficulties which otherwise could have been avoided became insurmountable. New York thereafter adopted, in connection with its free banking policy, provision of law which required that associations freely engaged in banking might issue notes only upon deposit of securities of the United States or of New York with the state comptroller. This method of restraining the note issue and of protecting the note holder was relatively sound and it was the precursor of the method of note issue provided by the National Bank act of 1863.

The Condition of the Currency to 1863.—Despite the meritorious efforts of the Suffolk bank, of the New York Safety Fund and of other reasonably appropriate bases for bank-note issue, it may be said that the condition of the currency in the country as a whole was deplorable, and increasingly so, in the years prior to the Civil War. The state bank notes constituted a most varied currency; varied in design, size and material, and varied, too, in respect of degrees of protection of the note holder and of limitation of total issue. Consequently, apart from the notes of the New York banks and of the New England banks (because of the Suffolk system), most state bank notes had only local circulation. So varied and numerous were the notes issued that at one time, so it is reported, about 1,600 banks issued in all approximately 10,000 different kinds of notes. Every principal financial house made use of a publication known as a "note detector," which purported to identify counterfeit and genuine notes; and the notes of the several state banks circulated, in parts distant from their place of origin (if at all), at discounts ranging up to 10% and 15%.

It was this unsatisfactory condition of the currency of the country, together with needs associated with the financing of the Civil War, which led to the passage of the National Bank act in 1863.

National Bank Act of 1863.—In 1863 the federal government resumed its monetary responsibilities with the National Bank act, which provided that banks under federal charter and known as national banks should issue notes on the security of United States government bonds pledged in Washington, D.C., with the comptroller of the currency. These notes were uniform and of standard denomination, and provision for their redemption, modeled after

the procedure followed by the Suffolk bank, gave the country a currency that circulated everywhere at par. The immediate incentive to passage of the act was not banking or currency reform, though that was achieved by it, but increased funds for waging the Civil War, the expectation being that national banks would buy great quantities of government bonds in order that they might issue as large a volume of notes as possible. This expectation was disappointed; the deposit business of banks already exceeded their note circulation and was growing far more rapidly. Moreover, the system was not established till so late in the war that it could not contribute significantly to the financing thereof.

It had been expected also that national charters would be so attractive that state banks would convert to the national system; and when this did not occur. a tax of 10% was imposed on state bank notes, the assumption being that this would render note issue unprofitable and drive state banks out of existence. But this assumption, again, was based on the false notion that note circulation was essential to banking. So state banks that had no circulation remained untouched, and others gave it up, continuing as banks of deposit only.

The National Bank act was based in its essentials and in much of its language upon the New York Free Banking act, which had already been the pattern for bank laws in many other states. It provided that any number of banks might be established, the organization of each having to satisfy certain stipulations of the law. It continued and amplified official bank examination, which was to become an increasingly important characteristic of Gnited States banking.

After adoption of the National Bank act the most important monetary and banking measures were those taken by the federal government. Before the Civil War, banking practice and banking control were diverse and experimental. Different states followed different courses—some being restrictive. some being loose. some having a good experience, some having disasters and some changing from one thing to another. Beginning with the National Bank act, banking practice and banking legislation developed a new national unity. Substantial improvements in banking practice resulted therefrom, particularly with respect to the currency. National bank notes circulated at par throughout the country. The note holder was entirely protected by virtue of the redemption provision. The federal government's liability in the matter was covered through the pledge of U.S. securities with the comptroller of the currency by the issuing banks.

The system which emerged under the National Bank act had, however, certain inherent defects which resulted in frequent bank failures and recurrent financial stringency. The defects related both to the factors affecting the volume of currency and to the concentration of pyramiding of bank reserves.

The currency, while entirely safe as indicated above, failed to expand and contract in volume in response to the changing needs of the business community because through the bond security requirements it was more clearly related to the fiscal operations of the federal government than it was to the level of economic activity.

The national banks were required to hold reserves in varying proportions to their deposits, depending upon the location of the bank. The banks in the central reserve cities. New York, Chicago and St. Louis, were required to hold their reserves in the form of vault cash; however, the banks in reserve cities (a substantial number of other financial centres) were permitted to hold a proportion of their reserves in the form of deposits with other banks in the central reserve cities, and the so-called country banks (national banks located neither in central reserve nor reserve cities) were permitted to hold a proportion of their reserve in the form of deposits with national banks located in reserve cities of either category. This system produced the pyramiding of reserves noted above, the concentration being most serious in New York. It is widely believed that this concentration led to recurrent financial panics since, in periods of monetary stringency, many banks mould call upon their reserve city correspondent banks for cash. This action, in turn, would involve substantial withdrawals from the New York city banks and the latter—being aware of this eventuality—typically had their funds invested in call money loans which would have to be called with consequent liquidation and declines in security prices.

To these substantial defects must be added certain others. some major and some minor: provisions for the clearing of checks were inefficient or unsatisfactory and there was no unified "banking system" in the sense of a central bank with powers to influence and control the flow of money and credit. During this period, moreover, the independent treasury system established in 1836 continued to be operative in spite of the fact that national banks could be employed both as fiscal agents and depositories.

The defects here described led to serious discussions of the monetary and banking system, culminating in the establishment of a national monetary commission in 1908 and leading, ultimately, to the establishment of the federal reserve system (*q.v.*). The enactment of the federal reserve system in 1913 effected substantial improvements in the banking system of the United States but—at least in its original formulation—it fell far short of meeting the most important requirements of a central banking system.

Bank Suspensions and Crisis of 1933.--Beginning before 1900 there was a prolonged increase in the number of banks; for the whole country the number more than doubled between 1900 and 1920. Most of this increase mas in farm regions and comprised small banks that could survive only under the most favourable conditions. About 1920 a fall in agricultural prices occurred which immensely reduced the income of farmers and made impossible the situation of those who had gone into debt in the period of prosperity. The upper Mississippi valley states, which were predominantly agricultural, were subjected to a general reduction of income while remaining under the necessity of repaying indebtedness and purchasing supplies. The creditors and suppliers mere largely in the eastern industrial regions so that there arose what is known in international trade as an adverse balance of payments, the agricultural west owing more to the outside world than it received therefrom for the products it sold. The banks were inescapably involved as their deposits dwindled and as their debtors became unable to pay. Bank failures became common. From 1921 to 1933 the number of banks was reduced by about 16,000—a reduction that offset the corresponding growth of the earlier two decades. It was not all a matter of insolvencies, for many banks consolidated and some liquidated without loss. Most of the contraction occurred among the small banks in the middle west which were, of course, the most vulnerable. Iowa, for example, which in 1924 had 1,600 banks, lost 1.000 of them by 1934.

By Jan. 1933 panic began to spread eastward. Holidays, or moratoria, were proclaimed in state after state in order that banks might close under cloak of legality and avoid devastating runs, and almost the first act of the Roosevelt administration, on March 6. 1933, was a proclamation making the closure nationwide. Thereafter, banks deemed to be in satisfactory condition were gradually authorized to reopen. The greater part of the weeding-out process was a matter of weeks. At the end of the next year. 1934, the number of banks was 16,000; 12 years before it had been more than 30.000.

The banking crisis of 1933 was probably the most severe in U.S. history. There had been general suspensions before the Civil War, but they had not necessarily entailed closure; suspension had then meant that a bank would not redeem its obligations in gold and silver but continued operations otherwise. In 1933 and in the years preceding, suspension meant absolute closing, which was, however. temporary in most cases. But meantime it entailed a drastic stoppage of the customary means of payment. The condition affected whole regions and whole economic groups involved in the aftermath of a prolonged rise in prices and values that was inordinate and could not be sustained. It might theoretically have been avoided but, once developed, no credit institution could stop its consequences. The government revived the War Finance corporation for the purpose of agricultural financing, developed a farm-loan system with intermediate credit banks and in 1932 set up the Reconstruction Finance corporation, which lent on a larger scale to banks. It also liberalized the terms

on which federal reserve banks might lend, but all these emergency measures, though they tempered the inevitable, could not prevent it.

The problem was complicated by the fact that the agricultural depression mas simultaneous with speculative booms in Florida real estate and in corporate stocks. Funds intended for relief in depressed regions found their way swiftly into speculation; and measures intended to restrain speculation threatened recovery in agriculture. In 1929 a collapse in stock-market speculation began a period of general depression lasting several years.

The great weaknesses manifested in this period renewed a dormant advocacy of branch banking and also developed a variation of it in organizations comprising separate banks owned by holding companies. In the larger cities of the east and the far west, banks built up systems of numerous offices; and in many states, including notably California. branch organizations of considerable size were formed, partly by the establishment of new offices and partly by the merging of independent banks.

There was intense controversy over the question in congress, but the opponents of branch banking, who were strongest in the regions where there was no branch banking and where bank failures were most numerous, resisted successfully all attempts to do more than make federal law as liberal as state law in those states where branches were not forbidden. As a result, banking in the United States at mid-20th century was still typically conducted by individual banks, mostly small, local and having but one office. This situation was a peculiarity as compared with banking elsewhere in the world and as compared with other kinds of business in the United States. Yet despite the disinclination of most small banks to become units in large organizations and despite the disinclination of most large metropolitan banks to undertake the responsibilities of widespread branch systems, the ratio of the number of banks to the number of banking offices continued to rise after 1933. Though peculiarly resistant. the banking business seemed to be gradually yielding to a general trend toward large-scale organization. In this period unincorporated banks practically disappeared. In 1900 they numbered about 5,000, mostly very small. Though little is known of them collectively, some were important, the most famous being J P. Morgan and Company, New York, which did not incorporate until 1940.

The crisis of 1933 occasioned establishment of the Federal Deposit Insurance corporation, to insure deposits in all member banks of the federal reserve system and in nonmembers which qualified. Each insured bank was to pay an annual assessment for the insurance, which was to cover deposits up to $5.000 (later $10,000) in each account. The corporation was also authorized to take over insured banks in difficulties to rehabilitate or liquidate them. Bank failures diminished to almost nothing after 1933.

The Late 1930s and World War 11.—In 1935 there was an important reorganization of the federal reserve system, involving the federal reserve board (the legal name of which was changed to board of governors of the federal reserve system), the federal open market committee (which thenceforth comprised the board members and five reserve bank presidents) and the management of the federal reserve banks. This change increased the authority of the board and the committee and also recognized more fully the primary importance of open-market operations.

When the system was established in 1914, it was expected that banks in need of reserve funds would borrow from the reserve banks and that in consequence the discount rate of the reserve banks would have a regulatory effectiveness. Actually, it came about that banks were extremely reluctant to borrow. The result was that the scope of regulatory action was much diminished and the monetary authorities were left little initiative. Open-market operations—the purchase and sale of government securities by the federal reserve banks—were found to be immediately effective in augmenting or reducing the reserves of banks, and they allowed the authorities to take the initiative in regulating credit. The usefulness of open-market operations was first realized in the early 1920s but their effectiveness depended on unified action by all 12 federal reserve banks. The Banking act of 1935 recognized in law the results of about 15 years' experience.

This accomplishment was already in process of being nullified. however, by the sale of gold to the United States by the rest of the world. Political and economic uneasiness in Europe was mainly responsible for the pouring of the world's gold into the United States, and its domestic effect was such an augmentation of bank reserves that regulatory powers were inadequate to offset it. The authorities were committed to an easy money policy because they wished to encourage business recovery, but they could scarcely have chosen otherwise, even though they received and from time to time used the power to require member banks to maintain larger reserves. Toward the end of the 1930s, however, preparations for war began to quicken activity decisively; there began, also, an expansion of the public debt which raised the total from $45,000,000,000 in 1940 to $279,000,000,000 in 1945. A large part of the debt was acquired by banks and paid for by an increase in their deposit liabilities. Still further inflationary potentials were created when the banks sold their government obligations to the federal reserve banks and enlarged their reserves and thereby their lending power. The federal reserve banks were inhibited from declining to purchase the government securities because to do so would have depressed their market price, impaired the government's credit and raised the interest cost.

The dilemma thus faced by the monetary authorities—whether to follow policies primarily directed to the maintenance of low interest rates on the federal public debt or to exercise greater control over inflationary pressures—was not resolved until early 1951. In the course of the discussions leading to the resolution of the dilemma, the semi-independent status of the federal reserve system was brought into question in some quarters. (See FEDERAL RESERVE SYSTEM, THE.)

In March 1951, however, a joint announcement was made indicating that the treasury and the federal reserve system had reached an agreement with respect to the "debt management and monetary policies to be pursued. . . ." Thereafter, the federal reserve system did exercise certain of its powers anew. During 1952 and 1953 policies looking to the control of inflation and to the restraint of credit expansion were followed. They were modified as a consequence of the mild recession of 1954 and thereafter were again strengthened in the interest of credit control until the autumn of 1957 when business conditions again suggested the desirability of further easing the flow of bank credit.

There was substantial discussion in the late 1950s of the possible establishment of a national monetary commission or other device to re-examine the banking and financial system of the United States. No official body had been established for this purpose at the beginning of the 1960s but the Committee for Economic Development, a private organization, had established a commission of outstanding experts charged with the task of studying the problem in its broadest aspects. The multiplicity of financial agencies together with defects alleged by some to characterize the current banking system have combined to suggest a re-examination of the whole. (FK. L. K.)

II. PRINCIPLES OF BANKING

As noted in the introduction to this article, banking institutions may perform a wide variety of services for their customers. But, apart from the one function which characterizes a commercial bank—the creation of credit—these functions are not peculiar to banks and none requires theoretical analysis of a kind peculiar to banking.

The theory of banking, then, has to do primarily with the operations of commercial banks. The distinguishing characteristics of commercial banks is that claims against them, called bank deposits, are themselves money. Commercial banks, by accepting deposits against which checks may be drawn, provide a means of payment. This means of payment, the circulation of bank deposits by check, constitutes the major part of the circulating medium in all Anglo-Saxon countries and in many other highly developed countries. In the United States at mid-20th century, for example, commercial bank deposits accounted for approximately 75% of

the money supply. It was estimated that in excess of 80% of all transactions measured in terms of total value were effected by the transfer of such deposits by check.

Money is defined as anything that is generally acceptable in exchange for goods and services and in the discharge of business obligations and that has a fixed price in terms of the unit of account. Clearly, then, in all countries mith highly developed banking systems, commercial bank deposits — deposits subject to withdrawal or transfer by checks drawn upon them — are viewed as a part of the money supply. All contemporary literature in the theory of money and banking proceeds from this fundamental definition.

It is true that the theory of banking deals largely with the operations of commercial banks and in particular with the way in which those operations influence the supply of money. In connection with these topics it is necessary not only to treat the operations of commercial banks but also to consider the relationships which exist between commercial banks, central banks and national treasuries.

The term commercial bank embraces institutions ranging from a small neighbourhood bank such as is found in most medium-sized communities to a huge metropolitan institution or a widely spread organization with hundreds of branches. In the United States there are many banks, approximately 1,300 at mid-century, most of which are relatively small banks conducting the whole of their business in a single banking office; there is also a substantial number of banks operating many branch offices. In the United Kingdom, and in most other parts of the world mith developed banking systems, there are a few large banks each of which operates many full-scale branch offices.

A. Creation of Deposits

The act of lending money may take any one of three forms: All three forms may be observed in the day-to-day work of a commercial bank but it is to the third that the theory of banking primarily addresses itself. Some have viewed these three forms as successive stages in the historical development of the art of lending although the validity of this view is difficult to demonstrate by the methods of historical scholarship.

Methods of Lending Money. — The first method of lending money involves the simple act which takes place when one person lends his own money to another in return for the promise of the latter to repay it at some future time usually, and always in commercial lending, together with interest. This simple act of lending is the process which most people have in mind as the essence of the typical transaction. It may be observed in the operation of a commercial bank to the extent that such a bank may extend a loan of funds accumulated from its earnings. If the bank in this case were to purchase. for example, a government bond, it would be practising the first method of lending, that of lending its own money.

The second method involves an intermediary. It occurs, for example. when a government bond or other debt instrument is purchased by the bank with funds left with the bank by a depositor. In this case the bank has acted as an intermediary between the depositor who wished to leave cash for safekeeping, and for, perhaps, a small return, and some other person or institution desiring cash and with a debt instrument to sell.

In such transactions as these, where there is a transfer of bonds or commercial paper to a bank, the borrower is not necessarily the one who receives the money from the bank. Unless the individual who gets the money is also expected at a later date to pay the obligation, the transaction amounts to a passing on of a debt from one creditor to another. In the above example the government is clearly, from the standpoint of the bank, the borrower. Likewise when a businessman discounts a customer's note at a bank, the bank becomes a lender not to the businessman but to his customer. The owner of a government bond who sells it to a bank, or the businessman who discounts a trade acceptance at a bank, thereby steps out of the role of lender; and the bank steps into the role of lender:

From an economic standpoint, in this case the bank acts primarily as an intermediary in lending of the second type since it takes the money of depositors and places it at the disposal of borrowers or of those who previously occupied the position of lenders. The legal position, however, is that the bank owes the depositors; and the borrowers (*i.e.*, the ultimate payers) owe the bank.

In lending of the third type, banks furnish neither their own money nor money received from others; instead, they establish deposit credit against which the bank's customer can draw checks. These deposits are created as part of the lending operation. New money is created.

In the simplest case, a businessman with an established credit rating with his bank and in need of ready funds in the amount, for example, of $10,000 borrows from the bank, tendering to the bank his own promissory note as evidence of the debt. In this case the bank acquires an income-yielding asset and the businessman will ask thnt the loan be credited to his deposit account. Assuming that the bank has adequate reserves to meet its legal reserve requirements and disregarding, for the moment, the existence of other banks, the bank's customer has acquired an addition to his checking account and the bank has acquired a new earning asset. The results of this operation may easily be seen in the changes in the bank's balance sheet which flow from it.

Table I. — A Bank's Balance Sheet for a Customer

Assets		Liabilities	
Notes	$10,000	Deposits.	$10,000

It should be noted that the addition to the borrower's deposit account is a net addition to the deposits of the banking system as a whole. It has been created through the process of an expansion of bank loans; and since deposits constitute a part of the money supply it represents an increase in the quantity of money in the society.

This is frequently a difficult idea for many people to accept. In essence the process is simple but the preoccupation of those who identify "money" solely with coin or currency stands in the way both of their ready understanding or acceptance. Hence, it is worthwhile to examine the process in more detail and to raise and reply to some of the common questions concerning it.

The Nature of Deposits. — Contrary to the usual understanding of the word deposit, the expression "bank deposit" does not signify something which is physically present. A bank deposit is simply an entry on the books of a bank recording its obligation to a customer. While it may arise out of the transfer of cash or other assets to the bank, it is not itself an asset but a liability of the bank.

The terms primary and derivative deposits relate to the manner in which demand deposits (those bank deposits against which checks are freely drawn) originate. A primary deposit is one which arises out of the deposit of checks or currency at a bank. The balancing item on the books of the bank is an addition to so-called nonearning assets in the form of cash or claims on other banks. A derivative deposit, on the other hand, is one which results from a loan or investment by the bank. The balancing item is an addition to the bank's earning assets under the classification of "loans and discounts" or "investments." The creation of derivative deposits, which may be thought of as identical with the third stage of the art of lending, is sometimes described as the "monetization of credit." The adjectives derivative and primary refer only to the way in which a deposit gets on the books of a bank. When a derivative deposit is transferred to another account by being checked against, it becomes a primary deposit. The deposit which emerged in the transaction illustrated in the balance sheet entries above. is a derivative deposit, *i.e.*, it arose from the lending operations of the bank.

The distinction between primary and derivative deposits is of great importance in relation to the effect of banking operations on the total volume of circulating medium. A deposit of checks merely transfers demand deposits from one bank to another or from one checking account to another and does not alter the total. When demand deposits are created by the deposit of cur-

rency, the expansion of deposits is accompanied by an equivalent reduction in the amount of currency at the disposal of the public; the effect is to exchange one medium of payment, currency. for another, demand deposit, but not to increase the total means of payment available to the public. A primary deposit, at most. may change the form of circulating medium but does not directly alter the total volume. When derivative deposits are created, on the other hand, there is an increase in total circulating medium.

In the normal operation of the banking system, the second and third stages of the art of lending are not so distinct as may appear from the description. Once the volume of bank deposits has grown to a size more or less adapted to the current requirements of a community, new loans will be made as old loans are repaid and a growth in the deposits of one customer will correspond to a decline in the deposits of others. In such a situation the banking system can be looked upon as an intermediary in the disposal of demand deposits already in existence. Alternatively, of course, each repayment of a loan might be regarded as involving a destruction of old deposits and each new loan as leading to the creation of new deposits. It would still be true, however, that a net creation of demand deposits occurs only when the total is rising. The great majority of'credit operations, whether of an individual bank or a banking system, involve no significant change in total deposits and are in effect similar to the second type of lending operation. The effect of banking operations in bringing about a change in the supply of circulating medium is particularly apparent in periods of rapid expansion such as occurred in World Wars I and II and of sharp contraction such as has usually occurred in periods of severe depression. See also CURRENCY; INFLATION AND DEFLATION; MONEY.

B. RESERVES AND THE LIMITATION OF DEPOSIT CREATION

The basic limitation on the process of deposit creation is the necessity of maintaining reserves of currency or its equivalent. In order to provide for routine operations and to be able at all times to redeem deposits on demand, banks must have at their disposal an adequate amount of currency or its equivalent relative to the volume of their deposit liabilities. There must be enough till money to meet day-to-day demands and there must be additional funds on hand or on deposit with other banks to meet a sudden increase in demand for cash payments. The proportion of cash to deposit liabilities may vary from time to time and it customarily differs for different sizes and types of banks. Whatever the precise relationship of reserves to deposits and however it is determined, the necessity of maintaining adequate reserves sets the ultimate limit to the process of deposit creation.

Reserve Provisions.— In some countries, notably the United States, certain minimum ratios of reserves to deposits have been prescribed by law. In other countries, such as England, the ratio of reserves to deposit liabilities is left to the discretion of the banks themselves. Whether the ratio is established by law or custom, the creation of deposits must be halted when deposits have reached that multiple of the reserves held by banks which corresponds to the accepted ratio of reserves to deposits. Similarly, a reduction of reserves below this point would force a contraction of the amount of deposits based upon these reserves. Just as the banking system can expand deposits by a multiple of any addition to reserves, so deposits would be expected to contract by a multiple of reserves which are lost. The size of the multiple is the reciprocal of the reserve ratio.

Illustrations of the extent to which the process of deposit creation is limited by required or customary bank reserves and of the manner in which changes in the size of bank reserves may result in multiple expansion or contraction of deposits may aid in understanding the process. Assume, for the moment, an economy with one commercial bank. Assume, moreover. that the bank has deposits of $1,000,000 and a reserve account of $200,000 on deposit with the central bank, in the United States a federal reserve bank. Assume, moreover, that the reserve required by statute is 20% of deposits. The bank, then, is fully "loaned up," that is, it could not expand its loans unless it could acquire new reserves. The bank would, of course, have assets and liabilities other than its reserve account and its deposits. Their totals and changes in them, however, are not essential to the present illustration. The situation of the bank, then, might appear as follows:

TABLE 11.—A Commercial Bank's Required Balance

Assets		Liabilities	
Cash	$ 70,000	Deposits	$1,000,000
Investments	500,000		
Reserve acct.	200,000	Other liabilities	10,000
Notes & discounts	230,000		
Bldg., equip., other assets	100,000	Capital surplus.	90,000
Total	$1,100,000	Total	$1,100,000

It will be noted that the reserve account of this bank is exactly equal to the minimum 20% of deposits as required. The bank, therefore, is not in a position to expand the total of loans and investments since this would give rise to deposits and would, therefore, mean that its reserve account was different. Moreover, since we are operating upon the assumption that this is the only commercial bank in the system, it would not be possible for this bank to augment its reserves by the sale of securities to another bank. The system as a whole is "loaned up."

Now suppose that an increase occurs in the reserves of the bank arising from the importation of gold in the amount of $100,000. In effect, in the United States, the gold would be purchased by the treasury. The treasury would pay for the gold with a check on its account with the federal reserve bank. The seller of the gold would deposit the check to his account in our single commercial bank which, in turn, would deposit the check to its reserve account in the federal reserve bank. The balance sheet of the commercial bank would then appear as follows:

TABLE *111.—A Commercial Bank's Balance Sheet*

Assets		Liabilities	
	$ 70,000	Deposits	$1,100,000
Cash	500,000		
Investments	300,000	Other liabilities	10,000
Notes & discounts	230,000		
Bldg., equip., other assets	100,000	Capital surplus.	90,000
Total	$1,200,000	Total	$1,200,000

It will be seen that our single bank has acquired an addition to its deposits of $100,000 which, upon the assumption of a 20% required reserve, would require an increase in the reserve account of $20,000; but the reserve account has increased by $100,000. Hence our single bank has reserves in excess of the requirement in the amount of $80,000. Since this would provide required reserve for a further increase in deposits of $400,000 the bank may make loans or investments and thereby create new derivative deposits in that amount. Thus the increase in reserves of $100,000 provides a base for a multiple expansion of deposits, the multiple being equal to the reciprocal of the reserve ratio. (Possible expansion of deposits = increase in reserves ÷ reserve ratio or $\$500{,}000 = \frac{\$100{,}000}{.20}$). Clearly, if our single commercial bank were fully "loaned up" and reserves were to leave the system, a multiple contraction of deposits of the same proportion would ensue. The assumption of a single bank is, of course, an artificial assumption; but so long as the reserves of the system of commercial banks as a whole remain unchanged, it is not unrealistic for, in these circumstances reserves lost by one commercial bank must be acquired by another and thus, in this respect, the system may be likened to a single bank. But, as we shall see below, the existence of many banks does make a difference. The allocation of reserves between banks and the distribution of new reserve funds in the system between banks and nonbank holders will be considered subsequently.

Because reserves are the basic factor limiting demand deposits, the theory of the behaviour of bank deposits is essentially a theory of the determination and allocation of reserves. The ultimate restraining influence of reserves would apply in a banking system entirely devoid of laws or institutional controls. It is

the key to the operation of the individual bank or of the entire system of banks. In addition, reserves are the principal basis by means of which central banks, as will be noted later, undertake to control bank credit in the interests of general economic stability.

Internal Drain. — The allocation of reserves is most clearly described in terms of the so-called internal and external drain of reserves. It is to be observed, first of all, that the presence of other banks within a banking system modifies the behaviour of any individual bank within that system. This is because a bank which is one of many having mutual relations is subject to the possibility of an internal drain of reserves. By this is meant the shift of reserves from one bank to other banks in the system. It is regarded as internal because, while external to the particular bank losing reserves, it is internal to the banking system.

The shift of reserves to or from a particular bank results from the necessity of settling balances between that bank and other banks in the system. The net amount that must be paid by a bank is governed in turn by the dollar volume of checks drawn against the bank relative to the sums drawn on other banks which are payable to it. Payments between banks in settlement of checks drawn can be offset against one another (*i.e.*, "cleared") but any remaining difference must be paid in cash. Such payments are likely to involve a corresponding shift in reserves. The mechanical operations of check clearances are conducted through central banks, correspondent banks, clearinghouses and by direct collection between banks.

The way in which internal drain controls the lending operation of a particular bank may be seen by supposing that a bank, having received additional reserve money, expands its deposits more rapidly than others in the system. It would almost immediately be subjected to a drain of reserves as checks drawn against the new deposits were exchanged for cash or deposited with other banks. Withdra als over the counter and payments to settle balances due other banks would sharply reduce the reserves of the original bank. Because of internal drain, therefore, it is generally assumed that an individual bank can expand deposits by little more than the amount of the addition to its reserves. Provided that all reserves drawn out of the first bank were redeposited in other banks, the banking system as a whole, however, would be able to expand. as indicated in the illustration above, by approximately the full reciprocal of the reserve ratio. If the reserve ratio were 20%, total deposits could rise about fivefold. An increase in reserves at one bank will, in any case, be shared with other banks in the system as a result of the checks drawn against the deposits created by the initial deposit of new reserve money being placed to the credit of deposit accounts in other banks.

External Drain. — The assumption that all new reserve money remains within the banking system is, of course, highly unrealistic. It is probable not only that most of the reserves will be drawn out of the original bank and into other banks but also that a part will be drained entirely out of the banking system. Such a movement of reserves is known as external drain. There are two principal places where funds may go which are withdrawn from the banking system. A certain amount of currency may be drawn out to circulate within the country and under certain circumstances reserve money may be sent out of the country to settle foreign-exchange balances. (*See* EXCHANGE, FOREIGN; INTERNATIONAL PAYMENTS.)

Whether an external drain involves withdrawal of cash from the banking system only or from both the system and the country, the effect in either case is to restrict the possible creation of deposits. This is because external drains represent a reduction in the volume of bank reserves within the banking system. Whereas internal drain restricts the expansion of deposits for an individual bank but not for the system, external drain restricts it for both.

Both internal and external drain relate to the movement of reserves away from banks. They are the reverse of primary deposits, which represent the movement of checks or currency, and therefore of reserves, to a bank. The same transaction would be called a primary deposit if viewed from the standpoint of the bank in which a check was deposited and internal drain if viewed from the standpoint of the bank against which it was drawn.

The expressions primary deposit, internal drain and external drain, then, identify the movement of reserves to, within and from the banking system. They refer to specific operations related to the mechanics of the allocation of reserves. They do not, however, explain what causes the movements which they serve to designate.

Allocation **of** Reserves. — Reserves are allocated throughout the financial system in response to the necessity of effecting settlements between countries, regions, communities and individuals. These settlements are simply the residual of payments that result from the existing volume of business transactions and the manner in which they are carried out. If economic activity expands in a particular area more rapidly than elsewhere. the change in the relative proportion of business carried on will find its logical sequel in a correspondingly larger proportion of bank reserves concentrated in that area, and likewise of deposits based upon them. While the regional allocation of reserves will be altered by a change in the regional structure of business activity, the normal expectation is that at any given time an addition of new reserve money, no matter where it enters, will tend to be distributed throughout the financial system according to the same pattern as the existing stock of reserve money.

The presumption is that at the end of a period of expansion each bank in the system will have gained reserves approximately in proportion to the size of its reserves relative to the total of reserves held by all banks in the system. This will tend to be true also of the bank which receives the original deposit of additional reserve money. Depending on its relative size, the permanent increase in its deposits might well be less than the original deposit of additional reserve money and also less than that of other banks in the system. Moreover, if two banks, one large and the other small, were to receive new reserve money in equal amounts the first bank could expect to retain a correspondingly larger proportion of the increase than the smaller bank.

Following a net gain in reserves, each bank will tend, after all adjustments have worked themselves out, to experience an expansion of demand deposits corresponding to the reciprocal of its reserve ratio. The basic factor in the analysis of the banking process, however, is not what happens to deposits but what happens to reserves. Deposits are to be thought of as a result and reserves as the governing, or at least the limiting, ,causal factor. Theoretically, the pattern by which reserves are distributed will also determine the pattern by which deposits are created.

(*C.* R. *WY.;* FK. L. K.)

C. Central Banking in Relation to Commercial Bank Reserves

The expansion of central banking in the 20th century mas accompanied by a fundamental alteration in the composition and behaviour of commercial bank reserves. Until the early years of the 20th century the reserves of commercial banks throughout most of the world consisted chiefly of gold and silver and. to a limited extent only, of the obligations of central banks. As a result of policies introduced in World War I, reserves came to consist mainly of the liabilities of central banks. Automatic forces governing the movement of commercial bank reserves became relatively less important; and monetary management, in a variety of forms but usually under the guidance of central banks, became more important.

The principal function of a central bank is to act as a stabilizer by attempting to prevent or moderate economic disturbances. In the latter part of the 19th century it came to be generally agreed that in order to maintain confidence and prevent financial panic. a central bank should stand ready at all times to lend additional cash when needed, but at a price high enough to discourage less deserving borrowers. Back of this conception of the role of a central bank as lender of last resort lay the belief that in time of crisis a spirit of panic is promoted by fear of not being able to secure ready money including additional reserves

for commercial banks. The ability of the central bank to discharge the function of lender of last resort was expected to give assurance that deserving borrowers could always obtain additional money when it was needed, but at the same time, that unwarranted borrowing could be effectively deterred. Provision of potential bank reserves was integrated with the use of the discount rate, at one time the most important instrument of credit control by central banks.

Creation of Commercial Bank Reserves.— In order to be able to provide commercial banks with additional reserves whenever it may be necessary, the central bank must be able to create reserves if called upon to do so. The manner in which this can be accomplished is by resorting to the third stage of the art of lending, which was described above in explaining how demand deposits may be created by commercial banks. In countries where the legal reserves of commercial banks consist of deposits with the central bank, the creation of deposits for commercial banks, through the discounting of commercial paper, extension of advances or purchase of government obligations by the central bank, constitutes an increase in their reserves. Where reserve ratios are prescribed by law, reserves may be-made available by a reduction of the legal reserve requirement. The principles involved are the same where central banks create liabilities in the form not of deposits but of bank notes, which may either circulate as currency or be used as reserves by commercial banks.

The basic factor limiting the ability of a central bank to create commercial bank reserves or currency is similar to that which limits the ability of the commercial bank itself to create deposits; namely, the necessity of maintaining reserves against its note or deposit liabilities. As in the case of commercial banks. the maximum amount of liabilities which a central bank can create on the basis of a given amount of reserves is determined by the reciprocal of its reserve ratio. The reserve ratio may be set by custom or law and is subject to modification in time of emergency. Under an international gold standard the amount of reserves nas determined primarily by gold movements between countries. In the absence of a metallic standard, reserve limitations are ordinarily set by law.

The ability of central banks to create reserves greatly extends the limits of deposit expansion by commercial banks as they were described earlier. In a system where commercial banks must keep a 20% reserve and the central bank a 25% reserve, the maximum deposit expansion possible on the basis of the addition of new basic reserve money is 20 to 1 in contrast with an expansion of only 5 to 1 within the central bank. The larger figure represents a combination of the third stage of the art of lending both at the member bank level and at the central bank level. Credit expansion by a reciprocal of the commercial bank reserve ratio is superimposed upon credit expansion by a reciprocal of the central bank reserve ratio. Substantial as credit expansion by the commercial banks is, the possibility of expansion that can result from the action of the central bank is much greater. This feature of central banks is the source of great flexibility if it functions well, but it can also be the source of extreme inflation and deflation if it operates badly.

The foregoing description of deposit creation may be summarized by noting that there are three distinct levels of deposit expansion. In the first place, a single bank can expand its deposits by little more than a 1-to-1 ratio with an addition to reserves. This is because of the loss of reserves to other banks within the system; *i.e.*, internal drain. 'Second, the commercial banks as a group can expand collectively to the limit of the reciprocal of the reserve ratio. Finally, the system of commercial banks together with the central bank can expand far beyond this amount, theoretically up to the limit of the reciprocal of the reserve ratio of the commercial banks multiplied by the reciprocal of the reserve ratio of the central bank.

The Control of Credit.— Probably the most familiar aspect of central banks in relation to the reserves of commercial banks has to do with the control of credit by the central bank. The principal general instruments of credit control are the making of discounts and advances at prescribed discount rates, open-market operations (*i.e.*, purchase or sale of government securities) and changes in reserve requirements. All of these instruments represent devices for influencing the volume of commercial bank reserves. The theoretical basis on which these policies rest is that since reserves limit deposits the way to control deposits is to control reserves.

Certain selective controls designed to limit particular types of credit directly, as through restricting or even prohibiting the amount of stock-market or installment credit that may be used, became familiar in the United States and various other countries after 1930. Despite substantial modifications in the art of central banking, the control of credit remained the principal method by which central banks attempted to promote economic stability, and the general methods operating through commercial bank reserves continued to be the principal means of exercising credit control. Chief reliance is likely to be upon the general instruments under relatively normal economic conditions. The selective instruments have found their greatest use in times of severe disturbance such as war.

The effectiveness of the general instruments of central bank control depends upon the fulfillment of certain well-defined conditions. The first of these is a governable relationship between the reserves and deposits of commercial banks. This means either the maintenance of a constant ratio or of a ratio which can be controlled by the action of the central bank. The second requirement for effective control of credit is the ability of the central bank to influence the volume of commercial bank reserves. In certain countries these conditions were vitiated at times after 1930, first by the emergence of excess commercial bank reserves and later by the pursuit of policies which enabled commercial banks to obtain reserves almost at will through the sale of government securities to the central bank. The consequent impairment of the power of central banks to exercise effective control over credit was partly a reflection of the more dominant place occupied by treasury policies. See also CENTRAL BANK.

D. Theory of the Banking Firm

The banker has been described as a dealer in debts. In contrast with other businessmen, he holds few assets of a tangible sort; his resources consist almost entirely of the debts of businessmen and the government. At the same time, he owes large sums in the form of time and demand deposits. The demand deposits impose an unqualified obligation to pay in currency whenever it is requested and the time deposits, even though a short period of grace is allowed by law, are usually expected to be paid when the customer wishes. Thus, the bulk of the bank's liabilities are subject, nominally at least, to payment on call. In actual practice, of course, net payments are likely to be relatively small. It is absolutely essential, however, that the resources of the bank be managed in such a way that it can meet all demands for currency as they are presented.

The problem confronting any bank, therefore, is to keep the realizable value of assets equal to the bank's liabilities to depositors.

The Fundamental Banking Problem.— In practice. the fundamental banking problem may be divided into two parts, the immediate and the long run. The immediate, or short-run, problem is that of keeping liquid assets equal to liquid liabilities. The question of the liquidity of liabilities is not so much a matter of form or legal provisions as it is of the actual presentation of claims for payment in currency, or its equivalent. The short-run phase of the banking problem, in other words, is the problem of liquidity; *i.e.*, of being able to meet all demands as they are presented. The long-run banking problem, on the other hand, is the problem of solvency. It is a question of keeping the realizable value of total assets equal to that of total liabilities; it turns on the question of whether the bank could be dissolved without loss to anyone.

Of the two, the short-run banking problem is the more critical. Failure to remain in a position to meet all claims as they are presented leaves the bank with no choice but to close its doors. It is synonymous with bankruptcy. The long-run problem, on the

other hand, would presumably be of direct importance only if it became necessary to close out the bank. There is a classic instance of a Canadian bank which was technically insolvent for 40 years but continued to remain open throughout that entire time because it was able to maintain short-run liquidity and meet all claims for cash as they nere presented. The long-run banking problem is likely to be of great practical significance in an indirect manner. Unless proper consideration is given to the ultimate safety of bank assets. a situation is much more likely to develop where the bank will not be able to meet the critical problem of short-run liyuidity.

The bases of a solution of the fundamental banking problem are implicit in the statement of the problem: since the object is to keep assets equal to liabilities, it follows that the solution lies in maintaining the value of assets and in preventing an undue expansion of liabilities. In the long-run phase of the problem the solution relates to all assets and liabilities, and in the short-run phase it relates to those which are highly liquid. While much depends on the quality of management. certain general lines of policy in meeting the fundamental banking problem may be indicated.

Policies directed toward the restriction of liabilities require much less attention from bankers and are ordinarily less important than those directed toward the maintenance of assets. In time of crisis, as during a run on a bank, banks may seek to delay presentation of claims. Attempts may be made to reassure depositors and persuade them that it is unnecessary to demand cash. Most of the paying windows may be temporarily closed and excessive time may be taken in counting out currency. Safeguards, or guarantees, may be introduced under governmental sponsorship. More fundamental methods are also employed to restrict not the presentation but the expansion of liabilities. The most familiar of these is the imposition of legal requirements with respect to the ratio of reserves against deposit liabilities. At times the authorities have attempted with less success to enforce certain ratios of capital accounts to deposit liabilities. Certain types of bank liabilities, particularly bank notes, have been prohibited or subjected to quantitative limitation.

Portfolio Policy.—The problem of maintaining the realizable value of assets is complicated by the fact that the features which enable particular assets to satisfy banking needs may be more or less in conflict with one another. A bank which held cash equal to its deposit liabilities would be assured of meeting all demands for withdrawal but it is unlikely that such a bank would be able to cover necessary expenses, let alone show a profit. On the other hand, if it were to put all its available funds into high-yield, relatively illiquid instruments, it might find itself in a position where it could not meet its promises to pay currency when requested to do so. Between these two extremes lies the path the successful banker must follow.

The amount of currency, or its equivalent, which a bank holds is set partly by law and partly by what experience demonstrates to be necessary for the satisfactory conduct of the business. In acquiring earning assets, a banker must constantly consider the criteria of liquidity, safety and profitability. The first of these tests is addressed primarily to the short-run phase of the banking problem and the second to the long-run phase. Profitability ordinarily varies inversely with safety and liquidity. Portfolio policy (*i.e.,* the bank's policy toward various types of earning assets) is directed, therefore, to effecting a satisfactory compromise among these three criteria; *i.e.,* to obtaining assets which are as profitable as possible while providing as great safety and liquidity as the bank considers essential.

While profitability is ordinarily measured by the interest on the securities owned, it may also include an appreciation in the principal value of the assets between the time of purchase and the time of sale. Safety relates to the realization of all anticipated payments because of interest and principal. A security is not necessarily unsafe merely because its market value may decline temporarily. If the stipulated payments for principal and interest are fully met and if the payments are never in doubt, the security must be regarded as possessing safety even though its market value may vary from time to time. The quality of liquidity, on the other hand, refers to the ability to exchange a particular asset promptly for cash without loss. Rhile a substantial decline in the market value of a particular security would not necessarily destroy its safety, it would impair its liquidity.

Liquidity may be achieved through holding a security until the maturity date is reached. The so-called self-liquidating commercial paper and the short-term bills and notes of governments are customarily expected to provide liquidity in this way. An asset is also liquid. however, if it can be sold or borrowed upon at its full book value. This type of liquidity is said to depend upon shiftability. From the standpoint of the individual bank, it is immaterial whether the shifting takes place to another bank, to a central bank or to any agency of the government, except so far as the difference affects the certainty of being able to make the shift. The difference may be highly significant from the standpoint of the banking system, however, since shifting to another bank does not provide liquidity for the system as a whole. While shifting to another bank would merely transfer existing reserves, shifting to the central bank would presumably increase total bank reserves and thereby make the entire system more liquid.

E. Development of Banking Principles

What came generally to be regarded as the traditional theory of commercial banking was first clearly set forth by Adam Smith in *An Inquiry Into the Nature and Causes* of *the Wealth of Nations (1776).* This theory focuses on the part played by commercial paper and is sometimes referred to as the "real-bills doctrine." It proceeded in its simplest terms from the assumption that commercial banks would confine their lending operations to the purchase of short-term, self-liquidating bills and notes arising out of production and trade.

The Real-Bills Doctrine.—An increase in production and trade was presumed to give rise to a larger volume of bills and promissory notes. By the discount of this commercial paper at banks, demand deposits would be increased with the result that the growth in volume of business would lead directly to a corresponding increase in the volume of circulating medium. Likewise, with declining business, fewer bills would be draun so that as old bills matured there nould be an automatic contraction in the volume of commercial paper held by banks and with it a corresponding reduction in demand deposits.

An essential part of the theory was the so-called law of reflux, whereby any excess of deposits was expected to flow back and be canceled through the retirement of maturing loans. Shortness of term to maturity was, in part, a device for enabling the process of reflux to operate promptly, and the necessity of paying interest was expected to provide an inducement for credit to flow back when it was no longer required.

The basic assumptions of the real-bills doctrine were that the volume of commercial paper would be proportional to the volume of trade, that a roughly constant proportion of commercial paper would be presented for borrowing at the banks, and that on the basis of commercial paper alone the banks would create demand deposits. These were the fundamental features, conceptually, of a mechanism whereby the volume of circulating medium was expected to adjust automatically to the changing level of economic activity.

The banks performed an important function in passing judgment on the credit worthiness of borrowers and by inference at least on the economic soundness of the undertaking out of which the commercial paper arose. At the same time, banks were assumed to be passive since the initiative lay with the businessman who presented commercial paper at the bank. Thus. the banking process was conceived of as operating automatically. In addition to guiding the allocation of deposit credit among competing uses and users, the banks performed two other important functions: (1) they raised the quality of credit available to the public by exchanging their own well-known credit for the less well-known credit of the borrower; and (2) they made credit available in more convenient forms and amounts.

Not only was the real-bills doctrine a theory of the adjustment of the circulating medium to the "needs of trade" but at the same time it implied a solution to the fundamental banking problem of maintaining assets equal to liabilities. Insistence on the short-term feature of commercial paper was presumed to assure liquidity of assets and insistence on the self-liquidating feature was presumed to assure safety. Short-term commercial paper was regarded, then, as offering the most satisfactory means of meeting the portfolio requirements of safety, liquidity and profitability.

The real-bills doctrine, as Lloyd W. Mints pointed out in his *History of Banking Theory in Great Britain and the United States*, had a long and influential history. It was the basis of the defense of the Hank of England during the restriction period from 1797 to 1821. Under the name of "the banking principle" it was widely endorsed by bankers, economists and government officials; it was a major factor in the conception, organization and early operation of the federal reserve system in the United States. The doctrine, however, was by no means free from attack. The most significant criticism related to what R. G. Hawtrey described as "the inherent instability of bank credit." The basis of the argument was that the volume of commercial paper may vary with changes in the value rather than the physical volume of what is produced and traded. Rising prices and increasing business activity tvould lead, it was said. to more commercial paper and so to an expanding volume of bank deposits. The expansion of deposits, by further raising prices: would contribute to a continuation of the upward movement of the money volume of business and the quantity of commercial paper, with a resulting tendency toward a self-inflammatory upward spiraling of prices. Conversely, falling prices and business activity would cause loans and discounts to decline, which would cause a contraction of demand deposits. This destruction of circulating medium would induce a further decline of prices, business and volume of commercial paper, thus feeding a continuing downward spiral of prices. The substance of this line of reasoning is that bank credit is not only inherently unstable but that it is unstable in a manner which is sympathetic with and conducive to swings of the business cycle.

Critics of the real-bills doctrine also maintained that in actual operation changes in the rate of lending by banks were likely to reflect differences in the expectations of bankers with regard to the future profitability of business rather than changes in the physical volume of business activity. To the extent that credit standards applied by bankers varied in different phases of the business cycle, bank lending on commercial paper mould not provide an accurate adjustment of deposits to the physical volume of business activity. It was also argued that, on the one hand, rigid insistence on real bills would rule out many types of productive lending which mere desirable from the standpoint of both borrower and lender and, on the other hand, paper which formally gave the appearance of being short-term and commercial might fail, in actual practice, to demonstrate these qualities. Nor was it to be assumed, in view of the changes constantly taking place in methods of business financing, either that fluctuations in business activity would lead to corresponding variations in the volume of cosnmercial paper or that a constant. proportion of the commercial paper that did arise would find its way to the banks.

Criticisms such as these challenged the view that bank lending on commercial paper would provide a satisfactory automatic means of increasing and decreasing the quantity of circulating medium. The view was also questioned that commercial paper provided an ideal solution for the fundamental banking problem. Experience had shown that at times of rapidly falling prices substantial losses on commercial paper might occur. Apart from the possible impairment of the safety and liquidity of commercial paper at a time of declining business, the entire conception of a general liquidation of bank-held commercial paper implied the contraction of credit and circulating medium on a scale that might be severely disruptive to business. Finally, the diminished use of commercial paper relative to other methods of financing meant that it could no longer be counted on as an adequate source of banking income.

Composition of Bank Assets.—Traditional banking theory, especially as developed along the lines of the real-bills doctrine, was not a general theory of banking. It applied to a special case; *i.e.*, one where bank assets consisted of the particular type represented by short-term, self-liquidating paper arising out of production and trade. In many areas, especially outside English-speaking countries, the theory was never entirely applicable, and elsewhere, notably in the United States, it became highly unrealistic after 1930 and especially after 1940. Where there is a high proportion of treasury obligations and other noncommercial securities in the portfolios of commercial banks, a situation which became general after 1930, the theory of banking as traditionally formulated requires substantial modification.

The change in the composition of bank assets did not alter fundamentally the mechanical operation of the banking system or the general principles of deposit creation. It did, however, signify a change in the consequences of bank operations and in the cyclical behaviour of banking.

In the first place, the different basis of deposit creation signifies a change in the economic functions performed by banks. To the extent that assets consist of treasury obligations, the credit operations of banks are no longer directly related to the production and exchange of goods and services, and banks cease to play the same part in allocating economic resources among competing users and uses that they do when making commercial loans. Moreover, since treasury obligations are assumed to have the highest credit standing, banks can hardly be said to be raising the quality of credit when they exchange their credit for that of the government. The one major function that remains substantially unchanged is that of providing, in the form of demand deposits, the principal element in the circulating medium. As part of this activity banks continue to be the centre of a clearing organization by means of which payments and financial transfers are conveniently and efficiently effected throughout the economy.

A further consequence of the relative shift from assets of a loan type to those of an investment type is to make the operation of banks less automatic than before. When banks extend credit on the basis of loans and discounts the initiative rests primarily with the businessmen who offer them to the bank. In acquiring or selling bonds and other treasury obligations, on the other hand, banks are able to take the initiative by entering the open market in the same manner as any other buyer or seller of securities. As banks become less passive the banking process becomes less automatic.

Most important of all, a shift to assets of a noncommercial type implies a modification of the cyclical behaviour of bank credit. This follows partly from the decline of automatism but even more from the fact that the volume of investment securities and particularly treasury obligations, unlike the volume of commercial paper, does not tend to vary directly with the total money value of business transactions. To the extent, therefore, that deposits are tied to investment securities rather than to commercial paper, the basis of the automatic adjustment of circulating medium to business activity disappears. The effect is to remove the principal reason for expecting banks to provide automatic elasticity of the money supply. By the same token, there is likewise less justification for regarding bank credit as inherently unstable, and particularly as unstable in a manner tending to aggravate cyclical fluctuations in business activity.

The course of banking development in the mid-20th century demonstrated the shortcoming of the real-bills doctrine as the central core of a general theory of banking. In altering the basis of banking functions and behaviour the change in character of bank portfolios also weakened the force of much of the familiar criticism of banking. The readjustment of bank portfolios away from the extreme concentration on treasury obligations that existed at the end of World War II was notable not so much for a return to earlier proportions of short-term self-liquidating commercial paper as for the expansion of newer, noncommercial types of assets. These included term loans with a maturity often of several years, mortgages and various categories of consumer installment paper. In the course of time, then, banking theory has

become more general by becoming less narrowly identified with any specific type of asset. The composition of bank assets continues to provide a key to the operation of the banking system at any given time. It is, moreover, the most important element to be borne in mind when comparing the banking system of one country or one period with that of another. See also COMMERCIAL PAPER.

III. PRACTICE OF BANKING

The legal framework within which banks carry on their activities differs widely from country to country. In the United States there are three supervisory bodies within the federal government in addition to one in each of the states. Banks are subject to detailed regulation and to close and sometimes duplicating examination. At the other extreme are the banks of the United Kingdom and the continent which, for the most part, operate under the provisions of laws governing business corporations in general and are subject to no official supervision or examination. In some countries banks are not even required to make public annual reports of their operations.

While banking practices likewise differ substantially in the various countries, the contrasts are less pronounced than differences in legal status might suggest. The character of banking practices is influenced to a considerable extent by the banking organization of the country, depending, for example, on whether or not there is a strong central bank.

Banking Structure.— The most usual form of corporate organization is the branch banking system, which consists of a home office at some central point with branches situated elsewhere. The number of branches may range from one or two to several thousand, and the branch system may be local or may extend over the entire country and even beyond into foreign countries. At the other extreme is the unit-bank form of organization with all of the bank's operations carried on at one central establishment. Where two or more banks are under common ownership, they are known as a group banking system if the ownership is vested in a holding company, and as a chain banking system if they are owned by an individual or a small group of individuals. Outside the United States banking is carried on principally by branch banking systems. In the United States the typical form or organization is the unit bank; although the other forms are also encountered, they are less common and are not widely distributed geographically.

The capital structure of a bank includes three principal accounts: capital, surplus and undivided profit. (See FINANCIAL STATEMENTS: Accounting *Terminology.*) The last is an operating account which is increased by current earnings and decreased by payment of certain expenses, dividends and occasionally by transfers to surplus. The other two accounts are relatively permanent. Aside from the use of these accounts in the starting of the bank, they act as a cushion to protect depositors against possible loss. Since they represent the stockholders' stake in the business, they are usually regarded as providing an inducement to exercise care in the management of the bank. A certain amount of surplus may be paid in at the time of subscription to the original capital, and the surplus account is likely to be built up further out of earnings. When losses have been incurred greater than can be charged against undivided profit, they may be absorbed by transfers out of surplus account.

The administrative structure of a bank is headed by a board of directors, who ordinarily serve without direct compensation other than fees for attending meetings or for special services performed. They are chosen for their standing in the community as well as for the breadth and variety of their business experience and their connections which may serve to attract business to the bank. They are responsible for electing officers, determining major policies of the bank and ordinarily for deciding on transactions in which relatively large sums of money are involved. The actual administration and operation of the bank are under the guidance of the bank's officers. whose numbers, duties and degrees of specialization vary greatly according to the size and character of the bank. The president, or chief executive officer, is customarily on the board of directors and other officers may be. In small banks the position of president is often more or less honorary and he may serve without salary.

A. DEPOSITS

Deposits constitute the great bulk of the liabilities of banks. They ordinarily far exceed the capital accounts. Other liabilities such as unearned interest, deferred maintenance and reserve for contingencies are chiefly of an accounting character and usually are of minor proportions. It is through the holding of deposits that banks perform their most distinctive services to the public.

According to the terminology employed in the United States, deposits are of two general types: demand and time. The demand deposits. called current accounts in England and sight deposits in France, are payable in currency or by transfer via check (*q.v.*) to other banks at any time the depositor requests. In the case of time deposits, known as deposit accounts in Great Britain, the bank has a legal right, though it may not be exercised, to require notice of perhaps 15 to 30 days or even longer in advance of payment. Time deposits include not only savings deposits, which have the character of thrift accounts and are usually relatively small in size, but also deposits of businesses and others which may amount to large sums. Such deposits are sometimes evidenced by time certificates bearing specific maturity dates. These correspond to the "fixed deposits" of British banks. It is customary for banks to pay interest on time deposits but not on demand deposits. (See also SAVINGS BANKS.)

Differences in the ownership of demand deposits are a matter of great concern in the operation of banks. Since these differences largely govern the behaviour of deposits, they help to determine the policies which a bank must follow in maintaining a liquid position; *i.e.,* in making sure that it will always have sufficient cash to meet demands. Small persona1 deposits are highly stable in gross amounts; inward and outward payments tend to offset each other and such fluctuations in totals as do occur are mainly seasonal and can readily be anticipated and provided for. Large deposits are much more unstable and the extent and character of variations in their amounts differ widely with the type of depositor. In general, the deposits of financial institutions such as banks and insurance companies are subject to greater and more sudden fluctuations than those of other types of corporate depositors. Other large deposits may vary seasonally or with particular business transactions, such, for example, as the purchase of additional rolling stock by a railroad company, which the officers of the bank are often able to learn about in advance. Large corporate depositors sometimes keep their banks informed of impending requirements. Similarly. in the United States the treasury gives advance notice of expected withdrawals, something that can readily be done since funds are left with banks only for safekeeping, actual payments being made against deposits at the federal reserve banks.

Large deposits may become particularly volatile in periods of uncertainty and fear. It is deposits of this type rather than the small deposits of individuals that are likely to be withdrawn first when doubt arises concerning the future solvency of a bank. This may be partly because of the greater amount which a large depositor has at stake but is probably chiefly because such depositors pay more careful attention to such matters and are in a position to be better informed.

Practices With Respect to Deposits— Banks often devote great attention to the character of the deposits they carry and to their possible future behaviour. In addition, it may be the practice for the bank's comptroller or some other operations officer to be notified the moment a large check is presented for payment. The purpose of such notification is to assist in enabling the bank to provide adequate cash to meet all demands without maintaining greater liquidity than is needed, since this would have the effect of encroaching on income.

The amount of earning assets a bank can own is directly related to the total of its deposit liabilities. Consequently. a strong incentive exists for attempting to expand deposits. Efforts to attract and retain deposit balances may take the form of advertising and direct negotiation, providing various types of free serv-

ice and appointing influential businessmen to the bank's board of directors. At one time it was customary for banks to compete for deposits by means of the rate of interest paid on them. This form of competition carries the danger of unduly increasing the costs of banking operations. To the extent that it merely results in taking deposits away from other banks without expanding the total of all deposits, costs may be raised with no corresponding benefit to the banking system as a whole. Because it was felt that the effect of such a practice might be to weaken the banking system, governments intervened in some countries to restrict the payment of interest on deposits. In the United States, for example, banks are forbidden to pay interest on demand deposits and are limited as to the rate that may be paid on time deposits.

Since smaller reserves are necessary against time deposits than against demand deposits, economy may be effected by encouraging depositors to transfer balances from demand accounts to time accounts. Under certain circumstances, the release of reserves by such transfers may contribute to an inflationary expansion of the volume of demand deposits. The administration of deposit accounts necessarily involves certain expenses for the bank. If the activity of a particular deposit account is great relative to the average size of the account, the cost to the bank may exceed what it can earn because of the deposit. It is customary, therefore, for banks to analyze deposit accounts and, on the basis of the number of checks drawn and deposits entered relative to the average balance maintained, to determine whether or not service charges should be levied and, if so, what these charges should be.

Banks may also require or expect depositors to maintain certain minimum or average balances in their deposit accounts. Loans may be granted upon the understanding that the borrower will leave 20% or 25% of the loan on deposit at all times. Such practices help to assure that the cost of operating the account will be met and increase the stability of deposit liabilities.

The handling of deposit accounts involves a great amount of rather mechanical, routine work in connection with scrutinizing and counting coins and other currency and with sorting, recording and distributing checks drawn on the bank itself and on other banks. Much of this work can be carried out with the aid of highly complex machines. In banks located in smaller communities most check transactions pass directly through the hands of paying and receiving tellers. In large city banks most of them may be conducted by mail. A bank may assume the task of receiving and crediting directly to the customer's deposit account payments for dividends, interest, bills receivable and the like, supplying the customer with a detailed record of the transactions handled by the bank. The work of handling mail deposits and of the transit department, which receives and forwards checks, may be on a continuous basis day and night seven days a week.

B. Lending Operations

The granting of loans to business borrowers has traditionally been regarded as the primary basis of commercial banking. During the first half of the 20th century and especially in the 1930s and 1940s, the extension of bank credit through purchase of investment securities by banks became increasingly common while the granting of commercial and industrial loans declined in relative importance. Investments generally carry a lower rate of return than loans but the work entailed in making investments is less than in granting and administering loans.

A bank may lend on a promissory note which bears interest until the note is due. It may also lend on drafts or acceptances which are in the form of noninterest-bearing obligations to pay a stipulated sum of money at some future time. Little distinction is made between the two types and they are ordinarily combined in a common account called "loans and discounts." When a bank acquires a noninterest-bearing obligation, it calculates the proceeds by subtracting from the face value a sum equal to interest on this amount from the date of purchase to maturity, a procedure known as "discounting." The fact that interest is deducted in advance makes the net rate on the sum actually lent by the bank slightly higher than the nominal rate.

It is a common practice for banks to grant their regular customers a "line of credit" under which the bank agrees to extend loans up to a certain maximum when requested to do so, subject, of course, to the meeting of certain specified conditions. The potential borrower can carry out his business plans with greater assurance because of the knowledge that he will be able to obtain funds quickly when they are needed. Banks often require a customer to maintain a deposit balance of from 10% to 25% of the line of credit granted. This practice is frequently criticized and is by no means universal. Borrowers sometimes pay a small interest charge, amounting to perhaps ½% of the unused part of the line of credit, under so-called "stand-by" agreements. A slightly different practice, common in Great Britain and a few other countries, is to grant customers an overdraft privilege. Under this arrangement the bank agrees to honour drafts up to a specified amount and charges interest on such overdrafts until they are paid off. Where this method is used, the overdraft privilege becomes a means of granting loans automatically and without separate formality as they are desired.

Larger banks maintain departments of substantial size for soliciting and serving loans. New business departments may engage aggressively in competing for loans and in seeking opportunities for the extension of credit. Credit departments maintain extensive files on the credit standing of actual and potential customers. Officers of the bank may furnish financial counsel and the bank may supply the services of technical experts to advise on plans designed to increase the operating efficiency of the borrower's business. Sometimes such assistance is related to the provision of additional credit by the bank or to the safeguarding of past loans. At other times it is designed to strengthen good will by promoting the customer's prosperity.

Types of Loans.—At one time bank lending was largely confined to short-term, self-liquidating paper arising out of actual business transactions. The maturity of such paper was usually from 30 days to 6 months, or somewhat longer in the case of agricultural operations. Through the granting of renewals, the credit might, in actual practice, be extended for a much longer period of time. Many bankers adhered to the so-called "golden rule" of banking by requiring customers to clear up their indebtedness to the bank at least once a year. Others were less strict; there are records of loans which were nominally of a short-term character but which had a continuous life, through renewals and extensions, of 25 years or longer.

Other types of loans are also commonly granted by commercial banks. Term loans have a maturity longer than that of the ordinary commercial and industrial loan. They usually run not less than 1 year and may run 15 years or even longer. In the case of term loans running more than five years, the loan contract may be divided with banks taking the earlier period of the loan and an investor of some other type taking the later period. Term loans may be used to provide working capital but are more likely to be used to pay for fixed capital, modernize equipment, obtain rolling stock and the like. Such loans may be drawn in such a manner as to permit changes to be made within the life of the loan, as by shortening or extending the time to maturity or expanding the loan to meet supplementary requirements. Term loans are usually of the amortizing type with current installments applied both to payment of interest and gradual reduction of principal.

Considerable flexibility and variety have been introduced into lending practices. For example, loans may be granted for the construction of tankers with provision for the payment of interest and principal out of the earnings of the ships. Loans of this sort are often extended jointly by commercial banks and long-term investors such as insurance companies. Again, loans are sometimes made on security of underground oil reserves, payment being provided for through the gradual pumping and sale of the oil.

Various types of collateral may be pledged as security for loans granted by banks. The most familiar types of collateral are real estate, stocks and bonds and bills of lading, warehouse receipts and trust receipts. The market value of the collateral at the time the loan is made is always expected to be substantially greater than the face value of the loan and provision is often made for

posting additional collateral if necessary to protect this so-called "margin." Collateral loan agreements ordinarily permit the borrower to substitute different collateral of suitable amount and quality in place of the collateral originally pledged. This feature is designed to protect the borrower against possible loss through inability to sell or against being deprived of possible gain if a favourable time to sell should occur, either of which might happen if the collateral were completely immobilized for the duration of the loan. While the collateral pledged against outstanding loans is subject to continuous scrutiny, the attention devoted to it is particularly close during periods of weakness in the markets with which the collateral is concerned. Likewise the size of the margin required may be increased to provide against the possibility of sharp price declines. In addition, central bank authorities may stipulate increased margin requirements with a view to restricting the volume of credit extended for use in the stock market.

With the expanded use of relatively expensive durable goods, such as automobiles and household appliances, the banks gradually turned to lending for consumption purposes. Techniques were devised for insuring the automobile or other durable consumer goods against theft or damage during the life of the loan, and for seizure and sale of the article purchased in case of default. Banks also entered the field of so-called personal loans, usually made for such purposes as medical expenses, education and the consolidation of indebtedness. Loans of this sort are ordinarily granted without the pledge of specific collateral and without requiring a cosigner of the note.

Repayment of both consumer and personal loans is typically provided for by a series of uniform payments which combine payment of interest with amortization of the principal. The debt may be represented by a book of coupons, each of which represents one of the payments due, the coupon being torn out and receipt acknowledged on the stub at the time the payment is made. Consumer and personal loans proved profitable to banks, despite the relatively high costs of operation resulting from the small sums involved in each individual transaction and the large amount of administrative detail. Rates, although considerably below those charged on similar loans by most other lenders, are higher than on other bank assets. Banks in larger communities maintain separate consumer credit and personal loan departments and engage in extensive advertising and promotional activities to expand this type of business.

Banks furnish credit to their competitors in these fields by lending to companies which specialize in the granting of consumer and personal loans. Furthermore, while rates charged by banks on consumer and personal loans are in general the highest received by banks, the rates charged consumer finance and personal finance companies are among the lowest.

Rates.—As has been indicated, the rates charged by banks on different types of loans vary substantially. The principal factor in such differences appears to be the size of the loan, though the type of the loan, which is likely to be closely related to size, is also an important consideration. Customers who borrow in large amounts, such as finance companies, large industrial corporations and transportation companies, are likely to enjoy a high credit standing. Furthermore, the fact that the sums involved are so large usually means that the costs of administration are small when calculated on a percentage basis. There is the further fact that large borrowers find it easy to tap alternative sources of credit so that a bank must offer as favourable terms as possible if it is to attract and retain their business.

The relation of collateral to rates charged by banks is somewhat ambiguous. Security loans, which consist chiefly of collateral loans to brokers dealing in securities, carry a low rate of interest. This is particularly true of call loans, which are subject to payment whenever the lender demands. Other types of collateral loans, on the other hand, are likely to carry a relatively high rate of interest. This may be explained largely on the grounds that where a borrower's credit position is weak added protection may be demanded in the form of collateral. It is not that collateral makes a loan weak, but that a weak loan may require the further strengthening which collateral affords. Somewhat similarly, loans bearing one signature ordinarily command a lower rate of interest than loans requiring a cosigner because only loans of the very highest credit standing are issued on a single signature.

Bank rates show considerable variation along regional and geographical lines. They are typically much higher on the average in rural areas than in cities, and are higher in the small cities than in the large. These differences are accounted for to a minor extent on grounds of differences in risks or degree of competition among lenders, but are chiefly attributable to differences in sizes of loans. It happens that geographical differences in rates tend to coincide with differences in average size of loans; loans are generally smaller in the country than in cities, and in small cities than in large. When allowance is made for the factor of size of loan, regional differences in rates charged by banks (within a particular country, of course) appear to be relatively slight.

C. Investment Practices

The form in which banks extend credit has always been influenced by the nature of the economy in which they operate, and especially by the apparent credit needs of the community and the methods of supplying those needs. It was natural that in England, where the traditional conception of commercial banking grew up during the 18th and 19th centuries. great emphasis should have been placed upon the short-term commercial loan. In a trading nation it was working capital that was chiefly needed and there was an abundance of foreign and domestic bills of exchange which could be used in providing such capital.

In other countries the same degree of concentration on commercial paper was never feasible, and other types of credit instruments played a correspondingly larger part in the operations of banks. Even in Great Britain and other Anglo-Saxon countries where the British conception of commercial banks exerted greatest influence, holdings of longer-term securities of the investment type came to occupy an important place in the portfolios of banks. The shift toward investments was stimulated by the great expansion in governmental financing which characterized World Wars I and II and the severe depression of the early 1930s. It was influenced, no doubt, by disturbances of world trade and changes in the financing methods of business which entailed a decline in the relative volume and availability of commercial paper.

Because real-estate mortgages are usually issued for fairly long periods of time and no general market for them characteristically exists, they were usually regarded as unsuitable for purchase by commercial banks. Accordingly, such investments were either prohibited or restricted. In the course of time, however, government guarantees, together with greater use of the amortization feature, tended to increase the popularity among banks of investments of this character.

Types of Investments.—Investment in mortgages may be limited to some prescribed ratio of capital and surplus or of time deposits. As in the case of other types of assets. such as common stocks or real estate itself, the limit may be exceeded temporarily if the asset is acquired to protect a loan or investment previously made. There is a tendency for certain types of restricted assets to constitute a larger proportion of the earning assets of banks in depressions than in good times. This is partly because commercial and other loans decline more rapidly than other types of assets in a period of falling business. It is also influenced by the fact that banks are likely to acquire, as a result of default, collateral which was pledged as security on loans granted earlier.

The principal types of investments held by banks are mortgages, government obligations and corporate bonds. In the United States ownership shares in corporations are ordinarily not held by banks except to the extent that they may have been acquired to protect a loan previously made, and when this has occurred it is expected that the security so acquired will be sold as soon as can be done without undue sacrifice.

Government obligations are by far the most important category of bank investments. They consist predominantly of securities of the federal government, but obligations of provincial or local units of government, sometimes called "municipals," may also be included. Investments in treasury obligations include a wide range

of securities. Typically they may be thought of as embracing short-term securities with maturities of from 3 months to a year. intermediate securities with maturities up to 5 years and bonds with maturities up to 25 years or even longer. While banks may hold a limited proportion of their assets in the issues having the longest maturities they tend to concentrate their holdings overwhelmingly in the shorter-term issues. It would be wholly erroneous, therefore, to regard the investments of commercial banks as being made up of relatively illiquid long-term issues.

Problems and Policies.—The holding of investments of a longer-term character gives rise to a number of distinctive problems and policies. Certain investments, such as mortgages, may possess little or no marketability so that the bank must ordinarily plan on retaining them until maturity. A bank can safely afford to hold a certain amount of illiquid earning assets since. even though all of its deposits may be payable on demand, it will not be required to liquidate more than a small proportion of its assets at any one time. Some of its other long-term assets may be shiftable to other lenders in case a bank requires greater liquidity. The disadvantage that at the very time when one bank wants to sell other banks may not be willing to buy is partially overcome in situations where the central bank undertakes to support the securities market; the lack of shiftability to other banks may then be made up by shiftability to the central bank.

One of the most important devices for counteracting the illiquidity inherent in long-term assets is that of spacing maturities. By regularly acquiring bonds having a maturity of five years, a bank will come to have in the course of time a block of securities averaging half that Iength of time to maturity. Even though all the securities had a maturity of five years at the time of purchase, one-fifth of them at any time will have a maturity of one year or less and none but those just bought will have a maturity as long as five years. Spacing permits the bank to realize the yield that goes with a longer maturity while achieving much of the liquidity that goes with a shorter maturity.

Ownership of relatively long-term investments exposes a bank to the risk of fluctuations in the market value of these securities as changes occur in the level of interest rates. A fall in the market price of a particular security would impair its liquidity but would not necessarily affect its safety. It follows that by holding until maturity a bank can avoid loss of principal on securities that experience a decline in market value, provided that that security is entirely safe. This consideration, and with it the presumption in favour of a policy of holding to maturity, is especially important in respect to investments of the highest quality; in the case of treasury obligations in particular, repayment in full at date of maturity is presumably never in question. It applies to other investments as well, in the sense that the possibility of loss is greatly influenced by the bank's own decision with respect to selling.

The possibility of a loss in market value on long-term investments in case interest rates rise implies also the possibility of a rise in their market value if interest rates decline. The shift from loans to investments serves not so much to increase the vulnerability of bank portfolios to market fluctuations as to alter the character of the instability to which they are subject. Experience has demonstrated that loans may be jeopardized by a decline in commodity prices; and investments, by a decline in security prices. In exceptional circumstances such as occurred during certain years in the 1930s, gains or losses resulting from the appreciation or depreciation of loans and investments were greater than the net income from banking operations.

From an operations standpoint the greatest single advantage of investments is that the bank is not dependent on borrowers coming to ask for loans. Whenever a bank has funds available for lending it can take the initiative by going out and purchasing securities in the open market. At the same time, changes in interest rates, analysis of security values and market psychology are matters of increased concern to banks. Larger banks maintain separate bond departments and carry out elaborate statistical and analytical investigations. In addition, banks in general make use of various statistical and advisory services which specialize in providing information bearing on the security market.

Maintenance of Liquidity and Solvency.—Some of the devices for maintaining liquidity have already been indicated. The first recourse when payment is demanded by depositors is the vault cash regularly carried by the bank. A bank may also draw upon its legal reserves, even reducing them below legal requirements, subject to certain limitations on its freedom (as, for example, to make loans or declare dividends) as long as reserves are deficient. Banks which have deposits with other correspondent banks may draw on these deposits to meet unexpected demands upon them.

These immediate cash resources may be supplemented by the liquidation of certain earning assets. Investments consisting of short-term treasury obligations are likely to be the most liquid assets, other than cash, which a bank possesses. They are the principal element in so-called secondary reserves. Largely because of the desire of banks to retain and increase their commercial loans, by reason both of their profitability and of their possible effect in bringing other business to the bank, commercial paper is not likely, in actual practice, to be treated as a secondary reserve. Methods also exist whereby funds may be temporarily shifted, on payment of a relatively small interest charge, from a bank with excess reserves to one with a reserve deficiency.

Securities in a bank's portfolio are ordinarily spaced in such a way as to provide a steady inflow of cash through the simple maturing of loans and investments. Certain loans, specifically loans to brokers secured by stork-market collateral, may be redeemable on call. It may be possible to sell short-term assets in the open market, to other banks or to the central banks with little or no sacrifice. Or a bank may elect to borrow from other banks or the central bank on its own promissory note, pledging certain of its assets as collateral for the loan. In general, tradition against borrowing by banks tends to hold borrowing to a minimum and to lead to the prompt repayment of loans by banks in case they are made.

As a safeguard not so much of liquidity as of solvency, loans to a bank's officers are likely to be strictly limited by law or custom. In the United States loans to a single borrower are restricted to 10% of the bank's capital and surplus, with some extension of the limit under certain conditions. In some jurisdictions provision is made for the segregation of assets held against time deposits. The purpose of this practice is to prevent the withdrawal of deposits which are payable on demand from leading to the exhaustion of the best assets. Otherwise, time deposits might be left with only inferior assets behind them when the time came that they were eligible to be paid.

Banks frequently accumulate what are known as concealed assets by nriting down certain assets, such as the bank building, to an insignificant value by charge-offs against undivided profit. At a later fime depreciation of loans or investments could then be equalized on the bank's books by writing up the value of the property to something closer to its actual worth. A similar result may be achieved by establishing contingency reserves to be used for writing off possible losses on loans and investments. Investments acquired at a premium, or other assets on which a future decline in value seems possible, may be written down to a lower figure by charging off certain amounts against current income. Under certain circumstances a considerable tax saving may be realized by following this practice.

D. Relations With Other Financial Institutions

In countries with a strong central bank the reserves of commercial banks are likely to consist largely of deposits at the central bank. In the United States the legal reserves of member banks take the form exclusively of deposits with the federal reserve banks. In other countries, and in the United States for nonmember banks, deposits with other banks may usually be counted as reserves. In some countries deposits in banks abroad may also, within certain limits, be included as reserves.

The clearing and collection of checks and other cash items necessarily involve close relations with banks and other institutions. Clearinghouses exist in most cities to facilitate the collection of checks among banks in the same city, with representatives of the

participating banks meeting two or three times a day for the interchange of checks and the settlement of balances. (See CLEARINGHOUSE.) Checks on banks at a greater distance may be collected through what are known in the United States as correspondent banks, through the central bank and its branches or through some other transfer organization. The federal reserve banks maintain a wire transfer system which enables banks to transmit large sums of money from one end of the country to another in a matter of minutes.

On the continent of Europe transfers are effected chiefly by what are often known as **Giro** accounts. Such accounts may be owned by individuals as well as by banks and usually operate through the postal system and the central bank and its branches. Special messengers may be employed for the purpose of saving time in the transfer of large checks between banks.

Banks perform many services for other banks. The central bank and even larger commercial banks may occupy the position of bankers' hanks. In this capacity they may discount commercial paper, make advances in the form of loans and assist in the clearing and collection of checks. Correspondent banks frequently supply credit data and other financial information. They may act as agents in providing foreign exchange and in the purchase of securities for other banks or their customers. These are but a few of the services which banks may afford one another. They may also share in the granting of loans, as where a particular loan is larger than one bank would be able or willing to grant alone.

Banks may organize for mutual benefit into such national groups as the bankers' associations of the United States and Canada which sponsor exchange of information, research on operational and policy matters and extensive educational programs. The syndicate of banks in France goes so far as to set interest rates paid on deposits. In the United States county or regional clearinghouse associations may undertake to establish standards with respect to banking practices, as in the determination of service charges to be imposed by the member institutions. Upon occasion, members of clearinghouse associations have rallied to the aid of banks which were in difficulties or have taken other steps to meet conditions of crisis. In countries where banking is predominantly in the hands of a small number of large branch banking systems there is presumably less occasion for the organization of bankers' associations such as exist in the United States.

Conditions of Competition. — The nature and extent of competition among banks, and between banks and other financial institutions, are greatly influenced by the character of the financial organization of a country. Where banking is confined to a relatively narrow field of operations, as was long traditional in Great Britain, there are fewer points of contact, competitively speaking, with other types of lending institutions than where banks engage in a wide variety of lending activities.

Banks of the so-called "department-store" type, which are common in the United States, may find themselves in competition with trust companies, mutual savings banks, investment counselors, consumer finance companies and investment trusts, to name but a few. One effect of the extension of banking operations into a wider area was to bring about increased con~petitionwith other financial institutions. To some extent, increased competition resulted from the entry of other lending institutions into fields already occupied by banks.

Where there are a few large branch banking systems, competition is different, though not necessarily less keen, from what it is nhere there are a great number of unit banks. In relations with other banks, banks have tended to avoid such forms of competition as the payment of higher rates on deposits or the acceptance of lower rates on loans, and to rely more on providing special services or other accommodation.

In certain European countries, notably France, the German Federal Republic and the Netherlands, lines of demarcation between commercial and investment banking are not sharply defined. Assets may not only include securities of an investment character; banks in the Netherlands and Germany sometimes hold stock-market membership, while German banks may hold shares in business enterprises and participate in their management. Similar practices are followed in other countries, even to the extent of banks specializing in particular types of businesses.

The central banks of many countries deal directly with the public. Where this is the case banks are likely to find themselves in competition mith the central bank. In the United States the federal reserve banks are authorized to lend to private borrowers but the field of such operations is so restricted and their amount so small that no significant con~petitioncan be said to have existed.

A more important type of competition is that which developed between banks and governmentally sponsored financial institutions. One of the first such undertakings was the postal savings system, which played an important role in the Ketherlands and other European countries and also assumed substantial proportions in the United States. Extension of governmental activity into the field of private lending seems to have been inspired first of all by a belief that gaps existed in the structure of lending institutions mith the result that certain borrowers, such as farmers, lacked adequate access to sources of credit. It was stimulated even more by the desire to provide relief or stimulate recovery during periods of business depression. **A** further impetus was given by the financial needs resulting from war. Some of the institutions established under these circumstances declined or disappeared with the passing of the emergencies which gave rise to them. Others seem to have become a permanent part of the financial structure. In general. governmental lending institutions assumed chief importance in the fields of agricultural credit and housing and real-estate credit.

Bankers are likely to feel that their interests are threatened by an expansion of the lending activities of the government. The probability of injurious competition from this source is presumably greatest in the fields of agricultural and real-estate credit. The amount of actual competition with banks cannot be judged precisely. In certain cases banks benefit directly or indirectly by the lending activities of the government. Perhaps the principal basis for the opposition of bankers to lending by governmental agencies is the danger they see in it of an unwarranted trend toward socialism.

Customer Relationships. — Banks maintain important customer relationships with other financial institutions. They are a major source of the credit employed by investment bankers, brokers, finance companies and others. The bill broker (*q.v.*), who occupies a particularly strategic position in the functioning of the London money market, relies heavily on commercial banks for the credit used in his business. Government lending agencies may be financed in part by securities sold to banks. Banks may be the purchasers of securities sold by investment bankers and brokers and of bills sold by commercial paper houses.

The sharing of loans mith other banks has already been mentioned. Banks may lend on a participating basis whereby a governmental lending agency provides part of the loan. The guarantee by a governmental department of exp'ort credits or of a credit for military expenditures in time of war may enable a bank to undertake commitments that would otherwise be regarded as too risky. In the United States the guarantee of mortgages by the Federal Housing administration lifted this category of real-estate obligations into a class virtually as high as that of government bonds and so made them acceptable to banks and other conservative lending institutions. At times banks have found it advantageous to shift certain assets to government lending agencies, thereby increasing their ability to extend other kinds of loans.

Still another type of sharing transaction occurs where a bank and an insurance company participate jointly in extending a term loan. In such cases it is usual for the bank to take that part of the loan which involves a shorter commitment and for the insurance company to take the part having the longer maturity. Such an arrangement makes it possible for the borrower to obtain a single loan of the size and terms he finds appropriate and for each of the lenders to satisfy its particular requirements with respect to liquidity and yield.

Overseas connections may be maintained through relations with other financial institutions. Some banks, notably in the United States, have overseas branches. Leading dominion and colonial

banks have offices in London. Banks may carry on foreign business through foreign correspondents or affiliates. The British maintain a number of overseas banks which usually have their headquarters in London but conduct the bulk of their business in some foreign country or countries. BANK OF ENGLAND. One of the first commercial banking companies to be set up in England, the Bank of England subsequently became so much concerned with governmental business that it came to assume the position of the United Kingdom's central bank (*q.v.*). In this capacity, it performs seven main functions—acting as the note-issuing authority, as the government's banker, as banker to the commercial banks, as manager of the national debt, as the government's agent for operating the exchange-control machinery, as its agent for implementing monetary policies and as adviser to the government on all major monetary and currency issues. Although nationalized only in 1946, the bank has been operated during the greater part of its life on the principle that the national interest rather than profit-making should be its main consideration. (See also BANKING: *History of Banking.)*

Formation and Early History.—The emergence of the bank was basically the outcome of the rapid expansion in banking activity in England during the 17th century. By the early 1700s the goldsmiths, who had originally been primarily concerned nith trading in gold and bullion, had come to dominate the money-exchanging and moneylending business. Before 1640, however, they had confined their operations to the lending of their own money. But in that year Charles I, unable to persuade parliament to vote the money needed for his army, seized the £200 000 of bullion City merchants had deposited with the mint for safekeeping. This led to an intensive search for storage places beyond the reach of the monarch. Since the goldsmiths with their strong rooms were able to offer the necessary facilities, the custom sprang up among the merchant community of entrusting to their care money, bullion and other valuables.

In acknowledgment of such deposits, the goldsmiths issued "notes accountable" which, being often equivalent to a specific sum of money, came to be accepted as money. The inauguration in this way of the bank note gave a powerful fillip to the development of the banking business of the goldsmiths. They realized that, as there was almost always a substantial money balance in their strong rooms, it would be reasonably safe to employ some of the wealth entrusted to them for safekeeping in developing the moneylending side of their business. Later they realized that there was nothing to stop them from issuing notes that were not specifically related to money held by them but simply contained their promise to pay on demand a given sum of money.

The great increase in commercial activity in the second half of the 17th century generated a considerable demand for credit and so encouraged the full exploitation by the goldsmiths of the new banking techniques. Although some continued to conduct their businesses in ways that were beyond reproach, others had no compunction about practising the most flagrant abuses to advance their profits. In consequence, the demand became more and more insistent in England for the establishment of a trustworthy national banking institution such as had been operating in many continental countries for several centuries.

A number of early schemes fell through, however. It was largely by chance that a plan put forward by a Scotsman, William Paterson, for the formation of a national bank mas put into effect to bring about the foundation of the Bank of England in 1694. William of Orange approved the Paterson scheme because it offered him a way of circumventing the serious financial embarrassment in ahich he found himself as a result of the cost of his war against Louis XIV of France. ,The plan hinged upon the establishment. mainly by a group of merchants, of a joint-stock undertaking (that is, a concern with many shareholders) with a liability to its depositors limited to the amount of its uncalled capital. The capital subscribed was to be £1,200,000 and it was agreed that this sum would be immediately loaned to the king at 8% in return for a royal charter granting the new bank a number of privileges, including the right to issue notes payable on demand up to the amount of and against the security of the loan to the crown. The money needed was subscribed in ten days and the bank opened in the Mercers' hall in Aug. 1694, moving later in the same year to the Grocers' hall where it stayed until it was transferred to Threadneedle street 40 years later. Its first governor was a City merchant, Sir John Houblon. Apart from the governor, deputy governor and 24 directors constituting its court (or board), it had initially a staff of 17 clerks and two doorkeepers.

The establishment of such a powerful competitor naturally alarmed and annoyed the goldsmith bankers, partly because it caused them the loss of much patronage and partly because the bank's entry into the moneylending business was followed by a sharp fall in the rate of interest. However, a petition presented to parliament a few months after the bank's formation calling for the repeal of the Ways and Means act of 1694 (which had actually authorized its creation) on the grounds that the "said bank is ruinous and destructive to trade in general and is only a private advantage to the said corporation" was rejected, while attempts to set up rival institutions failed. With the government's continuing need of financial assistance, the bank was able to strengthen its position in the late 17th century, though it had to overcome a number of relatively serious teething troubles, including, early in 1696, its first serious run. The next major landmark in the history of the bank was the act of 1709 renewing its charter. This was the outcome of a new bargain with the government.

The new act stipulated that, while the bank endured, no corporation or partnership of more than six persons should borrow or take up any sums of money on their bills or notes payable at demand or within six months. This last clause, which modified limitations on other banks imposed by the 1697 renewal of the bank's first

charter, was most important for it effectively gave the bank a monopoly of joint-stock banking in England which lasted for almost a century, keeping all other banking activity in the hands of private individuals.

South Sea Bubble.—The bank narrowly escaped disaster in the wave of financial speculation that culminated in 1720 in the bursting of the South Sea Bubble (*q.v.*). The South Sea company had been formed in 1711, but at the outset did little business. In 1720, encouraged by the favourable response of the treasury in the previous year to its offer to convert an expensive 1710 lottery loan into South Sea stock, it put forward a plan for the conversion of all other outstanding government debt, except that owed to the Bank of England and the East India company. Fortunately for itself, its proposal was not acted upon, with the result that it was in a better position than many other commercial concerns to contend with the financial crisis that gripped the country when the South Sea company ran into serious difficulties in 1720.

The bank played a part in solving the numerous financial problems generated by the 1720 crash, raising its capital by £3,400,000 to £8,960,000 in order to take over some of the obligations of the South Sea company. To strengthen its own financial structure the reserve fund or "rest" was created in 1722. During much of the remainder of the 18th century the bank continued to develop its business energetically, though progress was impeded from time to time by runs and other crises. By the closing decades of the century it was managing the greater part of the national debt and when its charter was renewed in 1781 the prime minister, Lord North, described it as "from long habit and usage of many years a part of the constitution," adding that it was "to all important purposes the public exchequer."

Competitors.— Despite its favoured position, the bank was not wholly free from competition from other banking concerns. The private banks had soon discovered that their note issues could not stand up well to the notes of the infinitely more powerful and respected Bank of England. To overcome this difficulty they began to make increasing use from about 1730 of a new banking invention—the printed check. Once this had been introduced, the private bankers found that they could, without issuing notes, attract money which their depositors could draw upon on demand for themselves or for payment to other persons. The system worked so well that toward the end of the 18th century many private banks in London ceased to avail themselves of the right to issue notes in favour of complete reliance on the check system of deposit banking. This development, by enabling the private banks to lend more generously, helped greatly to ease the industrial financing problem generated by the Industrial Revolution. But the challenge to the bank's supremacy inherent in the growth of the check system caused it a ,good deal of concern.

In June 1780 the bank was the subject of an attack by an armed mob during the Protestant riots led by Lord George Gordon. This was repulsed with the aid of the military and it is from this incident that the bank's nightly military guard takes its origin.

American and Napoleonic Wars.—The financial upheaval produced in England by the American Revolution imposed severe stresses on the bank. But it came through the critical months by a narrow margin, its gold bullion reserve having fallen by the early months of 1783, to £1,321,000 against a note circulation of £7,675,000. After the opening of the war with France in 1793, the bank again found itself in serious trouble, partly because of withdrawals in bullion of funds by private banking houses and partly because of the heavy demands made upon the bank by the government for money to finance the cost of the war. including the granting of substantial loans to Britain's continental allies. A crisis was narronly averted with government help in 1793. But an invasion scare caused a serious new run on the bank in 1797 and it had to seek official permission to suspend its obligation to repay its notes in gold. Although the bank's circumstances subsequently showed improvement, the suspension of payment was not in fact ended for more than 20 years.

Public concern about the fall in the purchasing power of the currency during the period of currency inconvertibility that had opened in 1797 led to the appointment of a house of commons bullion committee in 1810 "to consider the cause of the high price of gold bullion and the state of the circulating medium and the cxchanges." 'The investigation was concentrated upon Bank of England notes, they having become, with the decline in note-issuing activity by other banking concerns, the national currency. The report drew attention to the danger of inflation, contending that the cause of the high price of bullion was mainly the overissue of bank notes. It argued that the exchanges could be set right only by fixing a date—but not nearer than two years—at which the suspension of cash payment by the bank must cease and that the bank should work toward this date and this cessation by curtailing its public and private advances, and so its note issues. However, with the commercial situation deteriorating, the recommendations of the report were not acceptable to the house of commons and inflation continued. It was not until after 1815 that economic conditions improved to a sufficient extent to create a situation wherein the recommendations of the 1810 committee could be put into effect. By 1821 the bank had returned to a full gold standard payment system on its original basis of 77s. $10\frac{1}{2}d.$ per standard ounce of gold.

19th Century Trends.—With industry and commerce progressing rapidly, the disadvantages from the national viewpoint of the bank's monopoly of joint-stock banking were becoming more and more apparent. In London the demand for banking facilities which the bank itself was not in a position to satisfy was met fairly competently by the private bankers. But in the provinces it was often traders and shopkeepers who filled this role, and as their qualifications were limited they were often in trouble. Yet as the demand for finance rose they became bolder, with the result that in the financial crisis of 1825 there were no fewer than 90 failures. It was then decided to organize the opening of a series of Bank of England branches in the main provincial centres. Still more important, it was decided that, in the future, joint-stock banks would be allowed to operate outside a radius of 65 mi. from London, while in 1833. despite some opposition from the bank and London private bankers, another act authorized the establishment of joint-stock banks within this zone provided they did not issue notes. As it had been realized that banking houses could develop their business without issuing notes, there now opened a period of rapid banking development all over the country and the relative importance of the Bank of England in the field of commercial banking began to decline.

Concern about the low level of the bank's bullion reserves in the early 1840s and a growing feeling that banking activity should be more strictly supervised led to a decision to separate the bank's note-issue functions entirely from its general banking business when legislation renewing its charter was introduced by Sir Robert Peel's government in 1844. The act also laid it down that, apart from a fiduciary issue of £14,000,000 which could be covered by government securities, every note issued by the bank would thenceforth have to be backed by gold. Provision was, however, made for this requirement to be lifted with government permission in an emergency—an operation known as suspending the Bank act.

On three occasions during the remainder of the 19th century, financial crises imposed such stresses on the bank that the Bank act had to be suspended. The first in 1847 was due to the aftermath of a wave of railway speculation and also of high grain prices and heavy importation of corn. This imposed tremendous pressures on country banks and, in endeavouring to limit the damage, the bank overstrained its own resources. The 1857 crisis arose from the spreading to England of a financial crisis in the United States resulting from overintensive development. The 1860 crisis was a sequel to the failure of the well-known London banking house of Overend Gurney, an event which was itself a product of the unhealthy growth of industrial speculation. On each occasion the suspension of the Bank act was successful in easing tension. The collapse of the banking company of Baring Brothers in 1890 caused another crisis involving the bank. But this time it got by with help from the Bank of France.

The Bankers' Bank.—The bank had already begun to act as a bank to other bankers in the 17th century. The rapid growth of other commercial banking houses after the termination of its

monopoly of joint-stock banking in England naturally acted as a powerful stimulus to this side of its business. It was further encouraged by the strengthening of the bank's structure by the act of 1844. This development inevitably had the effect of giving the bank a key position in the monetary field.

Its emergence as the focal point of the now rapidly developing London discount market accentuated this tendency. By the second half of the 19th century it had become essentially a central bank, though it continued to cater for all private customers that were willing to come to it and was accordingly to some extent in competition with other banks. The significance of the change in the bank's status was demonstrated to it in the works of Walter Bagehot and Viscount Goschen (*qq.v.*). They explained that the Bank of England's gold stock was the basis of the nation's credit structure. so that it had the main responsibility for maintaining a proper relationship between the gold stock and the credit supply (*see* BANKING; MOSEY MARKET).

World War **I.**—With the country achieving a record level of economic prosperity, the early years of the 20th century were an uneventful period for the bank. Upon the outbreak of World War I, however, there was a major run, a four-day bank holiday was proclaimed and the Bank act was suspended. For a while the bank was technically in a position wherein it could have met its obligation to redeem its notes in gold, for during the closing months of 1914 the gold reserve was strengthened. But in view of the need to conserve the country's gold stocks for dealing with balance of payments stresses generated by the war. the suspension of the gold standard was eventually given permanent form. To meet the growth in the demand for currency that occurred as prices rose in response to inflationary pressures, the treasury introduced its own issue of inconvertible currency notes and these circulated side by side with the bank's issue. which also increased materially during the war, until late in the 1920s. During the war the government borrowed from the bank on a substantial scale and entrusted it with the responsibility for raising many loans from the public. Arrangements were also made for the whole of the country's gold stock to be concentrated in the bank.

A committee was appointed under the chairmanship of Lord Cunliffe, governor of the Bank of England. in 1918 to consider postwar finance and currency problems. In accordance with its findings the bank was instructed by the treasury that after the beginning of 1920 currency notes should not be issued in excess of a total of £320,600.000 except against gold or Bank of England notes and that subsequently the maximum fiduciary issue in any year should be the maximum actually attained in the previous year. This marked the opening shot in a deflationary policy which ended the boom of 1919 so effectively that markets collapsed and thousands of business concerns suffered ruinous losses on stocks.

Return to the Gold Standard. — The severe business recession in the early 1920s reduced the level of prices in the United Kingdom and, with other factors, notably the settlement of war debts, strengthened the pound, which had fallen far below its prewar parity of $4.86; in terms of the U.S. dollar in the initial postwar period. After much discussion the proposal of Montagu Norman (later Lord Norman [*q.v.*]), who had become governor of the bank in 1920 (an office he continued to occupy until 1944), that the pound should be stabilized on a modified gold standard basis was accepted and put into effect in 1925. Because it was felt that the country could not afford to devote its reserves to the restoration of a gold currency for internal purposes, the move to stabilize the exchange at its prewar level entailed only the establishment of a gold bullion standard. Thus, while the bank was obliged to buy gold in any quantity, it was obliged to sell it only in multiples of 400 oz. or more, the broad effect being that the pound became convertible into gold only for external purposes.

It was recommended by the Chamberlain committee in 1924 that the country's internal currency arrangements should be tidied up by amalgamating the two note issues — the bank's and the treasury's — that had been circulating since early in the war. partly because it was thought that the continuance of this situation could in certain circumstances give rise to technical complications after the return to gold. This proposal was put into effect in 1928. The Currency and Bank Notes act of that year arranged for the gradual withdrawal of treasury notes, leaving the sole right of note issue with the bank. The bank was given power to issue notes backed only by government securities (the fiduciary issue) up to a limit of £260,000,000 with, however, the right to seek treasury permission to exceed this limit for six-month periods of not more than two years in all. At the same time. the bank's weekly return or balance sheet was made more informative. The item previously known as "other deposits" was split into bankers' deposits and other deposits, the former consisting of the balances of U.K. commercial banks and the latter of those of the bank's other customers. (Other customers had, since the early 1900s, been only those who had a special case for keeping an account with the bank, such as certain overseas organizations, the bank having been unwilling to take on new private business of a kind that would put it in competition with commercial banks.) The "other securities" item was divided into "discounts and advances," which includes money made available to the money market through loans or the rediscounting of bills, and "other securities." No other changes were subsequently made in the return except that for a number of years after 1948 a new form of deposit temporarily appeared in it — the treasury special account. This represented the unspent portion of the sterling counterpart of certain U.S. aid under the European Recovery program. In 1960, the "special deposit" (see below) made its appearance.

At first the return to the gold standard strengthened the pound by attracting foreign money to London. But the high value placed on the currency by the new exchange rate exposed Britain's balance of payments to severe stresses during the world-wide depression of the early 1930s. There was a serious outflow of gold from the hank's reserves. Reinforcements obtained by borrowing in New York and Paris proved insufficient, and in Sept. 1931 it was decided that the gold standard would have to be suspended at once and the exchange rate placed on a floating basis.

This decision, coupled with the fact that the fall in the pound that followed the freeing of the rate had left the currencies of many other countries materially overvalued in relation to the pound, led during the next few years to a strong revival of confidence in sterling. After the U.S. devalued its currency in 1933, sterling returned to its old parity of $4.86⅔ in terms of the dollar and stayed close to this figure until it was forced down by nervous selling before the outbreak of World War II. Moreover, with the country's trade position improving and capital flowing in from other countries, the gold reserves were materially strengthened. At the height of the 1931 crisis the bank's gold stock, valued at the old price of 77*s.* 10½*d.* per standard ounce. was worth £135,600,000. By June 1937 this reserve was worth £376,400,000 at the then current price of 140*s.* per fine ounce. In addition. the exchange equalization account had by that time accumulated a gold reserve of £537,600.000. The account had been formed by the government in 1931 so that the ebb and flow of gold arising from the floating of the exchange rate would not disturb the internal monetary situation as it would have been apt to do if such operations had been allowed to find a full reflection in the bank's own stock of bullion. The bank has managed the account throughout its life as the treasury's agent.

Meanwhile, to reverse the internal trade recession that had developed in the early 1930s and had resulted in widespread unemployment, the government adopted a cheap money policy. To implement this the bank rate was reduced to 2%. Advantage was taken of the resulting drop in the general level of interest rates to convert a substantial portion of the national debt into securities bearing a much lower rate of interest.

During 1938 fears that political developments on the continent might involve Britain in a major war caused a big outflow of funds from London and a corresponding drain on the gold holdings of the exchange account. To reinforce them, the bank sold £200,000,000 of its own gold to the account early in 1939, the resulting drop in the gold cover of the note issue being made good by raising the fiduciary issue to £400,000,000. Shortly afterward, a new act authorized the bank to value its gold stock in relation to the current market price of gold (hitherto it had been obliged to fix

its value on the basis of the 77*s*. 10½*d*. per standard ounce ruling before the abandonment of the gold standard). part of the "profit" being used to bring the fiduciary issue back to £260,000,000.

World War II.—As Britain's central banking institution, the bank naturally played a large part in devising and implementing official measures to deal with the financial and economic consequences of the country's war effort between 1939 and 1945. Immediately after the outbreak of war. it was decided that, in the future, the size of the country's gold stock would have to be kept secret and the remainder of the bank's stock, except for a trifling amount of gold coin. was transferred to the exchange equalization account which thereafter held the whole of the gold and foreign exchange reserve. No information about the size of the reserves was subsequently given until after the war when it was disclosed that at one time they had been almost exhausted. Thereafter figures were published first at three-month and later at one-month intervals. Other precautionary measures taken at the end of 1939 included the transfer of part of the bank's activities to Hampshire and the mobilization of privately held securities for safe custody and eventually for the purpose of providing collateral for government loans raised abroad. Subsequently, the bank had three main tasks to perform: to neutralize as far as possible the inflationary impact on the economy of heavy government spending; to issue war loans; and to enforce exchange control.

It had been decided that it would be necessary to keep interest rates at low levels throughout the war to keep down the cost of government borrowing for war financing. The bank rate. which had been raised in Sept. 1939 to 4% from the level of 2% at which it had been standing since the opening of the cheap money era in 1932. was therefore brought back within two months to the prewar level where it remained for the next 12 years. To neutralize the impact on the monetary system of government credit creation arising from heavy short-term borrowing from the banking system. the bank secured the approval of the treasury for the introduction of the treasury deposit receipt system. This provided for what were in reality compulsory six-month loans by the banks to the government. However, this and the other measures the bank took to restrict the creation of credit served only to slow down the growth of inflationary pressures. and by the end of the war the bank's fiduciary issue had been raised to £1,350,000,000 from the prewar £300,000,000.

The bank's issues of long-term stock to cover the government's wartime budget deficit took two main forms—a series of 2½% national war bonds maturing at various dates and. side by side with this. a series of 3% savings bonds also maturing at various dates. It was customary for the bank to issue both types of loans "on tap." that is. without any published limits on the amount or on the time that the lists remain open. But periodically the lists for one issue were closed and those for another issue with different dates opened. Thus the bank was kept active constantly in dealing with loan operations. while. by the early postwar period, the amount of debt managed on the government's behalf had risen to £14,492,000,000 from the 1939 level of £7,121,000,000.

The exchange-control system developed by the bank during the early stages of the war entailed the fixing of exchange rates. broadly speaking on the basis of the rate ruling at the outbreak of war. It also entailed the supervision. with the help of the commercial banking system. of all private exchange operations to ensure that they were in the national interest.

The Postwar Period.— After the war the bank turned its attention to the problem of rehabilitating the country's financial and economic machinery. In view of the government's feeling that the cost of borrowing should be kept down during the period of intensive capital development that was expected to follow the war. no major change was made for six years in the cheap money policy that had been pursued throughout the war. Financial restrictions of other kinds were employed in an effort to curb inflation. These included a request by the bank to the commercial banking system to grant loans only for purposes that could be shown to be essential from the national viewpoint and the control of capital issues. But the rise in the price level continued. calling for further big increases in the bank's note issue.

As a first step toward the restoration of normal commercial relations with other countries the government with the help of the bank concluded a series of payments agreements with many other countries providing for transactions between them to be settled in sterling or in some other suitable medium. In 1947. in accordance with the terms of the loan agreement concluded with the United States shortly after the war. an attempt was made to restore the pound sterling to the status of a fully convertible currency on the basis of the system of fixed exchange rates introduced shortly after the end of the mar. But confidence in sterling abroad was still at a low level and in consequence there was a big rush by foreign holders to take advantage of this opportunity to con ert their balances into dollars. The official gold and foreign currency reserves. which had been reinforced by dran-ing~on the United States loan. was rapidly reduced and the convertibility experiment had to be promptly suspended.

Sterling having suffered the further indignity of a devaluation from $4.03 to $2.80 in terms of the U.S. dollar in 1949, the bank subsequently worked. with the government's approval, to bring about its rehabilitation more gradually. Exchange-control restrictions were dismantled in stages. while arrangements for allowing sterling to be used for financing transactions within specified regions — that is. a restricted form of convertibility — were introduced. In 1953 this transferability for sterling was extended by the bank to permit sterling to be transferred freely in connection with current or capital account operations between all nondollar countries. while two years later it was decided to assist the work of bringing the exchange rates quoted for the different varieties of sterling closer together by allowing the exchange equalization account to operate in overseas free markets instead of being restricted to dealing in the market handling authorized deals in London. By these means a considerable measure of informal convertibility was achieved early in the second half of the 1950s and the way cleared for the United Kingdom's participation in a general western European move to formal convertibility at the end of 1958. All sterling accruing to other countries from transactions with the pound area on current account was then granted the right to automatic conversion into dollars at rates falling within ¾% of the $2.80 parity. This time confidence in the pound was strengthened by restoring formal convertibility.

Even so, sterling was involved in a new crisis in 1961. Devaluation fears were aroused by a serious deterioration in the country's basic payments position, and the threatened re-emergence of inflationary pressures caused a sharp reversal of the inflow of short-term money from abroad that had been prompted in the previous

year by high London money rates. The bank arranged for continental central banks to furnish large-scale temporary assistance in combating the resulting run-down of reserves under what was known as the Basel agreement. This was replaced in midyear by help to the value of $2,000,000,000 (including both cash and stand-by credit facilities) from the International Monetary fund, granted in support of the economic rehabilitation program simultaneously launched by the U.K. authorities.

The New Monetary Policy.— The Conservative government which took office at the end of 1951 decided that traditional instruments of credit control, such as the manipulation of interest rates, should be brought into play in the battle against inflation. The bank was consequently much more active thereafter in the monetary policy field, for the task of implementing the new monetary policy was to a large extent left in its hands. As a first move the bank rate was raised to $2\frac{1}{2}\%$ and subsequently to 4%. It was reduced to 3% in 1954, the general economic situation of the country having shown some improvement, but there were further increases when the fall in the purchasing power of the pound caused by inflationary stresses brought sterling' under pressure in the exchange markets in the mid-1950s, and a level of 7% was reached in 1957. As the new policy had had only a limited success: in 1957 the government appointed a committee under Lord Radcliffe to inquire into the functioning of the money and credit systems. The committee had a number of recommendations to make when it reported in mid-1959, the most important of which was that greater use should be made of the official power to manipulate long-term interest rates in economic management. But the government did not take the view that the results of its investigations called for substantial changes in monetary policy procedures; in particular it resisted the committee's proposal that the bank's technical control should be shared more fully with government departments functioning in the economic field.

But while the committee was still sitting the bank had, at the treasury's request. shaped a new instrument of monetary control. Thus when the directive method of influencing the commercial banks' lending activities was discontinued in mid-1958 as part of a general easing of economic policy aimed at combating recession tendencies, the bank devised a system requiring the commercial banks to make special deposits with itself that would reduce the availability of funds for lending. This system was to be held in reserve for use in the future if existing instruments proved inadequate. The new control was first used in mid-1960 when a rapid rise in bank loans was thought Iikely to generate inflation. But it proved only partially effective, and when the bank rate was raised to 7% at the height of the crisis a year later, the directive form of control was re-introduced, the banks being instructed to keep their loans from rising beyond existing levels during the remainder of 1961 irrespective of their liquidity circumstances.

Domestic **Affairs.**—Among changes in staff arrangements made by Lord Norman during his 24 years in office was the inauguration of the practice of appointing a number of full-time directors.

The Labour government, which came to power in 1945, took the view that the bank, previously owned by private stockholders who had the duty of electing the directors, should be brought under full government control. The bank was therefore nationalized in 1946. stockholders being compensated through an issue of government stock at a rate of £400 of government stock for each £100 nominal of bank stock. Apart, however, from the fact that the court (or board) was widened to include representatives of industry and the trade unions (previously it had been largely composed of bankers), the bank continued to operate on much the same lines as before. The court mas, however, deprived at least nominally of some of its power as a result of the government's decision late in 1959 that it should cease to have responsibility for formulating bank rate policy, this matter becoming the concern only of the governor and deputy governor. This step was a sequel to recommendations made by the Radcliffe committee after examining the implications of the report of a judicial investigation early in 1958 into allegations, which proved to be unfounded, of prior leakage of the raising of the hank rate to 7% in the previous year. Lord Catto, who had succeeded Lord Norman in 1944, continued as governor until 1949 when Cameron Cobbold was elected. He was succeeded in 1961 by Lord Cromer, a merchant banker formerly of Baring Brothers and Company.

The act that nationalized the bank gave it power to request information from and make recommendations to other banks and, if authorized by the treasury, to turn these recommendations into directions with the force of law. But as the bank retained its prenationalization influence with the banking system, it managed to obtain their voluntary co-operation in carrying out any plans affecting their interests which it considered necessary on national grounds. It was in addition decided, in the late 1950s. that the bank should keep the country as a whole better informed about its activities. The departure from the traditional silence manifested itself at first in periodic public speeches by the governor and later in the inauguration. of a much more informative annual report and the introduction of quarterly bulletins, as well as in the preparation of a film for public distribution. BANK OF ISSUE: see CENTRAL BANK.

BANKRUPTCY is the status of a debtor who has been declared by judicial process to be unable to pay his debts. The terms bankruptcy and insolvency, although sometimes used indiscriminately. have distinct legal significations. Insolvency, as the term is used in the equity receivership courts in the United States, in state insolvency laws and in the English and most European bankruptcy laws, means inability to meet debts as they mature, but in England, for example, there is no special procedure relating to one who is merely "insolvent." Insolvency as it is defined in the U.S. federal bankruptcy act means that the aggregate of the debtor's property, at a fair valuation, is insufficient to pay his debts. A debtor may be insolvent without becoming a bankrupt.

Conversely, since proof of insolvency is not required where the debtor files a voluntary petition in bankruptcy or where an involuntary petition filed by his creditors alleges the commission of certain acts of bankruptcy, a debtor may become a bankrupt without being insolvent. A bankruptcy adjudication is merely a legal declaration that the debtor has filed a proper voluntary petition or that creditors have filed and supported a proper involuntary petition against him and the adjudication initiates a statutory proceeding for the administration of the debtor's property, which is thereby taken out of his personal control.

The primary objects of bankruptcy legislation are to obtain justice while not pressing unduly on debtors, to discriminate between involuntary inability to meet obligations and willful refusal or neglect and to secure to creditors an equitable share of the debtor's assets available for the payment of his liabilities. Another object has marked modern legislation, namely, the fostering of a higher tone of commercial morality and the protection of the trading community at large from the evils arising through the reckless abuse of credit and unnatural trade competition. Since creditors have conflicting interests and are therefore incapable of acting together as a homogeneous body, it is necessary to obtain the aid of professional assignees or trustees, solicitors and other agents, who make it their special business to deal with such matters, exercising both administrative and quasi-judicial functions, in return for the remuneration which they receive out of the property for their services.

BANKRUPTCY IN THE UNITED STATES

History.— In the United States control over the administration of insolvent estates is divided between the federal and state governments. The constitution (art. i, sec. 8) gives to congress power to establish "uniform Laws on the subject of Bankruptcies throughout the United States." But the supreme court has held that the states have power: (1j to establish and administer their own bankruptcy or insolvency laws in the absence of any regulation of the subject by congress and subject to certain restrictions on impairing the obligations of pre-existing contracts; and (2) to

enact insolvency, assignment or stay laws that do not conflict with any statute which congress may have enacted.

In exercise of its constitutional grant, congress has enacted four different statutes. The first was passed by the Federalists in 1800 during the John Adams administration. Its repeal in 1803 by the incoming Jeffersonians was an expression of the farmers' view that it favoured the merchant class and of Republican opposition to extension of federal powers. The second statute was passed during the John Tyler administration in 1841, took effect in 1842 and was repealed in 1843, in part as a manifestation of the then-common view that debtor relief was "immoral."

The third statute was a product of economic crisis following the Civil War; it was enacted in 186; and repealed in 1878, partly because of administrative defects and partly because of creditors' opposition to new benefits conferred on debtors. The last statute was enacted in 1898 in belated response to demands for debtor relief originating in the panic of 1893, and has apparently become a permanent institution. It has been frequently amended and mas extensively revised in 1938; there has been no agitation for its repeal.

These statutes and amendments reveal a constant expansion of the federal power. The act of 1800 was confined to merchants and traders, made no provision for voluntary proceedings and put severe restrictions on discharging the debtor from his obligations. In 1841 provision was made for voluntary proceedings by nearly all persons, involuntary proceedings against merchants and traders were retained and the provisions for discharge were liberalized. The act of 1867 included corporations within its coverage, made voluntary and involuntary proceedings applicable to traders and nontraders alike, provided for conipositions (arrangements to pay made between the bankrupt and his creditors) and made discharge still more easily obtainable. Each of these changes was opposed or contested on constitutional grounds and each was finally approved or acquiesced in by the supreme court.

The present act is more comprehensive than any of its predecessors. It authorizes liquidation proceedings for all individuals and all corporations except municipalities, railroads, insurance companies. banks and building and loan associations, and it provides reorganization or rehabilitation proceedings for the municipalities and railroads excluded from its liquidation provisions. With these exceptions, the statute of 1898, augmented by amendments adopted prior to 1939, offers voluntary liquidation proceedings to all debtors and provides for involuntary liquidation proceedings against all debtors owing debts of $1,000 or over except farmers, wage earners whose rate of compensation does not exceed $1,500 per year and such noncommercial enterprises as social. religious, educational and charitable institutions. Discharge and composition provisions are more liberal than those of any previous act.

The most extensive innovations appear, however, in amendments adopted after 1932. By these amendments. compositions and extensions of payment are authorized for the unsecured debts (those debts which are not covered by any assurance of payment such as a mortgage or other lien) of individual or corporate debtors (ch. xi), for debts secured by real property (ch. xii), for all debts of municipalities (ch. ix) and for all debts of wage earners whose total income does not exceed $5,000 per year except debts secured by real property (ch. xiii). Moreover, sec. 77 offers a procedure for reorganization to railroads engaged in interstate commerce, and ch. x offers a somewhat similar procedure to corporations and to railroads not engaged in interstate commerce.

Insolvency administration of national and federal reserve banks is governed by other federal statutes. and the insolvencies of insurance companies, building and loan associations and tate banks are left to administration by state courts or departments. A 1935 decision (294 U.S. 211) of the supreme court impairs effective state administration where the debtor's business transcends state lines. The court held that while an Iowa "statutory successor" to an insolvent Iowa insurance corporation took "title" to assets in Montana, judgment creditors in Montana could be allowed to seize and sell such assets in satisfaction of their individual judgments. This makes necessary expensive ancillary proceedings in all states where the debtor has property. But in its determinations of what state statutes "conflict" with the national act, the supreme court has been generous to the states. A state insolvency or assignment statute is in conflict only if it supplies a discharge for the debtor; and to determine whether or not a statute supplies a discharge the court promises to look to the "interpretation*' of state courts (287 U.S. 527). Finally, in theory equity receiverships in the state courts remain available to all classes of corporations; in practice ch. x is likely to deprive the state courts of this business.

Liquidation. — The liquidation sections of the Bankruptcy act —designed to secure an equal distribution of assets among creditors and a discharge of the debtor — set up administrative machinery that is fairly simple, but offer rules for administration that are exceedingly complex. The proceedings are begun by a petition filed either (1) by the debtor; or (2) against a debtor by (*a*) three or more creditors whose provable claims aggregate $500 or more in excess of security; or (*b*) by a single creditor with a provable claim of such amount if the creditors are less than 12 in number. When the petition is involuntary: adjudication does not follow as a matter of course but only on a showing that the debtor has committed an act of bankruptcy within four months of the filing of the petition.

The statute proscribes as acts of bankruptcy: (1) fraudulent conveyance of the debtor's property to put it beyond the reach of creditors; (2) payments which prefer some creditors while the debtor is insolvent; (3) suffering or permitting a creditor to obtain a lien by legal proceedings on the debtor's property while he is insolvent; (4) transfer of the debtor's property to an assignee for liquidation for the benefit of creditors; (5) procuring, suffering or permitting the appointment of a receiver while insolvent or unable to pay debts as they mature; and (6) an admission in writing of inability to pay debts and willingness to be adjudged a bankrupt. By special statutory definition applicable only to the liquidation provisions of the Bankruptcy act, a debtor is insolvent whenever the aggregate of his property. excluding that fraudulently conveyed, is not at a fair valuation sufficient in amount to pay his debts.

The petition must be filed in the federal district court of a district where the debtor has had his principal place of business, resided or had his domicile for the preceding six months or for a longer portion thereof than in any other district. When a voluntary petition is filed, the debtor is given an opportunity to appear and has the right to a jury trial on the question of the commission of an act of bankruptcy and on the issue of his insolvency, where it is relevant. The court after a hearing either makes an order of adjudication or dismisses the petition. If an order of adjudication is made, the court normally refers the case to a referee.

Under 1946 amendments to the act, referees are appointed by the bankruptcy courts for terms of six years. Their salaries within a fixed statutory maximum are prescribed by the judicial conference of senior federal circuit judges. They have broad judicial and administrative powers over allowance of claims and collection of assets. Their orders, however, are always subject to review by the bankruptcy courts.

The referee. when a case is referred. secures from the debtor a statement of assets and liabilities and calls a meeting of creditors. At this meeting a trustee is usually elected. a majority vote in number and amount of allowed claims of all the creditors present being necessary to elect. If the creditors are unable to agree, the court or referee may appoint a trustee.

The trustee is an executive officer whose fee is fixed by the bankruptcy court within a statutory maximum. It is his duty to take possession of the property of the bankrupt and convert it into cash. Creditors are given six months after the first creditors' meeting to file proofs of claims against the estate. Claims duly proved are allowed by the referee unless objected to by the trustee or other creditors. Secured creditors are allowed to prove for the amount of their claims in excess of the value of the security. The valuation of the security is made under court supervision.

To facilitate liquidation the trustee is given title to all of the bankrupt's nonexempt property as of the date the bankruptcy petition is filed and to all such property bequeathed to or inherited by the bankrupt within six months thereafter. He is also given power to set aside liens acquired by judicial proceedings while the debtor was insolvent and within four months of the filing of the petition. preferential payments made by the debtor within four months of the filing of the petition. fraudulent conveyances made by the debtor within one year of the filing of the petition and transfers made by the debtor which any creditor with a provable claim could have set aside under state law. Finally, he is emponered to take over assets held by a liquidating receiver or an assignee for the benefit of creditors where the receiver was appointed or the assignment was made within four months of the filing of the petition.

Limitations. — The actual distributive process does not effect complete equality of distribution. The act prescribes five classes of claims which are to be paid in full before any dividends are paid to general creditors. These claims, in the order of their priority. are: (1) costs of administration and of preserving the estate. together with certain filing fees and attorneys' fees; (2) wage claims of the debtor's employees, not exceeding $600 each, earned within three months before the filing of the bankruptcy petition: (3) costs incurred by creditors in successfully opposing the discharge of the bankrupt, or in adducing evidence of certain criminal offenses committed in the bankruptcy proceeding, where a conviction results: (4) taxes due to the federal government or to any state or subdivision thereof; (5) dehts which have priority under any other federal law (principally claims due the United States) and claims for rent which accrue within three months before the petition is filed, where such rent claims are entitled to priority under state law.

A limitation from the debtor's point of view is that he is not entitled to a discharge on claims not paid in the bankruptcy proceeding as a matter of right. If the trustee or creditors do not object. and if the bankruptcy court does not request a federal district attorney to investigate, the discharge is granted. But the trustee. district attorney or creditors may successfully object by proving that the bankrupt has violated certain provisions of the federal criminal code; or destroyed. falsified or failed to keep books of account or records; or obtained money, property or credit by making false written statements concerning his financial condition: or made a fraudulent conveyance within 12 months of the filing of the hankruptcy petition: or received a discharge or secured a composition or extension of his debts in a prior bankruptcy proceeding initiated within 6 years of the filing of the petition: or refused to obey a lawful order of the referee or court; or failed to explain satisfactorily any losses or deficiencies of assets. But this limitation is more apparent than real since lethargy of creditors has produced a situation where nearly all bankrupts, save those who have received a previous discharge in a proceeding initiated within six years or who are guilty of the most flagrant dishonesty. are granted discharges. The power given the bankruptcy court by the 1938 amendment to the act to request an investigation by a federal district attorney is rarely invoked.

Another limitation from the debtor's point of view is that even though a discharge is granted all debts are not thereby released. Only provable claims are eligible to participate in the bankruptcy distribution and are dischargeable. What debts are provable has been a question of extended litigation because of the ambiguous wording of the statute; but for the most part contract claims incurred before the filing of the petition are provable and thus dischargeable, and claims for personal injury or property damage not reduced to judgment before the bankruptcy proceeding begins are not. Among the provable debts, specific exceptions in the act exempt the following from discharge: (1) taxes levied by the federal government or by any state or subdivision thereof: (2) liabilities for certain fraudulent acts, willful and malicious injuries or immoral conduct; (3) alimony and support orders; (4) claims for wages earned within three months of the filing of the petition; and (5) claims of creditors not notified of the bankruptcy proceeding in time to prove their claim.~.

Reorganization, Compositions, Extensions. — The later amendments to the Bankruptcy act are designed not to produce liquidation (*i.e.*, distribution of the debtor's assets among his creditors) but to permit the debtor to retain control of assets after liabilities have been reduced in amount or time for payment extended. This is accomplished by giving the bankruptcy court power to confirm plans of reorganization, composition or extension that bind dissenting minorities of each class of creditors. These amendments are often defended upon the ground that creditors will ultimately receive more from such capitalization of a debtor's future earning power than they would receive from liquidation at forced-sale prices, but as applied to individual debtors and small corporations they are primarily designed for the relief of distressed debtors.

The amendment of most practical importance is ch. x. which supplies a procedure for the reorganization of all corporations subject to a voluntary or involuntary petition in bankruptcy and for all railroads not engaged in interstate commerce. This procedure is similar to that of the creditor-initiated equity receivership previously developed by the federal courts. But substantial changes have been made. The debtor is permitted to file a petition without first arranging for a friendly creditor to begin the proceedings for him. Ancillary receivers are no longer necessary; the bankruptcy court is given exclusive jurisdiction of the debtor and its property wherever located. Cash is not always required for the payment of dissenters nor a judicial sale for determining the amount of payment to dissenters; the court may on certain conditions confirm a plan by decree. The conditions for confirmation without sale or payment of dissenters in cash are that the court find the plan to be fair and equitable and feasible; that creditors holding two-thirds in amount of each class of claims allowed accept the plan, or, as to any class which does not so accept. that adequate provision be made for protection of the value of its claims against property dealt with by the plan; and that, if the corporation is not found insolvent, a majority of the stockholders of each class allowed accept the plan. or. as to any class which does not so accept. that adequate provision be made for the protection of the value of its interest in the property dealt with by the plan. Before confirmation the court may submit the plan to the Securities and Exchange commission for examination and advisory report, and if the debts of the corporation exceed $3,000,000 the court must submit the plan. To obtain the benefits of this chapter a corporation need not allege that it is insolvent, as that term is defined in liquidation sections of the act. but only that it is unable to pay its debts as they mature. Three or more creditors with claims amounting to $5,000 or more, secured or unsecured, may file a petition against the corporation.

The procedure under sec. 77 for the reorganization of railroads engaged in interstate commerce is generally similar to that under ch. x. although there are some differences. Where ch. x requires acceptance by a majority of the stockholders of each class, sec. 77 requires acceptance by two-thirds, and under sec. 77 all reorganization plans must be first approved by the Interstate Commerce commission.

Proceedings for compositions and extensions under ch. ix. xi, xii and xiii may be initiated only on the debtor's voluntary petition. which must allege that the debtor is either insolvent or unable to pay his debts as they mature. Before confirming the plan the court must find that it is fair and equitable and feasible, and under ch. ix and xii the plan must have been accepted by creditors holding two-thirds in amount of each class of claims affected or, as to any class which does not so accept, provision must be made for protection of its interests. Cnder ch. xi the plan must be accepted by a majority in number and amount of each class of creditors affected, and under ch. xiii it must be accepted by a majority in number and amount of unsecured creditors and by all secured creditors afiected.

A 1933 amendment to the act also added, in sec. 75, special proceedings for composition and extension of secured and unsecured debts of farmers. In 1934 sec. 7j was amended to provide that when a farmer was unable to get the necessary acceptance of a

majority in number and amount of creditors. or when he was dissatisfied with the composition or extension. he could get a court order allowing him to remain in possession of his property under a five-year moratorium from the claims of mortgagees, upon payment of a reasonable rent. The 1934 amendment was held unconstitutional by the supreme court as a violation of the due process clause (293 U.S. 511). It was then revised to restrict the moratorium period to three years. with some discretion in the bankruptcy court to restrict it further, and as revised was held constitutional (300 U.S. 440). Sec. 75 was originally enacted as a five-year emergency measure. was four times extended and, under the terms of the last extension. expired in 1949. There has been some agitation for its revival as a permanent part of the Bankruptcy act.

Chapter ix, providing compositions and extensions for municipal indebtedness, was also held unconstitutional in its original form as an impairment of state sovereignty (298 U.S. 513). but a revised version was found to be "carefully drawn so as not to impinge upon the sovereignty of the States" and was sustained (304 U.S. 27).

In a 1934 decision (294 U.S. 648) the supreme court gave its approval to the reorganization provisions of sec 77, by likening them to the composition procedures in the act of 1867, and remarked upon the striking capacity of the bankruptcy power to expand to meet new conditions.

By a 1948 amendment to the Interstate Commerce act, congress provided for railroads an alternate method for adjustment of secured and unsecured debts upon consent of three-fourths in number and amount of each class of creditors and stockholders affected. and approval by the Interstate Commerce commission. There is no requirement that the commission find the plan "fair and equitable" and no provision for judicial review. (V. CN.)

BANKRUPTCY IN ENGLAND

Bankruptcy is entirely a matter of statute law. The earliest English statute on the subject, 34 and 35 Henry VIII, ch. 4 (1542), like the statute of 13 Elizabeth I. ch. 7 (1571). was directed against fraudulent debtors and gave power to the lord chancellor and other high officers to seize their estates and divide them among the creditors. but afforded no relief to the debtor from his liabilities. The objects of modern bankruptcy legislation are to provide. in the case of a person who has no reasonable prospect of meeting his debts. for (1) distribution of the debtor's property among his creditors in an orderly and economical manner; and (2) a new start in life for an honest debtor, freed from the demands of his creditors. These laudable objects are susceptible of abuse by dishonest and cunning individuals. so that provision has to be made for those who have culpably contributed to their insolvency or have concealed their assets dishonestly or are otherwise guilty of abuses of the system.

The courts exercising jurisdiction originally consisted of commissioners appointed by the lord chancellor. But as a result of legislation in 1831 and 1869 the bankruptcy laws are now administered by certain of the judges of the chancery division specially appointed by the lord chancellor, with bankruptcy registrars, who deal with the ordinary judicial routine of bankruptcy procedure in the London district. while similar duties are performed by the county-court judges and their registrars throughout the country (with certain exceptions). The high court also exercises appellate jurisdiction on appeals from county courts.

The Act of 1883.—A feature of the act of 1883 was the separation it effected between the judicial and the administrative functions, which had previously been exercised by the court. and the transfer of the latter to the board of trade as a public department of the state directly responsible to parliament. Under the powers conferred by the act a new department was subsequently created under the title of the bankruptcy department of the board of trade, with an officer at its head called the inspector general in bankruptcy. This department exercised, under the direction of the board of trade. a general supervision over all the administrative work arising under the act. It had extensive powers of control over the appointment of trustees, and conducted an audit of their accounts; and it might, subject to appeal to the court, remove them from office for misconduct, neglect or unfitness. A report upon the proceedings was annually presented to parliament by the board of trade, and although the department was practically self-supporting, a nominal vote was each year placed upon the public estimates. thus bringing the administration under direct parliamentary criticism and control. The act also provided for the appointment and removal by the board of trade of a body of officers entitled official receivers, with certain prescribed duties having relation both to the conduct of bankrupts and to administration of their estates. including the interim management of the latter until the creditors could be consulted. These officers acted in their respective districts under the general authority and directions of the board of trade. being also clothed with the status of officers of the courts to which they were attached. The main objects of the measure were to secure: (1) an independent and public investigation of the debtor's conduct; (2) the punishment of commercial misconduct and fraud in the interests of public morality; (3) the summary and inexpensive administration of small estates where the assets did not exceed £300 by the official receiver, unless a majority in number and three-fourths in value of the creditors voting resolved to appoint a trustee: (4) full control in other cases by a majority in value over the appointment of a trustee and a committee of inspection; (5) strict investigation of proofs of debt. with regulations as to proxies and votes of creditors: (6) an independent audit and general supervision of the proceedings and control of the funds in all cases. Besides amending and consolidating previous bankruptcy legislation. the measure also contained special provisions for the administration under bankruptcy law of the estates of persons dying insolvent, and for enabling county courts to make administration orders for payment by installments in lieu of immediate committal to prison, in the case of small judgment debtors.

An amending act, under the title of the Bankruptcy act, 1890. was passed in that year, more particularly with regard to the conditions under which a bankrupt should be discharged or schemes of arrangement or composition be approved by the court. These two acts were supplemented by a large body of general rules made by the lord chancellor with the concurrence oi the president of the board of trade. which may be added to, revoked or altered from time to time by the same authority. These rules are laid before parliament and have the force of lam.

Besides these general acts, various measures dealing with special interests connected with bankruptcy procedure have from time to time been passed since 1833, the chief of which are as follows: the Bankruptcy Appeals (County Courts) act, 1884; the Preferential Payments in Bankruptcy act. 1888, regulating the priority of the claims of workmen and clerks. etc., for wages and salaries; and the Bankruptcy (Discharge and Closure) act. 1887, dealing with unclosed bankruptcies under previous acts. In 1906 the board of trade appointed a committee to inquire into and report upon the effect of the provisions of the laws in force at the time in relation to bankruptcy, etc.

The Law in the 20th Century. — The English law of the bankruptcy in force at the beginning of the 1960s is contained principally in the Bankruptcy act. 1914, a consolidating act which repealed and re-enacted the provisions of the amending act of 1913. That act had made considerable changes in the law and had introduced a number of provisions relating to bankruptcy offences. These provisions have since been aniended by the act of 1926. The act of 1914 authorized the making of rules which regulate the practice in bankruptcy. The rules in force in the early 1960s n-ere made in 1952 and were slightly amended in 1956.

Who May Be Made Bankrupt. — Generally speaking any person who is a debtor owing not less than £50, may be made bankrupt in England and Wales. The term debtor as used in the act of 1914 (unless the context otherwise implies) includes any person. whether a British subject or not. who at the time when any act of bankruptcy was done or suffered by him (1) was personally present in England; or (2) ordinarily resided or had a place of residence in England; or (3) was carrying on business in England, personally, or by means of an agent or manager; or (4) was a

member of a firm or partnership which carried on business in England. It will be seen from this that a foreigner may in certain circumstances be subject to the English bankruptcy laws. Every adult may be made bankrupt, whether engaged in trade or not; but an infant cannot usually be made bankrupt although he is engaged in trade and obtains credit in the course of his business. If he can be made bankrupt at all, it can be only in respect of a judgment debt for "necessaries" — a phrase which has a special meaning among lawyers. An infant may be made bankrupt, however, if the petition is based on an enforceable debt. With regard to a married woman, although she could not formerly have been made bankrupt at all, by virtue of the Law Reform (Married Women and Tort-feasors') act, 1935, she is subject to the law relating to bankruptcy and to the enforcement of judgments and orders in all respects as if she were a single woman. A lunatic can be made bankrupt, but the trustee takes subject to the title of the appointed receiver in lunacy.

Peers and members of the house of commons although having "privilege of parliament" may be made bankrupt. Although a corporation or limited company is for some purposes a "person," a receiving order (the order which leads to adjudication) cannot be made against any such body. Such bodies are dealt with under the Companies acts.

Petition and Receiving Order. — Any court exercising bankruptcy jurisdiction in the district in which a debtor resides or carries on business in England or Wales may make a receiving order against the debtor, whether a trader or not, either on his own petition or on that of a creditor or creditors whose claims aggregate not less than £50.

In the case of a creditor's petition proof must be given of the debt (unless the debtor admits it at the hearing of the petition) and of the commission of an act of bankruptcy within three months preceding the date of the petition. An act of bankruptcy is most commonly committed if the debtor fails to satisfy the creditor's claim upon a bankruptcy notice; also if he makes an assignment for the benefit of his creditors generally; if he absconds or keeps house (*i.e.,* refuses to see creditors); if he gives notice of suspension of payments; if his goods are sold or seized under execution; if he files in court a declaration of inability to pay his debts; if he grants a fraudulent preference or conveyance; or if, upon an application being made to commit him under the Debtors act, a receiving order is made in lieu of an order to commit. In such a case the judgment debtor is deemed to have committed an act of bankruptcy. By a bankruptcy notice is meant a notice by a judgment creditor or creditor who has obtained an order for payment calling upon his debtor to pay, secure or compound for the debt to the satisfaction of the creditor or the court. Such a notice must be in the prescribed form, must state the consequences of noncompliance and must be served in the prescribed manner. Failure to comply with the notice within seven days (if the debtor is in England) constitutes an act of bankruptcy upon which a petition is founded.

Bankruptcy notices are constantly used by the judgment creditor as a means of enforcing his judgment, since most debtors whose credit is at stake will make every effort to pay rather than face the consequences of a petition in the bankruptcy court. A bankruptcy notice may be founded on an order to pay a water rate.

An assignment for the benefit of creditors generally is a fairly common act of bankruptcy and it is none the less so because it is registered as a deed of arrangement. Such a deed, however, cannot be relied on as an act of bankruptcy by any creditor who is a party to or assents to it, or by any creditor who does not present a petition founded on the execution of the deed within one month after rereiving notice of its execution from the trustee. In default of such notice, the deed is available as an act of bankruptcy for three months from the date of its execution.

Bankruptcy proceedings are initiated by a petition, which may be presented by a creditor or by the debtor himself. Any body or person who can take proceedings to recover a debt at law or in equity may present a bankruptcy petition. A man may take an assignment of a debt for the express purpose of founding a petition upon it. But a creditor may not present a petition unless the debt is a liquidated, or determined, sum amounting to £50 or more payable immediately or at some future time.

The act of bankruptcy on which the petition is founded must have occurred within three months of the date of the petition and the debtor must be domiciled in England or must have ordinarily resided or had a dwelling place or place of business in England; or (except in the case of a person domiciled in Scotland or Ireland, or a firm or partnership having its principal place of business in Scotland or Ireland) he must have carried on business in England by means of an agent or manager; or (except as aforesaid) he must have been within the said period a member of a firm or partnership of persons which has carried on business in England by means of a partner or an agent or manager. The petition, if successful, results in a receiving order being made against the debtor, but this is not made until eight days after the service of the petition. If presented by a creditor who has been party to a deed of assignment for the benefit of creditors generally, the petition will normally be dismissed. The court, however, will usually have regard for the wishes of the creditors, though an order may be made against their wishes. Another creditor may be substituted for a petitioning creditor who does not show diligence.

At any time after the presentation of a bankruptcy petition any action, execution or other legal process against the property or person of the debtor may be stayed. The general rule, however, is that there will not be restraint proceedings to which the discharge of the debtor from his bankruptcy would be no defense. For example, a claim in tort against a debtor for fraudulent breach of trust would not be restrained, nor a committal order for nonpayment of rates or local taxes.

A receiving order does not divest a debtor of his property; it merely protects it by placing it in the control of the court through the official receiver. No creditor may then commence legal proceedings against the debtor without the leave of the court. If a receiving order is made on a debtor's own petition, adjudication follows as a matter of course, unless a composition or a scheme of arrangement is accepted by the creditors. It may be rescinded if the court is satisfied that the debtor has paid all his debts since it was made. Where there is an estate or business to be managed, the official receiver may appoint a special manager: who receives such remuneration as the creditors or, failing them, the board of trade may determine.

Statement of Affairs. — As a consequence of the receiving order the debtor must make out and submit to the official receiver within a prescribed period (seven days in case of creditor's petition) a statement of his affairs. The statement must be verified by affidavit, and must show the particulars of the debtor's assets, debts and liabilities, the names, residences and occupations of his creditors, the securities held by them respectively, the dates when the securities were respectively given and such other information as may be prescribed or as the official receiver may require. The official receiver supplies the bankrupt with a form of statement and may employ someone to assist him to prepare it. Failure to furnish it may involve adjudication; and the omission of material facts may render the bankrupt criminally liable.

The statement of affairs is open to the inspection of creditors and may be used against the bankrupt in any proceeding connected with his bankruptcy. The debtor must also in every case submit to a public examination in court, in which the official receiver, the trustee and any creditor who has proved his debt may take part. His evidence may be used against him. The examination may be adjourned from time to time at the discretion of the registrar. He must attend the first meeting of creditors, wait upon the official receiver, trustee and special manager and give all necessary information and generally do all acts which may reasonably be required of him with the view of securing a full investigation of his affairs.

He may be arrested if there is reasonable ground for believing that he is about to abscond, destroy papers or remove goods, or if he fails without good cause to attend any examination ordered by the courts. The court may also for a period of three months order his letters to be readdressed by the post office to the official receiver or trustee.

First Meeting of Creditors. — This meeting is summoned by the official receiver not less than *14* days after the receiving order, notice being given in the *London Gazette* and in a local paper and sent by post to each creditor. A summary of the statement of affairs should accompany the notice, with any observations by the official receiver which he may think fit to make.

The object of the meeting is to decide whether any proposal for payment of a composition or for a scheme of arrangement submitted by the debtor is to be entertained, or whether an application should be made to the court to adjudicate the debtor bankrupt. In the latter case the meeting may by an ordinary resolution appoint a trustee with or without a committee of inspection. It may also give any directions as to the administration of the estate.

The meeting is presided over by the official receiver or his deputy, who, subject to appeal to the court, admits or rejects proofs for the purpose of voting. For the transaction of business three creditors qualified to vote, or all the creditors if fewer than three, must be present or represented. Broadly speaking, a creditor may not vote unless the debt owing to him is a liquidated sum. Only persons who have proved their debts are entitled to vote, and detailed regulations respecting proofs and the valuation of securities are laid down in the act of *1914.*

One of the chief features of the law on this point is the condition imposed on creditors on bills of exchange to deduct from their claims the value of the liability of prior obligants before voting, thus canceling the power of controlling the proceedings previously possessed by persons who had no real interest in the estate. Votes may be given in person or by proxy.

The creditors entitled to vote may, at their first or any subsequent meeting, appoint from among the creditors generally, or the holders of general proxies, or general powers of attorney from such creditors, a committee of inspection to superintend the trustee in his administration of the bankrupt's property. A person may also be appointed subject to his subsequently becoming the holder of a general proxy or general power of attorney, but he must not act until he has obtained this power. The committee must not consist of more than five or less than three persons. It generally includes the more important creditors.

A creditor who is appointed a member may not act until he has proved his debt and his proof has been admitted, and he must not, except by leave of the court, become a purchaser of any part of the estate, nor may he, except with like permission, receive any payment out of the estate for services rendered by him in connection with the administration of the estate. One of the functions of the committee is to audit the trustee's accounts, and certain functions of the trustee can be exercised by him only with the sanction of the committee.

If the creditors so resolve, or if a composition or scheme of arrangement is not proposed by the debtor or entertained by the creditors, or if entertained is not approved by the court, or if without reasonable excuse the debtor fails to furnish a proper statement of his affairs. or if his public examination is adjourned sine die (without assigning a day for a further hearing) the court adjudicates the debtor bankrupt and thereupon his property vests in a trustee, and, subject to the payment of the costs and fees of administration, is divisible among his creditors until all his debts are paid in full uith interest at the rate of 4% per annum.

An order may also be made on the application of the official receiver where the debtor has absconded, or where the court is satisfied that the debtor does not propose a composition or scheme. Notice of every order of adjudication stating the name. etc., of the bankrupt is published in the *London Gazette* and advertised in a local paper.

Duty of a Bankrupt and Bankruptcy Offenses. — A debtor adjudged bankrupt must aid in the realization of his property to the utmost of his power, and in the distribution of the proceeds among his creditors. He must also, at the request of the official receiver. furnish trading and profit-and-loss accounts and a cash-and-goods account for a period not exceeding two years before the date of the receiving order. If required, he must also attend and be cross-examined as to the whereabouts of his property, and may be arrested on a warrant if he refuses to attend.

The onus of proving that he is not guilty of any intent to defraud is, generally speaking, placed upon the debtor. If he fails to make full discovery of or to deliver up his property or books, conceals his property or debts, prevents production of books, etc., or conceals, mutilates or falsifies his books he may be guilty of a misdemeanour unless he proves that he had no intent to defraud.

He is also liable to be found guilty of an offense if he removes property worth more than £10 after or within six months before the date of the petition, or if he fails to disclose the fact that a false debt has been proved by anyone in the bankruptcy. Other offenses are the fraudulent parting with or alteration of books; declaration of fictitious losses; obtaining credit by false representations within six months before or after the date of a petition.

Again, a bankrupt is guilty of an offense if, having been engaged in any trade or business and having outstanding at the date of the receiving order any debts contracted in the course and for the purpose of such trade or business, he has within two years before the date of the petition materially contributed to or increased the extent of his insolvency by gambling or speculation. A prosecution for this offense, however. cannot be initiated save by order of the court. Failure by a man who has once been bankrupt or who has compounded with his creditors to keep books of account within two years before a second bankruptcy may also be an offense.

An undischarged bankrupt cannot sit or vote in the house of lords. He cannot be elected to sit or vote in the house of commons, or be elected or act as a justice of the peace, or mayor, alderman or councilor. Nor can he be a guardian or an overseer of the poor or member of a county council. He cannot be a member or chairman of a parish council, rural district council or board of guardians if he has within five years before his election or since his election been adjudged bankrupt or compounded with his creditors.

These disqualifications disappear on the annulment of the bankruptcy. or if the court grants a certificate to the effect that the bankruptcy was caused by misfortune without any misconduct on the part of the debtor.

Discharge. — The court may at any time after the conclusion of the bankrupt's public examination, and after hearing the official receiver (who renders to the court a report as to the bankrupt's conduct and affairs), the trustee and any creditor, to all of whom previous notice of the application must be given, grant the bankrupt, on his application, a discharge either absolutely or under conditions, but subject to the following qualifications:

1. If the bankrupt has committed (*i.e.*, has been tried and convicted of) a criminal offense connected with the bankruptcy, the application must be refused unless for special reasons the court determines othenvise.

2. If the assets are not equal in value to *10s.* in the pound of the unsecured liabilities (unless the bankrupt can show that he is not responsible); or if proper books have not been kept; or if the bankrupt has traded after knowledge of insolvency; or has contracted debts without reasonable probability of payment; or failed to account for his deficiency; or contributed to the bankruptcy by rash speculation, gambling, culpable neglect. or by unjustifiable expenses; or has taken or defended legal proceedings on frivolous grounds; or has uithin three months preceding the receiving order given an undue preference; or has increased his liabilities with the view of making his assets equal to *10s.* in the pound; or has previously been bankrupt or made an arrangement with creditors; or has been guilty of any fraud or fraudulent breach of trust; then the court shall, on proof of any of these facts. either (a) refuse the discharge; or (b) suspend it for a period of not less than two years, or until a dividend of not less than *10s.* in the pound has been paid; or (*c*) qualify the order by the condition that judgment is entered up against the bankrupt for payment of any unpaid balance of his debts, or of part of such balance out of his future earnings or property. Assets are deemed to be equal to *10s.* in the pound when the court is satisfied that the property of the bankrupt has realized, or is likely to realize, or with due care in realization might have realized an amount of *10s.* in the pound on his unsecured liabilities. If of the facts referred to the only fact proved

is that the assets are not of a value equal to 10s. in the pound the discharge may be suspended for a period of less than two years.

The bankrupt may, however, after two years apply to the court to modify the conditions if he is unable to comply with them. An order of discharge releases the debtor from all his obligations except debts due to the crown and other obligations of a public character which can be discharged only with the consent of the treasury, debts incurred by fraud and judgment debts in an action for seduction or as a corespondent in a matrimonial suit or under an affiliation order, which are released only to such extent and subject to such conditions as the court may expressly order. Debts incurred by fraud insofar as they are the subject of actions of tort are not provable and are not therefore affected by an order of discharge.

The discharge of the bankrupt does not operate as a release of any partner or co-obligant with him, and it does not release him from liabilities incurred since the date of the receiving order to persons who did not prove in the bankruptcy. Neither does it release the bankrupt from liability to criminal prosecution. Notwithstanding his discharge a debtor is still bound to help the trustee to distribute the assets. The discharge does not revest in the bankrupt his property.

Composition or Scheme of Arrangement. — After a receiving order has been made the debtor may submit a proposal for the payment of a composition or for the liquidation of his affairs, by a trustee or otherwise, with adjudication. The proposal must be lodged with the official receiver in sufficient time to allow notice, together with a report by that officer, to be sent to the creditors before the meeting is held at which it is to be considered. A person who has a contingent or future claim is not a creditor. If the proposal is entertained at the meeting by a majority in number and three-fourths in value of all the creditors who have proved their debts, and if it is thereafter approved by the court, it becomes binding upon all creditors who would be bound by an order of discharge had the debtor been adjudicated bankrupt. A similar proposal may be made after adjudication, and if entertained by the creditors and approved by the court the adjudication may be annulled.

The debtor's release will be subject to the terms of the scheme, but his future acquired property will not pass to the creditors unless there is an express stipulation to that effect.

Property Divisible Among the Creditors. — No part of the law of bankruptcy is more intricate or has been the subject of more litigation than this, and any detailed view of the effect of legal decisions can be gathered only by a perusal of the cases; but the following general principles may be stated. The term property includes not only property of which the bankrupt is the true owner, but property in his possession, order or disposition in his trade or business with the consent of the true owner, in such circumstances that he is the reputed owner thereof. The application of the doctrine of reputed ownership is restricted by trade customs, in accordance with which property is frequently lent under a contract of "hire and purchase" or otherwise; and by the decisions of the courts that where such custom is sufficiently proved the doctrine does not apply. Further, the trustee's title not only includes property in the actual possession of the bankrupt, but relates back to the date of the first act of bankruptcy committed by him within the three months preceding the presentation of the bankruptcy petition, and thus invalidates all payments and assignments to creditors made during that period with knowledge on the part of the creditor or assignee of the commission of the act of bankruptcy.

In such cases the trustee may, therefore, require the money or property to be restored to the estate. And even where no prior act of bankruptcy is proved, any payment made to a creditor with the view of giving such creditor a preference over the other creditors, within the three months preceding the presentation of the petition on which the payer is made bankrupt, is rendered void as against his trustee. In practice this provision is difficult to apply by reason of the necessity of proving the debtor's intention to prefer. Settlements of property within the two years preceding the bankruptcy, unless made before and in consideration of marriage, or made in good faith for valuable consideration, are also void, as are similar settlements within ten years, unless it is proved that the settlor was (independently of the settled property) solvent at the date of the settlement and that the interest in the property passed to the trustees on the execution of the deed.

Certain settlements made in consideration of marriage are also made void or voidable against a trustee in bankruptcy. Thus any covenant or contract by a settlor in consideration of marriage for the future payment of money for the benefit of wife or child, or for future settlement on wife or children of property in which the settlor had no interest at the date of the settlement is void against his trustee in bankruptcy, if it has not been executed at the date of the bankruptcy. This is subject to the exception that beneficiaries may claim dividends in the bankruptcy, such claims, however, being postponed until the claims of the settlor's other creditors have been satisfied. Settlement by other persons may make the interests of a bankrupt determinable on bankruptcy under what are known as "protective trusts," with discretionary trusts for maintenance of the bankrupt and others.

Executions by a creditor not completed at the date of the receiving order are also void, and the proceeds of an execution in the hands of the sheriff must, with certain exceptions and subject to deduction of costs, be handed over to the trustee. Monies paid to a creditor who has levied execution in part satisfaction may, however, be retained by him as against the trustee. But all property held by the bankrupt on trust, and tools of trade, wearing apparel and bedding to a total value not exceeding £20 are excluded from the property divisible among the creditors. With respect to property acquired by the bankrupt, whether by gift or legacy, or consisting of accumulations of business or other profits after the commencement of the bankruptcy and before he obtains his discharge, the trustee's title also prevails; but the bankrupt has a right of possession until the trustee intervenes and so bona fide transactions by the debtor for value, other than transactions relating to freehold property, appear to be valid. Where the bankrupt is in receipt of a salary, income or pension, etc., the court may order any part thereof to be paid to the trustee; but where he is an officer of the army, navy or civil service such order is to be made only with the consent of the chief of the department concerned.

When a banker has ascertained that a person having an account with him is an undischarged bankrupt, it is his duty to inform the trustee or the board of trade of the existence of the account, and thereafter the account cannot be operated on except under the order of the court.

When a bankrupt who owns the copyright of a work is liable to pay royalties or a share of profits to the author, the trustee may not sell copies of or perform the work, except upon terms of paying the royalties due to the author. Nor can he assign or license the copyright without the consent of the author or the court except upon terms which will secure to the author payments not less than those which the bankrupt was liable to pay.

Claims of Creditors. — In the distribution of the debtor's property certain claims are entitled to priority over others. Thus the landlord, although not entitled to a preference out of the funds in the hands of the trustee, can distrain for unpaid rent on the goods and effects of the debtor remaining on the landlord's premises; but where the distraint is levied after the commencement of the bankruptcy this right is limited by the act of 1890 to six months' rent due before adjudication, the remainder of his claim ranking for dividend with the claims of other creditors. The gas board and water companies have powers of distraint under special acts, but the policy of recent legislation has been to discourage any extension of such privileges. Where the bankrupt holds an office of trust in any savings bank or friendly society, any balance in his hands due to such bank or society has been held under the acts relating to those bodies to be payable in preference to any other claim against the estate. Contributions payable by a bankrupt under the National Insurance act, 1946, are also entitled to preference. Other preferential claims are regulated by the Bankruptcy acts and include taxes, parochial and other local rates for not more than one year, wages and salaries (whether of clerks and servants or labourers or workmen) for four months, but not exceeding £200

(Bankruptcy act, 1914 s. 33, as amended by the Companies acts, 1947 and 1948) and agricultural labourers' claims not exceeding one year's wages, if hired by special contract for payment of a lump sum at the end of a year. These claims are entitled to preference not only over funds in the hands of the trustee! but also over the proceeds of any distraint levied by the landlord within the three months prior to the receiving order, the latter in that case becoming a preferred creditor for the amount so paid. Articled clerks and apprentices may also be allowed repayment of a proportion of the premium on their unexpired agreements. On the other hand, usual trade discounts (exceeding 5%) must be deducted from traders' proofs, and the following claims are postponed until the general creditors are paid in full, namely, claims by a married woman for loans to the husband for the purposes of his business, claims for loans advanced to any person in business at a rate of interest varying with the profits and claims for interest in excess of 5% per annum.

Where a married woman has been adjudged bankrupt, her husband cannot claim any dividend in respect of money lent to her for her trade or business until all claims of her other creditors have been satisfied. Subject to these exceptions all debts proved in the bankruptcy must be paid *pari passu* (without preference). Any surplus after payment of 20s. in the pound and interest at the rate of 4% per annum, from the date of the receiving order, is payable to the bankrupt.

All claims and liabilities present or future, certain or contingent. arising out of obligations incurred before the date of the receiving order are provable in the bankruptcy: an estimate of the liability in the case of contingent debts being made by the trustee subject to appeal to the court. But demands in the nature of unliquidated damages arising otherwise than by reason of a contract, promise or breach of trust are not provable, nor are gaming debts or debts barred by the statutes of limitation.

A secured creditor if he proves must either surrender his security or value the security and prove for the balance, and the trustee can thereupon, subject to the creditor's power in certain circumstances to amend the valuation, take over the security by paying the amount of the valuation or may require it to be realized. He may be required by the creditor to elect which of these courses he will adopt, failing which the equity of redemption will vest in the creditor.

After payment of costs of administration and preferential debts it is the duty of the trustee to distribute the estate with all convenient speed—the first dividend within four months after the first meeting of creditors and subsequent dividends at intervals of not more than six months; but the declaration may be postponed for sufficient reason by the committee of inspection.

Trustee's Administration.—While the interim preservation and management of the estate is conducted by or under the direct supervision of officers appointed by and responsible to the board of trade, the ultimate realization and distribution of the assets devolve upon the trustee appointed by the creditors. But besides acting as receiver prior to the first meeting of creditors. the official receiver also becomes trustee by operation of law on the making of an order of adjudication.

He vacates the office when a trustee is appointed by the creditors and certified by the board of trade, but again becomes trustee on the creditors' trustee being released, dying, resigning or being removed from office. As the bankrupt's property vests in the trustee for the time being, and passes from trustee to trustee by operation of law, and without any formal act of conveyance, the continuity of the office is thus secured.

The trustee is required to take immediate possession of the bankrupt's property, including deeds, books and accounts. and has the powers of a receiver in the high court for the purpose of enforcing delivery. After payment of the costs of administration it is his duty to distribute the estate in dividends as speedily as possible. Property vests in the trustee subject to any restrictions under which it was held by the bankrupt. So if a lessee who is under covenant not to assign or underlet without the consent of his landlord is made bankrupt, his trustee is bound by the covenant.

Where any part of the property is held subject to onerous obligations, such as the payment of rent, etc., the trustee may disclaim the same, subject in certain cases to the leave of the court, and the disclaimer operates to determine all interest in or liability in respect of the property on the part of the estate. The trustee is required to keep a record book (which is commenced by the official receiver), containing minutes of the proceedings in the bankruptcy, and a cash book in the prescribed form, in which all receipts and payments by him must be entered. . All monies received must forthwith be paid into an account at the Bank of England, entitled the "bankruptcy estates account," which is under the control of the board of trade, unless where in special circumstances the sanction of that department is obtained to open a local banking account, but in no circumstances must estate monies be paid to the trustee's private account. When monies are required for the purpose of the estate! special checks or money orders are issued by the board of trade on the application of the trustee.

The trustee's remuneration is fixed by the creditors or by the committee, if so authorized by them. A trustee receiving remuneration is not allowed the costs of any other person for duties which ought to be performed by himself. All bills of solicitors and other agents employed must. be taxed before payment, as being in accordance with the prescribed scales of costs; and the taxing master must satisfy himself that the employment has been properly authorized before the work was done.

All bills of costs must be delivered to the trustee within seven days after request; otherwise, the estate may be distributed without regard to such costs.

When the property: so far as it is capable of realization, has been realized and distributed, the trustee must apply to the board of trade for his release, forwarding to each creditor a notice of his having done so, together with a copy of his final accounts.

Small Bankruptcies.—When the official receiver reports, or the court is otherwise satisfied that the debtor's property is not likely to realize more than £300, the court may make an order for the summary administration of the estate; in which case, if the debtor is adjudged bankrupt, the official receiver in the ordinary course becomes and remains trustee and certain other modifications are effected with the view of simplifying and accelerating the procedure.

BANKRUPTCY IN SCOTS LAW

In Scots law the term bankruptcy is not capable of any exact definition. Indeed, it has no technical legal meaning and may refer to any one of the three stages in the process of divesting a debtor of his property for the benefit of his creditors—insolvency, notour bankruptcy or sequestration.

Insolvency is the condition of a debtor who is unable to meet his debts and obligations. Two tests of its existence are possible. It may be either "absolute" or "practical." Absolute insolvency arises when at a particular time a debtor's liabilities exceed his total assets; practical insolvency, when a debtor cannot pay his debts as they fall due although he may not be insolvent in the absolute sense. for his assets when realized may exceed his liabilities. Absolute insolvency is considered in questions relating to the validity of dispositions made by the debtor; practical insolvency, in questions between the debtor and his creditors.

Creditors are chiefly interested in obtaining payment of their debts and consequently it is practical insolvency which is considered in ascertaining insolvency as an ingredient of what is called "notour bankruptcy." a state of insolvency which has attained publicity, as evidenced by definite statutory indications. This situation is often that indicated by the use of the word "bankruptcy." but most commonly the term is used to denote the condition of a debtor's affairs under the process of sequestration, involving diversion of the bankrupt's estate for distribution among his creditors.

Unlike the bankrupt in English law. a notour bankrupt is not deprived of his property but is restricted only as to his capacity to deal with it. The object is to prevent him from disposing of his assets to favoured creditors and to preserve his property for the whole body of his creditors.

Sequestration is the process corresponding to an adjudication

in English law whereby a debtor is divested of his property for the benefit of his creditors.

In Scotland (as in England) the law of bankruptcy arose as a remedy against the frauds of debtors. By an act of the Scottish parliament (1621) all gratuitous alienations made by a debtor at a time when he was "absolutely insolvent" to "conjunct and confident persons" (*i.e.,* near relations or confidential friends and servants) are annulled in the interests of prior creditors. The onus of showing that value has been given or that the debtor was in fact solvent at the time of the alienation lies upon the person who received the property.

The act of 1696, ch. 5, defined a notour bankrupt and struck at preferences to creditors. Under it all voluntary dispositions made at or after notour bankruptcy or within 60 days before to any creditor by way of security for prior debts may be set aside at the instance of prior creditors. No proof of fraud or collusion is necessary and it is immaterial whether the debtor was or was not insolvent at the time of the disposition. This act does not affect any payment to a creditor made in the ordinary course of business.

Notour Bankruptcy. — The matter is now regulated by the Bankruptcy (Scotland) act, 1913, which repealed the Bankruptcy act, 1856, and the Debtor's act, 1880, and consolidated the law of bankruptcy but left in force the acts of 1621 and 1696. By this act "Notour bankruptcy shall be constituted by the following circumstances: — (1) By sequestration or the issuing of an adjudication of bankruptcy or the granting of a receiving order in England or Ireland; or (2) By insolvency (*i.e.,* practical insolvency) concurring (a) — (i) with a duly executed charge for payment when a charge is necessary, followed by the expiry of the days of charge without payment; (ii) where a charge is not necessary, with the lapse without payment of the days which must elapse before poinding or imprisonment can follow on a decree or warrant for payment of a sum of money; (iii) with a poinding or seizure of any of the debtor's movables for nonpayment of rates or taxes; (iv) with a decree of adjudication of any part of his heritable estate for payment or in security; or (b) with sale of any effects belonging to the debtor under a sequestration for rent" (s. 5).

Notour bankruptcy continues in case of a sequestration till the debtor obtains his discharge and in other cases until practical insolvency ceases (s. 7). The notour bankrupt is not divested of his property, for, as has been stated above, the object of notour bankruptcy is not to transfer the debtor's property to his creditors but to preserve it in his hands for their benefit.

The effects of notour bankruptcy on preferences to creditors under the act of 1696 have already been noted; in addition notour bankruptcy has the effect of equalizing diligences (*i.e.,* executions of all kinds). Arrestments and poindings used within 60 days prior to the constitution of notour bankruptcy or within four months thereafter are ranked *pari passu* as if they had all been used of the same date (s. 10).

Sequestration. — Sequestration of the estate of any person may be awarded in the following cases: (1) in the case of a living debtor subject to the jurisdiction of the supreme courts of Scotland: (a) on his own petition with concurrence of creditors for not less than £50; (b) on the petition of a creditor or creditors for not less than £50, provided the debtor be notour bankrupt and has within a year before the date of the presentation of the petition resided or had a dwelling house or place of business in Scotland; (2) in the case of a deceased debtor who at the date of his death was subject to the jurisdiction of the supreme courts of Scotland: (a) on the petition of a mandatory; (b) on the petition of a creditor or creditors for not less than £50 (s. 11).

A petition for sequestration may be made either in the court of session or in the sheriff court (s. 16), and a petitioning or concurring creditor must lodge with the petition an oath as to the verity of his debt (s. 20 and 21). When the debtor presents or concurs in the petition, sequestration must be awarded forthwith, the court having no discretion in the matter (s. 28). The interlocutor (*i.e.,* order of the court) awarding sequestration declares that the debtor's estate belongs to his creditors for the purposes of the act. The election of a trustee must be confirmed by an interlocutor of the sheriff, and this interlocutor — called the "act and warrant" — vests the property of the debtor in the trustee for the benefit of the creditors (s. 70). Instead of electing a trustee, the creditors may decide to have the estate wound up by a deed of arrangement. This requires the support of a majority in number and three-fourths in value of the creditors present and must be approved by the lord ordinary or the sheriff (s. 34).

Sequestration is declared by s. 104 of the act to be equivalent to an arrestment in execution and decree of forthcoming and to an executed and completed poinding. No arrestment or poinding (*i.e.,* no process of execution) executed of the funds or effects of the bankrupt on or after the 60th day prior to the sequestration is effectual, and any funds or effects attached must be given up to the trustee.

After the trustee's appointment has been confirmed, the sheriff names a day for the public examination of the bankrupt (s. 83) and may order that the bankrupt's family and confidential servants be examined also (s. 86). Creditors lodge claims for ranking and must value and deduct their securities (s. 61). The trustee may require the creditor to hand over the security at the valuation he (the creditor) has placed on it. S. 118 contains a list of debts which are entitled to preference. The first dividend is paid at the end of six months from the date of the sequestration (s. 126); the second, ten months from the sequestration (s. 128); and subsequent dividends, if any, at three-month intervals (s. 129).

Discharge. — The bankrupt may be discharged either on composition or without composition with his creditors. An offer of composition may be made at the "meeting for election of trustee" or at any subsequent meeting, and if it is to be accepted it must be approved by a majority in number and three-fourths in value of the creditors present and finally by the lord ordinary or sheriff (s. 134 to 142).

No discharge can be given whether with or without composition unless it is proved to the lord ordinary or the sheriff that a dividend of 5*s.* in the pound has been paid or that the failure to pay such a dividend is caused by circumstances for which the bankrupt is not responsible (s. 146). The debtor is freed by the discharge from all debts except those due to the crown and certain other obligations. After a final division of the funds the trustee is entitled to his discharge whether the bankrupt has been discharged or not (s. 152).

The Scots law thus resembles that of England, where the debtor can apply for discharge after administration.

(W. V. B.; Ds.)

COMPARATIVE LAW

Irish Bankruptcy Law. — The Government of Ireland act, 1920, provided that all laws in force in Ireland at the date of the act should remain in force unless modified by the parliaments of either the Irish Free State or Northern Ireland or in certain other specified ways. Art. 73 of the "constitution" of 1922 also provided that the laws in force in the Irish Free State at the date of the coming into operation of that constitution should continue to be of full effect until any or all of them should have been repealed or amended by enactment of *oireachtas* (the parliament). No modifications in the law relating to bankruptcy had been made by the early 1960s, so that branch of the law remained unaffected by the passing of the act or the constitution.

The law is regulated by the two leading statutes of 1857 and 1872, together with the Irish Debtors act, 1872, and corresponds in its main features to some of the older English enactments, with modifications adopted from the English act of 1869. A special act was passed in 1888 for establishing local bankruptcy courts in certain districts in Ireland, and an act of 1889 applied the main provisions of the English act of 1888, relating to preferential payments in bankruptcy, to Ireland.

In 1897 the court of bankruptcy was abolished and its jurisdiction was vested in the queen's bench division of the supreme court of judicature in Ireland.

The Deeds of Arrangement act, 1887, though repealed with regard to England by the Deeds of Arrangement act, 1915, is still in force in Ireland and is supplemented by the Irish Deeds of Ar-

rangement Amendment act, 1890. This last-mentioned act requires the registration of all petitions for arrangement under the Bankruptcy act, 1857.

Northern Ireland. — Having adhered to the Government of Ireland act, 1920 (referred to above), the law of bankruptcy in Northern Ireland is very similar to that in force in England. But the Bankruptcy (Northern Ireland) act, 1929, amended the law in certain important particulars. It provides, among other things. that where there is a deed of arrangement in operation, a creditor who is party to the deed cannot present a petition in bankruptcy against the debtor.

It also modifies the law as to compositions; provides for the "relation back" of the trustee's title in certain cases; repeals and re-enacts. with amendments. certain existing sections of Irish bankruptcy acts as to the effect of bankruptcy on antecedent transactions; regulates dealings with undischarged bankrupts; and provides for the administration in bankruptcy of the estates of persons dying insolvent.

It also provides specially for the bankrupt who is guilty of gambling. or who fails to keep proper accounts. It should be mentioned that in Northern Ireland a married woman can be made bankrupt only if she carries on a trade or business.

Commonwealth of Nations. — Great progress has been made in the consolidation of the law in the various parts of the commonwealth and especially with regard to the laws of bankruptcy. In Australia a consolidating act was passed by the commonwealth parliament in 1924 (Bankruptcy act, 1924, no. 37 of 1924), but the law on the subject is now to be found in what is called the Bankruptcy act, 1924–32. In New Zealand the law is consolidated by the Bankruptcy act, 1908 (Consolidated Statutes, 1908, no. 12).

All these statutes follow closely the English bankruptcy acts. In Canada the dominion parliament passed the Bankruptcy act of 1919, subsequently amended by acts of 1920. 1921, 1922, 1923, 1925. 1927 and 1931. The last-mentioned act conferred upon a workman the right to recover from the insurance company in case his employer went bankrupt. It also gave the workman a right to preferential treatment in the bankruptcy of his employer. As regards Alberta, the Fraudulent Preference act, 1922, ch. 224. to all intent assimilates the law on that subject to that which operates in England.

India and Pakistan. — There were two systems in insolvency law in force in India before July 18, 1947, one applicable to the presidency towns and the other to the rest of the country. The first depended on the Presidency Towns Insolvency act, 1909 (act iii of 1909), as amended by acts x of 1914, xi of 1921, ix and xxxiv of 1926 and xi and xix of 1927, and the second on the Provincial Insolvency act, 1920 (act v of 1920), as amended by actsxixof 1925, ix, xxxiv and xxxix of 1926 and xi and xii of 1927. Here again the English law was the model. The Indian Independence act, 1947 (10 and 11 Geo. VI, ch. 30). made special provision for the continuance of existing laws. By s. 18 (3j it was enacted that, save as expressly provided in the act, the law of each of the new dominions and the several parts thereof "shall, so far as applicable and with the necessary adaptations, continue as the law of each of the new dominions" until other provision was made by the separate legislatures.

British Colonies, Protectorates and Trust Territories. — The Indian Provincial Insolvency act was used as a convenient code of bankruptcy law for colonies or territories. In Kenya protectorate, for example. the Indian Provincial Insolvency act, 1907, was adopted as law by an ordinance of 1910 (ch. 106) and continued in force, although a separate code superseding the Indian act was set out in the Bankruptcy ordinance, 1926 (no. 1 of 1926).

In other parts of the commonwealth, English law is adopted specifically. For example. in Tanganyika. by the Bankruptcy ordinance no. 8 of 1920. English bankruptcy law as at the date of the ordinance was declared to be the law of the territory. In British Guiana, Gambia. Jamaica, Hong Kong. Mauritius, Grenada. Trinidad. Tobago and the Straits Settlements the law was modeled on the English pattern.

France. — Bankruptcy in France is regulated by the Commercial code of 1807, amended and supplemented by the law of June 9, 1838. By art. 437 of the code, bankruptcy is defined as the state of a trader who is unable to meet his commercial engagements. Simple insolvency of this kind is known in France as *faillite*. Insolvency attended with circumstances of misconduct or fraud is known as *banqueroute simple* or *banqueroute frauduleuse*. Only a trader can become bankrupt. The debt. too, for obtaining adjudication must be a commercial debt, the lams regulating bankruptcy being designed exclusively for the protection of commerce. To be made a bankrupt a trader need not be insolvent; it is sufficient that he has suspended payment. Commercial companies of all kinds are liable to be declared bankrupt in the same manner as individual traders. A trader-debtor can be adjudicated bankrupt upon his own petition, or upon the petition of a creditor, or by the court itself by its own motion. A petitioning debtor must within 1 j days file at the office of the tribunal of commerce of the district a declaration of suspension, with a true account of his conduct and of the state of his affairs, showing his assets, debts, profits and losses and personal expenses. On adjudication the tribunal of commerce appoints a person. called a *syndic provisoire,* to manage the bankrupt's estate, and a *juge commissaire* is also named to supervise the syndic. A bankruptcy terminates by an ordinary composition *(concordat),* a sale of the debtor's assets *(union)* or a composition by relinquishment of assets. It is a striking feature of the French system, and highly creditable to French commercial integrity. that a discharge in bankruptcy, even when accompanied by a *declaration d'excusabilité,* leaves the unpaid balance a debt of honour.

At the time of the French Revolution the National Convention passed a resolution that any man who contracted a debt should never be free from liability to pay it. The spirit of this resolution still survives. for until a trader has paid every penny that he owes he is not rehabilitated and remains under the stigma of various disabilities; he has no political rights, he cannot hold any public office or act as a stockbroker or sit on a jury. *Banqueroufe simple* is the condition wherein the bankrupt has been guilty of grave faults in the conduct of his business, such as extravagance in living, hazardous speculation or preferring creditors. *Banqueroute frauduleuse* involves the worse delinquency of fraud. Both *banqueroute simple* and *banqueroute frauduleuse* are punishable — the latter with penal servitude which may range from 5 to as many as 20 years.

Germany. — Bankruptcy of a person in Germany does not cause his property to be vested in a trustee as in England. hut it has the effect of transferring its possession and management (except as to certain kinds of property) to an administrator. who has to apply the proceeds for the benefit of creditors in the same way as an English trustee in bankruptcy. Before World War II the law n-as to be found in a code passed in 1877, as amended by a supplementary law dated May 1;. 1898. The same distinction is drawn in Germany as in France between mere commercial failure and bankruptcy, simple or fraudulent. Simple bankruptcy is established by such offenses as gambling. dealing in "futures." disorderly bookkeeping or extravagance in living; fraudulent bankruptcy, by offenses of a deeper nature — the concealment of property. the falsifying of books. the manufacture of fictitious debts and the giving of illegal preferences.

Both kinds of bankruptcy are punishable, fraudulent bankruptcy by penal servitude or, in case of mitigating circumstances, by imprisonment for not less than three months. Accessories in fraudulent bankruptcies (for instance. a creditor who conspires with the debtor to secure an advantage to the prejudice of the other creditors) are liable to penal servitude. The creditors are called together within one month from the date of adjudication. and at their meeting they may appoint a committee of their number to advise with the trustee. It is the duty of the court to see that the trustee performs his functions. Estates are liquidated with great rapidity. In order that the creditors may receive dividends at the earliest moment it is customary to sell the assets by auction. The creditors by a majority in number and three-fourths in value may accept a composition. but such an arrangement must have the appro\-a1 of the court. The fees are very moderate: in an

ordinary bankruptcy the attorney's fees do not, it is said, exceed £5. An insolvent estate may be administered in bankruptcy on petition by the heir.

Italy.— Bankruptcy in Italy is regulated by the Commercial code of 1883 (part iii). Only traders can pass through the bankruptcy court. Traders are defined by the code as those who as a habitual profession, engage in commercial business. This definition includes merchant companies. Bankruptcy proceedings may be taken either by the debtor or by a creditor for a commercial debt. or may be ordered by the court. The amount of the debt is immaterial; a small sum will suffice, provided its nonpayment is proof of insolvency. Bankruptcy can be declared only where there is insolvency.

The judgment adjudicating a debtor bankrupt deprives the bankrupt of the right to administer his affairs and nominates a trustee to realize the property under the superintendence of a judge and a commission of creditors. All the property of the bankrupt, movable and immovable, is sold by auction and distributed in dividends. This is one way of closing the bankruptcy, but it may also be closed by an arrangement.

No minimum percentage is required for such arrangement, but it must have the assent of creditors representing three-fourths of the bankrupt's indebtedness. Composition before bankruptcy is not recognized by Italian law.

Spain.— The law of bankruptcy in Spain is to be found in the 4th book of the commercial code, ss. 870 *et* seq., as modified by the law of June 10, 1897.

BANKS, SIR JOSEPH (1743–1820), English explorer-naturalist, noted principally for his patronage and promotion of science rather than for his own researches. He was born at London on Feb. 2. 1743, and after schooling at Harrow and Eton attended Oxford from 1760 to 1763. In 1761 he inherited an ample fortune from his father.

Banks traveled to Newfoundland and Labrador (1766), around the world with James Cook (1768–71) and to Iceland (1772). In 1778 he became president of the Royal society. The order of knight commander of the Bath was bestowed upon him in 1795, and two years later he was admitted to the privy council. He died on June 19, 1820, at Isleworth.

Banks's herbarium was one of the most important in existence and is now at the British museum, as is also his library, which consisted chiefly of unrivaled holdings of works on natural history and transactions of learned societies. He was interested in economic plants and their introduction into countries that might benefit from them, was the first to suggest (1805) the identity of the wheat rust and barberry fungus. Either at his own expense or in his capacity of honorary director of the Royal Botanic gardens at Kew, he sent out many botanical collectors to various countries. His house was for many years a centre for the meeting of scientists and the exchange of ideas. As president of the Royal society he raised the state of science in Britain and was successful in cultivating friendly relations with scientists of other nations.

BANKS, NATHANIEL PRENTISS (1816–1894), U.S. political leader and Civil War general, was born at Waltham, Mass., on Jan. 30, 1816. After being admitted to the bar, he entered politics, serving in the Massachusetts legislature from 1849 to 1853 and as president of the state constitutional convention in 1853. He entered congress in 1853, holding the support of Democrats and of Free Soilers for a time, and later of the Know-Xothing party. He joined the newly formed Republican party in 1855, and in that year was elected speaker of the house of representatives. He served in congress until elected governor of Massachusetts in 1858.

His military career began in 1861 when he was named a major general of volunteers. He served in the campaigns of early 1862 in the Shenandoah valley, and later in the year was in command of the department of the gulf in New Orleans. Forces under his command eventually captured Port Hudson, La. In 1863 and 1864 he was in command of expeditions in Texas, but proved unsuccessful as a tactician. Mustered out of the army at the end of the war, Banks re-entered politics and was a member of the house of representatives 1865–73 and again 1875–77, as a Democrat. He was returned as a Republican in 1877–79. He served for a time (1879–88) as U.S. marshal for Massachusetts; in 1888 he was re-elected to congress for the term 1889–91. He died at Waltham, Sept. 1, 1894. (E. E. R.)

BANKSIA, an Australian genus of over 40 species of evergreen shrubs and trees (family Proteaceae; *q.v.*), with leathery leaves often deeply cut, and handsome, bracted, spikes of yellowish flowers, followed by a woody, conelike cluster of fruits. It is named after the naturalist Sir Joseph Banks.

Over 20 species are cultivated for ornament, mostly in the greenhouse where they need a porous, lime-free soil and a temperature of 50°–60°. They need plenty of water, but suffer as badly from overwatering as drought. A few are cultivated outdoors along the Gulf coast and in California. They are known in Australia as honeysuckle trees. BANKURA, a town, headquarters of Bankura district in the Burdwan revenue division of West Bengal, India, lies on the north bank of the Dhaleswari river about 96 mi. N.W. of Calcutta. on the Adra to Midnapore branch of the South Eastern railway. Pop. (1961) 62,673. The population is engaged mainly in trade and silk weaving. There are four colleges, including a medical college. The collector's residence is an imposing building with fine gardens surrounded by the other public buildings.

BANKURA DISTRICT covers 2.658 sq.mi. and its population was 1,319,259 in 1951 and 1,667,527 in 1961. The eastern part is a low alluvial plain, fertile and densely populated; on the west the district occupies the eastern fringe of the Chota Nagpur gneissic plateau of Archaean Age, clothed with patches of sal forest and scrub jungle and dotted with isolated hills of which Susinia (1,450 ft.) and Biharinath Parbat (1,483 ft.) are the most conspicuous, the former being the only hill in West Bengal bearing a rock inscription of Asoka; across the middle from north to south runs a belt of older alluvium of Pleistocene Age covered with lateritic soils and very sparsely populated. The district is drained by the Damodar in the north. Silai in the middle and Kangsabati in the south. Rainfall is insufficient and irregular, necessitating irrigation of arable land from wells and storage tanks. The Damodar valley schemes provide irrigation water to 79,000 ac. of land. and a hard-surfaced road over the Durgapur barrage. Rice and sugar cane are the main crops. Laterite, china clay and building stones are quarried, and shellac, silk fabrics and brassware are manufactured. Yishnupur (pop. [1961] 30,952). a former capital, is noted for its fine temples, picturesque lakes and a fort. Sonamukhi (15,045) is a silk-weaving town. (S. P. C.)

BANN, the largest river in Northern Ireland, falls into two distinct parts. The upper Bann rises in the Mourne mountains in the south of County Down and flows northwest to Lough Neagh

(*q.v.*). The lower Bann runs northward through Lough Beg and carries the waters of Lough Neagh to the sea below Coleraine, a small port and linen town. The total length is 85.5 mi. The lower river occupies a depression in the basalt flows which form the plateaus of Antrim and north Derry. It is floored with glacial drift and with postglacial deposits including, besides extensive bogs, a layer of diatomaceous earth which is worked commercially in several places. The river has valuable eel and salmon fisheries, and is a classic archaeological site for remains of the Mesolithic and Neolithic periods. The chief town on the upper Bann is Portadown (*q.v.*), near Lough Neagh, a linen town in a district known especially for apples and roses. Farther upstream the water power of the river played an important part in the industrialization of the Ulster linen industry. (E. E. E.)

BANNATYNE, GEORGE (1545–?1608), compiler of an important collection of 15th- and 16th-century Scottish poetry, was born at Newtyle in Angus. and became a prosperous Edinburgh merchant. His anthology of verse. known as the *Bannatyne Manuscript,* was "writtin in tyme of pest" in 1568. It contains many of the best-known poems of Robert Henryson, William Dunbar and Sir David Lyndsay; it preserves work by poets such as Alexander Scott who would otherwise be no more than a name; and it also has much interesting anonymous verse. It influenced the 18th-century Scottish revival, when Allan Ramsay reprinted many of the poems (though often in doctored form) in his *Ever Green* (1724).

BIBLIOGRAPHY.—The *Bannatyne Manuscript* was ed. *by* W. T. Ritchie, 4 vol, Scottish Text Society (1928–34). *See* also *Memorials of George Bannatyne,* Bannatyne Club (1829); G. G. Smith, *Specimens of Middle Srots* (1902). (E. G. M.)

BANNERET, a knight privileged to display in the field a square banner (as distinct from the tapering pennon of a simple knight). The term, used in countries of French and English speech, first occurs in the 13th century. In late 13th-century England, commanders of troops of ten lances and of larger formations, who were not earls, were usually bannerets. During the next two centuries, the style of banneret ceased to be the normal accompaniment of military command: "banneret" became a select title of honour conferred for distinguished services (especially military). Creations continued until the middle of the 16th century. In France. the term seems to have evolved in the same direction and according to a similar chronology, though there the title was sometimes annexed to a fief, and heritable. The banneret was expected to possess means superior to those of an ordinary knight, as befitted his superior status.

Some English bannerets received individual writs of summons to parliament, though their heirs were not usually summoned. There is no connection between bannerets and the English order of baronets established by James I.

See J. Selden, *Titles of Honor,* 3rd ed. *(1672)*; J. E. Morris, *Welsh Wars of Edward I* (1901); T. F. Tout, *Chapters in Mediaeval Administrative History* (1920–33). (ER. S.)

BANNOCKBURN, a town of Stirling, Scot., lies 2 mi. S.S.E. of Stirling on the burn (stream) from which its name is derived, the Bannock (Gaelic, *ban oc,* "white, shining stream")! an affluent of the Forth. Pop. (1951) 4,759. It has textile manufactures including carpets, though at the beginning of the 19th century it was only a village.

The Bore stone, in which according to tradition Robert the Bruce planted his standard before the battle, is preserved by an iron grating. Bannockburn house was Prince Charles Edward's headquarters in Jan. 1746.

The Battle of Bannockburn. — The battle of Bannockburn was fought on June 23–24, 1314. By that time all Scotland had been cleared of English troops with the exception of Stirling castle, which the governor, Alexander Mowbray, had promised to surrender if not relieved by St. John the Baptist's day. To meet the large army which Edward II collected for this purpose Bruce assembled his smaller force at the Torwood, about 4 mi. N.W. of Falkirk.

On learning of Edward's approach, however, he moved to the new park, a mile or two south of Stirling, where the trees would hamper attack by the superior English cavalry. He had taken up his position there when the English vanguard appeared on June 23. On the dry ground, between the park and the swamps to the east, where the enemy must pass on the way to the castle, he had pits dug, a foot broad and knee-deep, and covered with sticks and grass. He sent his nephew, Thomas Randolph, earl of Moray. to block the way by St. Ninian's church, but a small force under Robert de Clifford almost slipped past Moray before he effected its repulse.

Meanwhile the earls of Gloucester and Hereford advanced to reconnoitre the main Scottish position. With them was Hereford's cousin, Henry de Bohun, who, catching sight of Bruce mounted on a palfrey and without a sword, rode at him, hoping to win victory in single combat, only to be slain by the king's battle-ax, while Gloucester was unhorsed nearby. Thus worsted in two preliminary skirmishes, the English army halted for the night, probably behind the Bannock burn.

The main battle. of which the exact site is disputed. was fought next day. Edward began at dawn to draw up his force for assailing the Scots. but the ground proved too restricted for their deployment. so that Bruce, seeing their disorder. decided. contrary to his usual practice, to attack. Sending out three "battles" of pikemen under his brother Edward. the earl of Moray and Sir James Douglas (with Walter Stewart), respectively, he kept the fourth in reserve under himself. Hard fighting ensued. "Sic a frusching of speris wair," wrote John Barbour, "that fer away men mycht it her." For a time the Scots were harassed by the English archers, until these were dispersed by a charge of 500 horse under Robert Keith, the marischal. In their cramped position the rear ranks of the English could not reach the fighting, while they hampered the retreat of those in front. At length Bruce led in his reserve to win the day. The rout was completed by the charge — whether of light armed troops or camp followers is uncertain — of those who had been watching the fight from the Gillies hill to the west and now rushed down. shouting "Sla. sla."

Many of the English, unharmed by the enemy, perished in the Bannock and the morasses beyond. Edward II, seeking refuge in Stirling castle. was refused admission by Mowbray on the ground of its imminent surrender and escaped by a circuitous route around the new park to Dunbar and thence to England. Exact estimates of the numbers engaged are impossible, but the English had probably about 3,000 horse and 20,000 foot, the Scots perhaps 10,000 altogether, or even as few as 5,000. English losses in killed and prisoners included the earls of Gloucester and Hereford, more than 60 barons and bannerets and many scores of knights; the Scots claimed to have lost only two knights but numerous pikemen. Sir Charles Oman, who gives high praise to Bruce's conduct of the battle, calls it "the most lamentable defeat which an English army ever suffered." Scotsmen regard it as the culmination of the War of Independence. For evolution of English tactics *see* also FALKIRK; DUPPLIN, BATTLE OF.

BANNS OF MARRIAGE, the public legal notice made in a church proclaiming an intention of impending marriage with the object that persons aware of any impediment to the marriage may make their objection known. The church in earliest days was forewarned of marriages (Tertullian, *Ad uxorem, De pudicitia,* ch. 4). The first canonical enactment on the subject in the English church is that contained in the 11th canon of the synod of Westminster in London (A.D. 1200), mhich orders that "no marriage shall be contracted without banns thrice published in the church, unless by special authority of the bishop." It is, however, believed that in France the practice is as old as the 9th century. The Lateran council of 1215 made the publication of banns compulsory. In early times it was usual for the priest to betroth the pair formally in the name of the Blessed Trinity. In England, under the

canon law and by statute, banns are the normal preliminary to marriage; but a marriage may be solemnized without the publication of banns by authority of a special licence granted by the archbishop of Canterbury, or of a common licence granted by a competent ecclesiastical authority, or by a superintendent registrar's certificate. The legal position in England is now governed by the Marriage act, 1949. Banns remain valid for three months after their complete publication on three Sundays prior to the marriage during morning or evening service. If any persons knowingly intermarry after the expiration of the banns, or in any place other than a place where banns may be published, or without the due publication of banns, or after joint and intended concealment of the true name of one or of both of the parties, the marriage is void. In the United States there is no statutory requirement, and the practice of banns (though general in the colonial period) is almost entirely confined to Roman Catholics. See BETROTHAL; MARRIAGE, LAW OF. (W. T. Ws.)

BANNU, a town and military station in West Pakistan, lies on an upland plain near the west bank of the Kurram river 93 mi. S.W. of Peshawar. Pop. (1961) 31,623. Being of military origin it has wide streets laid out in gridiron pattern and is enclosed by a 12-ft. earth wall, with ten iron gates which are closed daily at sunset. It is at the junction of hard-surfaced roads running north to Peshawar, east and south to the Indus valley and west into the frontier country of Waziristan; and is at the end of a metre-gauge railway from Kalabagh and Mari Indus on the Indus. These communications make it the chief market town of the area. It is also the headquarters of the Bannu administrative district and the seat of Government college affiliated to Peshawar university. Local industries include the making of *chappals* (sandals) and wooden articles, and there is a large woolen mill.

Bannu was founded in 1848 by the British officer Lieut. (later Sir) Herbert Edwardes as a base for military operations, a bazaar for his troops and a refuge against the Pathans for local Hindu and Sikh communities. It was at first known as Dhulipshahar after Dhulip Singh, the last Sikh ruler of the Punjab, and its fort was called Dhulipgarh. In 1869 it was renamed Edwardesabad, but in 1903 this was changed to Bannu after the district, only the fort keeping the name Edwardes.

BANNU DISTRICT is a circular alluvial plain or basin hemmed in by low hills. Pop. (1961) 432,000, mainly Pathan or Afghan tribespeople (see NORTHWEST FRONTIER). Area 1,696 sq.mi. The plain slopes gradually southeastward and is watered by mountain torrents and drained by the Kurram and its tributary the Tochi or Gambila. The narrow Bannu or Kurram-Gambila doab (the area between the two rivers) in the centre is the district's most highly irrigated, cultivated and populated area, with wheat, maize and barley as the chief crops. The rest of the district is largely sandy, growing winter wheat and grain. Fields are embanked to hold the floodwaters. The Kurramgarhi project, completed in 1960, with dams on the Kurram and Baran rivers, provides irrigation for 270,000 ac. and generation of 4,000 kw. of electricity.

In ancient and medieval times the Kurram-Bannu route afforded one of the ways into India for invaders and colonizers from the northwest. The Akra mounds, 7 mi. from Bannu, probably represent the ruins of a regional capital of the Bactrian or "Indo-Greek" rulers of the 2nd century B.C.—1st century A.D. Bannu was traversed by the raids of Mahmud of Ghazni in the early 11th century A.D.; and in the century of chaos which followed was colonized by the Afghan tribe called Bannuchi or Bannuwal, who still occupy part of the district to which their name was given. Timur (Tamerlane) is said to have crossed Bannu in his massive raid on the Punjab and Delhi in 1398. During the Muslim period in India the wild tribal Bannu was but nominally subject to central authority. By 1838 it had fallen to the Sikh kingdom of Ranjit Singh, but 11 years later the second Sikh War brought it under British control. Bannu district was formally constituted in 1861. (K. S. AD).

BANQUE DE FRANCE. Founded on Jan. 18, 1800, as a limited company, on the instigation of Napoleon Bonaparte, the Banque de France began operations on Feb. 20 of the same year. Because it had been called to help to finance the war, the new institution had to face certain difficulties as early as 1806 which caused its statutes to be recast; the modified statutes were put into force in 1808, and their main provisions still remain valid. Napoleon declared: "The bank does not belong to the shareholders only; it also belongs to the state, since the state has entrusted to it the privilege of issuing money. I wish the bank to be in a sufficient measure in the hands of the state, but not too much so."

According to a law of April 14, 1803, the privilege of issue had been granted to the bank for the Paris area only. The privilege was extended to metropolitan France in 1848, after the economic and financial upheavals which had led to the disappearance of the local banks of issue, and subsequently renewed at intervals up to 1945, in which year the bank was nationalized. The bank has 259 agencies in metropolitan France (namely, 159 branches [*succursales*] and 100 offices [bureaux *auxiliaires*]) and maintains correspondents in 1,130 ancillary towns (*villes* rattachkes). It has no agency in the French dependent overseas territories.

A governor and two deputy governors appointed by the government manage the bank's business. Otherwise it is administered by a general council of 12 persons, of whom 4 are ex-officio members (namely, the general manager of the Caisse des Depots et Consignations, the governor of the Crédit Foncier de France, the general manager of the Crédit National and the general manager of the Caisse Nationale de Crédit Agricole). Seven other members are appointed by the minister of finance; one member is elected by the staff of the bank. After nationalization the former shareholders received in 1945 fixed interest securities of a par value of 7,000 fr. at 3%; one old share was exchanged for four new securities, plus a cash bonus of 29 fr.

The Banque de France functions as a central bank (*q.v.*), acting as a bankers' bank. Although it is authorized to deal directly with private persons and firms, the volume of its transactions with the general public substantially decreased after World War II. Such transactions were originally intended to give greater efficiency to the discount rate policy. Since 1945, however, this has been achieved through the bank's ability to control the credit operations of the banking system. Because the provisions of the original statutes were strict, it was at first unnecessary to limit the note issue. Between 1848 and 1850, however, the bank having been relieved of the obligation to redeem its notes in specie, the government fixed a maximum limit for the note issue. A ceiling was enforced once more in 1870 and was increased periodically. This system was abandoned in 1928, when the law of June 25, 1928, which restored the franc convertibility suspended since the outbreak of World War I, obliged the bank instead to keep a gold reserve of at least 35% against its sight liabilities (namely, the amount of the note circulation and of credit balances on current account). In 1936 the bank was again relieved of the obligation to redeem its notes in specie, and at the outbreak of World War II all provisions governing the note issue were repealed.

Up to 1938 the bank could influence the volume of credit and, consequently, the amount of the note issue only through changes in its discount rate. After 1938 it was empowered to regulate the working of the money market through its open-market operations.

One of the objectives of the nationalization law of Dec. 2, 1945, was to tighten control over the note issue through the supervision of credit distribution. Although this function was entrusted to a new organization, the Conseil National du Crédit, the Banque de France nevertheless plays an important part in this field, because its governor is ex-officio vice-president of the Conseil National du Crédit and because it surveys the application of the measures agreed upon by the Conseil. This permits the bank to promote a credit policy through quantitative as well as selective control of credit facilities granted by the whole banking system. According to the provisions of the original statutes, the operations that gave rise to the issue of notes were to be limited to gold transactions and to the discount of commercial paper. The Banque de France was subsequently empowered to grant advances upon gold or securities as collateral, to buy and sell foreign exchange and to engage in open-market dealings. It was also called upon, especially after World War I, to grant advances to the government. As a result, note circulation remained at very high

levels. Gold dealings between the Banque de France and the general public were suspended in 1936, as far as purchases and sales or advances upon gold collateral are concerned. These transactions were later entrusted to the French Exchange Stabilization fund.

Bills of exchange. and other commercial paper, and warrants, checks and short-term treasury maturities are acceptable for discounting by the bank. Except in the case of short-term treasury maturities, the paper offered for discount must bear three signatures of persons of standing (a collateral in the form of securities or goods may replace the third signature). The maturity must not exceed three months. To meet special needs (credits to cattle breeders, or the financing of purchases of cereal crops) the bank extends its facilities up to nine months through quarterly renewals of the relevant paper. Moreover, in order to overcome capital shortage the bank finances certain investments and foreign operations by discounting short-term paper issued on medium-term credits having a maturity not exceeding five years.

For open-market operations to regulate the working of the money market, the Banque de France was empowered by a decree of June 17, 1938, to purchase and to sell short-term commercial and government paper eligible for rediscount. In fact, the bank's purchases and sales mainly concern treasury bills, banker's acceptances, promissory notes issued by the nationalized railways, and acceptances of the Crédit National. On Dec. 31, 1960, the above-mentioned credit operations totaled 22,680,000,000 new fr. (1 new fr. = 100 old fr.) and the notes in circulation 39,320,000,300 new fr. The gold and foreign assets were 10,066,000,000 new fr.

Before World War I, the advances of the Banque de France to the government reached only 180,000,000 old fr. Since then the government has increasingly applied to the bank for assistance. The permanent advances totaled, at the end of 1959, 6,500,000,000 new fr. The temporary advances, granted to enable the government to meet exceptional expenditures, amounted to about 901,000,000 new fr. or 90,000,000,000 old fr. on Dec. 31, 1960. The Banque de France puts its technical facilities at the disposal of the public treasury for the movement of public funds between the treasury and the treasury's local agencies as well as for the subscription and servicing of the loans issued by the state and by local authorities. The bank accepts deposits on current account from the public. It also holds securities on deposit and is prepared to handle purchase or sale orders for such securities. Finally, the bank rents strong rooms and safes to its customers. See also BANKING: History *of* Banking. (HI L.)

BANSHEE (Irish, bean sidhe; Gaelic, ban sith, "woman of the fairies"), a supernatural being in Irish and other Celtic folklore whose mournful "keening" or screaming at night was held to foretell the death of one of the household visited. In Ireland banshees were believed to warn only families of pure Irish descent: the Welsh banshee, the gwrach y Rhibyn ("witch of Rhibyn") only visited families of old Welsh stock. Sir Walter Scott mentions belief in a kind of banshee or household spirit in certain Highland families (Letters on Demonology and Witchcraft, p. 351, 1830).

BANSKA BYSTRICA, an ancient town of western Slovakia, Czechoslovakia, scene of the Slovak national rising in 1914, lies in the valley of the Hron river at the confluence of the Bystrica with the Hron, 1,188 ft. (362 m.) above sea level. Pop. (1957 est.) 19,126. The valley is between the Low Tatra ranges to the north and the Slovak Ore mountains to the south. The site at the sharp bend of the Hron river to the south was historically of strategic importance, as is shown by the castle (now a museum) on its limestone rock. Upstream the Hron valley is well watered, wooded and fertile. The traditional importance of Banska Bystrica was that of a mining town, profiting from the near and good supplies of gold, copper and iron. The late medieval German church, distinct from the 15th-century Slovak church, recalls the importance of the immigrant mining group. There has been great development of local industry, housing and cultural activities since World War II. (H. G. S.)

BANSTEAD, an urban district, constituted in 1933, in the Carshalton parliamentary division of Surrey, Eng., on the North Downs, 14 mi. S. of Hyde Park Corner, London, by road. Pop. (1961) 41,573. Area 20 sqmi. The district, which is mainly residential, comprises Banstead, Chipstead, Kingswood, Walton-on-the-Hill and Woodmansterne, where the Oaks became Lord Derby's seat in the 18th century and gave its name to the horse race run on the Epsom racecourse west of Banstead. In 1243 Hubert de Burgh (*q.v.*), lord of the manor, died at Banstead. In 1952 excavations for a housing site at Preston Hawe led to the discovery of the plan of a medieval manor.

BANSWARA, a town and headquarters of a district of the same name in the former state, now division, of Udaipur (*q.v.*), Rajasthan, India, is situated about 80 mi. S.E. of Udaipur city. Pop. (1951) 15,558.

BANSWARA DISTRICT, pop. (1951) 356,559 (1961) 474,192; area 1,946 sq.mi., comprises the former princely state of the same name (pop. [1941] 258.760; area 1,606 sq.mi.) absorbed into Rajasthan on April 18, 1948, and additional territory.

The Banswara prince. or maharawal, was a Sisodhyia rajput of the Dungarpur family. During the decline of the Delhi empire Banswara passed under the Marathas. Wearied by their oppressions, its chief in 1812 petitioned for English protection. By a treaty of 1818 the British guaranteed the prince against external enemies and refractory chiefs; he, on his part, pledged himself to be guided by a British representative. The state was subsequently controlled through the Southern Rajputana subagency. Kushalgarh state, to the southwest, was feudatory to Banswara.

(S. M. T. R.)

BANTAM, a former city of Java, Indon., lying on Bantam bay at the extreme northwest of the island. Now in ruins, Bantam was once the capital of the powerful kingdom and sultanate of Bantam, which was converted to Islam in the 16th century and flourished until the following century when the Dutch reduced it to a state of vassalage. Bantam was the most important Javanese port for trade with Europe and an entrepôt for pepper and other spices. By the end of the 18th century, however, alluvial deposits had silted up the harbour, and by mid-20th century the site of the city was several kilometers from the sea. Its trade meanwhile had shifted to Jakarta (Batavia). There are ruins of buildings of Javanese and Dutch origin, such as the Pakuwonan palace, built in 1680 and surrounded by a bastioned wall, Fort Speelwijk, and several mosques, the oldest and largest of which, built between 1562 and 1596, has detached minarets.

Under Dutch occupation Bantam was the westernmost residency of Java, comprising the districts of Pandeglang, Serang and Lebak, with the capital at Serang. The area produces rice, coconuts, maize and rubber, and gold mines have been developed in the south.

BANTENG (BANTING), *Bibos* (Bos) *sondaicus,* the oftendomesticated wild ox of southeast Asia (especially Borneo and Java). The white patch on the rump distinguishes the banteng from its ally the gaur (*q.v.*). Adult bulls of the banteng are completely black except for the white rump and legs, but the cows and young are reddish brown. In Burma the species is represented by the tsine, in which the bulls are reddish fawn. *See* BOVIDAE.

BANTING, SIR FREDERICK GRANT (1891–1941), Canadian scientist, who, with Charles H Best, was the first to extract the hormone insulin, was born in Allison, Ont.. on Nov. 14, 1891, and was educated at the University of Toronto. He served in World War I and then practised medicine in London, Ont , until May 1921, when he and Best began a search at the University of Toronto, in J. J. R. Macleod's laboratory, for the internal secretion of the pancreas. In the autumn of 1921 it was announced that Banting and Best—who worked alone from May to November—had succeeded in preparing insulin, which proved to be a specific in the treatment of diabetes. Banting became the first head of the Banting and Best department of medical research created by the government of the province of Ontario at the University of Toronto in 1923. Together with Macleod he received the Nobel prize for medicine in the same year; Banting divided his share of the prize equally with Best. In 1923 the Canadian parliament voted an annuity of $7,500 to enable Banting to carry

on his investigations. In 1924 the Banting Research foundation was established, and in 1930 the Banting institute was opened at Toronto. Banting was created knight of the British empire in 1934. He was killed in an airplane accident on Feb. 21, 1941. in Newfoundland. *See* also INSULIN. (C. H. B.)

BANTING, WILLIAM (1797–1878), known for the slimming diet named after him, was a cabinetmaker and undertaker in St. James's street, London. He was only 5 ft. 5 in. tall, but suffered from such increasing fatness that before he was 60 he was unable to tie up his shoes and had to go downstairs backward. On medical advice he took up long-distance walking and rowing, frequented Turkish baths and consumed "gallons of physic." These measures only improved his appetite and added to his weight. In 1862, when he weighed 16 st. 6 lb. (230 lb.), he consulted William Harvey, an aural surgeon, for deafness. Harvey, believing that obesity was the cause of the trouble, placed him on'a diet composed mainly of flesh meat, fish and dry toast. Bread, butter, milk, sugar, beer, soup and potatoes were forbidden. As a result Ranting's weight decreased by 46 lb. and he greatly benefited in health. In 1863 he published a *Letter on Corpulence,* setting out in simple language the method which had brought him such relief. The pamphlet sold in thousands, and "Bantingism" and "to bant" became household words. He died in London on March 16, 1878. (W. J. BP.)

BANTOCK, SIR GRANVILLE (1868–1946), English composer whose works are remarkable both for their colourful and imaginative expression and the grandeur of their conception, was born in London. Aug. 7, 1868. After preparing for the Indian civil service, he studied at Trinity College of Music and the Royal Academy of Music, and, during these years, developed a sympathy with eastern culture and philosophy which had a lasting influence on his work. He served a lengthy apprenticeship, as editor of a musical magazine (1893–96) and conductor and concert promoter, before his appointment in 1900 to the directorship of the Birmingham School of Music. In 1907 he succeeded Sir Edward Elgar as Peyton professor of music at University of Birmingham. This was a productive period: his massive masterpiece, *Omar Khayyam,* for solo voices, chorus and orchestra was performed in three parts (1906, 1907 and 1009) and a series of compositions for unaccompanied voices culminated in *Atalanta in Cnlydon* (1912) and *Vanity of Vanities* (1914), which are outstanding examples of his feeling for vocal tone colour.

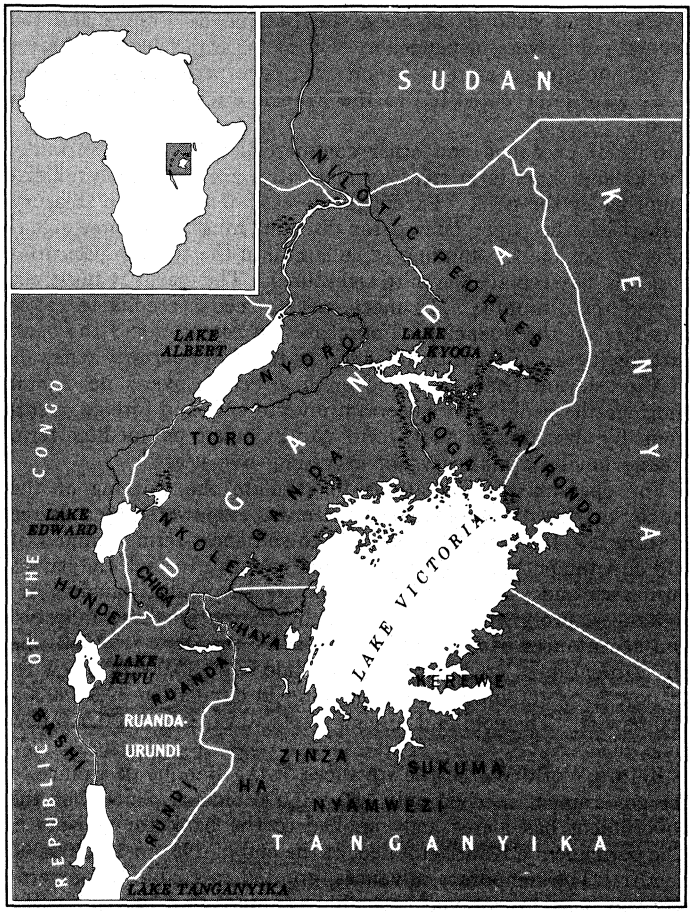
Bantock's range was wide and he was as inspired in his songs for children as in his large-scale works. His invention was unflagging, although he was forced to abandon the use of lavish resources, which endangers the survival of *Omar Khayyam* as a regular part of the concert repertory in England. His orchestral works range from the impressive *Hebridean Symphony* (1916) and the large tone poems—Fifine *at the Fair* (1912), *Dante and Beatrice* (1911)—to small concert pieces such as *The Pierrot* of *the Minute* (1908) and *Helena Variations* (1901). His output of songs, part songs and instrumental music was as vast as it was varied.

Bantock also found time to advance the competitive festival movement, and through his wide sympathies English audiences were introduced to many contemporary works. He remained at Birmingham until his retirement in 1934, and was knighted in 1930. He died in London: Oct. 16, 1946.

See H. Orsmond Anderton, *Granville Bantock* (1915); complete catalogue of his compositions in the article in Grove's *Dictionary* of *Music and Musicians,* 5th ed. (1954). (C. ED.)

BANTRY (BEANNTRAIGHE), a town of County Cork, Republic of Ireland, 57 mi. W.S.W. of Cork by road. Pop. (1956) 2,211. Bantry bay. an inlet made by a drowned river valley, is 22 mi. long and 3 to 6 mi. wide. In this fine bay. which gives anchorage to the largest ships! an indecisive battle took place in 1689 between an English fleet under Adm. Arthur Herbert, later earl of Torrington, and a French fleet; troops were at different times landed there by both sides during this period. In 1796 an abortive attempt at invasion was made by a French fleet. The ancient thriving pilchard fishery has declined; tweeds are made. but the main industry is catering for tourists. Bantry house has a rich art collection.

BANTU (INTERLACUSTRINE), a group of Bantu-speaking peoples of east central Africa. so called because they inhabit the highlands between Lakes Victoria, Kyoga Albert, Edward, Kivu and Tanganyika. In Uganda, the group includes the Soga. Ganda. Nyoro, Toro, Nkole and Chiga; in the Republic of the (former Belgian) Congo and Ruanda-Urundi. the Ruanda, Rundi. Bashi and Hunde; in Tanganyika, the Haya, Zinza, Ha, Kerewe and. for some purposes, the Sukuma and Nyamwezi. Excluding the latter, the Interlacustrine peoples number about 8,000,000. They fall into three linguistic subgroups: one formed by the Ganda and Soga; a second made up of the remaining Uganda and Tanganyika tribes; excepting the Ha; and a third consisting of the Ha and the Congo and Ruanda-Urundi groups. The Sukuma and Nyamwezi are not linguistically part of the Interlacustrine cluster (though they are Bantu), but they share important cultural features with the latter.



AREA INHABITED BY THE INTERLACUSTRINE BANTU OF AFRICA

Besides their linguistic unity, these peoples share a tendency to form powerful states ruled by hereditary kings. In most African states, effective political authority was widely diffused, the ruler sharing it with fellow aristocrats or with hereditary commoner chiefs who could effectively assert the interests of their kinsmen. In the Interlacustrine states, however, rulers could often assert personal authority over appointment to chieftainship and thus secure hierarchies of quasi-bureaucratic officials personally loyal to themselves. Kinship groups existed in these societies but, particularly in the more powerful kingdoms, lacked the ability to act as effective political units, being confined to such domestic functions as the control of inheritance and exogamy. The two strongest kingdoms in the last half of the 19th century were the Ganda and Kuanda. In each case the king ruled with almost despotic authority, appointing most major officials and often assigning to them overlapping jurisdictions to encourage them to compete for his favour and to prevent their combining against him. The power of the kingdoms was enhanced by the prosperity of their economies. which combined cattle keeping with the cultivation of plantains, millet and sweet potatoes. In many areas the

basic food supply was so completely provided by women's labour that many men could regularly be spared for military service and labour on public works.

Not all Interlacustrine peoples created powerful kingdoms. The Chjga, for example, although closely akin to the Nkole linguistically and culturally, achieved no political integration wider than the local community. However, the Chiga shared with the peoples of the kingdoms a common basic culture which underlay local variations in political structure. A prominent feature of this common culture was the magico-religious complex centring upon spirit possession The spirits of ancestors. kings, hero gods and natural phenomena were believed to influence the lives of men, and communication with these spirits was held through mediums who became possessed by them. Among all tribes the word *mandwa* (or some phonetic variant) was used to denote the medium or the process of possession. Among the Nyoro subgroup, as well as the Sukuma and Nyamwezi, the most important spirits were the *bacwezi,* a dynasty of legendary kings. Among the Ganda and Soga, some of the same figures appear as hero gods, called *balubaale.* One of the Nkole *bacwezi,* Mugasha, is recognized by the Ganda as Mukasa, while Ndahura, the first of the bacwezi kings of the Nkole. appears as Ndawula in the Ganda royal genealogy.

These legends, and the occurrence among some Interlacustrine peoples of castelike distinctions between pastoralists and cultivators, suggested to earlier ethnologists that the kingdoms had resulted from the conquest of indigenous agricultural Negroes by invading Hamitic pastoralists. The physical differences between pastoralists and agriculturalists are real enough in some areas. J. Hiernaux, for example, found very significant differences between the two groups in Ruanda-Urundi in mean stature and other features. However, detailed social anthropological studies have not yielded specific evidence of Hamitic influence in either language (the tall pastoralists speak the same Bantu languages as do the cultivators) or culture, though they have in some cases revealed traditions relating the Nilotic origin of reigning dynasties Among the Ganda and Soga there is neither physical nor social differentiation into castes, and in the Nyoro subgroup the differentiation is very attenuated. While Hamites may have contributed to the area's population, clearly its history has been more complex than was previously believed. *(See* HAMITIC RACES; NILOTES.)

The Interlacustrine peoples were discovered by Europeans. and came under colonial rule during the second half of the 19th century. The Ganda became the nucleus of the British protectorate of Uganda, while the peoples to the west of Lakes Albert. Edward, Kivu and Tanganyika were incorporated into the Congo Free State, later the Belgian Congo. Germany ruled Tanganyika and Ruanda-Urundi until World War I, after which the former passed to Great Britain, becoming independent in 1961, and the latter to Belgium under League of Nations mandate. The Interlacustrine peoples generally prospered in the 20th century. Their high, well-watered and fertile lands enabled them to grow profitable cash crops and their political cohesiveness prevented large-scale alienation to European settlers, though Ruanda-Urandi developed severe overpopulation. Both Britain and Belgium ruled through indigenous political institutions and these institutions responded with flexibility to the demands of modernization, but the individual kingdoms' strong sense of separate identity made them difficult to absorb into wider political units. See also GANDA; HAYA; NKOLE; RUANDA; RUNDI; SOTHO; UGANDA: *The People.*

BANTU LANGUAGES. Of the African languages (*q.v.*), those which constitute the Bantu group are spoken throughout most of the southern projection of the continent. The western limit of the area in which they are spoken is the borderland of Cameroun and Nigeria. The area extends southward and eastward across the continent, and lies, except at one point in the centre, south of the 5th parallel of north latitude. The area reaches approximately to the centre of South-West Africa, in the hinterland of Walvis bay. at its southwestern extremity; it reaches the eastern and northern portions of Bechuanaland protectorate and the fringes of the Kalahari desert, at the centre of its southern boundary; and its southeastern extremity continues around the southern edge of the continent as far west as the neighbourhood of Port Elizabeth, in the eastern Cape of Good Hope Province. Bantu is the speech of by far the greatest number of inhabitants in every political division on the equator and southward. Bantu is spoken on the islands of Pemba, Zanzibar, Mafia, Ibo, and the Comoro Islands, in the east, and Fernando Po. in the west. There is said to be some Bantu also in northwestern Madagascar.

The number of distinct languages that are spoken over this vast area cannot be stated with accuracy.

Some Bantu languages have become basic means of communication among African groups, and are employed by Europeans, Arabs and Indians in their relations with Africans. Notable among such languages is the Swahili language (*q.v.*), which is an efficient lingua franca along the eastern coast and in southern Republic of the Congo. Lingala, in northwestern Republic of the Congo, and Nyanja, in Northern Rhodesia and Nyasaland, are less widely used.

Swahili has for a long time been a written language. Under the stimulus and encouragement of the International African institute, increasing numbers of Africans are writing in their native languages, and a Bantu literature is developing, particularly in the southern and eastern parts of the continent. Over a wide area. Bantu languages are employed in missionary and government schools.

"Bantu" is a frequently occurring plural form of the word meaning "person." consisting of the plural prefix *ba-* and the stem *-ntu.* Wilhelm Bleek proposed the word as a designation for these languages in 1856; their affinity. or that of a number of them, had been previously established It should be recognized that *bantu* is not a constant form, for the prefix and the stem may vary phonologically in different languages. Compare the following:

Language	Singular	Plural
Chewa	*mu-nt^{h}u*	*pa-nt^{h}u*
Ganda	*omu-ntu*	*aba-ntu*
Herero	*omu-ndu*	*ova-ndu*
Kwena	*mU-t^{h}U*	*ba-t^{h}U*
Lamba	*umu-ntu*	*aβa-ntu*
Luba	*mu-ntu*	*ba-ntu*
Lembwe	*mu-ntu*	*ba-ntu*
Nyanja	*mu-nt^{h}u*	*a-nt^{h}u*
Shona	*mu-nhu*	*pa-nhu*
Swahili	*m̀-tu*	*wa-tu*
Umbundu	*omu-nu*	*oṃa-nu*
Zulu	*umu-nt'u*	*aba-nt'u*

(Note: *t^h,* aspirated f; *t',* glottalized *t; β,* bilabial fricative; *b̂,* implosive *b; m̀,* syllabic *m; U,* open *u.* Tones and stress are not indicated.)

The stem *-ntu* occurs with other prefixes in different meanings. In Chewa, *chi-nt^{h}u* "thing" (pl. *vi-nt^{h}u*); *ka-nt^{h}u* "anything," "something" (pl. *tu-nt^{h}u* "serious trouble"); *u-nt^{h}u* "humanity." In other languages there are similar forms based on this stem.

Classification.—Diedrich Westermann first demonstrated that the connection of Bantu with the languages of west Africa is genuine, and Joseph Greenberg has provided evidence which shows clearly that Bantu has membership in a major linguistic family extending entirely across western Mali as far north as the Senegal river. Greenberg christened this family Niger-Congo, making use of the names of two of the great rivers that flow through the territory over which it is spread, and he divided it into eight subfamilies. although there is some probability that the number may be reducible to seven. Bantu thus has the status of a sub-subfamily. It is a member of the subfamily called by Greenberg the Central branch of Niger-Congo. The Central branch consists of 22 language groups. including Bantu; the other members are distributed over the drainage of the Cross and Benue rivers, from southern

Nigeria and the Cameroun Republic to central Nigeria. The closest affinities of Bantu, according to Greenberg, are Batu, Bitare, Jarawa, Munshi (Tiv), Mambila and Ndoro.

These genetic relations suggest that Bantu probably had its origin in this region and subsequently spread eastward and southward, becoming differentiated into the great number of languages which are its present-day representatives.

There has been no equally satisfactory division of the Bantu languages. All classifications so far presented are primarily based on geographic propinquity or gross typological resemblances and do not seem to merit repetition.

Phonology. — The evolution of Bantu has resulted in a greater diversification in phonology than morphology. A few words and phrases suffice for the identification of almost any Bantu language, although there may be a great variation in the sounds represented. Open e and open *o* have a wide distribution, and *a*, similar to English *a* as in "father," is also common to most of the languages. Consonantal clusters, except those involving a nasal or lateral. are rare; the syllable terminates in a vowel or sometimes in a nasal (thus *ba-ntu*). Syllabic nasals seem to have universal occurrence. The labiovelar sounds, *kp* and *gb,* occur in the Bantu languages that neighbour west African languages, where these sounds are frequent. In some of the languages of the south, clicks (*q.v.*), said to be borrowed from Khoisan, are found. The sounds of Proto-Bantu as reconstructed by Carl Meinhof are *p, t, k, β, l, g* (voiced velar fricative), *m, n,* possibly *η* (as *ng* in "song"), *w,* y. Palatalized *ṫ, l̇,* k and *g̈* were early secondary developments within the Proto-Bantu period; *a, I* (open), *i* (close): *U* (open), *u* (close), with *ɛ* (open) and *ɔ* (open) and possibly the close varieties of *i* and *u* developed from vocalic coalescence, also during this period.

Tone seems to be an important feature in the phonology of all Bantu languages, with the possible exception of Swahili. Tone is not as significant lexically as it is in west Africa, but no analysis of a Bantu language can be complete if the tonal phonemes are neglected, as they so often are. In Kwena, for example, the difference between the singular forms of the second and third person in most forms of the verb is expressed only by a difference in tone.

Greenberg has shown that in Proto-Bantu there were two level tones, low and high. The latter seems to have been replaced in Swahili by a primary stress accent. In Swahili phrases there is an overlying intonation pattern somewhat resembling that in English.

Morphology. — The principal morphological classes into which Bantu words are grouped are nouns, pronouns, verbs and adjuncts (or qualificatives), including numerals. There also are various particles and other words that fill syntactic roles but are not included in distinctive formal classes.

A noun usually consists of a stem preceded by a prefix which changes according to number. Some nouns are limited to a singular or a plural form. In Proto-Bantu, all nouns contained prefixes, but some of these prefixes have been lost. There are certain stems to which suffixes as well as prefixes are attached and on which both nouns and verbs are built. In some languages, diminutives are formed by suffixation. The prefixes are part of the system of inflection in Bantu syntax. Noun suffixes have a derivational function.

Bantu nouns are arranged in several categories, or noun classes, on the basis of their prefixes and the morphemes that are employed for expressing their syntactic relationships to verbs, qualificatives and other forms. These morphemes, together with the noun prefixes, where they exist, make systems of concordances that are partially alliterative. In the Kwena sentence, *mUnwana wáxáxwé Útswá madi* "his finger is bleeding," the noun prefix *mU-,* possessive prefix *w-* (from *U-*) and verb prefix *U-* are the syntactical concordances. In the Swahili expressions, *kidɔlɛ kirêfu kinaɔñéša* ("finger long it is pointing") "the long finger is pointing" and *vidɔlɛ virêfu vinaɔñɛ́ša* "the long fingers are pointing," the concordances form perfect alliterations, but such precise alliteration is exceptional in Swahili and in other languages.

Following is a transliteration of Meinhof's reconstruction of the noun prefixes for Proto-Bantu, with the classes regrouped:

Class	Singular	Plural
1.	*mU-*	*βa-*
2.	*mu-, (mU-)*	*m[-, (mi-)*
3.	*lI-*	*ma-*
4.	*kI-*	*βI-, (βi-)*
5.	*nI-*	*linI-*
6.	*lU-*	*linI-, (tU-)*
7.	*ka-*	*tU-, (βU-)*
8.	*βU-*	—, *(mI-), (ma-)*
9.	*kU-, (ġI-)*	—
10.	*Pa-*	
11.	*mU-*	—
12.	*pi-*	*tU-*
13.	*@-*	—, *(ga-)*
14.	*gi-*	—

It is probable, as Meinhof and others have recognized, that additional prefixes existed in Proto-Bantu. In some of the languages, noun prefixes are reduplicated partially, as in Zulu *umu-, aba-* or Ganda *omu-, aba-*. The first elements of the reduplicated forms have been called preprefixes and are shown in some reconstructions of Proto-Bantu.

The use of concordances as a syntactical system embraces the first and second persons. The divisions of noun classes are for the third person. This syntactical system, then, rather than the noun prefixes; which are merely a part of it. is the essential characteristic of this type of formalism, and is one of the principal morphological features of the languages. The functional interrelationship of the morphemes outweighs the significance of their formal resemblance.

The formative elements that are employed in the structure of Bantu verbs include characteristically these prefixed concordances, without which. with few exceptions (as in the imperative), no finite verb form is complete. Since the verb infinitive also bears a prefix and is a noun (class 9, above), it follows that the great majority of Bantu verbs always include one or more prefixes. Thus the systems of concordances rather than merely the noun prefixes are the outstanding badge of Bantu syntax. These languages, therefore, might be called more appropriately "prefixed-and-suftixed-concordance-using" in preference to "noun class denoting."

Although with few exceptions the concordances are prefixed in verb forms, as in nouns, they may occur as suffixes and even as stems, as in possessive pronouns and demonstratives. The complete syntactical systems are the classes, and each contains prefixes and other concordances, the former predominating.

According to an oft-repeated historical hypothesis, this formal grouping once corresponded to a classification of all aspects of life (objects, acts, ideas, etc.) in the Proto-Bantu world. This hypothesis is not verified by the data which the present-day languages furnish. There is a tendency for nouns that refer to human beings to come under the class conventionally allotted the first number (class 1) and it is possible to assign meanings to other classes, the locatives, for example. Since in most instances the exceptions are more numerous than the assumed norms, it must be concluded that these categories are formal rather than semantic. They are simply cultural products, patterns of speech, and constitute genders comparable to the so-called sex genders of Indo-European languages. The imposition of a semantic classification on either kind of gender results in some regularity, but much arbitrariness. The essential characteristic of all languages is the high degree of formal congruity which gives each of them its distinctive grammar. Bantu prefixed concord, like Latin suffixed concord. is neither a naturalist's nor a logician's response to the world of concrete experience.

Conjugation. — The verb in Bantu languages is made of a stem, to which are attached at least one prefix, except in the imperative, and one or more suffixes. There are a few irregular verbs which in some forms have doubtful suffixation. The concordances that are employed in verb forms express the categories of person and number or, in the locative classes (numbers 9, 10, 11, above), local relations. Other prefixed elements, not connected with the system of concordances, symbolize such categories as tense-aspect,

negation, voice and mood Verb suffixes are associated primarily with mood, voice and tense; some are associated uith negation, person and number. In the infinitive and in most finite forms, the terminal verb suffix is *-a.* In its singular form, if no object is expressed, the simple imperative consists of the stem and suffix *-a;* some negative, imperative, and perfective forms have the final suffix *-i, -I, -e* or *-ɛ*; and derivative suffixes usually come next to the stem.

The following Kwena forms are built on the stem *-rút-* (Proto-Bantu *-tund-,* from *-tunl-*) and illustrate some categories of the verb and the role of derivative suffixes: *xU-?,zit-a* "to teach"; *xU-rút-án-á* (reciprocal form); *xU-rút-ís-á* "to cause to teach," "to help teach"; *xU-rút-él-á* "to teach for"; *xU-rút-íw-á* "to be taught"; *xU-rút-ɛ́x-á* "to be teachable." The future is *xU-tla-rut-a,* with prefix *-tla-,* from *xU-tl-a* "to come"; the reflexive is *xU-i-tʰút-a,* with object pronoun *i-.* Nouns are *mU-rút-i* "teacher"; *mU-rút-ís-i* "drillmaster"; *mU-rút-iw-á* "student", *mU-rút-w-aná* "pupil," with diminutive suffix *-aná;* and *tʰút-ɔ* "education" or "learning."

Principal Features of Bantu Morphology.—(I) There is a relative high degree of synthesis, forming somewhat elaborate words. (2) The morphemes of a word are joined in a manner which preserves their formal identities and generally shows clearly their grammatical functions. Partial concealment of a form may result from phonological modification. (3) There is a tendency for the same word to include both inflectional and derivational elements.

BANVILLE, (ÉTIENNE CLAUDE JEAN BAPTISTE) THÉODORE (FAULLAIN) DE (1823–1891), French poet who linked Romanticism and Symbolism. was born at Moulins (Allier) on March 14, 1823. His first book of verse. *Les Cariatides* (1842), showed him to be a disciple of Victor Hugo. whom he admired all his life, and also reflected the Hellenistic revival of the 1840s. Interest in Greek .mythology grew in *Les Stalactites* (1846; critical ed. by E. M. Souffrin, 1942) which. with its plastic imagery, was to make Banville a leader of the Parnassian school. *Les Exile's* (1867) deplored the passing of the Homeric gods. Technical problems were of paramount importance to Banville: according to his *Petit Traité de poésie française* (1872), the most important element in French verse is rhyme, which should preferably be double. This was criticized by Paul Verlaine who, nevertheless, learned much from Banville's experiment's with all sorts of metres, including the rhythms of folksong. Banville pleaded for a return to fixed forms, not merely to the sonnet, already rediscovered by Sainte-Beuve—Banville wrote a sonnet cycle, *Les Princesses,* in 1874—but to those forms practised by François Villon, Charles d'Orléans and Clément Marot which had been banned by the Pléiade, and used them in *Trente-six ballades joyeuses* (1873) and *Rondels* (1874).

Unlike Leconte de Lisle's, Banville's poetry is full of wit and gay fantasy, a feature which appealed to Stéphane Mallarmé and other Symbolists, like Jules Laforgue. Banville was fascinated by the characters of the *commedia dell'arte,* particularly Pierrot, and by acrobats and clowns, who inspired his famous poem, "Le Saut du Tremplin," and also the title of his collection *Odes funambulesques* (1857). In this work, the Parisian scene of the second empire, which Banville also drew in prose—in *Esquisses parisiennes* (1859), *Les Camées parisiens* (1866), etc.—furnished the subject matter for a new type of humorous verse in which comic effects were obtained .through rhyme. Banville aimed at poetic drama, but of his 16 plays only *Gringoire* (1866), a one-act historical play with two ballades, is still performed. He prepared the posthumous edition of the works of his friend Charles Baudelaire, whom he recalled in *Mes Souvenirs* (1882). He died in Paris on March 13, 1891.

BANYAN a species of fig *(Ficus benghalensis)* that assumes a remarkable form as a tree; in a spectacular fashion, aerial roots emanate from its branches, descend and take root in the soil to become new trunks. The banyan, native to tropical Asia, reaches

E. AUBERT DE LA RÜE

AERIAL ROOTS AND TRUNKS OF THE BANYAN TREE (FICUS BENGHALENSIS)

tremendous proportions: a height up to 100 ft. and an indefinite lateral spread by means of its aerial roots. One tree may in time assume the appearance of a very dense thicket as a result of the tangling of stems and trunks.

At the botanical gardens in Sibpur, near Calcutta, India, there is a banyan tree having a main trunk, 12 ft. in diameter, and 200 additional trunks. the whole encompassing an area 900 ft. in circumference. The tree is regarded as sacred in India. Originally the name mas bestowed by Europeans on a specific tree of this species on the Persian gulf; beneath the tree some Hindu merchants, or banians, had built a pagoda.

"Banyan" once was used as a term for all Hindus in western India. "Banyan days" was a term used to describe the two days in each week when meat was excluded from the men's rations in the Royal Navy, "banyan" being an allusion to the vegetarian diet of the Hindu merchants. *See* also FIG; MORACEAE.

BAOBAB, a tree. *Adansonia digitata* (family Bombacaceae), native of tropical Africa, remarkable for its barrellike trunk, which in some cases reaches 30 ft. in diameter, though the height is not great. It has a large gourdlike, moody fruit. containing a pleasant. cool-tasting mucilaginous pulp in which the seeds are buried. The bark yields a strong fibre used locally for ropes and cloth. The wood is light and soft, and the trunks of living trees are often excavated to form houses.

So queerly shaped is the baobab that an Arabian legend has it that "the devil plucked up the baobab, thrust its branches into the earth, and left its roots in air." It is grown as a curiosity in Florida and elsewhere in warm climes. A related species, *A. gregorii,* occurs in Australia, where it is called baobab or bottle tree (however, the latter name is more correctly applied to swollen-base trees of an entirely different family, Sterculiaceae). See also BOMBACACEAE; STERCULIACEAE.

THE AUSTRALIAN BAOBAB, OR BOTTLE TREE (ADANSONIA GREGORII)

BAPTISM, CHRISTIAN. Baptism, the initiatory rite of the Christian church, has been observed well-nigh universally by all who call themselves Christian. The meaning and effect of baptism, however, have been the subject of considerable controversy among Christians, especially since the 16th century.

Ceremonies and symbols of ritual washing have appeared in the religions of mankind at so many different times and in so many different places that some sort of baptism probably may be regarded as a universal element in the history of religions. In those religions that have no ceremonial washings as such, there are other rites with a parallel significance. From such sources as the Dead sea scrolls it is evident that at the time of Jesus Judaism was in possession of various baptismal rites, none of which, however, had replaced circumcision as the rite of initiation into the community. Christian contact with these rites came through the work of John the Baptist, who, according to the New Testament, not only heralded the coming of Jesus Christ, but baptized him as well. John apparently confined his baptizing to the Jordan river and made the rite an integral part of his call for repentance and for a break with the sinful past.

Early Church. — When the writers of the New Testament gave this description of the baptism of John, they were trying to distinguish it from their own baptismal practice. Although some critical scholars have been inclined to dispute the claim that Christian baptism was instituted by Jesus himself, such was the unanimous claim of the early church. There is no actual account of the institution of baptism, but the Gospel of Matthew portrays the risen Christ issuing the "Great Commission" to his followers: "Go therefore and make disciples of all nations, baptizing them in the name of the Father and of the Son and of the Holy Spirit, teaching them to observe all that I have commanded you." Other passages in the New Testament substantiate the impression that Jesus had instituted baptism earlier. Around this basic rite a wealth of imagery and meaning was centred, as the epistles of the New Testament, especially those of Paul, indicate. Baptism was likened to the deluge in the time of Noah—an analogy that achieved wide circulation among early Christian writers Paul's epistle to the Romans says that baptism grants a share in the death and resurrection of Christ. Through it men were to obtain the forgiveness of their sins. Like the baptism of John, Christian baptism required repentance; but unlike the baptism of John, it was associated with the gift of the Holy Spirit, as is especially evident from the Book of Acts. On the basis of these and similar declarations by the writers of the New Testament it may be concluded that in the Christian community of the 1st century baptism occupied a place of great importance and was regarded as essential to the new birth and to membership in the Kingdom of God. The Gospel of John claims the authority of Jesus Christ himself for this interpretation of baptism: "Unless one is born of water and the Spirit, he cannot enter the kingdom of God."

A study of the New Testament, supplemented by the testimony of archaeology and of tradition, provides some conception of the baptismal customs observed by the early church. It seems that the irreducible minimum for a valid baptism were the use of water and the Trinitarian invocation, although the conclusion has repeatedly been drawn from the Book of Acts that a baptism in the name of the Lord Jesus was current at some places during the 1st century. The candidate, after being instructed in the Christian faith, was required to prepare for the rite by prayer and fasting. He abjured the power of the devil and confessed his sins, and thereupon he was usually immersed three times; there are, however, references to baptism by pouring as well. Most of those baptized were undoubtedly converts from Greco-Roman paganism, and therefore adults. The earliest Christian literature makes no explicit reference to the custom of baptizing infants. Both the New Testament and the Church Fathers of the 2nd century make it clear that the gift of salvation belongs to children as well as to adults, and the apostle Paul draws a parallel between baptism and circumcision. On the basis of such evidence it has been argued that infant baptism was a custom that had come down from the apostles themselves, as Origen seems to have been the first to maintain. On the other hand, Tertullian seems to have been the first to object to infant baptism; this suggests that by the end of the 2nd century it was already a practice of the church, and indeed one over which there was no serious controversy,

What did produce controversy in the early church was the question whether baptism by heretics was valid and whether, consequently, those who came over to orthodox Christianity from the heretical groups were to be baptized a second time. During the 3rd century the north African church was enforcing such a requirement, and thus it provoked a controversy with the church of Rome, which argued for the objective validity of baptism even when it was administered by a heretical priest. The same question came up, though in a different form, two centuries later, in the controversy of St. Augustine against the Donatists (*q.v.*). The Catholic answer to the question, as formulated by St. Augustine, was that not the "who" but the "what" in baptism determined its validity. If, therefore, a heretic or even a pagan baptized according to the prescribed form and intended his act to be the baptism of the church, this would be a valid baptism — such is the position Roman Catholic, Orthodox, Anglican and Lutheran theologians have taken on the basis of these early controversies. St. Augustine likewise made use of baptism in his controversy with the Pelagians, arguing that baptism conferred supernatural grace upon those who received it, whether infants or adults, and that it thus expunged the stain of original sin from them. In these teachings Augustine summarized the doctrine of baptism that had developed during the first several centuries in the Christian west.

In the east the doctrinal development did not contradict these western emphases, but it did manifest emphases of its own. One of the favourite motifs of the Greek fathers was the idea that baptism prepared the Christian for the resurrection. Connected with this idea was the "seal of the Spirit," which was said to impart to the candidate a character that set him off from other men. Another favourite metaphor was the notion of "illumination" through baptism. In the eastern churches baptism is accompanied by confirmation (*q.v.*); thereafter the candidate received Holy Communion even as an infant. The baptismal formula of some eastern churches was (and still is): "This servant of Christ is baptized in the name of the Father and of the Son and of the Holy Spirit," instead of the "I baptize you, etc." employed in the west. Despite some theological conflict over the propriety of the eastern formula, the western church finally approved it; it also took over into its piety and its theology many of the emphases that characterized the baptismal thought of the Greek Christians. The so-called Nicene creed spoke for all of Christendom when it declared: "We acknowledge one baptism for the remission of sins." (See CREED.)

Middle Ages. — Drawing upon both the biblical and the traditional themes of baptismal theology, medieval scholasticism gave to this doctrine a precision it had not always had in the earlier writers of the church. This precision was accomplished by at least two means. First, scholasticism refined the terminology of theology with the aid of philosophy, and thus it was able to relate the various themes of the tradition to one another by the use of Aristotelian distinctions such as form and matter, principal and

instrumental cause, etc. Second, scholasticism incorporated its teaching about baptism into a comprehensive sacramental system, in which the doctrine of baptism both contributed to and received from the church's definition of what constituted a sacrament. The careful and lucid presentation of the doctrine of baptism near the end of St. Thomas Aquinas' *Summa Theologica* took advantage of both these means to put the doctrine into the form which, except for relatively minor points of clarification, it still possesses in Roman Catholic theology. Baptism is a means of grace in which, through the use of water and of the divinely instituted formula,' the neophyte is admitted to membership in the visible church; sin, both original and actual, is forgiven, an indelible character is implanted, and the gift of the Holy Spirit is conferred. This is, in summary, the baptismal doctrine of both Roman Catholicism and Eastern Orthodoxy.

Reformation and After.— This doctrine of baptism was not a primary target of Reformation criticism. Here as elsewhere, most of the Anglican reformers took a position that manifested considerable continuity with the medieval teaching. Baptism was regarded as a means of grace, and it worked both regeneration and forgiveness, even in infants. Luther taught that baptism granted forgiveness of sins, life and salvation. Calvin also acknowledged that baptism effected regeneration, but only in the predestined; in general, there was less room in Calvin's system than there was in Luther's for a doctrine of the means of grace. Zwingli took a more extreme position than either Calvin or Luther in his stand against Roman Catholic sacramentalism. The logical outcome of Zwingli's position was to question not only the sacramental definition of baptism, but the very necessity of baptism at all.

This logical outcome was not drawn by the reformers. But another group of reformers alongside the "magisterial" leaders at Wittenberg, Zurich and Geneva introduced a radically new outlook into the doctrine and practice of baptism. These were the Anabaptists (*q.v.*). The hostility of the Anabaptists to the union of church and state caused them to look for a pure church, into which one would come, not automatically by birth and infant baptism, but consciously by the decision of faith. This view of the church and of the individual represented a fundamental break with the baptismal tradition sketched above. Instead of infant baptism the Anabaptists insisted upon believers' baptism, *i.e.,* a baptism that followed faith and was not thought to create faith. Although the lines of descent from Anabaptism to more recent Protestant denominations are not easy to draw, this insistence did set the pattern for several denominations to formulate doctrines of baptism that differed from the medieval doctrine much more sharply than the teachings of the reformers had. Because they hold that the church is composed of true believers who have made personal confession of their faith, these denominations, among whom the Baptists and the Disciples of Christ are the most prominent, argue that the decision of faith may be neither anticipated nor taken away from the child by its parents and the church. Therefore baptism must be postponed until such a time as the child becomes capable of making this decision personally. This shift in baptismal teaching was of a piece with the more general revision of traditional sacramentalism by Protestant theology.

For further information about the baptismal practices and teachings of the various Protestant denominations *see* the appropriate sections of main articles such as BAPTISTS; DISCIPLES OF CHRIST; etc. Despite the confusion which a study of this material may suggest, most Christians are agreed as to the necessity of baptism; they are not agreed as to why baptism is necessary. *See* also references under "Baptism" in the Index volume.

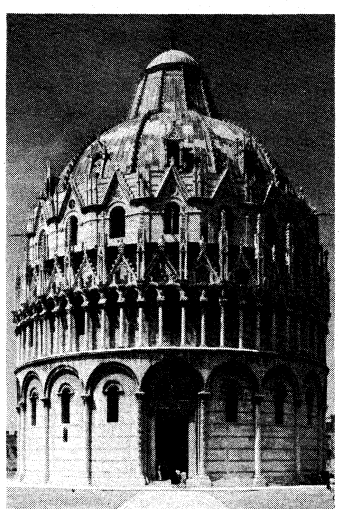
BAPTISTE (BAPTISTE AÎNÉ; stage name of NICOLAS ANSELME) (1761–1835), French actor, was born in Bordeaux on June 18, 1761. After two provincial engagements he went to Paris in 1791. His first success came when he played the principal part in *Robert, chef de brigands* (1792 at the Théâtre du Marais). In 1793 he joined the Théâtre de la Republique and in 1799 the Comédie Française, from which he retired in 1823. In tragedy Baptiste was not successful. Among his comedy parts the title role of Destouches' *Le Glorieux* remained his greatest achievement. The Parisians of the Napoleonic era, however, associated Baptiste primarily with the *pères nobles* for which Beaumarchais in his *Eugénie* and Diderot in his *Père de famille* had set up the more or less lachrymose pattern. Baptiste *aîné* died in Les Batignolles near Paris on Dec. 1 (or Nov. 30), 1835. He was survived by a younger brother, PAUL EUSTACHE ANSELME, called Baptiste *cadet* (1765–1839), who had made a name for himself as a comedian. (A. M. N.)

BAPTISTERY, the hall or chapel connected with a church, in which the sacrament of baptism is administered. Baptisteries were among the most symbolic of all Christian architectural forms. Originally they were small rectangular chambers with an apse containing the font (*q.v.;* the receptacle for the water used in baptism) at one end. From the 4th century they were customarily roofed with a dome, the symbol of death to sin and of that heavenly realm toward which baptism is the first step (*see* DOME). The baptistery was commonly octagonal in plan, eight being that number which marks a new beginning (following the "complete" number, seven) as the sacrament of baptism marks the beginning of the Christian life. Similarly fonts were usually octagonal and set beneath a domical ciborium or canopy. These were characteristics of what is probably the earliest baptistery extant, that of the Lateran palace in Rome (dating largely from the time of Constantine), and with a few exceptions (notably in Syria) remained constant thereafter.

INSTITUTO INTERNAZIONALE DI STUDI LIGURI

INTERIOR OF OCTAGONAL BAPTISTERY AT ALBENGA, ITALY: 5TH-CENTURY EARLY CHRISTIAN

Up to the 11th century. baptisteries were commonly separate buildings, often large and richly decorated. but they were gradually reduced to the status of small chapels inside churches, or omitted entirely. In most modern churches, the font alone serves for baptism; something of earlier symbolism survives, however. in its location near the church door, in allusion to entering the Christian life. Doctrinal emphasis on immersion results in prominent baptisteries located usually behind the chancel (*e.g.,* modern Baptist churches). (AN. G.)



G E KIDDER SMITH

EXTERIOR OF THE BAPTISTERY (1153–1278) AT PISA, ITALY: DESIGNED BY DIOTISALVI

BAPTISTS are members of a religious denomination that originated within English Puritanism in the 17th century as an offshoot of Congregationalism (*q.v.*). The name was derived from the denomination's insistence that baptism be administered only to adult believers. In the earlv 1960s there were more than 23.-000.000 Baptists throughout the world, the vast majority concentrated in the United States where they constitute the largest Protestant community. There are 27 Baptist bodies in the United States with an inclusive total of slightly more than 20,500,000 members. Of these 90% are in-

cluded in four major conventions: the Southern Baptist convention with more than 9.000.000 members; the National Baptist convention, U.S.A., Inc., with 5,000,000 members; the National Baptist Convention of America with over 2,500,000 members; and the American Baptist convention with over 1,500.000 members. The multiplicity of Baptist groups in the United States is accounted for by the 19th century controversy over slavery; by racial and nationality differences: and by divergence of opinion on questions of doctrine and organization.

Outside the United States, major Baptist communities are to be found in the British Isles (325.000 members), the U.S.S.R. (500,000), India (400,000), Burma (180,000), Congo (135,000), Brazil (134,000) and Canada (170,000).

HISTORY

Origins. — There were two major currents in early Baptist life: the Particular Baptists adhered to the doctrine of a particular atonement and mere strongly Calvinist in orientation; the General Baptists held to the doctrine of a general atonement and represented the more moderate Calvinism of Jacobus Arminius *(see* ARMINIANISM).

The two currents also were distinguished by a difference in churchmanship, which was related to their respective points of origin. The General Baptists emerged from among the English Separatists, whereas the Particular Baptists had their roots in non-Separatist independency. Both the Separatists and the non-Separatists were congregationalist. They shared the same convictions with regard to the nature and government of the church. They believed that church life should be ordered according to the pattern of the New Testament churches, and to them this meant that churches should be self-governing bodies composed of believers only.

The point at which they differed was with regard to their attitude toward the Church of England. The Separatists took what is commonly described as a sectarian position; they contended that the Church of England was a false church and insisted that the break with it must be complete and uncompromising. The non-Separatists, more ecumenical in spirit, sought to maintain some bond of unity among Christians. While they believed that it was necessary to separate themselves from the corruption of parish churches: they also believed that it would be a breach of Christian charity to refuse all forms of intercourse and fellowship with them. While the parish churches were sufficiently disfigured. when viewed from the perspective of the New Testament model. to cause many of the non-Separatists to withdraw and to establish a purer worship of their own. the non-Separatists would not go so far as to assert that the parish churches were utterly devoid of the marks of a true church.

Most scholars find no evidence of decisive influence having been exerted upon the English Baptists by the continental Anabaptists, but they acknowledge that the General Baptist wing of the English Baptists exhibits Anabaptist influence at several minor points.

Growth in England and **Abroad.**—Although the Particular Baptists were to represent the major continuing Baptist tradition, the General Baptists were first in the field. In 1608 religious persecution had induced a group of Lincolnshire Separatists to seek asylum in Holland. One contingent settled in Amsterdam with John Smith (or Smyth), a Cambridge graduate, as minister; the other contingent moved on to Leyden under the leadership of John Robinson. The group at Amsterdam soon was debating the meaning of church membership, and the question of baptism arose. Smyth came to the conclusion that, if the Separatist contention that "the churches of the apostolic constitution consisted of saints only" was correct, baptism should be restricted to believers only. This, he contended, was the practice of the New Testament churches, for he could find no scriptural support for the baptizing of infants. Smyth published his views in *The Character of the Beast* (1609), and in the same year proceeded to translate them into action by baptizing first himself and then 36 others who joined him in forming a Baptist church. Shortly thereafter. Smyth became aware of the existence of a Mennonite (Anabaptist) community in Amsterdam, and he began to question his procedure in baptizing himself. Such an act could be justified, he concluded. only if no true church existed from which a valid baptism could be obtained. After some investigation. Smyth arrived at the conviction that the Mennonites did constitute a true church and he recommended union with them. This was resisted by Thomas Helwys and other members of the group, who returned to England in 1611 or 1612 and established a Baptist church in London. The parent group in Amsterdam soon disappeared.

The Particular Baptists stemmed from a non-Separatist church that was established in 1616 by Henry Jacob at Southwark across the Thames from London. In 1638 a number of its members withdrew under the leadership of John Spilsbury to form the first Particular Baptist church.

The two decades from 1640 to 1660 constituted the great period of early Baptist growth, for the Baptist preachers found their great opportunity to win adherents around the campfires of Oliver Cromwell's army. The greatest gains were made by the Particular Baptists. the General Baptists suffering numerous defections to the Quakers. After the Restoration of the Stuarts in 1660. both groups were subjected to severe disabilities, being forced to go underground until the Act of Toleration of 1689 granted them a measure of relief.

During the following decades, the vitality of the General Baptists mas drained away by the inroads of skepticism. and their churches generally dwindled and died or became Unitarian. The Particular Baptists took an opposite course. retreating into a defensive, rigid hyper-Calvinism that prevented any effective evangelism. Among the Particular Baptists in England, renewal came as a result of the influence of the Evangelical Revival, the new surge of growth being initiated by the activity of Andrew Fuller, Robert Hall and William Carey. The latter formed the English Baptist Missionary society in 1792—the beginning of the modern foreign missionary movement in the English-speaking world—and became its first missionary to India. A New Connection General Baptist group, Wesleyan in theology. was formed in 1770; and a century later: in 1891, it united with the Particular Baptists to form the Baptist Union of Great Britain and Ireland.

By this time! Baptists, together with the other Nonconformist churches, were reaching the peak of their influence in Great Britain, numbering among their preachers several men, such as C. H. Spurgeon, Alexander Maclaren and John Clifford, with international reputations. Baptist influence was closely tied to the fortunes of the Liberal party. of which the Baptist David Lloyd George was a conspicuous leader. After World War I English Baptists began to decline both in influence and numbers.

Baptist churches were first established in Australia (1831) and New Zealand (1854) by missionaries of the English Baptist Missionary society. In Canada, Baptist beginnings date from the activity of Ebenezer Moulton, a Baptist immigrant from Massachusetts, who organized a church in Nova Scotia in 1763; Baptist work there was nurtured by the Philadelphia Baptist association as it was in the other 13 Atlantic seaboard colonies (see below). In Ontario, the earliest Baptist churches were formed by United Empire Loyalists who crossed the border following the American Revolution, while other churches were established by immigrant Baptists from Scotland and by missionaries from Vermont and New Tork. The Baptists of Canada are united in the Baptist Federation of Canada.

Development in the United States. — Baptist churches in the English colonies of North America were largely indigenous in origin, being the product of the leftward movement that was occurring among the colonial Puritans contemporaneously with that in England. While some migrated to the new world as Baptists, more typical was adoption of Baptist views after arrival in the colonies, as represented by Henry Dunster, the first president of Harvard, and Roger Williams.

Colonial Period. — The first Baptist church in the American colonies was established by Roger Williams (*q.v.*) at Providence in 1639, shortly after his banishment from the Massachusetts Bay colony. While Williams' general Calvinist theological position was roughly analogous to that of Spilsbury, prior to becoming a Baptist, he had adopted the narrower Separatist view of the

church. Williams soon came to the conclusion that all existing churches: including that newly established at Providence. lacked a proper foundation, and that this defect could be remedied only by a new apostolic dispensation in which new apostles. divinely commissioned, would appear to re-establish the true church.

The defection of Williams left the church with no strong leadership, and this made it possible for it to be reorganized on a General Baptist platform in 1652. There was scattered General Baptist activity throughout the colonies, but the only real cluster of General Baptists was in Rhode Island, where the churches formed themselves into an association or yearly meeting in 1670. The early General Baptists never gained great strength. Most of their churches decayed, and some, including the Providence church, were reorganized as Particular Baptist churches. The half-dozen churches that survived never entered the main stream of American Baptist life, and they exerted no real influence upon its development.

The earliest strong Particular Baptist centre in the colonies was at Newport, R.I.. where. between 1641 and 1648, the church that had been gathered by John Clarke adopted Baptist views. Except for a church that had a brief existence at Kittery, Me., there were only two other Particular Baptist churches in New England for the better part of a century. One of these was at Swansea, Mass.! where a church was formed by a group of Welsh immigrants under the leadership of John Myles; the other mas organized at Boston in 1665. Another Particular Baptist church was established at Charleston, S.C., in 1683 or 1684.

The great centre of Particular Baptist activity in early America was in the Middle Colonies. In 1707 five churches in New Jersey? Pennsylvania and Delaware united to form the Philadelphia Baptist association: and through the association they embarked upon vigorous missionary activity. By 1760 the Philadelphia association embraced churches located in the present states of Connecticut, New York, New Jersey, Pennsylvania. Delaware, Virginia and West Virginia; and by 1767 further multiplication of churches had necessitated the formation of two subsidiary associations, the Warren in New England and the Ketochton in Virginia. The Philadelphia association also provided leadership in organizing the Charleston association in the Carolinas in 1751. and this in turn fostered the formation of the Kehukee association in North Carolina in 1765.

While this intercolonial' Particular Baptist body provided leadership for the growth that characterized American Baptist life during the decades immediately preceding the American Revolution. that growth was largely a product of the Great Awakening. Baptists participated directly in the awakening only during its last phase in the south, but they attracted large numbers of recruits from among those who had been "awakened" by the preaching of others. In addition to strengthening and multiplying the "regular" Baptist churches, the awakening in New England produced a group of revivalistic Baptists, known as Separate Baptists. who soon coalesced with the older New England Baptist churches. In the south, however, they maintained a separate existence for a longer period of time. Shubael Stearns, a New England Separate Baptist, migrated to Sandy Creek: N.C. in 1755 and initiated a widespread revival that quickly penetrated the entire Piedmont region. The churches he organized were brought together in 1758 to form the Sandy Creek association. Doctrinally these churches did not differ from the older "regular" Baptist churches, but their emotional excesses and ecclesiastical irregularities created considerable tension with the older churches. By 1787, however, a reconciliation was effected.

In several of the colonies, Baptists laboured under legal disabilities of varying severity. The public whipping of Obadiah Holmes in 1651 for refusing to pay a fine imposed for holding an unlawful meeting in Lynn, Mass., caused John Clarke to write his *Ill* News *From* New England (1652). Fourteen years later Baptists of Boston were fined, imprisoned and denied the use of a meeting-house they had erected. Payment of taxes for support of the established church was a cause of continuing controversy in New England, while the necessity to secure licences to preach became an inflammatory issue in Virginia.

19th Century.—The problem of travel had made it difficult for the Philadelphia association to serve as a bond uniting Baptists, and the rapid multiplication of churches made it impossible. It has been estimated that immediately before the American Revolution there were 494 Baptists congregations; 20 years later, in 1795, Isaac Backus estimated the number at 1,152. The initial expedient of the Philadelphia association had been to organize subsidiary associations: but during the war the churches, left to their own devices, proceeded to organize independent associations. By 1800 there were at least 48 local associations, and the great problem was to fashion a national body to unite the churches. The final impetus in this direction came from an interest in foreign missions. Adoniram Judson and Luther Rice had been sent to India as the first missionaries of the newly organized Congregational mission board. On shipboard they became convinced by a study of the Scriptures that only believers should be baptized. Upon arrival at Calcutta, Judson went on to Burma while Rice returned home to enlist support for him among American Baptists. As a result of Rice's efforts, a General Convention of the Baptist denomination was formed in 1814. Its scope was almost immediately broadened to include, in addition to the foreign mission interest: a concern for home missions: education and the publication of religious periodicals. In 1826 the General convention once again was restricted to foreign mission activities, and in the course of time it became known as the American Baptist Foreign Mission society. Other denominational interests were served by the formation of addiiional societies with similar specialized concerns. such as the American Baptist Home Mission society and the American Baptist Publication society.

The unity that was achieved through these societies was partially disrupted as a result of the slavery controversy. During the decade prior to 1845 various compromises between the pro-slavery and antislavery parties in the denomination were attempted, but they proved to be unsatisfactory. As a result the Southern Baptist convention was organized at Augusta, Ga., in 1845. Although its constitution provided for boards of home and foreign missions, education and publication, its energies were devoted largely to foreign missions. Consequently the American Baptist Home Mission society and the American Baptist Publication society continued to operate in the south after the Civil War and enjoyed a large measure of support from the churches. Toward the close of the 19th century, however, the Southern Baptist convention began to develop its own home mission and publication work and to protest the intrusion of the older societies in the south. The final separation between Baptists of south and north was formalized in 1907 by the organization of the Northern Baptist convention (after 1950, called the American Baptist convention), which brought together the older societies and accepted a regional allocation of territory between the northern and southern conventions.

Negro Churches.—Negro churches constitute an important segment of American Baptist life. Following the Emancipation Proclamation and the close of the Civil War, Negro Baptists began to organize their own churches. A state convention of Negro Baptist churches was formed in 1866 in North Carolina, and in 1880 the National Baptist Convention of America was organized. A dispute over the control of property and publications led to a division in 1916. The smaller of the two factions retained the original name; while the larger body adopted the name the National Baptist Convention; U.S.A., Inc.

Education.—From the beginning, American Baptists displayed an interest in an educated ministry, and their interest in higher education increased steadily as they grew in numbers. The Philadelphia association in the 18th century collected funds to help finance the education of ministerial candidates. Hopewell academy was established in 1756, and in 1765 Brown university was founded midway between Nova Scotia and Georgia, in Rhode Island. Eight other institutions were established before 1825; 25 more were established between 1825 and 1850.39 between 1851 and 1875: and 70 between 1876 and 1900. The educational advance culminated in 1891 in the founding of The University of Chicago, which was intended to be a great national Baptist super-

university that would tie together the smaller Baptist colleges.

In the north, regional education societies were the usual channels through which support was given to education, while in the south the institutions more often were sponsored directly by state conventions or the Southern Baptist convention. After the Civil War, the American Baptist Home Mission society established a number of Negro Baptist colleges in the south, which came to be administered by Negro boards of trustees with the co-operation of the American Baptist Home Mission society and the board of education and publication of the American Baptist convention.

20th Century.—After 1900 Baptists were troubled by theological controversy that led to the formation of several new Baptist groups. Some of the tensions arose over questions of polity; some arose over refusals to adopt an authoritative creedal statement; some were the product of dissatisfaction with the affiliation of the American Baptist convention with interdenominational and ecumenical bodies. Questions of polity were involved in the formation of the American Baptist association in 1905 by churches located primarily in Oklahoma, Texas and Arkansas. Two other groups were products of the "fundamentalist" controversy: the General Association of Regular Baptist Churches. organized in 1932; and the Conservative Baptist association (1947).

A phenomenon of the post-World War II period was the abandonment by the Southern Baptist convention of its regional limitations. Because of increasing mobility of population, the Southern Baptist convention felt it necessary to follow its members to the growing urban centres of the north and west; by the second half of the century Southern Baptist churches were to be found in almost every part of the United States.

Growth Outside the U.S.—While Baptists have been troubled by divisive tendencies during the 20th century, a parallel tendency has been toward greater unity and cohesiveness through the Baptist World alliance. The 19th century was the great period of Baptist missionary endeavour. Penetration of Asia was led by William Carey in India, Adoniram Judson in Burma and Timothy Richard in China, and by the late 1950s there was a Baptist community of about 750,000 adherents in 17 Asian countries. The first Baptist activity in Africa was initiated in 1819 by Negro Baptists of Richmond, Va., and the total communicant membership in the late 1950s was 300,000. Of later origin is the Baptist community of 275,000 in Latin America.

The pioneer Baptist on the continent of Europe was John Gerhardt Oncken, who organized a church at Hamburg in 1834. Oncken had become acquainted with Barnas Sears of Colgate Theological seminary, who was studying in Germany, and with six others he was baptized by Sears. From this centre evangelistic activity was extended throughout Germany and missions were established in Austria, Hungary, Rumania, Bulgaria, Switzerland, Belgium, Holland. Denmark. Poland and Russia. Baptist activity was initiated independently in France, Italy and Spain. Swedish Baptist beginnings date from the conversion of Gustaf W. Schroeder, a sailor baptized in New York in 1844. and Frederick O. Nilsson, also a sailor, who was baptized by Oncken in 1847. From Sweden Baptists penetrated Norway and Finland. Excluding the British Isles. there were over 800,000 European Baptists in 1958.

It was this expansion of the Baptist community in Asia, Africa, Latin America and Europe that led to the formation of the Baptist World alliance at London in 1905. The purpose of the alliance is to provide mutual encouragement, exchange of information, coordination of activities and consciousness of the larger Baptist fellowship. Periodic world congresses are held, and a headquarters secretariat is maintained in Washington and London.

The most notable growth occurred in Russia, where a Russian Baptist union was formed in 1884 as a result of influences stemming from Oncken. Another Baptist body, the Union of Evangelical Christians, was organized in 1908 by a Russian who had come under the influence of English Baptists. Persecution of Baptists, which had been severe, was relaxed in 1905, and within the remaining disabilities a moderate growth occurred. The Revolution of 1917, with its proclamation of liberty of conscience, ushered in a period of astonishing advance: by 1927 the Russian Baptist union numbered some 500,000 adherents, while the Union of Evangelical Christians embraced more than 4,000,000. The Soviet constitution of 1929 subjected them to pressure once again, however, and in 1958 the two groups, which had combined in 1944 to form the All-Union Council of Evangelical Christians-Baptists, reported 518,973 baptized believers.

POLITY, WORSHIP AND DOCTRINE

Polity.—Baptists insist that the fundamental authority, under Christ, in church life is vested in the local congregation of believers, which admits and excludes members, calls and ordains pastors and orders its common life in accord with what it understands to be the mind of Christ. These congregations, which are manifestations of the whole Church of Christ, are linked together in co-operative bodies to which they send their delegates or messengers—regional associations, state conventions and national conventions. These larger bodies, it is insisted, have no control or authority over a local church; they exist to implement the common concerns—missionary, educational, philanthropic—of the local churches.

The pattern of organization of the local church has been undergoing change during the 20th century. Traditionally the pastor was the leader and moderator of the congregation; more recently there has been a tendency to regard him as the employed agent of the congregation and to elect a lay moderator to act in his stead at corporate meetings of the church. Traditionally the deacon's functions were to assist the pastor and to serve as agents to execute the will of the congregation in matters both temporal and spiritual; more recently there has been a tendency to multiply the number of church officers by the creation of boards of trustees, boards of education, boards of missions and boards of evangelism. Traditionally decisions were made by the congregation in a church meeting; more recently church meetings have become less and less frequent and there has been a tendency to delegate decision-making to various boards. The relationship of local churches to the co-operative bodies has been undergoing similar change, and this has occasioned continuing discussion among all Baptist groups.

Worship.—Baptist worship is hardly distinguishable from the worship of the old Puritan denominations of England and the United States. It centres largely around the exposition of the Scriptures in the sermon, and the emphasis is upon extemporaneous rather than set prayers. Apart from the centrality of the sermon, hymn singing is one of the most characteristic features of worship. Communion, received in the pews, is customarily a monthly observance. Baptism is by immersion.

Doctrine.—Initially Baptists were characterized theologically by strong to moderate Calvinism. The dominant continuing tradition in both England and the United States was Particular Baptist, whose confessions of faith—the London (1658) and the Philadelphia (1742)—were slightly altered transcriptions of the *Westminster* Confession of Faith (1648), with a hyper-Calvinist triple covenant being substituted for the double covenant of the Westminster confession. By 1800 this older tradition was beginning to be replaced by the evangelical doctrines fashioned by the leaders of the evangelical revival in England and the Great Awakening in America and further elaborated by subsequent New England divines and frontier revivalists. By 1900 the older Calvinism had almost completely disappeared, and Evangelicalism was dominant. The irenic tendency of Evangelicalism and its almost complete preoccupation with heart-religion and the conversion experience largely denuded it of any solid theological structure, however, and this opened the door to a new theological current, which in its later phases became known as Modernism. Modernism, which was an attempt to adjust the Christian faith to the new intellectual climate, made large inroads among the Baptists of England and the United States during the first two decades of the 20th century, and Baptists provided many outstanding leaders of the movement. William Newton Clarke, Shailer Mathews, George Burman Foster and Harry Emerson Fosdick were among conspicuous exponents of the new views. To many these views seemed to pose a threat to the uniqueness of the Christian revelation, and they precipitated a counterreaction that became known as Fundamentalism (*q.v.*).

As a result of the controversy that followed, many Baptists

developed a distaste for theology and became content to find their unity as Baptists in promoting denominational enterprises. By 1950 both Modernists and Fundamentalists were becoming disenchanted with the positions into which they had been forced in the heat of controversy, and it was from among adherents of both camps that a more creative theological encounter began to take place. While the majority of Baptists remained nontheological in their interests and concerns; there were multiplying signs that Baptist leadership was increasingly recognizing the necessity for renewed theological inquiry.

Distinctive Aspects.—The unity and coherence of the Baptists is to be found in six distinguishing. although not necessarily distinctive, convictions they hold in common.

1. The supreme authority of the Bible in all matters of faith and practice. Baptists are a noncreedal people, and their ultimate appeal always has been to the Scriptures rather than to any confession of faith which they may have published from time to time to make known their commonly accepted views.

2. Believer's baptism. 'This is the most conspicuous conviction of Baptists. They hold that if baptism is the badge or mark of a Christian and if a Christian is one in whom faith has been awakened, then baptism rightly administered must be a baptism of believers only. Furthermore. if the Christian life is a sharing in the life, death and resurrection of Christ, if it involves a dying to the old life and a rising in newness of life, then the act of baptism must speak in these terms. The sign must be consonant with that which it signifies. It is for this latter reason that Baptists were led to insist upon immersion as the apostolic form of the rite, in addition to their initial insistence upon the baptism of believers only.

3. Churches composed of believers only. Baptists reject the idea of a territorial or parish church and insist that a church is composed only of those who have been gathered by Christ and who have placed their trust in him. Thus the membership of a church is restricted to those who—in terms of a charitable judgment—give clear evidence of their Christian faith and experience. The basis of their church life is a church covenant wherein they covenant with God and one another to walk together in Christian obedience.

4. Equality of all Christians in the life of the church. By the doctrine of the priesthood of all believers, Baptists not only understand that the individual Christian may serve as a minister to his fellows, but they believe that it also confers upon each member of a church equal rights and privileges in determination of the affairs of the church. The church officers—pastor and deacons—have special responsibilities, derived from the consent of the church, which only they can discharge, but they do not have unique sacerdotal status.

5. Independence of the local church. By this principle Baptists affirm that a properly constituted congregation is fully equipped to minister Christ and need not derive its authority from any source. other than Christ. outside its own life. Baptists, however, have not generally understood that a local church is autonomous in the sense that it is isolated and detached from other churches. The local church is but one manifestation of the Catholic Church, and as individual Christians are bound to pray for one another and to maintain communion with one another: so particular churches are under like obligation. Thus the individual churches testify to their unity in Christ by forming associations and conventions through which they can seek counsel and advice and cooperate in common concerns.

6. Separation of church and state. From the time of Smyth. Baptists have insisted that a church must be free to be Christ's church, determining its own life and charting its own course in obedience to Christ without outside interference. It was for this reason that Smyth asserted that the "magistrate is not by virtue of his office to meddle with religion or matters of conscience. to force and compel men to this or that form of religion or doctrine, but to leave Christian religion free to every man's conscience." Baptists were in the forefront of the struggle for religious freedom in both England and America; they cherish the liberty that was established in early Rhode Island: and they played an important role in securing the adoption of the "no religious test" clause in the federal constitution as well as the guarantees embodied in the first amendment.

Few Baptists have been willing to become sectarian by denying the Christian name to other denominations. With the exception of the Southern Baptists, the vast majority of Baptists co-operate fully in interdenominational and ecumenical bodies, including the World Council of Churches.

BA'QUBAH, a market town and capital of the Diyala *liwa* (province). Iraq, lies near the left bank of the Diyala river 34 mi. N.N.E. of Baghdad. Pop. (1957) 18.517. Its chief importance arises from control of rail and road crossings of the Diyala by main direct routes between Baghdad and central Iran. It also has some importance as a market for the agricultural produce of an extensive irrigated area, grain, dates, oranges and vegetables being the chief items of trade. It has frequently been occupied in the past by the Persians. and received large numbers of Assyrian refugees during World War I. (W. B. FR.)

BAR, COUNTS AND DUKES OF, the holders of extensive domains on the old frontier between Champagne and Lorraine. the nucleus of which was the town eventually known as Bar-le-Duc (*q.v.*) in the modern French *département* of Meuse. In A.D. 951 the emperor Otto I gave the countship of the Barrois (*i.e.*, the district of Bar), then a fief of the duchy of Lorraine (*q.v.*), to Frederick of Ardenne, who in 959 was made duke of Upper Lorraine. In 1033. on the death of Duke Frederick II, it passed to his younger daughter Sophia, who married Louis, count of Mousson. Ferrette and Montbéliard. On the death of their son Thierry (Dietrich) II. his estates were divided between his sons, and the third. Renaud (Raynald), received the Barrois and founded the house of Bar. The counts of Bar increased their demesne and soon became the most powerful vassals of the dukes of Lorraine. with whom they carried on endless struggles. They usually fought in the French ranks, while the dukes adhered to the German. Henry II was an ally of Philip Augustus and distinguished himself at the battle of Bouvines. The annexation of Champagne to France, however: made them neighbours of the French king. with whom Thibaut II got into difficulties. His son Henry III made an alliance against France with Edward I of England and the German king Adolf of Nassau, but. abandoned by his allies, was defeated at Louppy-le-Château (1296) and, under the treaty of Bruges (1301). did homage to Philip IV for that part of the Barrois west of the Meuse which was claimed as being in the *mouvance* or feudal dependency of France and which from then on was called the Barrois mouvant. In 1354 Robert of Bar, who had married the daughter of John II of France. n-as made marquis of Pont-à-Mousson by the emperor Charles IT and took the title of duke of Bar. In the 14th century the Barrois fell under French influence. Edward III of Bar was killed. with his brother and his nephew, at Agincourt in 1415 and so was succeeded as duke by his other brother. Louis, bishop of Châlons and a cardinal. Louis in 1419 chose as his heir René (*q.v.*) of Xnjou. his sister Yolande's grandson. who in 1420 married Isabella, daughter and heiress of Charles II, duke of Lorraine, so that on Charles's death in 1431 the Barrois and Lorraine were united. Though he gave up the duchy of Lorraine to his son John of Calabria in 1453, René retained the Barrois till his death in 1480. By his will (1474) he had left it to his grandson René II, duke of Lorraine since 1473. Meanwhile, Louis XI of France had ordered the occupation of the Barrois mouvant, but aiter Louis XI's death it was recovered by René. From then on. the Barrois shared the fate of Lorraine. being annexed to the French crown on the death of Stanislaw Leszczynski (the former king of Poland, to whom it had been granted in 1738) in 1766.

BAR, FRANÇOIS DE (1538–1606), French scholar, born at Jézencourt, near St. Quentin, became prior of the Benedictine abbey of Anchin, near Pecquencourt, on March 22, 1576. He spent much of his time in the valuable library of the abbey studying and compiling ecclesiastical law, and also wrote treatises on geography, cosmography and canon law. Bar made a catalogue of the manuscripts at Anchin and annotated many of them. He died at Anchin on March 25, 1606. During the French Revolution his manuscripts were removed to the library at Douai.

BAR, in physical geography, a ridge of sand or silt deposited on the bed of a stream, sea or lake. When a river enters a tidal sea its rate of flow is reduced, and the material it carries in suspension is deposited in a shifting bar lying athwart the channel. Where the channel is only partly closed and the bar is attached to the land on one side, the feature is called a spit. A bar may also be produced by tidal action alone in an estuary or narrow gulf (as at Port Adelaide) where the tides sweep the loose sand backward and forward, depositing it where the motion of the water is checked. In lakes and other bodies of water bars are produced where the rate of flow of shore currents carrying material in suspension is reduced. *See* also WAVES AND SHORE CURRENTS.

BAR, CONFEDERATION OF, a league of the Polish nobles and gentry formed at the little fortress of Bar in Podolia in 1768 to defend by insurrection the privileges of the Catholic Church and the independence of Poland against the encroachments which the Russian government was making through its ambassador in Warsaw, Prince Nikolai Vasilievich Repnin (*q.v.*). The originators of this confederation were Adam Krasinski, bishop of Kamieniec, Jozef Pulaski and Michal Krasinski. The king of Poland, Stanislaw II Poniatowski. was at first inclined to mediate between the confederates and Russia. Finding this impossible he sent a force against them under Gen. Ksawery Branicki, who captured Bar. The simultaneous outbreak of a *jacquerie* in the Ukraine checked the extension of the confederation throughout the southeastern provinces of Poland. The confederates thereupon appealed for foreign help and contributed to bringing about the Russo-Turkish War of 1768–74. So serious indeed was the situation that Frederick II of Prussia advised the Russian empress Catherine to come to terms with the confederates.

The confederates' troops under Ignacy Malczewski, Prince Karol Radziwill and, most important, Kazimierz Pulaski (*q.v.*), who later distinguished himself in the American War of Independence, ravaged the land in every direction, engaged in several battles and at last, utterly ignoring the king, sent envoys on their own account to the principal European powers.

In 1770 the council of the confederation was transferred from its seat at Teschen (Cieszyn), in Austrian Silesia, to Presov in Slovakia whence it conducted diplomatic negotiations with France, Austria and Turkey with the view of forming a league against Russia. The French court sent C. F. Dumouriez to act as military instructor of the confederates. It was he who induced them to proclaim, on Oct. 22, 1770, the deposition of King Stanislaw II as tyrant and traitor—at the very moment when he was about to accede to the confederation. The king thereupon reverted to the Russian faction and the confederation lost the confidence of Europe. Nevertheless, its army. thoroughly reorganized by Dumouriez, gallantly maintained the hopeless struggle for several years, and it was not until 1772 that the last traces of it disappeared.

BAR, THE: *see* LEGAL PROFESSION.

BARABANKI, a town and district in the Fyzabad division of Uttar Pradesh, India. The town, 17 mi. E.N.E. of Lucknow, is contiguous with Nawabganj, with which it forms the municipality of Barabanki (Nawabganj). Pop. (1951) town 28,958. The district courts and "civil lines" (administrative quarter) are in Barabanki, the main market and educational institutions in Nawabganj. The town is on the hard-surfaced road from Lucknow to Fyzabad, and on the Fyzabad loop of the Northern railway. It is also an important junction for the Northeastern railway metre-gauge system serving the districts along the Nepal frontier. Barabanki is a major centre of the handloom industry and trades in sugar and cotton. About one-fifth of the town's population depends on agriculture for a living.

BARABANKI DISTRICT (1,714 sq.mi.: pop. [1961] 1,411,883) is a level plain lying mainly between the Gumti and Gogra rivers, dotted with *jhils* (marshy lakes). The higher ground to the west has sandy soil, while the lower areas are clayey and produce cereals, mainly rice, wheat and gram. Some areas become waterlogged in years of heavy rainfall. Only about 6% of the district's population is urban and 82% of the people depend on farming or farm labour for a livelihood.

At Deva, an ancient village 7 mi. N. of Barabanki lived one of the greatest Muslim Sufi or mystic saints, Haji Hafiz Sayyed Shah Warris Ali (1819–1905), whose mausoleum is a place of pilgrimage for people of different religions and faiths. A large annual fair is held there. Another important fair is held at Bansda in honour of Abd ur-Razzaq, the 14th-century Persian Sufi. (B. SI.)

BARABRA (literally "Berbers"), a name applied in a restricted sense by the Egyptians to the inhabitants of lower Nubia (*q.v.*) from Aswan south to Argo Island. It includes the Kenuz, Sukkot and Mahas and sometimes the Danagla farther south. Apart from the Kenuz, whose Arab ancestors occupied the First Cataract in the 11th–12th centuries A.D.; the basic stock is proto-Egyptian, reinforced by Libyan immigration from the west and diluted with Negro blood from the south. Since the fall of the Christian town of Dongola in the 14th century, the Barabra have been Muslims and increasingly Arabicized. They vary in colour from the fair-skinned Kenuz to black but generally preserve the bronze skin, oval face, regular features and slim build of their Hamitic ancestry, together with their Nubian dialects. The women know little Arabic. Like the Ga'alin (*q.v.*), the Barabra use razor cuts on cheek or temple to indicate tribal or religious affinity.

The Barabra supplied Egypt with its 25th dynasty and later colonized Kordofan and Jebel Meidob, following the Wadi al Melik south from the Nile bend. (According to Meidob tradition a large party went on to settle west of Chad.) Their learned families provided the Fung sultans with many famous religious leaders. In the 18th century the raids of the neighbouring Shaikia led to further emigration by Barabra and Danagla to settle as traders and teachers in the market centres of Kordofan, Darfur and Wadai. After the Egyptian conquest of 1821–22 the Danagla rivaled the Ga'alin as slave traders, penetrating far into the south, where their descendants remain as traders, the Gellaba of modern terminology. In the 20th century they have provided Egypt and the Levant with "Berberine" servants, whose remittances enable the villages of Nubia to cling precariously to the rocks above their drowned date gardens and wheat fields and the ever encroaching waters of the Aswan dams. Enterprise in individual emigration is accompanied by a deep attachment to the ancestral home and reluctance to move to other areas.

See also ARAB. (K. D. D. H.)

BARACALDO, a city in northeastern Spain, in the province of Biscay, on the navigable estuary of Bilbao, 8 km. (5 mi.) N.W. of that city and linked to it by the Bilbao-Portugalete railway. Pop. (1950) 41,163 (mun.); area 47 sq.km. (18 sq.mi.). Following the establishment in Baracaldo of Altos Hornos and a complex of heavy industries, it provided one of the clearest examples of the modification of a rural community into an industrial concentration. From a town which in 1900 had only 15,000 inhabitants, it became a large urban concentration. Its growth was matched by the provision of housing and public services, its houses, parks and plazas making Baracaldo a model town. Its main rivers are the Cadagua and the Galindo. It has an important iron-mining area, the ore being exported from Luchana. (M. B. F.)

BARAHONA, a province in southwestern Dominican Republic with an area of 976 sq.mi. Pop. (1960) 79,880. It consists of the high Sierra de Bahoruco, a broad peninsula jutting into

the Caribbean south of the range, and a broad coastal lowland north of the range. The main crops are sugar cane in the alluvial lowland irrigated by the Rio Yaque del Sur and coffee in the mountains. A huge deposit of rock salt and gypsum is worked in the arid lowland. Coastal forests provide mahogany and other fine hardwoods. Barahona was established in 1888 as a maritime district and was separated from Bahoruco province in 1943. The capital, also named Barahona (pop. [1960] 20,3981, is an important port. (D. R. D.)

BARAHONA DE SOTO, LUIS (*c.* 1548–1595), Spanish poet, whose best-known work is the *Primera parte de la Angélica* (1586; facsimile. 1904), a continuation of the Angelica and Medoro episode in Ariosto's *Orlando furioso,* was born at Lucena, Córdoba, and studied at Antequera under the humanist Juan de Vilches, later practising medicine in Madrid and the principal towns of Andalusia, where he moved in humanistic and literary circles. His friendship with the "divine" Fernando de Herrera survived his parodying of the irascible older man in a sonnet entirely made up of resounding Herreran neologisms. Barahona himself is a poet of understatement, and in his cool and unemphatic style appears as a precursor of the younger generation of eastern Andalusian poets represented in the *Flores* of Pedro Espinosa and Agustín Calderón and the *Cancionero antequerano* of Toledo y Godoy. Barahona has also been shown to be the author of an anonymous treatise on hunting, the *Diálogos de la montería* (ed. by F. R. de Uhagón, 1890), which contains numerous quotations from the *Angélica,* including fragments of a lost second part. (F. S. R.)

BARAMULLA, a town and district in Jammu and Kashmir state, India, lies 31 mi. W. of Srinagar. Population of the town (1951 est.) 15.184; of the district (1961) 602,273. The town is on the left bank of the Jhelum river, at the point where it leaves the broad Kashmir valley and enters the gorge through the Pir Panjal range. It is a holiday resort and houseboats may be hired for trips on the river and Wular lake. The economy and geography of the district are essentially parts of those of the vale of Kashmir (*q.v.*). At Patan, 16 mi. S.E., are two temples of the 9th century, and 21 mi. S.E. at Parihasapura are Buddhist remains of the 8th century. (S. GL.)

BARANTE, AMABLE GUILLAUME PROSPER BRUGIÈRE, BARON DE (1782–1866), French historian and statesman, a member of the Académie Française and a representative of liberal tendencies in the period under the Restoration. He was born at Riom, Auvergne, on June 10, 1782. At 16 he entered the École Polytechnique in Paris and at 20 formed an attachment in Geneva with Mme. de Stael, to whom he proposed marriage. This was, however, to be complicated by his later platonic attachment to Mme. Récamier. Between 1806 and 1815 Barante was auditor to the council of state, prefect of the Vendée and, under Napoleon. prefect of the Loire *Inférieure.* An ardent royalist. he nevertheless upheld liberal tendencies and when. in 1819, he was created a peer he used his rank to promote liberal reforms. Removed from the council of state by the duc de Richelieu, he was offered, after the Revolution of 1830, the post of ambassador at Turin and, in 1835. ambassador at St. Petersburg. Throughout the reign of Louis Philippe he remained a supporter of the government, and after the fall of the monarchy, in 1838, he withdrew from political affairs. He died at Le Dorat (Puy-de-Dôme), Nov. 21, 1866.

Barante's historical writings include the *Histoire des ducs de Bourgogne* (1824–28) and biographies of Joan of Arc, Mathieu Molé and Royer-Collard. His political tracts deal with contemporary views on aristocracy and social organization.

See C. de Barante (ed.), *Souvenirs du baron de Barante* (1890–1901).

BÁRÁNY, ROBERT (1876–1936), Austro-Swedish physician of Hungarian descent, who won the Nobel prize in 1914 for his work on the physiology and pathology of the balancing apparatus of the internal ear, was born in Vienna on April 22, 1876. He studied medicine in his native town. Early in the 1900s he became assistant at the ear clinic of Vienna university, which was conducted by Adam Politzer. In 1909 he was made lecturer on otological medicine. In the same year he found a new method of examining the interrelationship of the vestibular apparatus, the brain and the spinal marrow, a method known as the indication test. From 1917 until his death, April 8, 1936, he was professor at Uppsala university and head of the ear, nose and throat clinic. Bárány published numerous treatises. His works include *Physiologie und Pathologie des Bogengang-Apparats beim Menschen* (1907). (F. L. A.)

BARAT, SAINT MADELEINE SOPHIE (1779–1865), French nun: foundress of the Society of the Sacred Heart, was born at Joigny, Burgundy, Dec. 12, 1779, of peasant stock. She received from her brother Louis an exceptional education fitting her for her lifework. After the reign of terror she went to live in Paris with Louis, who had joined the Fathers of the Faith. His superior, Joseph Varin, was looking for a young woman to head an educational order dedicated to the Sacred Heart of Jesus, and in the shy, gifted Madeleine Sophie he found her.

With three companions she made her first consecration on Nov. 21, 1800; in 1801 the first Convent of the Sacred Heart was opened at Amiens, Mother Barat becoming superior in 1802. In 1804 she journeyed to Grenoble to found her second convent and receive into the order Rose Philippine Duchesne (*q.v.*), its first missionary. In 1806 Mother Barat was elected superior general for life, and in 1815 the constitutions and rules of the order, drafted with Varin's help, were adopted. The Society of the Sacred Heart received ecclesiastical approval in 1826.

With clear educational objectives and constantly improved methods, the order spread during the lifetime of the foundress from France to 11 countries of Europe, Algeria and North and South America. Under Mother Barat's guidance remarkable union and uniformity were established. She died in Paris on May 25, 1865, and her body is enshrined at Jette-Saint-Pierre. Belgium. In 1908 Madeleine Sophie Barat was declared blessed, and in 1925 she was canonized. Her feast day is May 25.

BARATYNSKI, EVGENI ABRAMOVICH (1800–1844), foremost Russian philosophical poet contemporary with Aleksandr Pushkin (*q.v.*), was born at Vyazhli (Tambov), of noble parentage, March 3 (new style; Feb. 19, old style), 1800. Expelled from the imperial corps of pages, he entered the army (1819), was commissioned (1825) and retired (1825). He married and settled in Muranovo, near Moscow. His early romantic lyrics are strongly personal, sometimes epicurean. sometimes elegiac. His narrative poems *Eda* (1826), *Bal* (1828; "The Ball") and *Nalozhnitsa* (1831, "The Concubine," rewritten as *Tsyganka,* "The Gipsy Girl." 1842) treat the emotions analytically. He published three other books of verse (1827. 1835, 1842). Tragic pessimism predominates in his later poetry, mainly on philosophical and aesthetic themes. Modern critics value his thought more highly than his contemporaries. He died in Naples, July 11 (N.S.; June 29, O.S.), 1844.

See his complete works, ed. by M. L. Hoffman, 2 vol. (1914–15) and collected poems, 2 vol., in "Biblioteka poeta" (1936, 1957). (E. HL.)

BARBADOS (formerly often BARBADOES), a British island colony. one of the West Indies group, is located about 100 mi. E. of St. Vincent. It is 21 mi. long. 14 mi. at its broadest and 166 sq.mi. in extent (somewhat larger than the Isle of Wight). Its coasts are almost encircled with coral reefs, which extend in some places more than 2½ mi. seaward. The capital and only port of entry is Bridgetown (*q.v.*). From fine sandy beaches and coastal strips or small plains the ground rises in a series of terraces to Mt. Hillaby, 1,105 ft., in the north-central part of the island. Nearby is the Scotland district which, with its steep slopes and jagged scenery, looks like the crater of an extinct volcano, though it is not one. Geologically, a basement of much folded sandstones and shales (the Scotland series) is covered unconformably by chalklike rocks of the Oceanic series. Except in the Scotland district, both series are covered unconformably with a layer of limestone, of thicknesses up to 240–250 ft. Streams are few and insignificant.

Climate. — The climate of Barbados is generally pleasant. The temperature rarely rises above 86° or falls below 65° F. In the

dry season (roughly, from December to May) the heat of the sun is tempered by the easterly trade winds and, because of the ocean breezes, it is only occasionally that the weather during the remaining months becomes disagreeably hot or humid. The average rainfall varies markedly from district to district within a range of approximately *75* in. to *50* in. The island is free from malaria. Barbados lies on the southern border of the West Indian hurricane zone. The hurricanes of *1780* and *1831* caused great devastation and others of lesser intensity have visited the island, one in 1955 after an interval of *57* years.

Vegetation and Animal Life. — Only about *40* ac. of the forest or scrub that once covered the island still remain. Palm trees of different kinds, mahogany, breadfruit, tamarind, casuarina and other trees, including the magnificent flamboyant or poinciana (Delonix **regia)** and the frangipani, are found in many places. Flowering shrubs adorn parks and private gardens; but the characteristic landscape of inland Barbados is one of wide undulations pervaded with the pale green of sugar cane.

There are very few wild animals. Some monkeys live in the wooded area and give pleasure to visitors but annoy local cultivators. The mongoose, introduced to destroy rats, has become something of a pest. There are some hares and — Barbadians insist — a few raccoons. The few species of resident birds include two kinds of hummingbird, two kinds of dove, and the ubiquitous "Barbados sparrow" — a relative of the English sparrow. A night-long piping or whistling comes not from a bird but from a diminutive tree frog. Fish caught in local waters include flying fish, grouper, kingfish, snapper and bonito.

Population. — The population at the census of *1960* was *232,085*. This represents a density of almost *1,400* persons per square mile — one of the highest in the world for such a community. The *1946* census gave the racial divisions as: African descent, *77.3%*; mixed descent, *17.5%* ; European descent, *5.1%*. The people are Christian (mostly Anglican) and the language spoken is English.

No legal distinction is made between the races, either in theory or in practice; but there is truth in the charge often brought by the other West Indian colonies that colour discrimination exists in social life to a degree that has become outmoded elsewhere. Even in this most conservative of colonies, however, changes in basic attitudes have taken place. Moreover, an intense local patriotism is characteristic of all Barbadians; white and nonwhite are equally ready to declare that if anything could conceivably be wrong in their island they themselves would be capable of putting it right in their own time and in their own way.

Administration. — The legislature consists of two bodies: the house of assembly, which celebrated its tercentenary in *1939*, contains *24* members who are elected under full adult suffrage for a period of five years; and a legislative council with *15* appointed members. The crown has only a veto on legislation. Barbados retains a governor. The position of the executive bodies and their relationship with the legislature is complicated, since historical survivals have been more or less fitted into a modern framework. The practical effect has been that Barbados has enjoyed self-government in internal affairs. Elementary education is free but not compulsory. Harrison college (boys) and Queen's college (girls) are state aided secondary schools known throughout the West Indies; Codrington college, on the windward coast, was founded in *1710*. After undergoing various changes in its functions, it is today a priory and seminary of the Community of the Resurrection (the "Mirfield Fathers").

The only town besides Bridgetown is Speightstown (pronounced "Spikestown") which once carried on a flourishing trade with Bristol. Barbados has produced many fine cricketers.

History. — Much about the early history of Barbados is obscure — including the origin of its name, which may come from a Spanish word meaning "bearded fig trees." Remains show that the island once supported a considerable population of Arawak Indians; and it is probable that it was visited by raiding or hunting parties of the savage Caribs, who, like the Arawaks, came to the Antilles from South America. Columbus failed to sight the island, but there is evidence that Spaniards had landed there by *1518* and had taken Indians from it for slaves in their colony of Hispaniola. By *1536*, apparently, no Indians remained.

There is uncertainty about the beginnings of the English connection and the story of the landing from the ship "Olive Blossom" in *1605* is almost certainly a myth. Whatever the precise details, Barbados, uniquely in the West Indies, has not changed hands since the original British settlement. Simon Gordon claimed to be the first Englishman to set foot on the island, which was then presumably without inhabitants. He may have been in a ship under the command of Sir Thomas Warner that called there some time between *1620* and *1624*. In *1624* or early *1625* John Powell landed a party, who set up a cross and inscribed on a tree: "James K. of E. and of this Island." In *1627* Capt. Henry Powell, John's younger brother, landed a party of settlers near the same spot. This expedition had been fitted out by Sir William Courteen. a protégé of the duke of Marlborough. to whom James I had granted the island. In *1627* a new patent was granted by Charles I to Lord Carlisle. Proprietary rule ended in *1652* when Barbados, which was being governed by Lord Willoughby of Parham in the name of the king, surrendered to a force dispatched by the Commonwealth. The instrument of surrender provided that the government of the island should be vested in the governor, council and assembly, according to ancient and usual custom, and established the principle that there should be no taxation without consent. After the Restoration the claims of the Carlisle patent and others were revived, and an agreement was eventually reached under which the patent was surrendered to the crown for compensation in the form of a $4\frac{1}{2}\%$ duty on exports, which until *1838* remained a constant grievance to the colony. The abolition of slavery in *1834*. and the complete freeing of slaves in *1838*, shook but did not destroy the island economy which has shown a remarkable power of survival.

Some rioting took place in *1876* as a result of an attempt to bring about a federation of Barbados and four other islands. Rioting next occurred in *1937* when, primarily as a result of the world depression and the rapid growth of population, economic conditions had become very bad. The disorders were widespread though the British West Indies, and the modern history of Barbados and of the other Caribbean colonies may be said to begin with the subsequent dispatch to the area of the Moyne commission to investigate conditions, and the adoption by the United Kingdom parliament of the first Colonial Development and Welfare act, *1940*, under which large sums were provided for the benefit of these and other colonies. The Development and Welfare organization. which was a major factor in the growth of a regional spirit in the West Indies, had its headquarters in Barbados from *1942* until it came to an end in *1958*. With the coming into being of the federation of The West Indies in *1958*, the premier of Barbados, Sir Grantley Adams, became the first federal prime minister.

Trade and Finance. — Since the middle of the *17th* century the basis of the entire economy of Barbados has been sugar, which is cultivated with great skill, and its by-products, rum and molasses, though the growing tourist industry is a helpful adjunct. An agreement made in *1951* between the United Kingdom government and commonwealth sugar producers enables Barbados to sell most of its sugar crop to the United Kingdom at a guaranteed price which is reviewed each year. The chief export trade is thus naturally directed to the United Kingdom. Most of the colony's imports come from the United Kingdom and other commonwealth countries, chiefly Canada. The West Indian dollar, with a value of 4s. *2d*. sterling, is the monetary unit.

Transport and Communications. — The island is provided with a network of good roads. It has long been a port of call for ships of many nations. At Bridgetown a deep-water harbour costing B.W.I. *$25,000,000* began operations in *1961*. Several international airlines run regular services to Seawell airport near the south coast. and British West Indian airways connects Barbados with all parts of the West Indies. The schooner fleet of the eastern Caribbean has its headquarters there. The receiving and transmitting stations of Cable and Wireless, Ltd. are of major importance in international communications.

BARBARA, SAINT (*c.* A.D. 200), a virgin martyr of the early church. According to the legend, which is not older than the 7th century, she was the daughter of a pagan, Dioscorus, who kept her guarded in a tower. When she admitted having become a Christian he took her to the prefect of the province to be tortured and beheaded. On his way back from the execution her father was struck by lightning. Some accounts name Heliopolis. others Nicomedia or a town in Tuscany as the scene of her sufferings. The original Greek accounts of her martyrdom are lost, but Syriac, Latin and other versions are extant. Her story, reproduced in great detail in the *Golden Legend,* was very popular in the middle ages. She is venerated as one of the 14 Auxiliary Saints (Holy Helpers), especially as the patroness of artillerymen and firemen; she is also invoked in thunderstorms. Her feast day is Dec. 4.

See *Butler's Lives of the Saints,* ed. *by* H. Thurston and D. Attwater, vol. iv, pp. 487–489 (1956). (H. C. G.)

BARBARIAN (Gr. BARBAROS), the name among the early Greeks for all foreigners, including the Romans. The word probably represents the uncouth babbling of which languages other than their own appeared to the Greeks to consist. It soon assumed an evil meaning, becoming associated with the vices and savage natures which the Greeks attributed to their enemies. The Romans adopted the word for all peoples other than those under Greco-Roman influence and domination. The name Barbary, for northwestern Africa, is derived from that of its Berber inhabitants, not from *barbaros.*

BARBAROSSA ("Redbeard"), the European name for KHAIR ED-DIN (d. 1546), a Barbary pirate and later admiral of the Ottoman fleet, whose activities in Algeria and Tunisia influenced the political development of the area for the next three centuries. He was originally named Khidr but adopted Khair ed-Din as an honorific title. The name Barbarossa often was applied to his brothers and son also.

The founder of the family was a Turk, probably of Albanian origin, from the island of Lesbos. His four sons Elias, Ishak. Aruj and Khidr soon took up a life of piracy. Elias was killed in an encounter with the Knights of St. John in 1503, and Aruj, now the head of the family, moved with his brothers from a base in Egypt to Djerba, an island in the western Mediterranean.

It was a time of crisis in north Africa. Between 1505 and 1511 increasingly numerous attacks by the Portuguese and Spaniards culminated their seizure of certain ports. Morocco maintained its independence after the establishment of the native Sa'adi dynasty, but the rulers of Tlemcen and Tunis had to contend with domestic disorders and the Spaniards were able to establish themselves at Mers al Kebir, Oran, Bougie, Tripoli and on the islet of Algiers. The weakness of the Muslim rulers, and hatred for the Christians exacerbated by Spanish successes, encouraged Aruj and Khidr in their aggressive policy. From the outset the two brothers were successful in piracy and hoped, with the aid of their Turkish compatriots and Muslim emigrants from Spain. to wrest an African domain for themselves. In 1516 the Muslims of Algiers appealed to Aruj, who had been based at Djidjelli since 1512. Unable to capture the Spanish fortress on the island, he nevertheless founded a principality on the littoral with the capture of Miliana, Médéa, Ténès and then Tlemcen. In 1518, however, the last was retaken by the Spaniards and Aruj was killed in the fighting there.

Khidr, who had been his brother's lieutenant, assumed the title of Khair ed-Din. He realized that all the brothers had built up was now threatened, for the Muslim peoples were trying to free themselves from their Turkish oppressors and the Spaniards were not less threatening. Khair ed-Din conceived the bold stroke of offering homage to the sultan of Istanbul for his possessions; in return the sultan granted him the title of *beylerbey* and dispatched military reinforcements (1518). With this help Khair ed-Din was able to re-establish his authority and, having driven the Spaniards from the islet of Algiers (subsequently called Peñón; 1529), to build up Algiers itself as the great stronghold of Mediterranean piracy.

In 1534 he took Tunis and conquered the whole of Tunisia for the Turks, Tunis itself becoming the base for piracy against the Italian coast. In 1535 a powerful expedition sent by the emperor Charles V on behalf of the Tunisian Hafsid sultan recaptured Goletta and Tunis. Khair ed-Din had just carried out a daring raid against Malta when he was summoned to Istanbul, where. in 1533, the sultan had made him admiral in chief of the Ottoman fleet. He took up his duties in 1536 and was one of the great figures of the court at Istanbul until his death there in May 1546. His work in Africa was continued by his successors, in particular by his son Hassan, who, like his father, became admiral in chief. Through Khair ed-Din's initiative Algeria and Tunis. for centuries separate from the eastern caliphates, became part of the Ottoman empire, the Christian threat was removed and the Spanish foothold in Africa reduced to Oran and Mers al Kebir. For three centuries the Mediterranean coastal tomns and villages suffered the depredations of Barbarossa's successors.

See P Achard, *La Vie extraordinaire des frères Barberousse Corsaires ef rois d'Alger* (1979); A. Papell, *Reyes y Corsarios. Los Barbarroja* (1935). (H L E T)

BARBARY or BARBARY STATES. part of northern Africa bounded east by Egypt. west by the Atlantic, south by the Sahara and north by the Mediterranean, comprising Morocco, Algeria, Tunisia and Libya. The name comes from the Berbers, chief inhabitants of the region.

BARBARY APE (MAGOT), *Macaca sylvana,* a tailless monkey inhabiting Algeria, Morocco and the Rock of Gibraltar and belonging to the group of macaques (*q.v.*). It is light yellowish-brown above and yellowish-white below, with the naked part of the face flesh-coloured. The barbary ape is terrestrial and travels about in droves

BARBARY PIRATES, Moorish sea robbers operating from the coast of north Africa, who were at their most powerful during the 17th century. but continued their depredations down to the 19th century. North African piracy had very ancient origins but gained a new significance during the 16th century mainly through Khair ed-Din, or Barbarossa (*q.v.;* d. 1546), who united Algeria and Tunisia as military states under the Ottoman caliphate, and maintained his revenues by piracy. With the arrival of powerful Moorish bands in Rabat and Tetuan (1609), Morocco became a new centre for the pirates and the Alaouite sultans who quickly gained control of the two small republics and encouraged piracy as a valuable source of revenue.

The maritime side of this long-lived brigandage was conducted by the captains or *reises,* who, in Algiers and Tunis, formed a class or even a corporation. Cruisers were fitted out by rich men and commanded by the *reises.* The treasury of the ruler who bore the title of agha or dey or bey, received 10% of the value of the prizes. Bougie was the chief shipbuilding port. Until the 17th century the pirates used galleys, but Simon Danser, a Flemish renegade, taught them the advantage of using sailing ships. During the 17th century the Algerian and Tunisian corsairs joined forces and in the first half of the century more than 20.000 captives were said to be imprisoned in Algiers alone. The rich were allowed to redeem themselves, but the poor were condemned to slavery. Their masters would not in many cases allow them to secure freedom by professing Islam. In the early part of the 19th century Tripolitania (*q.v.*), as a result of its piratical practices, was several times involved in war with the United States. After the general pacification of 1815 the British made two vain attempts to suppress Algerian piracy, which was ended only by the French conquest of Algiers in 1830. (H. L. E. T.)

BARBAULD, ANNA LAETITIA (1743–1825). English poet, miscellaneous writer and editor, probably best known for the lyric. "Life! I know not what thou art," was born at Kibworth-Harcourt, Leicestershire, on June 20, 1743 In 1758 her father became theological tutor at the Dissenting academy at Warrington, Lancashire. and she was brought into contact with a distinguished circle which included Joseph Priestly. In 1773 she

published *Poems* and co-operated with her brother, John Aiken, in *Miscellaneous Pieces in Prose.* Her most important poems—*Corsica* (first published in 1768) and "The Invitation"—show her as an idealistic writer, concerned with political and social questions. Her prose, especially the essay "On Romances," was acknowledged by Dr. Johnson to be the best of the many imitations of his style.

In 1774 she married Rochemont Barbauld, Presbyterian minister of Palgrave, Suffolk, where they established a school. Her *Hymns in Prose for Children* (1781) were written "to impress devotional feelings as early as possible in the infant mind." In 1787 the Barbaulds moved to Hampstead and later to Stoke Newington, where they remained until his death in 1808. In 1794 she published an edition of Mark Akenside's *The Pleasures of Imagination* with a critical essay, followed in 1797 by an edition of William Collins' *Poetical Works.* In 1804 she edited a selection from the 18th-century essayists, with a critical introduction, and also a selection from Samuel Richardson's correspondence prefaced by a perceptive biographical essay which is still of critical value. In 1810 she edited *The British Novelists* in 50 volumes, and in 1812 appeared her longest poem, *Eighteen Hundred and Eleven,* a gloomy meditation upon the position and expectations of Great Britain which, despite its late date, belongs essentially to the tradition of 18th-century meditative verse. She died at Stoke Newington on March 9, 1825.

Her works were edited with a memoir by Lucy Aikin, 2 vol. (1825).

BIBLIOGRAPHY—A. L. le Breton, *A Memoir of Mrs. Barbauld (1874);* G. A. Ellis, *A Memoir of Mrs. Anna Laetitia Barbauld, With Many of Her Letters* (1874); and an appreciative essay in the *Times Literary Supplement* (June 19, 1943). (JN. C.)

BARBED WIRE: *see* **WIRE.**

BARBEL, a common name for a fish (*Barbus barbus*) of the carp family (Cyprinidae), found in the rivers of central and western Europe. The name is derived from the four feelerlike barbels, or barbs, near the crescent-shaped mouth. As in other barbed fishes, the barbel has sense organs for taste concentrated on these appendages and uses the barbels to search for food along the river bottom. *Barbus barbus* has a rather elongate body, and attains a weight of 50 lb. in the Danube.

In Africa and Asia many species of *Barbus* are called barbel, or barb. Some of these are small and are kept in home aquariums; others, such as the mahseer (*q.v.*) of India, are important food and game fishes. (C. Hu.)

BARBELLION, W. N. P. (pen name of BRUCE FREDERICK CUMMINGS) (1889–1919), English diarist and biologist remembered for his autobiographical *Journal of a Disappointed Man,* was born at Barnstaple. Devon, on Sept. 7, 1889. He won a position at the Natural History museum, London, in 1911, but his health deteriorated. He suffered from multiple sclerosis and. although his wife was told before their marriage in 1915, Cummings did not discover the truth until later. He had to resign from the museum in 1917 and died at Gerrard's Cross, Buckinghamshire, on Oct. 22, 1919.

The Journal of a Disappointed Man (1919) was prepared from his diary covering 1903–17 and is, in the author's words, "a self-portrait in the nude." "I am the scientific investigator of myself," he remarked, and the book is an objective account of Cummings' struggle against increasing. ill-health, written in a graphic and sensitive style. Of his two other books, posthumously published, *Enjoying Life and Other Literary Remains* (1919), which he prepared for publication before he died, included literary and scientific essays too long for the *Journal. A Last Diary* (1920), written for publication. and more deliberately self-conscious than the *Journal,* shows the same keen observation of nature and humanity.

BARBÉ-MARBOIS, FRANÇOIS, MARQUIS DE (1745–1837), French statesman, who in 1803 negotiated the Louisiana Purchase (*q.v.*), was born at Metz. Having served as a diplomat in Germany and with the American revolutionaries, he was intendant of Santo Domingo (1786–89) and then returned to France. He was from 1795 a moderate deputy of the *conseil des anciens,* from which he was expelled on 18 Fructidor (Sept. 4, 1797) and deported to French Guiana; he was set free in Jan. 1800 and became a counselor of state. In 1801 he became director and then minister of the treasury. In the Louisiana negotiations he got a better price than had been expected, but his excessive advances to contractors in 1805 caused a grave financial crisis and Napoleon dismissed him (Jan. 1806). However, he was made first president of the *cour des comptes* in 1807 and a senator and a count in 1813. Hastily attaching himself to the Bourbons, he was made a peer of France (1814) and a marquis (1817) by Louis XVIII. He was minister of justice from Sept. 1815 to May 1816, when he again became president of the *cour des comptes* until he resigned in March 1834, having declared himself in favour of the July monarchy in 1830. He died in Paris on Jan. 12, 1837.

Barbé-Marbois' works include *Réflexions sur la colonie de Saint-Domingue* (1796), *Histoire de la Louisiane et la cession de cette colonie par la France aux États-Unis* (1829) and *Journal d'un déporté non jugé,* the story of his deportation (1834).

(C. E. Du.)

BARBER, SAMUEL (1910–), U.S. composer, one of the most expressive representatives of the lyric and romantic trends in American composition, was born March 9, 1910, in West Chester, Pa. He studied the piano from an early age (his mother was an amateur pianist, and his aunt was the contralto Louise Homer) and soon began to compose. In 1924 he entered the Curtis Institute of Music in Philadelphia, where, in addition to piano and composition, he studied singing and conducting.

After graduation in 1934, Barber devoted himself entirely to composition. He developed a distinctive style, absorbing some technical procedures of modern music but without indulging in experimentation for its own sake. His *Overture to "The School for Scandal,"* op. 5 (1932), based on Sheridan's comedy, and composed while he was still a student, and *Music for a Scene from Shelley,* op. 7 (1933), inspired by *Prometheus Unbound,* established his reputation.

Although literary allusions occur in many of Barber's works, his music is not programmatic in the literal sense. Significant in this respect are the two *Essays for Orchestra,* op. 12 (1937) and op. 17 (1942), which are intended as musical counterparts of the literary form. Structural considerations govern Barber's instrumental writing; there is great astringency in harmony, but the basic tonality remains secure; the rhythmic lines are very strong, without loss of coherence.

In 1936 Barber wrote his First String Quartet, op. 11, the slow movement of which, arranged for string orchestra, was performed under the title *Adagio for Strings* by the NBC Symphony orchestra under Arturo Toscanini in New York on Nov. 5, 1938, and acquired extraordinary popularity both in America and in Europe. Barber's First Symphony, op. 9 (1936; revised, 1942), is in the romantic tradition; in the Second Symphony, op. 19 (1944; revised, 1947), commissioned by the U.S. army air forces (which Barber had joined in 1943), he introduced a special electronic instrument imitating the radio signals for air navigation, replaced in the revised version by an E-flat clarinet.

Barber wrote also a *Violin Concerto,* op. 14 (1939), and a *Cello Concerto,* op. 22 (1945). His *Piano Sonata,* op. 26 (1948), is the most ambitious work in this form by an American composer. Other compositions are *Dover Beach,* op. 3, for voice and string quartet (1931); two vocal works with orchestra, *Knoxville, Summer of 1915,* op. 24 (1947), and *Prayers of Kierkegaard,* op. 30 (1954); the ballet *Medea,* op. 23 (1946), and the opera *Vanessa,* New York (Jan. 15, 1958); and many songs. The opera won a Pulitzer Prize for him in 1958.

See N. Broder, Samuel Barber (1954). (N. SY.)

BARBER (from Latin *barba,* beard), one who cuts and trims hair, shaves beards, etc. The barber shop was a familiar institution in ancient Greece and Rome, and then as now was a centre for the exchange of gossip and opinion. However, the more prosperous citizens, particularly in Rome, had household barbers. The great houses of ancient Egypt also had barbers among their retainers, and offered the services of these as part of their hospitality to guests,

For six centuries the barbers of Europe practised surgery.

This custom began with the papal decree of 1163 that forbade the clergy to shed blood. Monks were required to undergo bloodletting at regular intervals, and some of them had been performing this task, along with minor surgery. Now they turned these duties over to the barbers — familiar figures at the monasteries since 1092, when the clergy had been required to be clean shaven. This arrangement was satisfactory to the doctors of the era, who considered that bloodletting was necessary but beneath their dignity, and were glad to relegate to the barbers other physical tasks such as the lancing of abscesses and treatment of wounds. At the beginning of his career Ambroise Par6 (*q.v.*), one of the great pioneers of surgery, was among those who gave shaves and haircuts for a living.

In France a royal decree of 1383 declared that "the king's first barber and valet" was to be head of the barbers and surgeons of the kingdom, who had been organized in a guild in 1361. The barbers of London were first organized as a religious guild, but were granted a charter as a trade guild in 1462 by Edward IV. This guild was amalgamated with that of the surgeons in 1540 under a charter granted by Henry VIII, and the members of the joint corporation were accorded the right to be addressed as "Master" — colloquially, "Mister." British surgeons still prefix their names with "Mr." instead of "Dr."

The barber-surgeons were sometimes called "doctors of the short robe" to distinguish them from university-trained physicians and surgeons, whose superiority was apt to be only in their knowledge of Latin and their title of "doctor of the long robe." In England the guild of surgeons was separated from that of barbers in 1745. However, the Royal College of Surgeons did not receive its charter until 1800.

Discussing colonial barber shops in the first half of the 18th century, William Chauncey Langdon says in *Everyday Things in American Life* (Charles Scribner's Sons, New York. N.Y., 1937): "'Barber and Chirurgeon' was the familiar sign, and the red stripe on the barber's pole represented the blood he spilt, the white the bandage. . . . "

The barber's trade was acquired only by a long apprenticeship until the 1890s, when schools for harbering were established. A traditional male sanctuary. the barber shop was invaded by thousands of women in the 1920s, when the shingle bob came into vogue. Widespread use of the safety razor and the electric shaver has transformed U.S. barber shops, once adorned with rows of individual shaving mugs, and tended to limit the function of barbers everywhere to haircutting, shampooing, etc.

BARBERI, DOMENICO (called DOMINIC OF THE MOTHER OF GOD) (1792–1849), Italian Passionist and mystic who worked as a missionary in England, was born of peasant stock near Viterbo on June 22, 1792. Brought up without any formal education he entered the Passionist order as a lay brother and was admitted to the priesthood in 1818. In 1821, when he had finished his studies, he became lecturer in theology at a Passionist college near Vetralla, Viterbo. In 1824 he moved to Rome, where he continued to teach. An early inspiration had convinced him that he should work for the conversion of England, and he now met a number of English converts to Roman Catholicism from whom he learned much. But his appointments to Lucca in 1831 and as provincial for southern Italy in 1833 seemed to preclude his hopes, until in 1840 he was sent to Belgium, to found a Passionist house at Ere, near Tournai. English friends helped him there, and in 1841 offered him a house at Aston, Staffordshire. He was already following with keen sympathy the growth of the Tractarian movement. and it was he who in 1845 received Newman into the Roman Catholic Church. In Staffordshire Barberi incurred constant insults and even violence with undaunted patience. He always spoke English with difficulty, but he made converts everywhere, among all classes, by his ardent apostolic zeal. He founded four Passionist houses in England, and had planned the subsequent Irish foundation before his death in Reading on Aug. 27, 1849. He was declared venerable in 1911.

See Denis Gwynn, *Father Dominic Barberi* (1948). (D. G.)

BARBERINI, an aristocratic Italian family, probably of Sienese origin, but established in Florence by the 14th century. During the pontificate of Paul III (Alessandro Farnese) part of the family settled in Rome; and by the lifetime of Maffeo Barberini (1568–1644), elected pope as Urban VIII in 1623, their energies were concentrated in that city about the papal court. Able pontiff though he was, Urban won distinction also for his nepotism: one brother. Antonio, and two nephews. Francesco and Antonio, he created cardinals; on another brother, Carlo, he bestowed lucrative offices; and for a third nephew, Taddeo, he secured the principality of Palestrina. Together their revenues were enormous and their power such as to provoke war in the papal states and the jealousy of neighbouring princes. When Innocent X, Urban's successor as pope, began an investigation into the Barberini nephews' use of public money, Antonio fled to France (1645), followed by Francesco and Taddeo (1646). Cardinal Mazarin gave them his protection and Innocent eventually decided to pardon them. Francesco returned to Rome in 1648, Antonio in 1653; Taddeo had died in 1647. Taddeo's son Maffeo married Olimpia Giustiniani, Innocent's protégée. Cornelia Barberini, daughter and heiress of this Maffeo's son Urbano (d. 1722), in 1728 married Giulio Cesare Colonna di Sciarra, who added her family name to his own and secured the title prince of Palestrina for his house. The name and title were later extended likewise to Luigi, marchese Sacchetti, who in 1891 married Maria Barberini-Colonna di Sciarra, heiress of the last Colonna prince of Palestrina. The Barberini palace and library in Rome witness to the Barberini's magnificence and to their patronage of the artist Bernini (*q.v.*). Bernini, it is said, advised the removal of the ancient bronze girders of the Pantheon to be melted down for guns in 1625, which inspired the epigram: "Quod non fecerunt barbari, fecerunt Barberini" (What the barbarians did not do the Barberini did).

(P. J. J.)

BARBERRY, any shrub of the genus *Berberis* (family Berberidaceae), which comprises more than 200 species, many of them handsome, spiny evergreens, used as ornamental plants. The common Eurasian *B. vulgaris* is naturalized in Great Britain and the eastern United States, and grown as an ornamental; but, because it serves as a host plant for the destructive wheat rust, its culture is often prohibited, and rust-resistant species such as *B. thunbergi,* the Japanese barberry, are often grown instead. *(See* also WHEAT: *Diseases.)*

Far more important horticulturally are the splendid, mostly evergreen, species introduced from western China and Chile. Over 30 are in common cultivation in the United States and England. Nearly all of them have yellowish flowers, often in hanging clusters, and many have showy red or yellow fruits. Among these evergreen shrubs are *B. buxifolia,* a reasonably hardy species from Chile; *B. darwinii* from Chile, hardy in milder climates; and *B. julianae* of China, the hardiest of the evergreen species.

(N. TR.; X. j

BARBER'S ITCH, known also as ringworm of the beard, is a contagious disease caused by the fungus *Tinea barbae trichophytia.* There is a superficial scaly affection of the bearded region which involves the hairs. There is also a deeper infection called *Sycosis parasitara* which may result in small abscesses. The treatment varies with the stage of the disease, and fungicidal remedies, except of a nonirritating character, are not to be used in the acute stage. *See* SKIN DISEASES. (F. L. A.)

BARBERTON, an industrial city of Summit county, O., U.S., situated on the Tuscarawas river, and adjoining Akron on the southwest. (For comparative population figures *see* table in OHIO: *Population.)* Barberton's principal industries include the manufactures of automobile tires, chemicals, iron and metal products. high-tension insulators, steam boilers and marine power plants. A deposit of limestone more than 345 ft. thick and ½ mi. below the surface of the earth is one of the deepest mines of its kind in the world and is the source of raw material for the manufacture of soda ash (used in glassmaking), sodium bicarbonate and chlorine.

O. C. Barber. with his associates, founded Barberton in 1891 as the new site of his match works (later called the Diamond Match company), which had been established as the Barber Match company in Akron in 1867. Lake Anna, a natural pool in the heart

of the city, was named for Barber's daughter. (W. D. Ov.)

BARBET, the general name for small birds of the family Capitonidae, closely allied to the honey guides (*q.v.*) and placed with the woodpeckers in the order Piciformes. Barbets inhabit the tropical regions of the world, but are absent from Australia. They have brilliant plumage, predominantly green, and a large, stout bill, more or less beset with bristles. Being almost exclusively arboreal, they feed mainly on fruit and lay several white eggs in holes in trees. The blue-throated barbet (*Megalaima asietica)* of eastern Asia is the best-known in captivity. The family also includes the coppersmith and the South African tinker (*Pogoniulus pusillus*), the latter a small black, yellow and brown bird with a red cap. (G. F. Ss.; X.)

BARBEY D'AUREVILLY, JULES AMÉDÉE (1808–1889), French novelist and one of the most independent and penetrating critics of the 19th century, was born on Nov. 2, 1808. at Saint-Sauveur-le-Vicomte, Manche. His father belonged to the minor nobility of the region, with which the family of Barbey had long connections (the writer adopted the additional surname d'Aurevilly about 1837, eight years after the death of an uncle who had borne it). In his youth Barbey made two important friendships, the first with Maurice de Guérin (*q.v.*), whom he met while at the Collège Stanislas in Paris (1827–29), the second with Guillaume Stanislas Trebutien. a bookseller whom he met while studying law at Caen (1829–33). From 1833 to 1836 he divided his time between Paris and Normandy, but he finally set himself up in Paris in Jan. 1837 and began to earn a precarious living by writing for periodicals. Despite poverty, he went to great lengths to establish himself as a dandy, and his sartorial splendours and magnificent attitudes became legendary. He took Beau Brummell, whose rise to pre-eminence in English society fascinated him, as his model and in 1844 published a treatise *Du dandysme et de Georges Brummell* (dated 1845). After years of hardship he was appointed, in 1868, to alternate with Sainte-Beuve as literary critic for *Le Constitutionnel,* and on Sainte-Beuve's death in 1869 he succeeded to his position on that paper. Thenceforward his reputation grew, particularly among younger writers, for instance Paul Bourget, Léon Bloy, and some of the Symbolists, and he came to be known as *le Connétable des Lettres* ("Lord High Constable of Literature"). He died in Paris on April 23, 1889.

A romantic in an age of materialism, a fervent royalist with a contempt for democracy and an ardent but by no means orthodox Catholic, Barbey d'Aurevilly sought to live in superiority and detachment, disdaining everything that seemed to him vulgar or commonplace. In some ways he belonged to a bygone age, in others he was ahead of his contemporaries. Often arbitrary and vehement in his criticism, he was especially caustic about the realists and the naturalists, Émile Zola in particular. Some of his verdicts, however, have stood the test of time, and he recognized the attainments of Balzac, Stendhal and Baudelaire when they were far from being fully appreciated. His critical articles were collected in *Les Prophètes du passe'* (1851), *Les Oeuvres et les hommes,* 26 vol. (1860–1909), and *Le Théâtre contemporain,* 5 vol. (1888–96). His various *Memoranda* and his extensive correspondence constitute an invaluable source of information about his life and personality.

Barbey d'Aurevilly was much influenced by Sir Walter Scott and by Lord Byron, and his novels are sombre in tone and often strained or melodramatic. They are written, however, with verve and poetic imagination. *L'Ensorcelée* (serialized 1852; in book form 1854). *Le Chevalier des Touches* (1864), both dealing with local insurrections in the French Revolutionary period, and *Un Prêtre marié* (1865), all notable for their vivid evocations of his native Normandy, are perhaps his best novels. *Les Diaboliques* (1874), *a* collection of six short stories illustrating the power of evil, is often considered his masterpiece.

BARBEYRAC, JEAN (1674–1744), French jurist, famous chiefly for the preface and notes to his translation of Samuel Pufendorf's treatise *De Jure Naturae et Gentium,* was born at Béziers in lower Languedoc. Migrating with his family into Switzerland after the revocation of the Edict of Nantes, he studied jurisprudence at Geneva and then at Frankfurt am Main, and became professor of belles-lettres in the French school of Berlin. Then, in 1711, he was called to be professor of history and civil law at Lausanne, and finally settled as professor of public law at Groningen.

In theory Barbeyrac follows closely Locke and Pufendorf, but he works out with great skill the theory of moral obligation, referring it to the command or will of God. He indicates the distinction, developed more fully by Christian Thomasius and Kant, between the legal and moral qualities of action. The principles of international law he reduces to those of the law of nature, and combats many of the positions taken up by Hugo Grotius. He rejects the notion that sovereignty resembles property and makes even marriage a matter of civil contract.

Barbeyrac also translated into French Grotius' *De Jure Belli et Pacis* (1724), dedicated to "Sa majesté Britannique, George I"; Cumberland's *De Legibus Naturae;* and Pufendorf's small treatise, *De Officio Hontinis et Civis.* Among his own productions are a treatise, *De la morale des pères,* which criticized the fathers of the church; a history of ancient treaties contained in the *Supplément au grand corps diplomatique;* and the curious *Trait6 du jeu* (1709), in which he defends the morality of games of chance.

BARBIER, ANTOINE ALEXANDRE (1765–1825), French librarian and bibliographer, who produced a standard reference work of lasting value, the *Dictionnaire des ouvrages anonymes et pseudonymes,* was born Jan. 11, 1765, at Coulommiers, Seine-et-Marne. He took priest's orders, from which, however. he was released by the pope in 1801.

In 1794 he became a member of the temporary commission of the arts and was charged with the duty of distributing among the various libraries of Paris the books confiscated during the Revolution. In the execution of that task he discovered the letters of Pierre Daniel Huet, bishop of Avranches, and the manuscript of the works of Fénelon. He became librarian successively to the Directory, to the *conseil d'état* and, in 1807, to Napoleon, for whom he carried out a number of commissions. His *Dictionnaire des ouvrages anonymes et pseudonymes* was published during the years 1806–09 (3rd ed. 1872–79). Only the first part of his *Examen critique des dictionnaires historiques* was published (1820). He had a share in the foundation of the libraries of the Louvre, Fontainebleau, Compiègne and St. Cloud. Under Louis XVIII he became administrator of the king's private libraries, but in 1822 he was deprived of all his offices; as a result, his health broke down and on Dec. 5, 1825, he died in Paris.

See a notice by his son Louis and a list of his works prefixed to the 3rd ed. of the *Dictionnaire des ouvrages anonymes,* vol. i *(1872).*

BARBIERI, GIOVANNI FRANCESCO: *see* GUERCINO.

BARBITURATES, a group of compounds that, in proper doses, can produce sleep (hypnotic action) or sedation; these two properties have rendered them indispensable to the practice of medicine. Barbital, phenobarbital, amobarbital, butabarbital, pentobarbital, secobarbital, thiopental and thiamylal are most commonly used.

Uses.—The choice of a barbiturate for application to a therapeutic problem is determined by consideration of the particular drug's duration and mode of action *(see* below). Barbital and phenobarbital are employed extensively, for example, in conjunction with other drugs for treatment of certain convulsive disorders (epilepsy) where prolonged depressant action is desired. Secobarbital and pentobarbital comprise the active ingredients of preparations commonly referred to as "sleeping pills"; their relatively short period of effectiveness enables the induction of sleep without, as a rule, undesirable aftereffects. Thiopental is extremely useful as an anesthetic agent. In skilled hands this drug induces unconsciousness smoothly and rapidly, and can be supplemented by other agents when longer periods of anesthesia are necessary.

Metabolism and Duration of Action.—The most useful clas-

sification of barbiturates takes into account duration of action; that is, the length of time following administration of a therapeutic dose over which sedative or hypnotic action may be expected to persist. Barbiturates, then, are divisible into (1) long-acting (barbital, phenobarbital); (2) intermediate-acting (amobarbital, butabarbital); (3) short-acting (pentobarbital, secobarbital); and (4) ultrashort-acting (thiopental, thiamylal) groups. As a rule, administration of a hypnotic dose to a human subject will produce, in the case of the long-acting compounds, an effect persisting for six hours or more. The other groups act for correspondingly shorter periods (intermediate, three to six hours; short, less than three hours).

The ultrashort-acting compounds are never administered via the usual routes (oral, intramuscular) but are used principally as intravenous anesthetic agents.

The duration of action of a barbiturate is determined by several factors, including (1) the rate of destruction (conversion to physiologically inactive compounds); (2) the rate of excretion via the kidneys; and (3) distribution within tissues and organs of the body. As a general rule, all but the long-acting compounds are transformed more or less rapidly by enzyme reactions in the liver (and to a lesser extent, kidney) into substances possessing little or no hypnotic or sedative action of their own (metabolites), which are ultimately excreted by the kidney. Barbital and phenobarbital, on the other hand. are metabolized to a much lesser extent; sizable amounts of a given oral dose are recoverable from the urine in a form not different from that given above.

This knowledge is of practical importance to intelligent clinical use of barbituric acid derivatives. The administration of long-acting compounds is contraindicated in the presence of decreased kidney function (may cause retention and persistence of the effects of the drug), while other types must be used with caution in any condition manifesting reduction of the functional capacity of the liver. Thiopental and thiamylal, in addition to their rapid destruction by the liver, are stored to an appreciable extent in body fat. Their comparatively short duration of action and ineffectiveness by routes of administration other than intravenous are explained on the basis that the operation of both these factors does not permit the maintenance, for long periods of time, of concentrations in the blood or other organs compatible with sleep.

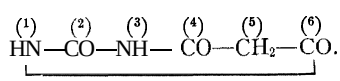
Barbiturate Poisoning and Addiction. — The incidence of barbiturate poisoning resulting from accidental or intentional overdosage has increased markedly. This situation, a reflection perhaps of the stress of modern times, is abetted by the tendency to overprescribe barbiturates and by laxity in enforcement of laws governing sales. Overdosage may be fatal due to brain damage caused by lack of oxygen and on the basis of other complications (pneumonia) incident to a prolonged, inactive, depressed state.

Methods employed in the treatment of acute barbiturate intoxication vary considerably and have been subjected to critical study. The use of stimulant drugs (picrotoxin, Metrazol) in conjunction with supportive measures (removal by lavage of barbiturate still present in the stomach, maintenance of open airway, adequate oxygenation and administration of intravenous fluids) is not universally accepted.

Therapeutic use of these compounds is not without hazard. and studies comparing mortality in groups of patients treated with stimulants and those given supportive treatment alone indicate no marked difference in survival rate. Each point of view, however, has its own merits, and it would seem that the treatment problem rests in individualized management for each case of acute barbiturate poisoning.

Prolonged use of the barbiturates (especially secobarbital and pentobarbital) for relief of anxiety or insomnia may in time progress to a point at which the user requires amounts of the drug much in excess of the initial therapeutic dose. This represents a state known as tolerance (ability to withstand amounts larger than the usually effective dose). Denial of a barbiturate to the habitual (tolerant) user may precipitate a series of systemic reactions described collectively as the withdrawal syndrome. indicative of physiologic dependence on the drug (addiction). Symptoms observed vary among patients but may include restlessness. anxiety, weakness, insomnia, nausea, delirium and convulsions. Severe reactions may be ultimately fatal. Treatment of the barbiturate addict involves gradual withdrawal of the drug under medical supervision, followed by a program of rehabilitation. The habitual user of barbiturates presents much the same therapeutic problem as the chronic alcoholic or morphine addict. The common denominator in all these is a basic character (psychological) defect; a combination of proper medical and psychiatric care offers the barbiturate addict some hope of restoration to a normal, useful life.

Chemistry. — The barbiturates are derived from barbituric acid (malonyl urea), a substance that in itself produces no marked physiologic effects on animals or man. It is prepared by condensation of the diethyl ester of malonic acid with urea, and may be depicted structurally as follows:



The barbiturates are prepared by addition to the parent compound of various chemical groups, usually (exceptions occur) at position 2, or 5, or both (a second group introduced at the 5-position is designated 5′). Examples are:

Name	2-Position	5-Position
Barbital	C=O	5-ethyl, 5′-ethyl
Phenobarbital	"	5-ethyl, 5′-phenyl
Amobarbital	"	5-ethyl, 5′-isoamyl
Butabarbital		5-ethyl, 5′-(1-methylpropyl)
Pentobarbital		5-ethyl, 5′-(1-methylbutyl)
Secobarbital		5-allyl, 5′-(1-methylbutyl)
Thiopental	C=S	5-ethyl, 5′-(1-methylbutyl)
Thiamylal		5-allyl, 5′-(1-methylbutyl)

The compounds listed are, with the exception of the thiobarbiturates, white, crystalline and odourless (thio compounds are yellow-green and crystalline; thiopental possesses a garliclike odour). The "free-acid" forms, characterized by a C=O or C=S group at position 2, are insoluble in water. For medicinal use, the free-acid form is converted to the soluble sodium salt by addition of a sodium atom at position 2.

See L. S. Goodman and A. Gilman, ***The*** *Pharmacological Basis of Therapeutics,* 2nd ed. (1955); H. Isbell, "Addiction to Barbiturates and the Barbiturate Abstinence Syndrome," **Ann.** *Int.* Med., 33:108 (1950). (L. **B.** AR.)

BARBIZON SCHOOL, an important school of 19th-century French painting. The name is derived from that of Barbizon, a village oh the edge of the forest of Fontainebleau, about 30 mi. S.E. of Paris, where the school's leaders, Théodore Rousseau and J. F. Millet, driven from Paris by poverty and lack of success, settled in 1847 and 1849 respectively. There they led lives of struggle and sacrifice. which achieved in the end a belated recognition. A colony of landscape painters and animal painters gathered about them. Among these were N. V. Diaz, J. Dupré, H. Harpignies, F. L. Français, C. Jacque and C. Troyon, while J. B. Corot, P. Huet, A. L. Barye and Gustave Courbet occasionally made visits.

Historically. the painters of Barbizon belong to the generation that was born at the end of the first empire and was frustrated by its defeat. Socially, they were confronted with the hostility of the bourgeoisie which had assumed power and favoured academic conventions. Artistically. these painters were the children of the romantic movement, from which they inherited restlessness and nostalgia for greatness; but, wearied of imagination. they turned to nature and reality. The forest of Fontainebleau, with its fantastic scenery of rocks. oaks and pools, offered an ideal refuge. They based themselves on the French 17th-century tradition. on examples of the old Dutch masters and on the new English school of landscape painting.

Rousseau became absorbed in a mystic communion with nature and found fulfillment in it. "The soul of the artist," he said, "must take its fullness from the infinite in nature." He listened to the mysterious murmur of the forest, "the voice of the trees, the surprises of their movements, the variety of their forms . . ." Millet

was more responsive to the nobility of man. "In art it is the human aspect which touches me most deeply," he confided. He chose Barbizon in order to contemplate the open country beyond and its husbandry, and the age-old movements of the peasant, who embodied for him the dual faith of 1848, the people and nature.

Barbizon became an international centre, and its influence extended over all Europe as well as the United States. It was also in the forest of Fontainebleau that the future Impressionist painters began their work.

BARBON, NICHOLAS (c. 1640–1698), English economist, probably the son of Praise-God Barbon, was born in London, studied medicine at Leyden, graduated M.D. at Utrecht in 1661 and was admitted an honorary fellow of the College of Physicians in 1664. He took considerable part in the rebuilding of London after the great fire of 1666, and has a claim to be considered the institutor of fire insurance in England, which he started about 1680. He died in 1698, having appointed John Asgill his executor, with instructions that none of his debts should be paid.

Barbon's writings on economics are interesting as expressing views much in advance of his time and very like those of modern times on such important topics as value, rent and foreign trade. He anticipated to some extent the conclusions of Adam Smith on the division of labour and the theory of currency as expounded by David Ricardo.

The more important of his works were *Apology for the Builder; or a Discourse Showing the Cause and Effects of the Increase of Building* (1685), in which he discussed the theory of rent; *A Discourse of Trade* (1690), which insisted that exports could be paid for only by imports; and *A Discourse Concerning Coining the New Money Lighter* (1696).

BARBON (BAREBONE OR BAREBONES), **PRAISE-GOD** (*c.* 1596–1680), was the English leather seller and sectarian preacher from whom Barebone's parliament derived its nickname. He was admitted freeman of the Leathersellers company in 1623 and liveryman in 1634; and about the same time he became minister to a congregation which assembled at his own house, the "Lock and Key," in Fleet street. His preaching attracted large audiences and was sometimes the occasion for riots, as on Dec. 19, 1641, when a mob attacked his house and one man was kicked "as if they meant to beate him into a jelly."

Barbon, who was a man of substantial property, was summoned by Cromwell on June 6, 1653, to sit as member for the city of London in the assembly of nominees which met on July 4, 1653. and which was later named after him. He appears to have taken no part in the debates, and after the members' resignation in Dec. 1653 he sat in no other parliament. But the prospect of the Restoration roused him to political activity and in Feb. 1660 he presented a petition to parliament deprecating any reconciliation with the Stuarts. He was also responsible for the circulation of Marchamont Needham's pamphlet *News From Brussels in a Letter From a Near Attendant on His Majesty's Person . . .* (1660), which retailed unfavourable anecdotes relating to Charles II's morals. Even after the Restoration (May 1660), he made no secret of his opinions, boldly visiting friends in prison, and he was himself held in the Tower of London from Nov. 26, 1661, to July 27, 1662. He died in London and was buried on Jan. 5, 1680.

Barbon's opponents styled him a Brownist (*see* BROWNE, ROBERT) and Anabaptist (*q.v.*), but his congregation originally chose him for his advocacy of pedo-baptism, a practice in defense of which his two books were written. Otherwise the exact nature of his religious opinions is not perfectly clear. In the preface of *A Discourse Tending to Prove. . . Baptism to be the Ordinance of Jesus Christ. As Also That the Baptism of Infants . . . is Warrantable . . .* (1642), he displayed a gift of toleration unusual in a period of much acrimonious controversy.

See Jane Lane, *Puritan, Rake and Squire (1950).* (S. R. BT.)

BARBOSA, RUY (1849–1923), Brazilian statesman and jurist, noted for his championship of the principle of equality of nations, was born at San Salvador, Braz., on Nov. 5, 1849. A lawyer by profession and an orator by temperament, he entered Brazilian public life in the movement to abolish slavery and subsequently took an active part in the republican revolution of 1889. Appointed vice-president and finance minister of the provisional government in 1889, he was one of the principal authors of the constitution submitted to the constituent assembly. He represented the state of Bahia in the Brazilian senate from 1891 until his death.

In 1907 at the second Hague Peace conference, Barbosa achieved international repute as the result of his advocacy of the principle of the legal equality of all sovereign states. He was subsequently appointed to the panel of judges of the Permanent Court of Arbitration at The Hague; upon the establishment of the Permanent Court of International Justice in 1921 he was elected a judge, but because of ill-health, he was unable to take up his duties. Barbosa's writings, among which should be noted his *Letters From England,* deal not only with jurisprudence but also with sociology and politics. He died at Rio de Janeiro on March 1, 1923.

(OR. S.)

BARBOUR (BARBERE; BARBIER), **JOHN** (1325?–1395), author of the first substantial Scottish poem. He may have been at first a scribe or clerk in a noble household, or at court, under the patronage of David II's queen, Joanna. He speaks highly of her in his poetry, and he received his only ecclesiastical preferment as archdeacon of Aberdeen while yet a young man and just before the queen left Scotland in 1357. In Aug. 1357 Edward III granted him a safe-conduct to travel to Oxford. In the September following he was nominated by his bishop as one of three procurators-general to discuss the terms of David II's release from captivity in England. In Nov. 1364 he was granted another safe-conduct into England, probably again on an academic visit. It has been suggested that he spent part of his youth in France; it is certain that he went on pilgrimage to St. Denis in 1364, and that his studies took him again to France in 1368 cum *duobus valettis et duobus equis* ("with two servants and two horses") . . . *causa studendi.* In 1372 he was one of the auditors of exchequer, and in 1373 a clerk of audit in the king's household. He received many grants from the royal bounty, and in Dec. 1388 he was given a life pension of £10 "for faithful services." He died at Aberdeen on March 13, 1395, assigning his pension to the cathedral church.

Barbour completed *The Actes and Life of the most victorious Conquerour, Robert Bruce King of Scotland,* an historical romance in 20 books (nearly 7,000 octosyllabic couplets) in 1376. The background of the *Bruce* is the political history of Scotland from the death of Alexander III (1286) to the death of Douglas and the burial of Bruce's heart (1332). Barbour is a serious historian, writing of "nocht but sothfast thing" in a metrical form which was then judged proper for chronicle. Allowance must be made for literary conventions, and also for the freer medieval notions of historiography; but in the main line of the narrative, and in much of his detail and anecdote, Barbour's concern for accuracy and truly critical assessment of events wins respect. Yet his intention is patriotic and practical as well as commemorative: his story exemplifies the chivalry and idealism of the Scottish heroes, and ends with a prayer that the successors of Bruce and his men may emulate "thair nobill elderis gret bounte." To this end, and appropriately, Barbour draws the devices of metrical romance into service: "he is writing history which has all the qualities of romance in real life." But the *Bruce* remains a harshly realistic story of recent events in the style of the *chansons de geste* rather than in that of the later high romance of idealized chivalry and courtly love. Barbour's knights are not out *en aventure;* they are defenders of their country's independence through what a 15th-century historian calls "disasters, flights and dangers, hardships and weariness, . . . guile, banishment, imprisonment, slaughter, and destruction of those near and dear." Their chivalry is functional, concerned with the defense of freedom and with upholding the rights of the weak against the tyranny of the strong. The style of the poem is vigorous, direct, admirably suited to the

matter. Barbour describes mortal combat with economy and enthusiasm, not as it looks to a literary observer, but as it feels to a participant. His narrative manner has much in common with that of the Scottish border balladry.

A convincing attempt was made by R. L. Graeme Ritchie to identify Barbour as the author of *The Buik of Alexander,* a translation of two French romances *(Li Fuerres de Gadres* and *Les Voeux du Paon)* which are "branches" of the *Roman d'Alixandre. The Buik of Alexander* survives in an apparently unique copy of Arbuthnet's edition (c. 1580); the colophon dates the version 1438. If Ritchie's thesis is correct, Barbour schooled himself in French romance in the most practical way, and brought to the composition of his national epic not only the ideals of chivalry but an arduous apprenticeship in the art of heroic narrative in the French manner.

Wyntoun speaks *(Cronykil,* VIII, 1445–50) of the "Stewartis Oryginalle," a genealogy of the Scottish kings, which Barbour "has tretyt haille / In mater fayr" This work has not survived. It is probable that the "tretis" of "Brutus lynnage" made, says Wyntoun *(ibid,* III, 621), by Barbour "intill a genology," is the same work; medieval genealogists habitually started from the beginning, and Brutus of Troy was by now a popular British original. Modern critical opinion is against the identification of Barbour's "Brut" as a "Troy book" based on Guido delle Colonne's *Historia Destructionis Troiae.*

Correspondences between *The Buik of Alexander* and the short *Ballet of the Nine Nobles* (incorporated in two manuscripts of Scottish chronicles, written in 1510 and 1521, and in Edinburgh University library), and further correspondences between the *Ballet* and the *Bruce,* led Ritchie to attribute the *Ballet* to Barbour. His arguments are inconclusive. Another uncertain attribution is the immense verse *Legends of the Saints,* which was probably begun at Aberdeen touard the end of Barbour's life.

BIBLIOGRAPHY.—(1) *Bruce.* The *Bruce* survives in two manuscripts: one in the library of St. John's college. Cambridge (1487), and the other in the National Library of Scotland (1489). Extracts were incorporated by Andrew of Wyntoun in his *Orygynale Cronykil of Scotland,* the manuscripts of which are earlier than those of the *Bruce.* The earliest surviving printed edition is Henry Charteris's (1571); the second is A. Hart's (1616). Bad 18th-century issues are common. Modern editions: J. Pinkerton (1790)—the first edition to be based on a manuscript; J. Jamieson (1820); C. Innes (Spalding Club, 1856); W. W. Skeat (Early English Text Society, 1870–79; revised for the Scottish Text Society, 1893–95); W. Mackay Mackenzie (1929). On the recension of the text, *see* J. T. T. Brown, *The Wallace and the Bruce Restudied* (1900). For critical discussions, *see* J. M. Ross, *Scottish History and Literature* (1684); T. F. Henderson, *Scottish Vernacular Literature,* 3rd ed. (1910); J. Kinsley, *Scottish Poetry: A Critical Survey* (1955). (2) *The Buik of Alexander,* ed. by D. Laing (Bannatyne Club, 1831); ed. by R. L. Graeme Ritchie, with full critical discussion and the French originals printed facing the Scottish text, 4 vol., Scottish Text Society (1921–29). BARBUDA: *see* ANTIGUA.

BARBUSSE, HENRI (1873–1935), French novelist, author of *Le Feu,* an authentic picture of the life of French conscripts in World War I, was born in Asnibres, Seine, May 17, 1873. He had published a book of poems, *Pleureuses* (1895), and two novels, *Les Suppliants* (1903) and *L'Enfer* (1908), a fiery mixture of naturalism and symbolism, before becoming editor of *Je Sais Tout* (1910). In 1914 he volunteered for the infantry, was twice cited for gallantry and was invalided out in 1917. *Le Feu, journal d'une escouade* (1916; Eng. trans. *Under Fire,* 1917), a merciless report of his two years in the trenches, won him the Prix Goncourt. His pacifism led him to become a Communist and to write for *L'Humanité*: his later books, from *Clartk* (1919; Eng. trans. *Lzght)* to *Staline* (1935; Eng. trans.), were openly propagandist. He died in Moscow, Aug. 30, 1935.

See J. Duclos and J. Freville, *Henri Barbusse* (1946), a Communist biography (RE. L.)

BARCA (Arabic BARQAH), a town and the official name of the eastern province of Libya, Africa, coincident to the conventional western name of Cyrenaica (*q.v.*). The Arab name reflects the fact that during the first centuries after the Islamic invasion the district was administered from Barca, the name of which survived long after the town itself had decayed.

Ancient Barca was founded in the mid-6th century B.C. by Greeks, who had fled from the tyranny of Arcesilaus II *(see* CYRENE) and formed an alliance with the Libyan tribes. After a Persian attack *(c.* 515 B.C.) the city was sacked. In the Hellenistic period it was overshadowed by the port Ptolemais (modern Tolmeita or Tulmaythah) and during Roman and Byzantine times was of minor importance. Its recovery began with the Islamic invasions of the 7th century A.D. when it became the seat of government. In the 9th century new defensive walls were built, but after the Hilallian invasions of the 11th century Barca declined and was soon entirely abandoned. Its modern revival dates from 1835 when the Turks constructed a fort on the ancient site of Barca, round which a township grew up, taking the name alMarj ("the meadows"). The new town expanded notably during the Italian occupation (1913–41), when it was linked with Bengasi by road and rail.

AlMarj (also called Barca) is now the seat of a *mutassarifiya* (district administration) and had an urban population in 1954 of 9,982. It is principally an agricultural and marketing town, with extensive private and governmental farms in its vicinity. Of its ancient history there are few visible remains, though Greek tombs and early Islamic Kufic inscriptions are periodically found.

(R. G. *G.)*

BARCAROLLE or BARCAROLE, a name given to a piece of music, deriving from the songs sung by the *barcaruoli,* the old Italian word for boatmen, particularly, in this case, of the gondoliers in Venice. It is usually in 6/8 time and in a gentle rhythm that was associated with the motion of the boat and the lapping of the waves. Nineteenth-century barcarolles are stylized examples of this model. Ferdinand Hérold, Auber, Donizetti and Offenbach are among the composers who introduced the barcarolle into opera, the last in *The Tales of Hoffmann.* Schubert used the barcarolle rhythm in his song "Auf dem Wasser zu singen" and Mendelssohn in his "Songs without words." Well-known barcarolles for the piano are by Chopin (Opus 60) and a series of 13 pieces bearing this name by Gabriel Fauré.

BARCELONA, COUNTS OF. The county of Barcelona came into existence in 801 when a Frankish army under Louis of Aquitaine (afterward the emperor Louis I) freed the city and surrounding territory from the Moors and incorporated it into the kingdom of the West Franks. The first count of Barcelona, installed in 801, was a Goth, BERA, but after his deposition (820) the county usually was conferred upon prominent Franks. Of these the most important was BERNARD of Septimania (d. 844), who was also count of Narbonne and for a short time exercised great influence at the imperial court.

The first hereditary count was GUIFREDO (Vifredo, Joffre) the Hairy (d. 898), who was awarded the counties of Barcelona and Gerona by the Frankish king Louis II le Bbgue in 878. Guifredo was also count of Urgel and so ruled territory constituting the nucleus of the future principality of Catalonia. He was an able and energetic man who brought about the resettlement of central Catalonia and founded the monasteries of Santa Maria de Ripoll and San Joan Guifredo was succeeded by his sons GUIFREDO BORRELL (d. 911) and SUNYER (abdicated 947), who gradually freed themselves from Frankish control. Independence finally was secured during the reign of Sunyer's son BORRELL (d. 992), partly because the Carolingian dynasty had been replaced by the Capetians and partly because the Franks failed to respond to an

appeal for help when Barcelona was attacked by the Moors in 985.

Borrell's son RAMÓN BORRELL (972–1018), who became count in 992, organized an expedition to Andalusia and sacked Córdoba in 1010. His son and successor BERENGUER RAMÓN I (c. 1006–35) inherited the county in 1018 under the regency of his mother, Ermesindis (d. 1058). Berenguer Ramón's son RAMÓN BERENGUER I the Old (1024–76) imposed taxes (*parias*) on neighbouring Moorish kingdoms, promulgated the celebrated legal code Usatges *de* Barcelona and secured the enfeoffment of the adjacent counties of Ampurias and Pallars. He was succeeded by his sons RAMÓN BERENGUER II (1054–82) and BERENGUER RAMÓN II (1054–97) who reigned jointly from 1076 until 1082, when Ramón Berenguer was murdered, apparently by his brother. Berenguer Ramón reconquered the Tarragona area and reigned until 1097, when he retired to Jerusalem where he died, probably in that year. He was succeeded by the son of Ramón Berenguer II, RAMÓN BERENGUER III the Great (1082–1131), who reigned from 1097 to 1131. He acquired the counties of Besalú (1111) and Cerdaña (1117), fought against the Almoravids and undertook, with the Pisans, a joint expedition against the Balearic Islands (1114–15). He married Douce, countess of Provence, in 1112 which county he bequeathed to his second son. His eldest son, RAMÓN BERENGUER IV (1115–62), who succeeded him in 1131, was the last count of Barcelona to take this as his principal title, for from 1137, when he was betrothed to Petronila, queen of Aragon, Ramón Berenguer IV was also ruler of Aragon (though he himself never assumed the title of king). From the reign of his son, who in 1162 succeeded him with the title ALFONSO I, the counts of Barcelona styled themselves, in the first place, kings of Aragon. By his conquests from the Moors—Tortosa (1148), Lérida and Fraga (1149), Mequinenza, Prades and Siurana (1153)—Ramón Berenguer IV definitively established the boundaries of the principality of Catalonia (*q.v.*).

BARCELONA, the chief Catalan province of northeastern Spain, was formed in 1833 from a number of districts stretching between the Pyrenees and the Mediterranean coast. Pop. (1960 est.) 2,560,464; area 7,734 sq.km. (2,986 sq.mi.); density of population 331 per sq.km. (857 per sq.mi.). The province follows the axis of the river basin of the Llobregat, from which its regions are symmetrically arranged. No province has more diversity of landscapes; it is a cross section of many varied geological zones, namely, the Pyrenees, the scarps and basins of the interior of Catalonia, the Serralada interior, the central depression, the Serralada del Mar, and the coastal plains. Bergada on the borders of the Pyrenees is a mountainous tableland, framed by the Sierra del Cadi to the north. A pastoral region, it centres on Berga (pop. [1950] 7,870) with its lignite mines and cement works. Southwest, in the Cardona valley, the salt hills have been exploited since Roman times, but the potash deposits of Suria, discovered in 1912, produce over 1,000,000 tons annually and are of much greater economic importance. Westward is the arid Segarra, an inlier of the Segre depression, presenting a monotonous series of tablelands and scarps. In the northeast is the geological trough of the *Plana* de Vich at about 2,000 ft., dominated to the north by steep scarps and high tablelands (2,200–2,500 ft.) and merging southward into the rolling country of the Cabreres. The region is drained by the upper Ter and Congost: Vich (16,710) is located as an important route centre in the latter valley. A comparable geological basin of scarps and "badlands" to the southwest is Bages, drained by the Llobregat. Manresa (40,021) with its textile industry is already within the industrial influence of Barcelona. Downstream, the Llobregat cuts through an impressive defile at Montserrat (4,054 ft.), the Catalans' sacred mountain towering over 1,000 ft. above the river, with conglomerate pinnacles sometimes with a sheer fall of 400 ft. It is difficult to imagine these mountains as the ancient deltas (Oligocene) deposited on the northwestern edge of an ancient continent, still represented by the smooth skyline of the *Guillérias* (3,940 ft.) and Montseny (5,617 ft.). These granitic massifs northeast of Montserrat are deeply cut by the rivers separating high plateaus by gorges, a silent forested world formerly notorious for its banditry. Eastward from these remnants of the Serralada interior, the valleys of the Llobregat and Besós etch out a discontinuous lowland in the central depression (300–200 ft.), termed *Vallés* in the northern sector and *Panedés* south of the Llobregat. The clay lands of *Vallés* are the granary of the province with its twin woolen towns of Sabadell (57,594) and Tarrasa (57,729) (*qq.v.*). Granollérs (15,476) is an old centre of the region. The stony lands of the Panedks, gently folded into rolling hills, are famous for their vineyards and the wine centre of Villafranca (10,773).

Overlooking the central corridor to the east are the coastal ranges, interrupted by the valleys of the Llobregat, Besós and Tordera as the limestone massif of Garraf, Tibidabo overlooking Barcelona, the Sierra de Levante and the Costa Brava respectively. The coastal plain is discontinuous except at Mataró (31,011) and the delta of the Llobregat. The latter is Barcelona's market garden with over 50,000 ac. under intensive horticulture.

Barcelona province is the heart of the greatest industrial concentration of Spain and the chief seaport, having three-quarters of the textile manufactures and a high proportion of the chemical and engineering industries. It utilized the hydroelectric power sources of the Pyrenees and its strategic location for its own advancement. See also BARCELONA, city.

See Solé Sabaris (ed.), *Geografía de Catalunya,* 15 parts (1958–). (J. M. Ho.)

BARCELONA, the capital of the province of Barcelona, Sp., since 1833 (until which date it was the capital of Catalonia; *q.v.*), a port, commercial centre and seat of a bishop, is built on a gentle slope facing southeast to the Mediterranean, on the eastern coast of Spain. The city lies in a fertile plain, between the rivers Besós, to the northeast, and Llobregat, to the southwest, and is backed by an amphitheatre of mountains which culminate in the Tibidabo (1,745 ft.). The fortified hill of Montjuich (630 ft.) rises from the sea and separates the city from the mouth of the Llobrégat. Pop. (1960 est.) 1,503,062 (mun.); municipal area 91 sq.km. (35 sq.mi.).

The oldest part of the city is built on a small hill, called by the Romans Monte Taber. The Roman walls are still visible in the Via Layetana, which runs north from the Plaza de Antonio López near the harbour. They can also be seen in other streets including the Avenida de la Catedral, which joins the Via Layetana at right angles in the Plaza de Antonio Maura. In the centre of the old city stands the cathedral. The present structure was built between 1289 and 1450 and the west front was added in the 19th century. Excavations, however, brought to light the remains of a 6th-century basilica. Close by, in the Plaza del Rey, are the chapel and great hall of the Palacio Real Mayor, the royal palace of the counts of Barcelona (mainly 14th century, but with earlier parts) and the 16th-century palace, housing the archives of the crown of Aragon, the most important series consisting of medieval documents and records. South of the cathedral are the archdeacon's house (16th century), containing the city's archives, and the episcopal palace. In the Plaza de San Jaime are the Diputación (congress hall), which was built in the 15th and 16th centuries and contains the chapel of San Jorge and the Orange Tree court. The Gothic town hall is a 14th- and 15th-century building with a modern facade.

Cutting through the old city to the west is the street called the Ramblas leading from the Puerta de la Paz to the Plaza de Cataluiia, the centre of the modern Barcelona where there are numerous banking houses. In the Puerta de la Paz is the Columbus monument (199 ft. high and put up for the 1888 International exhibition) which overlooks the port, and also the Atarazanas, a 14th-century arsenal housing the maritime museum. The Ramblas, known for its charm, has seats beneath the double row of trees down either wide pavement, and many stalls where birds and flowers are sold. The opera house (1847, 1862) and other theatres are there. The Rondas, occupying the ground where the fortifications once stood, enclose in a semicircle the old city and the more modern part west of the Ramblas which, though

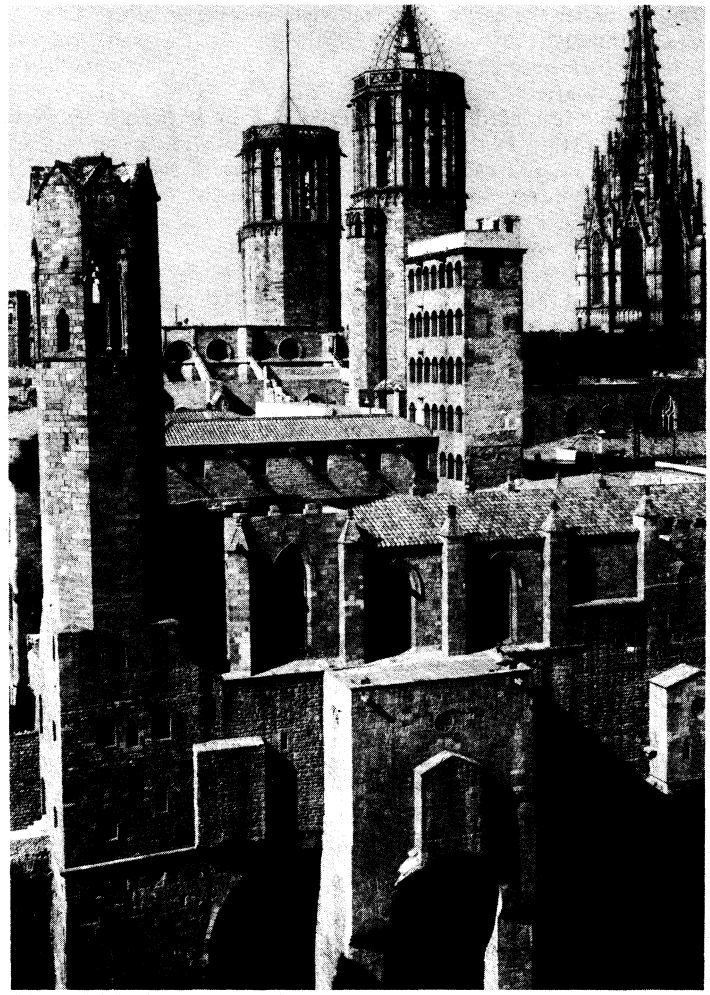
it has lain within the city bounds since 1350, was not built over until the 18th century. At the northernmost point of the Rondas is the Plaza de la Universidad through which runs the broad Avenida José Antonio (formerly known as the Avenida de las Cortes) with, at either end, an arena for bullfighting. The other great thoroughfare, the Avenida Generalisimo Franco (formerly Gran Via Diagonal) is a residential street running southwest-northeast across the upper part of the town to the slopes of Pedralbes where a 14th-century monastery stands on the hillside. In the new part of Barcelona, laid out with broad straight roads crossing each other at right angles, is the huge and elaborate church of the Holy Family designed by Antonio Gaudi and begun in 1882 but far from finished by the early 1960s. The city park. to the east of the old city, occupies the site of the citadel erected in 1715 and destroyed during a revolt in 1868; it contains a zoological garden and aquarium, a natural history museum and a museum of modern art. East of the park, on a tongue of land that forms part of the port, the suburb of Barceloneta was built between 1752 and 1775 in rectangular blocks by order of the Marqués de la Mina, the commandant of the port. From 1864 onward the rapidly-increasing population of Barcelona poured out to the northwest and five villages were incorporated in the city between 1897 and 1904; Horta, to the northeast, was added before 1908 and that of Sarriá in 1922. Much of the hillside of Montjuich has been made into a fine park with terraced gardens, statues and an open-air theatre. Two of the palaces there, built for the International exhibition of 1929, house the Museum of Fine Arts of Catalonia and the Museum of Archaeology.

The university (Universidad Literaria) was founded in 1430 by the magistracy of the city and received a bull of confirmation from Pope Nicholas V in 1450, though Barcelona was a seat of learning long before. The college of medicine and surgery was confirmed by a bull of Benedict XIII in 1400. The university was transferred to Cervera in 1714, restored in 1841, and enlarged in the 1950s when a big group of buildings was put up close to the royal palace of Pedralbes on the lower slopes of the hills near Sarriá. There are also academies of letters, natural sciences and fine arts. The principal charitable foundations are the Casa de Caridad ("House of Charity") and the hospital of Santa Cruz. which dates from 1401 but was moved to a new building outside the city. The old hospital contains the Central library and other learned bodies. while in its grounds is the Royal Academy of Medicine, founded at the end of the 18th century.

Communications within the municipal area were improved in Dec. 1924 by the opening of a tube railway. The Prat airport, 7 mi. W. in the plain of Llobregat, serves international airlines. Railways connect Barcelona with the rest of Spain and with France

The Port and Industries.— The port of Barcelona, at first little more than an open roadstead, was improved in 1474 by the construction of a mole, the Moll de Santa Creu, but the harbour proper dates from the 17th century. It was greatly enlarged after 1873, and again after 1903, and includes an outer and inner harbour. The outer harbour is protected by two breakwaters, the easternmost of which was extended, and is entered by a channel 33 ft. deep; the inner harbour can usually provide accommodation alongside the quays for vessels drawing 24 to 27 ft. The floating dock is able to admit vessels of 10,000 tons. Transatlantic ships call at Barcelona and also those from Mediterranean and northern European ports.

As a commercial city, Barcelona is the centre for the entire industrial area of Catalonia, which has its warehouses there. As an industrial city, it is characterized both by the great variety of its manufactures and by the amount of almost domestic manufacture, carried out in small workshops. The textile industry. especially the cotton industry, revived around 1750. is the most important, but the engineering works, including works for the construction of rolling stock for the railways, employ large numbers of persons. Foodstuffs, raw materials and combustibles form the greater part of the imports, but a considerable quantity of foreign manufactured goods is also imported. The principal exports are wine. olive oil, silk, cork, sandals, fertilizers, woolen and cotton goods and paper.



AMPLIACIONES Y REPRODUCCIONES MAS

ROOFTOPS OF THE OLDEST PART OF BARCELONA WHICH DATES FROM THE 6TH CENTURY

History.—During the Roman period Barcino, a town of the Lacetani, raised to the rank of a colony under the name of Pía Faventia and Julia Augusta (afterward Pía and Augusta), gradually replaced Tarraco (Tarragona) as a seaport. The Bardjaluna of the Moors, who captured it in 713, it became, after its reconquest by the Franks in 801, the chief town of the Marca Hispánica and. by the end of the 9th century, of the independent countship of Barcelona with recognized supremacy over its neighbours. The union in 1137 of Catalonia and Aragon was followed by the rise to political importance of the wealthy merchant class. from which were elected, at first exclusively, the members of the municipal council (*Consell* ***de Cent)*** of Barcelona. Barcelona now became one of the foremost trading cities of the Mediterranean, the rival of Genoa and Venice, and its maritime code, *Consulado* ***de*** *Mar,* dating from the late 13th century. was for long widely recognized as authoritative (see "CONSULATE OF THE SEA")

By 1479, the date of the union of Aragon with Castile, the city had extended its direct jurisdiction by the technical inclusion within the municipality of protected areas scattered over Catalonia. In municipal politics a democratic tradition had been established. The merchants, and sometimes representatives of the lower classes. ruled the council with a marked independence of royal authority which was shown by the successful resistance of the city to John II of Aragon during the ten years ending in 1473.

The power of the Turks in the Mediterranean and the difficulties of commerce due to their politics strongly prejudiced Barcelona and its commerce, as did also the monopoly of the American trade retained by Castile until 1778. Barcelona like most of Catalonia took the part of the Austrian pretender during the War of the Spanish Succession. The city was taken in 1705 by the

English under the earl of Peterborough, and the archduke Charles was enthusiastically welcomed by the population, who paid the price of their enthusiasm when the *Consell de Cent* was abolished by Philip V after the recapture of the city in 1714. No permanent traces were left of the French occupation of Barcelona between 1809 and 1813. In the modern period after 1815, the history of Barcelona was marked by episodes indicative of social, industrial or political unrest, the combination of different forms of unrest in one complex movement being characteristic of the city. Specially serious were the uprising of 1835, when 11 convents were destroyed, and of the "tragic week" in 1909, when over 60 churches and religious buildings disappeared from the city's architectural inheritance.

The military committees of defense had their headquarters there in 1916, and it was there that the movement began which led to the establishment of the military directory in 1923. The evolution of the labour movement from the earlier, pacific phase of the General Workers' union (*Unión General de Trabajadores*), founded at the second Barcelona congress in 1888, to the phase characterized by the terrorist action of the anarchist *Sindicato único* led to the revolutionary strikes of 1919 and 1920. Barcelona was also the headquarters of the Catalonian separatist movement, and on Aug. 2, 1936, following the outbreak of civil war in Spain, it became the seat of an autonomous Catalonian government. During the civil war it became the main centre of Republican strength and suffered some damage from bombing. The fall of Barcelona almost without resistance, on Jan. 26, 1939, doomed the cause of the Republican government and led to its final surrender in March. The city later prospered and expanded.

BARCELONA, a city and river port in Venezuela. It is the capital of the state of Anzoátegui and lies on the west bank of the Neveri river 3 mi. inland from the Caribbean and 150 mi. E. of Caracas. Pop. (1961) 40,733. It is connected by rail with its port of Guanta, 11 mi. distant, and with the Naricual coal fields. The site has not been a healthful one but the surrounding area is fertile and productive. Thus Barcelona naturally became the commercial focus for a region productive of cattle, coal, coffee, cotton, salt, sugar cane and tobacco. Cotton is ginned in the city and leather goods and jerked beef are produced. The development of petroleum in central Anzoátegui brought some prosperity to Barcelona, even though it and Guanta became overshadowed by the phenomenal expansion of Puerto La Cruz (*q.v.*) 6 mi. to the east.

Barcelona dates from 1634, when it was situated several miles farther inland; it was moved to its present site in 1671.

(L. WE)

BARCLAY, ALEXANDER (c. 1476–1552), English poet whose adaptation from the German of the popular Renaissance satire, the *Ship of Fools,* became famous. His nationality is a matter of dispute. William Bulleyn, who probably knew him when he was at Ely, asserts that he was born "beyonde the cold river of Twede" but the records of his ordinations describe him as "of the diocese of Lincoln." Whatever his birthplace, his language is English, not Scots, and his writings belong to the history of English literature. By 1508 he had become chaplain of the college of St. Mary Ottery, Devonshire. Here he adapted the German satire *Narrenschiff* ("Ship of Fools," 1494) by Sebastian Brant (*q.v.*) and even introduced his neighbours into the satire:

> For if one can flatter, and beare a Hauke on his fist,
> He shall be parson of Honington or Clist.

Later on he became a monk in the Benedictine monastery of Ely. There he probably wrote his eclogues, but in 1520 "Maistre Barkleye, the blacke monke and poete" was desired to devise "histoires and convenient raisons to florisshe the buildings and banquet house withal" at the meeting between Henry VIII and Francis I at the Field of Cloth of Gold. He at length became a Franciscan friar of Canterbury. It is presumed that he conformed with the change of religion, for he retained under Edward VI the livings of Great Baddow, Essex, and of Wokey, Somerset, which he had received in 1546, and was presented in 1552 by the dean and chapter of Canterbury to the rectory of All Hallows, Lombard street, London. He died shortly after this last preferment, at Croydon, Surrey, where he was buried on June 10, 1552.

The *Ship of Fools (The Shyp of Folys of the Worlde,* first printed 1509) is not a close translation of Brant but an adaptation "some tyme addynge, somtyme detractinge and takinge away." It describes an imaginary ship's company of fools and worse—the bibliophile who collects books but learns nothing from them, the evil judge who takes bribes to favour the guilty, those too eager to follow the fashion, the priests who spend their time in church telling "gestes" of Robin Hood, and so forth. Some of the scenes have a certain vigour and occasional lines are effective; but for the most part the writing is prolix and pedestrian and the metre (ostensibly "rhyme royal") is very incompetently handled.

Certayne Egloges of Alexander Barclay Priest (reprinted as *Eclogues,* ed. by B. White, Early English Text society, no. 175, 1928) written in his youth, appeared in several partial editions from about 1530. The first complete edition is that in John Cawood's reprint (1570) of the *Shyp of folys.* These were the first formal eclogues in English. In them Barclay gives some entertaining pictures of rustic life: the Sunday games in the village, football, and the struggle for food at great feasts; but they are, like his Italian models, also satires on social evils. Though Barclay drew extensively upon humanist writers, he remained largely medieval in his treatment of their themes. His prose is more accomplished than his verse.

BIBLIOGRAPHY.—His other works are: *The Castell of Labour,* not certainly his (first printed in Paris *c.* 1503; by Wynkyn de Worde, 1506), tr. from the French of Pierre Gringoire; the *Introductory to write and to pronounce Frenche* (Robert Copland, 1521); *The Myrrour of Good Maners* (Richard Pynson, undated), a translation of the *De quattuor virtutibus* of Dominicus Mancinus; a *Cronycle compyled in Latyn by the renowned Sallust* (Pynson, undated), a translation of the *Bellum Jugurthinum; The Lyfe of the glorious Martyr Saynt George* (Pynson *c.* 1515; ed. by W. Nelson, Early English Text society, no. 230, 1955). *The Lyfe of Sainte Thomas* and *Haython's Cronycle,* both printed by Pynson, are also attributed to Barclay, but on very doubtful grounds.

See T. H. Jamieson's edition of the *Ship of Fools* (1874), which contains an account of the author and a bibliography of his works; *A.* Pompen, *The English Versions of the Ship of Fools* (1928). (N. D.)

BARCLAY, JOHN (1582–1621), Scottish satirist and Latin poet whose *Argenis* had great influence on the development of the romance in the 17th century, was born at Pont-à-Mousson, near Nancy, where his father held the chair of civil law. In 1603 he went to London, but in 1605 he was again in Paris. His *Sylvae,* however, was printed in London in 1606, and he remained in London until 1616. He then went to live in Rome, where he died on Aug. 15, 1621.

His *Satyricon* (1603–07), a severe satire on the Jesuits, is modeled on Petronius. His most celebrated work was the *Argenis* (1621. trans. 1623?, 1625, 1629), a long poem of romantic adventure. Its political implications were so marked that many editions were supplied with a key to the characters and names. Its fame on the continent persisted. and inspired learned studies. notably by K. F. Schmid (1904) and L. Bardino (1939).

See also *G.* Langford, in University of Virginia *Abstracts of Dissertations* (1940).

BARCLAY, JOHN (1734–1798), Scottish founder of a religious sect called Bereans because of their diligent study of the Scriptures (Acts xvii, 10, 11), was born at Muthill in Perthshire and educated at St. Andrews university. He was expelled from the Church of Scotland on May 24, 1773, mainly because of his unorthodox assertion that faith was an intellectual act, not merely a passive state. He formed congregations at Sauchyburn in Kincardineshire and in Edinburgh and visited London and Bristol, but after his death in Edinburgh on July 29, 1798, his teafhing was quickly forgotten. His writings, which included paraphrases of the Psalms, were edited by J. Thomson and D. Macmillan (1852).

BARCLAY, ROBERT (1648–1690), Scottish apologist of the Society of Friends, was born at Gordonstoun, near Elgin, on Dec. 23, 1648. He was educated at the Scots college in Paris, and after his return to Scotland joined the Society of Friends. A public discussion of his Theses Theologiae, printed in English, Latin, French and Dutch, was held at Aberdeen (March 14, 1675). Barclay's great work, An Apology for *the* True Christian Divinity held by the Quakers (1678), was written in defense of his Theses. The number of editions through which the Apology has gone since its appearance gives some indication of its importance. In it the Quaker movement defined itself against both Roman Catholicism and classical Protestantism, including Anglicanism, as a religion of the "inner light." Neither the church nor the Scriptures could claim completeness or ultimate authority, hut the Holy Spirit working within the believer granted the assurance of salvation. The Apology was one of the first, and is still one of the. most popular, of systematic statements of Quaker doctrine.

Barclay himself experienced to some extent the persecutions inflicted on the new society, and was several times thrown into prison. In later years he had much influence with James II, who as duke of York had given to 12 members of the society, under the leadership of Penn, a patent of the province of East New Jersey, Barclay being made nominal governor (1682–88). He is said to have visited James with a view to making terms of accommodation with William of Orange, whose arrival was then imminent. He died on his estate at Ury, near Aberdeen, on Oct. 3, 1690. His wife, née Catherine Gordon, who was also a Friend, lived until Dec. 14, 1722.

See Barclay's collected works under the title of *Truth Triumphant* (1692; 2nd ed. 1717–18); and M. C. Cadbury, *Robert Barclay, His Life and Work* (1912). (J. J. PN.)

BARCLAY DE TOLLY, MIKHAIL BOGDANOVICH, PRINCE (1761–1818). Russian field marshal important for his services in the Napoleonic wars, was born at Luhda-Grosshof in Livonia, on Dec. 27 (new style; Dec. 16, old style), 1761. of a Scottish family that had settled in Russia in the 17th century. Entering the Russian army in 1786, he served against Turkey (1i88–89), against Sweden (1790) and against Poland (1792–94). In the 1806 campaign against Napoleon he took a distinguished part in the battle of Pultusk and was wounded in the battle of Eylau, where his conduct won him promotion to the rank of lieutenant general. In 1808–09 he commanded against the Swedes in Finland. In 1810 he became minister of war, a post which he retained until 1812.

In 1812 Barclay was made commander of one of two Russian western armies operating against Napoleon. His tactics of avoiding decisive action and retreating into Russia, however, aroused strong criticism; and after defeat at Smolensk he resigned his command to serve under the veteran general M. I. Kutuzov, who followed the same tactics with success. Barclay was present at the battle of Borodino, but soon afterward left the army. In 1813, however, he was recalled to service and took part in the campaign in Germany. After the battle of Bautzen he was made commander in chief of the Russian forces. In this capacity he was present at the battles of Dresden, Kulm and Leipzig. After the last battle the emperor Alexander I bestowed on him the title of count. Barclay took part in the invasion of France in 1814 and in Paris he received the baton of field marshal. In 1815 he was again commander in chief of the Russian army that invaded France, and at the end of this war he was made a prince. He died at Insterburg (now Chernyakhovsk, R.S.F.S.R.) in East Prussia, on May 26 (N.S.; 14, O.S.), 1818. (I. GY.)

BAR-COCHBA (BAR-COCHEBA; originally SHIMON BAR KOSEBAH or BAR KOZIBA) (d. A.D. 135), leader of the Jewish revolt against the Romans in Palestine during the reign of the emperor Hadrian. The revolt of Bar-Cochba, which began in A.D. 132, was provoked by Hadrian's repressive edicts against Judaism (see PALESTINE) and received considerable impetus when the great rabbi Akiba (*q.v.*) hailed him as the Messiah, giving him also the name Bar Kokhba ("son of a star") instead of his original one. Though the detail of its course is obscure, the rising was at first very successful against great odds. Bar-Cochba took the title of prince of Israel and struck coins in his name and that of the high priest Eleazar. The Romans, however, sent a large army to Palestine under Julius Severus, who reduced the rebel strongholds one by one. Bethar (Bittir, near Jerusalem) fell to the Romans in A.D. 135, Bar-Cochba being killed in the fighting. The remnant of his followers took refuge in the desert by the Dead sea.

In 1960 the Israeli archaeologist Y. Yadin discovered 15 dispatches by Bar-Cochba in a bundle of papyri in a cave in the desert by the Dead sea. From these he appears as a dynamic, stern commander, prompt to enforce obedience.

BARD, a word of Celtic origin applied by classical authors (Gr. bardos, Lat. *bardus*) to Celtic composers of eulogy and satire who formed a learned order lower than those of the druids and the *vates* ("seers"). The word is not used by Caesar, in his account of the manners and customs of Gaul and Britain, but he appears to ascribe the functions of the bards to a section of the druids. Later Latin authors, such as Lucan, used *bardi* as the recognized title of the national poets or minstrels of Gaul and Britain. In Gaul the institution disappeared, but in Ireland and Wales it survived. The Irish *bárd* assisted the *fili* and chanted the eulogies composed by the latter (see IRISH LITERATURE). The Welsh word bardd has always been used as a general term for "poet," but the Laws, codified by Hywel Dda in the 10th century, mention three grades: the *pencerdd* ("chief poet"), the bardd *teulu* ("poet of the war-band") and the cerddor ("minstrel"). In Wales the bardic order declined toward the end of the middle ages, despite a series of *eisteddfodau,* representing formal congregations of bards, held during 1450–1600. However, the bardic technique and conception of poetry continued in the system of *cynghanedd* ("harmony" dependent on alliteration and internal rhyme), the distinctive feature of the canonical metres. In the modern eisteddfod the chaired poet (bardd y *gadair*) composes in strict *cynghanedd* metres, whereas the crowned poet (bardd y *goron*) composes in free metres. For the spurious grading of the bardic order, see EISTEDDFOD.

BARDEEN, JOHN (1908–). U.S. theoretical physicist, a winner of the Nobel prize for physics in 1956, was born May 23, 1908, in Madison, Wis. After receiving the B.S. and M.S. degrees at the University of Wisconsin, he obtained the Ph.D. degree in mathematics and physics at Princeton university. During 1935–38 he was a junior fellow in the Society of Fellows, Harvard university.

Before World War II he was on the staff at the University of Minnesota. During the war he served as principal physicist at the U.S. naval ordnance laboratory, Washington, D.C. In 1945 he joined the Bell Telephone laboratories. While there the work on the transistor (*q.v.*), a device which replaced electronic tubes in many applications, was done. It was for this work that the Nobel prize was awarded—the award being shared with William B. Shockley and Walter H. Brattain (*qq.v.*), also members of the Bell Telephone laboratories.

Bardeen is especially recognized for a theory of superconductivity—the vanishing of the electrical resistance of some metals at low temperatures—and for contribution to theoretical understanding of semiconductors.

In 1951 he joined the staff of the University of Illinois. He was awarded the Ballentine medal of the Franklin institute (1952), the Buckley prize (1954) and the Scott medal (1955), and was elected member of the National Academy of Science. (J. W. B.)

BARDESANES (BARDAISAN; BAR-DAISAN) (154–222), an early Christian writer, was born and died at Edessa in Syria. He lived at court and wrote scholarly treatises and hymns in Syriac, becoming in a sense the creator of Syriac literature. His works were sufficiently popular after his death to cause Ephraem Syrus to write some of his poems to counteract their theological errors. Bardesanes also had a great influence on Mani and Manichaeism.

The only complete work of Bardesanes that has survived,

Dialogue of Destiny, or the Book of the Laws of the Nations, usually is identified with the treatise on fate mentioned in Eusebius' church history, in Jerome's sketches of famous men and in Epiphanius' treatise on heresies. Considerable passages of it in Greek translation are quoted by Eusebius in his *Praeparatio evangelica,* and other fragments of Bardesanes in Greek translation also survive.

Bardesanes often has been treated as a Gnostic, and was even called a Valentinian in Hippolytus' work against heresies. In his own day the orthodox Christians were probably a small minority at Edessa, ranking below Marcionites, Jewish Christians and Encratites. It would be fairer, perhaps, to regard Bardesanes' conceptions as the optimistic reaction of a gifted Christian against Gnosticism. Though he owed not a little to astrology, Greek philosophy and indeed to Gnosticism itself, it would appear that in his own period he was not heterodox. Bardesanes is neither an emanationist nor a dualist. His cosmogony accounts for the universe as the work of the Logos. This work, however, is still incomplete: some darkness remains to be overcome by the forces of light. Christians to him are the "new race," partaking in the conquest of darkness by their free obedience to God. Their outer circumstances depend on fate, but their ethical decisions are free. His emphasis on faith ("you have only to believe the faith and you will be able to know everything"), his monotheism and the fact that his contemporaries accepted him as orthodox seem to indicate that any heretical views he may have held concerned only peripheral matters, on which speculation was inevitable in his day.

BARDI, an Italian family conspicuous among the rich nobility of Florence. Having risen from obscure origins to become during the 13th century the most powerful of Florentine business houses engaged in international trade and banking, the Bardi were naturally one of the overmighty families penalized in the Florentine antimagnate ordinances of justice of 1293 and 1295, of which they remained among the most active opponents. In 1341 they were forced to surrender the lordship of Mangona and Vernio, one-time fiefs of the Alberti counts in the hills behind Florence, which they had lately acquired by purchase; but they soon recovered Vernio. Their political importance ceased abruptly in 1345 when injudicious loans to Edward III of England, aggravated by the cost of local war with Lucca, involved them in the most publicized and resounding bankruptcy of medieval times. However, they continued trading and retained a place among the richer nobles of Florence. Notable among them was Giovanni, conte de Vernio (1534–1612), student and patron of music and letters. The family died out in the 19th century, but the name survives in the Via de' Bardi in Florence, where their urban properties were situated.

See F. de' Bardi, *Vernio, vita e morte di un feudo* (1883); *A.* Sapori, *La crisi delle compagnie mercantili dei Bardi e dei Peruzzi* (1926).

BARDI, GIOVANNI, COUNT OF VERNIO (1534–1612), Italian musician, writer and scientist, who was born in Florence, Feb. 5, 1534, was the leader of the group known as the Florentine *Camerata,* which he founded about 1580. Their attempts to revive Greek music created the monodic style which prepared the way for opera (*q.v.*). The group included the poet O. Rinuccini, the theorists V. Galilei and G. Mei, and the composers G. Caccini, J. Peri, P. Strozzi, E. de Cavalieri and C. Malvezzi, with most of whom Bardi collaborated in court entertainments from 1579 to 1608. His *Discorso mandato a Caccini sopra la Musica Antica* (1580) develops ideas similar to those of Galilei and Caccini: counterpoint obscures the words in musical settings, and should be abandoned; music should consist of a single vocal line, lightly accompanied, exactly reflecting the rhythm and intonation of speech. Ironically, Bardi's only surviving compositions are two highly contrapuntal madrigals. He died in Florence in 1612.

BARDSEY, an island off the tip of the Llyn (or Lleynj peninsula of Caernarvonshire, north Wales. Pop. (1951) 14. Area 0.7 sq.mi. The name is derived from Old Norse "Baror" (a personal name) and "ey" (island) and dates from the Viking age. The Welsh *Ynys Enlli* means "island of the current," referring to the swift and dangerous tide race of Bardsey sound. The island is a continuation of the Caernarvonshire hills separated from the mainland by a submergence of Pleistocene date. The sound thus formed is about 2 mi. wide and connects Caernarvon and Cardigan bays. A religious house, the earliest in Wales, was founded on the island by St. Cadfan in the early 6th century. It was later superseded by an Augustinian abbey, dedicated to St. Mary. The legendary burial place of 20,000 saints, Bardsey was famous as a goal of medieval pilgrimages. After the Dissolution, the abbey was granted to a Caernarvonshire squire, whose descendant retains ownership of the island. A favourite haunt of 16th-century pirates, the island was later ruled by a "king" chosen from among its fisher-farmers. It has a lighthouse, erected in 1821, and is a nature reserve. A bird and field observatory was established on the island in 1954. (W. O. W.)

BAREILLY, a city in Uttar Pradesh, north central India, headquarters of the Rohilkhand division and Bareilly district, is on the Ramganga river, 133 mi E.S.E. of Delhi. Pop., city, (1961) 273,204. Municipal area 23 sq.mi. It has a suburb for railway employees and an extensive military cantonment. Its architectural monuments include a fort built in 1657 and a number of fine mosques of which the chief are the Mirzai Masjid (1579), Jamma Musjid ("great mosque") built in 1667, Gudri-ka-Masjid and Husain Bagh Baradari. Other places of note are the palace of the nawab of Rampur, the Mirzai Bagh and Company Bagh gardens. the garden and temple of Champat Rai, the tomb of Hafiz Rahman Khan (1775) and the American Methodist Episcopal mission. Bareilly college, affiliated to Agra university, was founded in 1837. The Indian Veterinary Research institute is in the suburb of Izatnagar.

Bareilly is a commercial centre on the road and railway (Northeastern metre-gauge system) linking Mathura and the plains with the Himalayan districts. It is at the junction of these routes with the main road and Northern railway system (broad-gauge) main line from Delhi to Lucknow. Another Northern railway system link runs westward to Chandausi on the Moradabad-Aligarh line.

Bareilly is known for its indigenous sugar industry. Manufactures also include rosin, catechu, matches, textile bobbins, cotton rope, tents, *durris* (coarse cotton rugs) and furniture.

The city, a 16th-century settlement, was built mainly by Makrand Rai, a governor appointed by the Mogul emperor Shah Jahan in 1657. It was the capital of the Rohillas *(see* below) in the 18th century, and in the 1857 ,Indian mutiny was the centre of a considerable popular rising against the British.

BAREILLY DISTRICT is open country on the southern fringe of the Himalayas, sloping gradually from north to south. Pop. (1961) 1,481,311. Area 1,591 sq.mi. Its soil is fertile and is watered by the Ganges tributary Ramganga and its subtributaries, and by canals. To the north of the district is a continuation of the *Tarai* (*q.v.*), whose forest (jungle) intrudes into it at several places for a few miles. Two-thirds of the people depend on agriculture; the main crops are wheat, rice and sugar cane.

Twenty-one miles northwest of Bareilly is the ancient fortress city of Ahichhattra, near the modern village of Ramnagar. In the *Mahabharata* it is mentioned as the capital of the kingdom of northern Panchala and a centre of Vedic culture. The Chinese Buddhist traveler Hsuan Tsang records in the 7th century A.D. that there were ten Buddhist monasteries with 1,000 monks and nine Brahmanical temples of Siva. Buddha is said to have

preached there for seven days to convert the Naga king, and the emperor Asoka (*q.v.*) later built a stupa or relic mound on the hallowed spot. These structures are now marked only by mounds and heaps of ruins.

ROHILKHAND DIVISION consists of the districts of Bijnor, Budaun, Moradabad, Pilibhit, Rampur, Shahjahanpur (*qq.v.*) and Bareilly. Total pop. (1961) 8,505,041. Area 11,705 sq.mi.

The Rohillas, a migrant Afghan or Pathan clan, gained control of a rich tract corresponding roughly with the modern division during the breakup of the Mogul empire in the early 18th century. It was the Rohilla raider-chief, Ghulam Kadir, who, enraged at not finding treasure in the Delhi palaces, blinded Shah Alam in 1788. (B. Sr.)

BARENTS, WILLEM (d. 1597), the most important Dutch navigator to search for a northeast passage to Asia, was born about the middle of the 16th century. In 1594 he left Amsterdam with two ships and reached the west coast of Novaya Zemlya, which he followed northward until forced to turn back near its northern extremity. In the following year he commanded another expedition of seven ships which made for the strait between the Asiatic coast and Vaigach Island, but was too late to find open water. On his third journey he had two ships and sighted both Bear Island and Spitsbergen. The ships then separated and Barents' vessel, after rounding the north of Novaya Zemlya, was beset by ice and he was compelled to winter in the north. As his ship was not freed in 1597, his party abandoned her, leaving in two open boats on June 13, and most of its members escaped. Barents himself died on June 20, 1597. In 1871 the house in which he wintered was discovered, and many relics from it are preserved at The Hague. In 1875 part of his journal was found. The arctic sea between Spitsbergen, Novaya Zemlya and Scandinavia was named after him.

See Gerrit de Veer, *Three Voyages . . .*, trans. by the Hakluyt Soc. (1876) from de Veer's text (1598).

BARENTS SEA, a part of the arctic water system, is framed by north Norway and the U.S.S.R. on the south, by Novaya Zemlya on the east, by Franz Josef Land on the north, and by Spitsbergen and Bear Island on the west. It is shallow, being entirely on the continental shelf, and occupies an area of 529,096 sq.mi. The first voyages into the sea were probably those of the Vikings in the 9th century. Russians appeared on the Murman coast in the 12th century, and in 1496 the Russian ambassador to Denmark sailed to his post through the Barents sea. In the 16th century English and Dutch seamen penetrated into it when searching for a northeast passage. In particular the Dutch sailor Willem Barents in 1594–97 crossed it several times, and died on the east coast of Novaya Zemlya while wintering there. The sea was first named after him on a map published by A. Petermann in 1853. In the 19th century a number of scientific expeditions, Russian and Norwegian, worked there, and Franz Josef Land was discovered in 1873. Since 1898 there has been a permanent Russian scientific station working on Barents sea problems. The zoologist N. M. Knipovich (1862–1939) was closely associated with this work at its start and for many years thereafter.

The air temperature over the Barents sea rarely goes far above 50° F. in summer, but in winter temperatures range from 14° to below zero. The Gulf stream (the North Atlantic current) brings to the southern part of the sea salt and relatively warm water of Atlantic origin from the west coast of Norway. In the northern part, however, the surface water is mostly polar, relatively fresh and cold. This cold water reaches to the neighbourhood of Bear Island and, when south winds bring relatively warm air to this region, extensive fogs are formed over the cold water. Ice never covers the whole sea, but in winter all but the southwest quadrant is covered. Access by ships to the White sea is thus impeded, but not to Murmansk (*q.v.*) which is almost the only Soviet port remaining ice-free all the year round. In the summer the ice retreats to the extreme north of the sea, and navigation to northern Novaya Zemlya and even Franz Josef Land is not difficult. The ice is almost all sea ice of local origin, but icebergs from the glaciers of Spitsbergen and Franz Josef Land are also found.

The importance of the fisheries in the Barents sea is increasing, the greater number of fish now found there being due in part to the general warming of the climate *(see* ARCTIC, THE: *Climate).* In the southern parts with their warmer water a number of marketable fishes are found on the sea floor. There are Russian fisheries in the White sea, reserved exclusively for them, and in the territorial waters on the coast; in the open sea the catches are made mostly by Russian, Norwegian and British trawlers which work even in winter in spite of great difficulties due to storms and the long darkness. The development of the steam trawler industry in the Barents sea and in Icelandic waters is partly due to the diminished returns from the fishing of the North sea. The most important fish in the Barents sea are cod, haddock and plaice, also Norway haddock. The most important mammals are the Greenland seal, which gather for breeding in January and February at the entrance to the White sea. Bearded seal, ringed seal, some toothed whales, polar bears and walrus are also found.

See also ARCTIC, THE: *The Arctic Ocean.* (T. E. A.)

BARÈRE DE VIEUZAC, BERTRAND (1755–1841), French revolutionary and member of the committee of public safety, was born at Tarbes on Sept. 10, 1755. He served as an advocate in the *parlement* of Toulouse (1775) and as a councilor in the *sénéchaussée* of Bigorre and became a member of the academies of Montauban and of Toulouse and of a masonic lodge. He married Elisabeth de Monde, a pious young woman of the impoverished nobility, in 1785, hut saw no more of her after 1792. Elected to represent Bigorre in the estates-general of 1789, he frequented the house of Mme. de Genlis in Paris and founded an interesting and objective periodical, *Le Point du jour.*

Under the Constituent assembly, he was a member of the committees on *lettres de cachet* and on domain property. He joined the Society of Friends of the Truth and the Jacobin club, but rarely appeared at the latter. Appointed tutor to Paméla, the future Lady Fitzgerald, a natural daughter of the duc d'Orléans (Philippe Égalité), he seems to have remained attached to the latter and his family. Elected a judge in the tribunal of cassation in 1791, then deputy for Hautes-Pyrénées in the Convention in Sept. 1792, he served in the committees on legislation, on the constitution and on education and presided over the assembly on several occasions. In 1793 he voted for the death of Louis XVI and played an important part in the refusal of the stay of proceedings against him. He also did much to bring about the arrest of the Girondin deputies after June 2.

Barère's clearheadedness and extensive knowledge made him an important member of the committee of public safety, and he produced more than 200 reports on a great number of subjects. Believing that only vigorous measures could save the country, he collaborated with Robespierre, who regarded him as "a weak man but never the enemy of the public welfare." Yet Barère showed his opportunism and social conservatism on 9 Thermidor (July 27, 1794), when he deserted Robespierre's party. Even so he was proscribed by the Thermidorians in April 1795, and imprisoned first on the Isle of Oléron, then at Saintes. In the following winter he escaped and spent five years in hiding in Bordeaux. There he wrote *La Pensée du gouvernement, La Libertk des mers,* and began his *Mkmoires,* but had to sell most of his possessions to keep himself alive. Barère was a secret agent under Napoleon I, but in 1816, after the Restoration, had to go into exile as a regicide at Brussels. He returned to France in 1830, settled at Tarbes in 1832 and was elected to the general council of Hautes-Pyrénées in 1834. Louis Philippe granted him some allowances. He died on Jan. 13, 1841.

See R. Launay, *Barère de Vieuzac, l'Anacréon de la guillotine* (1929); L. Gershoy, "Barère in the Constituent Assembly," *American Historical Review, vol.* xxxvi *(1930).* (MA. Bo.)

BARETTI, GIUSEPPE MARC' ANTONIO (1719–1789), Italian critic who attacked some literary fashions of his time, and was a friend of Samuel Johnson, was born in Turin on April 25, 1719, and educated in Milan and Venice. In 1751 he went to London and became associated with Johnson's circle; he returned to Italy in 1760 and described his journey in his *Lettere familiari* (1762–63), later elaborated in *A Journey From London to Genoa* (1770–71). Under the pseudonym Aristarco Scannabue

he published the periodical *Frusta letteraria* (1763–65), in which he attacked contemporary writers. In 1766 he went to live in England, where in 1769 he was involved in a street fight in which he killed, in self-defense, one of his attackers. At his trial, at which he was acquitted, evidence was given for him by Johnson, Sir Joshua Reynolds, David Garrick, Oliver Goldsmith and others. Baretti published the *Discours sur Shakespeare et sur monsieur de Voltaire* in 1777 and a *Scelta di lettere familiari* which, apart from providing a text for students of Italian, is the most serious expression of his moral and literary opinions, in 1779. His numerous other publications include *An Account of the Manners and Customs of Italy* (1768), in answer to Samuel Sharp's libelous *Letters from Italy* (1766), *A Dissertation Upon the Italian Poetry* (1753) and *The Italian Library* (1757), which was intended to make Italian literature better understood in England. In his letters he shows himself an enemy of pedants and amateurs alike. He died in London on May 5, 1789.

Baretti's works were collected in seven volumes (1813–20) and in four volumes (1838–39); the *Prefazioni, Scelta delle lettere, Frusta,* and *Epistolario* were edited by L. Piccioni in the "Scrittori d'Italia Series" (1911–36).

BARGEBOARD, also VERGEBOARD, as sometimes written, in architecture, the exposed board running down the slopes of a projecting gable roof: a false rafter. Bargeboards are frequently decorated. In the Tudor period in England, and in the late Gothic period throughout Europe, they became extremely rich decorative features.

BARGES AND CANAL CRAFT. The term "barge" was originally applied to a small sailing vessel, but later came into general use to designate a flat-bottomed boat used for carrying goods on inland waterways. A state barge was a heavy, often highly ornamented vessel used for carrying passengers on cêremonial occasions. This article describes the barges and other craft used for commercial transport on canals and rivers in the United States and in Europe, their methods of propulsion and their cargo. For related information *see* INLAND WATER TRANSPORT; RIVER AND RIVER ENGINEERING; WATERWAYS, INLAND.

UNITED STATES CRAFT

Early Types.—In the United States and Canada the use of lighters, barges to load and unload vessels in harbours, was introduced from England in colonial times. The earliest craft used in river transportation were the canoes and dugouts of the pioneers. Then the boxlike bateaux came as the requirements of commerce grew. Bateaux, lacking maneuverability and cargo capacity, were succeeded by Durham boats, which had semi-pointed bows and were typically 60-ft long with a 15-ton capacity. They were usually provided with a sail for use when the wind was astern. but if it blew from any other direction they were unmanageable.

To meet requirements for maneuverability and speed, the keelboat appeared at the end of the 18th century. As the name implies, this type was fitted with a keel,. and it also had a pointed bow and stern. Propulsion was provided by sail, oars or poles, the latter being most common in shallo rivers. One end of each pole was fitted with a "button" or shoulder piece, while the opposite end was ironshod for digging into the river bed or bank. Polers pushed in relays while walking along planks mounted on the gunuales. On the Willamette river in Oregon a keelboat was successfully propelled by paddles operated by six horses on a treadmill. By 1810 there were over 400 keelboats in service on the Mississippi and Ohio rivers; some of these were packet boats on scheduled runs.

River Barges.—Around 1817, by which time the western river steamboat had proved its superiority on the Mississippi system (*see* MISSISSIPPI RIVER STEAMBOAT), keelboats gave way to scowlike barges. Until shortly after the middle of the 19th century, barges were towed alongside side-wheelers. Then, with the rising popularity of the stern-wheeler, modern Mississippi system towboat methods evolved. Barges are now pushed, linked closely together by prawls, cables and ratchets. They can be readily broken off and moored to the river bank or levee for exchange of cargo without loss of time to the towboat. Pushing, as opposed to towing reduces crew requirements and eliminates the adverse current produced under the barges by the propellers. Frequently more than 20 barges are pushed by one diesel towboat. Over 67,000 tons have been carried in a single tow—more than five times the capacity of many modern seagoing freighters.

The technique of pulling barges astern has been in general use in tidal rivers such as the Hudson. Among the earliest barges to be towed on this stream were the safety barges, passenger craft which had sleeping accommodations; they were towed by steamboats. Their use stemmed from a justified fear of boiler explosions.

Specialization in cargo on western rivers produced many kinds of barges. There are carriers for coal, chemicals. petroleum, automobiles. metal products, grain and general cargo. A typical river barge is 175 ft. long with a 26-ft. beam. General cargo carriers are larger, typically 300 ft. by 48 ft. with a capacity of about 3,000 tons.

To satisfy demands for speedy transportation, the integrated. articulated tow is widely used on the Mississippi and Ohio rivers and to some extent on the Columbia. This is a streamlined linkage of boxlike steel barges of equal dimensions, the width of the linkage generally matching that of the towboat. A headpiece, or special barge with a spoon bow, is secured at the forward end of the tow to act as a bow for the entire linkage.

Canal Craft.—The horse-drawn canal boat appeared during the construction of the Erie canal (1817–25). For a full century this craft was a familiar sight on an intricate system of canals which spread from New York to western Indiana. Typical of luxury packet boats of the 1830s was the 49-ton "Congress," capable of making 100 mi. a day. She was 77 ft. long with a beam of 14 ft., 3 in. to fit 15-ft. locks.

The opening of the New York State Barge canal in 1918 increased manyfold the volume of traffic between the port of New York and Lake Erie. Scowlike barges, chiefly of wood construction and with a 900-ton capacity. have traditionally been towed on this route. However, several types of self-propelled barges driven by diesel machinery have found favour. Low power, a maximum speed of 10 knots, and a large cargo-carrying capability are characteristic of these vessels, some petroleum barges being capable of transporting over 700,000 gal. of fuel in bulk. Because of the low bridges spanning this canal, self-propelled barges are devoid of superstructure, and many are equipped with telescoping pilot houses.

Seagoing Barges.—On the Atlantic coast, barges were originally hulks of schooners. Most modern construction is of steel, but barges have retained many schooner features, such as masts for aiding the tug with sail when the wind is favourable. On the Pacific coast, barges are built in the form of huge steel scows. The largest of these is 300 ft. long with a 75-ft. beam and with a capacity of 3,000,000 gal. of petroleum and 170,000 cu.ft. of dry cargo. (C. W. TH.)

EUROPEAN CRAFT

Early Sailing and Drawn Barges in England.—The boxlike "swim-ended" lighter of the Thames was improved into the round-bowed hull, spritsail barge, which was rigged so efficiently that two or three men could sail it as far as the ports of France, Belgium and Holland. "Stumpies" for river use carried a mainsail, foresail and mizzen; seagoing barges had also a topsail and jib, while the coasting type sometimes carried a square sail for

running before the wind. On the Tyne, Trent and Humber rivers bluff-ended keels had one or two square sails, as did the western barges of Samuel Pepys' day. On the Norfolk Broads, keels were replaced by wherries, which had a high-peaked mainsail only. The Severn "trows" originally had a square sail, but later were ketch- or schooner-rigged. The Mersey had its round-chined "flats" with foresail and mainsail.

On canals narrow boats, horse-drawn or towed by men, carried goods far inland. In every type shallow draft was essential, hence hulls were flat-bottomed, and on Thames and Humber craft leeboards facilitated sailing to windward and masts could be lowered for going under bridges. All made full use of the tides, assisted by sail and oar, but beyond tidal limits haulage against the current was laborious. Sails are no longer used, except in a few auxiliaries. Many hulls. often over 50 years old. have been fitted with diesel engines, while self-propelled narrow boats have supplanted animal traction. (E. J. MA.)

Modern Barges.—Craft used for inland navigation must be adapted to suit special conditions. The aim is to utilize as fully as possible the depth of water available, which in western Europe generally varies between 5 and 16 ft. However, because a craft in motion lies deeper in the water than when at rest, the whole depth cannot be made use of, and barges generally have a draft of 5–10 ft.

Sizes and Speeds.—Where a waterway is curved the barge must lie obliquely to the banks. The length of each craft therefore depends upon the radius of the curves and the width of the channel, as well as upon the length of the locks encountered. The greatest length of craft possible on the rivers of western Europe is about 400 ft., but most barges are shorter and some are only about 125 ft. long. They need to be as broad as is compatible with the design of the locks and yet, on a river. as slim as their speed requires. Compromises between these two requirements result in widths of 16–36 ft. Modern waterways are generally suited for the passage of craft of from 280 to 2,000 tons, although the large Russian rivers can accommodate barges of 4,500 and even 10,000 tons.

On rivers, the speed of the craft must be markedly greater than that of the current, and barge speeds range from 8 m.p.h. on a slow river like the Seine to 14 m.p.h. on the Rhône. Because of the laws governing the resistance of the water to the progress of a boat (see NAVAL ARCHITECTURE: Resistance and *Propulsion*), a fast craft must be longer than a slow one, and on a swift-current river like the Rhône the minimum economical length is about 240 ft. On a canal a boat can only move forward if the water flows around and behind it, and when a certain speed has been reached the resistance to the barge's forward movement increases considerably and can cause serious damage to the bank. For this reason the speed limit on canals is low—about 3 m.p.h. on the small French canals. On very large canals, however, barges can travel at 12 m.p.h.

Living Arrangements.—The usual custom in western Europe is to have on board a crew which navigates only during the day, the craft stopping at night. The crew and their families live on board, and modern barges have spacious, comfortable quarters. In a few cases, however, navigation is continued at night, the boat having two crews whose families do not live on board.

Propulsion.—On waterways where the traffic is slight. diesel tractors are often used for haulage. and animals were still sometimes used at the beginning of the 1960s. Electrical trolley tractors are employed where the traffic is large enough to justify the cost of installation. However, most craft are self-propelled or hauled by tugs.

Propulsion by steam, first used for a tug on the Forth and Clyde canal in 1802, has virtually disappeared from the rivers of western Europe, being used only on some Rhine tugs. Because the power required is too slight to justify the use of turbines, almost all the motors are diesels. The power of self-propelled barges varies from as little as 80 h.p. on small canals to 1.000 h.p. on the Rhône. while that of tugs ranges from 500 to 3.000 h.p.

In the early 1960s a few large tugs on the Rhine still had side paddle wheels, and tugs with stern wheels were in use on African, Asian and South American rivers, but propulsion was usually by screw propellers. The use of propellers with vertical blades was becoming popular, especially on the Rhine, because of the greater ease such propellers give in handling the craft.

When the water is sufficiently shallow, it is inevitable that the screw is partly above the surface or, if submerged, that it operates inefficiently. In the first case, the water can be made to rise artificially around the screw by placing a cover over the screw, a technique that is widely used in western Europe; in the second case, the action of the screw can be improved by placing it in a tunnel.

Where the water is very shallow, perhaps only two feet, as on some rivers of the U.S.S.R. and in Africa, propulsion is sometimes accomplished by a pump which forces the water back toward the stern.

The powerful craft on the Rhine and the Rhône have steering devices composed of three rudders working together. This arrangement allows the pilot to maneuver the rudders without using a servomotor. A boat fitted with a Voith-Schneider propeller has no need of a rudder, because the propeller itself steers the boat. When a movable Kort nozzle is fitted, it too acts as a rudder. Craft which are towed have a rudder composed of two parts. The rear part folds up vertically beside the other part so that when the rudder is put hard over at right angles in a lock, the over-all rudder length does not exceed the width of the craft. These barges are often provided with a small bow rudder in order to resist the tendency to drift with the wind when they are empty.

On the Seine, craft towed by a tug are attached to one another by a single cable. On the Rhine, where the current is strong, each barge is attached to the tug by an individual cable in order to ease the cable strain and to make the barges easier to maneuver. It has, however, become a common practice to use a self-propelled barge to haul another, called a dumb barge, which has no motor. By 1960 this method was gradually eliminating the use of tugs in France. although they were still in steady use on the Rhine and Danube.

In the U.S.S.R., as in the United States, propulsion from behind is much used. Coupling the pushing tug close to dumb barges converts these temporarily into a self-steering, self-propelled unit. This method. which requires less power and obviates the need for crews of the craft so propelled, has spread less quickly in western Europe, where the rivers lack the necessary width. However, a French device allows the craft to be so attached that the whole train can respond to the curve of the banks or to the swell of the current while still under the control of the propelling tug.

Types of Cargo.—Dry goods carried in bulk are chiefly coal, grain, sand and iron ore. For coal, and especially coke, both of which have a low density, the capacity of the barge must be as great as possible and the hatches must be large to facilitate the handling of the goods by grab bucket and crane. The same is true of grain, with the added requirements that the plank lining at the bottom must not let the grain through, and the covering must he rain proof. Sand can be carried in the same type of craft, but when loaded by the force of a jet of water. the barge must have watertight longitudinal coinpartments to facilitate unloading by grab bucket. Iron ore has a high density and it is therefore best loaded into a small compartment having a plank lining to allow unloading with grab buckets. For iron ore use is also made of floating containers small enough to be placed on railway wheels for unloading at the steelworks; these containers are assembled in a large train between a propelling and a guiding tug.

Dry goods carried in packages require maximum capacity with rainproof coverings. When the cargo is of low density, *e.g.,* bales of cotton, the steering wheel is placed forward so that the steersman's view is clear. Barges for frozen cargo are uncommon in western Europe, though less so in the U.S.S.R.

Liquids carried are principally hydrocarbides, for which the hull itself acts as a tank. For heavy hydrocarbides and asphalts, a heating system is provided. In view of the danger involved in carrying hydrocarbides, particularly those which are highly volatile, the construction of these craft is subject to strict regulations.

Barges of this kind are sometimes used for carrying edible oils and molasses. In France, tanker craft transport much wine in bulk. To avoid adulteration, the tanks have special linings cleaned after each voyage. Chemical firms have special craft for the bulk transport of liquid chlorine, sulfuric acid and other chemicals.

(J. E. P. V.)

BARGHEST (BARGUEST, BARGEST), the name given in northern England, especially Yorkshire, to a monstrous goblin dog with huge teeth and claws which appeared only at night, the sight of which was supposed to be an omen of death. The Demon of Tidworth, the Black Dog of Winchester, the Padfoot of Wakefield and the Barghest of Burnley were all similar apparitions. Their Welsh counterparts were red-eyed *Gwyllgi,* "the dog of darkness," and *Cwn Annwn,* "the dogs of hell": in Lancashire the monster was called Trash; Skriker or Striker because its broad, sometimes backward-pointing feet made a splashing noise and because it howled or "skriked" horribly; in east Anglia, where it was thought to be amphibious, it howled, but had only one eye and moved silently and was known as Black Shuck or Shock; in the Isle of Man it was called *Mauthe* Doog and is mentioned in Scott's *Lay of the Last Minstrel* as "the spectre hound in Man." The Manchester barghest was said to be headless. Those who saw one clearly, it was believed, would die very soon, whereas those who glimpsed it only faintly would not die until some months later. "Barghest" has been explained as deriving either from Old English *burg-gast* ("town-ghost"), or from German *Bahrgeist* ("bier-demon") or *Bargeist* ("bear-demon").

BARHAM, RICHARD HARRIS (pseudonym; THOMAS INGOLDSBY) (1788–1845), English humorist and author of *The Ingoldsby Legends.* was born at Canterbury on Dec. 6, 1788 At the age of seven he inherited a small Kentish estate including the manor of Tappington Everard, scene of many of the *Legends.* Educated at St. Paul's school and at Brasenose college. Oxford, where he developed his habit of working through the night. he first studied law but was ordained in 1813. The next year he married; he had many children, five of whom predeceased him. He lived in Kent until 1821. when he moved to London on being appointed a minor canon of St. Paul's cathedral. A staunch Tory and High Churchman, he was made priest in ordinary to the Chapel Royal and held various city livings.

He had begun to write at 14 while recovering from an accident, and had published two novels. He joined the Garrick club of which his friend Charles Bentley, the publisher, was a member, and there he met Dickens In 1837 he began to contribute to the new *Bentley's Miscellany* the series of exuberant tales, ranging from the macabre to the hilarious, which were published as *The Ingoldsby Legends* (1840, 1842 and 1847; selected and edited by J. Tanfield and G. Boas. 1951). Most of them are in flowing verse of great sweep and variety, often satirical and with comic rhymes; but the medieval ritual and traditions they portray are based upon solid antiquarian research.

Although the best of entertainers. Barham remained primarily a priest His kindness and sound judgment made him a trusted counselor. valued friend and frequent peacemaker, and he was intolerant of all that was mean or false. He died in London on June 17, 1845. The poem "As I Laye A-Thynkynge," composed on his deathbed, has quiet beauty.

See R. H. D Barham, *The Life and Letters of the Rev. Richard Harris Barham,* 3rd ed. *(1880).*

BAR-HEBRAEUS ("Son of the Hebrew") (1226–1286), known also by the Arabic name Abu 'l-Faraj, one of the greatest Syriac writers and a man of wide learning, made noteworthy contributions to most branches of science and literature. He wrote treatises on grammar astronomy. mathematics, medicine, philosophy, theology and history. reinvigorating the Syriac language and making Islamic learning accessible to his fellow Jacobites. The son of a Jewish physician, he was born at Melitene (mod. Malatya). He studied there and at Antioch and Tripolis (Lebanon). becoming a monk when he was about 17 years of age and being ordained Jacobite (Monophysite) bishop of Gubas near Melitene when he was 20. Bishop of the neighbouring diocese of Lakabhin in 1247 and of Aleppo in 1253, he was made *maphrian,* the rank next to patriarch, of the east in 1264 by the patriarch Ignatius III.

Diligent in the care of his diocese and in study and writing. he died at Maragah, Persia. on the night of July 30. 1286. mourned even by his rival, the Nestorian patriarch, and was buried at Mosul, Iraq, under the inscription: "This is the grave of Mar Gregory John," John being his baptismal name and Gregory probably the name he adopted when he became bishop.

His brother enumerates 31 books written by Bar-Hebraeus, some in Arabic, some translated from Arabic and the rest original Syriac works. Most widely known is his Syriac *Chronography,* comprising a secular history from the Creation and an ecclesiastical history dealing chiefly with the patriarchate of Antioch and with the Eastern Syrian Church. Using earlier works. which it supplements and corrects, it contains, besides history, much miscellaneous information. Of the secular history Bar-Hebraeus prepared an abridged Arabic version, adding references to Moslem sources. Important also is his *Ausar Raze* ("Storehouse of Secrets"), a biblical commentary more philological than theological, but citing various Fathers as well as the Syriac and Greek biblical versions.

The *Chronography* was translated from the Syriac by E. A. W Budge. 2 vol. (1932): Bar-Hebraeus' *Scholia on the Old Testament,* pt. i: Genesis–I1 Samuel, was edited by M. Sprengling and W. C. Graham (1931).

See A. Baumstark, *Gesrhichte der syrischen Literatur,* pp. 312–320 (1922); J. Gottsberger, *Barhebräus und seine Scholien zur heiligen Schrift* (1900). (W. D. McH.)

BARI, a Nilo-Hamitic-speaking people living near Juba in the southern Sudan. They number 35,000 and live in small villages scattered across the hot, dry, flat countryside of the Nile valley. Their staple crops are millet and eleusine and they also keep cattle. They are tall, slender Negroes, and until recently the men went naked while the women wore an apron of iron chains decorated with beads.

They are divided into freemen and serfs. Blacksmiths, professional hunters and similar groups are regarded as inferior and are associated with the serfs. There are some 150 patrilineal, exogamous and totemic clans, most of which are composed of freemen. Both men and women undergo initiation by the extraction of the lower incisors and by cicatrization. Men then enter age sets (*q.v.*) which have distinctive names and ornaments. Age mates regard themselves as intimately linked and assist one another in many situations. The people have no single chief, but many "big men." These include ritual functionaries, the rainmakers, who are few but extremely powerful, and the "fathers of the earth" who are found in every village and are responsible for magic to ensure successful cultivation, hunting and warfare. Both these offices are hereditary and are held by certain descent lines. There are also secular functionaries: clan heads, village headmen and wealthy individuals. The Bari believe in a god, *Yun,* who has two aspects: a benevolent god who dwells in the sky and is concerned with rain, and a malevolent god who lives in the earth and is associated with cultivation. Sacrifices are made to the spirits of the dead.

They have been in contact with Europeans since the 1840s. Under Turko-Egyptian rule there was much slave raiding and the Bari and their neighbours are still suspicious of Arabs. In general the Bari area is poor, being remote from world markets and political centres. The culture and language are shared by many of the small tribes in the region. The most important are the Kakwa (45,000), Mandari (36,000), Kuku (26,000), Pöjulu (25,000), Nyangbara (18,000) and Nyefu (3,000). *See* also AFRICA: *Ethnography (Anthropology): Northeast Africa.*

BARI, a city of southeastern Italy, Puglia region, capital of

the province of Bari and the seat of an archiepiscopal see, is an important Adriatic port situated in the coastal plain, 113 km. (70 mi.) N.W. of Brindisi by road and 294 km. (183 mi.) E.N.E. of Naples by road. Pop. (1957 est.) 304,642 (commune). The city is divided into three parts: the old city, on the peninsula dividing the old from the new harbours; the modern city, built on a chessboard plan; and the industrial area. inland, to the south of the railway. The chief features of interest are in the old city which has a network of narrow streets, many of them passing under arches. The 11th-century basilica of S. Nicola is in the Romanesque style and has a majestic façade. The relics of St. Nicholas. patron saint of Bari, are preserved in the crypt. Nearby is the 11th-century Romanesque church of S. Gregorio, small with a simple and austere interior. The 12th-century cathedral of S. Sabino, with a fine rose window, is situated nearer the base of the peninsula. Also in the Romanesque style it was sadly spoiled by baroque additions, now removed from the interior. The city is bounded by a promenade 9 km. (5½ mi.) long and on the eastern end is the provincial picture gallery. The archaeological museum is in the buildings of the university (founded 1924) in the new part of the town.

Bari is on the main east coast railway from Milan and Bologna to Brindisi and the "heel" of Italy. There are international air services from Palese airport (10 km. [6 mi.] N.W.) and steamer services to Adriatic ports and the Mediterranean and Black sea. The district is rich in olive and fruit trees and vines, and in lime-bearing soils. Industries include the production of wine, olive oil, fruit preserves, tobacco, sulfide, building materials, textiles, Armenian-type carpets, machinery and ironwork, and boat building and fishing. Bari is also a military centre.

The site of Bari may have been inhabited since 1500 B.C. Greek influence was strong as coins showed. and under the Romans, who called it Barium, it developed into a considerable port, the harbour being mentioned as early as 180 B.C. Fishing was important in Roman days. In the 9th century A.D. it became a Saracen stronghold and in 885 the residence of the Byzantine governor of Apulia. In 1071 it was captured for the Normans by Robert Guiscard. Peter the Hermit preached the first crusade in Bari in 1096 and a large party of crusaders started from there. In 1156 it was razed to the ground by William the Bad, hut acquired new greatness under the emperor Frederick II (1194–1250). The Sforzas were the last of various masters, and in 1557 the emperor assigned it to Naples by arbitration. After Garibaldi had overthrown Naples in 1860, Bari became part of the Italian kingdom. In World War II it was occupied by Allied forces on Sept. 12, 1943.

BARI PROVINCE (area 1,980 sq.mi.; pop. [1961] 1,259,757) extends for 60 mi. along the Adriatic coast and has a maximum width of 30 mi. The country rises from the coastal plain to the Murgia mountains, which reach their summit in Monte Caccia (680 m. [2,231 ft.]). Along the coast are the resorts of Barletta, Trani, Bisceglie, Molfetta (*qq.v.*), Polignano a Mare and Monopoli, nhile inland towns are Canosa di Puglia, Andria, Corato. Ruvo di Puglia, Bitonto (*qq.v.*), Conversano, Gioia del Colle, Castellana and Alberobello. The chief river is the Ofanto (anc. Aufidus) dividing Bari from Foggia province. On its banks is the battlefield of Cannae (q *v.*) (mod. Canne della Battaglia) where Hannibal defeated the Romans in 216 B.C. (M. T. A. N.)

BARILOCHE (SAN CARLOS DE BARILOCHE), resort town of Argentina's Andean lake district, is located about 2,500 ft. above sea level on the shores of Lake Nahuel Huapí, set in the heart of the beautiful national park of the same name. Chalet-type building construction, introduced in 1905 by the Swiss settlers of the region, provides an appropriate setting for skiing in the winter months, while the many lakes and streams afford excellent opportunities for fishing. The beauty of the surroundings and sport facilities make it one of South America's most popular resort areas. The town, which has approximately 3,000 inhabitants, is situated in the national territory of the Rio Negro and may be reached by rail, road or plane. It is approximately 800 mi. S.W. of Buenos Aires. Bariloche was the scene of a meeting in 1960 between Pres. Dwight D. Eisenhower of the United States and Pres. Arturo Frondizi of Argentina. (T. F. McG.)

BARINAS, a state of western Venezuela, lies in an alluvial plain. the llanos, north of the Apure and Uribante rivers and east of the Andes as far as the Portuguesa river. Area 13,591 sq.mi. Pop. (1961) 134,811. It is plagued by alternate drought and flood: aide stretches of savanna are inundated during the rainy season, which lasts from May to December. Barinas ranks second among Venezuelan states as a producer of cattle. Coffee is grown in the uplands and the usual tropical crops are produced along the rivers. Petroleum was discovered south of the city of Barinas and a huge area of oil concessions covers most of the state. A pipeline transports oil northward from Silvestre to a terminal at Puerto Cabello.

The state capital, Barinas (pop. [1961] 25,707), lies in the north central part of the state 260 mi. S.W. of Caracas. It is the centre of the cattle-trading business and is connected by highway, most of it hard surfaced, with Valencia, Puerto Cabello and Caracas. (L. WE.)

BARING, the name of a family important in the financial and mercantile ventures of the British empire beginning in the late 18th century. The financial house. Baring Brothers and Company, was founded by Sir Francis Baring (*q.v.*). By 1810, the extent of its activities on the continent led the French prime minister to remark that the sixth great European power was Baring Brothers. The control of the firm passed to Francis Baring's second son Alexander. later Lord Ashburton (1774–1848), who married Ann Bingham, a member of one of the wealthiest families in Pennsylvania. Her dowry added to the family connections enabled the Barings to gain control of an important share of the U.S. banking business. Thomas Baring (1799–1873), a grandson of Francis, assumed control of the firm in 1848, and after Thomas the firm was managed by Edward Charles Baring, later 1st Baron Revelstoke (1828–97). In 1890 a crisis in the fortunes of the Barings occurred when Argentina defaulted on bond payments and the Barings were left with £21,000,000 (approximately $100,000,000) in liabilities. The firm was saved by the intervention of the Bank of England and an important group of the City of London bankers, including the Rothschilds. The continuing importance of the firm was indicated by the decision to place in the hands of its director the liquidation of Britain's fixed assets in the United States during World War II.

Other important members of the family include Thomas George Baring, 1st earl of Northbrook (*q.v.*); Charles Baring (1807–79), bishop of Durham; and Evelyn Baring, 1st earl of Cromer (*q.v.*).

See B. Mallet, *The Earl of Northbrook: a Memoir* (1908); R. W. Hidy, *The House of Baring in American Trade and Finance . . . 1763–1861* (1949). (L.N.)

BARING, SIR FRANCIS, 1ST BARONET (1740–1810), British financier who established one of the most influential business firms in the history of the United Kingdom, was born near Exeter on April 18, 1740, the third son of a German immigrant. He went to London, where he gained experience in two mercantile firms, and in 1763 set up the partnership of John & Francis Baring & Company. At first he acted merely as an import and export commission agent for other merchants, but the house of Baring, known as Baring Brothers and Company after 1806, also bought merchandise on its own account, lent its credit in the form of acceptances and received deposits of friends and clients. It became a key aid to the British government in financing the wars against France after 1792. Sir Francis also underwrote marine insurance and took an active part in the management of the East India company, of which he was head in the year 1792–93 and for which he received his baronetcy. He was a friend of Jeremy Bentham, a follower in large measure of Adam Smith and adviser to numerous politicians, the most notable being William Pitt the Younger. Sir Francis died at Lee, Kent, on Sept. 11, 1810. One admirer stated in the *Gentlemen's Magazine* that he was, at the time of his death, "unquestionably the first merchant in Europe; first in knowledge and talents, and first in character and opulence." The house he created became the leading firm in financing U.S. trade and in marketing U.S. bonds between 1815 and 1860; for its subsequent history see the article BARISG.

See Ralph W. Hidy, *The House of Baring in American Trade and*

Finance, English Merchant Bankers at Work, 1763–1861 (1949).
(R. W. Hy.)

BARING, MAURICE (1874–1945), English man of letters, a singularly perfect representative of the social culture which flourished in England before World War I, was born in London on April 27, 1874. The fourth son of the 1st Lord Revelstoke, he was educated at Eton and Trinity college, Cambridge, and in 1898 joined the diplomatic service. In 1904 he became a journalist and reported the Russo-Japanese War in Manchuria; later he was a correspondent in Russia and Constantinople. In World War I he served with distinction on the headquarters staff of the royal flying corps. He published novels, including *C* (1924), *Cat's Cradle* (1925) and *Daphne Adeane* (1926); poems, parodies and essays, *e.g., Dead Letters* (1910), *Diminutive Dramas* (1911); and a study of *Sarah Bernhardt* (1933). He was also a distinguished Russian scholar and translator. He recorded his personality and experiences, until the outbreak of World War I, in *The Puppet Show of Memory* (1922) and his anthology *Have You Anything to Declare?* (1936) displays the width of his reading and his fine literary taste.

Baring's charm and original humour won him friends in many walks of life. He was a devout Roman Catholic convert. The fortitude with which he endured a fatal paralytic disease is described in Lady Lovat's book. He died at Beauly, Inverness-shire, on Dec. 14, 1945.

See Lady Laura Lovat, *Maurice Baring, a Postscript* (1947); Dame Ethyl Smyth, *Maurice Baring* (1938) gives a fuller account of his life.
(J. Sp.)

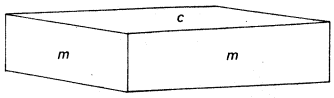
BARINGO, a lake in east Africa, is situated 3,200 ft. above sea level in the northern section of the Kenya rift valley with the Laikipia escarpment on the east and the Kamasia range to the west. It is 50 sq.mi. in area, 11 mi. long by 4½ mi. wide and it has an average depth of 17 ft. It has no visible outlet, but the freshness of its waters is maintained by a seepage into the lavas at its northern end where a rocky shore contrasts with the alluvial flat which borders the lake on the south. The Nilo-Hamitic peoples, Tugen and Njemps, who occupy the Baringo basin, catch *tilapia* (a perchlike fish) in the lake, herd cattle and with help from the Perkerra irrigation scheme practise agriculture. The earliest European travelers to reach the lake were Joseph Thomson (1883), Count Samuel Teleki and L. R. von Höhnel (1887) and J. W. Gregory (1893). Lake Baringo is approached from Nakuru by a rough road through Marigat. (S. J. K. B.)

BARISAL, a river port in East Pakistan, is in the Ganges delta 73 mi. S. of Dacca and more than 100 mi. from the Bay of Bengal. It is the chief town of Barisal district (part of former Backerganj). It lies on the west bank of a lesser deltaic distributary known locally as Kirtan Khola, an offshoot of the Arial Khan river. Pop. (1961) 70,025. It is linked by steamer with Dacca and westward with Khulna, the nearest railhead. Most of the jute and rice from east of the Brahmaputra are transshipped at Barisal to be carried in seagoing vessels to Chittagong. The town is a market for rice and betel nuts and exports fish in quantity. Its amenities include three colleges affiliated to Dacca university, a public library founded in 1855, and a public park. It has a good system of natural drainage, the *khals* (creeks) being flushed by the tides.

Barisal gives its name to a curious natural phenomenon, "Barisal guns," noises like cannon reports heard near Barisal and elsewhere and apparently coming from the sea. The phenomenon has not been satisfactorily explained, but many have a seismic origin.
(K. S. Ad.)

BARITE (Barytes), a widely distributed mineral composed of barium sulfate ($BaSO_4$), is the commonest barium mineral. Its most striking feature and the one from which it derives its name (from the Greek for "heavy") is its weight, also the source of its common name, heavy spar. Its specific gravity of 4.5 is about twice as great as that of salt and of many other colourless, transparent and glassy minerals not unlike barite in general appearance. The mineral is usually found in a state of considerable chemical purity, though small amounts of strontium and calcium sulfates may replace the barium sulfate.

Crystals of barite are orthorhombic; they are usually perfectly developed and present great variety of form. The simplest crystals are rhomb-shaped tables bounded by the two faces of the flat basal pinacoid (*c*) and the four faces of the prism (*m*); the angle between the prism faces (*m,m*) is 78° 23′, while that between *c* and *m* is 90°. The mineral has perfect cleavage parallel to the faces *c* and *m*, and the cleavage surfaces are smooth and bright. The crystals may be transparent and colourless, or white and opaque, or of a yellow, brown, bluish or greenish colour. The mineral occurs also in a granular, earthy or stalactitic condition. It is known as "cawk" in the Derbyshire lead mines. Barite is of common occurrence in metalliferous veins, especially those which yield ores of lead and silver.



BARITE CRYSTAL IN SIMPLEST FORM

Commercially, ground barite is used in oil- and gas-well drilling muds. Barite also is used in the preparation of barium compounds, as a body or filler for certain kinds of paper and cloth and in phonograph records, as a white pigment ("permanent white") (*see* Lithopone) and as an inert body in coloured paints. (L. J. S.)

BARITONE, a brass instrument with valves, pitched in B flat, the term usually denoting in the U.S. the wide-bore instrument (in England, called the euphonium, *q.v.*), but in England the narrow-bore instrument (in the U.S. tenor horn; *see* Saxhorn). For the use of the term to describe a type of voice between tenor and bass, *see* Singing; Voice: *Attributes of the Voice.*
(A. C. Ba.)

BARIUM, a metallic chemical element having a silvery white lustre when freshly prepared. It oxidizes very rapidly in air, and reacts readily with water and alcohol. Barium occurs chiefly in the form of barite (*q.v.*) or heavy spar, and witherite (*q.v.*), and to a less extent in baryto-calcite, baryto-celestine and various complex silicates. It is estimated that barium constitutes about .05% of the crust of the earth. The chemical symbol of barium is Ba. Its atomic number is 56 and its atomic weight is 137.36.

History and Preparation.—Barium takes its name from the Greek *Barys* (heavy) because of its presence in barite or heavy spar which was first investigated in 1602 by V. Casciorolus, a shoemaker of Bologna, who found that after ignition with combustible substances it became phosphorescent, and on this account it was frequently called Bolognian phosphorus. In 1774 K. W. Scheele, in examining a specimen of pyrolusite, found a new substance to be present in the mineral, for on treatment with sulfuric acid it gave an insoluble salt which was afterward shown to be identical with that contained in heavy spar.

The metal is difficult to isolate; Sir H. Davy tried to electrolyze baryta (barium oxide) but was unsuccessful; later attempts were made by him using barium chloride in the presence of mercury. In this way he obtained an amalgam, from which on distilling off the mercury the barium was obtained as a silver white residue. Barium was first isolated by Davy in 1808. R. Bunsen in 1854 electrolyzed a thick paste of barium chloride and dilute hydrochloric acid in the presence of mercury, at 100° C., obtaining a barium amalgam, from which the mercury was separated by a process of distillation. A. N. Guntz reduced barium oxide by aluminum powder at 1,200° C.; and C. Matignon reduced it in a vacuum at the same temperature by means of ferrosilicon (95% Si), barium of 98.5% purity distilling over.

The commercial production of barium depends upon the electrolysis of fused barium chloride or the reduction by aluminum of a mixture of barium monoxide and barium peroxide in a vacuum furnace which is heated electrically.

Uses.—The metal is used in the manufacture of radio vacuum tubes. It removes the final traces of gaseous elements remaining after the tubes have been evacuated almost completely by other methods. It is also used to remove oxygen in the refining of copper. It is a constituent of several alloys, one of the most important of which is Frary metal, a bearing or antifriction metal that contains lead and calcium as well as barium. An alloy of nickel and barium, which readily emits electrons when heated, is used for this reason in radio tubes and in the points of spark plugs. For the uses of the various barium compounds, see *Compounds.*

Properties. — Barium is one of the alkaline earths (*q.v.*) of Group II of the periodic system. It is slightly harder than lead and can be rolled and hammered. Other properties of the metal are listed below:

Atomic radius	1.98 Å (10^{-8} cm.)
Ionic radius	1.35 Å
Ionization potential (gaseous element)	
1st electron	5.19 v.
2nd electron	9.95 v.
Single electrode potential (metal-molal solution of Ba^{a}+ion)	2.90 v.
Density (20° C.)	3.59 g. per cubic centimetre
Melting point	850° C.
Boiling point	1,537° C.

The seven stable isotopes of the element have relative atomic masses of 138, 137, 136, 135, 134, 130 and 132 (listed in the descending order of abundance). Radioactive isotopes of mass numbers 126 to 129, 131, 133, 135, 137. and 139 to 144 have been prepared. The distribution of electrons in the outer levels of the barium atom is as follows: $4d^{10}$, $5s^2$, $5p^6$, $6s^2$; the superscript indicates the number of electrons in the corresponding sublevel.

As compared with the other metals of the alkaline earth family, barium has more pronounced base-forming tendencies than any other member of its group except radium. Its atoms are more readily converted into ions by the loss of their two outermost electrons and the element, consequently, is a more active reducing agent than magnesium, calcium or strontium. This behaviour is in keeping with the greater atomic and ionic radii, the smaller ionization potential and the lower position of barium in the periodic table as compared with other alkaline earth metals. The barium ion has a relatively high heat of hydration as compared with the ions of the alkali metals. This condition is one factor that causes the metal to be so readily oxidized.

The metal burns brilliantly in air or oxygen to form the monoxide, BaO. At high temperatures it reacts with nitrogen, carbon and phosphorus to form the nitride: carbide and phosphide, respectively. It reacts at ordinary temperatures with all the halogens to form halides, and with sulfur, when heated, to form the sulfide.

The valence number of barium in its compounds is +2. The barium ion, Ba^{++} is not easily reduced. It may be precipitated from solution by the addition of carbonate, sulfate, chromate, phosphate or certain other anions with which it forms slightly soluble salts. Volatile barium compounds: when heated in the Bunsen flame, impart a yellowish-green colour to the flame. The two characteristic lines of the barium spectrum have wave lengths of 455 and 493$\mu\mu$ (10^{-6}mm.), respectively.

Compounds. — Three oxides of barium are definitely known— the monoxide, BaO, the peroxide, BaO_2, and a suboxide, obtained by heating BaO with magnesium in a vacuum to 1.100° C. An oxide, BaO_4, has also been described. The monoxide is formed when the metal burns in air, but is usually prepared by the ignition of the nitrate, oxygen and oxides of nitrogen being liberated. It can also be obtained by the ignition of an intimate mixture of the carbonate and carbon or barium carbide. It is a grayish-coloured solid, which combines very energetically with water to form the hydroxide, much heat being evolved during the combination; on being heated at 500°–600° C. in a current of oxygen it forms the peroxide, which at higher temperatures (700°–800° C.) breaks up again into the monoxide and oxygen. The hydride, BaH_2, is obtained by direct combination at high temperatures; it is volatile and less stable than calcium or strontium hydrides.

Barium hydroxide. $Ba(OH)_2$, is a white powder that can be obtained by slaking the monoxide with the requisite quantity of water, but it is usually made on a large scale by heating heavy spar with small coal whereby a crude barium sulfide is obtained. This sulfide is then heated in a current of moist carbon dioxide, barium carbonate being formed, $BaS+H_2O+CO_2=BaCO_3+H_2S$, and finally the carbonate is decomposed by a current of superheated steam, $BaCO_3+H_2O=Ba(OH)_2+CO_2$, leaving a residue of the hydroxide. It is also made by electrolyzing a barium chloride solution, using a mercury cathode. Barium hydroxide is moderately soluble in cold water, readily soluble in hot water. the solution possessing an alkaline reaction and absorbing carbon dioxide readily. The solution, known as baryta water, has extensive applications, being used in gas analysis for the determination of the amount of carbon dioxide in the atmosphere; it is also used in organic chemistry as a mild hydrolyzing agent. E. Fischer has used it as a condensing agent in the preparation of ***a***- and β-acrose from acrolein dibromide. A saturated solution of the hydroxide deposits on cooling a hydrated form, $Ba(OH)_2.8H_2O$, as colourless quadratic prisms, which on exposure to dry air lose seven molecules of water of crystallization. It is used as a depilatory in tanning.

Barium peroxide, BaO_2, can be prepared as shown above, or in the hydrated condition by the addition of excess of baryta water to hydrogen peroxide solution, when it is precipitated in the crystalline condition as $BaO_2.8H_2O$. These crystals on being heated to 130° C. lose water of crystallization and leave a residue of the anhydrous peroxide. In the Brin process for the manufacture of oxygen, barium peroxide was formed by heating barium monoxide with air at 700° C. under pressure. and decomposed by lowering the pressure. (This process has been superseded by the fractionation of liquid air.) It is a white powder which is readily decomposed by dilute acids with the production of hydrogen peroxide.

Barium chloride, $BaCl_2.2H_2O$, can be obtained by dissolving witherite in dilute hydrochloric acid, and also from heavy spar by ignition in a reverberatory furnace with a mixture of coal, limestone and calcium chloride, the barium chloride being extracted from the fused mass by water, in which it is readily soluble. It can be obtained in the anhydrous condition by heating it gently to about 120° C. It has a bitter taste and is a strong poison. Barium bromide is prepared by saturating baryta water, or by decomposing barium carbonate, with hydrobromic acid. It crystallizes as $BaBr_2.2H_2O$, isomorphous with barium chloride. Barium chlorate. $Ba(ClO_3)_2$, is obtained by adding barium chloride to sodium chlorate solution; on concentration of the solution sodium chloride separates first; after further evaporation barium chlorate crystallizes out and can be purified by recrystallization. It can also be obtained by suspending barium carbonate in boiling water and passing in chlorine. It crystallizes in monoclinic prisms of composition $Ba(ClO_3)_2.H_2O$, and begins to decompose on being heated to 250° C.

Barium sulfate. $BaSO_4$ (barite?, is the most abundant of the naturally occurring barium compounds and can be obtained artificially by the addition of sulfuric acid or any soluble sulfate to a solution of a soluble barium salt, when it is precipitated as a white. finely divided crystalline powder of specific gravity 4.5. It is almost insoluble in water (about two parts per million at 15° C.), and is only very slightly soluble in dilute acids; it is soluble to some extent, when freshly prepared, in hot concentrated sulfuric acid, and on being cooled the solution deposits crystals of composition $BaSO_4H_2SO_4$. It is used as a pigment under the name of "permanent white" or *blanc fixe*, and with zinc sulfide in "lithopone." It is also used for weighting paper. A major use of barite is in the petroleum industry, where it is a constituent in the mud used to facilitate well drilling *(see* DRILLING MACHINERY: *Hole Maintenance)*. In radiology (*q.v.*) the compound is used as an artificial contrast medium.

Barium nitrate. $Ba(NO_3)_2$, is prepared by dissolving either the carbonate or sulfide in dilute nitric acid, or by mixing hot saturated solutions of barium chloride and sodium nitrate. It crystallizes in octahedra! having a specific gravity of 3.2, and melts at 592° C. It is decomposed by heat and is largely used in pyrotechny for the preparation of green fire. Barium carbonate, $BaCO_3$, occurs rather widely distributed as witherite, and may be prepared by the addition of barium chloride to a hot solution of ammonium carbonate, when it is precipitated as a dense white powder with a specific gravity of 4.3, almost insoluble in water. It is much more stable toward heat than calcium or strontium carbonates. It is used in rat poisons and in glass manufacture.

Analysis. — Barium and its salts can be readily detected by the yellowish-green colour they give when moistened with hydrochloric acid and heated in the Bunsen flame, or by observation of their spectra. when two characteristic green lines are seen. In solution, barium salts may be detected by the immediate precipi-

tate they give on the addition of calcium sulfate (this serves to distinguish barium salts from calcium salts), and by the yellow precipitate of barium chromate formed in the presence of dilute acetic acid on the addition of potassium chromate. Barium is estimated quantitatively by conversion into the sulfate. For a comparison of the chemical properties of barium with those of radium, *see* RADIUM: *Chemical* Properties.

See also Index references under "Barium" in the Index volume.

BARK **CLOTH,** a tropical textile produced until the 19th century from the inner bark (or bast) of several species of trees in Ceylon. the Nicobar Islands, parts of southeast Asia, the Malay peninsula, Indonesia, the Philippines, parts of Melanesia including most of New Guinea, some of the Caroline Islands and all of Polynesia; in America from Honduras southward to Amazonas and Mato Grosso in Brazil and eastern Bolivia; and in Africa in Uganda, Tanganyika, Nyasaland, Mozambique, and Madagascar, also on the upper Congo and Ubangi, and with scattered occurrences in west Africa.

In ancient times it was made in Hainan, Kwangtung, and Yünnan, and probably in all of southern China and parts of India. Archaeologically, bark cloth beaters appear in the earliest periods of Central America. and the cloth is found in the lowest levels (3rd millennium B.C.) of Huaca Prieta, Peru.

Bark cloth was replaced in most of the areas mentioned by woven cloth, imported or native, or, in Africa, by skins. In the 1960s it was made in Samoa and Tonga and parts of Melanesia and Indonesia, particularly Celebes, and by some South American tribes.

In Polynesia, paper mulberry (*Broussonetia papyrifera*) bast, which yields the best bark cloth, was used nearly everywhere. On a few islands breadfruit (*Artocarpus* altilis), figs (*Ficus tinctoria* and related species) and *Pipturus albidus* were common substitutes. The mulberry and breadfruit were cultivated. Various species of these genera furnished bast in Indonesia, as did *Trema, Antiaris, Sloetia,* and others; at Minahasa no fewer than 20 trees provided the material. In South America apparently only Ficus was used, as also in Africa, where it was often cultivated.

In Indonesia *fuya,* as it was there known, was used for jackets, ponchos. sarongs, loincloths, and as a thin material for headcloths. Where cotton cloth supplanted it, *fuya* was worn for religious ceremonies and for mourning; rougher kinds provided packing material, and a fine type was made for writing paper. Until the late 19th century, Celebes exported quantities of it to Singapore as underlay for coppering vessels. Polynesian uses included loincloths, skirts, mantles, bed covers, mosquito nets and burial shrouds. There the name was tapa. Tahitians prepared it in bales, sometimes 200 yd. long. A delicate white material was used in Fiji for turbans and coarser stuff for loincloths, which chiefs wore in long trains. South American bark cloth was used for tunics, aprons, breechcloths, mosquito nets, pouches and dance masks. In Africa only clothing was made of the material.

(LEFT) FREEHAND DESIGN OF BARK CLOTH FROM SANTA ISABEL ISLAND. SOLOMON ISLANDS; (RIGHT) STAMPED PATTERN OF HAWAIIAN TAPA

Basically, the manufacturing process, similar to making felt, consists of stripping off the bast and soaking, then beating it to cause the fibres to interlace and to achieve proper thickness. Polynesian bark cloth was generally superior to all others, and within Polynesia Hawaiian tapa was perhaps the best because of its great variety and beauty of design and texture. In Hawaii, the bast strips: peeled from mulberry shoots, were steeped in sea water, then beaten on stone anvils with round wooden beaters, causing the strips to expand in width. After being bleached they were again soaked and beaten together on wooden anvils, using squared wooden beaters with sides incised in various patterns, finishing with a beater having rectangular incising, which produced watermarked cloth. The finished piece was rectangular in shape. Special ribbed cloth was made by means of grooved anvils, and very fine, lacy material was also manufactured. Fourteen different plants yielded dyes of many colours. The general Polynesian methods of immersion dyeing and freehand painting were employed, plus the Hawaiian methods of overlaying, cord snapping, and printing with bamboo stamps.

In Polynesia outside Hawaii, beaters usually had only parallel grooves. dyes were fewer, block printing was absent, and there was less variety of decoration. Tahitian tapa, though of fine quality, had more limited design; sometimes it was waterproofed with varnish. In Samoa, Tonga, and Fiji, the cloth was laid on a design. tablet, made of leaves sewn together or of carved boards, and rubbed with swabs dipped in dye. To make large pieces, smaller ones were joined by pasting instead of by the usual felting method.

A coarser bark cloth was made in Melanesia. The designs, applied freehand, were often crude, though some New Guinea cloths had regular. well-drawn figures. Some Santa Cruz designs resembled Hawaiian types. In Indonesia, if paper mulberry was unavailable, coarser bast was boiled before beating, which took place in special houses in order not to offend certain spirits. Dyes were applied by immersing in plant infusions or mud, producing black cloth. Freehand drawing and design stamping were also known there, and oiled transparent cloth was produced for jackets and headcloths.

In South America and Africa, in contrast to the Pacific, bark cloth was often manufactured by men rather than by women. The process was essentially the same as in the Pacific but less elaborate, and the special beaters were sometimes replaced by hammers or stones. Decoration in South America was usually crude, but

Yuracare tunics were often elaborately designed. Some tribes practised design stamping. In Africa black stripes and simple patterns were sometimes applied, and Uganda royal cloth often had striking figures stencilled in black.

BARKING, a municipal borough and parliamentary division of Essex, England, on the river Roding near its junction with the Thames, 8 mi. E. of London. Pop. (1961) 72,282. Barking was celebrated for its double monastery, one of the oldest and richest foundations in England. It was founded about 670 by Erkenwald, bishop of London, and restored in 970 by King Edgar, about 100 years after its destruction by the Danes. Aldhelm (*q.v.*) wrote a famous treatise for Hildelith, the abbess, and nine of her nuns (c. 705). Barking is a bishopric suffragan in the diocese of Chelmsford. The borough (incorporated in 1931) includes the London county council Becontree housing estate, the important Beckton gas works and Creekmouth electric generating station. Eastbury house (*c.*1550) stands in the centre of a housing estate and is let by the national trust for a day nursery. There are rubber and chemical works.

BARKLA, CHARLES GLOVER (1877–1944), British scientist, specialized in electric waves and X-rays. In 1917 he was awarded the Nobel prize in physics for his work with the characteristic Röntgen radiation of the elements. He was born June 7, 1877, at Widnes, Lancashire. He was educated at Liverpool institute; University college, Liverpool; and Trinity and King's colleges, Cambridge. In 1902 he joined the faculty of Liverpool university; in 1907 he moved to the University of London (King's college). He was appointed professor of natural philosophy at the University of Edinburgh in 1913. Barkla died on Oct. 23. 1944.

BARKLEY, ALBEN WILLIAM (1877–1956), 35th vice-president of the United States, was born in Graves county. Ky., Nov. 24, 1877. Reared on a farm under modest circumstances and educated in country schools, he graduated in 1897 from Marvin college (Clinton, Ky.) and pursued further study at Emory college and at the University of Virginia law school. He moved in 1898 to Paducah, Ky., entered law practice in 1901 and participated in Democratic politics. His career followed the familiar pattern of the times in rural America. He served as prosecuting attorney of McCracken county, 1905–09, and as judge of the county court, 1909–13. Elected in 1912 to the U.S. house of representatives from the first congressional district, he served seven successive terms, winning recognition as a conscientious legislator and supporter of the policies of Woodrow Wilson. In 1926 he was elected to the U.S. senate and subsequently re-elected three times, serving until 1949. For several years he was ranking minority member of the house committee on interstate and foreign commerce. Increasing senatorial seniority enhanced his influence on the committees on foreign affairs and finance. He was an able parliamentary tactician, and served from 1937 until 1947 as senate majority leader. He was a leading spokesman for the domestic and foreign policies of the Roosevelt administration, though he disagreed with the president on a tax bill in 1945, resigned as majority leader and was re-elected by his colleagues. In 1948 he was elected vice-president.

Barkley was a loyal and uncritical partisan and an indefatigable campaigner in many elections. His sincerity, integrity. wit and geniality made him a popular figure in Washington and throughout the country. He was a professional politician, completely loyal to party tradition and leadership but'free from partisan bitterness and rancour. In the belief that he had substantial support, he sought the presidential nomination in 1952 but withdrew his name when informed that certain spokesmen for organized labour, though they respected his record, considered him too old for the presidency. Re-elected to the senate in 1954, he died at Lexington, Va., on April 30, 1956.

See his autobiography, *That Reminds* Me (1954). (T. S. BY.)

BARKLY TABLELAND, an Australian plateau with an area of about 50,000 sq.mi. that crosses the boundary of Northern Territory into Queensland, near 19° S. latitude. Its boundaries are indefinite, only its northern edge being marked by any appreciable change of slope. The general height is about 1,000 ft. Originally opened up for sheep about 1877–84, the tableland is now one of the main beef cattle areas of tropical Australia. The underlying Cambrian limestones have weathered into a soil supporting good Mitchell grass pastures so there are a number of large cattle stations, including the 11,000-sq.mi. Alexandria station. Surveys by the Commonwealth Scientific and Industrial Research organization ("Land Research Series, No. 3," The Barkly Region, Melbourne, 1954) indicate that with improved watering facilities, transport and techniques, stock capacity could be more than doubled, from 325.000 head to about 678.000, with 87,000 marketed each year. The motor highway and a major stock route leading to Townsville and Rockhampton on the Queensland coast follow the length of the tableland. The Mount Isa mining district lies near its eastern end. (O. H. K. S.)

BARKLY WEST (Afrikaans BARKLY-WES), a town of Cape province, Republic of South Africa, lies 21 mi. N.W. of Kimberley on the north bank of the Vaal, where a bridge spans the river. Pop. (1958 est.) 3,700, including 700 Europeans. The oldest town of Griqualand West, it was founded after the discovery in 1869 of diamonds in the Vaal valley at Canteen Kopje (Klipdrift); Stone Age implements also found there are in the local museum. A branch railway and hard-surface road link the town with the railway, road and airport at Kimberley. It is still the centre of a 70-mi. stretch of scattered river diggings along the Vaal, the diamonds being noted for their purity and lustre. But it is also the commercial, civic and educational centre of an agricultural district which includes ranching, dairying, wheat, vegetables and fruit.

BARLAAM AND JOSAPHAT. The story of Barlaam and Josaphat is an edifying work that was translated into most languages of medieval Christendom. Incorporated into the Golden Legend, a famous medieval manual of lives of the saints and short treatises on the Christian feasts (*c.* 1250). it provided Shakespeare with the subject of the parable of the caskets in The Merchant *of* Venice.

The tale is set in India, in the realm of the idolatrous king Abenner, persecutor of the Christians. To this monarch is born a son, Josaphat (Gr. Joasaph). At the child's birthday feast 55 astrologers prophesy his greatness as king; however, one of them declares that his renown will not be of this world, but of the heavenly kingdom. To frustrate this prediction, Abenner confines Josaphat in a beautiful palace, and shields him from knowledge of human misery. The prince grows restive at last, and insists on seeing the world outside. He encounters a maimed man, a blind man and one at the brink of death, and is stricken by this revelation of man's wretched and fleeting existence.

At this point Josaphat is visited by the holy hermit Barlaam, who preaches to him in parables and finally baptizes him. Abenner fails to reconvert his son by holding a mock debate on the faith, in which the Christians are victorious. The pagan sorcerer Theudas vainly tries to seduce the prince by means of evil spirits and alluring women. Abenner divides his kingdom with Josaphat, is himself later converted, and dies. Josaphat abdicates and goes off into the wilderness to be reunited with Barlaam. After their death, the relics of the two holy men are laid in a shrine, which becomes a centre of pilgrimage and miraculous healing.

In spite of similarities noted by early travelers to India, it was not until the studies of E. R. L. Laboulaye (1859) and F. Liebrecht (1860) that the story was definitely proved to be a Christianized and much modified account of the Buddha's great renunciation. Modern research on ancient central Asian Buddhist Sogdian texts and on Old Turkish and Persian fragments discovered at Turfan in Chinese Turkistan has shown that there was current in those parts a set of legends about the Bodhisattva prince, whose name occurs in the form "Bodisaf." His life story, with extraneous elements, took on connected shape among the central Asian Manichaeans. The latter transmitted it to the Arabs, who adapted it

into a book called Kitab Bilawhar wa Yudasaf. The first Christian version was made from the Arabic by the Georgians, probably in the 9th century; in this, the prince is called Iodasaph, his teacher Balahvar. The Greek recension, formerly attributed to St. John of Damascus, which is a highly embroidered rendering of the Georgian, was made on Mt. Athos by St. Euthymius (d. 1028) the Iberian (*i.e.*, Georgian), possibly in collaboration with Greek monks there. This Greek redaction incorporates the early Christian defense of the faith known as the apology of Aristides (see APOLOGISTS, EARLY CHRISTIAN). From the Greek come the Latin, Slavonic, Christian Arabic and other Christian versions.

Though never officially canonized, Barlaam and Josaphat (*i.e.*, the young Buddha) are venerated by the Roman Catholic Church on Nov. 27; the Greeks commemorate Josaphat by himself on Aug. 26, the Georgians on May 19.

BARLACH, ERNST (1870–1938), outstanding German sculptor of the expressionist movement who has often been called the modern Gothic. He was also a distinguished writer and graphic artist but his wood and bronze sculptures are his finest work. They combine strength, monumentality and expressive power.

Barlach was born Feb. 2, 1870, in Wedel, Holstein. He studied art in Hamburg and later in Dresden and Paris. After several years in Hamburg and Berlin and a visit to Russia he settled in 1908 in Güstrow, Mecklenburg, where he spent the remainder of his life and died on Oct. 24, 1938.

Barlach achieved great fame in the 1920s when he executed among other works the celebrated war memorials in Magdeburg and Hamburg and the religious figures for St. Catherine's in Liibeck, but he fell into disfavour under Hitler and his work was removed from the museums. After World War II Barlach's genius was once more recognized and several exhibitions of his work were held in Germany and abroad. A Barlach society was established in Hamburg and a small Barlach museum near Lüneburg. The best collections of the artist's works in the United States are in the Museum of Modern Art in New York city and the Busch-Keisinger museum in Cambridge, Mass.

BAR-LE-DUC, a town of northeastern France, capital of the *département* of Meuse, lies in the narrow valley of the Ornain 228.5 km. (142 mi.) E. of Paris by road. Pop. (1954) 14.969. The town extends along the valley, shut in by wooded and vine-clad hills; on the northeast is the Marne-Rhine canal, on the southwest the Canal des Usines. The Ville Haute (upper town), on the left bank of the Canal des Usines, has houses of the 15th. 16th and 17th centuries, the surviving part of the château (1523, the rest pulled down 1670) of the dukes of Bar and the church of Saint-Étienne (15th–16th century), in which is the "Skeleton," a statue by Ligier Richier (early 16th century). The lower town contains the official buildings and the church of Notre Dame (13th–14th century) which has an 18th-century facade. Industries include iron founding and the manufacture of machinery, corsets, hosiery, flannel and jam. There is considerable trade in timber and iron. An industrial zone to the east of the town was established in 1960; products include metalwork, rubber and chemicals. Although probably ancient, Bar-le-Duc only became important when it became the residence of the 10th-century counts of Bar, who later became dukes (see BAR, COUNTS AND DUKES OF). It was an important base for the southern quadrant of the western front during World War I.

BARLETTA, a port, seaside resort and episcopal see on the east coast of Italy in the region of Puglia and province of Bari, lies 55 km. (34 mi.) by road W.N.W. of Bari. Pop. (1957 est.) 69,160 (commune).

It was first known as Barduli and grew slowly. Only one of the medieval gates remains. The town is divided into two by the Milan-Brindisi railway, the northern part being the older and containing the Gothic cathedral (1150–1400) and the Norman castle (11th century) nearby. There are several palaces and museums. The people are mostly employed in viticulture and agriculture, and also grow olives and almonds. The main industries are electrical, automobile manufacture, sawmills, chemicals (especially acids and phosphates) and leather work. Wines, fruits, especially dessert grapes, and shoes are exported.

Barletta became part of the kingdom of Naples in medieval days. During the siege of Barletta (1503) a combat took place between 13 picked knights of Italy and France. The Italian victory was celebrated by Massimo d'Azeglio in *Disfida di* Barletta. During World War II the town was captured by the Allies on Sept. 24, 1943.

BARLEY. Barley is one of the five most important cereals, widely used for human food and malting, but more especially as a livestock feed grain. World-wide, approximately 3,200,000,000 bu. are harvested annually from about 136,000.000 ac.

Some investigators believe that barley is the most ancient of the cultivated grains, as ancient as the earliest traces of agriculture itself and extending back to perhaps 5000 B.C. in Egypt, 3500 B.C. in Mesopotamia, 3000 B.C. in northwestern Europe and 2000 B.C. in China. It was important to the Stone Age Swiss lake dwellers and was the chief bread plant of the Hebrews, Greeks and Romans. Barley is mentioned in the Bible and by the writers of antiquity and was included in mythology and the great festivals. It was probably the chief bread plant of continental Europe as late as the 16th century and was early transplanted to the pioneer fringe of the new world.

Barley was formerly believed to have originated somewhere in the dry lands of southwestern Asia. Later research pointed to two primary original centres of varietal diversity of cultivated barleys; *i.e.,* the highlands of Ethiopia and southeastern Asia. In any case, the kernels of the grain have remained apparently much the same during the whole of its history. Barley, of the genus Hordeum L. of the grass family Gramineae, includes both wild and cultivated types that differ widely.

The genus Hordeum includes four sections, of which one, Cerealia, includes the cultivated forms. Three species are recognized within the section Cerealia: (1) The six-rowed barley, *Hordeum* vulgare, in which the barley spike or rachis is notched on opposite sides with three spikelets at each notch and with each spikelet containing a floret. All florets are normally fertile and develop kernels. (2) The two-rowed barley, Hordeum *distichum,* with central florets fertile and lateral florets awnless and normally sterile. (3) The irregular barley, least known and sometimes referred to as Abyssinian intermediate barley, Hordeum *irregulare.*

Production. — This many-formed cereal race, in some one of its many varieties, is better adapted to a variety of climate than any other cereal, ranging through most types of temperate climate into the subarctic and the subtropical as well. It must, of course, compete with other cereals in the agricultural economy, whether primitive or technologically advanced, and its inclusion is related not only to natural factors but also to the nature and location of the specific economy and local consumer preferences.

Although it does better when the growing season is 90 days or more in length, its ability to grow and ripen within the shortest time known to cereals and with no more warmth than is required by other small grains permits it to be grown under subarctic conditions of very short seasons, 60–70 days, and at least as far as 71° N. in Norway and about 15,000 ft. altitude on the slopes of the Himalayas.

Total production under such marginal conditions is, of course, small, but possibly of vital importance locally. It is superior to other small grains in resistance to dry heat; it thrives on the desert margin of low rainfall, as in north Africa, where it is the important cereal and mostly a fall-sown crop. In the cooler, moist areas of western Europe and North America, spring-sown types reach their maximum in production.

Barley is a shallow rooted and rapidly growing grain which needs well-drained loams, almost as fertile as the soil needed for wheat. The land, however, should not have too high a nitrogen content if the plant is to stand well or if the grain is to be used for malting. Whether for fall or early spring sowing, the seed bed should be well prepared; the seed may be broadcast or drilled (preferred) at a rate of two to three bushels per acre. Harvest in the late spring or early summer by binder or combine gives widely varying yields depending on the area and year, but usually between 20 and 40 bu. per acre under modern agricultural practices.

Various insect pests, such .as wireworm, Hessian fly, frit fly, chinch bug and aphides, damage the barley crop. Among parasitic fungi attacking barley are *Helminthosporium* and three kinds of smut (Ustilago), which destroy the spikelets. Other diseases serious at times are mildew (Erysiphe *graminis* hordei), leaf rust (*Puccinia graminis*), leaf scald (Rhynchosporium *secalis*) and the foot rots. Fusarium blight, or scab (Gibberella saubinetti), which shrivels the grain and makes it unfit for hog feed, may be serious in the upper Mississippi valley. Mercury dust compounds proved useful in controlling scab, leaf stripe and some of the smuts by seed treatment.

Plant breeders have attempted to increase barley yields of desirable-quality grain by improving such characters as stiffness of straw, earliness, shattering, disease resistance, winter hardiness and industrial quality. In Great Britain various hybrids, examples of which are Sprat-Archer and Plumage-Archer, have been produced for stiff straw and good yield. In the United States considerable effort has been made through hybridization to produce adapted strains with disease resistance. Smooth-awned varieties of hybrid origin increased the popularity of barley culture.

The types of barley usually grown in Europe and North America are, however, less tolerant of moist heat than are corn and rice. The naked types of Japan and India are apparently more tolerant of warm, moist conditions. The fall-sown winter varieties are less resistant to winter kill than wheat or rye. The more important producing areas are the United States, U.S.S.R., China, Eastern Europe, Canada, France, the United Kingdom, Turkey, West Germany, India and Denmark, in that order.

Production in the United States has shown much shift in location and in varieties planted. Prior to the Civil War the northeast, particularly New York, was the dominant area, and the old six-rowed barley of northwestern Europe prevailed. For the next 30 years this dominance was shared by California, which in addition to the six-rowed type produced types from the North African coast area. The next 30 years was a period marked by the rise of Manchuria varieties and by midwest production. From the end of World War I until the beginning of World War II the notable changes were the appearance of Trebi barley in the more arid western parts of the United States and of smooth-awned hybrids in the more humid northeast. The major changes during World War II were a marked decline in barley acreage in the eastern states of the north central region, and increased production in the less humid northern plains; there was a high variability in yield from year to year and a decrease in general malting quality. The postwar years showed some reinstatement in the eastern section, but the Red river area apparently fully established its dominance. North Dakota, the leading state in the 1960s harvested almost 4,000,000 ac. producing more than 75,000,000 bu.; California was second with about 70,000,000 bu. and Montana third with about 50,000,000 bu.

Approximately 140 varieties of barley were being grown in the United States and Canada by the 1960s, varying greatly in their adaptation to different soil areas, climatic regimes, types of farming and use characteristics. Thousands of varieties had been tested. An average of two or three new varieties were being released annually to U.S. farmers, each having some advantages as compared with those already used in particular areas for particular purposes.

Three groups of varieties, all of old world origin, became established early in the United States and Canada. The Manchuria-O.A.C. 21-Oderbrucker group, probably of Manchurian origin, is widely grown in the more humid sections of the upper Mississippi valley and the northeast; its varieties are six-rowed, awned, spring type with medium-sized kernels, tall, of midseason maturity and reasonably tolerant of humid heat and rain. Those in the Coast group are of north African origin, fall or winter sown in areas of mild climate and also adapted for spring sowing in areas of limited rainfall; they are six-rowed, awned, with large kernels, mature early and do not shatter easily. The Tennessee Winter group, of disputed origin, is fall sown in the humid south. mostly south of the Mason and Dixon line; its varieties are six-rowed, awned, with medium to small kernels.

Uses.—It is estimated that more than one-half the barley crop is used to feed livestock. The grain contains approximately the same percentage of carbohydrates as does corn, about 3% more protein and slightly less fat. Because of the hull it contains 5% less digestible material. Nevertheless, it is considered a fattening food and therefore not so useful for horses as for cattle, hogs and perhaps poultry. Europeans consider that it produces a high-quality pork with comparatively firm meat and fat.

Barley apparently was used for beermaking in prehistoric times. Nearly all beer is made from barley and more than 10% of the world's crop is so used. In the United States and some countries of western Europe the percentage used for beer may be one-fourth or even higher.

In the process of malting, malt barley is steeped in water and allowed to germinate or sprout, at which stage it is called green malt. It is then killed, usually by drying or roasting in a kiln. The dried material includes, as a result of the sprouting process, the enzyme diastase. which is capable under proper conditions of saccharifying the starch of the malt and also that of raw grain which is mixed with it in brewing or distilling beer or whisky.

Two-rowed barleys are the typical malting barleys except in the United States; they require soils as good as those for the best wheats. Malting barley has been described as fully mature grain, plump, mellow, small kernelled, firm hulled. carefully threshed, all of the same type, sound and free of damage by weather or disease. Black kernels are difficult to distinguish from kernels damaged by heat; skinned kernels or frayed ends are objectionable because they do not convert properly in malting. High protein is objectionable unless starch is to be added. (See MALT.)

Though a porous loaf cannot be made from barley flour because of its low gluten content, substantial quantities of barley are consumed for human food, as flatbread or porridge, particularly in north Africa and parts of Asia where it is the staple food grain, and as pearl barley. Most of the barley used as human food in the United States and in some other parts of the world is in the form of pearl barley—whole kernels from which the outer husk and part of the bran layer have been removed by a polishing process. Pearl barley is commonly added to some types of soups.

Barley straw is of a soft type, used mostly as bedding for livestock or as a coarse bulk roughage feed.

Statistical data on production and prices are summarized annually in the *Britannica* Book *of* the Year. (J. K. R.)

BARLOW, JOEL (1754–1812), U.S. poet and public official, one of the "Connecticut Wits" and author of the mock-heroic poem The Hasty Pudding, was born in Redding, Conn., on March 24, 1754. He graduated from Yale in 1778, did postgraduate work there, and for three years was a chaplain in the Revolutionary army. In July 1784 he established at Hartford, Conn., a weekly paper, the American Mercury, with which he was connected for a year. In 1786 he was admitted to the bar. He was a member of the group of young writers, known as the Connecticut or Hartford wits, who were motivated by patriotism to undertake the creation of a national literature; the group included John Trumbull (*q.v.*)

and Timothy Dwight (see DWIGHT family). Barlow's *Vision* of Columbus (1787), a poetic paean to America in nine books, brought the author immediate fame; it was characterized by great verve and enthusiasm but was marred by failure in poetic technique and confusion of thought.

In 1788 Barlow went to France as the agent of the Scioto Land company, and induced the company of Frenchmen who ultimately founded Gallipolis, O., to emigrate to America. In Paris he became a liberal in religion and an advanced republican in politics. He was a member of the London Society for Constitutional Information; published various radical essays, including a volume entitled Advice to the Privileged Orders (1792), which was proscribed by the British government; and was made a citizen of France in 1792. Thomas Paine had become his friend in England, and during Paine's Paris imprisonment Barlow effected the publication of The Age of *Reason*.

His career took an increasingly romantic turn in subsequent years. In 1795–97 he was sent to Algiers to secure a release of U.S. prisoners and to negotiate treaties with Tripoli, Algiers and Tunis. He returned to the United States in 1805 and lived near Washington, D.C., until 1811 when he became U.S. plenipotentiary to France, charged with negotiating a commercial treaty and securing restitution or indemnity of confiscated U.S. property. In that capacity he became involved in Napoleon's retreat from Russia and died of exposure at Zarnowiec, Pol., Dec. 24, 1812.

In 1807 Barlow published in a sumptuous volume The *Columbiad*, an enlarged edition of his Vision of Columbus, more mature than the original but also more pretentious, and one of American literature's great failures. He is now best known for his much-anthologized Hasty Pudding (1796), a pleasantly humorous pastoral poem inspired by homesickness for New England and corn-meal mush.

He also published religious verse, and his political writings in collected form went through several editions in his lifetime.

See James Woodress, *A* Yankee's Odyssey: The Life of Joel *Barlow* (1958), the first full-length biography; Leon Howard, The Connecticut Wits (1943).

BARMECIDES (properly BARMAKIDS), a noble Persian family which attained great power under the Abbasid caliphs in the 8th and early 9th centuries A.D. (see CALIPHATE). Barmak was the title of their ancestors as hereditary high priests of a Buddhist temple near Balkh, for a time a centre of resistance to the Arab conquest. Khalid ibn Barmak (d. 781 aged about 75) became a Muslim and was given high offices under the first three Abbasid caliphs. His son Yahya ibn Khalid was made vizier by Harun al-Rashid when the latter became caliph (786), Yahya having previously been his tutor and the deputy-governor (under Khalid) or governor of various provinces. From 786 to 803 Yahya, with his sons Fadl and Ja'far, controlled the affairs of the caliphate. They brought the administrative machine to greater efficiency, and under their direction the caliph's vast territories reached a supreme degree of power and prosperity, while art and letters flourished. An exaggerated picture of the colourful life of Baghdad at this period is given in the Arabian Nights (see THOUSAND AND ONE NIGHTS) and elsewhere. The Barmecides' fall was sudden. One night in Jan. 803, Yahya, Fadl and others were arrested and imprisoned, while Ja'far, who had been Harun's boon companion as well as an administrator, was executed. The chief reason was perhaps Harun's desire to be master himself.

The expression "Barmecide feast," for an imaginary banquet, comes from "The Barber's Tale of His Sixth Brother" (Arabian Nights), where a Barmecide has a series of empty dishes served to a hungry man to test his sense of humour. (W. M. WT.)

BARMEN, a former German city in the Prussian Rhine province, lies along the valley of the Wupper and was once famous for its textiles and red dyeing. In 1929 it was joined with the city of Elberfeld and neighbouring towns to form a modern industrial city known since 1930 as Wuppertal (*q.v.*).

BARMEN, SYNOD OF, a meeting of German Protestant leaders at Barmen in the Ruhr, May 1934, to organize Protestant resistance to National Socialism. Representatives came from established Lutheran, Calvinist and United churches, although some of the church governments already had been captured by men loyal to Hitler and others—notably in Wiirttemberg, Bavaria and Hanover—had decided to limit their activities to passive resistance. The Pastors' Emergency League, headed by Martin Niemoller of Berlin-Dahlem, was the backbone of the active resistance (*Bekennende* Kirche, "Confessing Church"). Various unofficial men and movements, including leaders in the German Christian Students' movement (D.C.S.V.) and community religious emphasis weeks (*Evangelische* Wochen) led by Reinold von Thadden-Triegloff also rallied to the cause. After Barmen, representative semilegal "synods" were held at Dahlem, Augsburg and Bad Oeynhausen, until the government of the third Reich arrested Niemoller (1937) and drove the movement underground.

At Barmen representatives of the major Protestant confessions adopted six articles that defined the Christian opposition to National Socialist ideology and practice. The major theological influence was that of Karl Barth. The articles did not attempt a well-rounded system, but adopted the classical form of the great confessions of faith, affirming major biblical teachings and condemning the important heresies of those who were attempting to accommodate Christianity to National Socialism. The synod was a major event in European church history, and pointed the way to the Stuttgart Declaration of Guilt (1945) and the postwar renewal of the church in Germany.

See The Significance of the Barmen Declaration for the *Oecumenical* Church (1943); F. H. Littell, The German Phoenix (1960).

(F. H. LI.)

BARMER, a town, formerly headquarters of the Mallani district of Jodhpur state, is now headquarters of the district of Barmer in Jodhpur division of Rajasthan, India. It is on the Northern railway from Delhi and Jodhpur to the frontier of Pakistan, and thence to Hyderabad. The population of the town rose from 6.064 in 1901 to 20,812 in 1951. It has an observatory. The present town is said to have been founded in the 13th century by a Raja Bahada, and to have been called after him Bahadamer (the meru or "hill fort" of Bahada), since contracted to Barmer. It is built on the side of a rocky hill, crowned by an old fort.

BARMER DISTRICT had a population of 648,734 in 1961. Situated in the Thar desert, it has an annual rainfall of five to ten inches. Its western boundary is also the border of Pakistan. There are several outcrops of stone, and millstones are manufactured and exported to the neighbouring districts. The total area is 10,174 sq.mi., of which one-half is under cultivation. Irrigation is carried on mainly from wells, which are generally deep. The soil is poor and sandy. (S. M. T. R.)

BAR MITZVAH, the Jewish religious ritual and family celebration commemorating the 13th birthday of a boy. This birthday according to tradition marks a boy's religious coming of age. He is now deemed responsible for the fulfillment of all the commandments (Bar Mitzvah means "son of" or "one responsible for the commandments"). The boy is called up to the reading of the scroll of the Law on the sabbath following his birthday, and after the services (nowadays often on the next day) there is a family feast at which, in former days, the "Bar Mitzvah" recited a learned discourse on the Law. The age of 13 as the mark of religious maturity is mentioned by Rabbi Juda ben Tema (2nd century), but the ceremony of calling the boy to the Torah on the sabbath and the family festivities are not mentioned till the middle ages.

Reform Judaism, after 1810, developed confirmation as a substitute for Bar Mitzvah. At this ceremony a whole class of boys and girls are confirmed in a joint ceremony, usually on the Feast of Shabuoth (Feast of Weeks). In the 20th century many Reform congregations restored the individual Bar Mitzvah, while retaining the joint confirmation for age 15 or 16. Many Conservative congregations have instituted Bas Mitzvah, an individual ceremony for girls. (S. B. FR.)

BARMOTE COURT (also BERGHMOTE, BARGMOTE, BARGEMOTE, BARMOOT), a court held in the lead-mining districts of northern Derbyshire, Eng., to determine customs peculiar to the industry and to settle disputes among the miners. Barmote courts, which were in existence in the reign of Edward I, covered two main districts where the crown is entitled to mineral duties: (1) the

King's field in the High Peak comprising seven liberties; and (2) the soke *(see* SOCAGE) and wapentake *(q.v.)* of Wirksworth. Obsolete customs were erased and procedure regulated by the High Peak (1851) and Derbyshire (1852) Mining Customs and Mineral Courts acts conferring similar powers on both districts. Each holds a great barmote court once a year, and the small barmote courts function more often; they are presided over by a steward, and officials are known as barmasters.

BARMOUTH (ABERMAW), an urban district and seaside resort of Merioneth, Wales, is situated on the north bank of the picturesque Mawddach estuary, 10 mi. W. of Dolgellau by road. Pop. (1961) 2,348. The modern town occupies most of the narrow littoral between the sea and the foothills of the Rhinog range. Above the town and overlooking Cardigan bay are 4 5 ac. of cliff-land (Dinas Oleu) which were the first property acquired by the National Trust (1895). Twelve cottages on this land were bought by John Ruskin in 1874 to implement the social ideals of his St. George's guild, which still administers them. The Early English parish church of St. Mary, Llanaber, 2 mi. N., is perhaps the most interesting church in the county. Barmouth, with its fine sandy beach, has attracted a steadily increasing number of tourists since the beginning of the 19th century. A railway bridge (1866) spans the estuary and there are services to the Welsh border via Dolgellau or Machynlleth. (W. H. W. T.)

BARN: *see* FARM BUILDINGS.

BARNABAS, SAINT, although not one of the Twelve, was the most important early Christian apostle to the gentiles with the exception of Paul. He is mentioned occasionally in the Pauline Epistles (Gal. ii, 1, 9, 13: I Cor. ix, 6; Col. iv, 10), and is a central figure in Acts xi, 19–xv, 41. Acts iv, 36 tells of the adding of the surname Barnabas (interpreted to mean "son of encouragement" or "exhortation") to his original name, Joseph. The actual etymology of Barnabas is in doubt (perhaps it is the Greek transliteration of pagan-Semitic Bar-Nebo; *i.e.,* "son of [the god] Nebo"); in fact, there is reason to question the entire picture of Barnabas given by Acts. One of the major problems is the apparent discrepancy between Gal. i, 15–ii, 14 and Acts *(see* PAUL, SAINT; ACTS OF THE APOSTLES).

The critical search for reliable information behind the account in Acts has produced the following results: (1) Barnabas was a Jewish Hellenist from a Cypriot family who joined the Jerusalem church soon after Jesus' death, sold his property and gave the proceeds to the community (Acts iv, 36–37). (2) First in the list of the Antiochian prophets (Acts xiii, 1), Barnabas was one of the Cypriots who founded the church in Antioch (Acts xi, 19–20). It is quite possible that Barnabas, who called Paul from Tarsus as his assistant (Acts xi, 25), was actually the first Christian missionary to deny the necessity of the Jewish Law for the gentile Christians. (3) After a period of joint missionary activity (Acts xiii–xiv), Barnabas and Paul went to Jerusalem in A.D. 48 and successfully obtained the recognition of a gentile Christianity that was free from the Jewish Law (Gal. ii, 1–10; *see* also Acts xv, 1–29). (4) Shortly afterward a serious conflict (Gal. ii, 11–13; compare Acts xv, 36–41) led to a definite breach with Paul, after which Barnabas sailed to Cyprus (Acts xv, 39). Barnabas then drops from the scene, except for a brief reference by Paul a few years later (I Cor. ix, 6). Nothing can be said about the time or circumstances of his death (the apocryphal *Journeys and Martyrdom of Barnabas* is a forgery from the 5th century A.D.; *see* APOCRYPHA, NEW TESTAMENT).

Subsequent church tradition finds Barnabas again in Alexandria, and ascribes to him the Epistle of Barnabas *(see* APOSTOLIC FATHERS), or pictures him in Rome and assumes that he wrote the Epistle to the Hebrews. In order to stress its independence, the Church of Cyprus, and later even that of Milan, claimed to have been founded by the apostle Barnabas.

BARNABAS, EPISTLE OF, one of the "Apostolic Fathers," found in the 4th-century *Codex Sinaiticus* of the New Testament. *See* APOSTOLIC FATHERS.

BARNABITES (CLERICS REGULAR OF ST. PAUL), a religious order founded in 1530 by St. Antonio Maria Zaccaria (1502–39) and confirmed as an order by the Vatican in 1535 and 1579. In addition to monastic devotion, they give practical help to those in physical or spiritual need and are especially devoted to a study of the Pauline Epistles. In 1538 they acquired the ancient church of St. Barnabas in Milan (hence their name). They have monasteries in Italy, Austria, Belgium, Spain, and South America. *See* also ORDERS AND CONGREGATIONS, RELIGIOUS.

BARNACLE, generally the common name for any of the greatly modified marine crustaceans of the subclass Cirripedia. In a more restricted sense the name refers to the nonparasitic forms — the stalked or peduncled barnacles (family Lepadidae) and the sessile barnacles or acorn shells (Balanidae). Other members of the subclass include the parasitic barnacles, with even greater degeneration of body form (see *Parasitic Barnacles,* below).

General Description. — The stalked barnacles are most frequently found attached to driftwood and constitute one of the major groups of fouling organisms on hulls of ships in the open sea. The acorn shells also are important as fouling organisms, usually

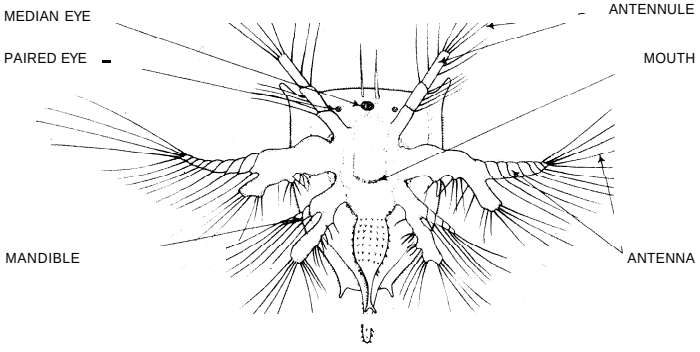

FIG. 1.—LATE STAGE NAUPLIUS LARVA OF A BARNACLE, VENTRAL VIEW. GREATLY ENLARGED

becoming attached while the ship is in coastal waters, but they are more frequently seen as the encrusting animals that may completely cover pilings, jetties and rocky areas within the intertidal zone. The shells of most species of sessile barnacles are composed of four to eight vertical wall plates that form a truncate cone, a membranous or calcareous basis that is attached to the substratum and four movable opercular plates (lids) on the free end of the shell, opposite the basis. All calcareous plates are connected at their interfaces by chitin and are lined internally by the fleshy mantle. In some of the stalked barnacles the body is well covered with hard, calcareous plates; in others the shell may be only partially calcified or almost absent, being represented by tiny vestiges. As originally postulated by Darwin in 1854 the

FIG. 3.— (LEFT)ACORN BARNACLE (BALANUS TINTINNABULUM) WITH CIRRI EXTENDED: (RIGHT) ACORN BARNACLE WITH SHELL PLATES REMOVED FROM ONE SIDE, SAGITTAL VIEW

continuous growth of the shell results from the deposition of new matrix and calcium carbonate by the mantle at the edge of the old portions of the shell.

Enclosed by the shell is the body, or soma, which carries out the functions of feeding, respiration and reproduction. The body more closely resembles the crustacean form in having jointed appendages and a soft chitinous body covering (exoskeleton) that also lines the fore-gut and hind-gut. Growth of the body occurs periodically by the molting of the exoskeleton; however, the shell plates are not shed and the continuous growth of the calcareous plates is not affected by the molting cycle.

Feeding is accomplished by the sweeping motion of the thoracic appendages, or cirri, which have fine hairlike processes. When the lids are open, the cirri are extended into the water, the fine hairs of the cirri acting as a net, enmeshing plankton and other particles, which are then carried down to the mandibles and ingested. Paired eyes. which first appear in the late stage nauplii and are carried over into the adult, are located within the mantle and apparently function only as light-sensitive organs.

Distribution.— Distribution of barnacles is normally accomplished by movement of the tiny larvae with tides and horizontal water currents. Some species *(Balanus tintinnabulum* and *Elminius modestus)* have been distributed over wide areas and accidentally introduced into new areas by the movement of ships and amphibious aircraft to which adults were attached. In intertidal barnacles a definite pattern of vertical zonation in relation to tide may be observed in most areas of the world. Some species are limited in their distribution by the salinity of estuarine waters, by seasonal fluctuations in temperature and by competition for space with other intertidal organisms. Although many species of sessile barnacles are exclusively marine animals—found only in salinities of 30 to 35 parts per thousand—other species occur throughout a wide range of estuarine areas and are found in waters in which the salinitv has been reduced to less than one part per thousand.

Many species will attach to any available surface. but some forms are extremely specific in their habitat. *Octolasmis mulleri,* a stalked barnacle, is found only in the gill chambers of certain marine crabs; and *Balanus galeatus,* a rock barnacle, is found always associated with the soft coral *Leptogorgia*

ROBERT C. HERMES FROM NATIONAL AUDUBON SOCIETY

FIG. 4.— GOOSENECK BARNACLES (LEPAS FASCICULARIS)

Reproduction and Development.— Adult barnacles are usually hermaphroditic (both sexes in a single individual), although dwarf males have been described for a few species. Cross-fertilization between adults occurs in most forms, but self-fertilization can produce viable eggs in some species. The eggs upon being laid are retained as two flat, yellow layers in the mantle cavity of the adult, on either side of the body. As embryonic development progresses the eggs darken and are a slate-gray immediately prior to hatching. The larvae are hatched as free-swimming nauplii (fig. 1) and expelled from the adult through the opercular opening. A typical barnacle nauplius—with a shieldlike carapace, median eye and an abdominal process—has three pairs of appendages which are used for feeding on smaller planktonic organisms and also for swimming In most barnacles the nauplii pass through a series of six stages. increasing in size and complexity with each molt. The final naupliar molt produces the bivalved cypris larva (fig. 2) which is free-swimming but does not feed. In the cypris six cirri are present, and the antennules are modified as cement glands by means of which the larvae attach to the substratum at the time of settling. The period of larval development may vary from about one to about eight weeks, depending upon water temperatures and available food. After attaching to the substratum the cypris metamorphoses into a "pinhead" barnacle and initiates development of the external calcareous shell.

In the natural environment predation of the larval stages by filter feeders accounts for a high percentage of mortality. The larvae are liberated in such large numbers in some areas that they constitute the major portion of the diet of some fish. The settled stages are also scraped from the substratum and eaten by sea urchins. carnivorous gastropods *(Thias lapillus)* and fish such as the sheepshead *(Archosargus probatocephalus).*

Control of Fouling Barnacles.— Although the development of antifouling paints has progressed considerably, many paints are effective only in certain waters and for limited periods of time. *(See* PAINT: *Antifouling Paints.)* (J. D. Co.)

Parasitic Barnacles.— Allied to the more normal Cirripedia just described are a number of more degenerate and, for the most part, parasitic forms. The most degenerate are the members of the order Rhizocephala. of which the genus *Sacculina,* a common parasite of crabs, is a familiar example. It has a simple saclike body attached under the abdomen of the crab by a short stalk from which rootlike processes ramify throughout the internal organs of the host. The body is enveloped by a fleshy mantle with a small opening and is without appendages, mouth or alimentary canal, the only organs which are well developed being those of the reproductive system. Only the larval development allows *Sacculina* to be referred to the Cirripedia. (For the effect of *Sacculina* on its host, *see* SEX: *The Effects* of *Parasitism.)* Largest of the Rhizo-

cephala is *Briarosaccus callosus,* found living on certain crabs of the family Lithodidae taken from more than 250 fathoms off the southeastern United States.

Classification. — Though complicated by the obscure relationship of parasitic forms to more normal cirripedes, the classification generally adopted is as follows:

Order Thoracica, with six pairs of cirri, divided into four suborders: Lepadomorpha, the stalked barnacles *(Lepas, Scalpellum, Mitella)*; Verrucomorpha, asymmetrical sessile forms (*Verruca*); Brachylepadomorpha, sessile, fossil only, *(Pycnolepas, Brachylepas)*; Balanomorpha, the sessile acorn shells and rock barnacles *(Balanus, Chthamalus, Coronula, Chelonibia)*.

Order Acrothoracica, somewhat degenerate forms with fewer cirri, boring in shells and corals (*Alcippe*).

Order Ascothoracica, six pairs of cirri, only cirripede with definite, at times segmented, abdomen, parasitic on coelenterates and echinoderms; affinities obscure *(Laura, Dendrogaster)*.

Order Apoda, no cirri, only known specimen described by Darwin; from mantle cavity of another cirripede *(Proteolepas)*.

Order Rhizocephala, degenerate parasites of decapod Crustacea, only cirripedes without any alimentary canal; no trace of segmentation in adult, wholly without appendages *(Sacculina, Peltogaster)*.

BARNARD, LADY ANNE (nte LINDSAY) (1750–1825), Scottish author of the ballad "Auld Robin Gray," was born in Dec. 1750, at Balcarres castle, Fifeshire. In 1793 she married Andrew Barnard and went to the Cape of Good Hope with him when he became colonial secretary there in 1797. When the Cape was ceded to Holland (1802), they returned to London, where she lived until her death on May 6, 1825. She wrote "Auld Robin Gray" to the music of an old song. Her letters from the Cape to Henry Dundas. then secretary for war, were published as *South Africa a Century Ago* (1901).

See *Auld Robin Gray,* ed. by Sir Walter Scott *(1825);* D. Fairbridge, *Lady Anne Barnard at the Cape of Good Hope, 1797–1802 (1925);* M. Masson, *Lady Anne Barnard (1948).*

BARNARD, EDWARD EMERSON (1857–1923), U.S. astronomer particularly noted for his work in celestial photography. He was born in Nashville, Tenn., on Dec. 16, 1857. He began his studies alone in boyhood. In 1887 he graduated from Vanderbilt university, after having charge of the observatory there for four years. In 1887 he was appointed astronomer at Lick observatory, and from 1895 until his death he was professor of practical astronomy and astronomer of Yerkes observatory, at The University of Chicago. He accompanied the U.S. Naval observatory eclipse expedition to Sumatra (1901). His contributions to observational astronomy were numerous and important. In celestial photography he obtained excellent results and discovered 16 comets, Jupiter's fifth satellite and the star (Barnard star) with the greatest known motion (1916). He was associate editor of the *Astronomical Journal* and the author of *Micrometrical Observations of Eros Made During Opposition of 1900–1901.*

A bibliography may be found in J. A. Parkhurst's "Edward Emerson Barnard," in *National Academy of Sciences — Report,* pp. *49–53* (1923). For further biographical material consult: *Royal Astronomical Society,* Monthly Notices, vol. lxxxv, pp. 221–225; Robert G Aiken's "Edward Emerson Barnard (1857–1923)" in *Astronomical Society of the Pacific,* vol. xxxv, pp. *87–94.*

BARNARD, FREDERICK AUGUSTUS PORTER (1809–1889), U.S. educator and for nearly 25 years president of Columbia college in New York city, during which time the college was transformed from a small undergraduate institution for men into a world-famous university. Barnard was born in Sheffield, Mass., on May 5, 1809, graduated from Yale college in 1828 and taught for several years in schools for the deaf-mute. Then he turned to college teaching in mathematics, science and English, first at the University of Alabama (1838–54) and later at the University of Mississippi (1854–56). He was president and chancellor of the University of Mississippi from 1856 to 1861, when he resigned because of his Union sympathies.

Earlier. Barnard had defended the traditional prescribed curriculum, with its emphasis upon the classics and mathematics as the best means of discipline of the faculties of the mind, opposing the introduction of utilitarian or professional subjects into the curriculum. But after he went to Columbia college, in 1864, Barnard changed his views. He urged Columbia to expand its curriculum and introduce the elective system into the last two years of college as the best means of developing advanced scholarship leading to graduate and professional education; besides, he argued, this was the best way to attract more students. Barnard was instrumental in establishing the school of mines and opening the university to women. Hence, Barnard college for women was named for him when it opened in 1889.

Barnard was a vigorous but somewhat prolix writer on political, economic and scientific as well as educational topics. He was a versatile man. a classical and English scholar. a mathematician, a scientist and a good public speaker. His annual reports to the Columbia trustees were particularly valuable as discussions of educational problems.

See also COLUMBIA UNIVERSITY.

(R. F. Bs.)

BARNARD, GEORGE GREY (1863–1938), U.S. sculptor whose works were characterized by a vitality and individuality that sometimes made them subjects of controversy, was born at Bellefonte, Pa., on May 24, 1863. At 13 he was apprenticed to a jeweler and he then attempted his first sculpture. He studied at the Art Institute of Chicago in 1880 and at the École des Beaux Arts and the studio of Pierre Jules Cavelier in Paris between 1883 and 1887.

His first important commission was for a grave monument to the Norwegian poet Severin Skovgaard. In 1894 he exhibited at the Paris salon where his work created a sensation and made the reputation of the young sculptor. One of the works shown then was "The Struggle of the Two Natures in Man" (Metropolitan museum, New York). His most important work was the two colossal groups at the entrance of the Pennsylvania state capitol building at Harrisburg. Barnard made a collection of early Gothic sculpture and medieval architectural fragments which in 1925 was purchased by the Metropolitan museum. His vigorous statue of Lincoln (in Lytle park, Cincinnati: O.) was the centre of a storm of criticism when it was unveiled in 1917. His last work. the so-called Rainbow arch. remained uncompleted. He died in New York city on April 24, 1938. Collections of his work are at Swarthmore college. Swarthmore, Pa., and the Jefferson County Historical society, Madison, Ind.

See Lorado Taft, *History of American Sculpture,* rev. ed. (1930); Beatrice I. Proske, *Brookgreen Gardens Sculpture* (1943). (A. T. G.)

BARNARD, HENRY (1811–1900), U.S. educator, whose contributions toward the stimulation and direction of popular education in the United States were very great as well as lasting, was born Jan. 24, 1811, at Hartford, Conn. He graduated from Yale with honours but interrupted his preparation for the legal profession to take charge of an academy at Wellsboro, Pa. In 1835 he was admitted to the Connecticut bar. In the same year, while in Europe. he became interested in the new theories of European educators — in particular, J. H. Pestalozzi, F. W. Froebel and P. E. von Fellenberg — and after his return to the United States in 1836 he abandoned law practice to begin a career of educational administration.

As a Whig member of the Connecticut state legislature, 1837–39, Barnard was instrumental in drafting and securing the passage in 1838 of a measure that created a state board of "commissioners of common schools." His administration as first secretary of this board featured the founding of the *Connecticut Common School Journal* in 1838 and the first teachers' institute in 1839. He ac-

cepted a similar school position in Rhode Island in 1843. Following his survey of the state's common schools, he became its first commissioner of public schools and reorganized the Rhode Island school system. Further, he activated community libraries for school use, introduced a popular traveling model school for demonstration of classroom methods during teachers' institutes and established an educational periodical, the *Journal of the Rhode Island Institute of Instruction.*

Illness forced his resignation in 1849. In 1851 he returned to Connecticut as the state superintendent of schools and principal of the new state normal school at New Britain. When poor health again led to his resignation in 1855, he left a well-integrated school system.

From 1858 to 1861 Barnard was chancellor of the University of Wisconsin. Madison. and agent of the normal school regents. In 1866 he accepted the presidency of St. John's college. Annapolis, Md.. and from 1867 to 1870 he was the first United States commissioner of education.

In addition to his annual reports as educational administrator, Barnard founded and edited three state school journals. His greatest contribution in this field, the *American Journal* of *Education,* established in 1855 and expanded to 32 volumes by 1882, was more of an encyclopaedia than a serial publication. It not only documented the pattern of thought in U.S. education during the 19th century's struggle for public schools, but also presented the best in foreign educational literature.

Barnard died at Hartford. Conn., on July 5, 1900.

BARNARD CASTLE, an urban district, market town and holiday resort of County Durham, Eng., is picturesquely situated on the north bank of the river Tees, which forms the border with Yorkshire, at the eastern end of the Stainmore gap through the Pennines, 16 mi. W. of Darlington by road. Pop. (1961) 4,969. The area has been occupied since the Stone Age, and two Roman roads intersected where the town now stands. When the stone castle, which gave the town its name, was erected (before 1200) by Bernard de Balliol a feudal settlement grew around it. The town received its first charter about 1178 from Bernard de Balliol. In the castle was born John de Balliol, founder of Balliol college. Oxford, and father of the John de Balliol (*q.v.*) who was for a short time king of Scotland. The ruins of the castle, including a 14th-century round tower, stand on a low cliff overlooking the rocky Tees, there crossed by a medieval bridge. The town retains many 18th-century buildings including the town hall (1747). The 17th-century trades of tanning, harness making and stockings were succeeded by woolen manufactures bringing much wealth and, in the 19th century, by carpet weaving and rope and shoe-thread making. Modern industries include the making of penicillin, gloves, cloth and concrete products. Rokeby, 2 mi. S.E., is the chief scene of Sir Walter Scott's poem of that name. while 14th-century Raby castle lies 6 mi. N.E. and ruined Eggleston abbey 1 mi. S.E. The Bowes museum, built in 1869–92 by John Bowes, contains a famous collection of pictures and other works of art. Charles Dickens was inspired by the locality to write *Nicholas Nickleby* and *Master Humphrey's Clock.*

BARNARD COLLEGE, for women, in New York city, founded as an affiliate of Columbia college in 1889 and named after F. A. P. Barnard, became a part of the university in 1900. *See* COLUMBIA UNIVERSITY.

BARNARDO, THOMAS JOHN (1845–1905), founder and director of homes for destitute children, was born in Dublin on July 4, 1845, where his father, a German immigrant of Spanish descent, was a furrier. In 1862, during the Protestant religious revival in Dublin, Barnardo experienced conversion, and in 1666 he went to London to train as a medical missionary for China. It was as a medical student teaching voluntarily in "ragged schools" that he discovered the homeless waifs of London sleeping on roofs and in alleyways. Speaking of this at a missionary rally brought him offers of money and help and he founded his first home for destitute boys in Stepney Causeway in 1870. "Dr. Barnardo's Homes." or the National Incorporated Association for the Reclamation of Destitute Waif Children, as they became in 1899, met a real need and grew rapidly in number. The slogans of the movement—"No destitute child ever refused admission" and "The ever-open door"—did not prevent a high quality of child care and instructional training, shown in the success of these former waifs and strays in later life. Barnardo died at Surbiton, Surrey, on Sept. 19, 1905.

BIBLIOGRAPHY.—S. L. Barnardo and J. Marchant, *Memoirs of the late Dr. Barnardo* (1907), with *a* bibliography of 71 items on the work of Barnardo; N. G. Wymer, *Father of Nobody's Children* (1954); *A.* E. Williams, *Barnardo of Stepney, the Father of Nobody's Children* (1954). (J. MY.)

BARNATO, BARNETT (BARNEY BARNATO) (1852–1897), English financier. who was one of the most colourful personalities associated with the development of the South African mining industry, was the son of a London Jewish shopkeeper, Isaac Isaacs. In 1873 he went to Kimberley in South Africa to join his brother Henry, a diamond dealer who had gone to Africa as an amateur entertainer under the stage name Barnato (which he and his brother had assumed in London). Barney too became a diamond broker. forming with Henry the firm Barnato Brothers in 1874. He began to buy up diamond mining claims in 1876 and the Barnato Diamond Mining company, which he formed in 1880, became the only serious rival to Cecil Rhodes's De Beers Mining company. The struggle for control of the industry ended in 1888 with Rhodes's victory and the amalgamation of the two companies as De Beers Consolidated Mines, in which Barney Barnato became a life-governor. The same year he entered the Cape Colony house of assembly as a member for Kimberley. Seeing the potentialities of the newly discovered Witwatersrand gold fields he began buying up claims and real estate there in 1889, and floated the Barnato Consolidated Mine's company and the Barnato bank. In 1895 his "bulling" operations saved the Rand from a serious slump. He did not participate in the Jameson raid conspiracy (Dec. 1895), and afterward strongly denounced the venture. On June 14, 1897, he jumped overboard on his way to England and was drowned. His son Woolf Barnato (1895–1948) was prominent in' British motor racing circles. (M. F. K.)

BARNAUL, a town and administrative centre of the Altai *krai* of the Russian Soviet Federated Socialist Republic, U.S.S.R., is situated on the left bank of the Ob, at its confluence with the Barnaulka. Pop. (1959) 320,000. Founded in 1738 as a silver-refining centre, Barnaul became the hub of the Altai mining region. It is now an important industrial town, with engineering (power station boilers. presses, diesel motors, radios), timber working (saw-milling, matches, furniture, turpentine), textile and boot and shoe making and food processing (milk, meat and flour-milling). A large cotton mill was constructed after 1960. At Chesnokovka, across the Ob, rolling stock is built. Barnaul is an important communications centre on the navigable Ob, on the south Siberian and Turksib railways, with a branch to Bisk, and on roads to the Kolyvan-Rubtsovsk mining area and Novosibirsk. There are four institutes, pedagogical, medical, agricultural and agricultural engineering. (R. A. F.)

BARNAVE, ANTOINE PIERRE JOSEPH MARIE (1761–1793), one of the foremost orators of the Constituent Assembly during the French Revolution, was born at Grenoble, in Dauphiné, on Sept. 21, 1761. Having made a name for himself, first with a pamphlet on the military edicts of May 1788 during the dispute between the *parlement* of Grenoble and the French government, then as a supporter of J. J. Mounier in the resistance of the estates of Dauphiné to the government, he was elected a deputy of the *tiers état* to the estates general of 1789. There he distinguished himself as an impromptu speaker and as one who could present complex issues clearly and incisively. In the debates of Sept. 1789 on the legislative chambers and on the right of veto, he broke with Mounier and identified himself with the left. He, Alexandre de Lameth and Adrien Duport then grouped themselves together as the "triumvirate." Together they contributed substantially to the formation of the Jacobins, the constitution of which Barnave drew up. In 1790 he opposed Mirabeau on the

question of the king's right to make war and peace and up to November enjoyed a popularity that rivaled Mirabeau's. but his support of the planters' organizations in the West Indian colonies enabled Jacques Pierre Brissot to begin discrediting him (with the pamphlet *Lettre à M. Barnave).* Harassed by Brissot and Robespierre, the triumvirs lost ground on the left and tried to come to terms with the king's ministers after Mirabeau's death (April 1791). When the royal family was brought to Paris from Varennes. Barnave, as commissary of the assembly, came into contact with Marie Antoinette, was moved to sympathy by her situation and began a secret correspondence with her. His impassioned speech on the inviolability of the monarchy (July 15, 1791) carried the assembly, whereupon the triumvirs broke with the Jacobins and founded the club of the Feuillants. In Aug. 1791, however, they failed in their attempt to strengthen the royal power under the constitution. Continuing his correspondence with the queen during the first months of the legislative assembly, Barnave had two more interviews with her (first with Lameth, then alone).

Barnave left Paris for Grenoble in Jan. 1792. In Paris. however, the attack on the Tuileries, in August, led to the discovery of a document bearing his name and Lameth's, in which a project for a committee of ministers was outlined. Arrested in Grenoble on Aug. 19, 1792, Barnave was kept in prison for 15 months (during which he wrote his *Introduction à la révolution française*), sentenced by the revolutionary tribunal on Nov. 28, 1793, and executed the next day. His remark. "It is very interesting to start a revolution, but hard to be obliged to bring it to its conclusion," summarizes his career. There are editions of Barnave's works by A. Bérenger de la Drôme (1843); of his previously unpublished correspondence of 1792 by G. Michon (1924); and of his secret correspondence with Marie Antoinette by A. Soderhjelm (1934).

See E. D. Bradby, *Life of Barnave* (1915); J. J. Chevalller, *Barnave, ou les deux faces de la Révolution* (1936). (J. J. CH.)

BARNBY, SIR JOSEPH (1838–1896), English composer, organist and conductor who promoted an interest in choral music: was born at York, Aug. 12, 1838. He studied at the Royal Academy of Music, London: and subsequently became organist at a succession of London churches. He gave Bach's *St. Matthew Passion* at Westminster abbey in 1871 and, appointed to St. Anne's, Soho, in the same year, he conducted annual performances there of the *St. John Passion,*. His choir was amalgamated in 1871 with the Royal Albert Hall Choral society, later the Royal Choral society. He gave the first performances in England of Dvořák's *Stabat Mater* (1883) and of a concert version of Wagner's *Parsifal* (1884). He became precentor of music at Eton in 1875, and principal of the Guildhall School of Music in 1892, and was knighted in the same year. His compositions consist chiefly of services, anthems and hymns. and part songs, of which the most popular was his setting of *Sweet and Low* (1863). He died in London on Jan. 28, 1896.

BARNES, BARNABE (1569?–1609), English poet, one of the Elizabethan sonneteers and the author of *Parthenophil and Parthenophe,* was the son of Richard Barnes, bishop of Durham. He was entered at Brasenose college, Oxford, in 1586 but took no degree and in 1591 joined the expedition to Normandy led by the earl of Essex. On his return he published *Parthenophil and Parthenophe* (entered on the Stationer's Register, 1593), containing sonnets, madrigals, elegies and odes, on which rests his claim to fame. In 1598 Barnes was prosecuted in the Star Chamber on a charge of attempted poisoning, but he escaped to the north. He also took part in the quarrels between Thomas Nashe and Gabriel Harvey (*qq.v.*) whose friend he was. His works include *A Divine Centurie of Spiritual1 Sonnets* (1595), *Foure Books of Offices* (1606) in prose and a play, *The Divil's Charter* (1607) At his best his poems, particularly the madrigals, have exuberance and occasional felicity of language; the sonnets show French influence.

BIBLIOGRAPHY.—*Parthenophil and Parthenophe* and *A Divine Centurie of Spirituall Sonnets* were included in *Poems of Barnabe Barnes,* ed. *by A.* B. Grosart (1875); *The Divil's Charter* was ed. by R. B. McKerrow, *Bang's Materialen,* vol. vi (1904). *See* also M. Eccles, "Barnabe Barnes," in C. J. Sisson (ed.), *Thomas Lodge and Other Elizabethans* (1933); J. G. Scott, *Les Sonnets élizabéthains* (1929); *M.* H. Dodds, "Barnabe Barnes," *Archaeologia Aeliana,* 4th ser., vol. xxiv (1946). (M. H. D.)

BARNES, ERNEST WILLIAM (1874–1953), Anglican bishop of Birmingham! a leader in the Church of England modernist movement, was born at Birmingham on April 1, 1874, and educated at Trinity college, Cambridge, where he subsequently became fellow, lecturer in mathematics and tutor. He was ordained in 1902. By 1915, when he was made master of the Temple, he had established a reputation for outspoken and provocative preaching which he maintained as canon of Westminster, 1918–24. Appointed bishop of Birmingham in 1924 on the recommendation of the prime minister?Ramsay MacDonald, he immediately attacked ritualistic practices and in 1929 evoked much protest by his refusal to install an Anglo-Catholic priest. His scientific approach to Christian dogma (exemplified in his Gifford lectures on *Scientific Tlzeory and Religion,* 1933) brought him into open conflict with his fellow bishops; his controversial *The Rise of Christianity* (1947) was condemned by the archbishops of Canterbury and York. An uncompromising pacifist, he refused during World War II to take part in national days of prayer and later vigorously opposed the use of the atomic bomb and German rearmament. Barnes retired in May 1953 and died on Nov. 29, 1953.

BARNES, GEORGE NICOLL (1859–1940), British statesman, who was an active propagandist for trade unionism and socialism, was born at Dundee, Scot., on Jan. 2, 1859. He left school at 11, became an engineer, and was attracted to socialism through the influence of William Morris. Barnes was general secretary of the Amalgamated Society of Engineers from 1896 to 1908, and entered the house of commons in 1906 as member for the Glasgow division of Blackfriars (renamed the Gorbals in 1918). He thus became one of the original members of the parliamentary Labour party, of which he was chairman in 1910. He was made minister of pensions in Lloyd George's government (Dec. 1916) and resigned from the Labour party in 1918, when it withdrew its support from the coalition, in order to retain office until the conclusion of the treaty of Versailles. He was responsible for the status of the International Labour organization within the League of Nations and attended the first meeting of the League in 1920. After his retirement from parliament (1922), Barnes published his autobiography *From Workshop to War Cabinet* (1923). He died in London on April 21, 1940.

BARNES, JOSHUA (1654–1712), English scholar and translator of Greek authors, was born in London, Jan. 10. 1654. Educated at Christ's Hospital and Emmanuel college, Cambridge. he became regius professor of Greek at Cambridge in 1695. In 1675 he published *Gerania: a New Discovery of a Little Sort of People . . . Called Pygmies,* a whimsical sketch to which Swift's *Voyage to Lilliput* may owe something. Among his other works was an informative life of Edward III (1688) and editions of Euripides and Homer which, however, are far from authoritative. He also wrote under the pseudonym of Philargyrius. He died on Aug. 3, 1712, at Hemingford, near St. Ives. Huntingdonshire.

BARNES (BERNES), **JULIANA,** unidentified 15th-century English writer on hunting. The only documentary evidence regarding her appears at the end of her treatise on hunting in the *Boke of St. Albans* (1486 ed.): "Explicit Dam Julyans Barnes in her boke of huntyng," and the name is changed by Wynkyn de Worde (1496) to "dame Julyans Bernes." Attempts have been made to connect her with the Bourchiers, the first Lord Berners' family, but no such person is to be found in their pedigree.

The first and rarest edition of the *Boke* (1486) was printed at St. Albans by an unknown schoolmaster; Wynkyn de Worde's edition included a "Treatyse of fysshynge with an Angle." not contained in the St. Albans edition. The other treatises are on hawking, hunting and heraldry. That on hawking derives from "the Boke of Hawking after Prince Edward. King of England" (14th-century, but preserved in the 15th-century manuscript Harleian 2340). That on hunting, the only one specifically ascribed to Dame Juliana, is a versified adaptation of a translation of the Anglo-Norman *Art de Venerie* by Guillaume Twiti, huntsman to Edward 11—with additions from the "Master of Game" by Ed-

ward, second duke of York, and other texts—largely concerned with terminology and procedure. The treatise on heraldry draws partly on Nicholas Upton's *De officio militari* (soon after 1430), partly on an anonymous compilation on coat-armour. An older form of the treatise on fishing was edited in 1883 by T. Satchell from a manuscript then in the Denison collection (later taken to the United States). A facsimile, *The Book of St. Albans,* introduced by William Blades, appeared in 1881. During the 16th century the work was very popular and was often reprinted.

See E. F. Jacob, "The Book of St Albans" and A. L. Binns, "A Ms. Source of the Book of St. Albans," both in the *Bulletin of the John Rylands Library,* vol. xxviii, no. 1 (1944) and vol. xxxiii, no. 1 (1950). (N. D.)

BARNES, ROBERT (1495?–1540), English Protestant martyr, was a protégé of Thomas Cromwell and helped to spread Lutheran opinions in England. Born in Norfolk, he was educated at the universities of Cambridge and Louvain and became a member and later prior of the Austin friars, Cambridge. Under the influence of Thomas Bilney, he espoused reformist ideas and ruined a promising academic career when on Christmas Eve, 1525, he preached a sermon attacking clerical litigiousness and worldliness which got him into trouble with the university authorities and with Cardinal Wolsey. He abjured his heretical opinions but was kept away from Cambridge and confined at the Austin friars first in London and later in Northampton. He surreptitiously continued to disseminate his views, however, until in 1528 he escaped to Antwerp, whence he went to Wittenberg. There he formed an enduring friendship with Martin Luther and published theological writings as Antonius Anglus. In 1531 Thomas Cromwell secured him a safe conduct which enabled him (though liable to be burned as an abjured heretic who had broken penance) to visit England. Thereafter he traveled frequently between England and Germany, attempting to obtain diplomatic support for Henry VIII's new antipapal policy. But he seems never to have been properly in government employ; the king disliked his opinions and his mixture of cocksureness and abjectness, and Cromwell could not get him any notable reward for services in themselves not particularly useful. As was Cromwell's custom, he employed Barnes in accordance with his special qualifications, exploiting his close contacts with Luther and the Lutherans; but the reformer never entered into favour. His fall, when it came, was rapid. During Lent in 1540 he engaged in controversy with Bishop Stephen Gardiner, was forced to recant and then once more relapsed The fall of Cromwell in June removed his single protector and on July 30, 1340, Barnes was burned as a heretic, with two other Lutherans. He was an ardent, rash and troublesome man, at heart sincere but somewhat unstable. His most important writings are *A Supplication to Henry VIII* (1531), *Vitae Romanorum pontificum* (1535) and *Confession of* Faith (1540), published in German as Luther's memorial to his English friend.

See E. G. Rupp, *Studies in the Making of the English Protestant Tradition* (1947). (G. R E.)

BARNES, THOMAS (1785–1841), British journalist who as editor of the *Times* for many years established its reputation and founded the tradition of independent journalism, was born in London on Sept. 16, 1785. The son of a solicitor, he was educated at Christ's Hospital and at Pembroke college, Cambridge. In his early days in London he was an intimate friend of Leigh Hunt and of Charles Lamb. After studying in the chambers of Joseph Chitty, he abandoned the idea of being called to the bar and made his mark as a robust writer on literature, the theatre and politics in Hunt's *Rejlector* and *Examiner* and in John Scott's *The Champion,* to which he contributed a series of literary portraits under the pseudonym "Strada." His political sketches in the *Examiner* were collected and published anonymously as *Parliamentary Portraits* in 1815. Meanwhile, he had already been contributing to the *Times* and in 1817 was appointed to the editorship which he held until his death. Despite ill-health and somewhat intemperate habits, Barnes brought the *Times* from comparative obscurity to the position of "the leading journal."

Barnes exerted his considerable influence in favour of the Reform bill and acquired for himself and his paper the nickname the "Thunderer." In 1834 he was described by Lord Chancellor Lyndhurst as "the most powerful man in the country." Barnes first collaborated with and then quarrelled with Lord Brougham and sponsored Disraeli's "Letters to Statesmen," signed "Runnymede" (1836–39). Barnes died in London on May 7, 1841.

See D. Hudson, *Thomas Barnes of The Times* (1943), which includes a selection from Barnes's essays ed. by H Child; and the *History of The Times,* vol. i, *The Thunderer in the Making, 1785–1841* (1935). (D. Hn)

BARNES, WILLIAM (1801–1886), English dialect poet and philologist whose linguistic theories and poetic practice influenced both Thomas Hardy and Gerard Manley Hopkins (*qq.v.*), was born Feb. 22, 1801, at Bagber near Sturminster Newton, Dorset. Barnes left school at 15 to work in a lawyer's office and was given tuition by local clergymen. He did wood engravings and wrote verses, publishing *Poetical Pieces* (1820) and *Orra, a Lapland Tale* (1822), and opened a school in 1823. The *Dorset County Chronicle* published his first Dorset dialect poems (1833–34). His name was on the books of St. John's college, Cambridge, as a "ten-year man," from 1838 until 1851, when he took his Bachelor of Divinity, having been ordained deacon in 1847 and priest in 1848. Poetry was his love, philology his passion. His many books included an Anglo-Saxon primer (1849), *An Outline of English Speech-Craft* (1878) and *Poems of Rural Life in Common English* (1868) as well as *Poems of Rural Life* (two series—1844, 1862; collected ed., 1879) and *Hwomely Rhymes* (1859) in dialect. His melodious poetry is essentially English in character—no other writer has given quite so simple and sincere a picture of the life and labour of rural England. A gifted linguist and metrist, he used the poetic techniques of many literatures yet wished to purge English of foreign elements. He was awarded a civil list pension in 1861 but taught at his school until in 1862 he was made rector of Winterbourne Came, where he died, Oct. 7, 1886.

BARNES, a residential suburb of London and a municipal borough in the Richmond parliamentary division of Surrey, Eng., on the south bank of the Thames between Putney and Kew. Pop. (1961) 39,757. At the time of Domesday, Barnes (Berne) formed part of the manor of Mortlake and was held by the dean and canons of St. Paul's, who still have the rights of the manor in Barnes common (126 ac.). Barn Elms, the manor house, was the residence of Sir Francis Walsingham, secretary of state under Elizabeth I, in the 16th century and later of Abraham Cowley. From 1854 until 1939 it was the club house of the Ranelagh club and after World War II negotiations were begun for its purchase by the Surrey county council. Adjoining Barn Elms was a cottage where meetings were held of the celebrated Kit-Cat club, founded at the beginning of the 18th century. The portraits of the members by Sir Godfrey Kneller, including that of Jacob Tonson, the founder, were acquired by the National Portrait gallery, London, in 1945. The town was incorporated in 1932 and includes Mortlake and East Sheen and a large part (731 ac.) of Richmond park. Mortlake brewery, on the site of the manor house and founded in the 15th century, is opposite the winning post of the Oxford and Cambridge boat race. Mortlake was known for its tapestries in the 17th century.

BARNET, an urban district comprising Barnet, Arkley and Totteridge, in the Barnet parliamentary division of Hertfordshire, Eng., 11 mi. N.N.W. of London, at the branching of the Great North and the St. Albans roads. Pop. (1961) 27,834. Barnet, a residential area, is built up a hill on which stands the parish church of Chipping Barnet (dating from 1250) and near which Barnet fair, founded by Henry II, still attracts thousands each September. The grammar school was founded in 1573. East Barnet and Friern Barnet (*qq.v.*) are urban districts adjoining Barnet.

BARNET, BATTLE OF, in English history, was fought around Hadley Green, now in East Barnet, on Easter day, April 14, 1471. Its result mas momentous. In routing his Lancastrian opponents and in killing their leader, the earl of Warwick, Edward IV struck the Lancastrian cause a mortal blow. He completed its

destruction a month later at the battle of Tewkesbury.

Six months before Barnet, Edward IV, largely through his own mismanagement, had been driven to the Low Countries, when the exiled Warwick, for long the chief prop of his power, was reconciled with Margaret of Anjou and returned to restore Henry VI. Helped by Charles of Burgundy, Edward came back with 500 men to Ravenspur on the Humber on March 14, 1471. He then marched boldly to London, seized the luckless Henry VI and, on April 13, turned to meet his enemies, now concentrated under Warwick and advancing south from St. Albans. That day Warwick halted on a carefully chosen position less than a mile north of Barnet, near the junction of the road from Hatfield with the old road from St. Albans, and just beyond the narrowest part of the north-south ridge from Wrotham to Barnet, where it is crossed by another ridge, running east-west from Hadley Wood to what is now the new St. Albans road. His right flank, under the earl of Oxford, held the western arm of the cross ridge. The duke of Somerset, lately a deserter from Edward's side, commanded the centre astride the old St. Albans road at Hadley Green. Warwick himself was in charge of the left flank, concentrated north of Hadley church. Reaching Barnet late on April 13, Edward's troops drove the Lancastrian patrols from the town and, advancing to the north of it, closed up on Warwick's position. There they camped in battle formation within earshot of their enemy. The duke of Gloucester, the future Richard III, held the Yorkist right opposite Warwick; Edward with his brother, the duke of Clarence, was in the centre; while Lord Hastings faced Oxford on the Yorkist left. Warwick had about 15,000 men, while Edward mustered around 10,000.

After a night of desultory and ineffective Lancastrian shooting, Edward attacked early before the mist cleared. His left flank was quickly overwhelmed by Oxford and some of Hastings' men fled straight to London, bringing false news of a Yorkist catastrophe. But the Lancastrians carried the pursuit recklessly south of Barnet and, when Oxford at last returned to the field, his men attacked their own centre by mistake. Gloucester, meanwhile, had made steady progress against Warwick's left flank, and as confusion spread among the Lancastrians Edward launched his reserve, which tipped the scale. Warwick, seeing the day lost, fled but was caught and killed in Wrotham park. A contemporary who was there reckoned the slain at more than 1,000. (GY. T.)

BARNETT, SAMUEL AUGUSTUS (1844–1913), English clergyman and social reformer in the East End of London, was born at Bristol on Feb. 8, 1844. After graduating from Wadham college, Oxford, he became curate of St. Mary's, Bryanston square, in 1867. and in 1872 vicar of St. Jude's, Whitechapel, one of London's poorest parishes. There he started evening schools for adults, provided music and other entertainment, served on the board of guardians and school committees, and discouraged outdoor relief (*i.e.*, in the home) as tending to pauperization. He also furthered the building of model dwellings, the establishment of the children's country holiday fund and annual loan exhibitions of fine art at the Whitechapel gallery. In 1875 Arnold Toynbee visited Whitechapel and two years later Barnett, who kept in touch with Oxford, formed a committee to organize university extension in London. An article by him in the *Nineteenth Century* of Feb. 1884, sketching the place of a university settlement in east London, led that same year to the foundation of Toynbee hall in memory of Arnold Toynbee (*q.v.*), with Barnett as its first warden. He became canon of Bristol in 1893 but retained the wardenship. In 1906 he was appointed a canon of Westminster. He died in London on June 17, 1913. Among his works is *Practicable Socialism* (1888; 2nd ed., 1894), written with the aid of his wife, Henrietta Octavia Rowland, who, in her younger days, was a co-worker of Octavia Hill. Subsequently, she joined in her husband's efforts for social reform and also wrote his biography, published in 1918. Barnett House at Oxford was founded for the study of social sciences in his memory. (G. HU.)

BARNEVELT, JOHAN VAN OLDEN: *see* OLDENBARNEVELT, JOHAN VAN.

BARNFIELD, RICHARD (1574–1627), a minor English poet, some of whose work is in the manner of Shakespeare, was born at Norbury, Staffordshire, and baptized on June 13, 1574. In 1589 he went to Brasenose college, Oxford, where he graduated in 1592. His first work, *The Affectionate Shepherd,* was published in 1594; a second volume, *Cynthia, With Certain Sonnets* (1595), followed it two months later. "Cynthia." a panegyric on Queen Elizabeth I, claimed to be "the first imitation of the verse of that excellent poet Maister Spenser in his Fayrie Queene." In 1598 Barnfield published his third and last volume. *The Encomion* of *Lady Pecunia,* a satire on money. For the remainder of his life he lived as a country gentleman on his estate at Darlaston, Stone, Staffordshire, where he died early in March 1627.

Barnfield was probably Shakespeare's earliest imitator. The sonnets of his second volume are closer in manner to Shakespeare's sonnets than any others of the period. Two of the poems in his third volume—the sonnet "If Music and Sweet Poetry Agree" and the ode beginning "As it fell upon a day." both of which appeared in *The Passionate Pilgrim* in 1599—were long believed to be Shakespeare's work.

BIBLIOGRAPHY.—A. B. Grosart (ed.), The *Complete Poems of Richard Barnfield,* for the Roxburgh Club (1876); Edward Arber (ed.), *Poems of Richard Barnfield (1594–98)* (1882); Montague Summers (ed.), *The Poems of Richard Barnfield* (1936).

BARNSLEY, a parliamentary and county borough in the West Riding administrative division of Yorkshire, Eng.. 14 mi. N. of Sheffield by road. Pop. (1961) 74,650. Area 12.2 sq.mi. It is situated on rising ground west of the river Dearne and in the old parish of Silkstone, which has become an important local name.

In Domesday Book, Ilbert de Lacy held Barnsley by gift of William the Conqueror, and the overlordship remained in his family until the reign of Stephen, when it was granted by Henry de Lacy to the monks of Pontefract. In 1249. Henry III granted a Wednesday market (still held) at Barnsley and a fair on the vigil and feast of St. Michael and two following days, and Henry VIII granted them a new fair on the day of the Conversion of St. Paul and two follouing days. Before 1744 the chief industry was wire drawing, but this trade began to decrease about the end of the 18th century, just as the linen trade was becoming important. Barnsley's later development was due to its central position in the south Yorkshire coal field. The coal was used locally in textile mills and exported. with coke, to London. The majority of workers in Barnsley are still employed in the coal mines. Glass, engineering, paper, metal canisters, safety lamps, clothing and rubber products are subsidiary industries.

The parish church of St. Mary was built in 1821 on an early site; the free grammar school dates from 1665, and a philosophical society was founded in 1828. There are also a mining and technical college and a teachers' training college. Barnsley has two parks, Locke park and Cannon Hall park. Monk Bretton priory, a Cluniac foundation of 1157, retains a Perpendicular gatehouse. some Decorated domestic remains and fragments of the church.

Barnsley was incorporated in 1869 and made a county borough in 1912. It was extended in 1921 and 1938.

BARNSTAPLE, a market town, seaport and municipal borough in the North Devon parliamentary division of Devonshire, England, 40 mi. N.W. of Exeter by road. Pop. (1961) 15,907. It lies on a wide plain surrounded by woods and hills on the north bank of the Taw estuary near the exit of the Yeo, about 10 mi. from the Atlantic, where a widened 15th-century stone bridge of 16 arches stands. Originally there was a settlement at Pilton a little to the northwest, one of Alfred's four Devonshire burhs against the Danes. but Barnstaple soon emerged as the main settlement before the end of the 10th century. The town (Beardastapol in 10th-century coins) was important enough to have its own mint in the time of King Aethelstan. The castle (now the municipal offices) was founded or reconstructed by Judhael of Totnes who obtained the manor in the reign of Henry I and founded a Cluniac priory. The town was walled nhen Henry I gave it its earliest authenticated charter; it was incorporated in 1557. Barnstaple, like Bideford. was a spinning centre for local and, later, Irish wool; as early as the reign of Edward III (1314) it was a naval port and in 1428 a royal port. For a while in the 17th and 18th centuries the town declined because of silt in the Taw mouth,

but in the 19th century coastal and foreign trade revived. The wool trade has gone but lace, gloves, furniture, light engineering products, pottery (Barum ware) and agricultural implements are made; the town is also an agricultural and tourist centre. The Friday cattle market, the Pannier market (twice weekly) for vegetables and the annual September fair are held by immemorial prescription. Of interest are the parish church of St. Peter (1318) with its timber-framed, leaded broach spire, the many 17th-century almshouses, and Queen Anne's walk, an ornate colonnade of 1704, near which is the Masonic lodge with a valuable collection of Masonic furniture. The North Devon technical college was opened in 1952.

John Gay, author of The Beggar's Opera, was born in Barnstaple and educated at the grammar school, formerly in the chapel of St. Anne (c. 1330). The chapel is now a museum.

BARNUM, PHINEAS TAYLOR (1810–1891), **U.S.** circus proprietor, was known as the greatest U.S. showman of his day. Born in Bethel, Conn., on July 5, 1810, he began his career in 1835 with the purchase and exhibition of Joice Heth, a Negro woman alleged to have been George Washington's nurse and over 160 years old. In 1841 he purchased Scudder's American museum in New York city, which, renamed Barnum's American museum, developed into a national showplace for freaks, improbable animals, curios, dioramas, models and "moral" plays. From 1841 to 1865, while he was director of the museum, Barnum toured Europe with Charles Stratton, the celebrated "General Tom Thumb"; engaged Jenny Lind for an American tour; excited New Yorkers with their first live hippopotamus; and in addition developed in East Bridgeport a model industrial and workers' community.

BY COURTESY OF THE HERTZBERG CIRCUS MUSEUM OF THE SAN ANTONIO PUBLIC LIBRARY

ADVERTISING POSTER FROM P. T. BARNUM'S CIRCUS SHOWING BARNUM PRESENTING "GENERAL TOM THUMB" AND HIS WIFE TO QUEEN VICTORIA AND PRINCE ALBERT

In 1871, at the age of 60, Barnum undertook with W. C. Coup and Dan Costello a novel circus and menagerie combination that, billed as "The Greatest Show on Earth," became a monumental enterprise when he was joined in 1881 by James Anthony Bailey, his foremost rival. Under Barnum's aegis, a second and later a third ring were added, delighting the public with an abundance of entertainment but causing performers to deplore his substitution of multiple spectacle for the concentration of attention traditional in European circuses.

Self-styled the "Prince of Humbugs," Barnum reveled in his notoriety but adhered, nonetheless, to a strict moral code of showmanship, justified his practice of exaggerating claims by giving the public more than it paid for, maintained his shows free from all indecencies and led a highly respectable personal life. Although considered the father of modern publicity practices and the reputed author of statements like "There's a sucker born every minute," this impresario drew a sharp, if somewhat personal line between fraud and innocent humbug. Among other works, he was author of The *Life of* P. T. *Barnum*, The *Humbugs of the* World, *How* I Made Millions and The *Art* of Money Getting.

Barnum died on April 7, 1891, at Philadelphia, requesting with his last words the day's receipts of the circus. In 1907 the circus was sold to the Ringling brothers. See also CIRCUS.

See Morris R. Werner, *Barnum* (1923); Harvey W. Root, *The Unknown Barnum* (1927). (E. B. P.)

BAROCCI (BAROCCIO), **FEDERIGO** (FIORI D'URBINO) (*c.* 1535–1612). Italian painter, the leading artist of the central Italian school in the second half of the 16th century, was born in Urbino. His first master was Battista Franco. He visited Rome shortly after 1550 to study Raphael's works, and again in 1561–62, when he executed frescoes in Pius IV's country house. Otherwise he lived in Urbino and confined his work to altarpieces and devotional paintings. His early style reflects the influence of Raphael, and his large "Descent From the Cross" (1569, Perugia cathedral) is in the tradition of Florentine Mannerists such as Rosso and Daniele da Volterra though it is more violent in composition.

There remains the somewhat puzzling problem of the relation of his work to that of Correggio. He had probably never seen the great Correggios in Parma in the original, yet Correggesque motifs appear in his compositions. Warmth of feeling, tenderness of expression and a painterly as opposed to a draftsmanlike approach are common to the work of both artists. This is particularly evident in the many paintings by Barocci on the theme of the Madonna, two of the most famous being the "Madonna del Popolo" (1579, Uffizi, Florence) and the exquisitely beautiful "Nativity" (1597, Prado, Madrid). He was also out of the ordinary in the Mannerist period in making frequent and extremely sensitive drawings from life; but he used Mannerist devices such as fluttering draperies, compositions based on receding diagonals and an indefinite treatment of space. His distinctive use of colour is central Italian, not Correggesque, in origin—pale fugitive colours blended chiefly from vermilion pinks, mother-of-pearl whites and grays. He was an important precursor of the baroque.

See G. P. Rellori, *Vita di Federico da Urbino pittore* (1572), the first extensive account of Barocci's work; H. Olsen, "Federico Barocci," *Figura,* no. 6 (1955). (M. W. L. K.)

BAROCLINIC. The distribution of mass in a fluid is said to be baroclinic if it is not barotropic (*q.v.*), that is, when the density varies along surfaces of constant pressure. A baroclinic atmosphere at rest will not remain at rest; a circulation will develop in which the dense air sinks and the light air rises.

An important cause of baroclinic conditions is differential heating. The circulation initiated in such an atmosphere translates the potential energy released by the redistribution of density into kinetic energy of circulation.

In general, the wind in a baroclinic atmosphere varies with height. A special case of the baroclinic atmosphere is the "thermotropic" atmosphere in which the vertical wind shear vector has the same direction at all heights. Therrnotropic atmospheres resemble the actual atmosphere and are useful in numerical weather prediction (see WEATHER FORECASTING). (H. A. A. P.)

BARODA, a city in Gujarat state, formerly part of Bombay state, India, the headquarters of Baroda district, is on the Viswamitri river, 66 mi. S.E. of Ahmedabad and 244 mi. N. of Bombay by rail. Pop. (1951) 211,407, (1961) 295,304. City corporation area 10.9 sq.mi. It is laid out with fine avenues, parks and buildings. Among its historic buildings is the Hajira (late 16th century), a relic of Mogul rule. The Mandvi gate in the centre of the old part of the city was built at the instance of the Maratha chief Damaji Gaekwar in 1736 to commemorate a Maratha victory over the Moguls in Gujarat. The Bhadar palace, with a marble bow window of singular beauty, is a building of the Muslim period.

Modern Baroda was developed by the later rulers of the Gaekwar (Gaikwar) dynasty: Makarpura palace was constructed for Khanderao (1856–70), Nazarbagh palace for Malharrao (1870–75) and Lakshmi Vilas palace (1890) for Sayajirao III. The grounds of the last-named palace enclose the Navlakhi wav or step well, built in 1405 by Zafarkhan Sulemani. Muslim fief-holder of Gujarat. Under Sayajirao III, who ruled from 1875 to 1939, most of modern Baroda was built, including Pratap Vilas palace (1918),

now the railway staff college; Baroda college (1885); Kalabhavan building (1922), housing the university faculty of technology and engineering; Kirti *mandir* or temple, built to commemorate the benefactors of Baroda; Nyaya *mandir* (1895); Khanderao market (1907); Sursagar lake and Sayaji hospital. The city has a museum and picture gallery and a zoo, both set in a well-laid-out park of about 150 ac., Sayajirao's gift to his people. The Maharaja Sayajirao University of Baroda was founded in 1949: it has nine faculties, an oriental institute, polytechnic, library, students' union and halls of residence. The city also contains an affiliated college of the Shreemati Nathibai Damodar Thackersey W0men's university in Bombay.

Baroda is connected by road and railway with Bombay, Ahmedabad and Delhi. In addition about 250 mi. of narrow-gauge railway link it with several parts of the district. It has an airfield but no regular service. The main industries are chemical, cotton and wool textile, metal manufactures and the crushing of castor beans for oil. A large quantity of pharmaceuticals is exported.

The earliest record of Baroda is in a grant or charter of A.D. 812 which mentions Vadapadraka as a hamlet attached to the flourishing town of Ankottaka. In the 10th century Vadapadraka displaced Ankottaka as the centre of this urban area. Vadapadraka seems also to have been known as Chandanavati, after Raja Chandan of the Dor tribe of Rajputs, who wrested it from the Jains. The name underwent periodic transformations. to Varavati (Gujarati "city of warriors"), Vatpatraka ("leaf of a banyan tree") and finally, by corruption, Baroda.

The history of Baroda can be divided into the Hindu period lasting until 1297; the period under the Muslim Delhi sultanate (to 1401 or 1403–04); the independent Gujarat sultanate period (to 1572–73); the period under the Mogul empire (to 1734); and the Maratha period from 1734 to 1947.

In 1451 Vadapadraka was plundered by Mahmud I Khilji. sultan of Malwa. The nucleus of the present town, built by Khalilkhan, son of Mahmud Begara, sultan of Gujarat (1459–1511), is enclosed by four gates. In 1734, taking advantage of the weakness of the Moguls, the Marathas plundered Gujarat. Pilaji Gaekwar wrested Baroda from the Muslims and in 1768 it became the capital of the Gaeknar family, one of the leading powers in the Maratha confederacy of the 18th century. The city became the centre of a progressive state under Sayajirao III and his able ministers. In 1802 the British established a residency in Baroda to conduct relationships between the East India company and the Gaekwars. By 1947, when it was closed and the British left India, this residency was also responsible for imperial relations with all the Gujarat and Kathiawar peninsula states.

BARODA DISTRICT stretches from the Narbada river northward to the Mahi river. It corresponds roughly with the capital division or district of the former princely state of Baroda (the Gaekwar dominions), which also included large tracts in and beyond the Tapti valley to the south. in northern Gujarat, and in the Kathiawar peninsula. The population of the present district was 1,194,746 in 1951, 1,527,044 in 1961, and the area 2,955 sq.mi. The cash crops are cotton, tobacco and castor. Wheat, pulses, corn (maize), rice and garden crops are grown for consumption and export.

Villages in Baroda district were long provided with amenities not generally found elsewhere in India before the late 1950s: primary education was made compulsory under Sayajirao, and most villages have primary schools, *panchayats* or village "parliaments," libraries and co-operative societies.

Dabhoi. 17 mi. S.E. of Baroda by rail. has a vast ruined fort. probably of the mid-13th century, nith four richly carved gateways largely intact. There are also three finely sculptured temples, one of which stands on a promontory in a large artificial lake or tank. Sankheda subdivision, in the east of the district, is noted for lacquer work.

BIBLIOGRAPHY.—B. Subbarao, *Baroda Through the Ages* (1953); *F. A.* H. Elliot, *Rulers of Baroda* (1934); *P. S. P.* Rice, *Life of Sayaji Rao III*, 2 vol. (1931). (V. A. M. J.)

BAROJA, PÍO (1872–1956), Spanish Basque writer and leading novelist of his generation. was born in San Sebastián on Dec. 28, 1872, and died in Madrid on Oct. 30. 1956. He studied in Madrid and received a medical degree in Valencia. After serving as village doctor in the north of Spain, he spent two years administering a bakery owned by his family in Madrid. His first two books appeared in 1900: a collection of short stories, *Vidas sombrías* ("Sombre Lives"), preliminary statements of his later themes. and *La casa de Aizgorri* (Eng. trans.. *The House of the Aizgorri*, 1958). Outstanding among nearly 100 novels are those reflecting city low life, such as his best-known trilogy. *La Lucha por la vida* (1904; Eng. trans., *The Struggle for Life*, 1922–24), and the novels on his native Basque country; *e.g.*, Las *inquietudes de Shanti Andía* (1911; Eng. trans., *The Restlessness of Shanti Andia*, 1959). A separate cycle of 22 novels deals with a conspirator relative and his 19th-century epoch. Baroja chooses to write about nonconformists and insurgents; in one period of 10 years he wrote 20 novels of vagabondage. His last books were six volumes of memoirs. His style is laconic and his dramatic suggestiveness depends on understatement. During the Spanish civil war. he narrowly escaped a Carlist fighting squad. Anti-Christian and nihilistic. Baroja was at odds with officialdom from the beginning of his career and he is buried in unhallowed ground. (AV. K.)

BAROMETER, an instrument for measuring atmospheric pressure. The first record of the use of a barometer was given in 1643 by Evangelista Torricelli, who had been an assistant to Galileo. He was the first to advance correct ideas concerning the existence of atmospheric pressure and vacuums. Using mercury and a glass tube, Torricelli, with Vincenzo Viviani. constructed a barometer similar to the one shown in fig. 1. The glass tube was filled with mercury, the open end closed with a finger. and then the tube was inverted with the open end under the mercury of vessel B. When the finger was released the mercury dropped to the level **A.** Torricelli was convinced that the mercury in the barometer tube exerted a pressure at the bottom which exactly balanced the pressure of the air exerted on the free surface of the mercury at the same level, and that a vacuum existed in the space above **A.** He also stated that the height of the mercury column would be lower on a mountain where the air is rarer. These conclusions stirred up a controversy with the Scholastics, who insisted on the Aristotelian doctrine that nature abhors a vacuum, or *natura abhorret vacuum*.

About 1647 Blaise Pascal performed several experiments that finally convinced people of the correctness of Torricelli's ideas. Pascal made many mercury barometers. using tubes of different shapes and sizes; he also inclined the tubes and found that the vertical height of the mercury columns was always the same. In the city of Rouen, France, where Pascal lived, there was a large glassworks from which he obtained glass tubes about 46 ft. long. These were filled with water and wine, and Pascal found that the height of the columns was in the correct relationship with the mercury column. Since mercury is about 13.6 times as heavy as an equal volume of water, it follows that the water column should be about 13.6 times as high as the mercury column; that is, 34 ft. of water corresponding to 30 in. of mercury. In 1648 Pascal, who was a semi-invalid, had his brother-in-lam-, Florin Périer, take a barometer up the mountain Puy-de-Dôme. He found that the height of the mercury column decreased as the barometer was carried up the mountain while a barometer at the foot of the mountain showed no variation during the day. This experiment demonstrated that the height of the mercury column varied with the amount of air above it and had no relationship to nature's abhorring a vacuum.

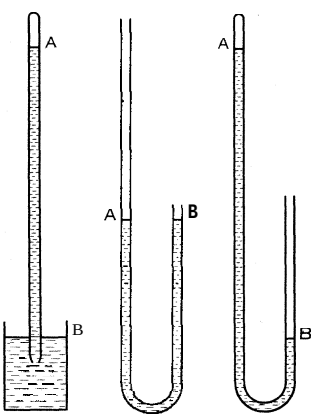

FIG. 1–3.—FUNDAMENTAL HYDROSTATIC PRINCIPLE OF MEASURING PRESSURE

Fundamental Principles.— Pressure is measured in terms of a force exerted on a unit of area.

Thus the pressure of the atmosphere is given as about 14.7 lb. per square inch or 1,000,000 dynes per square centimetre. This means that the atmosphere exerts a force of 14.7 lb. on each square inch of the earth's surface.

In the measurement of atmospheric pressure the fundamental idea is to balance this pressure against a column of liquid of which the height (h), density (d) and the value of gravity (g) acting upon it are known. If the atmosphere balances a column of mercury 76 cm. high and of density 13.6 g. per cubic centimetre at a place where the value of gravity is 980 cm. per second per second, then the pressure of the atmosphere is'hdg, or 1,012,928 dynes per square centimetre.

Fig. 2 shows both ends of the tube open to the atmosphere so the levels A and B are the same. In fig. 3 the upper end A has been evacuated and sealed so that the difference of level between A and B gives the barometric height h as about 76 cm. or 30 in. of mercury. Actually the mercury evaporates into the space above A, and this mercury vapour exerts a pressure that is relatively small and can be neglected except when the atmospheric pressure is being measured very exactly. The apparatus shown in fig. 3 is essentially the same as that shown in fig. 1 except that the open vessel of mercury has been replaced by the U tube. Other liquids can be used for barometers and are used in special types, but mercury is the common one because of its high density and relatively small vapour pressure at ordinary temperatures.

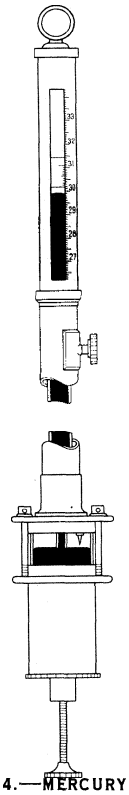

FIG. 4.—MERCURY BAROMETER (FORTIN TYPE)

An alternative type of barometer, called the aneroid or nonliquid barometer, is dependent on the elastic properties of a thin, flexible-walled, evacuated capsule in combination with a stiff spring. The credit for the invention of the aneroid is usually given to Lucien Vidie, who patented this instrument in 1844, but smaller instruments were in use much earlier. This instrument is not capable of giving the same high order of accuracy as a mercurial barometer, but it offers the advantage of considerably greater portability. (See Aneroid *Barometer,* below.)

International Barometer Standards. — In 1953 the executive committee of the World Meteorological organization adopted the following resolutions:

1. Standard temperature and density of mercury: the value of 0° C. shall be the standard temperature to which mercurial barometer readings are reduced for the purpose of relating the actual density of mercury at its observed temperature to the standard density of mercury at 0° C.

The standard density of mercury at 0° C. shall be considered to be *13.5951* g. per cubic centimetre [millilitre]; and for the purposes of calculating absolute pressures by means of the hydrostatic equation, the mercury in the column of a mercurial barometer shall be regarded conventionally as an incompressible fluid.

2. Standard (normal) gravity: Barometric readings shall be reduced from local acceleration of gravity to standard (normal) gravity. The value of standard (normal) gravity (symbol g_n) shall be regarded as a conventional constant,

$$g_n = 980.665 \text{ cm. per second per second}$$

(This is recognized by scientists as a gravity datum to which reported barometric data in millimetres or inches of mercury shall refer; it does not, however, represent the value of gravity at latitude 45" at sea level.)

3. Pressure units:

a. The millibar, defined as a unit of pressure equal to *1,000* dynes per square centimetre, shall be the unit in which pressures are reported for meteorological purposes.

b. In accordance with the provisions of paragraphs 1 and 2, a column of mercury at a standard temperature of 0° C. when subjected to an acceleration of gravity equal to standard (normal) gravity may be regarded as representing pressure due to the weight of mercury on a unit cross-section area (one square centimetre). When the mercury column under these standard conditions of temperature and gravity has a true scale height of one millimetre, it shall be considered to represent a unit of pressure called "one millimetre of mercury under standard conditions," with the symbol $(\text{mm. Hg})_n$. When it is clear from the context that standard conditions are implied, the briefer term "millimetre of mercury" may be used in reference to this unit. In view of the provisions of paragraphs 1, 2 and 3*a,* a column of mercury having a true scale height of *760* mm. when subjected to standard conditions of temperature and gravity yields a pressure of *1,013,250* dynes per square centimetre = *1,013.25* millibars.

Consistent with the foregoing the following conversion factors obtain:

1 millibar (mb.) = *0.750062* (mm. Hg),
1 (mm. Hg), = *1333224* mb.

c. Analogous to the case outlined above under b, "one inch of mercury under standard conditions," symbol (in. Hg)$_n$, shall refer to the pressure due to the weight of mercury per unit cross-section area when the column has a true scale height of one inch; provided the mercury is at the standard temperature of 0° C. *(32"* F.) and is subjected to an acceleration of gravity equal to the standard (normal) value. When it is clear from the context that standard conditions are implied, the briefer term "inch of mercury" may be used in reference to this unit.

In cases where the conventional engineering relationship between the inch and millimetre is assumed (1 in. = *25.4* mm.), the following conversion factors obtain:

1 mb. = *0.0295300* $(\text{in. Hg})_n$
I $(\text{in. Hg})_n$ = *33.8639* mb.
1 $(\text{mm. Hg})_n$ = *0.03937008* $(\text{in. Hg})_n$

In order to attain accuracy in the measurement of atmospheric pressure by means of a mercury barometer, the effects due to capillarity or surface tension must be made negligible and the mercury vapour above the mercury column must be removed. The latter is attained by means of a diffusion pump permanently attached to the top of the glass tube containing the mercury. Effects due to capillarity may be made negligible by using tubes with a bore diameter of four centimetres or more, and by vibrating the column to equalize the menisci before each observation. Corrections must also be made for the expansion of the scale for elevation above sea level and for gravity.

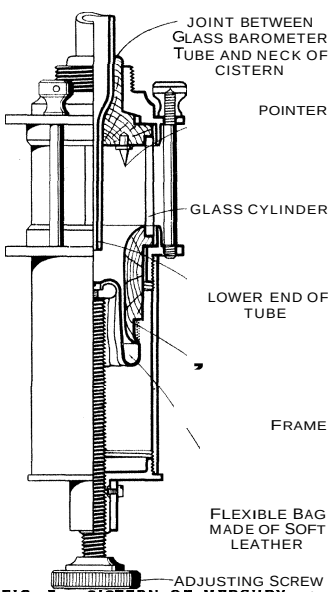

FIG. 5.—CISTERN OF MERCURY BAROMETER (FORTIN TYPE)

Chief Types of Barometers. — The different types of mercurial barometers vary largely with the methods employed to measure the difference in height between the levels A and B, shown in figs. 1 and 3. Both these levels change with variation of pressure. One of the earliest methods was to make the level B (fig. I) in the reservoir adjustable to the zero of a fixed scale that was used to give a direct reading of the level of A above B.

A serviceable barometer of this type called Fortin's barometer was devised early in the 19th century. Early in the second half of the 20th century Fortin-type barometers were still in wide use along with many other types, a listing of which, taken from the United States weather bureau Manual of Barometry, is given below.

1. Cistern types, mercurial
   a. Fortin-type (fixed scale; level of mercury in cistern adjustable to zero of scale)
   b. Movable scale (movable scale whose zero is brought to level of mercury in cistern)
   c. Fixed-cistern type (cistern not adjustable; fixed scale)
2. Siphon barometers, mercurial (cross-section areas equal for lower and upper mercury surfaces)
   a. Nonadjustable regarding level of mercury with reference to zero of scale
   b. Adjustable regarding level of mercury with reference to zero of scale
   c. Wheel mechanism, float-controlled
3. Two-liquid, expanded-scale barometers
4. Weight barometers
5. Aneroid barometers

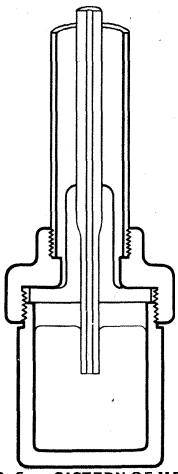

FIG. 6.—CISTERN OF MERCURY BAROMETER (KEW PATTERN)

6. Sympiesometer
7. Hypsometer
8. Recording barometers; barographs

Further information on these barometers can be found in the Manual of Barometry referred to above.

The *Fortin* Barometer.—A general view of a Fortin barometer is given in fig. 4. The distinctive feature of this type of instrument is Jean Fortin's arrangement for controlling the lower level of the mercury by means of a leather bag which forms the lower part of the reservoir of the barometer. By this means the mercury can be made to fill the tube and cistern on the instrument in case the barometer has to be transported. Fig. 5 shows the design of a Fortin cistern from which the mercury has been removed. The normal procedure in reading the instrument is to use the adjusting screw, at the lower end of the barometer, to raise the level of the mercury in the reservoir so as to just touch an ivory pointer. The latter is fixed to the ceiling of the cistern and serves as the zero point of the barometer scale. The barometric height is then determined by reading the level of the highest part of the mercury column by means of the scale and vernier. The scale is fastened to a metal tube that surrounds the glass tube and is suitably slotted so that the mercury level can be seen. In taking a reading the sighting edges, connected to the movable vernier, are aligned precisely to the top of the mercury meniscus: care being taken that the line of sight is horizontal, in order to avoid errors due to parallax. The inner diameter of the tube should be not less than $\frac{1}{4}$ in., and lead glass should be used in preference to Pyrex glass to reduce the possibility of a chemical reaction of the mercury with the glass.

The length of the graduated scale on the metal tube depends on the station at which the barometer is to be used. At sea level the maximum range of variation in atmospheric pressure is from about 31.1 to 27.3 in. of mercury. Consequently for use at stations near sea level a nominal working range of 31 to 27 in. (790 to 690 mm., or 1,050 to 920 mb.) is sufficient. If the barometer is to be used in a mine, the upper limit must be increased to allow for the increase in atmospheric pressure with the depth of the mine. The lower limit of the scale is governed by the maximum altitude at which the instrument is to be used.

Since the Fortin barometer is not a primary instrument, its instrumental errors must be determined by comparison with a standard barometer. These instrumental errors arise from the effects of capillarity or surface tension, imperfect vacuum above the mercury column, incorrect location of the zero of the scale. imperfect graduation of the scale, improper adjustment of the sighting edge to the zero line of 'the vernier, etc. It is necessary to know the temperature of the barometer, for this affects both the mercury and the metal scale. Despite this list of possible corrections the Fortin barometer proved to be a reasonably accurate instrument as well as a very convenient one.

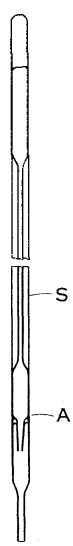

FIG. 7.—TUBE OF A KEW PATTERN BAROMETER

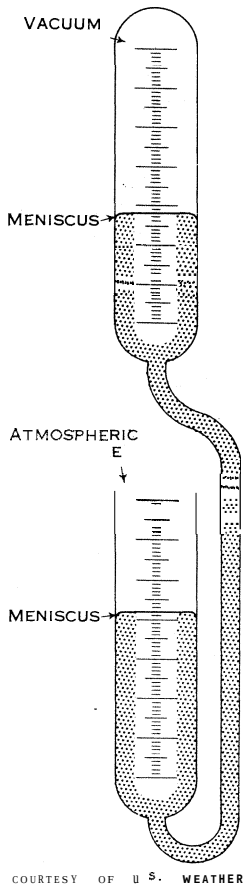
The *Kew* Pattern Barometer.—This type of fixed-cistern barometer of the Kew (English) pattern yields direct measurements of pressure by means of a single setting on the top of the mercury column. ***So*** setting is made on the mercury in the cistern. If the cistern (see fig. 6) and the glass tube of the barometer are exactly cylindrical. the change in level of the mercury in the cistern, corresponding to a given change in atmospheric pressure, is a definite fraction of the change in level of the top of the mercury column. The value of this fraction depends on the ratio of the inner diameters of cistern and tube.

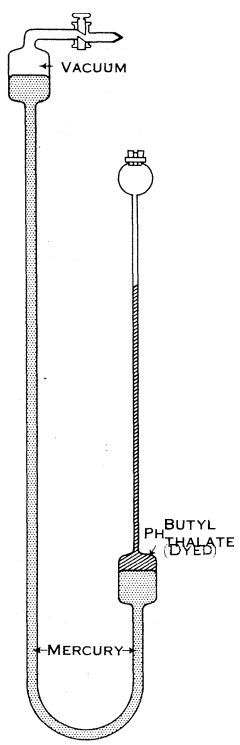
It follows that the movement of the mercury in the tube is always smaller than it would be if the mercury in the cistern were brought to a fixed point as in the Fortin barometer. Thus the scale on the Kew barometer must be contracted from a linear one, but the amount of this contraction is not large; a nominal pressure-inch of scale rarely measures less than 0.95 true inch. A Kew barometer, unless of exceptional size or design, is usually made portable by carefully tilting it until the mercury fills the glass tube completely. It may then be transported either horizontally or cistern upward, the latter position being preferred.

Mercurial marine barometers are often of the Kew pattern. Since the oscillation of the mercury produced by the motion of a ship is a serious obstacle in making an accurate reading, the glass tube is constricted so as to oppose the flow of mercury through it. The amount of constriction is arranged to compromise between the error due to oscillation, or "pumping" as it is technically called, and the error due to the lag of the mercury column in following the variations of atmospheric pressure. The glass barometer tube shown in fig. 7 illustrates the type commonly used. A funnel-type air trap at A is used to collect any air that may rise into the barometer tube from the cistern and to prevent it from reaching the space above the mercury column. The central portion S of the glass tube is usually of smaller diameter in all Kew barometers whether used on sea or land. In principle the main disadvantage of this instrument is that an accurate determination of the instrumental error and temperature correction factor requires pressure calibrations at two or more widely spaced tempsratures.



COURTESY OF U S. WEATHER

FIG. 8.—SIPHON BAROMETER



COURTESY OF U.S. WEATHER BUREAU

FIG. 9.—TWO-LIQUID MAGNIFYING SIPHON BAROMETER

Siphon Barometer.—This type of barometer, shown in fig. 8, is essentially a U tube with unequal arms, the shorter arm being open to the atmosphere while the longer one is closed and the space above evacuated. The axes of the arms are collinear and the diameters of the tubes comprising the arms are equal. By these means the capillarity effects due to surface tension are nearly balanced out and the effect of imperfect verticality is made negligible. By using large-diameter tubes of one inch or more, evacuating the space above the longer tube with a diffusion vacuum pump and measuring the difference in levels of the mercury with a cathetometer, this instrument can be used as a primary standard barometer. For less accuracy, fixed scales with a vernier attachment may be used to measure the difference in heights. In one type of siphon barometer the level of the mercury in the open tube is adjusted to a zero point by means of a screw pushing on a flexible leather bag that forms the base of the U tube.

Two-Liquid, Expanded-Scale *Barome-*

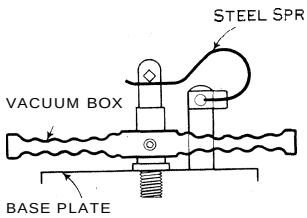


FIG. 10.—SECTIONAL VIEW OF VACUUM BOX AND CONTROL SPRING OF AN ANEROID BAROMETER

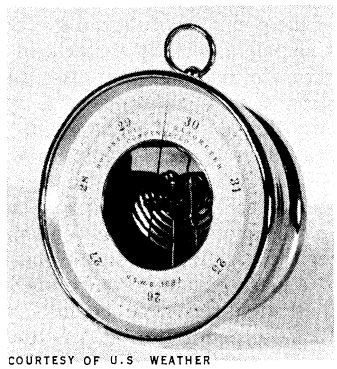
ter.—This type of instrument, shown in fig. 9, is used primarily for magnifying small changes in pressure, such as that between the lower and upper floors of a building. The change in level of the lighter liquid for a given change in the mercury level gives a measure of the magnification of the instrument. This magnification depends on the density of the lighter liquid (*e.g.*, butyl phthalate) relative to the density of mercury; and on the relative size of the cross-sectional areas of the tube containing the lighter liquid, of the upper mercury reservoir and of the reservoir containing both liquids.

Aneroid Barometer. — The aneroid barometer contains no liquid, is independent of gravity and is portable, so that it can be used under conditions that are prohibitive for mercury barometers.

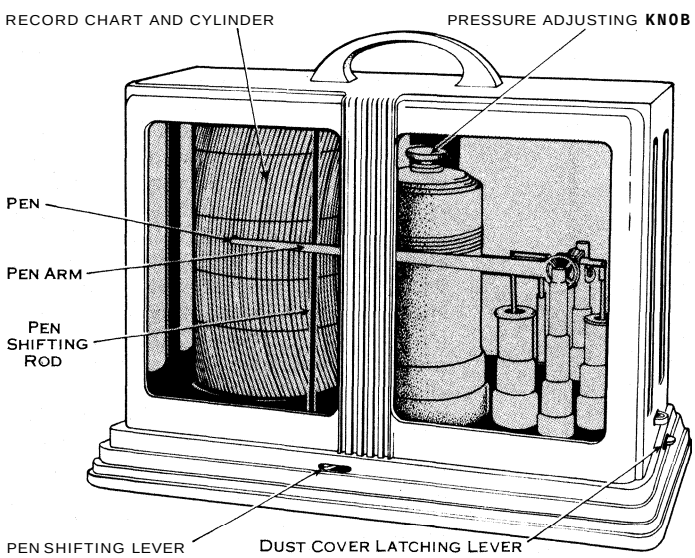
The fundamental element of an aneroid barometer is a corrugated chamber formed by two thin metal diaphragms, or a series of such chambers; the chamber is technically called the vacuum box, since it is usually exhausted of air. One face of the vacuum box is bolted to the base of the instrument (see fig. 10) while the other is connected through mechanical linkage to a pen or scale pointer. Movements of the upper face of the vacuum box caused by changing air pressure are transmitted to the pen or pointer so that pressures can be read directly. The face of a precision aneroid barometer, of which the smallest scale interval corresponds to 0.02 in. of mercury. is shown in fig. 11. It is called a holosteric barometer to signify that it contains no liquids.



COURTESY OF U.S WEATHER BUREAU

FIG. 11.—TEMPERATURE-COMPENSATED ANEROID BAROMETER

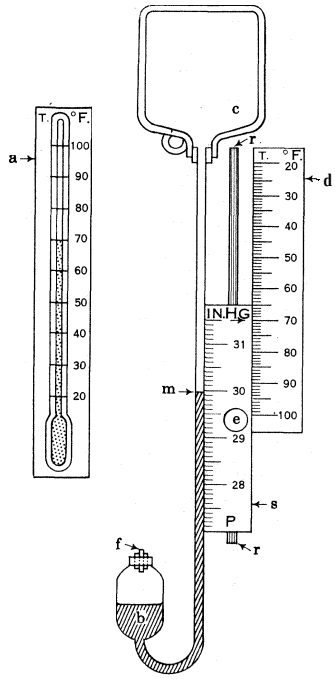
An aneroid barometer must be calibrated against a standard mercury barometer. Though the aneroid barometer has extensive use because of its portability and relatively small size. it does not have the reliability of a typical mercury barometer. However, with careful construction and fairly frequent calibration it can be relied on to give measurements of consistently good accuracy. Fig. 12 shows a recording aneroid barograph in which the pen moves 2.5 in. for a pressure change of 1 in. of mercury.



COURTESY OF U.S. WEATHER BUREAU

FIG. 12.— MICROBAROGRAPH

Sympiesometer.—This instrument: shown in fig. 13, is a sensitive device that is useful for giving pressure variations on an expanded scale. The upper chamber (c) contains a gas, usually dry air, at a pressure less than atmospheric. **A** liquid, shown at (b), having a relatively small density and vapour pressure, such as dyed butyl phthalate. serves to isolate the upper chamber from the atmosphere. Temperature effects are largely taken care of by employing two scales: the fixed one (d) marked in °F., and a movable one (s) called the P scale, that can slide on the rod (r) by means of the knob (e). In making a reading, the P scale is moved so the fiducial mark (the arrow in the diagram) is at the ambient temperature (shown by the thermometer [a]) and the height of liquid column is read on the P scale. This instrument, which can give a sensitivity magnification of from 10 to 12 compared with the mercury barometer, cannot be used for direct barometric readings, but must be calibrated against a standard mercury barometer.



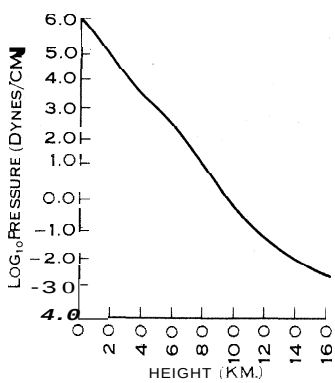
COURTESY OF U S. WEATHER BUREAU

FIG. 13.—SYMPIESOMETER

Hypsometer.—With this instrument the pressure of the atmosphere is obtained from the temperature of a boiling liquid. The principle of the hypsometer depends on the fact that the saturation vapour pressure of a liquid at the temperature of the boiling point is equal to the ambient pressure on the liquid. It is necessary to know the saturation vapour pressure at different temperatures of the liquid. The saturation vapour pressure of water at 100° C. is 760 mm. of mercury, while at 50" C. it is 92.5 mm. of mercury. These temperatures are those at which water boils at the corresponding ambient pressures. Carbon disulfide has been used as the hypsometer liquid in upper atmosphere work to measure pressures in the range of 1.5 to 0.06 in. of mercury. The boiling point temperature is measured by means of a small bead thermistor.

Practical Uses of the Barometer.—A good mercurial barometer became an essential part of the equipment of most laboratories because of the number of different scientific measurements dependent on a knowledge of atmospheric pressure. Early in the second half of the 20th century, barometers and other instruments were used widely by weather bureaus and meteorological stations responsible for the collection of information required for weather forecasting. Barometric readings were regularly taken on land and at sea over large areas in order to map the distribution of high and low atmospheric pressure near the earth's surface. (See WEATHER FORECASTING: Basic Practices.)

A considerable amount of work is done with aneroid barometers in the investigation of the meteorology of the upper atmosphere. The aneroids are carried aloft in balloons or rockets, and in many investigations the pressure and temperature are given by radio signals that allow a continuous record to be made on the ground. Fig. 14 shows a graph of pressure and altitude taken in a rocket flight above White Sands proving ground, N.M. Since the pres-



COURTESY OF UNIVERSITY OF CHICAGO PRESS. "ANALYTICAL EXPERIMENTAL PHYSICS" BY FERENCE, LEMON AND STEPHENSON, 1956 (2ND ED.)

FIG. 14.—PRESSURE-HEIGHT CURVE MADE FROM A ROCKET FLIGHT

sure change was so large the logarithm of pressure was used. Thus the logarithm of pressure at zero altitude is given as 6, which signifies that the pressure is 10^6 dynes per square centimetre (1.000 mb.), which is about standard atmospheric pressure. The smallest pressure ordinate is about -3, which corresponds to a pressure of 10^{-3} or $\frac{1}{1.000}$ dyne per square centimetre, or 10^{-6} mb. If the temperature of the atmosphere had remained constant, the curve would have been a straight line.

While the common aneroid barometers used in homes are marked with meteorological designations such as fair, rain, storm, etc., it should be noted that a single barometric reading is not of significant value in predicting weather. Some indication of the trend in the weather can often be obtained by noticing whether the barometric pressure is rising or falling. This can readily be done by setting the adjustable pointer at today's barometric reading and noticing whether tomorrow's reading is higher or lower.

See US. Weather Bureau, *Manual of Barometry (1957).* Many references may be found in this manual. (F. A. *G.;* R. J. SN.)

BAROMETRIC LIGHT, the luminous glow that appears in the vacuous space above the mercury in a barometer tube when the tube is shaken. It is a special case of the general effect that, if a sealed tube containing mercury and a rarified gas be shaken, flashes of light are produced. With the gas neon bright flashes of red light can be produced by shaking it with mercury, even when the pressure of the gas is atmospheric.

The barometric light is of interest as the first case of electrical discharge in gases at low pressure observed in the laboratory. The electrification is probably produced partly by the movement of the mercury over the glass surface, partly by the splashing of the mercury. Slight impurities in the mercury have a considerable icfluence on these effects and the barometric light, as ordinarily produced, is a complicated phenomenon which has not been analyzed in detail.

The barometric light was first observed in 1675 by Jean Picard, who noticed flashes of light in the Torricellian vacuum when his barometer was moved about. It mas made the subject of many experiments by Francis Hauksbee, who published an account of his work in 1709. He proved that the phenomenon was produced by the motion of mercury in either a glass or a varnished vessel, so that the glass was not a necessary factor, and that a very low pressure of the air was not necessary, as the light was strong when the air in contact with the mercury was at a pressure of an inch or two of mercury. He recognized that the rarefaction of the air was one of the conditions of the phenomenon, and he further stated that the light was electrical in origin, a conclusion suggested by the similarity in appearance of the light to that which he produced in exhausted vessels by the help of his electrical machine. *See* ELECTRICITY, CONDUCTION OF: *Conduction in Gases.*

(E. N. DA C. A.; X.)

BARON, MICHEL (1653–1729), French actor, the child of theatrical parents whose name originally was Boyron, was born in Paris. Orphaned at the age of 12, he joined the company of children known as the Petits Comédiens du Dauphin. He joined Molière's company in '1670. and later became a member of the company at the Hôtel de Bourgogne.

From that time until his retirement in 1691 he was undisputed master of the French stage, creating many of the leading roles in Racine's tragedies, besides those in two of his own comedies, *L'Homme à bonnes fortunes* (1686) and *La Coquette et la fausse prude* (1687). He retired in 1691, but in 1720 returned to the Comédie Française.

Baron died in Paris in Dec. 1729.

His son ÉTIENNE MICHEL BARON (1676–1711) was also an actor, and left a son and two daughters who all played at the Comédie Française.

BARON, now a title of nobility in Europe, but originally designating a tenant of whatever rank who held by tenure of barony direct from the king. Originally *baro* meant no more than "man" (as the Spanish word *varón* still does) and was so used in the Salic and other early laws. Gradually, however. the word came to mean a strong or powerful man, and thus a magnate. The connotation of baron differs considerably in the various countries of Europe.

France. — In the 12th century the term *barones,* in a restricted sense, was applied properly to all lords possessing an important fief, subject to the rule of primogeniture. Sometimes it included ecclesiastical lordships of the first rank. In the 13th century the register of King Philip Augustus places the *barones regis Francie* next to the dukes and counts holding in chief, the title being limited to vassals of the second rank. Toward the end of the century the title had come to mean that its bearer held his principal fief direct from the crown, and was therefore more important than that of count, since many counts were only mediate vassals. From this period. however, the title tends to sink in importance. In the 14th century the barons were ranked below counts and viscounts, though in power and possessions many barons were superior to many counts. In any case, until the 17th century the title of baron could only be borne by the holder of a territorial barony, and it was Louis XIV who first cheapened the title in France by creating numerous barons by royal letters. This process was completed by Napoleon's decree of March 1, 1808, reviving the ancient titles. By this instrument the title of baron was to be borne ex officio by a number of high officials; *e.g.,* ministers. senators, councilors of state, archbishops and bishops. The creation of barons continued by Louis XVIII, Charles X and Louis Philippe and, suspended at the revolution of 1848, was revived again on a generous scale by Napoleon III. Since the third republic the tolerant attitude of the French government toward titles, which it does not officially recognize, has increased the confusion by facilitating the assumption of the title cn very slender grounds of right.

Germany. — In Latin documents of the middle ages the term *barones* for *liberi domini* mas used, and in the 16th century the word *Baron* began to be used as a form of address for a *Freiherr,* or free lord of the empire. The style *Freiherr (liber dominus)* implied originally a dynastic status, and many *Freiherren* held countships without taking the title of count. When the more important of them styled themselves counts, the *Freiherren* sank into an inferior class of nobility. The practice of conferring the title *Freiherr* by imperial letters was begun in the 16th century by Charles V, was assumed on the ground of special imperial concessions by many of the princes of the empire, and was later exercised by all the German sovereigns.

Italy. — In the middle ages the barons had extensive powers of jurisdiction within their domains and could inflict the death penalty. There was a right of appeal, but it was of little value and in Sicily and Sardinia nonexistent. In the late middle ages the barons' powers became more extensive, especially in the south, and they had the right to mint money and wage private war. The title was recognized until 1945.

Spain. — In early medieval Navarre and Aragon "baron" described the senior nobility but later, perhaps under the influence of Castilian practice, it was displaced by *ricos hombres* ("rich men"). In Catalonia a baron was simply a magnate but in the later middle ages achieved a distinct status even more important than the French barons. Some nobles retained the title until it was abolished by the *cortes* of Cadiz in 1812.

England. — The word *baro* was introduced into England at the time of the Conquest but its numerous meanings make difficult an exact account of medieval tenure by barony. *Baro* could mean a "man" as in the phrase *"baron et feme"* or a "man" in the feudal sense of "vassal"; it might refer to the tenant in chief of a great lord, and it was also used of the tenants in chief of the crown. William I granted out estates (or "honours") in return for military service and the payment of a fee, or relief, by the tenant and his heirs on first entering upon the estate. These estates were all subject to strict rules of inheritance which maintained their identity and the relief. which was determined by the king, differed in each case. unlike that for the knight's fee which appears to have been fixed at £5. These honours or baronies were the basis of the early feudal army and also an important source of revenue to the crown.

In the 11th and early 12th centuries all tenants in chief were known as barons and their reliefs regulated more or less according to the size of their estates. By the year 1200, however, the *barones* were coming to be regarded as a distinct class whose customary relief was £100 irrespective of their estates. When this customary

relief of £100 was legally established by Magna Carta (1215), it became correspondingly important to a tenant in chief of the king holding less than 20 knights' fees (at £5 relief each) to establish that he held by tenure of knight service and not of barony. The criterion used to distinguish between these tenures is, however, not clear. One view holds that the extent of a lord's rights of legal jurisdiction determined the issue while another asserts that the size of his estate was a decisive factor. A third view, however, based on a study of early 13th-century law cases, suggests that the crown could prove that a man held by barony only by producing some record of enfeoffment or similar document bearing a reference to *baro* or *per baroniam*.

Thus all those who held direct of the crown by military service, from earls downward. might be "barons," but the great difference in their position and importance led to their being roughly divided into "greater" and "lesser" barons. Toward 1179 the *Dialogus de Scaccario* (II, x) distinguished their holdings as "greater" or "lesser" baronies, and by 1164 the practice of sending to the greater barons a special summons to the council already had arisen, while the lesser barons, as it is stipulated in Magna Carta, were to be summoned only through the sheriffs. This introduced a definite distinction, which eventually restricted the rights and privileges of peerage to the greater barons.

Thus far the barons' position was connected with the tenure of land. The great change in their status was effected when their presence in that council of the realm which became the house of lords was determined by the issue of a writ of summons, dependent not on the tenure of land, but only on the king's will. This change is now assigned by historians to Edward I, and the earliest writs accepted as creating hereditary baronies are those issued in his reign. Those who received such summons, however, were not as yet distinguished from commoners by any style or title. The style of baron was first introduced by Richard II in 1387, when he created John Beauchamp, by patent, lord de Beauchamp and baron of Kidderminster, to make him *unum parium* et *baronum regni nostri* ("one of the peers and barons of our realm"). But it was not till 1433 that the next baron was created. Such creations became common under Henry VI but "Baron" as a form of address could not evict "Sire," "Chevalier" and "Dominus." Patents of creation contained the formula "Lord *A* (and) baron of B," but the grantee still styled himself "lord" only, and to this day a baron is addressed in correspondence as "the Lord *A*," although other peers under the rank of duke are spoken of as "lords," uhile they are addressed in correspondence by their proper styles. To speak of "Baron *A*" is an unhistorical and quite recent practice. When a barony, however, is vested in a lady it is now the recognized custom to speak of her as baroness; e *g.*, Baroness Berkeley.

The solemn investiture of barons created by patent was performed by the king himself until the reign of James I when the delivery of the letters patent without ceremony was declared sufficient in law. The usual limits of inheritance are to the grantee and heirs-male of his body; occasionally, in default of male issue, to a collateral male relative or to the heirs-male of a daughter; and, in the case of Lord Nelson (1801), to the heirs-male of a sister. In 1821 the barony of Rayleigh was the first to be bestowed upon a lady with remainder to the heirs-male of her body. The baron is now fifth in rank in the English peerage (*q.v.*).

Barons of the exchequer were formerly judges who were competent in causes between the crown and the subject relative to matters of revenue. John Selden conjectured that they were originally chosen from among the barons of the kingdom, but more probably they were officers of a branch of the king's *curia* which was theoretically composed of his "barons." The title has become obsolete since 1875, when the court of exchequer was merged in the high court of judicature.

Barons of the Cinque Ports were at first the whole body of freemen, who were so spoken of in royal charters (*see* CINQUE PORTS). The style was afterward restricted to the mayors, jurats and (up to 1831) members of the house of commons from the Cinque Ports. Their right to the title is recognized in many old statutes. It was their ancient privilege to bear a canopy over the sovereign at his or her coronation and retain it as their perquisite; a deputation attended the coronation of Queen Elizabeth II.

BARONET. Although the origin of this title has been the subject of speculation, it is not known why it was selected as that of "a new Dignitie between Barons and Knights" created by James I of England. The object of its institution was to raise money for the crown. but the money was professedly devoted to the support of troops in Ulster; that is, each grantee was to be liable for the pay of 30 men, at 8*d.* a day for three years. This amounted to £1,095, the sum paid for the honour. When it was instituted, in May 1611, the king covenanted that he would not create more than 200 baronets, and that only those who had £1,000 a year in landed estate and whose paternal grandfathers had borne arms should receive the honour. These qualifications, however, were soon abandoned. As an inducement to apply for it, it was made to confer the prefix of "Sir" and "Lady" (or "Dame"), and was assigned precedence above knights, though below the younger sons of barons. Eight years later (Sept. 30, 1619) the baronetage of Ireland was instituted, the king pledging himself not to create more than 100 baronets. Meanwhile, questions had arisen as to the precedence of the baronets and James, by decree (May 28, 1612), had announced that it was his intention to rank them below the younger sons of barons. As this had the effect of stopping applications for the honour, James issued a fresh commission (Nov. 18, 1614) to encourage them and granted, in 1616, the further privilege that the heirs apparent of baronets should be knighted on coming of age.

The baronetage of Nova Scotia was devised in 1624 for promoting the plantation of that province, and James announced his intention of creating 100 baronets, each to support six colonists for two years (or pay 2,000 marks in lieu thereof) and also to pay 1.000 marks to Sir William Alexander (afterward earl of Stirling), to whom the province had been granted in 1621. For this they were to receive a "free barony" of 16,000 ac. in Nova Scotia, and to become baronets of "his Hienes Kingdom of Scotland." Charles I carried out the scheme, creating the first Scottish baronet on May 28, 1625, covenanting that the baronets "of Scotland or of Nova Scotia" should never exceed 150, that their heirs apparent should be knighted on coming of age, and that no one should receive the honour who had not fulfilled the conditions; viz., paid 3,000 marks toward the plantation of the colony. Four years later (Nov. 17, 1629) the king granted to all Nova Scotia baronets the right to wear about their necks, suspended by an orange tawny ribbon, a badge bearing an azure saltire with a crowned inescutcheon of the arms of Scotland and the motto *Fax mentis honestae gloria.* As the required number could not be completed. Charles announced in 1633 that English and Irish gentlemen might receive the honour. Even so, he was only able to create about 120. In 1638 the creation ceased to carry with it the grant of lands in Nova Scotia, and on the union with England (1707) the Scottish creations ceased, Englishmen and Scotsmen alike receiving thenceforth baronetcies of Great Britain.

Irish baronetcies continued to be created until the Act of Union (1801), since which baronets have been created, not as of Great Britain or of Ireland, but as of the United Kingdom.

In 1827 George IV revoked. for all future creations, the right of baronets' eldest sons to claim knighthood. The eldest sons of baronets of prior creation, however, were not deprived of their rights, and in 1874 Ludlow Cotter, son of Sir James Lawrence Cotter, 4th baronet of Rockforest, was successful in his claim to be knighted on coming of age. However. when Sir Claude de Crespigny's son applied for the honour in 1895, his application was refused on the ground that the lord chancellor did not consider

the clause in the patent (1805) valid. Since then few claims have been made and they have all' been refused, presumably on the ground that it was unconstitutional for a sovereign to bind his successors to confer titles in the future on persons unborn.

A fresh agitation was aroused in 1897 by an order giving the sons of life peers precedence over baronets, some of whom formed themselves, in 1898, into "the Honourable Society of the Baronetage" for the maintenance of its privileges. But a royal warrant was issued on Aug. 15, 1898. confirming the precedence of which the society complained. The society, however, continued in existence as the "Standing Council of the Baronetage" and succeeded in obtaining invitations for some representatives of the order to the coronation of Edward VII. A departmental committee at the home office was appointed in 1906 to consider the question of wrongful assumptions of baronetcies and the best means of preventing them. Following this, an official roll of the baronetage was established by royal warrant of Feh. 11, 1910, and was first gazetted on Feh. 23, 1914. Every person succeeding to a baronetcy must now exhibit to the registrar of the baronetage at the home office his proofs of succession. In 1929 baronets not of the Nova Scotia creation were given leave to wear, hanging from the neck by an orange ribbon with a blue border, a badge composed of a shield of the arms of Ulster, viz., a left hand gules (according to medieval custom "gules" is the name for red, represented by parallel vertical lines) on a silver field. surmounted by an imperial crown, the whole enclosed by an oval border. All baronets are entitled to display in their coat of arms, either on a canton or on a inescutcheon, the red hand of Ulster: except those of Nova Scotia. who display instead the saltire of that province. The precedency of baronets of Nova Scotia and of Ireland in relation to those of England was left undetermined by the Acts of Union. The premier baronet of England in the 1960s was Sir Edmund Castell Bacon, whose ancestor was the first to receive the honour in 1611.

See F. W. Pixley, *History of the Baronetage* (1900).

(J.H.R.; C.F.J.H.)

BARONIUS, CAESAR (1538–1607), Italian ecclesiastical historian and apologist for the Roman Catholic Church, was born at Sora in Latium, Oct. 30, 1538. He joined the Oratory in Rome in 1557. eventually succeeding S. Philip Neri as superior in 1593. Clement VIII, whose confessor he was. made him cardinal in 1596 and in the following year he became librarian of the Vatican. Spanish opposition prevented him from being elected pope in 1605. He died in Rome, June 30,1507.

His major work. the *Annales Ecclesiastici* (1588–1607), undertaken in reply to the *Centuriae Magdeburgexses* and under the inspiration of S. Philip. consists of 12 folios narrating the history of the church down to the year 1198. Hailed by Roman Catholic writers as the "father of ecclesiastical history" Baronius was scorned by Protestant critics for his ignorance of Hebrew and poor knowledge of Greek. It was also claimed that he had made numerous factual errors. The chief merit of the *Annales* lies in its enormous accumulation of sources—some not previously published. It is. however. extremely biased. Just as the authors of the *Centuriae* were able to find in the Gospels everything that Luther had maintained. so Baronius found in them the justification of the Roman Catholic Church. Other works which aroused considerable interest were *Tractatus de monarchia Siciliae* (supporting the papal claims to Sicily) and *Paraenesis ad Rempublicam Venetam*, an attack on Venetian politics. The most useful edition of the *Annales* is by A. Theiner, 37 vol. (1864–83).

See A. Kerr, *The Life of Cesare Cardinal Baronius* (1898); *B.* Croce, *Teoria e storia della storiografia, 3rd* ed. (1927). (F. Dı.)

BARONS' WAR, the name given in English history to the civil war of 1263–67. An attempt to achieve reform had been frustrated when the pope in 1261 absolved Henry III (*q.v.*) from his oath to observe the Provisions of Oxford (1258) and when, by the Mise of Amiens (1264), they were declared invalid by Louis IX of France. Led by Simon de Montfort, some barons took up arms and, in May 1264. captured the king at the battle of Lewes. From then until his death at the battle of Evesham in Aug. 1265, Simon de Montfort largely controlled England and made important administrative and parliamentary experiments. A settlement was achieved by the Dictum of Kenilworth (1266) and finally by the Statute of Marlborough (1267) which remedied some baronial grievances. *See* ENGLISH HISTORY: *The Barons' War;* EVESHAM: *The Battle of Evesham*; LEWES: *Battle of Lewes*; MONTFORT, SIMON DE; OXFORD, PROVISIONS OF.

BAROQUE AND POST-BAROQUE ARCHITECTURE. This article deals with the architecture of the baroque period and succeeding periods through the early part of the 19th century.

During the baroque period (*c.* 1600–1715) architecture, painting and sculpture were integrated into decorative ensemhles. Architecture and painting became pictorial, and painting became illusionist. Baroque was essentially concerned with the dramatic and the illusory, with vivid colours, hidden light sources, luxurious materials and elaborate, contrasting surface textures, all of which were used to heighten visual impact and sensual delight. Baroque space with its directionality, movement and positive molding contrasted markedly to the static, stable and highly defined space of the High Renaissance and to the frustrating conflict of unbalanced spaces in the preceding Mannerist period. Baroque space invited participation and provided multiple changing views. Renaissance space was passive and invited contemplation of its precise symmetry. While a Renaissance statue was to be seen in the round, a baroque statue had a principal view with a preferred angle. or was definitely enclosed by a niche or frame. A Renaissance building was to be seen equally from all sides, while a baroque building had a main axis or viewpoint as well as subsidiary viewpoints. Attention was focused on the entrance axis or on the central pavilion and its symmetry was emphasized by the central culmination. A baroque building expanded to include the square facing it, and often the ensemble included all the buildings on the square as well as the approaching streets and the surrounding landscape. Baroque buildings dominated their environment; Renaissance buildings separated themselves from it. (*See* also BAROQUE ART.)

During the period of the Enlightenment, about 1715 to 1815, various currents of post-baroque architecture were developed. The principal current refined the robust architecture of the 17th century to suit elegant 18th-century tastes. Vivid colours were replaced by pastel shades; diffuse light flooded the building volume; and violent surface relief was replaced by smooth flowing masses with emphasis only at isolated points. Churches and palaces still exhibited an integration of the three arts. but the building structure was lightened to render interiors graceful and ethereal. Interior and exterior space retained none of the bravado and dominance of the baroque but entertained and captured the imagination by intricacy and subtlety. Post-baroque spaces were also active and provided multiple changing views, but participation was rendered difficult by their exceeding elegance. (*See* also NEOCLASSICAL ART.)

BAROQUE

After almost a century of delightful variations and painful refutations of the style of Bramante and his High Renaissance contemporaries. baroque architects in the 17th century made architecture a means of propagating faith in the church and in the state. Baroque palaces expanded to command the infinite and subjugate the infinitesimal. One of its practitioners said that architecture was an art of flattery. Ceilings of baroque churches, dissolved in painted scenes, brought the infinite to the worshiper and lifted him to hedven.

The nork of Carlo Maderno (1556–1629) in Rome represented the first pure statement of the principles that became the basis of most of the architecture of the western world in the 17th century. A north Italian (Ticino canton in the Alps), Maderno worked most of his life in Rome where, about 1597, he designed the revolutionary façade of Sta. Susanna. Roman church façades in the late 16th century tended to be either precise, elegant and papery thin (S. Girolamo degli Schiavoni. 1587, by Martino Lunghi the elder) or disjointed. equivocal and awkwardly massive (Madonna dei Monti. 1580, by Giacomo della Porta). Maderno's Sta. Susanna façade is a totally integrated design in which each element contributes to the central culminating feature. Precision and elegance

were relinquished to gain vitality and movement. Disjointed and ambiguous features were suppressed to achieve unity and harmony. A towering massiveness mas obtained by an increasing use of surface relief and pilaster rhythm toward the central motif, replacing the papery thin walls and hesitant massiveness of the 16th century.

The basic premises of the early baroque as reaffirmed by Maderno in the face and nave of St. Peter's, Rome (1607), were: (1) subordination of the parts to the whole to achieve unity and directionality; (2) progressive alteration of pilaster rhythm and wall relief to emphasize movement and activity; and (3) directional emphasis in interiors through culminating spatial sequences.

Maderno's revolutionary concepts caught the imagination of European architects. Within a few years the baroque became international, with buildings in France (St. Gervais, Paris, 1616), Flanders (St. Walbruge, Bruges, 1619. and St. Loup, Namur, 1620, both by Peter Huyssens), the Netherlands (the Mauritshuis, The Hague, 1633, by Pieter Post and Jacob van Campen), Spain (La Clerica, plans, Salamanca, 1617, by Juan Gómez de Mora), South America (cathedral of Lima, Peru, facade, 1626, by Arrona), Africa (church. Luanda, Angola, 1648) and Czechoslovakia (Wallenstein palace, Prague, 1623, by Andrea Spezza). The baroque rapidly developed into two separate forms: the strongly Roman Catholic countries (Italy, Spain, Portugal, Flanders, Czechoslovakia, south Germany and Poland) tended toward freer and more active architectural forms and surfaces; in Protestant regions (England, Holland and the remainder of northern Europe) the architecture was more restrained and developed a sober, quiet monumentality impressive in its refinement. The Protestant countries (and France, even though the state religion was Roman Catholic) sought the spirit through the mind. Architecture in the north was more geometrical, formal and precise — an appeal to the intellect. In the Roman Catholic south, buildings were more complex, freer and done with greater artistic licence — an appeal to the spirit made through the senses.

Italy. — The four great masters of the baroque in Italy were Giovanni Lorenzo Bernini (1598–1680), Francesco Borromini (1599–1667), Pietro da Cortona (1596–1669) and Guarino Guarini (1624–83). Bernini, also a brilliant sculptor, was notable for the design of the vast square and enclosing colonnade (c. 1656) of St. Peter's in Rome, and for the exquisite small marble-encrusted oval church of S. Andrea al Quirinale. Rome, 1658. The works of Borromini and Guarini, both of whom were from the north of Italy, are characterized by inventiveness, ingenuity and originality. Borromini's works present highly active concave and convex surfaces (S. Carlo alle Quattro Fontane, Rome. 1634–44), and his spaces are complex irregular ovals or hexagons (S. Ivo, Rome. 1642). S. Lorenzo in Turin, 1667, and the Palazzo Carignano. Turin, 1679, with their swelling forms. terra-cotta construction, exposed structural members and intricate spatial compositions, show Guarini's relation to Borromini. In contrast to Bernini, both Borromini and Guarini preferred monochromatic interiors. Cortona's robust façade of Sta. Maria della Pace, Rome (1656), forms a city square that is half dominated by the church itself.

Spain. — Spanish baroque was similar to Italian baroque, but with a greater emphasis on surface decorations that was in some measure probably due to pre-Coluinbian architecture in the Americas. Alonso Cano (1601–67) in his facade of the Granada cathedral (1667) and Eufrasio López de Rojas (d. 1684) with the façade of the cathedral of Jaén (1667) show to what degree Spain absorbed the concepts of the baroque while maintaining its native tradition. The greatest of the Spanish masters was José Churriguera (1665–1725), whose work shows most fully the interest in surface texture and decorative detail that reflected new world architecture. His lush stucco decorative detail (courtyard of the Jesuit college, Salamanca, 1720) attracted many followers, and Spanish architecture of the last half of the 17th century has been labeled "churrigueresque." Narciso and Diego Tomé (d. 1732) in the University of Valladolid (1715) and Pedro de Ribera (d. 1742) in the façade of the Provincial hospital in Madrid (1722) proved themselves to be the chief inheritors of Churriguera, whose style spread throughout the colonies (*e.g.,* cathedral of Cajamarca, Peru, 1682; cathedral of Zacatecas, Mexico, 1718).

Belgium and Holland. — Roman Catholicism, political opposition to Spain, and Peter Paul Rubens (1577–1640) were responsible for the astonishing full-bodied character of Flemish baroque. Rubens' friends Jacques Francart (1577?–1651) and Peter Huyssens (1577–1637) created an influential northern centre for vigorous expansive baroque architecture to which France. England and Germany turned. Francart's Béguinage church. Malines (1629), and Huyssens' St. Charles Borromeo. Antwerp (1615), set the stage for the full baroque of St. Michel, Louvain (1650), by Willem Hesius and the abbey of Averbode (1662), by Jean van den Eynde.

The architecture of the 17th century in Holland is marked by sobriety and restraint. Pieter Post (1608–69), noted for the Swanenburgh house, The Hague (1645), and the town hall, hfaastricht (1656), with Jacob van Campen (1595–1657) who built the Amsterdam town hall (1648; now the royal palace), are the principal architects of the Dutch golden age. Dutch architecture exerted a strong influence on minor architects in France and England after the middle of the century.

Central Europe. — A stable political situation in central Europe and the vision of Rudolf II in Prague created. in the late 16th and early 17th centuries, an intellectual climate that encouraged the adoption of new baroque ideas. However, the Thirty Tears' War and the defense against the encroachments of the expanding French and Ottoman empires absorbed all the energies of central Europe. The full baroque appeared in Germany, Austria, Czechoslovakia, Poland and Russia after 1680 but flourished only after the end of the debilitating War of the Spanish Succession (1713). Germany and Austria turned principally to northern Italy for their models, and Guarini exerted a decisive influence on J. B. Fischer von Erlach (1656–1723), Johann Lukas von Hildebrandt (1668–1745) and Jakob Prandtauer (1660–1726). Fischer von Erlach's collegiate church in Salzburg (1696) is particularly noteworthy and shows direct Italian inspiration, while the Karlskirche, Vienna (1715), shows him in his strong, original, mature phase.

In Czechoslovakia the full baroque was heralded by the work of the French architect Jean Baptiste Mathey (1630–95). who went to Prague from Rome in 1675. However, Christoph Dientzenhofer (1655–1722) transformed the face of I'rague with his strong active buildings (*e.g.,* St. Nicholas, 1703j in baroque.

England.—Inigo Jones (1573–1652) virtually singlehandedly changed the course of English architecture from a tired Jacobean Mannerism (*e.g.,* Charlton house, Greenwich, 1607; Hatfield house, 1611) to something that is almost baroque. His Whitehall palace (1638) and Queen's chapel (1623) designs introduced English patrons to the prevailing architectural ideas of northern Italy of the late 16th century. Although he leaned heavily on Mannerist architects such as Andrea Palladio, Sebastiano Serlio and Vincenzo Scnmozzi, Jones approached the baroque spirit by unifying his works with a refined compositional vigour. Sir Christopher Wren (1632–1723), in St. Stephen, Walbrook (1672); with its multiple changing views and spatial and structural complexity, presents English baroque in its characteristic restrained but intricate form. Wren's greatest achievement, St. Paul's cathedral, London (1675 et *seq.*), owes much to French and Italian examples. but the plan shows a remarkable adaptation of the traditional English cathedral plan to baroque spatial uses. Wren is notable for his large building complexes (Hampton Court. 1690. and Greenwich hospital, 1698) which. in continuing the tradition of Inigo Jones, paved the way for the future successes of Sir John Vanbrugh (1664–1726). Vanbrugh's Castle Howard (1699) and Blenheim palace (1705) mark the culmination of the English full baroque.

France. — The role of Salomon de Brosse (1571–1626) in the history of French baroque architecture is much the same as that of Jones in England and of Mathey in Czechoslovakia. His Luxembourg palace (1615) and chateau of Blérancourt (1614) were the basis from which François Mansart (1598–1666) and Louis Le Vau (1612–70) developed their succession of superb country houses.

François Mansart was the more accomplished of the two architects, and his Orléans wing of the château of Blois (1635) and Maisons-Lafitte (1642) set a standard of refinement, subtlety and elegance toward which architects for the rest of the century as-

pired, but never attained. Mansart's Val-de-Grbce (1645) and his designs for the Bourbon mausoleum (1664) established the full baroque in France; it was a rich, subtle baroque that was quiet in its strength and restrained in its vigour.

Louis Le Vau mas Mansart's only serious competitor and in 1657 with his chbteau of Vaux-le-Vicomte he fired the imagination of Louis XIV and his minister Colbert. Vaux, though exhibiting certain Dutch influences, is noted for its integration of Le Vau's architecture with the decorative ensembles of Charles Le Brun (1619–90) and the garden and landscape designs of André Le Nôtre (1613–1700). By serving as a model for Versailles, the complex at Vaux was perhaps the most important mid-century European palace. Versailles then became a model for all regal palaces in Europe until the end of the 18th century. Le Vau showed a sensitivity to the beauty of Italian forms that was unusual for a French architect and his Collège des Quatre Nations (1662) was clearly inspired by Cortona's Sta. Maria della Pace and by S. Agnese in Piazza Navona. Le Vau, Le Nôtre and Le Brun began working at Versailles within a few years of their success at Vaux, but the major expansion of the palace did not occur until after the end of the Queen's War (1668). In Versailles Le Vau showed his ability to deal with a building of imposing size. The simplicity of his forms and the rich, yet restrained, articulation of the garden façade mark Versailles as his most accomplished building. Upon Le Vau's death Jules Hardouin Mansart (1646?–1708), grandnephew of François, succeeded him and proved himself equal to Louis XIV's desires by more than trebling the size of the palace (1678 et seq.). Versailles became the palatial ideal throughout Europe and the Americas. A succession of grand palaces was built, including the following: Castle Howard and Blenheim palace; the palace of Wiirzburg (1719) by Balthasar Neumann (1687–1753); the Zwinger, Dresden (1711), by Matthäus Poppelmann (1662–1736); the Belvedere, Vienna (1714), by Johann Lukas von Hildebrandt: the royal palace at Caserta, Italy (1752), by Luigi Vanvitelli (1700–73); and the royal palace at Madrid (1738), by G. B. Sacchetti (d. 1764).

J. Hardouin Mansart's Dôme des Invalides, Paris (1675), is unquestionably the finest church of the last half of the 17th century in France. The correctness and precision of its form, the harmony and balance of its spaces, as well as the soaring vigour of its dome make it a landmark not only of the Paris sky line but also of European baroque architecture.

POST-BAROQUE (18TH AND EARLY 19TH CENTURIES)

The relative similarity of approach among architects in the 17th century did not exist in the 18th century. Baroque spatial and organizational concepts underwent profound alterations. Simultaneously there was the birth of the rococo, a new approach in the decorative arts which in its search for freedom, lightness and airiness paralleled, to a degree, the spatial experiments in architecture. The decorative inventions and architectural evolutions which provided designers with a new vocabulary were, in a sense. complementary. But the middle of the century also saw the founding of a strong antibaroque, antirococo rationalist school that rejected categorically earlier principles. Rationalist architects held that baroque rules of beauty, harmony, balance and rhythm, as well as lush or elegant ornament and false or hidden structural systems, were fundamentally in error. Architecture, for the rationalists, was "to show nothing that did not derive from function," and was to conform "to the nature of the materials used."

Romanticism (in its adaptation of classic, Gothic and far eastern forms) was variously a reaction to rococo excesses, to rational unimaginativeness, and to the dreariness of an industrial society. It longingly sought escape in the fancied harmonies of another world.

Rococo Architecture

The early years of the 18th century saw the shift of the artistic centre of Europe from Rome to Paris. Pierre Lepautre, working under J. Hardouin Mansart on the interiors of the chbteau of Marly (1699), invented new decorative ideas that became the rococo. Lepautre changed the typical late 17th-century flat arabesque, which filled a geometrically constructed panel, to a linear pattern in relief, which was enclosed by a frame that determined its own shape, no longer limited by architectural considerations. White- and gold-painted 17th-century interiors (central salon, Versailles) were replaced by varnished natural wood surfaces (château of Meudon, Cabinet à la Capucine) or by painted pale greens, blues and creams (Cabinet Vert, Versailles, 1735). The resulting delicate asymmetry in relief and elegant freedom revolutionized interior decoration and within a generation exerted a profound effect on architecture. Architects rejected the massive heavy relief of the baroque in favour of a light and delicate, but still active, surface. Strong, active and robust interior spaces gave way to intricate, highly elegant but restrained spatial sequences. In the early years of the century the revolution was under way in England with Thomas Archer's St. Phillip's church, Birmingham (1709), and in Italy with Filippo Raguzzini's façade of Sta. Maria della Quercia, Rome (1730), and G. B. Scapitta's Sta. Caterina, Casale Monferrato (before 1714). In its second phase (1715–30) the rococo was diffused throughout Europe. One of its principal practitioners, Nicolas Pineau (1684–1754), went to Russia in 1716 and introduced rococo ideas to the newly founded city of St. Petersburg (*e.g.*, Peter's study at Peterhof, before 1721). The rococo in Russia flourished in St. Petersburg under the protection of Peter I and Elizabeth. Peter's principal architect. Gaetano Chiaveri (1689–1770), who drew heavily on north Italian models, is most noted for the library of the Academy of Science (1725) and the royal churches of Warsaw and Dresden. Bartolomeo Rastrelli (1700–71) was responsible for all large building projects under the reign of Elizabeth (1741–62), and among his most accomplished designs in St. Petersburg are the Smolny cathedral (1748–55), and the turquoise blue and white winter palace (1754–62).

After Pineau returned to France, he, with Gilles Marie Oppenordt (1672–1742) and Juste Aurèle Meissonier (1675 or 1693–1750), created the full rococo by developing its asymmetrical aspect. Meissonier and Oppenordt should also be noted for their exquisite and imaginative architectural designs a hich unfortunately never were built (*e.g.*, façade of St. Sulpice, Paris, 1726, by Meissonier). The last phase of French rococo, dominated by Jacques Ange Gabriel (1698–1782), was conservative — less free and less asymmetrical. Gabriel's gracefully precise Petit Trianon at Versailles (1762) is his finest work, the high point of late rococo architecture, and perhaps the most accomplished building in France in the 18th century.

In architecture the simple dramatic spatial sequences or the complex interweaving of spaces of 17th-century churches gave way to a new spatial concept. By progressively destroying the Renaissance-baroque horizontal separation into discrete parts, rococo architects obtained unified spaces, emphasized structural elements, created continuous decorative schemes and reduced column sizes to a minimum. Ceilings of side aisles were raised to the height of the nave ceiling to unify the space from wall to wall (Church of the Carmine, Turin, Italy, by Filippo Juvara, 1732; Pilgrimage church, Steinhausen, near Biberach, Ger.. by D. Zimmermann, 1727; St. Jacques, Lunéville, France, by G. G. Boffrand, 1730). To obtain a vertical unification of structure and space, the vertical line of a supporting column was often carried up through a broken entablature, through a pilaster applied to a pendentive, through a pilaster of the drum, and through a pilaster painted on the surface of the dome, through to the lantern itself (*e.g.*, Church of San Luis, Seville, Spain, 1730, by Leonardo de Figueroa). By 1742, to increase the vertical effect and the unification of space, main arches were raised, pendentives punctured, the drum eliminated and the dome ribbed and punctured (Sta. Chiara, Bra. Italy, by Bernardo Vittone, 1705–70). The entire building was often lighted by numerous small windows placed for dramatic effect or to flood the space with a cool diffuse light (Pilgrimage church, Weis, Ger., D. Zimmeimann, 1746). The spectacular rococo of Germany and Austria, which by 1720 had begun to influence Italian architecture, was itself a fusion of Italian baroque and French rococo. Its chief monuments are to be found in the Roman Catholic regions

of the two countries. Johann Michael Fischer (1692–1766), Balthasar Neumann, and Zimmermann (1685–1766) were the most accomplished of the native architects while Franqois de Cuvillés (1695–1777), Phillipe de la Guepikre (1715–73) and Nicolas Pigage (1723–96) made the most important foreign contributions to mid-century architecture in Germany. Fischer's austere, dignified faqade of the church at Diessen (1733) and Neumann's joyous, airy pilgrimage church at Vierzehnheiligen (1743) show Germany's international contribution to religious. architecture through its fusion of the French and Italian directions. Two influential country houses, La Guepikre's Solitude (1763), and Cuvillés' Amalienburg (1734), though graceful and refined, are but examples of French architecture on foreign soil.

In Spain the outstanding figure of the century was Ventura Rodriguez (1717–85) who, in his designs for the chapel of Our Lady of Pilar in the cathedral of Saragossa (1750), showed himself to be a master of the developed rococo in its altered Spanish form; but it was a Fleming, Jaime Bort y Melia, who brought the rococo to Spain when he built the west front of the cathedral of Murcia in 1733. A few years later the rococo was found in Peru where the church of Surco (attributed to a German Jesuit—Johan Rher) exhibits the typical studied odd placement of openings in large curved planal wall surfaces.

Rationalist Architecture

The rationalist revolt against the imagined excesses of the baroque and rococo necessitated a complete refutation of preceding aesthetic principles. Vasari praised Michelangelo for his use of ornamentation to cover defects of buildings or nature while Francesco Milizia (1725–98) condemned decoration as a "deceitful parasite." Baroque and rococo architects sought to devise buildings that would be characterized by unified and orderly conception; internal harmony and harmony with surroundings; composition of each part in relation to the whole; recognition and use of an architectural vocabulary and certain grammatical principles; and relatedness to man and his sensibilities. Mannerist architects violated grammatical principles but utilized the architectural vocabulary to create meaningful disharmony. In so doing they remained faithful to the prevailing aesthetic principles though only in a negative way. Rationalist architects, however, did not recognize the architectural principles of preceding ages and sought to devise buildings that exploited the precise simplified beauty inherent in pure geometrical forms without any reference to man. Unity as a guiding principle was replaced by diversity, with many points of emphasis. The harmony obtained by selecting from a family of forms was replaced by a fragmented, excited vitality obtained by freedom in the use of any geometrically derived forms.

In the early years the rationalists sought to combine many simple forms in a highly complex and involved manner which produced violent relief and an extremely active, unresolved surface character (Seaton Delaval, 1721, by Sir John Vanbrugh; Christ church, Spitalfields, 1723–29, by Nicholas Hawksmoor). Later in the century the pure forms became larger and more inclusive while the surface became simpler and less active (St. Chad's, Shrewsbury, 1791, by George Steuart; Ste. Genevikve, Paris, 1757–77, by Jacques Germain Soufflot; plans for a national theatre, Berlin, 1798, by Friedrich Gilly). Toward the turn of the century there were projects for entire buildings that were included within a sphere (Shelter for Rural Guards, c. 1780, by Claude Nicolas Ledoux) or a towering cone (Cenotaph, c. 1780, by Etienne Louis Boullée).

The intellectual basis for rationalist architecture was provided by the writings of T. Gallaccini (d. 1641), Louis Géraud de Cordemoy (1651–1722), Marc Antoine Laugier, Carlo Lodoli (1690–1761), Francesco Algarotti, Milizia, Friedrich Krubsacius (1718–90) and William Hogarth (1697–1764).

Romantic Architecture

Rococo architects valued Chinese lacquer panels for their brilliant colour and exotic uniqueness, but they did not attempt to produce an imagined idyllic setting with them. They used them to create delicate decorative ensembles like the Chinese rooms in the royal palaces at Turin and Stupinigi by Juvara (c. 1732). Late Gothic architecture, which was so similar to rococo in its lightness, delicacy and intricacy of structure, was also highly valued. Santin Aichel (1667–1723) in the church at Kladrau, Czech. (1712), and Horace Walpole in his residence Strawberry Hill (1748) attempted to capture some of the gay, transparent, veiled spaces and delicate surface decorations which were so precious to rococo sensibilities.

Romantic sensibilities, however, were excited by the vision of a society which could be evoked by its architecture, and architecture with a moral or ethical purpose was demanded. Romantic architects reacted against the reasoned skepticism and pompous artificiality of the rococo by idealizing earlier societies which were less complicated and more credulous. From its beginning in England, romanticism spread principally to the Protestant countries of northern Europe and North America. Romanticism was essentially Protestant, placing a high value on the emotions and on individual faith, as well as on the simple and the natural. With the romantics architecture became associative and was valued not so much for itself as for the literary visions it could evoke. Through the use of forms of earlier ages, romantic architects attempted to evoke visions of simple happiness and stable order which would inspire their contemporaries to strive toward proper ideals. Richard Mique (1728–94), in his Le Hameau (1780) at Versailles, through an informal grouping of modest farm buildings gave tangible form to Marie Antoinette's dream of a simple, honest peasant life. Fonthill abbey (c. 1795). by James Wyatt (1746–1813), was a residence in ecclesiastical garb, set in an informal park, which created an environment such as was thought to have existed when Christian principles were supposed to have guided the actions of men.

Neoclassical Architecture

The rebirth of interest in Greek and Roman architecture, generated perhaps by scientific archaeology, provided an ideal basis for the marriage of the previously opposed romantic and rationalist factions. The romantics saw in Greek architecture the expression of an ideal democratic state, proud of its freedom. the wisdom of its scholars, the production of its writers and artists, and its primacy in world affairs. The rationalists saw an apparently simple but highly sophisticated architectural expression that used large, simple, geometrical forms, reduced all elements to essentials, limited decorative features, and clearly stated its structural principles.

The marriage was internationally successful. In Russia two of the chief practitioners were Ivan Starov (1743–1808) and Andrei Voronikhin (1760–1814). Starov's Catherine hall in the Tauride palace (1783–88) and Voronikhin's Cathedral of the Virgin of Kazan (1801–11), both in St. Petersburg, are outstanding examples of their work. In Germany the chief neoclassical designer was Karl Friedrich Schinkel (1781–1841) who is justly noted for his fertile imagination (*e.g.,* Altes museum. Berlin, 1822–30). The rationalist architect Sir John Soane (1753–1837) in his Bank of England, London (1788–1808), provided the basis which Sir Robert Smirke (1781–1867) drew upon for his later neoclassical buildings (*e.g.,* British museum, London, 1825–27). The Madeleine, Paris (c. 1806), by Pierre Vignon (1763–1828) and St. Philippe-du-Roule, Paris (1774–84), by Jean Chalgrin (1739–1811) are two of the finest examples of the short-lived neoclassical interest in France.

In Italy, where romanticism was weakest, Roman architecture was revived by the sculptor Antonio Canova (1757–1822) and Ferdinand Bonsignore (1767–1843). Canova designed and built a tomb in his native Possagno (1819–30) that was modeled on the Pantheon, as was the Gran Madre di Dio in Turin (1818–31) by Bonsignore.

Outstanding examples in the United States are the Virginia state capitol, Richmond (1785–92), by Thomas Jefferson (1743–1826); the statehouse, Boston (1795–98). by Charles Bulfinch (1763–1844); the Bank of Pennsylvania, Philadelphia (1798), by Benjamin Latrobe (1764–1820); and the customhouse, Philadelphia (1819–24), by William Strickland (1787–1854).

URBAN DESIGN

Baroque.—The basic principles of Renaissance urban design, stated early in the Renaissance by Filarete, Alberti and Francesco di Giorgio, remained unaltered throughout the 17th century. Variations were made to provide for a particular desired spatial effect. The plan was adjusted to fit a realistic situation or varied to agree with the patron's economic condition, but the principles remained constant.

In Rome the basic street pattern was largely the creation of Domenico Fontana (1543–1607) who, under Pope Sixtus V in the years just before 1600, imposed an avenue pattern that linked all the major pilgrimage churches. The avenues were laid out over the most direct routes regardless of the terrain, and at the focal points (*i.e.*, piazzas in front of the major monuments) obelisks were erected. Fontana's meaningful emphasis on communication routes and gathering spaces became the model for most later large-scale urban designs or renovations. Christopher Wren's plan for London, submitted after the Great Fire of 1666, showed a series of avenues linking the major religious and commercial centres superimposed on a rational gridiron plan.

The regularized city square received its greatest development in France with the planning of the royal squares. The perfectly square Place des Vosges, Paris (1606), with its well-proportioned façade, shadowed arcades and balanced colour scheme, was the beginning of a series that culminated with the circular Place des Victoires, Paris (1685), and the Place Vendôme, Paris (*c.* 1690). Italian city squares tended to be either open, grand and monumental (St. Peter's square, Rome) or intimate, provocative and exciting (Sta. Maria della Pace, Rome).

18th Century.—Urban design in the 18th century placed greater emphasis on unity and direction through the subordination of lesser parts to the whole. Ideas introduced into garden planning by Le Nôtre became of fundamental importance and entire cities were laid out on his regularized axial schemes (*e.g.*, Washington, D.C., 1791, by Pierre L'Enfant). Spaces between the radiating avenues were divided either geometrically or on a gridiron pattern. New principles calling for a sequence of different spatial experiences were also introduced, as in the plan for Nancy (1752–55) by Emmanuel Héré (1705–63). In Italy outstanding examples are the splendid oval Piazza S. Ignazio, Rome (1727), by Filippo Raguzzini (d. 1771); the grand, solid military quarter, Turin (1716), by Juvara; and the Piazza del Popolo (1816), by Giuseppe Valadier (1762–1839). Notable among the many English examples of planned urban development are St. James's square, London (1726); the Circus (1764), and the Royal Crescent (1769), Bath, by John Wood the elder and the younger; and the Park Crescent, London (1812), by John Nash. In Reims, France, the solemn Place Royale (1756) by J. G. Legendre is deservedly noted, but perhaps the finest example of an 18th-century large urban pedestrian square is the Place Louis XV (now the Place de la Concorde), Paris (1755), by Jacques Anges Gabriel. On the banks of the Seine, in its original design, it served as a focal point for the gardens of the Louvre, for the street which led to the Church of the Madeleine, and for three radiating streets of the Champs Élysées.

LITERATURE

Treatises on the orders and on civil and military architecture which appeared in increasing numbers in the 16th century provided a theoretical basis for baroque architects. While many 16th-century architects published treatises on architecture (Vignola, Palladio, Serlio, Cesariano, Delorme, Du Cerceau, Dietterlin, Herrera and Vriedman de Vries) or prepared them for publication (Leonardo, Bramante, Raphael, Peruzzi, Ligorio and Ammanati), major 17th-century architects published very little. Borromini's two fragmentary volumes appeared years after his death, and Guarini's major contribution (though he brought out two volumes on architecture before he died) did not appear until well into the 18th century. It was only the highly successful book of Andrea Pozzo (four editions in 19 years) that kept Italian ideas in the foreground in the early years of the 18th century. Other Italian publications tended to be mere repetitions of previous ideas with the exception of the tardily published manuscript of T. Gallaccini. Gallaccini's treatise on the errors of Mannerist and early baroque architects became a point of departure for later rationalist theoreticians.

In France F. Blondel and A. Daviler published their notes for lectures given at the Academy of Architecture, but the most important publications were those of Freart de Chambray and Claude Perrault. Perrault was particularly interesting for his attack on established Italian theory. Other notable French works included the writings of R. Ouvrard, A. Felibien, P. Le Muet and J. Mauclerc. In England Sir Henry Wotton's book was an adaptation of Vitruvius, and B. Gerbier's was a compendium of advice for builders. Among the notable 17th-century German publications were the books by G. Boeckler, J. Furttenbach and J. von Sandrart.

In the 18th century there was a marked increase in the number of works devoted to antiquities. In the tradition of Palladio, Scamozzi, Duperac, Blondel and Desgodetz, works on various aspects of antiquity were published by R. Adam, J. Stuart and N. Revett, C. Cameron, J. Fischer von Erlach, D. Le Roy and G. B. Piranesi. There was also a large increase in the number of guide books but the treatises on architecture were fewer. In Italy only the works of F. Galli Bibiena and the two important volumes of B. A. Vittone rose above the general low level of theoretical thought. Particularly noteworthy in France were the works of J. F. Blondel, G. G. Boffrand, P. Bullet, S. Le Clerc and P. Nativelle. The books by J. Gibbs, W. Chambers, C. Campbell, B. Langley, W. Halfpenny and I. Ware in England are interesting but the remarkable success enjoyed by Palladio in his various English editions merits special attention.

BAROQUE ART is that which falls between the Renaissance and the neoclassical periods, extending from the late 16th to about the middle of the 18th century. As a period the baroque embraces the styles beginning with that of late Michelangelo and Rlannerism (*q.v.*) and ending with the rococo (*q.v.*). Two possibilities have been advanced for the derivation of the word. The older and more widely accepted one ascribes it to the Portuguese *barroco,* a large irregularly shaped pearl. Such a sphere, straining outward to the point of bursting, constitutes a valid analogy with some baroque architectural shapes and pictorial forms. **A** later and perhaps more plausible surmise derives the word from *barocco,* a term employed by Italian Renaissance philosophers to characterize extravagant or farfetched arguments in scholastic syllogisms.

As a style designation "baroque" was originally a derogatory term. It was so used by such late 19th-century admirers of Renaissance art as Jacob Rurckhardt and John Ruskin to express their disapproval of what they considered to be odd, bizarre, grotesque, exaggerated and overdecorated. Heinrich Wölfflin in his *Renaissance und Barock* (1888), however, addressed himself to the problem of separating the baroque from the Renaissance both as a style and as a period. While "baroque" can still be used to indicate disparagement or approval, it is more generally used as a neutral term indicating the period rather than a particular form. At first confined to use in the history and criticism of the visual arts, "baroque" has been broadened to include the concurrent period in music. Its application to the literature and philosophy of the corresponding time is rare.

Baroque art, born as it was out of the Mannerist struggle to free itself from Renaissance stereotypes, is an art of restless oppositions, of uneasy equilibriums, of violent clashes, of polarities brought momentarily into precarious balances, and of passions brought briefly under control. In architecture the baroque is discernible at St. Peter's in Rome, especially in Michelangelo's vast conception in which all component parts — architectural, sculptural and decorative — were to be merged into a single unified whole. In the massive masonry of the apse the rising forces seem to struggle upward against the pull of mighty weights to culminate in the soaring dome. Underneath the dome the four spiraling columns, supporting Giovanni Lorenzo Bernini's gigantic canopy over the high altar also carry the eye irresistibly upward. The baroque spirit continues in Carlo Rladerno's nave and façade and outward into Bernini's Piazza Obliqua, which extends from a trapezoidal plaza into the spacious open elliptical area embraced by the monumental fourfold Doric colonnades.

In sculpture the baroque is found in the diagonal composition, textural contrasts and swift movement of Bernini's marble group, "Apollo and Daphne." In painting the baroque is revealed in El Greco's clashing colour harmonies; in Rubens' gusty canvases, sweeping designs and nervous visual rhythms; and in Rembrandt's mysterious but dramatic play of light and shade. In literature it is evident in the passionate but stylized poetic tragedies of Corneille and Racine, in which strong emotional forces are contained by powerful aesthetic and intellectual restraints, as well as in the rich imagery and grandiloquent language of Boileau, Dryden and Pope. In music the baroque is expressed in Giovanni Gabrieli's colossal tonal murals in which unequal sonorous masses, solo and choral forces, vocal and instrumental colours contend with one another; in the throwing back and forth of large and small volumes of sound in Corelli's *concerti grossi;* in the spectacular "scenes and machines" and intricate vocalisms of Italian and French opera; in J. S. Bach's free-moving, florid toccatas and the uncompromising intellectuality of the ensuing fugues; and in the rich-textured. jubilant sounds Handel draws from his oratorio choruses. In later phases of the baroque some of these tensions were resolved in such grandiose statements as the Versailles palace. the pompous pageantry of baroque opera and the theatrical illusionism of such churches as Vierzehnheiligen in southern Germany and the abbey church at Melk, Austria.

Wölfflin's famous five pairs of categories for distinguishing baroque art from that of the Renaissance, first formulated in his *Principles of Art History* (1915), still retain their usefulness as critical criteria. (1) Basing his theory on differing forms of representation, he first opposes the linear to the painterly. Renaissance art, he demonstrates, is dominantly linear with incisive lines and clear contours, while the baroque is primarily painterly *(malerisch)* by reason of its blurred outlines, merging images and greater reliance on chiaroscuro and colour. A painting by Durer (1471–1528) contrasted with one by Rembrandt (1606–69) will clarify the point. (2) Plane ***v.*** recessional indicates differing concepts of space. Renaissance artists thought in terms of clearly defined horizontal planes and containment within a limited area, while those of the baroque emphasized composition in depth and suggested illusions of distance. Here the difference is illustrated by a comparison of Leonardo da Vinci's (1452–1519) "Last Supper" with a painting of the Last Supper by Tintoretto (1518–94), or the Pazzi chapel in Florence, which has a flat façade and low-relief decorative detail. with the Church of S. Carlo alle Quattro Fontane in Rome, which has a forward-backward movement and deep shadow effects. (3) Closed v. open form indicates the dis-

tinction between a balance consisting of horizontal and vertical elements that delimit the pictorial space and keep the eye within the picture on one hand, and an instability consisting of diagonal accents and open backgrounds that beckon the eye beyond the picture on the other. A typical-Renaissance church interior, for instance, will terminate in a well-defined apse, while the open apsidal arcades of Andrea Palladio's Venetian churches invite the eye into the indefinite space beyond. (4) Multiplicity v. unity is Wölfflin's next category. A Renaissance painting such as Botticelli's "Primavera" is based on fragmented vision in which the figures remain independent entities in spite of their harmonious grouping and balance arrangement, while an organic unity pervades a baroque example such as Rubens' "Garden of Love" in which all parts are subordinated to the single motivating rhythm that unites the whole. (5) Lastly, Wolfflin adduces absolute clarity *v.* relative clarity, or clearness opposed to unclearness. In the former all elements — line, dark and light, colour — are used to define and describe the structure of solid, three-dimensional forms, while in the latter each is used for its contribution to the dramatic theme.

Within the baroque itself, it is also useful to distinguish two divergent tendencies: the free and the academic. In architecture the impulse toward lavish ornamentation was held in check by the restraints imposed by the use of the classical orders; in sculpture Bernini's restless figures contrast with the repose of those of Antoine Coysevox and the violent movement of Rubens' canvases is opposed by the quiet grandeur of Poussin's pictures. Artists who were dominated by emotional forces insisted on a maximum of freedom in the execution of their designs, while those subject to the rigours of reason were willing to adhere to rules. The latter tendency was most apparent in France, where the academies of language and literature, architecture, painting and sculpture attempted to systematize the arts according to fixed principles. At best the academies upheld standards of craftsmanship, encouraged self-discipline and exercised a restraining influence on baroque extravagances; at worst they reduced art to a system of sterile conventions, suppressed individual expression and brought about aesthetic uniformity and regimentation.

Baroque art, for purposes of discussion, divides more readily according to sources of patronage than to geographical boundaries. The services of artists, for instance, were enthusiastically enlisted by Counter-Reformation forces and great monarchies to enhance the power and glory of church and state respectively. Similarly, art was used by the Reformation movement to establish a new religious tradition, and the rising middle class found in the arts an important adjunct to the enjoyment of the good life. Thus the four main sources of patronage for baroque art were the Counter-Reformation, the aristocracy, the Reformation and the bourgeoisie.

Counter-Reformation Baroque. — Following the Council of Trent (1545–63) the church mobilized its great resources for the propagation of the faith. Newly founded orders, such as the Society of Jesus. undertook building programs destined to have far-reaching consequences. In Rome, the mother church of the Jesuit order, the Gesù, exerted an enormous influence on church design. Planned by Giacomo da Vignola and finished after his death by Giacomo della Porta. it departed from the Renaissance tradition in many respects, notably in the striking volutes and spiraling scrolls that flank the upper story of its facade.

The full force of the baroque power to mold space into new and astonishing forms was felt during its climactic Roman phase from about 1630 to 1670. Departing from the neat rectangles, triangles, circles and other Euclidean forms favoured by Renaissance artists, Francesco Borromini's geometry in his Church of S. Carlo alle Quattro Fontane, as well as in his Church of S. Ivo, includes spheres, ellipses, parabolas, spirals and ovals. The interior of S. Carlo was organized over a flexible floor plan; its irregular walls strain upward toward an oval dome, the inner surface of which nas designed with a combination of unusual geometrical figures. The facade is not flat and static in the Renaissance manner, but ripples like a stage curtain in a series of convex and concave surfaces. This undulating, in-and-out movement allows for a maximum play of light and shade over the irregular surface and over the statuary set in niches. Such a façade produced much consternation among Renaissance partisans. Burckhardt, for instance, spoke of it as resembling something that had been dried in an oven.

Bernini's tortured and turbulent "St. Theresa in Ecstasy" expresses at its best the baroque spirit in sculpture. What Michelangelo expressed with the nude body, Bernini expressed through the fluttering, wind-swept drapery by which he externalized the soul states of the saint as she was torn between earthly and divine love, tormented with sensual and spiritual aspirations, and simultaneously borne aloft on her own swirling gales of passion. Deep undercutting gives greater play to light and shade, and the dramatic, even theatrical lighting filtered through a concealed, yellow-glazed window, completes the illusion.

Counter-Reformation churches in general were light, spacious and cheerful. Interiors such as that of S. Ignazio in Rome were like theatres in which all the arts — sculpture, painting, music and liturgical drama — played major roles in divine worship. Here the designers succeeded in bringing the arts together in an all-embracing rhythmic unity that culminated in Andrea Pozzo's mural that covers the vaulting of the nave of S. Ignazio. In it the sky opens up, and by masterly foreshortening effects the saint is borne upward by a heavenly host, twisting and turning in ever-winding spirals to infinity. The indefinitely extended perspectives achieved the desired mystical illusion of endlessness. The interest awakened and sustained by such flights of the imagination broadened the popular base of the baroque. The style readily spread throughout the Counter-Reformation countries of the continent and was carried to the new world by the missionary orders and Spanish, Portuguese and French colonists. In Latin America the European style blended with the exuberant colour and character of the native arts to produce rich and distinctive variants of baroque architecture and sculpture.

Aristocratic Baroque. — The palace as the secular counterpart of the church assumed a vast complexity of design during the baroque period. The antecedents of this style are discernible in such conceptions as Michelangelo's proposal for the Farnese palace in Rome, which would have extended its axis with a bridge over the Tiber river to include some gardens on the other side, and in Palladio's Villa Rotonda near Vicenza, which crowns a hilltop and commands a view of the countryside in a manner that brings the architecture and surrounding landscape into a close relationship. The arts as an adjunct to the cult of majesty were first employed on a grand scale by Philip II of Spain in the construction of the Escorial (*q.v.*) near Madrid. This strange combination of royal palace, fortress, monastery, seminary, national archive and mausoleum, according to Philip's commission, was to express "nobility without arrogance, majesty without ostentation." The stark exterior malls enclose a complicated system of courts and cloisters culminating in a domed church, an adaptation of Michelangelo's original plan for St. Peter's. The extreme simplicity of Philip's apartments contrasts with the lavish ornamentation of the church and reception rooms to set up a true baroque tension. After Philip's time Spanish art was engulfed by the flood of the florid baroque called the churrigueresque.

In Paris the aristocratic baroque swells in a mounting crescendo from the Luxembourg palace, through Claude Perrault's large-scale new wing for the Louvre, to Jules Hardouin Mansart's vast, all-encompassing spatial composition at Versailles. In one direction a highway begins between the two wings of the palace and extends to the Champs Élysées and the Louvre in Paris. In the other the axis moves through the garden paths. past the grand canal that bisects the gardens, and onward toward the indefinite horizon. Mastering nature was the order of the day, and interior and exterior space were conceived as complementary to each other. Adding together the formal landscape architecture of André Le Nôtre, the sculptural elaborations of Pierre Puget and Antoine Coysevox, the interior designs of Charles Le Brun, the dramatic productions of Racine and Molière and the ballets and operas of Lully, the sum amounts to a complete image of the baroque universe with the sun king, Louis XIV, as its solar centre. This image of absolutism was incorporated into the architectural vocabulary, and every continental aristocrat was determined to build as pre-

tentious a version of Versailles as his means would allow.

Reformation and Bourgeois Baroque. — The Reformation movement and the rise of the middle class can be treated together for the sake of convenience, though the two are not identical since bourgeois patronage can be found in some degree anywhere. It happened to be most extensive and effective, however, in the Protestant countries. Since the more austere Protestant sects followed the Old Testament injunction against the making of graven images, the result was not propitious for the development of a thriving religious art. Since church commissions were no longer forthcoming, artists had to look to secular sources for support, and it became necessary to take into account the tastes of the middle-class many rather than the aristocratic few. Town halls. commercial buildings and domestic dwellings superseded churches and palaces; figurines, ceramic work and furniture superseded monumental statuary; small easel paintings, etchings and book illustrations superseded large murals and tapestries; the cult of the home superseded the cult of majesty; and realistic everyday scenes superseded recondite mythological compositions. The forms and subject matter of the Dutch school strikingly illustrate this shift in taste. In addition to genre scenes, landscapes and still-life studies. there are single and group portraits that tend to dignify the individual, his work and his domestic pursuits.

The drama of the baroque style was played against a backdrop of crucial social. religious, scientific and philosophical changes The great geographical explorations of the late 15th and early 16th centuries were followed by colonization that started the flow of gold and silver from the new world into the coffers of Spain and Portugal; the establishment of East and West India companies similarly enriched France, England and Holland. The traditional internationalism of the church and its secular arm, the Holy Roman empire, was challenged by the rise of powerful national monarchies. The Reformation and Counter-Reformation split European countries asunder on religious grounds; the Christian world view collided with the new secularism; and the position of the landed aristocracy was threatened by the wealth of new merchant princes. The Copernican theory of a sun-centred rather than an earth-centred universe produced a shock reaction as men began to realize that the earth was no longer static but moving freely through space, and that man was no longer the sole centre of creation. Descartes' definition of the world as "matter in motion," Pascal's studies of conic sections? cycloid curves and theories of probability. Leibniz' dynamic mathematics allowing for the concept of infinity, and Newton's speculations on terrestrial and celestial mechanics were among the many attempts to come to terms with the new cosmic outlook.

Baroque art in this light becomes the aesthetic reflection of a new conception of the world and the exuberant affirmation of a modern dynamic attitude toward life. *See* BAROQUE AND POST-BAROQUE ARCHITECTURE; see also Index references under "Baroque Art" in the Index volume. (WM. F.)

BAROTROPIC. The distribution of mass in a fluid is said to be barotropic when the surfaces of constant density coincide with the surfaces of constant pressure. This article deals with the term as applied to atmospheric hydrodynamics. In the atmosphere. a barotropic mass distribution implies that constant-pressure surfaces coincide with constant-temperature surfaces, provided the small effect of moisture on density is neglected.

Since the distance between constant-pressure surfaces depends almost entirely on density, constant-pressure surfaces in barotropic layers are essentially parallel.

Because the geostrophic wind (*q.v.*) is determined by the slope of constant pressure surfaces, the geostrophic wind is invariant with height in a barotropic atmosphere, and since the geostrophic wind is usually a good approximation to the real wind, the horizontal wind distribution at a single level characterizes the wind distribution of a barotropic atmosphere.

In numerical weather prediction *(see* WEATHER FORECASTING), the actual atmosphere is frequently represented by an imaginary barotropic atmosphere which has the same velocity distribution as the actual atmosphere near the 18,000 ft. level. Such a barotropic model has two advantages over more complicated models: observations are required at one level only, making possible large horizontal coverage. and the horizontal divergence is small, simplifying forecasting equations. As a result of the large horizontal coverage in barotropic models, there are fewer errors resulting from lateral boundary conditions than would be present in more complicated models. (H. A. A. P.)

BAROTSE, a people of south central Africa comprising about 25 tribes of ebout six cultural groups and numbering (1960) approximately 298,000. They inhabit the British protectorate of Barotseland (48,170 sq.mi.) in Northern Rhodesia, which is administered by a resident commissioner. Formerly the Barotse nation extended into other provinces or' Northern Rhodesia and into Angola and the Caprivi strip. The tribes were all called Barotse as subjects of the paramount chief of the dominant Barotse tribe. This tribe was originally known as the Aluyi, and it ruled the basin of the Zamhezi from the Kafue confluence to about 12° S. In 1838 the Aluyi were conquered by the Kololo, a horde of Basuto which had fled under the impact of wars in Zululand. In Kololo speech "Aluyi" became "Barotse." In 1864 the Aluyi defeated the Kololo; and "Barotse" has since become "Lozi" ("Malozi"). "Lozi" refers both to the dominant tribe and all its subjects. It is the name now used in most government and other publications. though "Barotse" survives on maps, in government ordinances and in common reference.

A Portuguese. Silva Porto, has left the first written record of Barotseland and David Livingstone visited it twice, during the Kololo regime. By 1954 missionaries, travelers. administrators, technical experts and an anthropologist had described both the re-established Malozi kingdom and modern conditions.

The **Lozi.**—The dominant tribe occupies the Zambezi course between 14° 35' S. and 16° 25' S. There the river has excavated a plain about 120 mi. by 25 to 35 mi. in the Kalahari sands which. form the centre of Barotseland. though this stretches into adjacent physiographic regions. The products of the flood plain itself differ from those of the surrounding woodlands. and there is considerable trade. As the Zambezi's tributaries also centre on the plain, it is the ecological heart of the region, and this may explain why its inhabitants are dominant.

Lozi legends date their origin, in association with the Lunda and neighbouring tribes, by descent from their god, Nyambe, 11 generations and 19 kings ago. This genealogy cannot be used to date their arrival in the plain, probably from the northwest. The most to be said is that the kingdom has been established and has had wide sway over neighbouring tribes for at least two centuries.

The Zamhezi floods every year and the vegetation alters with water conditions, while people and other creatures move with the flood's rise and fall. The people move between two sets of villages, in the plain and on the margin. They have made skilful use of varying water levels and of different soil and grass conditions to develop an elaborate economy of agriculture, animal husbandry and fishing. The necessity for co-operation to exploit these resources has produced intensive social cohesion among the Lozi, but they have always been short of labour and have constantly imported people from their subject tribes and serfs from raided foreigners. Possibly for this reason both they and their Kololo conquerors never dealt largely in the slave trade. These serfs had substantial rights in Lozi law, within a social hierarchy of aristocrats, commoners and serfs. Royalty and commoners intermarried, for the aristocrats could not raise their standards of living above their fellows. Tribute flowed to rulers from their subjects and was redistributed. Some rulers acted tyrannically, but in theory and practice they were "constitutional monarchs." The exercise of rule was divided between various rulers at the main and other capitals and in an elaborate system of councils at each capital. In modern administration there are five district councils and a national council which are self-perpetuating, with an advisory elected national body.

Missionaries. — In 1884 François Coillard of the Paris Evangelical mission established a station in the country, and it has had a potent influence, especially in education. By the mid-20th century many other sects were working among the Barotse.

British Suzerainty. — In 1890 and 1900 the Barotse paramount

chief Lewanika signed treaties with the British South Africa company by which he accepted British protection. He granted certain land and mineral concessions and abandoned certain powers. In 1906 serfs were liberated and in 1925 tribute abolished. In 1924 rule was transferred to the colonial office. British political influence steadily extended with the social and economic involvement of Barotse in southern Africa. Certain administrative difficulties arose under the treaty and some were resolved by Barotse agreement to the passing of the 1936 Barotse Native Authorities and Native Courts ordinances. Despite their acceptance of these: the Barotse retain a comparatively large measure of political independence. In other ways they are dependent on western economy. for money to buy European goods, etc. They sell cattle and fish and many of their men migrate for periods to work for industries. Revenue also comes in from the exploitation of Rhodesian teak forests by a sawmill at Livingstone. Attempts are being made to develop rice growing.

BARQUISIMETO is the flourishing capital of the Lara state, Venez. Pop. (1961) 196,557. One of the older cities of the country, it was founded in 1552 by Juan de Villegas and called Nueva Segovia after his native city. On March 26, 1812, the city was totally destroyed by an earthquake. The modern city lies on the Barquisimeto river 1jo mi. W.S.W. of Caracas and 101 mi. by rail southwest of the Caribbean port Tucacas. The railroad connecting Barquisimeto with Tucacas is an extension of what was probably the first railroad to be built in South America. Barquisimeto lies at an elevation of only 1,856 ft. and is swept by drying trade winds much of the year. The climate is healthful with a mean average temperature of 78° F.

The city, a commercial and industrial centre, is the hub of a network of highways extending in all directions, even southward into the Llanos, and it has been growing rapidly. It has modern housing, public buildings, a fine airport and an impressive hospital. Its rural district population averages from 25 to 60 persons per square mile. The surrounding land is utilized mainly for subsistence crops, but there are some coffee and cacao plantations that provide exports. (L. .

BARR, AMELIA EDITH (née HUDDLESTON) (1831–1919), Anglo-U.S. novelist, best known for *Jan Vedder's* Wife (1885), a story set in the Shetland Islands. She was born in Ulverston. Eng., on March 29, 1831. In 1850 she married Robert Barr and four years later went with him to the United States, where they settled in Texas. There her husband and three sons died of yellow fever. Three daughters remained to her, and in 1869 she took them to New York city, where she was a teacher for two years and then wrote for magazines and newspapers. Her first novel! *Romance and Reality* (1872), was followed by more than 60 others. Her work is characterized by historical settings, generally English, Scottish or colonial American.

See *All the Days of My Life,* an autobiography (1913).

BARR, ARCHIBALD (1855–1931), Scottish engineer, noted for his share in the invention of the modern range finder, was born at Paisley, Renfrewshire, on Nov. 18, 1855. Having graduated in engineering at Glasgow university, he became assistant to the professor of engineering there. In 1884 he became professor of engineering at the Yorkshire college, later Leeds university, where he met William Stroud, who was professor of physics. Having read an advertisement from the war office for an instrument to measure range, within a week the two of them had evolved all the essential features of the famous Barr and Stroud range finder *(see* RANGE FINDERS: *Short Base Range Finders).* This entirely novel instrument was an immediate success, more than fulfilling the demands of the services. The two men founded the firm manufacturing optical and mechanical precision instruments bearing their name. In 1889 Barr was recalled to Glasgow university to the regius chair of engineering. which he occupied for 24 years. He became a fellow of the Royal society in 1923 and died at Milngavie, near Glasgow, on Aug. 5, 1931.
(J. M. S.)

BARRA (Gaelic BARRAIDH, probably meaning "St. Barr's Island")! an island of the Outer Hebrides, Inverness-shire, Scot., lies about 5 mi. S.W. of South Uist. Pop. (1961) 1,467; area 34.9 sq.mi. including a number of smaller islands and islets. From Scurrival point, the tip of the northern peninsula. the island measures 8 mi. in length. At Eoligarry, on North bay, aircraft can land at low tide on the Traigh Mhor. or Great Cockle beach; there is an air service with Glasgow.

A road 12 mi. long runs around the island and there is a concrete pier on the south coast at Castlebay, the chief village. There are steamer connections with Mallaig and Oban.

The rock formation is gneiss and along the west coast are stretches of shell sand. Heaval, the highest hill, is 1.260 ft. above sea level and there are several small lochs. On Barra head, the highest point of Berneray island and the most southerly point of the Outer Hebrides chain, is a lighthouse on the 580 ft.-high rock. There are Danish duns (castlesj on the hills, stone circles and ruined chapels, and Kishmul castle, the stronghold of the Macneils, one of the oldest Highland clans, stands on a rock in Castlebay. Hebridean folk traditions have survived with storytellers and singers and pure Gaelic is still spoken; 90% of the people are Roman Catholic. In the 20th century the decline of the herring fishery and the lack of industry have encouraged immigration to Canada and the Scottish mainland. By 1961 almost the only paid employment was in work on the roads or in the small cockleshell grit industry. Barra has a junior secondary school and six primary schools.

See J. L. Campbell (ed.), *The Book of Barra* (1936); D. Buchanan, *Reflections of the Isle of Barra* (1942).

BARRACKS. In the United States and some other countries, barracks are the buildings used for housing enlisted personnel of the armed forces, as distinct from quarters assigned to officers, married noncommissioned officers, or nurses. In Britain, and some other European countries, the word "barracks" is often a general term for all buildings that form part of the large military camps such as Aldershot (England). The term is normally applied to permanent peacetime buildings; temporary wartime quarters for troops have the term "camp" applied to them also. Some military posts in the United States are known as barracks, viz., Jefferson Barracks (Mo.) and Plattsburg Barracks (N.Y.).

Barrack Construction History. — Until about 1800, troops in central and western Europe were billeted or quartered in the homes of citizens, or sometimes in alehouses, inns, or unoccupied buildings. This system was a hardship on the people and was not popular. It was, for example, one of the abuses attributed to King George III by the Declaration of Independence. It was also subversive of discipline and exposed the troops to many temptations of both a moral and a political nature.

Though barracks had been built earlier in several parts of Ireland, it was not until 1792 that George III obtained parliamentary approval for the construction of permanent barracks in England. As the English barracks were used mainly in connection with the occupancy of fortifications, their construction was charged to the royal engineers but, in 1796, this work was transferred to a civil department of the government. In 1816, a civilian comptroller was appointed to supervise the construction and maintenance of military barracks, hospitals and storehouses on sites other than those occupied by fortifications. Bedsteads and hammocks were provided the men but, in some instances, bunks extending from wall to wall and occupied by 'as many as 30 or more men were found. Gradually kitchens were authorized where all food was prepared either by the soldiers in person or by certain ones selected for this purpose.

The civil department of the government relinquished control of military barracks in 1818 and their supervision was again assumed by the corps of royal engineers. In 1826 the School of Military Engineering, commanded by Col. Charles Pasley, included in its curriculum a course in practical architecture. During that period, Wellington directed the replacement of the wooden bedsteads, berths and bunks by double-decked, two-man iron beds; provision also was made for kitchens (known then as cookhouses) and for certain sanitary facilities known as ablution houses. Separate messes were later established for noncommissioned officers and provisions were made for athletics and other means of diversion for the soldiers. During the latter half of the 19th century, the British war office conducted an exhaustive inspection and study of quartering facilities, as a result of which many regulations were promulgated as to types of construction, quartering, cooking and sanitary rules, and provisions for the quartering of married men and their families. In 1904, a governmental civil department was again formed under a director, known as "director of barrack construction," but this agency functioned only until 1918, when it was abolished and the control of quartering and hospitals again reverted to the corps of royal engineers, where it has since rested.

Most of the barracks in Britain, including big military camps such as Aldershot, came into existence after the middle of the 19th century and owed their locations to the suitability of the surrounding country for training purposes. They were solidly built and proved reasonably suitable for modernization. Most of them were in pleasant surroundings and were near a large town where recreational facilities existed. The older British barracks consisted of two or three stories but many of those constructed after 1914 were on the bungalow principle. In general terms, the modernizing of British barracks took place in two stages. In the years before World War I, married quarters, canteens. and electric lights were added, and improvements were made in the cooking and feeding arrangements and in sanitation. The second stage began between World Wars I and 11 and continued into the 1950s. Canteens for all types of drink and food, and recreational areas were added to all barracks, as well as additional washing facilities and central heating. Stables for horses gave way to garages for motor transport. In many stations, good houses or flats for married officers were built.

Before World War I the history of barrack construction in the United States generally followed the practices of the British army. Troops were housed in tents, huts, and light frame structures or in more permanent barracks made of tile, cement block, brick, or stone. All types, with the exception of the hut, were found in various parts of the country. The type of barrack construction chosen for a particular site depended upon climatic conditions, availability of materials, and the degree of permanency of the garrison or camp.

In the United States, Britain, and Europe, few barracks were built during the years that followed World War I. In all countries, uncertainties as to the strength and deployment of forces led to modernizing existing barracks rather than building new ones. The most modern barracks in Europe in the 1930s were those built in Germany after the Third Reich began to rearm.

The outbreak of World War II set off a vast program of barracks construction and modernization, particularly in the United States. Huge training camps were established and provided uith sufficient barracks to house the millions of trainees brought into service. The typical U.S. army barrack was a frame 2-story building with electric lights, sanitary facilities, and perhaps a small recreational room. The additional accommodations required for Britain's expanded army were generally provided in the form of temporary huts, most of which were dismantled soon after the war ended.

After World War II. barracks of permanent type construction were erected at permanent military installations to house the authorized peacetime complement of enlisted personnel. These structures were three stories high and, with normal maintenance and upkeep, had a useful life expectancy of 25 years. Exterior materials were brick, concrete masonry units, or concrete. Barracks of this type were designed to accommodate one or two companies of enlisted men. Two-company barracks provided duplicate facilities for each company. Squad rooms of 35-man capacity provided sleeping quarters for enlisted men in the lower grades. A large "day room" afforded recreational and lounging facilities for these men. Noncommissioned officers slept in private or semi-private rooms. Other facilities found in these barracks included company administration and storage areas, kitchens and mess halls, toilets and showers. and laundry rooms equipped with washers and dryers. Each barracks was heated by hot water convectors or radiators supplied by individual or central boiler plants. The designs of the various buildings provided numerous windows to insure maximum quantities of fresh air and natural light. Where climatic conditions warranted, forced mechanical ventilation or evaporative cooling provided additional comfort during hot weather.

In 1957, a new concept of U.S. army troop housing and administration was developed to preserve unit integrity at the battalion (5-company) level rather than at the company level. This concept led to the development of a new 2-company barracks design which differed from previous designs in that company administration, storage, and messing functions were divorced from the barracks and placed in separate buildings. The new barracks afforded greater privacy for the lower grades of enlisted men by providing 8-man squad rooms instead of the 35-man rooms. Each squad room was divided into two-bed cubicles by the use of closets and low partitions. Accommodations for enlisted women were the same as those provided for enlisted men of the same grade except for the addition of a reception room and minor cooking facilities.

Bachelor Officers and Nurses.—Bachelor officers of the U.S. army were quartered in single or multistory apartment-type buildings known as bachelor officers' quarters (B.O.Q.). These were either of temporary or permanent-type construction. Accommodations in temporary structures were necessarily more austere than those found in permanent-type B.O.Q.'s. Before World War II, each officer was assigned a suite of rooms consisting of a living room, a bedroom, and a bath. In some instances, structures included central dining and kitchen facilities for the total complement of officers housed. A central lounge was provided for recreational and entertainment purposes. During and after World War II. cost and area limitations resulted in reduced accommodations for each officer. Designs of some B.O.Q.'s provided a private bedroom and a semi-private bath for each occupant, plus a central lounge room. Quarters for nurses and women officers in other branches of the armed forces provided accommodations similar to those found in B.O Q.'s except for the addition of limited cooking facilities.

BARRACUDA, the common name for many pikelike predatory fishes of the family Sphyraenidae. Typically, a barracuda has long, pointed jaws filled with teeth of razorlike sharpness and ranges in length from three to ten feet. Of about 20 species inhabiting the warmer seas, the Australian giant pike and the great barracuda (Sphyraena barracuda) (also called picuda, or becuna) are thought to represent the largest and most vicious types, while the smaller, slender barracuda off the coast of southern California has the highest food value. Though a fish of different habits, the barracuda is thought by some to be more dangerous than a shark. Many swimming tragedies attributed in the past to sharks have been since credited to the barracuda. Large barracudas are, for the most oart, solitarv: they lurk about tropical reefs, as the pike

BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

GREAT BARRACUDA (SPHYRAENA BARRACUDA)

does about the edges of pond or stream, and are often seen stationary in the water, or gliding slowly about, alert and watchful.

Barracudas approach fearlessly anything that moves in the nater, as though from curiosity. Being capable of high speed, at least for short distances. they rush out and seize smaller fishes nhich chance within their range. They are also said at times to swim on the outskirts of schools of small fishes in shallow water, herding them and preventing their escape until ready to feed.

Fish is their normal food, and the risk to bathers from their attack. as from that by sharks, is doubtless exaggerated in the popular mind, but there unquestionably is a risk though it may be slight. Because it is not easily exhausted and springs about in the most reckless fashion, the barracuda makes an excellent big-game fish. The very trait that makes it dangerous to bathers—that of pursuing any moving object—renders it easy to hook.

(J. T. N.; X.)

BARRAGE, a term once used by engineers for a dam constructed across a river to check the flow and so deepen the current or even create a lake. In a military sense the term is used for the continuous line of artillery or rocket fire intended to hold up the advance of an enemy or protect the advance of the combatant's own troops.

BARRANDE, JOACHIM (1799–1883), French geologist and paleontologist who specialized in the study of the Lower Paleozoic era, mas born at Saugues, Haute-Loire, on Aug. 11, 1799, and educated in the École Polytechnique at Paris. He was tutor to the grandson of Charles X, and when the king abdicated in 1830 Barrande accompanied the royal exiles to Prague.

The first volume of his important work, *Système silurien du centre de la Bohême* (dealing with trilobites), appeared in 1852; and from that date until 1881 he issued 21 volumes of text and plates. Two other volumes were issued after his death, in 1887 and 1894.

Barrande died at Frohsdorf, near Vienna, on Oct. 5, 1883.

BARRANQUILLA, a Caribbean port city of Colombia, South America, and capital of the department of Atlántico. It lies 450 mi. N. of Bogota on the left bank of the Magdalena river about 10 mi. above its mouth. Population (1961 est.) 452,140. Founded in 1629, it long remained in obscurity while the coastal ports of Cartagena and Santa Marta flourished. Barranquilla's access to the sea was hampered by sand bars that partially blocked the Magdalena's mouth, but connections with sea trade developed in mid-19th century via satellite ports on nearby Sabanilla bay. For years a railroad ran to that bay, but the clearing of the river mouth in the 1930s made transshipment to the bay unnecessary. It was the steamboat traffic on the river that especially caused the rise of Barranquilla. Barranquilla was the uncontested leader of Colombia's ports from the late 19th century until after World War II. Afterward a relative decline in Magdalena traffic and the growth of road-borne commerce pushed Buenaventura on the Pacific coast into the leading position, Barranquilla nevertheless continued to handle much coffee and petroleum from the interior and cotton from the surrounding region. An important industrial centre, its products include textiles, beverages, cigarettes, cement, fats and oils, flour, rice and plastics. It has modern transportation, telephone, water and lighting services. Its residential areas range from mud huts to the modern El Prado suburb, an early and attractive experiment in planning which was developed by Karl C. Parrish, a U.S. engineer. The city is linked by road with Puerto Colombia on Sabanilla bay and with areas to the south via Cartagena. Daily air service is maintained to Bogota and other important cities. (T. E. N.)

BARRAS, PAUL FRANÇOIS JEAN NICOLAS, VICOMTE DE (1755–1829), the only original member of the French executive Directory to remain in office (1795–99) until Napoleon's *coup d'e'tat* of 18 Brumaire, was born on June 30, 1755, of an ancient noble family of Provence. Before 1789 Barras gained military experience against the English in India. Elected deputy to the Convention for the *département* of Var (1791), he voted for the death sentence in the trial of Louis XVI. While on a mission to southeastern France: he took a leading part in repressing counterrevolutionaries after the recapture of Toulon from the British in Dec. 1793. His subsequent political career was significant chiefly because on three critical occasions he was invested with a virtual military dictatorship in Paris and because he actively contributed to the rise of Bonaparte. First, on July 27, 1794, he was nominated by the Convention as commanding officer of the national guard of Paris in the place of François Hanriot; in this capacity he arrested Robespierre at the Hôtel de Ville. Next, he was again appointed military commander during the crisis of Oct. 1795 when, with Bonaparte as his chief adjutant, he suppressed a royalist rising in the capital. Finally, having been elected a member of the Directory on Nov. 1, 1795. he was vested with dictatorial powers for the third time on Sept. 4, 1797, and for two years shared power with J. F. Reubell and L. M. de la Revellière-Lépeaux as a member of the ruling triumvirate of directors. Barras was partly responsible for Bonaparte's marriage with Josephine de Beauharnais—one of Barras' former mistresses—and for his nomination to the Italian command in 1796. His special department was the police, where his experience as a member of the Committee of General Security stood him in good stead. After the *coup d'état* of 18 Brumaire year VIII (Nov. 9, 1799) Barras was quickly discarded by Bonaparte, who mistrusted him. Removed from Paris, he was even exiled to Rome in 1813. Though he had voted for Louis XVI's death, he was able to remain in France under the Restoration, since he had not supported Napoleon during the Hundred Days. He remained faithful to his republican ideals, however, and in 1819 circulated a letter to all the newspapers entitled *Le Général Barras d ses concitoyens.* He died in Paris on Jan. 29, 1829. His *Mémoires* are ed. by G. Duruy, 4 vol. (1895).

BARRELL, JOSEPH (1869–1919), U.S. geologist who had few equals as a teacher of graduate students, was born at New Providence, N.J., Dec. 15, 1869. He was educated at Lehigh university and at Yale. From 1893 to 1897 and from 1900 to 1903 he taught at Lehigh and also practised mining engineering; from 1903 until his death he taught at Yale, for 11 years as professor of structural geology. His effectiveness as a teacher stemmed from his breadth of training, his thoroughness and his quantitative approach to problems. A great analyst, he used multiple working hypotheses. His career, cut short in its prime, reflected increasing interest in the broad, philosophical aspects of geology. He is best known for papers dealing with the differentiation of sedimentary rocks; an exhaustive treatise on isostasy, "Strength of the Earth's Crust" in the *Journal of Geology,* vol. 22 and 23 (1914–15); and the classic study, "Rhythms and the Measurement of Geologic Time" in the *Bulletin of the Geological Society of America,* vol. 28, pp. 745–904 (1917). He died at New Haven, Conn., on May 4, 1919. (F. M. FL.)

BARREL ORGAN. The term barrel organ is popularly understood to mean an instrument of street music in which a simple pianoforte action is worked by a pinned barrel turned by a handle. This is more correctly a "barrel piano."

In a true barrel organ, the barrel causes one or more ranks of organ pipes to play the tunes, the handle simultaneously actuating the bellows. The idea of the pinned barrel was known in the 16th century, generally used in conjunction with a clock mechanism. The handle-operated organ reached its greatest popularity during the late 18th and early 19th centuries, when such instruments were in regular demand and ranged from miniature bird organs used to encourage song birds. to large versions that played the psalms in village churches. Some of the latter remained in use until well into the 20th century.

Intermediate in size and reaching a peak of popularity about 1830 were the cabinet-sized domestic barrel organs, commonly supplied with one barrel for religious music and two for entertainment. Each wooden barrel is pinned with brass staples of varying length according to the lengths of the notes to be sounded. As the handle is turned, the staples raise levers that admit wind to the pipes as the melody and its harmony require. The levers are opposite their respective pipes and therefore well separated, leaving

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART, CROSBY BROWN COLLECTION OF MUSICAL INSTRUMENTS. 1889

ITALIAN BARREL ORGAN; EARLY 19TH CENTURY

space for ten or more tunes to be set on a single barrel; the staples serving, for instance, the note G in the second tune are placed just to the left of those for G in the first tune, and so on, the tune being selected by shifting the barrel in its wooden carrier bodily sideways and holding it in correct alignment by a catch on the outside. A common provision of pipes was one or two stopped wooden ranks and an open metal rank at the octave. Domestic models often included a drum and cymbal, actuated by additional pins.

Modern musicians find barrel organs of particular interest because they preserve evidence of old styles of musical execution and ornamentation, and Arnold Dolmetsch studied a French treatise on barrel organ making and published the results of his researches in 1915 in *The Interpretation of the Music of the XVII and XVIII Centuries*, new ed. (1949). (A. C. BA.)

BARREN GROUNDS (BARREN LANDS), a subarctic region of northern mainland Canada stretching westward from Hudson bay to the Great Slave and Great Bear lakes; its farthest extension southward is to lat. 59° N. along the Hudson bay coastal plain; it reaches northward to the Arctic ocean. The surface is a low, rolling plateau sloping gradually to the east and northeast from about 1,000 ft. The area forms part of the Canadian Shield and is underlain by Pre-Cambrian granite and granite-gneiss; the whole landscape was modified by the continental ice sheet which in its retreat covered the bedrock with glacial debris.

The plateau is crossed by many shallow rivers that wind through myriads of lakes often separated by streams in which rapids and falls occur. The main rivers draining northward are the Coppermine and the Back (*qq.v.*). The Dubawnt (*q.v.*), Kazan and Thelon drain the central area eastward to Hudson bay.

Although it lies north of the tree line, the region is not completely barren. Isolated clumps of stunted spruce occur in sheltered places. and thickets of willow and alder grow along some of the rivers. There is no continuous vegetation cover but grasses, sedges and herbaceous plants grow in the damper stretches of the plain. Rock surfaces are dominated by mosses and lichens. The ground is everywhere permanently frozen and only the top few inches melt during the summer months. The climate is characterized by long, rigorous winters, with temperatures averaging −25° F. in January, and short summers with an average July temperature of 50° F. Snowfall is moderate to light (30 to 40 in.) and about 5 in. of rain falls in the summer months. In July the surface is carpeted with an abundant vegetation enlivened by the bloom of many flowers. Warm weather, almost continuous hours of daylight and soil that is continually moist from the gradual thawing of the frozen ground promote rapid growth.

The region is the natural habitat of the barren-ground caribou. The other more numerous mammals are the arctic fox, musk ox, timber wolf, wolverine, muskrat and grizzly bear. The lakes and rivers abound in fish; the main species are lake trout, whitefish, northern pike and lake herring. The only inhabitants are the few Eskimo who live along the coasts and personnel at the few trading posts and scientific-research stations.

Samuel Hearne (*q.v.*) was the first to explore the Barren Grounds; in 1769–72 he traveled overland from Fort Prince of Wales (now Churchill, Man.) to the Coppermine river and Coronation gulf. During the 19th century the search for the ill-fated Franklin expedition led to several explorations in the north of the region. Systematic exploration and mapping began in 1893 when J. B. Tyrrell surveyed the Dubawnt and Kazan rivers, followed by Canadian government and mining company surveys. (B. V. G.)

BARRÈS, (AUGUSTE) MAURICE (1862–1923), French writer and politician, whose individualism and fervent nationalism greatly influenced his generation, was born Aug. 19, 1862, at Charmes-sur-Moselle (Vosges), in Lorraine. Barres always considered himself a Lorrainer, charged with the interpretation and the vindication of his own people. He was educated at the Collkge de Malgrange and the Nancy *lycée* and in 1882 went to Paris and studied law. He made his literary debut with some ironical pamphlets which successfully displayed his intellectual *dandysme*. Ernest Renan paid him the compliment of being annoyed by his *Huit jours chez M. Renan* (1888).

He enhanced his reputation by the three volumes of *Le Culte du moi: Sous l'oeil des barbares* (1888); *Un Homme libre* (1889); and *Le Jardin de Bérénice* (1891). These novels provoked much ridicule in the press, but the humour, charm and *préciosité* with which he developed his theme of the cultivation of the ego and thus a harmonious inner life was hailed with delight by the younger generation. Many of the ideas which permeate his later works may be found in *Un Homme libre*. The section dealing with Lorraine was described by Ernest Lavisse as an admirable piece of historical psychology. The third novel, *Le Jardin de Bkrknice*, showed great delicacy of feeling and subtlety of style and was inspired by the author's electoral campaign at Nancy as Boulangist candidate. He was only 27 when he was elected deputy, and from that time he led a life divided between literature and politics.

Intelligent, ardent, ambitious, modeling himself first on Benjamin Constant and then on Disraeli, Barrks, during the period between the end of Boulangism and the Dreyfus case, hesitated as to the wisest course to pursue. He stood for one of the Paris divisions as a Socialist patriot and was defeated (1896). He went through an anarchistic period, as is shown in the novel *L'Ennemi des lois* (1893). He traveled in Italy and in Spain. For about six months he edited a paper called *La Cocarde*. Charles Maurras (*q.v.*) was his colleague in this venture and together they roughly blocked out the future doctrines of the French nationalist party.

In 1897 he began the publication of the important trilogy, *Le Roman de l'énergie nationale*. The generation and milieu described are his own. His characters in *Les Dkracinks* (1897) are types rather than living beings, but as a delineation of a period it may be ranked with *Le Rouge et le noir* and *L'Éducation sentimentale*. The second volume, *L'Appel au soldat* (1900), contains a vivid account of the Boulangist movement, and the third, *Leurs Figures* (1903), a picture of parliamentary life at the time of the Panama scandal (1889; *see* FRANCE: *History: The Third Republic, to 1914)*.

The Dreyfus affair (1894–1906; *see* DREYFUS, ALFRED), in which he took an active interest, made him a vehement nationalist. He assumed the position of spokesman for Lorraine and undertook the series entitled *Les Bastions de l'Est*. *Au service de l'Allemagne* (1905) describes a young Alsatian's year of military service in the German army and *Colette Baudoche* (1909; Eng. trans. 1918) tells the story of a young girl from Metz. World War I brought these books a rather artificial success as propaganda. Meanwhile, Barrbs was writing admirable descriptions of travel: in France—*Les Amitiés françaises* (1903); in Greece—Le *Voyage de Sparte* (1906); in Spain—Greco *ou le secret de Tolède* (1911). They contain some of his best work and some of the finest prose in the language. In 1907 he was elected to the Académie Française.

World War I gave Barrbs the chance of expressing his patriotism to the full and he redoubled his activities. He resumed his seat in parliament and did much for the maintenance of morale by writing an article for the *Écho de Paris* every day for four years. These articles, collected in 14 volumes under the title *Chronique de la Grande Guerre* (1920–24), though of historical interest and often showing high literary quality, did not retain their original popularity.

After the war Barrbs carried on his role as defender of the French eastern front by a mediocre work, *Le Gknie du Rhin* (1921). He returned to pure literature with his novel *Un Jardin sur l'Oronte* (1922), which derives its inspiration from his earlier travels in the east. These he described in *Une Enquête aux pays du Levant*, which appeared in 1923 on the day, Dec. 4, of the author's sudden death at Neuilly-sur-Seine, near Paris. He left much unpublished work. The materials for the memoirs on which he was engaged were published by his son under the title of *Mes Cahiers*, 14 vol.

(1929–57), and a further posthumous collection, *N'importe où hors du monde,* appeared in 1959.

He was, when he died, the most significant figure among contemporary French men of letters. even more so than Anatole France. The influence of his political thought had worn itself out, but his literary authority still swayed the younger generation. He had the power to charm. The prejudices, the narrowness and the egotism. with which he had been reproached! gradually disappeared. The qualities of sympathy and reverence always commanded his esteem and his epic of the countryside, *La Colline inspirée* (1913), reveals the springs of his religious life, which was to find its most poetical expression in the essays of *Le Mystère en pleine lumière* (1926). This latter book, which contains a dialogue with the sibyl of Auxerre and meditations on Joan of Arc. on Claude Gellée and on Eugène Delacroix, is generally considered as his spiritual testament. Like Chateaubriand he created but one living figure. himself, but into that figure he breathed the soul of contemporary France, and thereby captured the heart of his generation.

BARRETT, LAWRENCE (1838–1891), U.S. actor, noted for his Shakespearean roles. was born in Paterson. N.J., April 4, 1838. His family name was Brannigan. He made his first stage appearance in Detroit. Mich., as Murad in *The French Spy* in 1853, and in 1857 first appeared in New York as Sir Thomas Clifford in *The Hunchback.* He served as a captain in the Civil War. From 1867 to 1870, with John McCullough, he managed the California theatre, San Francisco. Among his many parts may be mentioned Hamlet. Lear, Macbeth, Shylock. Richard III, Wolsey, Benedick. David Garrick, Hernani. Alfred Evelyn. Lanciotto in George Henry Boker's (1823–90) *Francesca da Rimini* and Harebell in *The Man o' Airlie.* He played Othello to Edwin Booth's Iago. and Cassius (in which role he won wide acclaim) to Booth's Brutus. He acted in London in 1867. 1881. 1883 and 1884. His Richelieu in Bulwer-Lytton's drama was considered one of his best parts. He wrote a life of Edwin Forrest in the *American Actors Series* (1881), and a sketch of Booth in *Edwin Booth and His Contemporaries* (1886).

He died March zo. 1891.

BARRIE, SIR JAMES MATTHEW (1860–1937), Scottish dramatist and novelist. who added a new character to the mythology of the English-speaking world with his creation of Peter Pan. the boy who refused to grow up. brought the supernatural to the stage at a time when the theatre was dominated by the concept of social criticism and gave impetus to the Scottish sentimental tradition in fiction. exemplified by the "Kailyard school" (*see* SCOTTISH LITERATURE).

THE MUSTOGRAPH AGEYCY

STATUE OF PETER PAN IN KENSINGTON GARDENS, LONDON

Born in Kirriemuir. Angus, on May 9. 1860, the son of a weaver, Barrie studied at Edinburgh university and spent two years on the *Nottingham Journal* before settling in London as a free lance in 1885 His first successful hook was *Auld Licht Idylls* (1888). iketches of iife in Kirriemuir ("Thrums") in which he made Scottish manner- appear quaint by broadening comedy into farce and drenching tragedy in tears. With *The Lzttle Minister* (1891). a novel in the same style, he became a best seller. Barrie was always a master of situation and dialogue, but the mixture of clowning and sentimentality in his early prose is overrich for modern taste, and of his novels the late *Farewell, Miss Julie Logan* (1931), a superbly macabre tale, seems most likely to continue to satisfy critical opinion.

Barrie began writing for the stage in 1891, and after the successful dramatization of *The Little Minister* (1897) most of his work was for the theatre. Some of his dramatic triumphs were made with ephemeral whimsicalities, but at least four of his full-length plays—*The Admirable Crichton, Peter Pan, Dear Brutus* and *Mary* Rose—and a number of one-act pieces were of the highest quality.

Barrie's work brought him fame. fortune and honours. He received the Order of Merit in 1922. became president of the Society of Authors in 1928 and chancellor of Edinburgh university in 1930. He died in London on June 19. 1937.

To some extent Barrie's success depended on his appeal to the common human unwillingness to face the inevitability of change and growth. In him this amounted to an emotional failure: like Peter Pan. he remained a boy. An entry in his notebook for 1907 reads—"Finest *Dream in the World* . . . it is time before I knew anything of sorrow pain or death. Everyone I have loved is still alive."

Barrie never fully recovered from the shock he received. when six years old. from a brother's death: the horror of the experience was increased by his realization of its grievous effect on his mother. who dominated his childhood and retained that dominance thereafter—he wished to recapture the happy years before his mother was stricken. His "Thrums" stories were written from her early memories of Kirriemuir, and he made her the heroine (under her maiden name) of *Margaret Ogilvy* (1896). which describes her both as the mother of her family of ten. and as a "little mother" to her motherless brothers and sisters during her girlhood. His autobiographical no\el. *Sentimental Tommy* (1896), on a boy who weaves a cloak of romantic fiction between himself and reality. again has a "Thrums" setting and a "little mother" heroine.

Barrie's marriage in 1894 to the actress Mary Ansell was childless. In 1897 he found another "little mother" in young Mrs. Sylvia Llewellyn Davies, and to her sons. through whom he began to live again the experience of childhood. he told his first Peter Pan stories, some of which were published in *The Little White Bird* (1902). The play *Peter Pan,* with its theme of heroic boyhood triumphant over the seedy, middle-aged schemer: Captain Hook. followed in 1904 and was revived thereafter in London during every Christmas season except 1940, a unique dramatic record.

But Barrie's idyl of boyhood re-experienced was followed by tragedy. His marriage ended in divorce in April 1910; Sylvia Davies, then a widow. died four months later; two of her sons. to whom Barrie acted as guardian, were killed. In *Mary Rose* (1920) he wrote a tragedy antithetical to *Peter Pan,* expressing the misery which a girl unable to grow up creates in her own life and in the lives of those around her; and *The Boy David* (1936). while glorying in the brave innocence of the young hero is deeply sympathetic to the harassed manhood of King Saul. who nas once such a boy as David.

During the period when he was idealizing childhood Barrie took a disenchanted view of adult life. Sometimes his disenchantment was expressed humorously. as in *The Adnzirable Crichton* (1903), on the butler who becomes king of a desert island, with his former employers as serfs; sometimes satirically, as in *The Twelve-Pozind Look* (1910), on the typist as the symbol of female emancipation; sometimes tragically, as in *The Will* (1913), on the defeat of love by the lust for wealth, and in *Dear Brutus* (1917), where nine men and women whose lives have come to grief are given a magical "second chance." only to wreck themselves again on the reefs of their own temperaments. The latter. with its subtle blend of nit, pathos, cruelty, pity, fantasy and realism, is the finest of Barrie's plays.

Barrie's letters, edited by Viola Meynell, were published in 1942.

BARRIER REEF, the most remarkable coral formation in the world. lies off the northeast coast of Australia. It extends for about 1,250 mi., from Torres strait to beyond the Tropic of Capricorn off Rockhampton, Queensland, including the Capricorn and Bunker groups as extensions. "Reef" in the singular is, of course, a misnomer, for the barrier is made up of an enormous number of separate reefs. In the north they are more or less continuous, except for deep, narrow gaps. Farther south they are arranged more or less in echelon. The main outer barrier follows fairly closely the edge of the continental shelf—the 100-fathom line—and is only about 20 or 30 mi. from the coast as far as Cairns but about 200 mi. from it in the extreme south; there the continental slope is much gentler than in the north. A number of outlying reefs, Osprey, Flinders, Saumarez, etc., not part of the barrier, rise from depths of 400 to 1,000 fathoms. Within the barrier the long lagoon, generally less than 200 ft. deep, is broken by numerous small and large coral patches, which in the south (Swain reefs) may be many miles broad. The sand or shingle-and-mangrove cays on these patches display a horseshoe shape, convex to the southeast, as a result of spit-building activity by waves from that direction—the direction of prevalent winds. North of Cairns, especially, island reefs or "low wooded isles" show a definite pattern: low shingle ramparts, scarped on the inner side, to windward; a moat sloping up to a flat of dead reef or coral shingle; a sand flat, often colonized by mangrove and submerged at high tide; a leeward sand-cay, normally dry and sometimes partly indurated.

Bores on Michaelmas cay (16° 36' S.) and Heron Island in the Capricorn group penetrated more than 425 ft. of coral and coral detritus to reach incoherent marine sands, either Recent or Pleistocene, to a total depth of 600 ft. on Michaelmas cay and 732 ft on Heron Island; bedrock was not reached in either bore. However, most of the islands within the barrier are "high" or "continental" islands, solid rock and definitely outliers of the mainland. On the whole the evidence summarized by J. A. Steers suggests that the main lineaments of this very complex system are in large part controlled by coastal down-warping and faulting, roughly parallel or at acute angles to coastal trends. Submergence was not continuous and was accompanied by sedimentation in the lagoon. It seems likely that reef-building began in the Pleistocene with, doubtless. interruptions due to changes in sea level; in this case the greater solidity and continuity of the northern outer barrier might be due to more continuous growth caused by higher temperatures, relative to the south, during glacial lowering of sea level.

The scenic beauty of a high and deeply-indented coast and high offshore islands, especially in the southern half, and the fantastic variety of colourful marine life—now far more accessible than before because of the development of "skin-diving," spearfishing, and similar aquatic sports—have naturally led to a considerable tourist interest, especially at Hayman and other islands of the Whitsunday group between Townsville and Mackay.

BIBLIOGRAPHY.—The reefs have naturally attracted a considerable literature. On the more scientific side, *see* the Great Barrier Reef Expedition *Reports* (1925–42), a joint product of British, Australian and New Zealand scientists; T. W. E. David, *The Geology of the Commonwealth of Australia*, ed. by W. R. Browne, ch. 13 (1950); J. A. Steers, *The Unstable Earth, 3rd* ed., ch. 6 (1942), valuable for a general review of the coral reef problem. *See* also T. C. Roughly, *Wonders of the Great Barrier Reef* (1936); F. Reid, *The Romance of the Great Barrier Reef* (1954). (O. H. K. S.)

BARRIER TREATY, the name given to each of three treaties granting to the United Provinces of the Netherlands the right to garrison and govern certain towns along the southern borders of the Spanish (subsequently the Austrian) Netherlands. The treaty of Rijswijk (1697) had allowed the Dutch government to garrison some of the main fortresses in the Spanish Netherlands, thus forming a defensive barrier against France, but these fortresses had been overrun by France in 1701 in the War of the Spanish Succession. By the first Barrier treaty (Oct. 29, 1709), Great Britain agreed to support a restoration of the barrier and a considerable extension of it into French-occupied territory, while the states-general of the United Provinces undertook to guarantee the succession of the house of Hanover in Great Britain. This treaty. however, was eventually set aside by Great Britain, and the second Barrier treaty (Jan. 29, 1713), which was confirmed by the treaties of Utrecht and Rastatt at the end of the war, did not concede so much to the United Provinces. The details of the barrier were further modified by mutual agreement in the third Barrier treaty (Nov. 15, 1715) signed by Great Britain, the United Provinces and the Holy Roman emperor Charles VI, then the ruler of the Southern Netherlands. The Dutch were particularly disappointed at the overthrow of the first treaty because it had contained the provision that any commercial advantages secured by Great Britain from Spain should equally apply to the Dutch. This concession had been secured in return for a promise by the Dutch to continue the war against France until all Spain should have been won from the Bourbons; and when it proved impossible to carry out this last policy, the new British ministry of 1710 did not feel bound by the commercial concessions made by its predecessors.

See R. Geikie and I. A. Montgomery, *The Dutch Barrier, 1705–1719* (1930). (I. F. B.)

BARRINGTON, GEORGE (1755–1804), Irish adventurer notorious for his activities as a pickpocket in England in the 1770s and 1780s, and allegedly the author of several histories of Australia, where he later made good, was born near Dublin in 1755, probably the son of a silversmith called Waldron. Educated in Dublin, he joined a troupe of actors, taking the name George Barrington. They introduced him to the pickpocket's art and eventually he found his way to London (1773). His education and personality is illustrated by his entry into London society as a gentleman of wit and breeding. Exploiting this advantage, he operated at race meetings, theatres and even royal levees, and although he was arrested several times, his eloquence earned him exceptionally light sentences, none of which was fully served. When he was tried for the eighth time in Sept. 1790 he was sentenced to seven years' transportation. On his arrival in Australia he soon gained a position of authority; he was given a conditional pardon in Nov. 1792, and was made high constable at Parramatta, New South Wales, in Sept. 1796, with a full pardon, later becoming superintendent of convicts. Genuinely reformed, he earned praise from successive governors. He was retired on half pay because of ill-health in 1800, and soon after became insane. He died at Parramatta on Dec. 27, 1804.

Several legends grew up around Barrington, mainly because publishers used his name as an advertisement for several works, including *A Voyage to New South Wales* (1795) and *The History of New South Wales* (1802). There is no evidence that Barrington had any connection with them, nor did he write the "Barrington prologue" for which he was especially famous, with its well-known lines:

> True patriots all; for, be it understood,
> We left our country for our country's good.

This was written by a Leicester gentleman, Henry Carter (d. 1806), published in the *Annual Register* of 1801 and included in one of the works ascribed to Barrington.

See J. A. Ferguson, *Bibliography of Australia*, vol. i, pp. 13–17 (1941).

BARRINGTON, JOHN SHUTE BARRINGTON, 1ST VISCOUNT (1678–1734), English lawyer and theologian, who was a firm supporter of the extension of civil rights of Protestant dissenters, was the son of Benjamin Shute of Theobalds, Hertfordshire, and took the name Barrington on inheriting an estate in 1710. Having been sent by Lord Somers to win over the Scottish Presbyterians to acceptance of the union with England, his success was rewarded by the appointment of commissioner of the customs in 1708, but he was dismissed by the Tory administration of 1711. He came to the notice of George I through an anti-Jacobite tract he had written in 1713 and became member of parliament for Berwick-upon-Tweed (1715). He was given an Irish peerage as Viscount Barrington of Ardglass in 1720. He was expelled from the house of commons in 1723 for being closely, although unwillingly, involved in the Harburg lottery, one of the many unsound financial ventures of the time. He died on Dec. 14, 1734.

His youngest son SHUTE BARRINGTON (1734–1826) was bishop of Durham for 35 years after 1791.

BARRIOS, EDUARDO (1884–), Chilean novelist whose literary fame rests upon the clearness of his style. the stimulative power of his language and his ability to portray unique characters. was born in Valparaíso on Oct. 25. 1884. He was educated in Lima, Peru. and at the Chilean Military academy, in Santiago. After holding sundry jobs in several Latin-American countries, he settled in 1913 in Santiago, where he served in such important positions as minister of public education and director of the National library.

Barrios began his literary career with a collection of naturalistic stories. *Del natural* ("In the Naturalistic Style": 1907), but he became better known with his later novels. These included El *niño que enloqueció de amor* ("The Love-Crazed Boy": 1915), a strange psychological case of a boy in love with a young lady several years his senior; *Un perdido* ("A Down-and-Outer"; 1918), the life story of a hero whose n-eak character drives him to corruption and failure; and El *hermano asno* (1922; Eng. trans., *Brother Ass*, 1942), an unusual episode in the life of a mentally disturbed monk who attacks a girl in order to be despised by those who consider him a living saint. Barrios' most successful work was *Gran señor* v *rajadiablos* ("Grand Gentleman and Big Rascal"; 1948), a best seller in which the novelist attempted to portray rural life on a typical Chilean farm.

The author's personal experiences played an important part in all these novels as well as in his other works: *Páginas de un pobre diablo* ("Pages from a Poor Devil"; 1923), a collection of short stories: Y la *vida sigue* ("Life Goes On": 1925), a series of autobiographical sketches: *Tamarugal* (1944), a novel dealing with life in the northern mining region of Chile: and *Los hombres del hombre* ("Men Within Man"; 1950), a novelistic study in human psychology. (H. Co.)

BARRIOS, JUSTO RUFINO (1835–1885), long-time ruler of Guatemala and advocate of Central American unity. He was born in Guatemala, studied law there and engaged in politics and revolutionary activities. He became army commander and the power behind the president in 1871 when the Conservative party was ousted. Barrios assumed the presidency in 1873 and held it until his death. He imposed internal peace and liberal measures upon his people, working through his obedient political machine of local governors. He fostered economic progress by the construction of railroads and telegraph lines and by attempts to diversify and expand agriculture and to organize an effective governmental revenue system. The president also sought to expand the school system and encouraged immigration. He drastically curtailed the power of the Catholic Church by acts such as the expulsion of the Jesuits, the closure of monasteries and the seizure of extensive church properties. Barrios intervened repeatedly in the affairs of the other Central American republics in an effort to restore the five-nation federation that had collapsed in 1838. When his political efforts failed, the dictator turned to military force in his attempt to compel a revival of Central American union. He was killed on April 2, 1885, while leading his troops in an invasion of neighbouring El Salvador. (T. F. McG.)

BARRISTER: *see* LEGAL PROFESSION.

BARRON, CLARENCE WALKER (1855–1928). U.S. financial editor and publisher, was born in Boston, Mass., July 2, 1855. Having been the financial editor for the *Boston Evening Transcript,* he saw a demand for daily financial news in bulletin form. As a result. he established the Boston News bureau in 1887 and the Philadelphia News bureau in 1897. In 1901 he acquired Dow, Jones and Co., which, under his leadership, became the principal financial news agency in the United States. At the same time, he acquired the *Wall Street Journal,* the nation's leading financial newspaper. To these several services he added *Barron's National Business and Financial Weekly,* in 1921, and in the meantime wrote several books. He died on Oct. 2, 1928. (H. J. SG.)

BARROS, JOÃO DE (c. 1496–1570), called the Portuguese Livy, born probably at Vizeu, may be termed the first great colonial historian and a pioneer orientalist. He was also one of the principal Portuguese humanists and an outstanding civil servant. Educated in the heir-apparent's household, he became a good classical scholar and attracted King Manuel's attention by writing a precocious chivalresque romance, *Crdnica do Emperador Clarimundo* (1520). Its verve and style induced the king to encourage him in his idea of writing an epic history of the Portuguese in Asia. Before this was printed (under Manuel's successor, King John 111), Barros published several moral, pedagogical and grammatical works of such importance that he has been compared with Froebel as an educational innovator. His influence was certainly lasting, since his elementary ABC primer-cum-catechism, published in 1539 (partly for Indian converts from Malabar), served as a model for all such works, including those compiled by the Jesuits for their neophytes in Asia and America.

In 1522 King John III sent Barros to Guinea; apparently the only occasion on which he left Portugal. Soon after his return he was appointed treasurer (1525–28): and then for more than 30 years (1533–67) factor of the *Casa da India* e *Mina,* a post corresponding to crown agent for the Portuguese colonies. As factor of the India house, he spent his scanty leisure in compiling his great chronicle of the Portuguese discovery and conquest of the seas and lands of the east, eventually published as *De'cadas da Asia.* The first draft was finished in 1539, but he was still making additions ten years later and publication did not begin until 1552. The second volume was printed in 1553, the third in 1563, but the fourth was not edited from Barros' unfinished draft till 1615. These volumes take the story only as far as 1538, but Barros' work was continued by Diogo do Couto, who carried it on to the end of the 16th century before his death in 1616.

Barros certainly made the best use of his official position when writing his *Ddcadas.* He consulted returned soldiers, merchants and administrators, apart from perusing all the official correspondence, and being directly concerned with the dispatch and return of the annual India fleets. He procured Persian, Arabic, Indian and Chinese manuscripts, engaging educated men of those nationalities to translate them. These manuscripts include the Persian chronicle *Shánámá* (since lost) of Turan Shah and an Arab one of Kilwa in east Africa, Barros' version of this being still the primary source for the pre-16th-century history of Kilwa. Barros also partly wrote a number of other works on the geography, commerce and navigation of the east, but these disappeared after his death (Oct. 20, 1570). He also helped to finance an expedition which tried to found a settlement in Brazil. He certainly earned his substantial pension, but died so heavily indebted that most of his heirs refused to accept their share of the ruined inheritance.

Opinions differ as to the merits of Barros' literary style, which he confessedly modeled on Livy, but his *Décadas* are of permanent value for their subject matter, although his position as an official historian prevented him from criticizing Portuguese actions closely.

BIBLIOGRAPHY.—There is no satisfactory modern edition oi the *De'cadas* and that most commonly consulted is the 24-vol. ed. of Barros and Couto published at Lisbon (1778–88) which includes standard biographies of both historians by Manuel Severim de Faria (d. 1655). *See* also Antonio Baião, *Documentos inéditos sobre João de Barros* (1917); C. *R.* Boxer, *Three Historians of Portuguese Asia: Barros, Couto, and Bocarro* (1948). (Cs. R. B.)

BARROS ARANA, DIEGO (1830–1907), one of Chile's and South America's most eminent historians, was born in Santiago on Aug. 16, 1830. Because of ill-health, he gave up the practice of law and became a professor in the University of Santiago. Twice rector of that institution, he was instrumental in modernizing the university's curriculum. He served in congress and on boundary commissions and was associated with a number of newspapers and reviews. He had a trenchant pen, and one of his articles attacking Pres. Manuel Montt (*q.v.*) led to the young author's exile early in 1859. He thereupon did extensive research in Argentina, Uruguay and Brazil, and later in Spain, France and England. He was one of the first Latin-American historians to explore the rich Spanish archives and had the good fortune to discover an important unknown 16th-century poem on the war in Xraucania. Barros Arana reached manhood during a period of growing nationalism in Chile, and his research and writing on the colonial and independence periods served to buttress the prevailing nationalist position. He is considered a painstaking investigator and annalist rather than

an interpreter. Though his bibliography includes scores of titles, his reputation as a historian rests upon his monumental *Historia general de Chile*, 16 vol. (1884–1902), written in the tradition of the best nationalist historians of 19th-century Latin America. Barros Arana died in Santiago in 1907. (J. J. J.)

BARROT, (CAMILLE HYACINTHE) ODILON (1791–1873). French statesman prominent as a liberal monarchist under the July monarchy, was born at Villefort (Lozère), on July 19. 1791, the son of a Lozère deputy to the Convention. In 1814 he was appointed barrister in the court of cassation. Having made his name as a defender of liberals, he was elected president of the Société "Aide-toi, le ciel t'aidera," an organization for promoting resistance, by legal means, against the reactionary government. During the revolution of July 1830, as secretary of the municipal commission at the Hôtel de Ville in Paris, he decided to support the proclamation of Louis Philippe as king of the French and was one of the three commissioners of the new government who escorted the former king Charles X to Cherbourg on his way into exile. Barrot was then appointed prefect of the Seine *département*. Elected deputy for Eure in 1830, he was for 18 years one of the most active and ambitious leaders of the opposition. He directed the party of the "dynastic left" and, from 1839, demanded the "broadening of the bases of the monarchy" by an electoral reform. During 1846–47 he was one of the managers of the "banquets" campaign to bring pressure on the government, in the hope that "a large and generous extention of the number of electors" would save France from a republican revolution. After the flight of Louis Philippe in 1848 he joined the moderate Republicans. Head of the first ministry called by Pres. Louis Napoleon on Dec. 20, 1848. and also minister of justice, he was dismissed in Oct. 1849, after the first contests between legislative assembly and the new president. After the coup d'état of Dec. 2. 1851, he was imprisoned for a few days and then retired to private life. In 1870 he refused to be again minister of justice. Instead the national assembly elected him a member of the new *conseil d'état*, of which he became vice-president in 1871. Odilon Barrot died on Aug. 6, 1873, at Bougival (Seine-et-Oise). His *Mémoires* were published posthumously in 4 volumes (1875–76).

See C. Alméras, *Odilon Barrot, avocat et homnze politique (1950).* (JE. V.)

BARROW (BARROWE), **HENRY** (*c.* 1550–1593). English Independent, one of the early martyrs of Congregationalism. was born about 1550 at Shipdam, Norfolk, of good family, related to the Bacon family. Educated at Clare hall. Cambridge. after a youth of dissipation there and in London he was converted by the chance hearing of a sermon and became a strict Puritan. He became friendly with John Greenwood (*q.v.*) and by him was led into separatism. When Greenwood was arrested in 1586. Barrow visited him in prison but was apprehended himself on Nov. 19. He was examined several times before the high commission presided over by Archbishop John Whitgift. but refused to take the *ex officio* oath and was imprisoned with Greenwood. He was brought before the privy council. where Burghley called him "a fantastical fellow" with "a hot brain" and "a delight to be an author of this new religion." During a period of freedom in autumn 1592. Barrow and Greenwood associated with Francis Johnson and John Penry (*q.v.*) in forming their own church. Barrow was imprisoned again. however, and in 1593 he and Greenwood were tried before a civil court under the act of 1581 against writers of seditious books. Both were sentenced to death on March 23 and executed on April 6, 1593. In prison Barrow wrote several works. defending separatism and congregational independency, particularly *A True Description out of the Word of God of the Visible Church* (1589) and *A Bvief Discovery of the False Church* (1590).

Barrow was the foremost representative of the church-democracy of separatism. carrying to their logical conclusion the principles of Robert Browne (*q.v.*). Barrow defined the church as "a company of faithful people, separated from the unbelievers and heathen of the land, gathered in the name of Christ." Its government, worship and discipline were to be taken from the New Testament only, it recognized no distinction of clergy and laity. and it set forth the pattern of ecclesiastical democracy, in which each local congregation was sovereign and autonomous, and the liberty of prophesying was secured to each individual. His church recognized fully the principle of "the people to be the orderers of things."

See H. M. Dexter, *The Congregationalism of the Last Three Hundred Years* (1876–79); F. J. Powicke, *Henry Barrow* (1900). (N. S.)

BARROW, ISAAC (1630–1677), English mathematician and minister, considered by his English contemporaries a mathematician second only to Newton. was educated at Charterhouse, Felstead, and Peterhouse and Trinity college, Cambridge, where he studied literature, science and philosophy. He traveled in France, Italy and the near east. On his return in 1659 to England he received ordination from Bishop Brownrig, and in 1660 he was appointed regius professor of Greek at Cambridge. In 1662 he was elected professor of geometry in Gresham college, London. In May 1663 he was chosen a fellow of the Royal society, at the first election made by the council after obtaining its charter. In 1664 he became first Lucasian professor of mathematics at Cambridge, resigning in 1669 in favour of his pupil, Isaac Newton. His uncle gave him a small sinecure in Wales, and Seth Ward, bishop of Salisbury, conferred upon him a prebend in that church. In the year 1670 he was created doctor in divinity by mandate; and, upon the promotion of John Pearson to the see of Chester, he was appointed to succeed him as master of Trinity college by the king's patent, Feb. 13, 1672. In 1675 Barrow was chosen vice-chancellor of the university.

Barrow was an able mathematician, who handled geometrical method admirably. In his *Method of Tangents* he approximated the course of reasoning by which Newton was afterward led to the doctrine of ultimate ratios; he introduced the differential triangle, and was the first to observe explicitly the reciprocal relation between differentiation and integration.

His major scientific works are: *Euclid's Elements; Euclid's Data; Optical Lectures*, read in the public school of Cambridge; *Thirteen Geometrical Lectures; The Works of Archimedes, the Four Books of Apollonius's Conic Sections, and Theodosius's Spherics, explained in a New Method;* and *Mathematical Lectures*. The above were all written in Latin.

The mathematical works of Barrow have been edited in Latin by W. Whewell (1860). An annotated English translation of Barrow's *Geometrical Lectures* was made by J. M. Child (1916).

See Percy H. Osmond, *Isaac Barrow, His Life and Times* (1944); also John Ward. *Lives of the Professors of Gresham College* (1740 ff.), and Whewell's biography prefixed to the 9th vol. of **A.** Napier's edition of Barrow's *Sermons* (1859). (I. B. C.)

BARROW is the term used in England for an ancient burial place covered with a large mound of earth or stones. In Scotland the equivalent term is "cairn" (*q.v.*); in the U.S., "mound"; and in Europe. "tumulus." The long or circular barrows found in England extend in time from Neolithic (*c.* 2000 B.C.) to late pre-Christian cultures (*c.* A.D. 600). They are most common in Wiltshire (*q.v.*).

BARROW-IN-FURNESS, a municipal, county and parliamentary borough of Lancashire, England, 34 mi. S.W. of Kendal by road. Pop. (1961) 64.824. Area 17.2 sq.mi. It is on the seaward side of the peninsula forming part of the district of Furness (*q.v.*), between the sandy estuary of the Duddon and Morecambe bay, where a narrow channel of the Irish sea, now bridged, intervenes between the mainland and the long, low island of Walney.

Barrow is of rapid modern growth through the working of veins of pure hematite iron'ore in the district of Furness. At the outset Barrow merely exported the ore to the furnaces of south Wales and the midlands. By early 19th century this export amounted to a few thousand tons. and though it had reached about 50.000 in 1847 the population of Barrow was only 325. In 1841 the first iron works were erected, and the first section of the Furness railway was opened in 1846.. connecting Barrow with the mines near Dalton; coke was later brought by rail from Durham. In the ensuing years a great increase in trade justified the opening of further communications, and from 1859 many ironworks were

instituted, and a great output of steel produced by the Bessemer process was begun. By mid-20th century the local ores were almost exhausted, and ores from Spain and elsewhere were being imported. Of other industries that followed, the shipbuilding works came to surpass the steel works in importance, but was founded on them. The first vessel was launched in 1873. Both naval and merchant vessels are built there, and one specialty of these yards (more than 130 ac. in extent) is the construction of submarines. Other industries include a paper-pulp factory, armaments, iron works and light industries. The docks system is adequate for modern requirements; there is also a graving dock.

Vickerstown. on Walney Island, is a residential suburb of Barrow, which is now a seaside resort with bathing and sailing. Barrow's educational facilities include grammar schools and a college for further education.

Ruins of antiquity remain within the boundary, notably the abbey of St. Mary of Furness (founded *c.* 1127) and Piel castle; from which Lambert Simnel in 1487 began his march to London to claim the throne of England. Barrow was incorporated in 1867 and became a county borough in 1888.

BARROW RIVER (AN BEARRBHA). flows for about 120 mi. from the centre of Ireland to the southeast, where it joins the Nore and, with the river Suir, forms the fine estuary of Waterford harbour. These rivers are aptly called the "three sisters" and all three in their middle and lower courses flow through gorges 50–100 ft. deep; above are broad lowlands from which mountain ranges rise. The upper course of the Barrow is quite different. Having its sources in mountain streams of the Slieve Bloom, a mountain range in counties Laoighis and Offaly (*q.v.*), the river flows through bogs and poorly drained lowlands in an easterly direction and then turns south into the wide and fertile lowland country between the Castlecomer uplands on the west and the hills and lowlands of County M'icklow to the east. In the last 15 mi. before the Barrow joins the Nore, it flows in a gorge 50–100 ft. deep with wooded sides, finally reaching a wide and frequently flooded lowland near New Ross; the charm of this area is accentuated by the views of Brandon mountain to the west and Mt. Leinster to the east. The Barrow was canalized to St. Mullins, the tidal limit, from 1759 onward and linked to the Grand canal from Dublin to the Shannon, but in 1954 barge traffic ceased. Market towns on the river include Athy (pop. [1961] 3,842), Carlow (pop. [1961] 7,707) and Graiguenamanagh-Tinnahinch (pop. [1956] 1,366). (T. W. FR.)

BARRY, SIR CHARLES (1795–1860), English architect, designer of the British houses of parliament. was born in London on May 23. 1795, the son of a stationer. He was articled to a firm of architects until 1817, when he set out on a three years' tour of Greece, Italy. Egypt and Palestine to study architecture. In 1820 he settled in London. One of his first works was the church of St. Peter at Brighton, in 1826. In 1831 he completed the Travellers' club in Pall Mall, a splendid work. the first in the Italian style built in London. In the same style and on a grander scale he built in 1837 the Reform club. He was also engaged on numerous private mansions in London, the finest being Bridgewater house (1847). In Birmingham. one of his best works, King Edward's school. was built in the Tudor style between 1833 and 1836. For Manchester he designed the Royal Institution of Fine Arts (1824) and the Athenaeum (1836), and for Halifax the town hall. He was engaged for some years in reconstructing the Treasury buildings. Whitehall. But his masterpiece, notwithstanding all unfavourable criticism, was the houses of parliament at Westminster. London (1840–60), on which Augustus W. Pugin (*q.v.*) assisted him. Barry was elected associate of the Royal Academy in 1840 and a royal academician in the following year. and received many foreign honours. He was knighted in 1852. He died suddenly at Clapham, London, on May 12, 1860. and was buried in Westminster abbey. In 1867 appeared a life of him by his son, Bishop Alfred Barry (1826–1910).

See H. H. Statham, The *Architectural* Genius of *Sir C. Barry* (1901).

His son. EDWARD MIDDLETON BARRY (1830–1880), also an architect. was born on June 7, 1830. He was professor of architecture at the Royal academy from 1873 until his death. He completed his father's work on the houses of parliament, and Halifax town hall. Other buildings designed by him were Covent Garden theatre, Charing Cross and Cannon Street hotels, the Birmingham and Midland institute, new galleries for the National gallery and new chambers for the Inner Temple. He died on Jan. 27, 1880.

The youngest son. SIR JOHN WOLFE WOLFE-BARRY (1836–1918), civil engineer, who assumed the additional name of Wolfe in 1898, was born on Dec. 7, 1836. He was educated at Glenalmond, and articled as engineering pupil to Sir John Hawkshaw, with whom he built the railway bridges across the Thames at Charing Cross and Cannon street. In 1867 he worked on his own account. Among the works on which he was engaged were extensions of the Metropolitan District railway, the St. Paul's station and bridge of the London, Chatham and Dover railway, the Barry docks of the Barry Railway company near Cardiff, the lock entrance, dock and graving dock at Immingham. Grimsby, the extensions of the Surrey Commercial docks on the Thames, the Tower and new Kew bridges over the Thames. On the completion of the Tower bridge. in 1894, he was made a commander of the Bath, becoming knight commander of the Bath three years later. Wolfe-Barry served on a number of important royal commissions, notably on that on London traffic (1903–05), and was one of the two British representatives on the International Suez commission (1892–1906). He led in promoting (1901–02) the engineering standards committee for the standardization of certain engineering projects. He died at Chelsea on Jan. 29, 1918.

BARRY, JAMES (1741–1806), British painter and Royal academician whose career was marked by violent altercation with his contemporaries. was born at Cork. Ire., on Oct. 11, 1741. He was self-taught, and his work attracted the notice of Edmund Burke, who introduced him to Sir Joshua Reynolds and James ("Athenian") Stuart, whose architectural drawings he copied in oil. At Burke's expense Barry studied in Italy (1766–70) and returning to London in 1771, exhibited "Adam and Eve" (National gallery, Dublin), a painting correct in draftsmanship but deficient in colour and grace. He became an associate of the Royal Academy in 1772 and a full academician in 1773, continuing to exhibit at the academy until angered by the cool reception accorded his "Death of General Wolfe" in 1776, a painting aimed against Benjamin West's treatment of the same subject in contemporary dress in 1771. During 1777–83 Barry completed his monumental decorative scheme for the Great room of the Society of Arts, on the theme "The Progress of Human Culture." These classical history pieces were engraved and are. in their magnitude. unique in British 18th-century painting. Appointed professor of painting at the academy in 1782, Barry. embittered by neglect. violently attacked his colleagues and in 1799 was expelled from the Royal Academy. He died in London on Feb. 22, 1806.

See E. Fryer. *The Works of James Barry, Historical Painter, edited with a Memoir,* 2 vol. (1809). (D. L. FR.)

BARRY, JOHN (*c.* 1745–1803), U.S. naval officer who won important naval engagements in the American Revolutionary War, was born in County Wexford, Ire.. and bred to the sea. At the age of 21 he was a merchant shipmaster out of Philadelphia. and, at the outbreak of the American Re olution, he outfitted the first Continental fleet in the fall of 1775. Commissioned captain of the Continental brig "Lexington." on March 14, 1776. he early distinguished himself by capturing, after a sharp engagement, the British tender "Edward," the first prize brought into the port of Philadelphia. When Howe's army advanced across New Jersey, threatening Philadelphia in Dec. 1776, Barry volunteered as aide-de-camp to General John Cadwalader, commanding a Philadelphia brigade, and saw action at the second battle of Trenton, or Assunpink Creek, and at Princeton. Meanwhile. congress had ranked him as seventh captain on the seniority list, and commissioned him to the frigate "Effingham." Before she was ready for sea, in Sept. 1777, Howe's advance from Brandywine forced Barry to take the unfinished frigate up the Delaware: where he scuttled and sank her by orders of General George Washington. In the winter of 1777–78, Barry commanded a spectacular boat foray, which ran the British batteries at Philadelphia. and raided enemy shipping in Delaware river and bay. Ordered to Boston to command the frig-

ate "Raleigh." he was unfortunate in being sighted by a superior enemy force shortly after he put to sea in Sept. 1778. Chased for 48 hours. he was finally cornered off Wooden Ball Island, near the mouth of the Penobscot, where he fought a gallant but futile action against a British 61-gun ship and a frigate, and actually managed to get about one-third of his crew ashore in safety. In the fall of 1780, Barry was placed in command of the frigate "Alliance." his first assignment being to convey Col. John Laurens on a diplomatic mission to France. This he accomplished, taking several prizes on the way, and. on his return, had a spectacular engagement with two British sloops of war, which attacked him. by means of sweeps, while the "Alliance" lay becalmed off Newfoundland. Barry was wounded and the "Alliance" badly mauled when a slight breeze arose, and he turned the tables on his opponents by bringing his guns to bear and quickly subduing both of them. His second voyage to France was to take the Marquis de Lafayette home after Yorktown. On the final cruise of the "Alliance," beginning in Aug. 1782, Barry ranged the shipping lanes from Bermuda to Cape Sable, was caught in the fringe of a hurricane which had wrecked the British fleet homeward bound from Jamaica, and took four ships of the fleet. as well as a half-dozen other prizes. He put into Lorient to refit, and was delayed by a mutiny among his officers. Sailing just in advance of the completion of the peace negotiations, Barry touched at Martinique and Havana on his homeward voyage; picked up a bullion shipment at the latter port, and, in the Gulf of Florida fought the last engagement of the Revolutionary War, on March 10, 1783. Three British frigates sought to intercept him and he beat them off. badly damaging the frigate "Sybil." After a voyage to Canton in the China trade. Barry retired from the sea, but was recalled to active service as senior captain of the new U.S. navy, on June 4, 1794, and superintended the construction of the frigate "United States." which he commanded thereafter. In the quasi-war with France he twice was in command of all U.S. ships in the West Indies, and took a number of French privateers. In 1799–1800, he carried two of the U.S. commissioners sent by John Adams to try to arrange a peaceful settlement of the differences with France. He landed them at Corunna after a stormy passage. Retained on the list of captains after Pres. Thomas Jefferson's naval reduction of 1801, Barry was too ill to respond to a request that he command a squadron intended for the Mediterranean in 1802 to deal with the Barbary powers. However, his success in training young officers—Stephen Decatur (1779–1820), Richard Somers. Charles Stewart. Jacob Jones. John Trippe, etc., who later became celebrated in U.S. naval history—had already gained him the courtesy title. "Father of our Navy." The entire nation mourned his death in Philadelphia, on Sept. 13, 1803.

See M. J. Griffin, *The History of Commodore John Barry* (1897); and William Bell Clark. *Gallant John Barry* (1938). (W. B. Ck.)

BARRY, PHILIP (1896–1949), U.S. dramatist, was best known for comedies of life and manners among the socially privileged. Born in Rochester, N.Y., on June 18, 1896, Barry was educated at Yale university. After graduation in 1919 he entered George Pierce Baker's Workshop 47 at Harvard university. His play, *A Punch for Judy*, was produced by the workshop in 1920; *You and I*, also written as a student. won the Herndon prize. and played 170 performances on Broadway in 1923. Over the next 20 years a succession of plays included such comedies as *Paris Bound* (1927), *Holiday* (1929), *The Animal Kingdom* (1932), and *The Philadelphia Story* (1939), which ran for 417 New York performances. They are characterized by witty and graceful dialogue and humorous contrasts of character or situation; many of them use a triangle theme or conflicts between the generations to point up with almost tender satire various truths about human nature. In *White Wings* (1926), a fantasy considered by some critics Barry's best play; *John* (1927), a drama about John the Baptist; *Hotel Universe* (1930), a penetrating psychological study; and *Here Come the Clowns* (1938), an allegory of good and evil, Barry's thoughtful and even sad approach to life is apparent. Many critics felt that his final play. *Second Threshold* (1951), revised by Robert E. Sherwood after Barry's sudden death in New York city on Dec. 3, 1949, combined the two facets of his genius. his flair for social comedy and his preoccupation with more serious drama.

BARRY (Y BARRI), a municipal borough in the Barry parliamentary division of Glamorganshire, Wales, 15 mi. S.S.W. from Cardiff on the Bristol channel. Pop. (1961) 42,039. A small brook named Barri runs there into the sea, whence the place was formerly known in Welsh as Aber-Barri; but the name of both the river and the island is supposed to be derived from Baruch, a Welsh saint of the 7th century, who had a cell on the island. His chapel: which still existed in Leland's time, was a place of pilgrimage in the middle ages. One of the followers of Robert Fitzhamon, about the end' of the 11th century, built a castle at Barry, of which only a gateway remains.

Barry comprises the ecclesiastical parishes of Barry, Cadoxton, Merthyr Dyfan and a portion of Sully in which is included Barry Island (194 ac.), now, however, artificially joined to the mainland. The total population of this area in 1881 was 478, that of Barry village being only 85. The town's growth was entirely brought about by coal exporting during the last quarter of the 19th century. The great demand for steam coal at that time gave opportunities for a number of colliery owners, especially David Davies (1818–90), to secure an alternative port to Cardiff, with an independent railway to it from the coal fields. After failing in 1883, they obtained parliamentary powers for this purpose in 1884, and the first sod of the new dock at Barry was cut in November of that year. The dock was opened in 1889 and a second dock in 1898. In 1921 Barry docks were taken over by the Great Western railway and are now administered by the Cardiff Port authority. They are 114 ac. in extent, and have accommodation for the largest vessels afloat. Imports include timber, grain, sand, oil and general, cargo; the chief export is coal and others are cement: flour, steel products, etc. At the docks are flour mills, timber ponds and oil storage tanks.

After 1918, in particular, Barry, together with Barry Island with its sandy beaches, lying immediately west of the docks, became a favourite seaside holiday place. Barry was incorporated in 1939. At Rhoose, a little to the west, is an airfield with service to Dublin. The Bulwarks, a prehistoric camp by the sea, is nearby.

BARRYMORE, the name of a distinguished U.S. theatrical family. ETHEL BARRYMORE (1879–1959), noted for distinctive style, voice and wit, was born in Philadelphia, Pa.. Aug. 15, 1879. Her father was MAURICE BARRYMORE (1848–1905), actor and playwright. who changed the family name from Blythe to Barrymore. Her mother was the actress GEORGIANA DREW BARRYMORE, daughter of Louisa Lane Drew (Mrs. John Drew. Sr.), who managed the Arch Street theatre in Philadelphia and starred with Joseph Jefferson. Her uncles were John and Sidney Drew. (*See* also DREW [FAMILY].)

Miss Barrymore and her brothers. John and Lionel, originally sought careers away from the theatre. Ethel as a pianist. John as an artist. Lionel as an artist and composer, but all three eventually turned to acting. Miss Barrymore made her professional debut in 1894 in Montreal in a company headed by her grandmother and Mr. and Mrs. Sidney Drew. For three years she understudied and played walk-on parts on Broadway and in touring companies headed by John Drew, then went to London in *Secret Service* with William Gillette. In 1897 and 1898 she scored a London success with Sir Henry Irving in *The Bells* and *Peter the Great*. She played in *Rosemary* with John Drew and Maude Adams in 1896 and was starred for the first time on Broadway in 1901 by Charles Frohman in *Captain Jinks of the Horse Marines*.

Miss Barrymore's notable plays include: *Alice-Sit-by-the Fire* (1905j. *Mid-Channel* (1910), *Trelawney of the Wells* (1911), *Déclassée* (1919), *The Second Mrs. Tanqueray* (1924), *The Constant Wife* (1928), *The Kingdom of Cod* (1928), *Scarlet Sister Mary* (1931), *Whiteoaks* (1938) and *The Corn is Green* (1942). In 1928 she opened the Ethel Barrymore theatre, named in her honour, with *The Kingdom of God*.

She also appeared in vaudeville. on radio and on television and made a number of motion pictures. Her first film was *The Nightingale* in 1914; the most noteworthy were *Rasputin and the Empress* (1932) and *None but the Lonely Heart* (1944). *Rasputin* was the only work in which she appeared with her brothers.

She was married to Russell Griswold Colt in 1909 and divorced in 1920. Her children were Samuel Pomeroy Colt, John Drew Colt and Ethel B. Colt (Mrs. Romeo Miglietta). She died in Hollywood, Calif., June 18, 1959.

LIONEL BARRYMORE (1878–1954), noted on stage for such plays as *Peter Ibbetson* (1917), *The Copperhead* (1918) and *Thr Jest* (1919), was born April 28, 1878, in Philadelphia, and died Nov. 15, 1954. He became a motion-picture and radio actor and is perhaps best remembered for his *Dr. Kildare* series and his radio performances in Dickens' *A Christmas Cnrol.* Arthritis forced him to spend his last years in a wheel chair.

JOHN BARRYMORE (1882–1942), stage and film actor, called the "great profile," was born in Philadelphia on Feb. 1j, 1882. He appeared on Broadway in *The Jest* (1919), *Richard III* (1920) and set a record with *Hamlet* in 1923. He died May 29, 1942.

BAR-SALIBI, JACOB id. 1171), who took the name Dionysius at his episcopal consecration, was a voluminous writer in Syriac, the most outstanding in the Jacohite (Monophysite) church in the 12th century, A native of Melitene (Malatya), he was made bishop of Marash in 1154, and a year later of Mabbog also. In 1166 he was transferred to the metropolitan see of Amid (Diarbekr), where he remained until his death on Nov. 2, 1171. The lengthy list of his works includes poems, prayers, homilies, liturgies, a commentary on the six *Centuries* of Evagrius with the text translated into Syriac, a treatise against heresies, expositions of the Syrian Eucharistic service and doctrine and commentaries on the Old and New Testaments. The Old Testament commentary, a compilation rather than an original composition, gives a material or literal exposition and a spiritual or mystical exposition oi the deeper meaning. For the Wisdom books and some others there are commentaries on both the Peshitta and Hexaplar texts. The New Testament commentary, less developed except in the Gospels, also deals with the text at two levels.

See A. Baumstark, *Geschichte* der *syrischen Literatur,* pp. 295–298 (1922).
(W. D. McH.)

BAR SAUMA, RABBAN (c. 1220–1294). Nestorian ecclesiastic and traveler, whose diary is an important historical source, was born in Peking c. 1220 of a Christian family of Uighur descent. After spending several years in a monastery in China, Bar Sauma started with his disciple Marcus on a pilgrimage to Jerusalem, but on reaching Armenia they were persuaded to abandon their journey and both accepted ecclesiastical appointments.

In 1287 Bar Sauma agreed to go to Europe as the ambassador of Arghun, the Mongol ilkhan of Persia. His task was to obtain support for a war against the Muslims in Syria and Palestine. It seems he had instructions also from the patriarch Jaballaha III (his former pupil Marcus). In Constantinople Bar Sauma was received by the emperor Andronicus II Palaeologus. In Rome, where the papal throne was vacant, he had conversations with some of the cardinals, who examined his faith. But Bar Sauma made it clear that he did not wish to be drawn into theological discussion. He went on to Paris where he was given a friendly welcome by the French king Philip IV, and in Gascony he visited Edward I, the king of England. The plea of Arghun was favourably received by both kings, but no practical agreement was reached. Returning through Rome, Bar Sauma received presents and letters for the ilkhan and the patriarch from the newly elected pope Nicholas IV. In Persia he was appointed chaplain to the royal court. Later he retired to Maragheh in Azerbaijan, where he died in 1294.

During his travels Bar Sauma, an intelligent observer, kept a diary in Persian. This was used by the anonymous compiler of a history of Bar Sauma and Jaballaha, written in Syriac (Eng. trans. by E. A. Budge, *The Monks of Kublai Khan,* 1928). (G. V. F.)

BART, JEAN (1650–1702), French privateer and naval officer, renowned for his achievements in Louis XIV's wars, was born at Dunkerque on Oct. 21, 1650, of a family with a long tradition of privateering. His personality and his career were bound up with his birthplace, but not limited by it, and he won not only local but national fame. Dunkerque is a port advantageously situated on the trade routes of the English channel and the North sea and well-defended by sandbanks, reefs and shoals, and Bart was a successor of the *capres* whose profession was privateering, who knew every detail of the coast and who thought nothing of enemy blockades. His first experience of war was under the Dutch admiral M. A. de Ruyter, but he returned to Dunkerque when the Dutch War of 1672–78 broke out. In command of small privateering vessels he fought six battles and took 81 prizes, and was made lieutenant by Louis XIV as a reward.

The War of the Grand Alliance (1687–9i) started badly for Bart. After a terrible fight the "Railleuse" and "Les Jeux," commanded by Claude de Forbin, were crushed by superior English vessels. Taken prisoner, Bart escaped from Plymouth with Forbin and rowed for 52 hours until he reached the French coast. Promoted captain, he commanded the "Alcyon" at the battle of Beachy Head (1690) and afterward a division at Dunkerque. He stood high in the esteem of the king and occasionally went to Versailles. Fair-haired, tall and awkward, but proud and with a great deal of common sense, he was not the ignorant lout portrayed in the sarcastic writings of his colleague Forbin and the courtiers.

Bart was Vauban's ad iser when he fortified Dunkerque and its defender during the English attacks of 1694 and 1695. In June 1694, when France was threatened by famine, he gave battle to a Dutch squadron off the Texel, boarded and took the enemy flagship and so recovered from the enemy a convoy of 96 ships of wheat from Russia and Poland which he succeeded in bringing almost intact to Dunkerque and Le Havre. The king then made him a member of the nobility, as the combat had been *"trbs glorieux pour lui, trbs utile à l'état"* ("of great glory to him, of great service to the state").

In the spring of 1696 Bart surprised a large merchant fleet near the Dogger bank, but was in his turn surprised by a strong squadron. He set fire to his prizes and proudly sailed off, weaving his way through the shoals among the English and Dutch ships. Given command of a squadron, he escorted the prince de Conti (François Louis de Bourbonj, candidate for the Polish crown, to Gdánsk (Danzig) in 1697, passing six frigates through a tight blockade. By the end of the war his di ision had destroyed 30 warships and captured 130 merchant ships in addition to those taken in the battle of the Texel. Bart died suddenly on April 27, 1702. A sailor of astonishing skill and daring, he is still especially commemorated at Dunkerque. (L. NI.)

BARTAS, GUILLAUME DE SALLUSTE: see DU BARTAS, GUILLAUME DE SALLUSTE.

BARTENSTEIN, JOHANN CHRISTOPH, FREIHERR VON (1690–1767), Austrian statesman who was the trusted counselor of the emperor Charles VI and the empress Maria Theresa, was born at Strasbourg on Oct. 23, 1690, the son of a university professor. He studied philosophy and law at Strasbourg and in 1712 went to Paris to study history at the Benedictine monastery of St. Maur. In 1714 he moved to Vienna where he worked for a time as a tutor. In 1716, however, he entered the provincial administration of Lower Austria, having been first received into the Catholic Church. In 1725 he married into a noble Austrian family and in 1726 joined the imperial chancellery. In 1727 he became protocol secretary of the secret conference of the emperor's councilors on foreign affairs. In this position he was the creator of the political system based on the guarantee of the Pragmatic Sanction (*q.v.*) and his was the controlling hand in the negotiations resulting in the marriage of Maria Theresa to Francis Stephen of Lorraine. In 1733 Bartenstein became privy secretary of state and was created *freiherr* (baron).

During the troubled years that followed Charles VI's death (1740), Bartenstein was regarded by Maria Theresa as her most trusted adviser and in this capacity he vigorously opposed any concessions to Prussia. In 1753 he was obliged to hand over foreign affairs to W. A. von Kaunitz, becoming vice-director of the ministry of the interior and finance. Besides this he worked on the educational program and also as history tutor to Joseph II. He took part in the organization of the royal and state archives.

Bartenstein was an outstanding jurist who perhaps overesti-

mated the effectiveness and reliability of treaties in foreign affairs. He n-as an honest servant of the state and dynasty with a remarkable memory and a bureaucrat's efficiency. He left a large fortune on his death, in Vienna, on Aug. 6, 1767.

Bartensteins Merkunft und Anfange," *Mitteilung der Institut fur osterreichische Geschichtsforschung, 61* (1953), *Versailles und Wien von Ludwig XIV bis Kaunitz* (19.52). (AD. WA.)

BARTH, HEINRICH (1821–1865), a distinguished German geographer, historian and linguist and one of the greatest explorers of Africa of all time. was born at Hamburg on Feb. 16, 1821. He was educated in the classics at the University of Berlin and his earliest travels. 1845–47, were undertaken in the lands bordering the Mediterranean sea. The results were published in 1849 in a book entitled *Wanderungen durch die Küstenlanden des Mittelmeeres (Wanderings along the Punic and-Cyrenaic Shores of the Mediterranean)*. Barth was then a competent linguist in modern European languages. speaking German, French. Spanish. Italian and English together with Arabic which he had acquired for his first journey.

He was giving lectures at the University of Berlin in 1849 when it was suggested that he should join James Richardson, who had previously traveled in north Africa and the Sahara, in an expedition to the western Sudan which the British government had agreed to support. Contact between Barth and Richardson had been made through the Chevalier Bunsen, Prussian ambassador in London, and the German geographers Alexander von Humboldt and Karl Ritter. A second German. Xdolf Overweg, a geologist and astronomer. also joined the expedition. Richardson was inspired by humanitarian and commercial motives; Barth and Overweg were interested in scientific exploration. They left Tripoli to cross the Sahara early in 1850. Richardson died a year later in Bornu and Barth assumed command of the expedition. He first of all explored the countries south and southeast of Lake Chad. discovering the upper reaches of the Benue at Yola. Overweg died in Sept. 1852 and Barth then began his great journey westward to reach Timbuktu in Sept. 1853. He remained there six months, returned to Bornu in Dec. 1854, reached Tripoli in August and London in Sept. 1855. His journeys, lasting more than five years, totaled over 10,000 mi. In spite of ill-health and the loss of his colleagues he persisted in his travels which ranged more widely than any previously in that part of Africa. He was the first European to return with an account of the middle section of the Niger, which had been traveled by Mungo Park but from whom no record had survived. In keeping records he was most assiduous and laid down his routes with great accuracy by dead reckoning, being unabl'e to take astronomical observations.

Within a very short time after his return from Africa Barth published the results of his journeys in German and English in five great volumes—*Travels and Discoveries in North and Central Africa* (1857–58). They remain one of the most comprehensive works on the western Sudan, containing not only the day-to-day details of travels but an immense amount of detailed anthropological, historical and linguistic information. Barth's travels received little attention from the general public and thereafter he remained a relatively neglected explorer. In recognition of his work he was made a commander of the Bath and received a financial reward from the British government. He was awarded the patron's gold medal of the Royal Geographical society, was made a foreign associate and addressed the society in 1858.

He was made professor of geography at Berlin in 1863 and was president of the Berlin Geographical society. Following his return from Africa he continued to travel widely in Asia Minor (1858), Spain (1861), Turkey (1862), the Alps (1863), Italy (1864) and Turkey (1865). He died in Berlin on Nov. 25, 186 j.

A two-volume edition of Barth's *Travels* was published in London in 1890. His great work *Collection of Vocabularies of Central African Languages* (1862–66) was not completed.

See G. von Srhubert, *Heinrich Barth, der Bahnbrecher der deutrchen Afrikaforschung* (1897) and *H.* Schiffers, *Der Grosse Reise* (1952). (R. M. P.)

BARTH, KARL (1886–), Swiss Protestant theologian, distinguished for the revolution he wrought in 20th-century Protestant theology by his uncompromising advocacy of the traditional Christian motifs of divine grace and freedom, was born in Basel, Switz., on May 10, 1886. the son of a pastor and professor of theology, Fritz Barth. He studied at Bern. Berlin. Tiibingen and Marburg, where he was deeply influenced by the liberal theologian Wilhelm Herrmann. Subsequently he taught theology at the universities of Gottingen (1921), Miinster (1925), Bonn (1930) and Basel (after 1935). After initial qualms about entering the ministry he served as Reformed Church pastor in Geneva (1909–11) and Safenwil, Switz. (1911–21).

During the period of his pastorate Barth's theological outlook changed drastically. World War I quickened his hope of a total reconstruction of society, away from militarism and the selfishness of early 20th-century industrial capitalism. It was a religious hope, for even at this early stage he had a strong conviction of divine predestination, not so much of individuals as of the social organism. By contrast, however, the theology of his university career was extremely individualistic. With Friedrich Schleiermacher (*q.v.*) and Herrmann he thought that the divine Spirit is directly present to the inner, spiritual man. This communion may be subjected to no external authority, not even that of the Bible. The interpretation of external events is necessarily left to secular scientific and historical understanding.

It was impossible to join this theological outlook to Barth's social convictions. Furthermore it did not contribute to his understanding of the task of the preacher who had to confront his communicants, in all the puzzlement of their lives. with the radical message of the Bible. which brings into question all human values. standards, philosophies and certainties. It seemed to Barth that by means of this radical challenge the Bible exacerbates the puzzlement in the human condition to the point of unbearable tension and at the same time shows this total crisis forth as divine judgment on man's sin. And yet, mysteriously, inexplicably or—as Barth would have it at that time—paradoxically, this divine judgment is the reverse side or veil of an equally radical, affirmative and sin-forgiving divine grace.

Barth's revolutionary break with theological liberalism, which became epoch-making for Protestant theology as a whole, is embodied in the second edition of *Der Römerbrief* ("Commentary on Romans." 1922). It marks the beginning of what is usually referred to as dialectical or crisis theology. Barth, influenced by Soren Kierkegaard (*q.v.*) among others, stressed the severe indirectness and startling novelty of the divine-human relation. Christ is neither an experienceable fact in the inner life nor an object of cultural and religious reflection. God, who is manifest in Christ, is the unapprehended, creative source of all being and knowledge from whom we are estranged. Truly to know Him is rather to be known by Him and to abide willingly in the distance of faith from Him. This death-bound universe. at its points of origin and limitation or crisis, is related radically to the transcendent source of all life. The great paradox that both symbolizes and consummates this relation is the death and resurrection of Christ. touching time decisively.

The second edition of *Der Romerbrief* coincided with the beginning of Barth's academic teaching career, which forced him to exchange the oracular and critical for a systematic and constructive mode of thought. After 1927 he broke with Kierkegaard and Existentialism. Thereafter he was engaged, in his monumental *Kirchliche Dogmatik* (1932–), in developing a dogmatic theology based solely on the incarnate Word of God as the concrete reality and norm underlying and enabling all finite being and knowing. In Jesus Christ the Triune God, the bestower of faith. becomes an object for human apprehension. Christ, who is both the electing God and the man elect from eternity, is the coincidence of divine judgment and mercy, since He, the elect: has taken God's rejection of sinful humanity on Himself. Thus man's predestination is an act of divine graciousness taking place in Jesus Christ. Barth affirms that all created life, cultural and political reality are founded on Christ. This affirmative attitude toward creation he combines with an equally decisive rejection of every

theological endeavour to understand creation apart from Christology. On this issue he has been in intense debate with the Existentialist theologian Rudolf Bultmann (*q.v.*) and with Roman Catholic natural theology.

After his break with liberalism Barth consistently stressed the concrete reality and the sovereign freedom of God. Both are set forth wholly and exclusively in the man Jesus of Nazareth in whom God is "God-for-us." But in the days of *Der Römerbrief* Barth saw the radical "No" toward creation of the same sovereign, free grace that later, in the *Kirchliche Dogmatik,* he came to' see as the foundation of God's covenant with men and the supreme "Yes" to all creation. Barth's critics say that this radical affirmativeness is bought at the price of the relative independence and spontaneity of the creature. that it amounts to a false identification of Jesus Christ with all reality, and that this identification in turn rests on many unexamined philosophical presuppositions.

During the Nazi period in Germany Barth was one of the chief leaders of resistance to the Nazification of the church. This stand broadened later into a theological decision to resist Nazism as a political system. The Hitler government deprived him of his post in Bonn in 1935. After the war Barth denied the necessity for a similar theological decision against Communism, although he rejected it as a political system.

Some of Barth's major works include *Das Wort Gottes und die Theologie* (1924), Eng. trans.. *The Word of God and the Word of Man* (1928); *Fides quaerens intellectum: Anselms Beweis der Existenz Gottes,* 2nd ed. (1958), Eng. trans.. *Anselm: Fides Quaerens Intellectum* (1960); *The Epistle to the Romans,* Eng. trans. of the 6th ed. of *Der Römerbrief* (1933); *Church Dogmatics,* Eng. trans. of *Die Kirchliche Dogmatik* (1936. 1955–): *Against the Stream* (1954); *Christ and Adam* (1957); and *Protestant Thought: From Rousseau to Ritschl* (1959).

(H. W. FR.)

BARTH, PAUL (1858–1922), German philosopher and sociologist. considered society as an organization, in which progress is determined by the power of idoas. He was born Aug 1, 1858, in Baruth in Silesia. He was professor of philosophy and education in Leipzig from 1897 Barth's *Philosophy of History of Hegel and the Hegelians* (1896) and his broad *Philosophy of History of Sociology* (1897) were outstanding works. He developed for the first time in German not only a history of the various sociological systems but also, in his critique of Hegel, the different philosophic systems of history (anthropological, political. individualist, collectivist and ideological).

Barth edited the *Quarterly of Scientific Philosophy* from 1899 until 1916. His *Elements of Education and Teaching Based on Psyclzology and Philosophy* (1906; trans. into Italian, Spanish and Russian) was concerned chiefly uith moral education and was designed to replace the old textbooks based on Johann Herbart's philosophy. Barth also wrote *History of Education in the Ligltt of Soczology and History of Ideas* (1911) and *The Necessity of a Systematic Moral Teaching* (1922). He died in Leipzig on Sept 30, 1922.

BARTHÉLEMY, JEAN JACQUES (1716–1795), French scholar. writer and numismatist, author of *Voyage du jeune Anacharsis en Grkce,* one of the most widely read books in 19th-century France. was born at Cassis. Provence. Jan. 20, 1716. He studied theology uith the Jesuits and became an *abbe'.* Of a gentle and scholarly disposition. he found the life congenial but. lacking a vocation renounced it at the age of 29 and set off for Paris In 1744 he became assistant to the keeper of the royal collection of medals, succeeding him in 1753. In 1755 he accompanied the French ambassador, the comte de Stainville (later duc de Choiseul). to Italy, nhere he spent three years in archaeological research. Choiseul and his wife had a great regard for him and after his return to France helped him obtain valuable preferments. He wrote a number of learned antiquarian works, but his fame rests on *Voyage du jeune Anacharsis en Grèce, vers le milieu du quatrième siècle avant l'ère chrétienne* (1788: Eng. trans. 1794). which he began in 1757. The hero is a young Scythian who goes to Greece for instruction and returns to his native country where, in his old age, he describes his experiences. This loose plan enabled Barthélemy to use his wealth of learning to describe the laws, government, religion, philosophy, art and antiquities of ancient Greece. A long introduction records early Greek history and there are dissertations on Greek music, Athenian literature and the life and society of the surrounding states. Barthélemy's well-documented and well-written introduction to Hellenic culture rekindled interest in Greece and provided suitable reading for generations of French schoolchildren. He was elected to the Académie Française in Aug. 1789. Arrested in 1793. he spent 16 hours in prison but was released on orders from the Convention. He died April 30, 1795, in Paris.

BIBLIOGRAPHY.—Barthélemy's correspondence was published in *Correspondance inédite du comte de Caylus,* ed. by C. Nisard (1877), *Voyage en Italie,* ed. by A. Serieys (1801) and *Correspondance complète de Mme du Deffand avec la duchesse de Choiseul, l'abbé Barthélemy et M. Craufurt,* ed. by the marquis de Sainte-Aulaire (1866). *See* also *Mémoires sur la vie de l'abbé Barthélemy, écrits par lui-même* (1824); *Oeuvres complètes,* 4 vol. (1821–22); E. Mâle, "Le 150e anniversaire du *Jeune Anacharsis," Revue de France,* vol. iv. pp. 273–281, no. 14 (1938); M. Badolle, *L'abbé Jean-Jacques Barthélemy* (1926).
(R. NI.)

BARTHÉLEMY SAINT-HILAIRE, JULES (1805–1895), French philosopher and statesman, was born in Paris on Aug. 19, 1805. After working at the finance ministry (1825–28) he became a journalist. For signing the journalists' protest on July 28. 1830. he was imprisoned for a few days until the overthrow of Charles X. Under Louis Philippe he continued his journalism and was one of the founders of *Le Bon Sens.* His main interests, however, were philosophy, languages, history. sociology and political economy. In 1832 he began a monumental translation of Aristotle. published in 35 volumes (1833–95).

Barthélemy Saint-Hilaire became professor of ancient philosophy at the Collège de France in 1838 and a member of the Académie des Sciences Morales et Politiques in 1839. After the revolution of 1848 he was elected deputy for Seine-et-Oise, but withdrew after the *coup d'ktat* of Dec. 1851. To supplement his academic pension he worked as a woodcutter near Meaux till he obtained a post on *Le Journal des savants.* Accompanying Ferdinand de Lesseps to Egypt in 1855, he was appoiried secretary of the company being formed to construct the Suez canal. but resigned in 1858. He described his journey in *Lettres sur l'Egypte* (1856).

Re-elected deputy for Seine-et-Oise in 1869. Barthklemy Saint-Hilaire sat with the moderates in opposition to Napoleon III. In Feb. 1871 he was among those who proposed that Adolphe Thiers become head of the executive power and was appointed his unpaid secretary. A senator for life in 1875, he became vice-president of the senate (1880) and minister of foreign affairs under Jules Ferry (1880–81). He died in Paris on Nov. 24. 1895.

In addition to his Aristotle and several studies of oriental religions, Barthklemy Saint-Hilaire published a translation of Marcus Aurelius (1876), *Fragments pour l'histoire de la diplomatie française 1880–81* (1882). *L'Inde anglaise, son ktat actuel, son avenir* (1887), *Étude sur François Bacon* (1890) and *Victor Cousin, sa vie et sa correspondance,* 3 vol. (1895).

BARTHOLDI, FRÉDÉRIC AUGUSTE (1834–1904), French sculptor, creator of the famous statue of "Liberty Enlightening the World" in New York harbour, was a native of Colmar in Alsace where he was born on April 2, 1834. Bartholdi created various works connected with America. Apparently of a somewhat commonplace imagination. the artist surpassed himself in the "Lion of Belfort" (in Belfort, France), his masterpiece. which may be regarded as the best of a number of patriotic sculptures inspired by the French defeat of 1870–71. He died in Paris on Oct. 4, 1904. *See* LIBERTY, STATUE OF. (A. K. McC.)

BARTHOLIN, the name of a distinguished Scandinavian family, whose members achieved renown in medicine, science and the humanities during the 17th and 18th centuries *(see* Table).

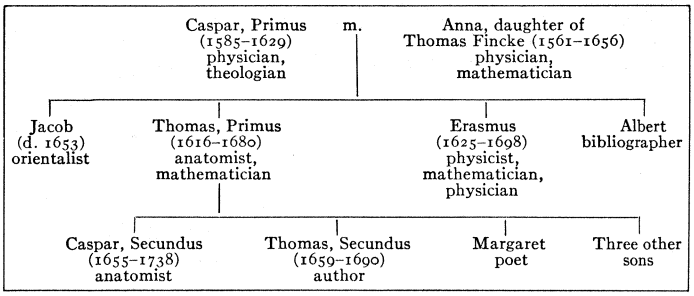
CASPAR, Primus (Gaspard Bartholinus) (1585–1629), the first

noted member of the line, was born in Malmö, Swed. He studied philosophy at Basel, Greek at Montpellier and anatomy at Naples and Padua; at the University of Padua he was a student of Fabricius ab Aquapendente. He took his medical degree in 1610, and from 1613 to 1624 served as professor of medicine in Copenhagen. After a serious illness he devoted himself to the study of divinity, became canon of Roskilde and professor of theology at Copenhagen, a position he held until his death at Sorö in Zeeland.

THOMAS, Primus (1616–1680), Caspar's second son, was born in Copenhagen and died in Hagested, Den. Associated with the Dutch school of anatomists, he was the first to give a full description of the entire lymphatic system, including the thoracic duct, in man. He also wrote in support of William Harvey's theory of blood circulation. His *Bartholinus Anatomy* was published in London in 1668. Thomas, Primus, was professor of mathematics in Copenhagen for two years before he assumed the chair of anatomy in 1648. He retired in 1661 but later returned to Copenhagen as the university librarian and physician to King Christian V.

ERASMUS (1625–1698), third son of Caspar, Primus, trained in

Genealogical Table of the Bartholin Family



medicine, is known chiefly for his mathematical studies, observations on snow crystals and discovery of double refraction.

CASPAR, Secundus (1655–1738), the eldest son of Thomas, Primus, was born in Copenhagen and studied anatomy in Holland under Frederik Ruysch and Jan Swammerdam and in Paris under G. J. Duverney. Stimulated by Duverney's discovery of the vulvovaginal glands in the cow, Caspar, Secundus, described these structures (the Bartholin glands) in the human as the source of the fluid that issues from the woman's genitals under sexual stimulation (*De ovariis mulierum et generationis historia* [Rome, 1677]). Bartholin's name is also associated eponymically with the duct of the submaxillary salivary gland. He devoted his later years to politics, and in 1731 was elevated to the nobility. (HD. ST.)

BARTHOLOMAEUS ANGLICUS (BARTHOLOMEW THE ENGLISHMAN) (fl. *c.* 1220–1240), Franciscan encyclopaedist, was born in England. He has occasionally been confused with a later English Franciscan, Bartholomew de Glanville, who was active about 1360. Bartholomew the Englishman became a professor of divinity at the University of Paris and about 1225 joined the recently founded Franciscan order. In 1231 he went to Magdeburg in Saxony on business connected with his order.

Bartholomew was famous for centuries after his death as the compiler of a very well-known and highly esteemed encyclopaedia, *De proprietatibus rerum* ("On the Properties of Things"). Though primarily interested in scripture and theology, he included all the customary knowledge of his time; and, in addition, was the first writer to make conveniently available the views of Greek, Jewish and Arabic scholars on medical and scientific subjects. The immense popularity of this pioneer work is shown by the very large number of manuscript copies of it to be found in European libraries and by the fact that it was regularly hired out to scholars at the University of Paris. There were 14 printed editions of the work even before 1500. It was translated into English by John of Trevisa and printed by Wynkyn de Worde about 1495, and it also appeared in other vernaculars. Very popular reading in Tudor England, it had much influence on English thought and writing in the 16th century. (E. MCD.)

BARTHOLOMÉ, PAUL ALBERT (1848–1928), French sculptor whose works, particularly his funerary art, made him one of the best known of modern French sculptors, was born at Thiverval, near Paris, on Aug. 29, 1848. He began his career as a painter and did not turn to sculpture until 1886. He had no formal training, but he made a careful study of nature and the masterpieces of the past. His reputation was established with the "Monument aux Morts" (1895) which was set up in the Père Lachaise cemetery, Paris. It is a piece of architectural sculpture on a grandiose scale with a number of mourning figures in differing postures of grief, and decidedly non-Christian in feeling, though destined for a Christian cemetery. This success led to a number of funerary monuments. In his later period he tended toward a somewhat Rodinlike impressionistic sculpture. There was a great deal of modulated chiaroscuro and pictorial quality in his many feminine nudes. He died in Paris on Oct. 31, 1928. (A. K. MCC.)

BARTHOLOMEW, SAINT, one of the 12 Apostles, mentioned only in the four Apostle lists (Mark iii, 18; Matt. x, 3; Luke vi, 14; Acts i, 13), always in the second of the three groups of four names. Nothing more is known about him from the New Testament. The name is an Aramaic patronymic, meaning "son (*bar*) of Tolmai" or "Talmai," so that he may have had another personal name. Because it is such a name, and because he was always associated with Philip in the Gospel lists, a 9th-century tradition identified him with Nathanael, whose call with that of Philip is recounted in John i, 43–51. This identification sought to explain how Bartholomew, an otherwise unknown personage, could be mentioned as one of the Twelve, while Nathanael, whose call is explicitly described by John, does not figure in the lists. His full name would then be Nathanael bar Tolmai.

Eusebius in his *Church History* relates that when Pantaenus of Alexandria visited India in the 2nd century he found the Hebrew "Gospel According to Matthew," which had been left behind by Bartholomew. His missionary activity is recorded also for Ethiopia, Mesopotamia, Parthia, Lycaonia and Greater Armenia. He is traditionally said to have been martyred (either flayed alive, beheaded or crucified) at Albanopolis or Urbanopolis in Armenia at the command of King Astyages after the conversion of King Polymios. His relics are said to have been transferred ultimately to the Roman Church of St. Bartholomew on an island in the Tiber. His feast is now celebrated in the Latin Church on Aug. 24, in the Greek Church on June 11; it varies in other Eastern rite churches. (J. A. FI.)

BARTHOLOMEW, a family of Scottish cartographers. JOHN BARTHOLOMEW (1831–1893) was born in Edinburgh, the son of a map publisher. He was for some time assistant to the German geographer, August Petermann, until in 1856 he took up the management of his father's firm. Among his numerous publications were the series of maps of Great Britain reduced from the ordnance survey to scales of $\frac{1}{2}$ in. and $\frac{1}{4}$ in. to 1 mi. Relief was shown on these maps by contours and systematic layer colouring, a method introduced into British cartography by his son JOHN GEORGE BARTHOLOMEW (1860–1920). He produced survey atlases of Scotland (1895) and England and Wales (1903), and initiated a great physical atlas of which, however, only two volumes were published, the *Atlas of Meteorology* (1899) and the *Atlas of Zoogeography* (1911). He also began compiling *The Times Survey Atlas of the World,* the best British atlas of its period, published in 1922 by his son JOHN BARTHOLOMEW (1890–1962). The firm has published in numerous editions reference and educational atlases and many maps in its distinctive style. John Bartholomew edited the new *The Times Atlas of the World* (1955, etc.). (G. R. CE.)

BARTHOU, JEAN LOUIS (1862–1934), French Conservative statesman and man of letters, was born at Oloron-Sainte-Marie on Aug. 25, 1862. He practised as a lawyer in Pau and in 1889 was elected deputy. He became minister of public works in Charles Dupuy's cabinet (1894), in which Raymond Poincaré also made his debut. Minister of the interior in F. J. Méline's cabinet (1896), he returned to the ministry of public works in 1906 under Ferdinand Sarrien, to remain there under Clemenceau. As prime minister from March to Dec. 1913, Barthou secured, against the opposition of the left, the passing on July 19, 1913, of the three years' service bill. He was minister of state in Paul Painlevé's cabinet (1917), minister of war under Aristide Briand

(1921) and minister of justice under Poincaré (1922). In 1922, moreover, he represented France at the Genoa conference, entered the senate and was appointed chairman of the reparations commission. In July 1926 he came back to the ministry of justice in another Poincaré cabinet. Foreign minister in the coalition ministry presided over by Gaston Doumergue (1934), he visited Warsaw, Prague, Bucharest and Belgrade, to discuss plans for an eastern pact. On Oct. 9 of the same year, he was assassinated in Marseilles together with King Alexander of Yugoslavia. A shrewd politician and a first-class debater. Barthou was also a great booklover. He was elected to the Académie Française in 1918. Among his many books were *Mirabeau* (1913); *Les Amours d'un poète* (1919), on Victor Hugo; *La Politique* (1923); and *Promenade autour de ma vie* (1933). (J. C. DE C.)

BARTLESVILLE, a city of northeast Oklahoma, U.S., the seat of Washington county, is on the Caney river, 18 mi. from the Kansas state line. It grew from a settlement started in the late 1870s near a trading post operated by Jacob Bartles. Oklahoma's first commercial oil well was drilled at Bartlesville in 1897, the year of the city's incorporation.

Oil contributed most to the city's growth. It is the home of Phillips Petroleum, Cities Service and National Zinc companies and many smaller industries. The 19-story Price Tower, designed by Frank Lloyd Wright and dedicated in 1956, is the city's most distinctive building. Woolaroc museum, established by oilman Frank Phillips and housing a collection including more than 50,000 regional items, is 11 mi. west of Bartlesville.

Bartlesville has had a council-manager form of government since 1927. For comparative population figures *see* table in OKLAHOMA: *Population.* (W. A. SE.)

BARTLETT, JOHN (1820–1905), is best known for his *Familiar Quotations* (1855), which went through nine editions in his lifetime and appeared in a 13th (centennial) edition in 1955. He was born in Plymouth. Mass., on June 14. 1820, and at the age of 16 became an employee in Cambridge, Mass., at the university bookstore, where he became so versed in book knowledge that the advice "Ask John Bartlett" became common on the Harvard campus. Eventually owning the store, he published the first edition of his *Familiar Quotations,* based largely on the notebook which he kept for the benefit of his customers. Later editions, greatly expanded, were published from the fourth on by Little, Bronn and Company, Boston, which Bartlett joined in 1863. Bartlett also wrote books on chess and angling, and, after many years of labour, a *Complete Concordance to Shakespeare's Dramatic Works and Poems* (1894), a standard reference work which surpassed any of its predecessors in the number and fullness of its citations. He died at Cambridge, Mass., on Dec. 3, 1905.

See J. D. Marshall, "John Bartlett and His Quotation Book," Wilson *Library* Bulletin, 30:250–252 (Nov. 1955).

BARTLETT, JOHN RUSSELL (1805–1886), U.S. bibliographer, made his greatest contribution to linguistics with his pioneer work, *Dictionary of Americanisms: a Glossary of Words and Phrases Usually Regarded as Peculiar to the United States* (1848). It went through four editions, and was translated into Dutch and German. He was born at Providence, R.I., on Oct. 23, 1805. Appointed commissioner for the survey of the boundary between the United States and Mexico in 1850–53, he wrote as a result *A Personal Narrative of Explorations and Incidents in Texas, New Mexico, California, Sonora and Chihuahua* (2 vol., 1854). As secretary of state of Rhode Island, he rearranged and classified the state records, and prepared bibliographies and compilations on state history. Bartlett assisted John Carter Brown in acquiring and cataloguing his noted book collection, now in the John Carter Brown library on the campus of Brown university (Providence, R.I.).

He died in Providence, on May 28, 1886.

BARTLETT, PAUL WAYLAND (1865–1925), U.S. sculptor, whose animal, historical and symbolic subjects were done in the French romantic tradition, was born in New Haven. Conn., on Jan. 24, 1865. When 1j, he began to study at Paris under Emmanuel Frémiet, modeling animals. He won a medal at the Paris salon of 1887. The greater part of his life was spent in France. Among his early works are: "The Bear Tamer," in the Metropolitan museum, New York; the equestrian statue of Lafayette, in Paris; and the equestrian statue of George B. McClellan in Philadelphia. Of his later works the most notable is the group in the pediment over the house wing of the Capitol, Washington, D.C. He was made a commander of the Legion of Honour before his death in Paris on Sept. 20, 1925.

See Lorado Taft, *History* of *American Sculpture,* rev. ed. *(1924).* (A. T. G.)

BARTÓK, BÉLA (1881–1945), Hungarian composer, pianist and folklorist, one of the dominant and most original figures in music in the first half of the 20th century, was born at Nagyszentmiklós, Hung. (now Sinnicolau Mare, Rum.), March 25. 1881. He showed musical talent early, and was taught by his mother. In 1894 he began more serious studies in Pozsony (now Bratislava) and in 1899 entered the Hungarian Royal Academy of Music in Budapest to study piano with István Thomán and composition with Hans Koessler. In 1903, under the influence of Richard Strauss, he wrote a patriotic symphonic poem, *Kossuth.* In 1905 he first became aware of genuine Hungarian peasant music (then almost unknown to musicians), in which he found the idiomatic basis for the national musical style that he wanted to create, and in 1906, with his lifelong friend Zoltán Kodály, he published a first small collection of peasant tunes, with simple piano accompaniment. In 1907 he was appointed, to the piano-teaching staff of the Hungarian Royal Academy of Music and in 1908 he produced what he later regarded as his first representative works, including the String Quartet No. 1. His one-act opera, *Duke Bluebeard's Castle* (1911), in which the melodic style is based on the characteristics of Hungarian folk music, was rejected in a competition and also by the Budapest Opera house. This and other discouragements caused him to give up composing and performing and to concentrate on the collection and editing of folk music. He took heart again only in 1917 when his ballet *The Wooden Prince* (1914–16) was produced at the Budapest Opera house with such success that in the following year *Duke Bluebeard's Castle* was also produced there. The important works of this period, the String Quartet No. 2 (1915–17), Five' Songs, Op. 16 (1916; settings of poems by Endre Ady), and the ballet *The Miraculous Mandarin* (1918–19), were characterized by increasing freedom of tonality and identification with the expressionist tendency of the time, which reached their extreme point in Bartók's music in the two sonatas for violin and piano (1921–22).

After World War I, when Universal Edition of Vienna took over the publication of his works, his international reputation grew rapidly. In 1923 he was commissioned to write an orchestral work for a concert celebrating the 50th anniversary of the union of Buda and Pest, and produced the *Dance Suite.* By 1926, after three fallow years again devoted to folklore during which he evidently went through a crisis as a composer, he had abandoned the expressionist style for a neoclassical one, though this was slightly obscured by the percussive dissonance of his language. The works of 1926 were all for piano (a concerto, a sonata and two sets of shorter pieces), and were written for Bartók's own use on his concert tours. Other important works in the next few years were the String Quartets Nos. 3 (1927) and 4 (1928), the *Cantata Profana* (1930) and the Piano Concerto No. 2 (1930–31). In the String Quartet No. 4 he made his most far-reaching application of the principle of symmetry, both in its formal plan and in its harmonic language, but in the cantata and concerto he reverted to a slightly simpler tonal idiom. After another period devoted mainly to folk music, Bartók produced the String Quartet No. 5 (1934), which again prominently exemplifies certain devices of symmetrical construction, but is less concentrated in style than No. 4. It is generally regarded as the first work of his "mellow" final period, in which he achieved a synthesis of his earlier experimental styles. It was followed by the Music for Strings, Percussion and Celesta (1936), the Sonata for Two Pianos and Percussion (1937), Violin Concerto (1938), Divertimento for Strings (1939) and String Quartet No. 6 (1939), all commissioned from abroad. During this period Bartók was released from his duties at the Royal Academy of Music so that he could prepare for publication

his vast collection of Hungarian folk music.

In 1940, Bartok immigrated to the United States, where he had difficulty in settling. His compositions were not often performed and he found few engagements as a pianist. An appointment to prepare for publication a Yugoslav folk song collection at Columbia university gave him modest security till 1942, but shortly after this his health. never strong, gave way completely. There was a turn for the better when in 1943 he composed the Concerto for Orchestra for the Koussevitzky Music foundation. This is even more accessible in style than the late European works. Several further commissions followed, but the only other works Bartok was able to complete were the unaccompanied Violin Sonata for Yehudi Menuhin (1044). the Piano Concerto No. 3 for his second wife, Ditta (1945), and a confused draft of a Viola Concerto for William Primrose, deciphered after his death by Tibor Serly. In addition to the major works mentioned above, Bartok published, among hundreds of small pieces, two important collections of piano pieces for educational use, *For Children* (1908–09) and *Mikrokosmos* (1926–37). He also published definitive works on Hungarian and Rumanian folk music and left behind important Hungarian. Rumanian and Slovak material. He died of leukemia in New York, Sept. 26, 1945.

Immediately after his death Bartok's music won wide acclaim and he is generally acknowledged, with Schonberg and Stravinsky, as one of the three great masters of his time. With Kodály he created the first genuinely Hungarian music of universal and enduring interest, comparable with the national music of Chopin, Dvofak and Smetana or of Borodin and Mussorgsky. In the range and variety of his output he surpasses even Dvořák, while in originality, proximity to the mainstream of music in his time and transcendence of mere "national" charm, his music is nearer to Chopin's. These two comparisons give a clue to what is likely to he the final assessment of his position among his contemporaries and in the history of music.

BARTOLI, DANIELLO (1608–1685), Italian Jesuit humanist, was born at Ferrara on Feb, 12, 1608, and entered the Society of Jesus in 1623. As author of the well-known and frequently translated *Dell' Huomo di Lettere,* he ranked among classic Italian writers. He also was a historian—biographer of Ignatius Loyola, Francis Xavier, Francis Borgia and other Jesuit saints and author of a history of the missionary works of his order in the orient. He died at Rome on Jan. 12. 1685. (J. F. BN.)

BARTOLI, MATTEO GIULIO (1873–1946), Italian linguist who deduced a general theory known as neolinguistics. or areal linguistics, was born on Nov. 22. 1873, in Albona (Istria). Having obtained his doctorate at the University of Vienna. Bartoli in 1907 became professor at the University of Turin, where he remained until his retirement. An important early study, *Das Dalmatische* (1906). concerns the now extinct Romance dialect of the island of Veglia (Dalmatia). Bartoli's chief interest was the Romance languages. According to his doctrine of neolinguistics, there exists a direct and causal connection between areal linguistic expansion and distribution on one hand, and linguistic change and its chronology on the other *(see* his *Introduzione alla neolinguistica* [1925], and *Saggi di linguistica spaziale* [1945]). From the well-attested Romance domain, Bartoli transferred his operations to that of reconstructed (Proto-) Indo-European. He also initiated the new *Atlante linguistico italiano,* and from 1926 to 1942 was coeditor of the journal *Archivio glottologico italiano,* in which he published numerous articles. He died on Jan. 23, 1946, at Turin.

See *Belfagor,* vol. 3, pp. 315–325 (1948) for a complete bibliography by Benvenuti Terracini. (E. PM.)

BARTOLOMMEO, FRA (BACCIO DELLA PORTA, sometimes called IL FRATE) (1472–1517). Italian painter of portraits and religious subjects of the Renaissance Florentine school. was horn Bartolommeo di Pagolo de Fattorino in the village of Soffignano. near Florence. on March 28. 1472. A pupil of Cosimo Rosselli, he was a close student of the works of Leonardo da Vinci. Of his early productions, the most important is the fresco of the '(Last Judgment," in which he was assisted by his friend Mariotto Albertinelli. He came under the influence of Savonarola, and was so affected by his death that he soon after entered the Dominican convent and for some years gave up his art. He had not long resumed it, in obedience to his superior, when Raphael came to Florence and formed a close friendship with him. Bartolommeo learned from the younger artist the rules of perspective, while Raphael owes to Bartolommeo the improvement in his colouring and handling of drapery. Some years afterward he visited Rome, and was struck with a feeling of his own inferiority when he contemplated the masterpieces of Michelangelo and Raphael. On his return he painted the magnificent figure of St. Mark (his masterpiece, at Florence) and the undraped figure of St. Sebastian. He painted a profile portrait of his friend Savonarola in the character of St. Peter Martyr. He died in Florence on Oct. 31, 1517. The majority of Bartolommeo's compositions are altarpieces. The best collection of his works is in the Pitti palace. Florence. The Louvre possesses an "Annunciation" and a "Virgin in Glory," and there are examples in the National Gallery, at Panshanger, Eng., in Berlin and elsewhere.

BARTOLOMMEO VENETO: *see* VENETO, BARTOLOMMEO.

BARTOLOZZI, FRANCESCO (1727–1815), Italian engraver, and engraver to George III of England, was born at Florence on Sept. 21, 1727. He was originally destined to follow the profession of his father: who was a gold- and silversmith, but he manifested so much skill and taste in designing that he was placed under the superintendence of two Florentine artists, who instructed him in painting. After devoting three years to that art, he went to Venice and studied engraving, being apprenticed to Joseph Wagner. He then moved to Rome, where he engraved works by Il Domenichino and other Italian masters, and completed a set of engravings representing events from the life of St. Nilus. After returning to Venice, he set out for London in 1764 at the invitation oi Dalton, librarian to George III. He became engraver to the king. For nearly 40 years he resided in London with his friend Giovanni Cipriani, in Warwick street, Golden square. London, and executed a large number of engravings for George III which are still in the royal collections, including the engravings after Holbein's drawings at Windsor. Among others are those of "Clytie" and "Silence," after Annibale Carracci; of the "Virgin and Child," after Carlo Dolci, and of the "Madonna del Sacco," after Andrea del Sarto. He engraved many works of Cipriani and Angelica Kauffmann. Bartolozzi also contributed a number of plates to Boydell's *Shakespeare Gallery.* In 1802 he was invited to Lisbon as director of the National Academy. He remained in Portugal till his death on March 7, 1815.

In his later years in London Bartolozzi had a studio where many works, signed with his name but to which he only put the finishing touches, were produced. He was not the inventor of the red chalk manner of engraving, which was already practised in France by Gilles Demarteau, but, encouraged by Angelica Kauffmann, Bartolozzi made it the fashion.

Bartolozzi's son, Gaetano Stephano (1757–1821), also an engraver, was the father of Madame Vestris (*q.v.*).

See A. Tuer, *Bartolozzi and His Works* (1882); *C*. H. S. John, *Bartolozzi, Zoffany, Kauffmann With Other Foreign Members of the Royal Academy, 1768–92* (vol. xvi of *British Artists,* 1924).

BARTOLUS (1313–1357). Italian jurist, the most famous of the post-glossators (or commentators), was born at Sassoferrato, whence his usual name of Bartolus de Saxoferrato. He studied law under Cinus at Perugia and under Oldradus and Jacobus de Belvisio at Bologna. He held the chair of lam at Perugia from 1343 onward, and made the law school of Perugia as famous as that of Bologna. He was also a legal practitioner and had been an assessor to the courts at Todi and Pisa.

He and the members of his school used the Corpus Juris of Justinian and the work of the glossators thereon. together with the canon law, as a foundation for a body of legal principles which could be used in practice. These principles became the common law of Italy. but were also recognized as law in other parts of Europe, particularly in Spain. Portugal and Germany.

Some writers have attributed, the introduction of the dialectical method to Bartolus; but this had been employed in the 13th century by Odofredus, a pupil of Accursius, whose successors had abused it by burying their subject matter under dialectical forms. Bartolus reformed this abuse and avoided excess; but his great reputation was probably due to his revival of the exegetical system of teaching law. His treatises *On Evidence* and *On Procedure* are his best-known works; his *Commentary on the Code of Justinian* has sometimes been exalted almost to an equal authority with the code itself. (RL. P.)

BARTON, BENJAMIN SMITH (1766–1815), U.S. physician and naturalist, whose *Elements of Botany* (1803) is considered to be the first elementary botany written by an American, was born at Lancaster, Pa., Feb. 10, 1766. When only 24 years old he was appointed to a professorship of natural history and botany at the College of Philadelphia, now the University of Pennsylvania—probably the first position of its kind in any U S. college. Later be became professor of materia rnedica (1795) and successor to Benjamin Rush in the chair of practical medicine (1813).

Having an ardent thirst for literary fame as well as wide scientific knowledge, Barton wrote books on such diverse subjects as the natural history of Pennsylvania, goitre, the rattlesnake, the honeybee, the stimulant effects of camphor on vegetables, and numerous other subjects in natural history, botany and materia rnedica. In 1802 he was chosen president of the American Philosophical society and was a member of honorary scientific societies in Russia, England, Scotland and Denmark. He died in Philadelphia, Dec. 19, 1815.

See W. J. Youmans (ed.), *Pioneers of Science in America* (1896).

BARTON, CLARA (CLARISSA HARLOWE BARTON) (1821–1912), founder of the American Red Cross, was born in Oxford, Mass., Dec. 25, 1821. At the age of 15 she became a schoolteacher and continued in that profession for 18 years, both in Massachusetts and New Jersey. In 1854 she took up residence in Washington. D.C., and became a clerk in the U.S. patent office. At the outbreak of the American Civil War she acted on her own initiative to obtain and distribute supplies for the relief of wounded soldiers. At the end of the war she organized at Washington a bureau of records to aid in the search for missing men. In 1869 Miss Barton went abroad for a rest but upon the outbreak of the Franco-Prussian War the following year she again plunged into the task of aiding the victims of war and associated herself with the International Red Cross. In 1873 she returned to the United States, where she at once began her efforts to establish a United States branch of the Red Cross and to bring her country into the 1864 Geneva convention (*q.v.*). Her efforts were successful in 1881–82. She became the first president of the American Red Cross, holding the position until 1904. She was the author of the so-called American amendment to the constitution of the Red Cross which provides that the society shall distribute relief not only in war but in times of such other calamities as famines, floods, earthquakes, cyclones and pestilence. She conducted the society's relief for sufferers from many disasters during the 1880s and 1890s. She wrote an official *History of the Red Cross* (1882); *The Red Cross in Peace and War* (1898); *A Story of the Red Cross* (1904), and *Story of My Childhood* (1907). She died at Glen Echo, Md., on April 12, 1912.

See P. H. Epler, *Lije of Clara Barton,* new ed. (1953); W. E. Barton, *Lije oj Clara Barton,* 2 vol (1922); Ishbel Ross, *Angel of the Battlefield: the Lije of Clara Barton* (1956).

BARTON, SIR EDMUND (1849–1920), Australian statesman, who helped bring the federal movement to a successful conclusion and became the first prime minister of the Commonwealth of Australia, was born in Sydney on Jan. 18, 1849. He graduated in classics from the University of Sydney, then studied law and entered the New South Wales legislature (1879). Periods as speaker of the house of assembly (1883–87) and as attorney-general (1889 and 1891–93) brought him nearly to the top of colonial politics, and he was acting premier for some months in 1892. Barton had become the leader of the federal movement after the retirement of Sir Henry Parkes in 1891 and had only joined the government that year on the understanding that he should be free to promote this cause. There was strong opposition to the movement throughout New South Wales, which as the oldest and most richly endowed colony had little to gain from federation. In taking up the cause, therefore, Barton risked his career; it was largely because of his tireless efforts, particularly during 1894–97 when he lost his seat in the legislative assembly, that a bare majority in the colony came to accept federation. Barton did much to shape the actual form of the Commonwealth constitution; he was chairman of the committee which drafted (1897) the constitutional bill, and he went to London to see the bill through the English parliament in 1900. He became the first Commonwealth prime minister the following year and for two years successfully led a difficult government composed mainly of colonial statesmen used to being leaders in their respective states. Knighted in 1902. he resigned the premiership and accepted the appointment of senior puisne judge of the high court of Australia in 1903. He died at Medlow, near Sydney, on Jan. 7, 1920.

In neither politics nor religion was Barton deeply committed to any creed. Traditionally he has been charged with indolence, but emphasis should be placed on his urbanity, enjoyment of life and powers of charm and friendship.

See John Reynolds, *Edmund Barton* (1948). (O. M. R.)

BARTON, ELIZABETH (*c.* 1506–1534), the "nun of Kent," English ecstatic whose outspoken prophecies fermented public disquiet over the matrimonial policy of Henry VIII and led to her own execution. Born in the archbishop of Canterbury's manor of Aldington, Kent, she served as a maid in the house of the steward there. She fell ill, showing physical and hysterical symptoms, in 1525, and began to experience trances and to utter prophecies. Archbishop William Warham instituted the customary inquiry through two monks of Christ church, Canterbury, one of whom. Edward Bocking, became Elizabeth Barton's confessor and manager. Her fame spread through the county: her exemplary life and sound counsel gained for her a group of devotees both clerical and lay, among them Warham and Bishop John Fisher. Even Sir Thomas More was for a time impressed by her. Cnfortunately for herself, her prophecies grew less mystical and more precise; either spontaneously or, more probably, by Bocking's guidance, she began to threaten Henry VIII with dire consequences if he did not drop his projected divorce from Catherine of Aragon and abandon Anne Boleyn. After Henry's marriage with Anne had been declared valid (May 28. 1533), Elizabeth Barton's utterances approached the treasonable, and the new archbishop of Canterbury, Thomas Cranmer, took steps to investigate her. Arrested and examined, she finally confessed to having feigned her trances and pretended her inspiration, and in the session of Jan.–March 1534 she was condemned, with her chief adherents, by act of attainder, the execution taking place at Tyburn, London, on April 21, 1534. Although the confession was extracted without torture, the proceedings seem utterly to have confused this woman of no education and little intellect; there is no certainty that she confessed the truth. It may at any rate be agreed that she had in her more of the hysteric than of the saint. and that the political tenor of her later prophecies represented an uncalled for exploitation of the faith she had aroused; but it is probable that she was in the main sincere—deluded rather than deluding.

BARTRAM, JOHN (1699–1777), the first native American botanist. noted for his naturalistic explorations, was born near Philadelphia, Pa., on May 23, 1699. A friend of Benjamin Franklin and an original member of the American Philosophical society, he was largely self-educated and was regarded as a liberal Quaker. Bartram farmed actively, yet followed an impelling scientific curiosity to explore the virgin forests. The seeds and plants that he collected were in great demand abroad and aided in his establishing friendships with European botanists, among them Peter Kalm and Linnaeus.

As early as 1739 he hybridized flowering plants. In 1743 the

British crown commissioned Bartram to visit the Indian tribes of the League of Six Nations and to explore the wilderness north to Lake Ontario in Canada. He reported not only on the negotiations but also on the soil types and the forest formations encountered On the banks of the Schuylkill river near Philadelphia. he established a botanical garden which became internationally famous for extensive plantings of local and foreign plants. Under George III he held the post of botanist to the king for the American colonies. *Bartramia,* a genus of American mosses was named for him He discovered the shrub *Franklinia alatamaha.* During 1765–66 Bartram explored extensively in Florida in company with his son William; the latter also became renowned as a naturalist and nature artist whose *Travels* (1791) greatly influenced English Romanticism. John Bartram died Sept. 22, 1777.

BARUCH, BERNARD MANNES, (1870–) U.S. financier and presidential adviser. was barn Aug. 19, 1870, in Camden, S.C. After graduating from the College of the City of New York in 1889 he began his career as an office boy at the age of 19, first in the linen business and then in Wall street brokerage houses. He amassed a fortune as a Wall street speculator and made generous contributions to a variety of charities and to the financing of public causes. Baruch came into public life through his appointment by Pres. Woodrow Wilson in 1916 to the advisory commission of the Council of National Defense. He later became chairman of the War Industries board during World War I. In 1919 he was appointed a member of the Supreme Economic council at the Versailles pence conference, an office which he combined with that of personal economic advisor to the president on the terms of peace. From that time forward his advisory services were sought by the presidents who succeeded Wilson. As an expert in wartime economic mobilization he was much in demand as an adviser during World War II but did not hold any administrative position. After the war he helped to formulate U.S. policy at the United Nations, particularly on the international control of atomic energy.

See his autobiography, *Baruch:* My *Own Story* (1937); Margaret L. Coit, *Mr. Baruch* (19.57). (FK. L. K.)

BARUCH, BOOK OF. The name of Baruch. Jeremiah's friend and secretary, is attached to several early writings *(see* BARUCH APOCALYPSES). One of these, the Book of Baruch, is included with the Apocrypha by Protestants and with the deuterocanonical books by Roman Catholics and Orthodox. The book has survived in Greek. from which all ancient versions derive. The sixth and last chapter purports to be a letter by Jeremiah *(see* JEREMY, EPISTLE OF). Bar. i, 1–iii, 8 may have formed part of the Book of Jeremiah, for the text bears the same characteristics as the Greek translation of the second part of Jeremiah.

The Book of Baruch falls into three parts. The first (i, 1–iii, 8) is a liturgical confession and prayer preceded by a historical introduction in which Baruch is said to have read the book before the Jewish exiles. Then a collection of money was made that was sent to Jerusalem for the offering of sacrifices. The second part (iii, 9–iv, 4) is a panegyric on Wisdom, which is here identified with the Law. The Law is the source of life. Israel is now wasting away in a foreign country because she has strayed away from the Law. If Israel will walk in the way of the Law, she will find life and enjoy happiness again. The third part (iv, 5–v, 9) is a moving appeal to Jerusalem together with a reassuring promise of her approaching deliverance. In iv, 5–29 Jerusalem cheers her exiled children, exhorting them to penitence and hope. and in iv. 30–v, 9 God himself consoles Jerusalem; promising her deliverance and threatening her enemies with retaliation. The second and third parts are poetry.

Older critics generally maintained that the whole book originally was written in Creek, while others advocated a Hebrew origin. Modern critics believe that the book originally was written in different languages. That the first part, or at least i, 15–iii, 8. was written in Hebrew is universally recognized, though some scholars believe that i, 1–14 n-as written in Greek imitative of the Septuagint. A Hebrew original also is assumed, though less confidently, for the second part. The third part is held by some to have been written in Greek. by others in Hebrew. These differences of language and literary forms indicate that Baruch is a composite work of more than one author. But the historical allusions in the book are so uncertain and internal evidence is so slender as to render the determination of the date of composition and final redaction extremely difficult and uncertain. That the book was written by Baruch himself is almost untenable, but it is equally difficult to bring its composition down to Roman times.

The dependence of Bar. i, 15–ii. 17 on Dan. ix, 7–19 and the historical confusion which it shares with Daniel of making Belshazzar the son of Nebuchadrezzar shows the first part to be later than the middle of the 2nd century B.C. Its historical situation is thought by some to fit the period after the destruction of Jerusalem in A.D. 70, but the references to the Roman period are difficult to prove. Indeed the confession is couched in such general terms and bears such striking affinity of ideas and expressions with similar confessions in Neh. ix, 6–37; Dan. iii, 26–45, ix, 4–19 that one doubts whether the writer is alluding to historical events or is using a stereotyped form that is applicable to any time of national calamity.

The date of origin of the second part is more difficult to determine. The historical situation of an age-long dispersion of the Jews among the nations may apply to any time after the exile. The dependence on the wisdom books and on Job is obvious. Protestant critics mostly place the origin of the second part during the Roman period, while Roman Catholics, who do not attribute the work to Baruch, prefer an earlier, though postexilic, date.

It is still more difficult to place the third part in any well-known historical situation. The people are, apparently, in exile, but deliverance is near. This seems to be applicable only to the last days of the exile when Deutero-Isaiah was announcing the impending deliverance. There remains, however, the possibility that a later writer adapted Deutero-Isaiah's literary style and ideas to his own times. The relation between the third part and the Psalms of Solomon is evidence that can be taken either way. While priority is generally given to the Psalms, a dependence in an inverse order is also possible. Those who hold to a Greek original naturally bring down the composition of the third part to the Hellenistic age.

Baruch is never quoted in the New Testament, and is very rarely read in the liturgy. The text "Afterwards he was seen upon earth, and conversed with men" (iii, 37, but 38 in Septuagint) was regarded by some Greek Fathers as a prophecy of the Incarnation.

BIBLIOGRAPHY.—For Greek text *see* editions of the Septuagint. Eng. trans. with introduction and notes by O. C. Whitehouse in R. H. Charles (ed.), *Apocrypha and Pseudepigrapha of the Old Testament in English,* vol. i (1913). *See* also W. O. E. Oesterley, *An Introduction to the Books of the Apocrypha* (1933); B. S. Salomonischen Psalms von letzten Kapitel des Buches Baruch," *Zeitschrift* fur *die alttestamentliche Wissenschaft,* vol. lxvii, pp. 251–263 (1955). (P. P. SA.)

BARUCH APOCALYPSES. Baruch was the amanuensis of the Old Testament prophet Jeremiah (Jer. xxxvi, 4). His close association with the prophet, the fact that he lived at a time of disaster. and an absence of other information about him caused his name to be chosen as a pseudonym by various apocalyptic writers. The list of knoan writings is as follows:

1. The Book oi Baruch as included in the Apocrypha *(see* BARUCH, BOOK OR,).
2. The Syriac Apocalypse of Baruch *(see* below).
3. The Epistle of Baruch, as in the Syriac Bible.
4. The Greek Apocalypse of Baruch *(see* below).
5. The Rest of the Words of Baruch, as in the Ethiopic Bible and some Greek manuscripts.
6. A Gnostic Book of Baruch, quoted by Hippolytus.
7. A Latin Book of Baruch, quoted by Cyprian.
8. A further Book of Baruch, quoted in *Altercatio Simonis Judaei,* etc.

Possibly the Baruch in the Apocrypha is based on part of the Syriac Apocalypse (which appears to be incomplete), and the Epistle is nine chapters of this work. The Apocalypses appear to be independent works, as does "the Rest."

Syriac Apocalypse.—This work (also called II Baruch) survived only in Syriac, though it is clearly a translation from the Greek. itself a translation from a Semitic language (Hebrew or Aramaic). Fragments of the Greek have been identified among the Oxyrhynchus papyri (a collection of 4th-century, and earlier, papyrus fragments found in Egypt). The book is commonly divided into seven sections: (1) God announces the fall of Jerusalem (i–xii); Baruch is told to remain in the ruined city for re\-elations of the end of the world. (2) He is given an explanation of the prosperity of the wicked and the suffering of the righteous (xiii–xx). (3) The time of the end has 12 divisions. each with its own tribulation (xxi–xxxiv); then Messiah mill inaugurate his reign, which will be followed by a general resurrection either to glory or to perdition (4) In vision, Baruch sees a vine destroy a mountain and cedar forest, foretelling the overthrow of the gentiles and the triumph of Israel (xxxv–xlvi). (5) He inquires after the nature of the resurrection body, which is explained as the restoration of the physical form which the earth received (xlvii–lii). (6) He sees in vision the history of Israel in the imagery of alternative periods of black rain and bright, but the last period (the messianic) is bright (liii–lxxvi). (7) He sends letters of admonition to the nine and one-half tribes and to the two and one-half tribes, but only the content of the former letter is given (lxxvii–lxxxvii).

Whether the book is the work of one author or a compilation is debated, but in its present form it probably dates between A.D. 100 and 130, and attempts to correct the overpessimistic outlook of IV Ezra.

Greek Apocalypse.—This (also called III Baruch) has survived only in Greek and, as condensed, in Slavonic. Baruch, weeping over the destruction of Jerusalem, is told to restrain his grief for he will be shown the mysteries of heaven. He is conducted through five heavens. In the first two are the men of the tower of Babel, smitten with brute stupidity. In the third he sees a dragon devouring the wicked, and is also shown a vine, the forbidden tree of paradise. (A Christian interpolation defends wine as that which becomes the blood of Godj. He then sees the chariot of the sun and the phoenix, and the moon and the stars in their motions. In the fourth heaven is the pool from which the souls of the righteous drink, and which is the source of fructifying dew on earth. In the fifth he sees Michael receiving the good deeds of the righteous from their guardian angels and returning them blessings. The angels of the wicked are bidden to go and punish them severely with sword and death and demons. Probably the original continued with a sixth and seventh heaven, but the manuscript comes to an abrupt close at this point.

Teaching.—The Syriac is a serious work, emanating from the same kind of background as IV Ezra, the teaching of which it parallels with interesting divergencies (see EZRA, FOURTH BOOK OF). These two books reveal the apocalyptic movement at its best. The Greek, on the other hand, illustrates the puerility into which apocalyptic cosmological speculation often fell. It is chiefly remarkable for its doctrine of guardian angels (*cf.* Matt. xviii, 10).

BIBLIOGRAPHY.—The Syriac test (II Bar.) was edited by A. M. Ceriani in *Monumenta Sacra et Profana,* vol. v, pp. 113–180 (1871), the Greek text (III Bar.) was edited by M. R. James in *Apocrypha Anecdote,* second series, pp. 84–94 (1897). English translations of both, with notes, are found in R. H. Charles, *Apocrypha and Pseudepigrapha of the Old Testament* (1913). (ST. B. F.)

BARYATINSKI, ALEKSANDR IVANOVICH, PRINCE (1814–1879), Russian army officer and viceroy of the Caucasus, was born in St. Petersburg on Nay 14 (new style; May 2, old style), 1814. Entering the army in 1833, he was sent to the Caucasus in 1835 and served with distinction in operations against the Circassians. Ordered again to the Caucasus in 1845, he distinguished himself as a battalion commander in the expedition against Dargo, especially in the routing of Shamil's warriors near Gogatl and Andi. In 1846, in Warsaw, he assisted I. F. Paskevich to destroy the Polish insurgents in Cracow. From 1847 he took a leading part in all the military operations in Chechenia. His energetic and systematic tactics inaugurated a new era of mountain warfare. In 1853 he was made general and appointed chief of staff. In 1854 he took part in the brilliant Kürük-dere campaign against the Turks. He became commander in chief of the Caucasian corps (later the Caucasian army) in July 1856 and viceroy of the Caucasus in the following August. Baryatinski was an advocate of a firm establishment of Russian rule in the occupied territories. Incessant offensive operations finally broke Shamil's resistance and his capture in 1859 brought to an end the war for the possession of Chechenia and Daghestan. Baryatinski was made a general field marshal, but was relieved of his post at his own request in 1862. He spent his last years abroad, dying in Geneva on March 9 (N.S.; Feb. 25, O.S.), 1879. (A. Gu.)

BARYCENTRIC CALCULUS, a method of geometric analysis developed by August Ferdinand Möbius (*q.v.*) and founded on the notion of centre of gravity (or centre of mass) of a system of mass particles. The prefix "bary" is from the Gr. *barys,* heavy. The method was known to Mobius in 1823 and he published a detailed account in 1827.

If two particles of weights a and β are located at the respective ends A and B of a weightless rod AB. then there is a unique point P on AB such that the rod may be balanced, under the force of gravity, on a support at P. The respective distances of P from A and B are in the ratio $\beta:\alpha$, and the pressure of the rod on the support at P is equal to that produced by a weight of $a+\beta$. The point P is called the centre of gravity of the two particles. Similarly, there is a centre of gravity or balancing point P for any finite system of particles, situated either in a plane or in space, and we may attach to P a weight equal to the sum of the weights of the given particles.

In the barycentric calculus, the notion of centre of gravity is generalized and its algebraic properties are studied. With a given point A there may be associated any real number *a:* (positive, negative, or zero), called its weight, the weighted point being denoted by a A. The barycentre or sum $a\,A+\beta B$ of two weighted points a A and βB is defined to be the weighted point $(a+\beta)G$, where G is the point of the directed line AB for which $AG:GB=\beta:\alpha$. Geometric considerations show that $(\alpha A+\beta B)+\gamma C = a\,A+(\beta B+\gamma C)=(a+\beta+\gamma)P$ for a unique point P, and the weighted point $(a+\beta+\gamma)P$ is defined to be the barycentre oi the system consisting of αA, βB, and γC. The notion can be extended to any finite system of points, and obeys simple algebraic rules. When the sum of the weights is zero, the corresponding barycentre may in some cases be regarded as a weighted point at infinity: in other cases, it is indeterminate.

With respect to a given tetrahedron of reference ABCD, the barycentric co-ordinates of a point P in space are numbers a. B, γ, and δ such that $\alpha A+\beta B+\gamma C+6\,D=(a+\beta+\gamma+6)P$. For $k\neq 0$, the numbers ka, kβ, ky, and kδ form another set of barycentric co-ordinates of P. Thus the barycentric calculus gives rise to a useful homogeneous coordinate system for representing the points of space; this has been an important tool in projective geometry.

A set of points in space is said to be convex provided it includes, with each two of its points A and B, the entire line segment AB joining them. The points on AB are exactly those which have the form $\alpha A+\beta B$ for some nonnegative weights a and β with $a+\beta=1$. More generally, consider any set S of points and let C denote the set of all points having the form $\alpha A+\beta B+\ldots+XL$, where A,B, . . . ,L are points of S and $a,\beta,\ldots,\lambda$ are nonnegative weights of sum one. It can be seen that C is merely the smallest convex set containing S. Thus the barycentric calculus is closely connected with the theory of convexity. A further generalization of the notion of barycentre is important in some infinite-dimensional aspects of the theory.

BIBLIOGRAPHY.—A. F. Mobius, *Der barycentrische Calcul* (1827), reprinted in his *Gesammelte Werke,* vol. i, pp. 1–388; and *Encyklopädie der mathematischen Wissenschaften,* vol. iii, pp. 1289–93 (1885–87). The former contains the original development of the barycentric calculus by Mobius; the latter gives a brief summary and a history, with references to the literature. For barycentric co-ordinates in the theory of convexity, *see* H. *G.* Eggleston, *Convexity,* pp. 14–16 (1958). (V. K.)

BARYE, ANTOINE LOUIS (1796–1875), French sculptor and painter, was born in Paris on Sept. 15, 1796, and died there on June 25, 1875. He studied under the neoclassical sculptor F. J. Bosio and at the École des Beaux-Arts, but his artistic tempera-

ment was chiefly formed by three painters: Baron Gros, whose pupil he also was; Delacroix, who admired his work and with whom he studied the animals at the Jardin des Plantes zoo; and Gericault. From these he caught the romantics' predilection for the exotic and the violent, and many of his best-known bronzes depict, with great skill, wild beasts locked in combat. Nevertheless his sculptures, and even more his animal paintings and drawings, lack the full flourish and verve of Delacroix and Géricault; Barye was indeed a close friend of Corot, Millet and other members of the more placid Barbizon group, and his few rather arid Fontainebleau landscape paintings show the influence of Theodore Rousseau. Among Barye's large sculptures are the stone groups for the Louvre (1855)—"La Guerre" and "La Paix" (Pavillon Richelieu), "La Force" and "L'Ordre" (Pavillon Denon); his smaller bronzes include "Tigre dévorant un gavial" (1831, Louvre), the table centrepiece "Lion Hunt" (1833) for the duke of Orleans (Walters museum, Baltimore) and "Thésée combattant le minotaure" (1847).

The son of a goldsmith, Barye at first earned his living at that craft and later often turned to decorative metalwork for a livelihood when his major sculpture failed to gain recognition; he was elected to the Academy only in 1868.

BARYTES: see BARITE.

BASALT, in petrology. one of the oldest rock names. is believed to be derived from the Ethiopian word basal, signifying a stone which yields iron. According to Pliny, the first basalts were obtained in Ethiopia. In current usage the term includes a large variety of types of igneous rock belonging to the basic (or low silica) subdivision, dark in colour, weathering to brown and comparatively rich in magnesia and iron. Some basalts are in large measure glassy (tachylytesj, and many are very fine grained and compact; but it is more usual for them to exhibit porphyritic structure, showing larger crystals of olivine, augite or feldspar in a finely crystalline groundmass. Olivine and augite are the commonest porphyritic minerals in basalts, the former green or yellowish (and weathering to green or brown serpentine), the latter pitch-black. Porphyritic plagioclase feldspars, however, are also very common, and may be one or two inches in length, though usually not exceeding a quarter of an inch. Basaltic lavas are frequently spongy or pumiceous, especially near their surfaces; and the steam cavities become filled with secondary minerals such as calcite, chlorite and zeolites.

Basalts may be broadly divided on a chemical and petrographical basis into two main groups—the calc-alkali and the alkali basalts. The lavas of the first group are characterized by essential basic plagioclase with augite, pigeonite or hypersthene and olivine as dominant mafic (basic) minerals. but basalts without olivine are also well represented. Basalts of this group show a range of silica content from 45% to 52%. They range from picritic (olivine-rich) basalts to higher silica varieties such as the andesitic basalts. Calc-alkali basalts, which include the tholeiites (basalts with lime-poor pyroxene), predominate among the lavas of orogenic belts and their flows may build enormous plateaus as in Washington and Oregon of the United States, in the Paraná basin of South America and in the Deccan of India. The active volcanoes of Mauna Loa and Kilauea in Hawaii erupt tholeiitic lavas, and similar basalts are found in the lower portions of the volcanic pile of other extinct volcanoes of the Hawaiian group.

VINCENT SERVENTY

HEXAGONAL COLUMNS OF BASALT OF THE GIANT'S CAUSEWAY. ANTRIM, N.IRE.

The normal alkali type of basalt carries among its mafic minerals olivine and commonly a diopsidic or titaniferous augite. Pigeonite and hypersthenic pyroxenes are typically absent. Among special types of alkali basalts of this group are the mugearites (oligoclase-basalts) and trachybasalts with a conspicuous content of alkali feldspar. Spilites which carry albite feldspar often of metasomatic origin may be more closely related to the calc-alkali group of basalts. Alkali types of basalt predominate among the lavas of the ocean basins and are common among the basic lavas of the forelands and backlands of the orogenic belts. In the Brito-Icelandic province the Tertiary lava flows of the Inner Hebrides: Antrim and the Faeroe Islands include great successions of both calc-alkali and alkali basalts.

Minerals of the feldspathoid group occur in a large number of basaltic rocks belonging to the alkali group; nephelite. analcime and leucite are the most common, but hauynite is occasionally present. If nephelite entirely replaces feldspar, the rock is known as nephelite-basalt; if the replacement is only partial the term nephelite-basanite is used. Similarly there are analcime- and leucite-basalts and leucite-basanites. The nephelite is in small six-sided prisms and usually cannot be detected with the unaided eye. Even with the help of the microscope nephelite-basalts are not always easy to determine, as the crystals may be exceedingly small and imperfect, and they readily decompose into analcime and zeolites. Most nephelite-basalts are fine-grained, very dark-coloured rocks and belong to the Tertiary period. They are fairly common in some parts of Germany and occur also in the United States, as in New Mexico, and in Tripoli, Asia Minor, Cape Verde Islands, etc. Leucite-basalts contain small rounded crystals of leucite in place of plagioclase feldspar. Rocks of this group are well known in the Eifel and other volcanic districts in Germany, also in Bohemia. Italy. Montana. Java, Celebes. etc. The young volcanic fields of the western rift of Equatorial Africa in south-western Uganda and the Republic of the Congo exhibit a series of undersaturated alkali basalts ranging from extremely potassic to comparatively sodic. They include types rich in melilite, leucite, potassic nephelite and kalsilite the potassic analogue of nephelite. See PETROLOGY; VOLCANISM; see also Index references under "Basalt" in the Index volume. (C. E. T.)

BASANAVICIUS, JONAS (1851–1927), "the patriarch of the Lithuanian renaissance." medical doctor and folklorist. was born in Ozkabaliai in the district of Vilkaviskis, Lithuania (then part of Russia), on Nov. 11, 1851. Leaving the secondary school in Marijampole in 1873. he studied history and archaeology in Moscow and, from 1874. medicine in Warsaw. He graduated in 1879 and for 25 years practised medicine in Bulgaria. His inspiring Lithuanian cultural and political magazine *Ausra* ("Dawn"): which began to appear in 1883, was produced in Tilsit and Ragnit (in East Prussia) and smuggled into Lithuania. From 1905 onward Basanavicius lived in Vilnius and engaged in many activities. Considered as the "moral president" of the nation. he presided over the diet of Vilnius which in 1905 demanded autonomy for Lithuania and was president of the congress that on Feb. 16, 1918, proclaimed the independence of Lithuania.

One of Basanavicius' outstanding contributions to the field of Lithuanian science was the founding of the Lithuanian Scientific society in 1907. For 20 years he was its president. the editor of its organ and the organizer of research in archaeology and folklore. His many publications include two volumes of Lithuanian songs (1902): four volumes of Lithuanian tales (1903–05): a work on ancient Lithuanian beliefs about souls and devils (1903—an outstanding collection on Lithuanian mythology); a study on Lithuanian crosses (1912): and a work on the Thraco-Phrygians and their migration to Lithuania (1921). Basanavicius died in Vilnius on Feb. 16, 1927. (MA. G.)

BASARAB (BASSARAB or BESSARABA), the name of a Rumanian dynasty, members of which, as voivodes, ruled Walachia from

(LEFT) COURTESY OF TURKISH PRESS BROADCASTING AND TOURIST DEPT.; (RIGHT) THAMES AND HUDSON, LONDON

(LEFT) HITTITE BASE WITH SPHINXES FROM PALACE OF BAR RAKAB. ZINCIRLI. TURKEY, 8TH CENTURY B.C.. IN ANTAKYA MUSEUM; (RIGHT) ITALIAN ROMANESQUE BASE FROM DUOMO SAN GEMINIANO, MODENA, 12TH CENTURY A.D.

the beginning of its independent history until 1658. The origin of the family is obscure. but it has been suggested the name may be connected with the Kuman word *aba*, "father."

BASARAB 1 (1310–52), who founded the independent feudal state of Walachia. came from the valley of the Olt in southern Transylvania (on which the Hungarians were progressively encroaching) and settled in Câmpulung. He collaborated with the Bulgars against the Byzantines and the Serbs and defended Walachia against the attempts oi Charles Robert of Hungary to conquer it, deieating him at Posada, in the Prahova valley. in 1330.

During the reign of MIRCEA THE OLD (1386–1418) the struggle against the Turks began. His forces and their allies were defeated in 1396 at the battle of Nicopolis (Nikopol on the Danube) and by the end of his reign Walachia was forced to acknowledge Turkish suzerainty (*see* RUMANIA: *History*).

During the 15th century the throne was usurped by a rival branch of the family. and the dispossessed members fled to Transylvania. The usurpers. VLAD DRAKUL or the Devil (1433–46) and VLAD TEPES or the Impaler (1456–62 and 1476–77), were notorious for their cruelties.

The reign of NEAGOE BASARAB (1512–21) was peaceful, the prince being concerned chiefly with cultural activities and with building. Among the buildings erected during his reign. the most beautiiul is the cathedral of Curtea de Argeş (1517), which is one of the finest monuments of Rumanian art.

MICHAEL THE BRAVE (Mihai Viteazul), who ruled from 1593 to 1601. is probably the most famous member of the family. He withstood the Turks and for a short time succeeded in uniting all Rumanians under one rule.

The most outstanding ruler of the 17th century was MATEI (Matthias) BASARAB, who took the throne in 1632 as a result of action against the Greek aristocracy. During his reign he carried out constructive economic. cultural and legislative reforms: he started replacing Slavonic with Rumanian as the official language and brought printing presses from Kiev; he had the first written code of law printed and built many churches and monasteries. He followed Michael the Brave's policy of allying himself with the Transylvanian princes against the Turks. He was succeeded in 1654 by CONSTANTIN ŞERBAN, on whose death in 1658 the male line of the ruling Basarab dynasty became extinct.

See N. Iorga, *Histoire des Roumains*, vol. 3 and 4 (1937).

BASCOM, JOHN (1827–1911), U.S. educator and philosopher. was born at Genoa, N.Y., on May 1, 1827. After graduation from Williams college, Williamstown, Mass. (1849), and the Andover Theological seminary (1851), Bascom became professor of rhetoric and English literature at Williams. He left Williams in 1874 to accept the presidency of the University of Wisconsin, Madison, and resigned 13 years later because of increasing interference by the university's governing board. Under his administration the institution substantially improved the quality and increased the variety of its instruction. His favourable disposition toward coeducation helped to resolve that issue at the university. He returned east in 1887 to lecture occasionally on sociology at Williams and at neighbouring colleges. and in 1891 he again attained full status at Williams as professor of political science. Bascom retired from teaching in 1903, ending 48 years of service as college teacher and administrator. He died on Oct. 2. 1911. at Williamstown. Bascom published 20 books and over 100 journal articles. Of his books. the seven on religion and theology reflect his liberal religious beliefs. The remaining 13 were products of his courses in economics. philosophy, sociology and literature. Bascom summarized his personal and social views in his autobiography. *Things Learned By Living* (1913), which includes a bibliography of his work. (J. M. BK.)

BASE. In architecture. a base is the lowest visible element on which rests a wall. column or pier. In the Greek Doric order. and in some Egyptian examples. the individual base was lacking. Individual stone bases were used originally to protect the foot of a wooden support from ground moisture, and to spread the load over a wider area. In the latter function it has also served in masonry construction. but in general the base became an aesthetic rather than a utilitarian feature. From the days of classical antiquity the base, as used in the Greek Ionic and later in Greek and Roman Corinthian orders. consisted of a series of moldings (*q.v.*) that combined the convex, half-round torus (*astragalos*) and the concave scotia (*trochilos*). These were separated by narrow, fat fillets, sometimes combined with small reed moldings as well. Two main types were the Attic Ionic (scotia between two tori) and Asiatic (torus above two scotias). From these were derived the greater number of base types of later ages in Europe and America. The base (or socle) has also been used at the foot of walls, either as a simple offset or in molded forms that resemble the profile of the column bases. Early bases in Asia Minor (Hittite period) frequently rested on the backs of guardian lions. a feature that reappeared in Europe, especially in northern Italy. during the middle ages. Square or polygonal plinths below round bases rarely appear until Roman times. (*See* also ORDER; CAPITAL; COLUMN.)

The word base has many uses other than architectural. For its sense in chemistry, *see* ACIDS AND BASES. (R. SL.)

BASEBALL (originally written "base ball") is the national

game of the United States. The modern sport is a contest between two teams of nine players each. involving the throwing, batting and catching (fielding) of a ball on a field on which are placed four bases at fixed points at the angles of a 90-ft. square. Competitors run from base to base, counterclockwise, a complete circuit scoring a run, and victory goes to the team tallying the most runs. Following are the main sections and subsections of this article:

I. TEAMS AND PLAYERS

The pastime's most skilled players usually are professionals and make the sport their full-time vocation from late February until late September or early October. Professionals in the United States belong to clubs representing various cities, and the outstanding players attain the status of local, or even national, heroes in the eyes of both adults and youths. The professional clubs compete as members of leagues and during the course of a championship season each team plays an equal number of games with each other league member, half in its own park and half in the park of its opponent. The ranking (or standing) of the teams is determined on percentages, based on games won and lost.

Operation of a professional league club is a highly organized commercial enterprise and usually is conducted by an incorporated business company (see Organized Baseball below for U.S. supreme court decision in 1953 on status of baseball). It involves an extensive investment in real estate and accommodations for spectators; the purchase and training of players; maintenance crews for upkeep of the field, stands and clubhouse; and refreshment-purveying personnel in proportion to the size of its home city and, park. There must also be an administrative staff that includes scouts, the experts whose duty it is to travel about the country in quest of new players who have, or show possibilities of attaining, the skill necessary in league play.

The method established for the founding of a professional baseball team is by the purchase of a franchise from the central authoritative body of the area. league or association concerned. A franchise is an official permit establishing the legality of a team and ensuring that it is entered on the roster of the league and thus permitting it to play competitively. It is normally owned by one person or by several acting in concert. The team will generally take its name from its home town or city with the addition of a particular nickname to identify it, as the Chicago White Sox or the New York Yankees.

Although nine players comprise a team at any point in a major league contest! the manager usually has more than twice that number in uniform and ready for duty during the course of the game. The two major leagues in the United States, the American and National, often have as many as 40 eligible men in uniform early in the season, although 25 is the usual limit enforced through most of the campaign. Similarly, though only one ball and one bat can be in play at any given moment, about three dozen balls are used in the course of the average game, and each team is equipped with several dozen bats.

The constant influx of new talent to the professional leagues comes from schools and colleges, and the independent teams representing factories, business houses and club teams of both city and rural districts throughout the country. In the United States almost every boy plays baseball and its variant, softball (*q.v.*), during his elementary school years, and those with skill often set the major leagues as their goals. Many amateur baseball leagues, organized for the purpose of training boys and helping curb juvenile delinquency, exist in the U.S. The American Legion junior league, formed in 1926 for boys up to 17 years of age, had more than 19,000 teams playing during 1961, and the same year more than 300 former American Legion players were listed on rosters of American and National league clubs. Since the inception of this program, more than 1,600 Legion graduates had appeared in the major leagues.

The Little league, for boys 8–12, had a phenomenal growth, starting in 1939 with only 3 Pennsylvania teams and expanding after World War II to include more than 15,000 teams by 1960. The Little-Bigger league. for boys 13–15, was organized on a national basis in 1952 and at the end of the 1953 season changed its name to the Babe Ruth league. Competition supervised by the Police Athletic leagues in various cities and the P.O.N.Y. (Protect Our Nation's Youth) league are among the many other organizations formed for promotion of the game among boys.

Outside the U.S., baseball is played widely in Cuba, Puerto Rico, Mexico. Canada, Venezuela, Australia and Japan. Extensive tours by U.S. major league players after the close of their seasons at home and the introduction of the sport in many countries where servicemen were stationed in the first half of the 20th century did much to interest peoples of other lands in baseball A number of Latin-American players became stars in the U.S. major leagues Italy adopted the sport after World War II, and several other European countries, including the Netherlands, Belgium, Spain and Germany, have started baseball leagues. An all-European championship is conducted annually and many servicemen and U.S embassy personnel have served as coaches. In Panamá and Tunisia leagues conduct regular schedules and round-robin championship play-offs at the season's end have been in operation.

II. HOW BASEBALL IS PLAYED

Baseball belongs to the extensive genus of civilized athletic competitions stemming from the primitive play urge to hit a fragment of rock with a club. Two boys with one stick of wood and a rubber ball portray baseball in its essence when they mark two fixed points on their playground with a couple of flat stones as bases and take turns whacking the ball with the bat. One, armed with the bat, stands at one of the bases. The other stands an agreed distance away and tosses the ball to the batter, who drives it as far as he can. Just how many times the batter must run between bases before he is credited with a run, or a score, is usually agreed upon between the two contestants. Each keeps count of his runs and, after each has had the same number of turns at batting. the one who has scored the most runs is the winner.

Baseball in all the leagues, in the big city stadiums with attendances of 50.000 or more, is a refined and more intensified form of this same competition. There are nine-man teams opposing each other instead of just two individuals. There are four bases instead of two. In scoring a run a batter must go to each of the other three bases before returning to his starting point to complete his run, but he may perch temporarily on a base on his way around until the opportunity is offered to continue his course.

Just as each batter has eight teammates to help him, there are nine players to pursue the batted ball instead of just the one boy who in the playground miniature game had to be both thrower and retriever.

The official baseball rules; uniformly in force internationally and unchanged in any conspicuous feature after 1920, prescribe the dimensions and markings of the playing field, the conditions under which the teams function when at bat and when in the field and the law of the game as it has evolved to cover every conceivable eventuality of the sport; variations in playing conditions in individual parks are provided for by local ground rules.

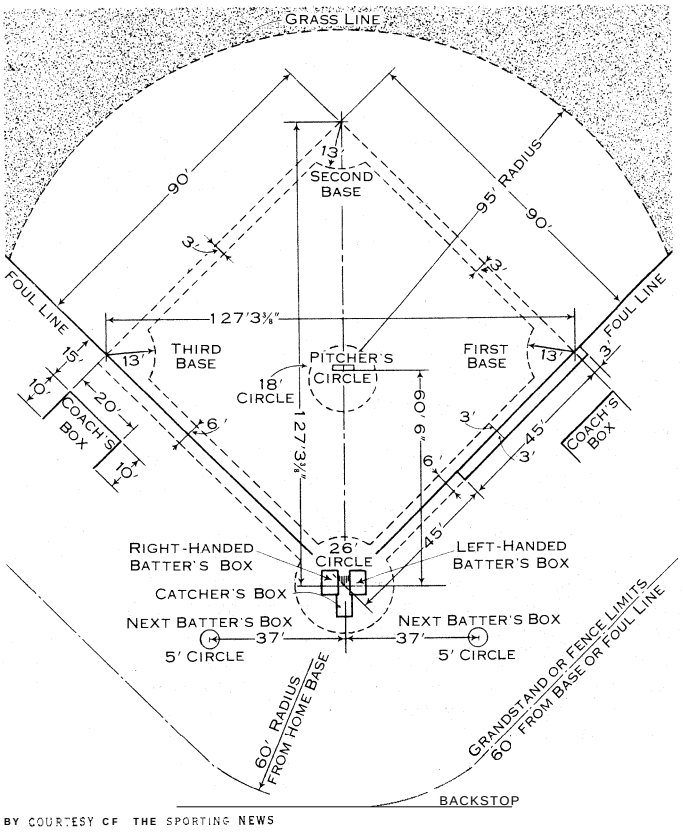
The rules give each team collectively nine turns at bat, or innings. and at the end of nine innings, the one with the most runs is the winner. When the home team: which bats second, has more runs after the first half of the ninth inning, it does not bat. If both teams have an equal number of runs at the end of nine innings. the game continues until one side or the other, in equal innings played, can show a plurality of runs.

1. Positions.——The bases are called first, second and third base and home base or plate. All batting is done at home plate. The base running proceeds from home plate along the base lines (the boundaries of the square). A run is scored when a player, having successively touched first. second and third: reaches home plate.

Seven of the nine players on the fielding team take their stations prepared to capture (field) the ball as soon as possible after it is hit by the batter. The other two, the pitcher and the catcher, form the battery. The catcher stands behind and within stepping distance of home plate: but not close enough to impede the batter's activities.

The pitcher stands near the centre of that portion of the playing field known as the infield. He puts the ball in play by throwing it to the catcher. The batter stands on one side of home plate, within a prescribed area marked on the ground (the batter's box). He gets his chance to hit the ball as it passes him on its may to the catcher, He therefore stands facing the plate. swinging the bat with both hands, and in such a position as to be able to put the full force of his shoulders and arms into his swing at the ball.

Players are termed right-handed batters or left-handed batters according to whether they swing the bat from their right side or their left. A right-handed batter stands on the side of the plate nearer third base and looks at the pitcher over his left shoulder as the pitcher begins his delivery (*i.e.*, the pitching of the ball to the catcher). A left-handed hitter's stance is the reverse.



BY COURTESY OF THE SPORTING NEWS

FIG. I.— OFFICIAL MEASUREMENTS FOR LAYING OUT BASEBALL FIELD

When the batter hits the ball inside fair territory. he is entitled to start running round the bases. Fair territory includes the area of the playing field between the foul lines. These are straight white lines along the ground marking two sides of the square (from home to first base and home to third:). and prolonged beyond first and third to the limits of the playing field. Since it is only a fair ball that entitles the batter to run. the fielding team's defensive arrangement places its seven movable men within the fair territory. Four of them (the infielders) patrol the ground between first and second and second and third. The other three (the outfielders) are stationed in the wide sweep of the playing field from foul line to foul line beyond the two base lines. This area is called the outfield.

The outfielders are called right fielder. centre fielder and left fielder with relation to a man standing on home plate and facing out across the playing field toward second base, but there are no visible boundaries separating right field, centre field and left field. With the exception of the pitcher and catcher (and in their case only at the moment of putting the ball in play), there is no restriction on the movements of the members of the fielding team. The four infielders are named first baseman, second baseman, shortstop and third baseman, stationed in that order from first base around the rim of the infield to third. Their fields of operation are nearly as flexible as those of the outfielders. The arrangement of the fielding team at any given point in a game is changed to meet the needs of the existing situation.

2. The Umpires.— Play is under supervision and control of one or more umpires, acting as impartial judges and announcing decisions on whether the pitched balls pass over the plate within or outside of the strike zone. whether batted balls are fair or foul, whether a base runner has been put out by a throw or by tagging, or is safe (*i.e.*, entitled to hold the base he has reached by running).

Four umpires are usually on duty in major league games. one stationed behind the catcher, the other three covering the plays that occur at first. second and third bases. The home plate umpire starts the game by calling play for the first inning. The ball goes into play when the pitcher pitches it to the catcher. It remains in play except when an umpire calls "time." which is done on all foul balls except flies that are caught before touching the ground. also upon the request of either team at a time when the ball is being held by a player of the fielding team and no base runner is attempting to advance. The request for "time" most frequently is made by a batter when he wishes to step out of the batter's box between pitches. Time is also called on the rare occasions when a batted ball strikes a base runner, and in other circumstances when the umpire's discretion so dictates.

3. Put-Outs.— The main offensive force at work in a baseball game at any given point is the batting team's ability to hit the ball arid drive it far, fast and straight enough to make it a fair ball (*i.e.*, to remain within fair territory on the playing field, or if hit beyond the limits to land inside the foul lines as they would be extended). Along with this batting power goes the running speed of the batting team in its efforts to traverse the bases.

To meet this force, the rules provide the fielding team with ways of making put-outs. A put-out removes the player from further offensive play until his next turn at bat. The batting team's inning continues until three put-outs are made; then it goes into the field and the rival team comes in for its turn at bat.

Most put-outs are made by (1) striking out the batter; (2) catching a fly; (3) throwing him out; or (4) tagging out a base runner. The batter is struck out when the pitcher succeeds in preventing him from hitting the ball into fair territory within the limit of three strikes. Strikes are counted on the batter whenever he swings at a pitched ball and misses, or when he does not swing at a pitched ball that passes him inside the strike zone, which is an imaginary rectangular plane in front of the batter. Its top and bottom are in line with his shoulders and knees respectively. Its long sides are perpendiculars extending upward from both ends of the front rim of home plate. which is a rubber slab, pentagonal in shape, level with the ground. two sides fitting exactly into the home plate angle formed by the third and first

base lines, and presenting to the pitcher a straight front margin 17 in. wide.

The strike zone is thus a rectangle 17 in. wide, facing toward the pitcher, the length of its vertical sides depending on the height of the batter. When the ball passes through this rectangle at any point and the batter does not swing, it is a called strike, counting exactly as if he had swung and missed.

A strike is counted when the batter fouls the ball to the ground or out of the field of play. Fouling the ball means striking it with the bat but not driving it inside fair territory. This foul strike is not counted if the batter already has two strikes against him, provided he swings at the ball in fouling it. If, with two strikes, he fouls in an attempt to bunt, that is, merely blocks the ball with his bat instead of swinging, his foul counts as his third strike and he is out.

A batter is put out if a member of the fielding team catches and holds a batted ball before it touches the ground, whether it is fair ball or foul. There is the exception that a foul tip, a pitched ball that the batter merely flicks slightly with his bat, counts as a strike if caught and held by the catcher. It does not count as a put-out unless it occurs on the third strike.

A member of the offensive team is tagged out when he is running bases and is touched by the ball in the hand of a member of the fielding team at a time when the runner is not in contact with a base. A member of the batting team is thrown, or forced, out when he bats a ball that touches the ground before being caught but that comes within reach of a fielder (usually an infielder or the pitcher) in time for him to throw the ball to the first baseman so that the latter catches it and touches first base with his foot or some other part of his person while holding the ball securely before the batter can reach first base.

Only one runner may have title to a base at any given moment. It is thereiore possible for a runner to be thrown out at second base, third, or even at home plate without being tagged. The batter becomes a runner entitled to try to reach first base safely the instant he hits a fair ball that strikes the ground. At that same instant, if there was a teammate on first when the ball was hit, that base runner is no longer entitled to first base and must run to second. If runners are on both first and second: or runners are on all three bases, they are all forced to run when the batter hits a fair ball that strikes the ground. Any base runner thus forced to run can be put out, or retired, without tagging, by the throw of the ball to a fielder who can touch the base to which the base runner is forced before the runner reaches it.

This method of retiring base runners is called the force play. With first base occupied and the ball driven along the ground to the pitcher or an infielder, the ball can often be first thrown to second base for a force-out of the man from first base. then relayed to the first baseman to retire the batter—two outs on one play. This is the usual form of the double play in baseball, one of the most effective and spectacular defensive tactics.

A runner can also be thrown out without being tagged if he has left a base to which he was entitled before the ball was hit and the batting of the ball results in a fly that is caught. With the catching of the fly, the runner must return to the base he just left before being eligible to advance. If the catcher of the fly can throw the ball to that base before the runner succeeds in returning to it and touching it, it counts as an out, retiring the runner as well as the batter by a double play of a different type than the force play "double up" described above.

In very rare cases a runner can be tagged out while standing on a base if, through confusion of mind or misjudgment of the play in progress, he remains standing on a base to which he is no longer entitled. In almost all situations of baseball, however, the bases form anchoring posts (isles of safety) for the players of the side at bat in their progress toward scoring runs.

Intentional Pass.—Frequently (sometimes as many as three or four times in a single game) there is a base on balls not due to the pitcher's inaccuracy (see Base on Balls, below) but performed by him for tactical reasons. The team at bat, for instance, has a runner in scoring position (*i.e.*, on second or third base, or both) but none on first. If, in the collective judgment of the pitcher, his catcher and his manager, the man at bat is more likely to make a safe hit than the man who will follow the man at bat in the opposing team's batting order, it is considered sound tactics to give the batter an intentional pass, or base on balls, to first base. The catcher moves from behind the plate to one side after the pitcher delivers the ball, and the pitcher delivers four pitches that the batter cannot reach while standing in the batter's box. The batter thus receives a base on balls and must go to first base, bringing to bat the man considered a weaker hitter.

The intentional pass has the additional merit of setting up a possible force play at second base which can materialize if the weaker hitter drives the ball along the ground within reach of an infielder or the pitcher or catcher. With runners on first and second a force play is also set up at third, and if both second and third are occupied when the intentional pass is given, there is made possible also a force play at home plate. The defensive side's advantage is in being enabled to make a put-out without tagging the runner trying for the base. Contact need merely be made with the base by a defensive player with the ball in his possession before the runner reaches the base. This advantage is of greater potency when there are fewer than two out, in which situation the batter's grounder can be converted into a double play, rescuing the pitcher and the deiensive team from a scoring threat.

So valuable is this double play opportunity that often, when there is no disparity between the batting abilities of the two batters under consideration, the intentional pass will be ordered by the manager, solely to create the double play opportunity.

As countertactic when an intentional pass is given. the team at bat frequently replies by sending in a pinch hitter, that is, taking the weaker hitter out of the line-up and substituting another player whose likelihood for driving the ball for a hit or a fly to the deep outfield is greater than that of the player brought to bat by the intentional base on balls. Such a pinch hitter must be a player not already in the line-up, nor in the batting order at any previous time in the game. Pinch hitters are sent into action in other situations than as a rebuttal to an intentional pass. In fact, in nearly every baseball game, the late innings are marked by one or more substitutions of this type, made by whichever team is behind in the score.

4. The Attack.—When the plate umpire calls "Play ball," thus ordering the game to start, he has in his possession the batting order of each team, a list of nine names delivered by each manager as the order in which his players will come to bat. regardless of their defensive positions. This list is in force throughout the game in its original order of precedence. A substitute entering the game takes the place in the batting order of the player for whom he is substituted. A player leaving the game is not permitted to return.

Each team in its innings strives to advance its players around the bases to score as many runs as possible before the third out ends its inning. Each inning is a new game in the sense that it starts with the bases empty. The first man in the batting order is the first batter in his team's first inning. In subsequent innings, the first batter up is the man whose name in the batting order follows that of the last batter in the previous inning whose completed turn at bat resulted in the third out.

In cases where the third out is 'made on a fielding play that did not involve any hit or strike out or base on balls, or any other completion of the batter's turn at bat, the man at bat when the third out was made becomes the first batter of the next inning.

The rules permit runners to advance on the bases at their own risk of being tagged out at any time the ball is in play. The regular basis of advance, however, is the batted ball when it is batted into fair territory outside the immediate control of the fielding team. The acme of successful batting is to drive a pitched ball beyond the confines of the playing field (usually into the stands among the spectators, or completely out of the park) inside fair territory (*i.e.*, between the foul lines). A ball so driven is called a home run. It has passed beyond the reach of any fielder and entitles the batter to run at any speed around the bases to score a run at home plate. Any and all runners who are on base when the home run is hit likewise make their way to the plate in

the order in which they reached base and register a run each.

Failing a home run, the batter aims to drive the ball in such a way that it cannot be caught before touching the ground in fair territory nor caught after touching ground soon enough to be thrown to first or any other base before the batter or other runners get there. If he succeeds in this, he has made a hit. If he reaches first base, it is called a one-base hit or a single. If he drives it far enough so that he can reach second base safely, it is a two-base hit. two-bagger or double. A hit long enough for the batter to reach third base is a three-base hit. three-bagger or triple.

With the ball thus hit by the batter into fair territory. any members of his team who are already occupying bases advance as close to home plate as possible before the ball is returned to the infield. They must reach their objectives without being tagged out; thus their judgment of how far they can go when the ball is hit safely is a major element in successful attack.

A batter hitting the ball inside fair ground and reaching first safely because of a fielding lapse (*i.e.*, failure to catch the ball or inaccurate throwing) is not credited with a hit. The failure of the fielder appears in the record of the game as an error committed by him. Failure to tag a runner with the ball when a chance offers to make a put-out by this method also counts as an error.

Base on Balls.—A batter may reach first base without having hit the ball. This is nearly always the result of inaccuracy by the pitcher in his efforts to make the batter hit a bad ball (*i.e.*, a ball passing the batter at a point where the batter cannot hit the ball with his full power). Whenever the batter does not swing at a pitched ball, and the ball does not cross the plate inside the strike zone, the umpire standing behind the catcher announces "one bail." If four balls are thus declared in a single turn at bat, that is. before the pitcher has thrown three strikes, the batter is entitled to go to first base without a play being made on him. the recipient of a base on balls. A game without a base on balls for any batter of either side is unusual. In an average game there are from four to a dozen bases on balls.

Hit by Pitched Ball.—The batter reaches first base without hitting the ball if a pitched ball at which he does not swing strikes any part of his person. The umpire then awards him the right to go to first base. A team may go for days, or even weeks, without any of its batters reaching first by being hit by a pitched ball.

Interference.—The batter also reaches first base if the catcher interferes with him by touching any part of his body or interferes with the swing of his bat as the pitched ball is on its way to home plate. If, in the umpire's judgment, this has happened, the batter is awarded first base and the catcher is charged with an error.

Missed Third Strike,—If with two out, or with the first base unoccupied regardless of how many are out, the batter swings and misses the ball for his third strike, and the catcher does not catch the pitched ball before it touches the ground, the batter is entitled to run for first just as if he had hit the ball along the ground in fair territory. The batter is also entitled to run to first base if the catcher misses a third strike that the batter does not swing at. The catcher must then get the ball and throw to first ahead of the batter in order to put him out. In instances when such a pitched ball rebounds off the catcher out into the infield, the pitcher or any infielder may make the pickup and throw to first just as if it were an infield grounder. This right to try for first base does not exist when first is occupied and there are fewer than two out, because, if it did, the catcher might drop the ball directly in front of him and thereby create the opportunity for a double play, throwing to second to force out the man on first, the double play then to be completed by a throw from second to first before the batter arrived at first, Missed third strikes are uncommon in the professional leagues.

The Infield Fly Rule.—Similar protection is afforded the batting side by the infield fly rule: in instances where, with both first and second occupied, or with first, second and third bases occupied, and fewer than two out, the batter hits a high fly that in the judgment of the umpire can readily be caught by an infielder or the pitcher or catcher, inside fair territory. When such a fly is hit in such circumstances, the umpire immediately declares the batter out. whether or not any member of the fielding team subsequently catches or misses the ball. This law was enacted in 1895 because clever infield players would pretend to catch the fly, but at the last moment would let it strike the ground, thus setting up a force play at both third base and second base. which could be made a double play by quick and accurate throwing. An attempt to bunt, however, under the conditions noted above, which results in a fair fly shall not be regarded as ah infield fly.

Stolen *Bases.*—The base runner can wait on a base until a teammate drives the ball out of reach of fielders. enabling him to travel further on his road to home plate to score a run. The rules do not compel him, however, to wait for the ball to be batted. His only restraint is the threat of being tagged out. that is, of being touched with the ball in the hand of a member of the fielding team at a time when he is not on a base. Obviously, a dash for the next base when the ball is being held by the pitcher, the catcher or an infielder. makes the runner almost a certain out. When the pitcher delivers the ball to the batter, however, the runner can match his speed with the strength and accuracy of the catcher's arm. If the runner makes such an attempt and succeeds in reaching the next base without being tagged out, he is said to have stolen a base.

In 19th-century baseball and the first 25 years of the 20th century. the stolen base was a prominent and spectacular feature of baseball. In the years immediately following World War I, better materials and improved machinery in the making of baseballs brought on the era of the "lively ball." It became more advantageous to wait for the batter to hit the ball than to risk the matching of speed against fast and accurate play by the catcher and the infielder guarding the base to be stolen.

Except in cases of speedy players with a flair for getting the jump on the pitcher and in avoiding the tagging stab of an infielder's hands, stolen bases as individual exploits ceased to be a usual procedure.

The Hit-and-Run.—Attempts at stealing bases in modem baseball usually take the form of the hit-and-run play, in which the batter co-operates with the runner. It requires a fast base runner and a coolheaded, keen-eyed and quick-thinking batter and is rated as a risk play, a gamble not highly favoured by most managers except in emergencies.

When it is used, the setup almost always calls for a runner on first, but on no other base. The runner starts for second as the pitcher begins his pitch. If the second baseman shifts to be in position to receive a throw from the catcher, the batter tries to drive the ball along the ground through the area ordinarily guarded by the second baseman. If it is the shortstop who has thus covered second. the batter tries to drive the ball through the shortstop's just-vacated sector.

When the batter succeeds in his effort. the ball goes to the outfield as a hit and the runner usually reaches third base easily. There are lesser degrees of success. The batter may hit the ball along the ground but not through the open sector. This results usually in an out at first base on the batter. with the runner reaching second safely, moderately advantageous, since it has placed the runner on second, in position to score on an ordinary one-base hit to the outfield by a subsequent batter and has removed the double play menace that always exists when a runner is on first base with fewer than two out.

If the batter hits a fly, the runner must quickly retrace his path and regain first base. which is usually done easily. If the batter misses the ball entirely. the most he has accomplished is to offer a visual hazard to the catcher's throw to second base. The play in this instance takes the pattern of a plain attempt to steal second. In every major league season a large percentage of the stolen bases credited to players are the result of hit-and-run plays in which the batter fails to hit the ball.

Since the hit-and-run play involves two players. there is usually the exchange of a secret signal between them. preceded by a signal to both of them by the manager or one of the coaches.

The coaches. two in number, are stationed outside the base lines, one near first base and the other near third. They are advisers to the base runners and liaison operatives between the manager,

batter and runner. Coaches are usually experienced men whose days as players have ended. Besides their duties during the game, they act as all-around assistants to the team's manager. In the major leagues the manager has at least two, often three, of these assistants.

The manager himself may elect to serve as a coach in the play of the game, usually choosing the position at third base, since it is there that the most vital decisions of base running must be made, namely. whether to stop the runner at third or to let him keep on running and try for home plate.

When the manager is directing play from the coach's box, the hit-and-run signal travels directly from him to the batter and runner. If he is a bench manager, he signals to one coach or the other. If the defensive team detects the signal or suspects from some action or attitude of either player that the hit-and-run play is about to be used, their defense calls for a pitch-out. As the runner starts his dash, the pitcher pitches the ball to the catcher at a point outside the reach of the batter's bat. thus putting the catcher in position to make a clear throw to second.

The most disadvantageous outcome of the hit-and-run play occurs when the batter hits a line drive that is caught by the pitcher or an infielder. Such a drive. traveling low and fast and caught within a fraction of a second of its leaving the bat, retires the batter instantly and makes a double play virtually inevitable, since the ball is caught within easy throwing distance of first and the runner. at the moment of the catch, has gone more than halfway to second. The fly catch rule requires him to return to his base. under penalty of being put out, before the ball is held on that base by a defensive player.

The Bunt.—Nearly every time a batter tries to hit a ball he takes a full swing, aiming to drive it as fast and as far as he can. He puts every ounce of muscle into his swing, stepping "into" the hall as it approaches him and lashing at it with the bat held in both hands and powered by wrists. arms, shoulders, back and hips. There are times. however. when he bunts the ball. tries to tap it lightly with the bat to make it spill along the ground 12 or 1 j ft. into a zone about halfway between pitcher and catcher and off to one side or the other of a straight line from catcher to pitcher. In bunting, the batter usually relaxes his grip on the bat and, instead of swinging, merely holds out his bat so that the ball strikes it and plops to the ground with only enough force to send it out at a point in the infield. The bunt is always a strategic action. The batter therefore tries to conceal his intent as long as possible so that neither the pitcher and catcher nor the infielders can get the jump on the play. The bunt is usually intended to be a sacrifice. that is, the batter expects to be thrown out at first base. His purpose is to enable one or more runners to proceed to their next base while the play is being made on his bunt. retiring him at first base. He thus sacrifices himself in the interests of advancing a potential run or two.

At most stages of any game, most managers will order a bunt whenever both first and second bases are occupied with none out. So faithfully is this done that sometimes the defensive team shifts its infield arrangement so that the first baseman and third baseman are stationed 10 or 20 ft. closer to home plate than ordinarily. This invites a tactical change by the batter to cross them up by swinging instead of bunting. but the sacrifice bunt is rated so sound a procedure that only rarely does the attacking team discard it, no matter how close the infielders play.

When a bunt is the expected tactic. the defensive team exerts every effort to defeat it. The pitcher resorts to high fast pitches because it is harder for the batter to dump the ball along the ground if he has to reach high and the greater the speed of the pitch the less likely the batter will be to hit the ball at all or, hitting it, to control its course. A bunted ball going foul counts as a strike even after two strikes; therefore, a pitcher having succeeded in getting two strikes on a bunting batter can usually count on the batter not risking a third strike on a foul bunt.

When the ball is successfully bunted, the defensive team is quick to seize any chance there may be to defeat it by fielding the hall to second or third base for a force play. Exact judgment is required for this play. for the runner, expecting the bunt. is off at top speed the moment the ball and bat are in contact. Catcher, pitcher and either the third baseman or the first baseman are usually rushing toward the ball. The one who reaches it usually gets shouted advice from the others as to where to throw the ball, whether to try for the force play or merely to throw to first to retire the batter.

When the ball is bunted toward first, drawing the first baseman toward home plate, it is the task of the second baseman to run over to first base to receive the throw for the put-out. In this situation the shortstop covers second base and the third baseman covers his own base.

When the ball is bunted on the third-base side of the diamond with first the only base occupied by a runner, the third baseman joins the pitcher and catcher in trying for the ball, the first baseman or the second baseman covers first and the shortstop moves over to defend second. The third baseman then drops back to protect third base in case of an error.

If there are runners on first and second when the ball is bunted toward third, it is the pitcher's play to field the ball, unless the bunt is so short that the catcher can overtake the ball. If the bunt is deep and directly down the third-base line, then the third baseman must come in to play it and throw to first base in an attempt to retire the batter. This is the "perfect" sacrifice, since the batter has bunted adeptly enough to make the third baseman leave his station, thus advancing the two base runners. The catcher is the man with the entire picture of the play in front of him. On any bunt, unless he can field the ball himself, it is usually the catcher who calls out instructions as to where the ball is to be thrown.

The Squeeze Play — The bunt is also used to sacrifice a runner home from third base, but the technique is somewhat different. On a prearranged signal, as the pitcher starts delivering his pitch the man on third must start running toward home plate. This is an all-or-nothing play. If the batter misses entirely, the catcher, by catching the ball, has the runner trapped between third and home, a certain out, unless the runner resorts to dodging back and forth and some error of throwing or catching allows him to escape The bunt nith a runner rushing home from third is called the squeeze play If the batter can bunt the ball into fair territory, it means a certain run scoring for his side, because of the runner's flying start. The best the defensive side can do is to throw out the batter at first base. The squeeze play is the most spectacular and most dangerous sacrifice bunt.

An expert batter. gifted with exceptional running ability, will sometimes bunt the ball when there are no teammates on the bases. The unexpectedness of his action and his speed sometimes enable him to reach first before the ball can be thrown there. This is known as beating out a bunt and counts as a one-base hit, just as if he had swung and driven the ball far enough to reach first safely.

A batter assigned to sacrifice sometimes beats out his bunt, but only rarely, because when the sacrifice is in order, he takes particular care to meet the ball fairly. The batter who aims solely to beat out a bunt for the purpose of getting on base himself takes a quick stab at the ball. In fact, such a batter starts to run for first base an instant before his bat touches the ball, whereas the sacrificing batter loses this flying start in his effort to assure himself and his team of a squarely bunted ball.

III. SPECIAL SKILLS

1. Offensive. — Each of the nine players on a team must take his turn at bat. The strongest hitters are grouped one after the other. starting with the third position in the batting order. The first two positions, lead-off and no. 2, are assigned to players with keen eyes and brains, those fast afoot, usually not so powerful in driving the ball for distance as the no. 3 and the cleanup man, no. 4.

The best lead-off man is one who can know whether the pitch will be a strike or a ball if he lets it pass him without swinging. Such a player is called a "waiter." By waiting out the pitcher, letting the bad ones pass, he draws many a base on balls which a less accurately judging batter would not receive. In his strategic

position. first hatter up in the first inning, and following the weak-hitting pitcher in the other innings in which he bats. a base on balls for him is usually just as advantageous to his team as making a one-base hit. Getting on base is the lead-off man's main offensive function. since over a stretch of games his run-driving opportunities are relatively few.

For no. 2 the manager selects his best hit-and-run man, the batter n-ho is most skilled in driving the ball toward the right side of the field. When there is a runner on first, the first baseman is "tied to the bag," that is, he takes his position on or close to first. thus opening a wider sector through which the ball may safely be driven along the ground into right field. The ability to hit the ball in this direction is important. especially on a hit-and-run play with the runner rushing for second as the pitcher pitches. The no. 2 man must also be a capable hunter.

So. 3 is usually the best all-around offensive player on the team. with speed afoot combined with batting power and skill. The greatest hitters of all time have been in the main no. 3 in their team's batting order — Tyrus R. ("Ty") Cobb. George Herman ("Babe") Ruth. Rogers Hornsby, Edward T. ("Eddie") Collins and George Sisler. for example. So. 4 and no. 5 are the long-distance hitters. not likely to hit the hall safely as large a percentage of times as no. 3, but often with greater distance. The remaining positions in the batting order scale downward. and it is there one finds the highly skilled defensive stars, players whose value to the team is their mastery of their fielding positions. No. 9 is invariably the pitcher. the most specialized of all players. whose hitting ability is usually negligible. There are rarely pitchers with batting ability, but because a pitcher is called on for duty only about once in four or five days. even pitchers so gifted do not have the chance to continue tuned up. Their batting ability is rarely considered; whereas in the other positions a man's worth always represents his combined batting and fielding skills.

2. Defensive. — There is no rule relating a man's position in the batting order with his position on defense: fielding positions may be rearranged at any point in the play. In the scale of defensive skills. pitcher is no. 1. shortstop is no. 2. second baseman is no. 3. then catcher. centre fielder. first baseman. third baseman. then the two flanking outfielders. whose degree of fielding importance relative to each other depends on the comparative areas and other physical hazards of their respective fields, determined usually by the contour of their home playing field's outfield boundaries.

This scale of skills is the basis of the hasebhll expert's argument in rating one team superior to the other defensively because it is stronger "down the middle." An outstanding team usually has a star player at each "middle position": catcher. "the keystone comhinntion," meaning the second baseman and shortstop, and centre fielder.

It is obvious that when two aspirants for one fielding position are equal in hatting ability. the better fielder is chosen to play that position in the. game; liken-ise. when the two are of equal defensive skill. the better hatter gets his name in the hatting order. The lower the position stands in the scale of skills the less there will be to choose among aspirants on the ground of fielding skill. It follows that batting ability will overshadow fielding considerations in positions such as right field or left field. third base and even first base. whereas in the middle positions the manager will weigh very carefully the fielding merits in making his selections. He must have for his shortstop the best possible fielder of the position he can find, regardless of batting, and whatever such a star fielder can furnish in hitting power is sheer profit. But his right fielder and his left fielder must be hitters, and their ability to run faster. to judge a fly ball more accurately or to throw a ball straighter is a secondary consideration.

3. Outfielders. — Of the three outfielders collectively, less is required in the way of special skill than in any of the other six positions. All the catching of thrown halls, all tagging of base runners and all plays on ground balls to retire runners at bases take place in the infield and the immediately adjacent terrain. The outfielders are stationed in order to be able to catch batted balls driven reasonably high in the air beyond the infield. They must be able to judge the trajectory of such flies and have speed of foot to run to the point where the ball will come down.

Batted or thrown balls that pass beyond the infielders along the ground must be run to earth and picked up by the outfielders. Strong throwing arms are essential, and the more accurately an outfielder can throw the ball to the right point in the infield. the more valuable his defensive services. An alert outfielder can also add to his value hy moving in as a backer-up of the infield when the hall has been batted to some point other than his own area and is being thrown about by his teammates in an effort to retire runners.

The centre fielder rates high in the fielding scale because of his central position in the outfield. He must he a "ball hawk." possessing great speed and expert judgment of a batted hall's trajectory. The accomplished centre fielder makes a study of all the important hatters of rival teams. He keeps a mental chart of each batter's power (*i.e.*, toward which point in the rim of the outfield the hatter's longest drives usually are directed). The centre fielder will not only station himself at a strategic point to meet each threat hut will direct the playing positions of his outfield teammates on either side. The difference between a three-base hit and a put-out is often such a stratepic shift of position. Almost invariably the great defensive outfielders of baseball history have been centre fielders (Tristram E. ["Tris"] Speaker, Max Carey, Terry Moore. Joseph P. ["Joe"] DiMaggio. to name a few). Not as much skill is demanded in right field or left field as in centre, but a right fielder or left fielder can employ all the talent he has in the way of speed. judgment. throwing, etc.. to enhance his own value and further his team's defensive solidarity. It is a thrilling play when an outfielder aids in a double play. Such rare feats occur when a base runner misjudges the fielder's ability to overtake and catch a well-hit fly ball that is returned to a base before the runner can scramble back to the base and tag up as the rule requires.

4. Infielders. — The outfielders form the outer ring of defense against the batting of the opposing team: the infielders form an inner ring. four strong. their function to field the ball at close range. They capture on the fly line drives when such drives come n-iihin resch. hut mainly their work on batted balls is the picking up of grounders. when the ball is batted so that it skips along the ground toward the outfield or shoots swiftly across the grass on one or more bounces. The fielding of a grounder is baseball's most characteristic play. setting it apart from most other sports. When a batted ball strikes the ground. the came becomes a race between the batter's speed in running from home plate to first and an infielder's agility and adroitness in gaining control of the ball and throwing it.

The four infielders shift positions to guard against each batter's individual power, as do the outfielders. They have the additional responsibility of guarding the bases when any or all of them are occupied. When a ball is batted along the ground. only one of them is called on for the effort to gain control of it, but at least one of the others is almost always involved in covering a base to take the thron.: sometimes two bases must be covered for a possible throw. sometimes all three.

In the many situations arising in the course of one game, the infielders must adjust themselves correctly. rapidly and in cooperation in order to be efficient. The fielding of grounders—pickup and throw—is the common skill of all four infielders. Each position has its special modifications of fielding requirements.

At shortstop the thron- is the longest and/or most difficult, whether the batted hall is a swift one shooting toward the outfield to the shortstop's right or left or straight at him. or is a tantalizing slow "skipper" for which he must rush toward the plate in order to field it quickly and have a chance to retire the batter.

The second baseman's function on grounders is the same, except that his throw has a shorter distance to travel to reach first. giving him an extra instant of time. Offsetting this advantage somewhat is the fact that the shortstop faces first in all instances except when a ball is off to his right. while the second baseman. on most of his grounders. must throw "around the corner." It is a baseball saying that a good shortstop can always move over and become a good second baseman, but even a very good second baseman can rarely

become an even adequate shortstop, mainly because of the extra throwing skill and power demanded by the shortstop's location in the fielding strategy.

On a force play at second. whether part of a double play or not, either the second baseman or the shortstop must cover second to catch the throw with his foot on the base. just as the first baseman does on an out at first. The force play is always a potential double play. The second baseman, coming to the base to take the throw, has first base over his left shoulder. so that he must throw around the corner to complete the double play. Thus. skill in pivoting is an important part of a second baseman's category of talent.

The third baseman, playing nearer the batter than the shortstop or second baseman, must be agile and nimble but is not called on to scurry over as nide a zone as they. The grounder aimed his way reaches him or is past him into the outfield sooner than is the case at second or short. On his most difficult play, the fielding of a bunt or a dribbling roller halfway between home plate and his position, the third baseman finds himself with a throw to first which is shorter than any the second baseman or shortstop is ordinarily called on to make and often has more time in which to make it.

The first baseman's fielding of grounders is made easier because of his proximity to the goal for which the batter is striving. Often he is able to touch base with his foot, with ample time to spare, after picking up the grounder. When there is not time for that, his throw is a mere underhand toss to the pitcher as the pitcher moves over to cover first.

The first baseman's most difficult play develops when there are runners on one or more of the bases and the fielding of a grounder involves a throw to second. third or home. Such plays are rare by comparison with the number of throws made by the other infielders. Because they are often important, it is considered an advantage for the first baseman to be a left-handed thrower: making it a more natural movement for him than for a right-handed thrower.

Second basemen. shortstops and third basemen in modern baseball are invariably right-handed throwers. Catchers in modern baseball are always right-handed. Pitchers and outfielders may throw with either hand.

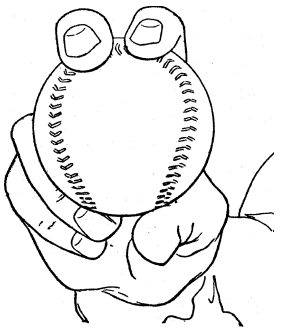
5. The Battery. — The pitcher and catcher together are known as the battery or as batterymen. The pitcher functions as an emergency first baseman when a grounder is driven toward the first baseman at a point so far from first that the first baseman has not time to field the ball and run to the base before the batter will reach it. This is not a difficult fielding play for the pitcher, provided he starts running promptly. The distance from the pitcher's box to first is roughly two-thirds as far as the distance the batter must run. The pitcher can easily get there ahead of the batter. All that remains is to catch the ball tossed to him by the first baseman and touch first base with his foot. It is a fairly common play, though sometimes throughout an entire game the pitcher may not be called on to make it.

Otherwise the pitcher's fielding functions consist of trying to field any ball batted in his direction. to catch it and hold it for the out if it is a line drive or a fly that does not go high enough into the air for the catcher or one of the infielders to reach it before it will strike the ground, to pick it up and field it to some base if it has struck the ground.

On bunts the pitcher functions as an infielder, covering his share of the zone between the foul lines and between the pitcher's box and home plate. Fielding skill is an important asset to a pitcher. It can save him many a game and make up for a moderate degree of deficiency in pitching skill. Without fielding talent a pitcher can be successful only by the possession of exceptional pitching ability.

The catcher. as a fielder, is mainly a catcher of high flies, a thrower and a guard at home plate. The flies he is called on to catch are "skyscrapers," batted balls that soar almost straight upward from the bat and come down somewhere between the base lines and the grandstand or else directly in front of home plate. Keenness of vision to perceive the angle at which the ball leaves the bat is the indispensable attribute necessary to get a quick start in the right direction from home plate. Unerring catching of such flies develops a special sense in catchers not required in any other position. The ball is high in the air directly overhead and coming down at him almost perpendicularly.

The "good hands" essential to every player are especially important for the catcher. Throughout the game he must catch the pitched balls not hit by the batter, sometimes pitches that strike the ground near the plate. Sometimes he must jump for high ones or wide ones. The bat swinging directly in his visual line as he reaches for the pitch is no hazard to him. From long use he has become accustomed to it. It is when the bat flicks the ball slightly in passing that the catcher's good-handedness pays off. If the batter has two strikes, the abilitv of the catcher to catch the ball and hold it makes the difference between a strike out, ending the batter's turn at bat with a put-out, and potential trouble. Such a foul tip, eluding the catcher's grasp, becomes a mere foul ball, counting nothing against the batter and, in fact, granting him one more chance to hit safely.



FROM ETHAN ALLEN, "MAJOR LEAGUE BASE BALL," THE MACMILLAN COMPANY

PITCHER THE BALL IN THE ACT OF DELIVERING IT TO THE BATTER

The catcher sometimes fields a bunt or a half-hit ball spilling just in front of the plate. Agility in pouncing upon the ball and accuracy in throwing to the proper base are then required. The catcher's throwing arm is a valuable item in his team's defense. Base runners will be chary of straying too far from their bases when the catcher has a quick and strong arm ready to shoot the ball to the baseman for a tag-out before the runner can scramble to safety. When a runner attempts to steal a base, the attempt usually begins as the pitcher starts pitching the ball to home. Unless the batter hits the ball, the play then becomes a match between the catcher's throwing arm and the runner's speed.

6. Pitching. — Important as is his fielding: the catcher functions even more importantly as the counselor of the pitcher. The catcher is, besides, the only player in the defensive line-up who has the whole game in front of him at all times. He is the man best placed for directing advice to teammates when necessary.

When a batter comes to bat, the pitcher and catcher operate against him as a unit, the battery. Up to the moment the batter hits the ball. the whole game is this duel between batter and battery. The pitcher is equipped with a strong arm. able to fire the ball across home plate so rapidly as to offer the batter only a flicker of time to decide whether or not to swing at it.

Besides sheer speed, the pitcher has other resources in the way of curves. change of pace. screwballs, sliders, etc. These represent ways of throwing the ball so that its course through the air diverts from the usual line of a fast ball, causing the batter to go off his stride. swing too early or too late at the ball, strike it merely a glancing blow or miss it entirely.

Before each pitch, the catcher, squatting behind the plate with his hands together between his knees: gives signs to the pitcher. With the fingers of his bare hand he transmits to the pitcher instructions for the next pitch. The catcher's knowledge of his pitcher's abilities shapes his decisions on each pitch, and his knowledge of the batter's abilities and peculiarities guide him in his choice.

Most batters get their greatest power into a drive when the ball comes to them a little above waist level. A minority are low-ball hitters, preferring a pitch between the belt line and the knees. With most batters it makes a difference whether the ball is inside or outside, that is, across the plate near the edge that is closer to the batter or the rim of the plate farther from him. Most batters can more readily hit a fast ball, that is, a straight one, than a curve or any of the breaking balls. Some gifted batters have more success when the ball breaks, a factor in this phenomenon being that the breaking ball is always less swift in its course than

the fast one. Searly all batters have a blind spot. or hole, of greater or less extent. somewhere in the strike zone. If the pitcher has good control, he can pitch the ball across the plate through this hole, and the batter is virtually helpless, either missing the ball or striking it an ineffectual glancing blow.

The mental capacities and experience of each pitcher determine how much of the battery's collective thinking is done by the catcher. In general, the catcher is the boss. Veteran pitchers, learned in the ways of batters in general and with their own special systems of pitching to each, need little assistance from the catcher. But for most pitchers. particularly young ones or new ones, it is the physical skills that occupy their attention: while the catcher does the thinking. makes the decisions of what to pitch and where.

Even in the case of a veteran pitcher, the catcher keeps his partner under constant study. alert to detect signs of weakening. In the major leagues for most clubs in the course of a season, only about half of their games, usually less than half, are transacted with a single pitcher playing the entire game. Sometimes three or four pitchers divide the work. It is often the catcher's verdict, upon consultation with the manager, that brings about the removal of one pitcher and the substitution of another.

In 19th-century baseball. up until about 1870. the pitcher was merely a player assigned to put the ball in play by pitching it to the batter to hit. One man usually did nearly all the pitching for a club all season. with a change pitcher to relieve him of some of the load at times. This change pitcher was usually an outfielder. The two would often merely exchange fielding positions without leaving the game.

With the start of league baseball in the 1870s, the pitcher became a stronger factor in defensive play. His use of speed and curves became a deciding element in championship contests.

A major league club has 25 players on its roster normally. Usually nine or ten of these are pitchers. A team's infield and outfield line-up may remain intact for weeks on end, barring injuries and illnesses. Its regular catcher occupies that position in about two-thirds of the season's games. Each regular pitcher,,however, requires about three or four days' rest between assignments, spending his time during his rest days at light exercise, running about the outfield during practice, seeing to it that his pitching arm is moderately exerted each day but in general merely keeping in shape until his next turn to pitch.

In a staff of ten pitchers, the manager earmarks his best four or five at any given time as starting pitchers. These are the regulars. They take their turns every four or five days, resting in-between. The remainder of the staff constitutes the bull-pen squad or the relief pitchers. When the catcher detects signs of weakening on the part of the pitcher in the game! these bull-pen pitchers begin warming up. Near their bench regulation-size home plates are embedded in the ground. At the correct distance from each of these plates is a pitcher's box. They warm up by throwing practice pitches to substitute catchers. The bench. together with the practice ground. is known as the bull pen. An effective relief pitcher is one who can depend upon his ability to control the placement of his pitches. as he often enters the game at a stage in which the offensive team poses a scoring threat with one or more base runners and a dangerous hitter at bat. Two or three relief pitchers each day are assigned to be ready for the call to substitute for the starting pitcher.

Control.—The catcher is quick to perceive signs of tiring on the part of the pitcher, a slowing up of his fast pitches. a dulling of the break in his curve. From other points of vantage, the pitcher's tiring becomes evident in loss of control.

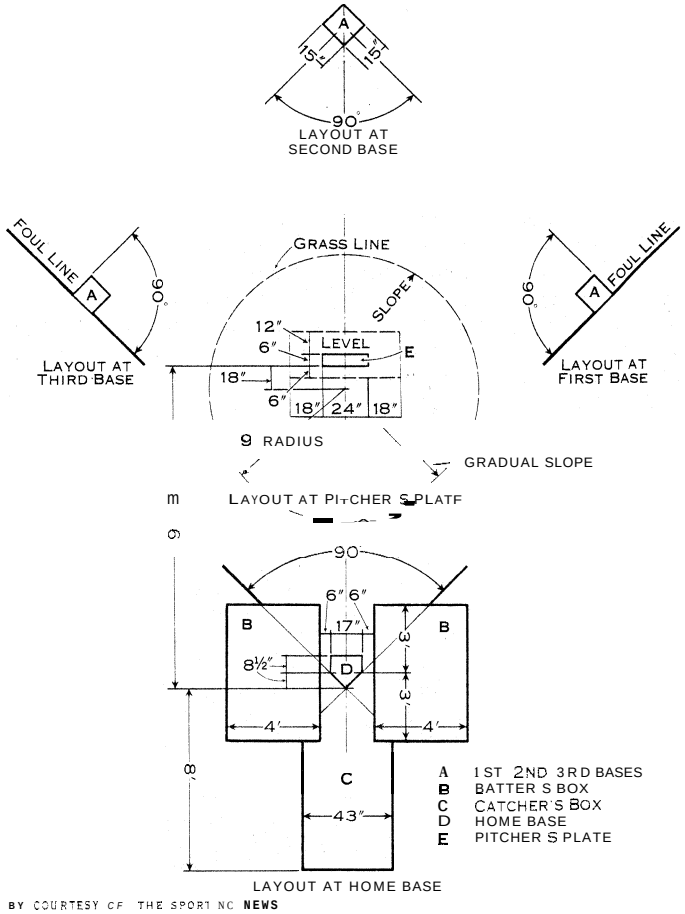
Pitching demands more of a man in the way of exact coordination of mental and muscular faculties than any other activity in the game. He is aiming at the strike zone, an area the width of the front rim of home plate (17 in.) and the height from the batter's shoulders to his knees (about $3\frac{1}{2}$ ft.).

The pitcher's "target" above home plate is at a point 60 ft. 6 in. from the plate against which the pitcher's pivoting foot must push in the act of pitching the ball. This plate is of composition, 24 in. long. 6 in. wide. placed with its long sides facing home plate and second base.

The term "pitcher's box" is a holdover from 19th-century baseball when an oblong area was marked out by white lines on the ground for the pitcher to occupy in the act of delivering the ball. In 1894 the actual drawing of a box on the ground was discarded in favour of a slab of rubber. 12 in. by 4 in.. for the pitcher to step on when delivering the ball. The term "box" has continued in use. however. referring loosely to both the pitching plate and the immediate area surrounding it for nine feet in every direction. This circular area is kept free of grass and rises in a gentle slope to the point where the pitching plate is imbedded. The plate is level with the ground at the summit of the slope. The rules specify that the summit shall be not more than 15 in. above the level of the base lines.

Lapses of control apparent to spectators take the form of bases on balls or numerous safe hits. Less often as a pitcher begins to tire, the loss of control results in hit batsmen. Each base on balls puts a potential run on first base, as does each hitting of a batter with a pitched ball. Sometimes a weakening pitcher's flustered nerves result in what is known as a balk. which can prove costly if occurring at a critical point in a close contest.

The Balk.—A balk is a departure from the restrictions imposed upon the pitcher by the rules and can only be committed with a runner or runners on base. In pitching the ball to the batter the pitcher must have his pivoting foot in contact with the pitching plate. If he does not. a balk is declared by the umpire. The pitcher must hold the ball in both hands in front of him at chest level before starting his delivery. Once started, he must continue his motion so that the ball is delivered to home plate. If he starts to make a throw to a base when a runner is occupying that base he may not stop, but must go through with the throw. otherwise a balk is called and all runners on bases at the time advance one base each. With a runner on third: a balk thus results in the gift



BY COURTESY OF THE SPORTING NEWS

FIG 3 — OFFICIAL MEASUREMENTS OF HOME BASE THE PITCHER'S PLATE AND THE THREE BASES

of one run for the offensive team. The balk rule was clarified at a meeting of major and minor league officials in Nov. 1953. Under the old regulations the ball was declared dead as soon as a balk was called. The runners, if there were any at the time, automatically moved ahead one base each as a penalty for the infraction, but the batter was not involved and anything he might have done on the pitch was nullified by the balk. Under the 1953 ruling the batter became definitely involved. If he hits a balk pitch for a home run or for a shorter safety, if he drives the ball through a fielder's position for an error. or if it is a fourth ball or a wild pitch, the hatter's team has the privilege of accepting the result more favourable to its interest. Thus, the balk is declined in most cases where the runners advance or in cases where the batter reaches base safely on the results of the balk pitch.

The Pitching Repertoire. — Apitcher's speed is usually the index of his general ability. *A* diminution in the speed of successive pitches is the symptom the catcher sees most often as a forecast of disaster. Originally, speed was the pitcher's sole reliance in his effort to thwart the batter. The curve was developed in the late 1860s. Other variations from the straight line of fast ball pitching have developed in succeeding epochs, but fundamentally the fast ball continues to be the basis of pitching skill.

The fundamental or regulation curve is a swerving pitch which breaks away from the straight line downward and across home plate in the direction of the catcher's right knee if the pitcher is right-handed; toward the catcher's left knee if the pitcher throws left-handed.

Many pitchers employ a curving ball whose break slants the opposite way from the regulation curve, a pitch known variously as the fadeaway (Christopher ["Christy"] Mathewson) or the screwball (Carl Hubbell), or some pet name applied by the pitcher himself who has mastered its secrets. The effect is to endow the pitcher with a reverse curve; thus Mathewson, a right-handed pitcher, used the conventional curve to break the ball away from right-handed batters, and his fadeaway to break it away from left-handed hitters. Hubbell, a left-hander, used his screwball to slant the pitched ball out and beyond the reach of right-handed hitters, using the regulation curve when facing a left-handed hitter.

In the case of both curves and reverse curves, the ball reaches the batter at a slower rate of speed than the fast ball. and the deception is almost as much due to the slower ball's falling away from the bat as to its swerving from the straight trajectory from the pitcher's hand to catcher's glove. Comparatively few pitchers use the "knuckle" ball, whose power lies in its almost entire lack of axial rotation as it sails toward home plate. This absence of spin makes it the plaything of air currents, so that, when the knuckles are expertly employed, the ball is wobbly as it approaches the batter, making it harder to hit solidly than a spinning ball sailing along "on the beam."

IV. UNIFORMS AND EQUIPMENT

1. Uniforms. — The uniform consists of a cap, a blouse, pants, stockings and shoes. In league baseball the home team always wears white blouses and pants. Gray is the prevailing solid colour of the blouses and pants of the visiting team. Baseball law requires that all the players of the same team must wear uniforms of exactly the same design and trimming in league games. An identification number is worn by each player on his blouse so that by referring to the printed scorecard the spectator can identify the player by name by observing the numeral he wears.

The cap has a visor as a shield from the sun. Sun fielders, outfielders whose location makes it necessary for them frequently to stare into the sun when judging the flight of the ball, have the peaks of their caps equipped with sunglasses. These are usually fastened on the underside of the cap's visor, snugly out of the way most of the time, but with a device that enables the outfielder to snap them into position when the ball is batted in his direction high in the air.

The blouse is collarless, with abbreviated sleeves usually ending halfway from shoulder to elbow. Under the blouse the player may wear a flannel undershirt.

The pants cover the player's knees. the elastic at the bottom pinching in just below the knee joint, with ample material to allow freedom of knee motion in running and to afford a degree of protection from abrasion by sudden. forceful contact with the ground, Most players wear. along the outside of each thigh, under the pants, sliding pads, two pieces of padded felt reinforced with leather and suspended from the waist. These pads protect the sides of the player's legs when he flings himself feet first along the ground (sliding to a base), as well as from abrasions that might be suffered in unintentional tumbles.

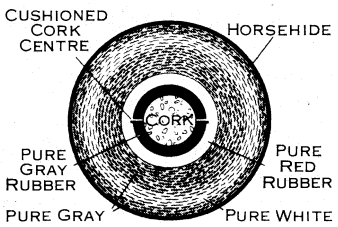


FIG. 4. — CROSS SECTION OF A BASEBALL

About nine inches in circumference, the ball weighs about five ounces

Players wear white cotton stockings underneath woolen coloured stockings. The woolen stocking usually is footless, its bottom consisting of an elastic band which passes beneath the player's instep.

The shoes are Oxford style, very light in weight, with flexible soles and heels. Each shoe has two spike plates, one for the sole, the other for the heel. These plates are triangular in shape, with a short prong (spike) at each angle giving the player a good grip on the ground, whether it be turf or the grassless dirt surface of the base lines. The pitcher also wears on his pitching foot (right foot for a right-hand pitcher; left foot for a southpaw) an additional pitcher's plate, a metal reinforcement at the inside of the toe, to give him a better foothold in the act of pivoting to deliver the ball. Umpires wear spiked shoes similar to those of the players.

It is in the lettering and the trimming of the caps, blouses and pants and in the colour and design of the stockings that the teams are easily distinguished from each other. *A* club's traveling uniform usually is lettered with the name of its city.

2. The Bat and Ball. — The bat used is a smooth. rounded stick, made either of a single piece of hardwood or of laminated construction, maximum length allowed 42 in., maximum thickness $2\frac{3}{4}$ in., smaller in diameter at its handle end. There is no restriction of the bat's weight. except that no metal or any other reinforcement may be used in its construction. It is allowable to apply to the gripping surface a covering of tape or other abrasive agent to give a firm hold for the batter's hands.

The legal professional ball is restricted to a weight of between 5 and $5\frac{1}{4}$ oz. and a circumference of from 9 to $9\frac{1}{4}$ in. It has a cork and rubber core, is wound tightly with woolen yarn and covered with two bispatular pieces of white leather, so shaped as to fit together tightly as a single-thickness cover over the entire surface when the two pieces are sewn together.

3. Gloves. — In preleague baseball, the game was played barehanded. One by one, starting with the catcher and first baseman, the players began wearing gloves to protect whichever hand bore the brunt of the ball's impact. In modern times every player wears a glove when in the field.

The gloves are leather, with some degree of reinforcement (padding) in all cases. The catcher's glove is the largest and heaviest, thickly padded at all points except the middle of the palm, in which the pitched ball imbeds itself. It is all one piece, except for the cleft between the thumb and the index finger. The first baseman's glove, thinner and much more flexible than the catching mitt, is a solid expanse of leather for the four fingers. The thumb, however, is separate: with a webbing connecting it with the index-finger edge of the rest of the glove. The gloves worn by pitchers, infielders and outfielders are finger gloves, usually with a separate compartment for each finger and for the thumb. Two or more leather straps connect the thumb with the index finger: enabling the player to get a tighter hold on a swiftly moving ball.

4. Protective Equipment. — Except for the catcher, the player in the field is considered adequately armoured when he wears his regulation uniform and glove. The catcher wears a mask, chest protector and shin guards in addition. The mask, a padded metal

frame with solid bars across its open front, fits the front half of his head. so that the catcher has full visibility but is protected from being hit in the face or about the head, ears and throat by the ball. The chest protector is a solid padded framework extending up over both shoulders and down between the legs, folding at about the waistline to allow stooping. The catcher's shin guards are of light metal over the shins, with padded leather extensions that fit over the knees. and at the bottom are shaped to the shoes so that a catcher blocking home plate has reasonable protection from the spikes of a player sliding feet first.

The umpire, whose uniform is a navy blue serge business suit, with a cap of the same shade. likewise wears mask, chest protector and shin guards when on duty behind home plate. The mask is similar to the catcher's. Most umpires wear a special umpire's body protector over or under the outer clothing. The umpire's shin guards are worn under his trousers, which extend full length to the insteps, so that from the stands the umpire's only visible protection usually is his mask.

At bat, the only protection worn by a player in addition to his regulation uniform is a "helmet." The most popular skull protector is a plastic cap, although a shell of composition, light metal or plastic fitting inside or outside the batter's cap on the side of his head which is presented toward the pitcher has been used.

V. ORGANIZED BASEBALL

As the national game, baseball is played informally by schoolboys on their playgrounds, by teams representing community groups—schools and colleges, factories, department stores, employed personnel of hotels, shipyards, mines, railroads, etc.—and by teams representing service units of the armed forces. While in the case of business firms some of the players receive financial compensation for their playing, the term "professional baseball player" applies exclusively to men employed as players by teams that are members of leagues subscribing to the authority and regulations governing nhat is known as organized baseball.

This system consists of a mutual agreement among the operators of teams representing cities and towns in leagues throughout the United States and in parts of Canada to recognize one central supreme authority, the commissioner, and to subscribe to the body of rules administered by this authority. Most important, these rules regulate the transfer of players from one league to another and among teams in the same league. The provisions aim at protecting the individual player from exploitation. while at the same time imposing restraint on his freedom of choice to the extent that at no time after signing up with any club in organized baseball can he, without the consent of his employer, obtain employment from any other club in organized baseball until he has received an unconditional release from the contract under which he plays in any given year.

The two major leagues and each of their member clubs are signatories to an agreement, called the Major League agreement, the first article of which creates the office of commissioner and sets forth its functions. The two major leagues, acting as one party. and the National association, representing the minor leagues as the other, are signatories to the Major-Minor League agreement, the first clause of which recognizes the office of commissioner as created by the Major League agreement

As an aftermath of the Chicago White Sox scandal in the 1919 world series, involving the bribing of players to throw games (see *Later* History: The *"Black Sox" Scandal,* below), the commissioner's office in 1921 took the place of the National commission. a three-man board of arbitration established in 1903, made up of the presidents of the two major leagues and an elected chairman. The framework of the commission continued under the commissioner's office in the form of the advisory council, the two league presidents with the commissioner as chairman. Nearly all the authority formerly vested in the commission was transferred to the commissioner. Kenesaw Mountain Landis (*q.v.*), former federal judge in the Chicago district, was chosen commissioner, beginning a term of service which continued until his death. Nov. 25, 1944, a period of about 24 years. He was succeeded in 1945 by Albert B. Chandler, who held the post until 1951, when Ford C. Frick was chosen for the office.

The minor leagues. whose number is variable from year to year, are classified according to the populations of their member cities as AAA (popularly known as the Triple-A), **AA,** A1. A, B, C, D and open. The open status is unique among minor league classifications. In order for a league to be classified in this open group, it must, among other things. remove all salary limits, show an average annual attendance of 2,250.000 or more over a five-year period, have an aggregate population of 10 000.000 and a combined park capacity of at least 120.000. The benefits of the open classification include the right of a player to naive, if he so desires, his chance to be drafted into the major leagues, and an increase in the sale price of those players drafted from $10,000 to $15.000. In 1956 only the Pacific Coast league met the qualifications. Many baseball authorities felt that the Pacific coast would eventually come into major league status, either as a third major league or by the adoption of one or more of its teams into an expansion of the existing major leagues. The Pacific Coast league, for years consisting of teams from the states of California, Washington and Oregon, added the city of Vancouver, B.C.. to its circuit in 1956 However the alarming sag in minor league attendance presaged future shifts in Pacific coast sites.

The tno Triple-A circuits, the International league and the American association. were forced to make several franchise changes in the early 1950s because of the marked decrease in gate receipts. Also. the entrance of Kansas City and Milwaukee (former American association cities) and Baltimore (which for years was an International league franchise) into the major leagues was another prime reason for a revamping of franchises in both these minor league circuits The AA included the Southern association and the Texas league. while the lower groups usually include teams from cities whose geographic locations are identified with their titles, such as the Eastern league. South Atlantic ("Sally") league, Western league, etc. With the introduction of radio broadcasts and telecasts of major league contests, a number of the smaller organizations suffered from the loss of attendance and revenue and ceased operating, many baseball fans apparently preferring to stay home and listen to or watch play-by-play accounts of big-league contests rather than to attend games in minor-league parks.

The year 1953 saw the first break in a half century in the alignment of cities in the majors when Lou Perini, president of the Braves, succeeded in transferring his National league franchise from Boston to Milwaukee. The last previous change in the line-up of major-league clubs had occurred in 1903 when the Baltimore Orioles became the New York Highlanders, who later changed their name to the New York Yankees.

The St. Louis Browns figured in another major realignment in Sept. 1953, when the American league franchise of the Bronns was sold to a Baltimore syndicate. Beginning with the 1954 season the former Browns became the Baltimore Orioles and moved into the Baltimore municipal stadium for their home contests. Another change in cities was effected before the start of the 1955 season nhen the Philadelphia Athletics' franchise was shifted to Kansas City.

The New York Giants and the Brooklyn Dodgers played in their respective cities for the last time in 1957. The National league approved a change in locations prior to the 1953 season: the Giants to San Francisco and the Dodgers to Los Angeles.

In 1961 the Washington Senators moved their American league franchise to Minneapolis-St. Paul and were renamed the Minnesota Twins. A franchise for a new team, also to be called the Senators, was granted in Washington. and another. to a team to be called the Angels. in Los Angeles. Thus. the American league for the first time became a 10-team organization. The National likewise increased to 10 teams in 1962 by placing new teams in New York and Houston.

The grading of leagues from top to bottom is part of the mechanism in organized baseball for assuring a player's opportunity for advancement. The grading represents different levels of salary limit By an annual draft empowering higher classification leagues to select players at fixed prices from leagues lower in the rating,

the advance of a player, when merited, is made inevitable. Transfers of players' contracts are on a buy-and-sell basis. not only among teams in the same league, but in interleague transactions. There are fixed prices applying at the various levels for the drafting process.

Each year before the arrival of the draft deadline in September, players of unusual ability may be transferred to higher leagues by the sale of their contracts at prices higher than the fixed draft price that would be obtained if a player's club chose to keep his contract beyond the date of the draft deadline on the chance that he would be overlooked by scouts seeking reinforcements for teams in higher-rated leagues. This trading in players' contracts evolved out of the baseball wars of the 19th century. In the years before teams were organized into leagues, rival clubs commonly raided each other's ranks and hired away each other's stars in free competition on an open market. In 1879, Arthur H. Soden, of the Boston club, effected the adoption of a resolution by the National league by which five players of each club might be named who could not be approached for hire by any other team in the league. This was the beginning of the Reserve rule, amplified in 1883 when Col. A. G. Mills, National league president, brought about an agreement among the National league and the American association, the two major groups operating at the time, and the minor leagues then in existence.

The Reserve rule, requiring the observance of each team's rights to the services of the players on its reserve list, is the cornerstone of organized baseball. The original list of 5 reserved players was increased to 11 as part of the 1883 agreement. The number of players permitted to be held on each club's reserve list was increased in all gradations of leagues in the intervening years. The modern maximum is 40, the limit for the reserve lists of clubs in the two major leagues.

In the 1940s major league players chose representatives from their own ranks to discuss problems and air any grievances with the club owners and the leagues' executive council. Higher travel allowances, pensions plans and other benefits are among the items handled by the athletes' spokesmen. The ownership of players resulted in a series of court fights in the 1950s, stemming from the baseball clause that bans a player from bargaining on his own with any club while he is under contract to another team. Charges that baseball violated the federal antitrust laws went as far as the United States supreme court, which on Nov. 9, 1953, handed down a ruling that baseball was a sport and not a business and thus was outside the scope of federal antitrust laws. The house of representatives judiciary committee, after an exhaustive survey of the monopolistic aspects of the sport, had issued a report in 1952 in which it found no grounds on which to recommend that the game be brought under antitrust regulations.

1. The Playing Rules.—"The Official Playing Rules of Professional Base Ball Clubs," as adopted at the meeting of the Joint Playing Rules committee of the National league and the American league, held at National league headquarters, New York city, March 2, 1904, and as amended in subsequent years by official major league committees, govern the playing of baseball not only in the professional leagues but universally.

2. The Averages.—Each league maintains a bureau in which are filed the statistics of all its contests. After each game the official scorer, appointed by the league, drafts a record of the game, with its detailed columns showing each player's hits, runs, eirors, etc. At the end of each season, the official averages for the entire campaign are compiled. With expansion of the major leagues in 1961–62 all previous averages and statistics, based on a 154-game season, became obsolete and comparison between old and new records became a matter of controversy.

3. League Games.—As is made apparent by the rules of play, the pitcher is the central figure in the game, which is a succession of "plays." Each play begins when the pitcher delivers the ball to the batter and lasts until the pitcher holds the ball again, standing with his foot against the pitcher's plate or "rubber," in position to deliver the next pitch.

If the ball travels past the batter to the catcher and is then tossed directly back to the pitcher, it is a complete play in itself. If the ball is batted, the play goes on until the ball has been fielded, all base running has stopped and the ball returned to the pitcher for the next pitch.

A substitution may be made at any point in the game when time has been called by the umpire. A player taken out of the line-up cannot return in the same game. When the manager makes two or more substitutions at one time, he must specify them one at a time to the umpire, so that each substitute's place in the batting order is immediately established. Such substitutions may be made regardless of the positions played by the players involved. For instance, the manager may take out of his line-up his pitcher and second baseman, substituting a second baseman to bat in the pitcher's place in the batting order, the new pitcher batting where the second baseman formerly batted. He may send in as many substitutions at one time as he wishes, up to the limit of his nine names, but each substitute takes a fixed position in the batting order at the moment the change is made. Without making any substitution, the manager may at any time in the game shift his players from one fielding position to another. He may shift all nine positions in fielding, but can never legally change a man from one place to another in his batting order.

The visiting team always has the first inning at bat in modern baseball, the home team's inning, by choice, coming second. In common parlance "inning" includes an inning at bat for each team. Originally a game was described as consisting of nine innings for each side. Usage has erased the last three words. A game, in modern baseball language, consists of nine innings. A team's sixth inning is now its "half of the sixth." In written accounts of ball games this is followed out further, so that a play is said to have occurred "in the first half of the sixth," or simply "in the top of the sixth," which conveys to the reader the information that the visiting team was at bat at the time in its sixth inning. If the home team was batting, the writer would place the play "in the last half of the sixth," or, more likely, "in the bottom of the sixth."

Whichever team has scored the most runs at the completion of a game is the winner. If the home team has scored more runs in eight innings than the opposing side has scored in nine, the game ends after the first half of the ninth. If the score is even after nine full innings, play continues until one side has more runs than the other in even innings played. At any time, starting with the latter half of the ninth inning, that the home team in an inning acquires one run more than the visiting team, the game immediately terminates, whether there be none out, one out or two out at the moment the winning run is scored. There is one exception to this, coming when the winning run is scored by a base runner who was on base when a teammate hits a home run. In such a case, the hitter of the home run is permitted to make the circuit of the bases and score his run as the final transaction of the game. If more than one of his teammates were occupying bases when the homer was hit, the others also score runs. It is thus possible for the team last at bat to win an extra-inning game by as great a margin as four runs, although the almost invariable score of a home team's extra-inning victory is by a one-run plurality. A game may be terminated by the umpire because of rain, darkness or other cause which in his judgment interferes with further play. If at least five equal innings have been played, the umpire may declare the game a tie or a decided game, depending on the score. A game may be suspended if there is light failure, a curfew requires play to stop, or under league time limits, and the suspended game is then completed at a later date.

4. The Baseball Season.—The championship season of a professional league extends from mid-spring until early fall. The major league season starts about mid-April and ends on the last Sunday in September or the first Sunday in October. The annual world series between the pennant winners of the two major leagues begins on the l'uesday or Wednesday following the closing day of the regular season. The world series continues until one of the pennant-winning clubs has won four victories, thus establishing it as the world champion of the year.

Preceding the opening of the championship season, each club has a period of spring training which lasts for a month or more during which time its men are conditioned for playing almost every

day over a period of months (5½ in the majors). It is during this training trip that new candidates are tried out. The manager and his assistants extend their efforts to select and train the strongest line-up possible from their squad. Practice games are played between teams picked from the squad; also exhibition games against teams representing other organized baseball cities. preferably cities in other leagues, whose training camps are located within ready reach.

Except when war or other considerations play a part, each club does its spring training in a locale where the temperature is likely to approximate the level of the summer temperature in its home city. Major-league clubs ordinarily choose locations in Florida, Texas. Arizona and California, though, in general. "somewhere south" describes the training location of every club of every league. major and minor. Several U.S. teams trained in Cuba in the 1950s. The number of games to be played by each team of a league is established so as to book an equal number of games home and away for each team against each of the other clubs. The major leagues in 1904 fixed on 154 games as a permanent figure. With expansion of the major leagues to ten teams in 1961 (American) and 1962 (National) the figure was revised to 162.

However, it is a rare year when every club plays exactly the specified number of contests. When games end in ties, the statistics of such games go into the records of the individual players, although subsequent dates for play-offs of those deadlocked contests are arranged. Postponements because of inclement weather, especially late in the pennant campaigns, often cause a reduction in the allotted number of encounters for the clubs involved because travel schedules of the teams might prevent the opportunity for a play-off before the scheduled closing day of the season.

In common practice, the play-off of ties and postponed games takes the form of the double-header, in which two games are played on the same date, with a short rest period intervening. The popularity of the bargain bill with the public has resulted in doubleheaders being placed in the schedule in its original draft before the season's start, usually on holidays and Sundays.

The games are arranged to take in 24 week ends and the three holidays nationally celebrated, Memorial day (May 30). Independence day (July 4) and Labor day (first Monday in September). These are the big days in the schedule.

Starting in the 1930s, additional big days appeared in league schedules in the form of night games. Experiments in playing games under artificial lighting were reported in 1880 (Nantasket Beach, Mass.), but because of the large area necessary to be illuminated to as near daylight level as possible, it was never tried in league games until 1930.

On April 28, 1930 (Muskogee at Independence, Kan., Western league), was played the first night game that counted toward a league pennant. Since to most patrons of professional baseball weekdays are workdays, the opportunity to see a game on a weekday evening instead of waiting until Saturday or Sunday came as a boon. Night baseball became popular.

By 1933 engineers had solved the problem of lighting the extensive areas of large stadiums. and in May of that year the first major league night game was played in Cincinnati (*v.* Philadelphia). By the outbreak of war in 1941. the majority of major league parks had lighting systems, and, thereafter. schedule makers each spring planned the night games with as much care as they devoted to week-end and holiday dates. By the 1960s all but one of the major league parks were equipped to play games at night. (The Chicago Cubs of the National league continued to play all their home games at Wrigley field during the daylight hours.)

5. The Championships. — Arranged in the order of their percentages, from the highest to the lowest, the list of clubs in a league on any given day is called the club standing. Half of the clubs, those with the higher percentages, are in the first division, the other half in the second division. After the last day of the season, the club standing at that point becomes the record for the year. The no. 1 team is victor. winning the right to fly from a flagpole in its home field a banner or pennant, combining the red, white and blue of the United States flag in a design of its own selection, with lettering and numerals proclaiming it the champion of its league for that year. This pennant is customarily raised at the champion's opening game at home the ensuing season and flown from the masthead throughout the new campaign.

For all but one of the clubs in each of the two major leagues, closing day means the disbandment of the players for the winter. The two pennant winners, however, meet in the world series (see *The World Series*, below). a postseason competition in which about half of the total cash receipts of the first four games forms a players' pool, to be divided among the first division teams of each league. The players of the pennant-winning teams. as world series opponents. fittingly receive the lion's share, 70%.

A record was set in the 1959 world series between the Chicago White Sox, champions of the American league. and the Los Angeles Dodgers, pennant winners in the National league. The six games required for a decision attracted a paid attendance of 420.874 persons and the net receipts totaled $5,626,973.44. Each full share for the Dodgers. who became world champions, was $11,231 18, while each of the White Sox voted a full share received $7,275.17.

The minor league counterparts of the world series are the junior world series, between the Triple-A champion teams of the International league and the American association (the "little world series").

Most of the minor leagues conduct, each within its own membership, a postseason series known as the Shaughnessy play-offs. taking the name from Frank J. Shaughnessy, former president of the International league. who was primarily responsible for its introduction in 1933. Played usually for a special trophy. the Governor's cup, etc., these series are participated in by the first four teams in the final standing of the regular pennant race. The team winning the Shaughnessy play-off is usually considered the league's champion, and the pennant winner often is beaten in the play-off.

VI. HISTORY OF BASEBALL

1. Origin **of** the Game. — On June 12, 1939, the National Baseball Hall of Fame and Museum was dedicated at Cooperstown, N.Y. This was the central ceremony of a countrywide. summer-long celebration of what was described as the national game's 100th anniversary. It was in Cooperstown, a village in Otsego county, north-central New York state, in the summer of 1839, that Abner Doubleday (later a general in the U.S. army) was alleged to have laid out the first baseball field and conducted the first game of baseball ever played. The players were cadets of the military preparatory school at which he was stationed as instructor. In 1919 the Cooperstown village fathers leased the site of the original playing field used by the cadets, dedicating it as a permanent memorial under the title Douhleday field, Sept. 6, 1920. On Sept. 29, 1923, permanent title to Doubleday field was transferred to the village of Cooperstown by a New York supreme court order. This version of the "creation" of what has come to be the U.S. national pastime was officially accepted by most of the major league leaders, but later research disproved it.

In the late 19th century, when baseball had grown to national stature as a professional sport, the question of its origin was a topic of wide discussion, because of its resemblance to rounders, a children's game originating in Great Britain, and to children's games flourishing in different sections of the United States. called town ball, one old cat. two old cat, three old cat and four old cat, all of which contained rudiments of baseball.

In 1907, A. G. Spalding, one of the most famous of the 19th-century players and founder of the sporting goods manufacturing company A. G. Spalding & Bros., appointed a commission of research to establish the exact date when the evolutionary transition of village green sports crystallized to a form from which 20th-century baseball could trace its direct descent.

The members of the commission were: Morgan *G.* Bulkeley, first president of the National league and subsequently a United States senator from Connecticut; A. G. Mills, third president of the National league; Nicholas E. Young, president of the National league from 1885 to 1902; Alfred J. Reach, big league player of the 1870s. president of the Philadelphia National league club for 20 years and senior member of the sporting goods firm of A. J. Reach & Co.; George Wright, the greatest player of baseball's

earliest days of league organization and head of the Wright and Ditson sporting goods company; Arthur Pue Gorman, U.S. senator from Maryland; and James E. Sullivan, president of the Amateur Athletic union. This commission published its report in the *Baseball Guide* of 1908. Its chief findings were two in number: first, that baseball is a distinctly American sport and had no connection with rounders or any other foreign game; secondly. that the first rules for playing baseball, according to all evidence obtainable to date, were devised by Abner Doubleday, in Cooperstown, N.Y., in 1839.

The playing field said to have been devised by Doubleday placed the bases at the corners of a go-ft. square, called the diamond, a term also loosely used for the entire playing field. His fixture of base locations and distances between bases has never been changed. In the games of cat. which were played prior to baseball, it was necessary to bat, run and touch a base, or bases. The number of bases to be touched depended upon whether it was one old cat, two old cat or three old cat. A run was scored when the batter touched an outlying base, retraced his steps and regained the batsman's base, or home plate, as it later became known in baseball. One old cat could be played with three players, but more enjoyably with four or more. In two old cat, in three old cat and in four old cat the number of players could be increased to 10, 12, 14 or more. No organized teams played, nor were sides formally chosen. The object of the game was to "stay in" as batsman as long as possible, runs being considered merely an accessory to "staying in."

From this primitive method of "bat the hall. run and tally" developed the game of town ball, in which the selection of teams upon the field, or competition of sides previously agreed upon or chosen, engendered the method of team competing against team. Thus when baseball was devised by Doubleday, the fact of team competition had been determined in town ball. The Olympic Town Ball club was organized in Philadelphia in 1833. This appears to be the first team bf that character assembled in the United States. Town ball was played with a field diagram laid out as *a* perfect square with four corners, or goals. each of them about 60 ft. apart. The batsman's position was halfway between the first and fourth goal. The catcher was behind the batsman and outside the square. There were no batted foul balls, and it was considered to be expertness on the part of the batsman to deflect the ball behind him.

Because town ball, also known as round ball, was thought by some to be'the newly invented game of baseball, two entirely different games became identified with the name of baseball. In 1845 the Knickerbocker Baseball club of New Pork drew up the first code of rules and the first match game of record was played under these rules between the Knickerbocker club and a picked team which, for this game, called itself the New York club. The game was played at the Elysian fields in Hoboken, N.J., in 1846. Games were played by the Knickerbockers with the Gotham, Eagle and Empire clubs of New York city, and with the Excelsior, Atlantic, Putnam and Eckford clubs of Brooklyn, then a separate city from New York. There were other clubs than these.

(W. E. Bt.; T.V.H.; D. Sr.)

The Controversy Over Baseball's Origin. —In the early days of modern U.S. baseball, no one who wrote of it seemed to doubt that it was an evolution from the English children's game known then and thereafter as rounders (*q.v.*). A simple change in the rules, according to these authorities,, transformed it into a man's game. In rounders, as then played, the fielder put out a runner making for a base, or caught off base, by throwing the ball at him and hitting him with it. This precluded the use of a hard ball and, since a soft ball cannot be batted very far, limited both the size of the field and the activity of the players. Then, presumably about 1840, some American had the idea of putting out the runner by tagging him—touching him with the ball or with the hand holding it. It became immediately possible to use a hard ball—at first, a kind of miniature cricket ball. And the game suddenly grew up. The rules of the pioneer Knickerbocker Baseball club of New York, drawn up in 1845, constitute the earliest known documentary record of this change.

However, many of the old-time players refused to entertain the thought that a foreign nation had anything to do with inventing a great U.S. institution like baseball, and especially A G Spalding, who had made a fortune out of sporting goods. Hence the Spalding commission. composed not of skilled investigators but of baseball men assisted by a United States senator, was appointed ostensibly to investigate the origins of the game but really to prove its exclusively U.S origin. In 1908 this commission reported in the official baseball guide that the game, including the essentials of the modern rules, the dimensions of the field and even the name. was invented in 1839 at Cooperstown, N.Y., by Abner Doubleday—afterward General Doubleday, a hero of the battle of Gettysburg—and that the foundation of this invention was an American children's game called one old cat. As most of the pioneer players were dead before 1908, this report caused so little controversy at the time that gradually even the standard reference books accepted its conclusions as seasoned history. Effective attempts to refute its data did not begin until 1939, the centenary of the alleged invention, when Robert W. Henderson, of the New York Public library, issued a pamphlet embracing some scholarly researches of his own, all casting doubt on the Doubleday theory and strengthening the case for an English origin. Others have since added a few corroborative details.

The main points in support of this contention are as follows:

The name "baseball" to designate some popular English game has been traced back to the first half of the 18th century. In the *Letters* of Mary Lepell, Lady Hervey, occurs a passage under the date of Nov. 8, 1748, satirizing Frederick Prince of Wales and his moronic habits. "The Prince's family is an example of cheerful and innocent amusements . . . they divert themselves at baseball, a play all who have, or have been, schoolboys, are well acquainted with." In *Northanger Abbey* (written about 1798) Jane Austen remarks of her heroine, "It was not very wonderful that Catherine, who had by nature nothing heroic about her, should prefer cricket, baseball, riding on horseback, and running round the country at the age of fourteen, to books."

But before this the name, and most probably the game, were already known in America. In 1744, *A Little Pretty Pocket-Book* was published in England. Illustrated with crude woodcuts, it pictures and describes in doggerel quatrains 26 children's sports—one for each letter of the alphabet. And "B" is represented by "Baseball." The text records that the batter hits the ball and runs from base to base. The illustration, which comprises only part of the field, shows a player at the plate, holding a bat with a curious flat, fanlike end, a catcher behind him, a pitcher preparing to throw a small ball underhand, two bases—marked by posts instead of bags—with a baseman beside each of them. This book, furiously popular in England, was reprinted twice in America—in New York city (1762) and Worcester, Mass. (1787).

There followed other references, some less definite, some good documentary evidence, to an American game of this kind. The journal of George Ewing, a soldier, written at Valley Forge in 1778, tells of "playing at base." Some boys "playing at ball" in the Wall street region of New York abandoned their game to join one of the riots which preceded the revolution. In 1787 the faculty of Princeton college forbade the students to "play with balls and sticks in the back common of the college." Thurlow Weed, editor and politician of Rochester, N.Y., mentioned in his memoirs "a baseball club organized about 1825." Corroborating this, Samuel Hopkins Adams turned up in a copy of Weed's newspaper dated in the 1820s an item stating that the Rochester Baseball club, with about 50 members, was in practice for its season's activities. The elder Oliver Wendell Holmes, Harvard 1829, mentioned to an interviewer that he had played a good deal of baseball while in college at Cambridge, Mass. These are only a few selected references from a number discovered incidentally and accidentally. Systematic search of books, documents and records before 1830 would most probably turn up many others.

Then came the unpretentious document that ties up English rounders to American baseball in their primitive forms. *The Boy's Own Book,* published in London in 1828 and so popular that it ran through many editions, was as the name suggests a treatise on boys' sports, with rules. The second edition includes a chapter

entitled "Rounders," with a note that the game is called "feeder" in London. As there described, it bears a far closer family resemblance to modern U.S. baseball than does Rugby football to its acknowledged offspring, U.S. intercollegiate football It was played on a diamond with a base at each corner. the goal or fourth base identical with the plate beside which the batter stood. The batter might run whenever he hit the ball across or over the diamond A ball hit in any other direction constituted a foul: he might not run on it. If he struck at it and missed it three times, he was out. A batted ball caught on the fly constituted an out. When a runner made the circuit of the bases, it counted one point or tally for his side. Then came the one vital difference which distinguished this from modern baseball When a grounder was fielded the fielder put the runner out by throwing the ball at him and hitting him with it. The same rule applied to a runner caught off base. The woodcut accompanying the article bears a strong resemblance to that illustrating the rhyme on "baseball" in A *Little Pretty Pocket-Book.* Even the bat is the same strange-looking implement. However, objects that look like flat stones serve as bases, and there seem to be two catchers — the second one, probably, to range for fly fouls. (W. I.)

Many English immigrants to America in colonial times were from those south counties of which Mary Lepell and Jane Austen were residents. That the old game was called "baseball" in that region, as it was called "feeder" in London and "rounders" in western England, and that south-county immigrants took both the name and the game to America seems a tenable hypothesis. There would seem to be little room for doubt that modern-day baseball evolved from such sport just as so many other present pastimes did from games of bygone eras.

As for the "old cat" versions, the critics of the Spalding report hold that in the 18th century those games were what they are today — substitutes for baseball when the boys did not have enough players for two full teams. In one old cat there was one base, one pitcher, one catcher and one batter. The more men available the higher goes the number of "old cats" — two, three, etc. Town ball seems to have been only another American name for rounders. feeder or old-time baseball, and near Boston the sport was known as the "Massachusetts game" at the turn of the 19th century. Reminiscences in the sporting periodicals of the 1850s and 1860s go to prove that it was played in New England even before 1833, when Philadelphia had a town ball club and drew up written rules. However, New England, unlike Philadelphia, distinguished between fair and foul balls. On the other hand. in part of New England, home base and batter's plate were not identical. but stood a few feet apart from each other, so that the line-up included a fourth baseman. Henderson's writings revealed the first United States book on baseball was the *Book of Sports,* written by Robin Carver in Boston in 1834. In it the author credits much of his material to the London publication *The Boy's Own Book,* put out six years eariler. Carver's book goes into details of the game of rounders. including an illustrated diagram for the placing of the posts (bases) in the shape of a diamond. Carver copied the English rules of rounders almost word for word yet called his game "base, or goal ball." Doubleday, Alexander J. Cartwright, a New York surveyor and amateur ball player, Harry Wright, who played as an amateur with the New York Knickerbockers and became a professional player and manager (Cincinnati and Boston), and Spalding have each been referred to as the "father of baseball." Doubleday no doubt did much to promote interest in the sport, probably while a cadet at West Point, for some sports historians place his years at the military academy as 1838–42. Unfortunately, the notes, statements and affidavits gathered by the Spalding commission were afterward lost in a fire, and only the finished report is extant. In this, an old resident named Abner Graves figured as the chief witness, and he testified that in the game taught to Cooperstown by Doubleday the fielder put out the runner by hitting him with the ball. This means, of course, that Doubleday's game was still much like the old English version and renders unlikely the statement that Doubleday laid out a diamond with the exact dimensions of the modern playing field. for any ball light and soft enough to be thrown full force against a player's head or body without danger of inflicting serious injury could scarcely have been batted out of an infield so large. Cartwright, who long had played the game with society friends about New York, became discouraged with the haphazard manner in which contests were conducted and organized a group to formulate a code of standard rules in 1845. Drawing heavily on Carver's book, the group submitted a set of regulations. which were adopted in Sept. 1845, and much of that original code is applicable today. It was then that tagging out a runner was adopted. which no doubt paved the way for the introduction of the hard ball that is the key factor of modern baseball.

Listing a few of the 1845 rules mill reveal how closely they paralleled those in force in organized baseball of today. For example: (1) a ball knocked outside the range of first or third (outside foul lines today) is foul; (2) three balls being struck at and missed, and the last one caught is a hand out (one out). but if not caught, it is considered fair and the striker bound to run: (3) three hand outs. all out (batting side retired); (4) a player running the bases shall be out if the ball is in the hands of an adversary on the base and the runner is touched by the ball before he makes his base, it being understood, however, that in no instance is the ball to be thrown at him (a definite departure from rounders).

With the introduction of the new rules by the New York Knickerbockers, the sport gained quickly in popularity. The Knicks, who were about to be ousted from their Manhattan playing field, found a new site across the Hudson River in Hoboken, **S. J**and made it their home field for the 1846 season. Their rules soon were taken up by such clubs as the Gothams, Eagles, Empires and Mutuals. The Olympic club of Philadelphia. although it had been playing town ball since 1833, did not switch to the Cartwright code until 1860. At about the time the new version of baseball was being popularized around the New York area the old soft ball variety had a sudden spurt in popularity in Boston. Until the Civil War, the game was called respectively Boston baseball and New York baseball. New York and New Jersey regiments taught their own versions of the sport to other Union soldiers. and when the war ended the more rugged and adult New York game held the field as the sport for grown men.

2. Later History. — From 1845 until 1854 baseball was played by the code of rules first written for the game. In 1854 there was a revision which provided specifications for the size and weight of the ball. On March 10, 1858, the first attempt was made at organization of clubs, their number having greatly increased and the game having expanded throughout the territory about New York city, extending to Philadelphia. Massachusetts still played town ball. In 1859 Washington, D.C.. organized a baseball club, follosved in 1860 by Lowell, Mass., Allegheny, Pa., and Hartford, Conn. From that time the game became more widespread, going to Maine, Kentucky and in 1866 to Portland. Ore. Baseball was played in towns and hamlets other than the cities mentioned during this period, but the clubs were considered to be town or minor clubs as against organized clubs! a distinction that has followed the progress of professional baseball since. The National Association of Baseball Players, organized in 1858, embraced 16 clubs in New York city. W. H. VanCott was its president. The Knickerbocker playing rules were amplified, and the ball and bat were made to conform to measurements approximating those of the present day. In 1863 the rules were further amplified. From 1861 to 1865 baseball languished except in the armies of the Civil War. In 1865 a convention was held in New York at which 91 clubs were represented, .including the cities of St. Louis (Mo.), Chattanooga (Tenn.), Louisville (Ky.): Washington (D.C.), Boston (Mass.) and Philadelphia (Pa.). It was strictly an amateur organization without schedules for games, and its purpose was to preserve the stability of the rules and the amateur status of the sport.

In 1865 and 1866 professionalism began to make its appearance. Players did not derive their livelihood from baseball, but the more expert accepted sums of money as members of any club that would engage them for occasional games. This was a new development, somewhat unexpected, and it seriously perturbed the equanimity of the amateur players. Gentlemen players openly

avowed their objection to what they expressed in caustic language as deterioration. In addition to the disposition of some players to accept hire for their services, open pool selling and bribery by gamblers. some of which was successful, outraged the better element among players and organizers of clubs. This conflict between amateurism and professionalism eventually led to a professional organization, the first of its kind, and a puny affair compared with the later great associations of clubs in leagues.

In 1867 the Nationals of Washington, under the lead of Arthur Pue Gorman, afterward U.S. senator from Maryland, made the first trans-Allegheny tour. The team went as far west as St. Louis. In that year the Rockford, Ill., club began the practice of paying salaries to some of its players. In 1868 the Cincinnati team was organized on what was known as semiprofessional lines, a characterization of athletes peculiar to the United States. A semiprofessional does not play baseball for a living, but is hired in occasional games. In 1869 the Cincinnati team was hired as an outright professional organization and made a successful tour of the United States from New York to San Francisco. The Cincinnati team did not lose a game that year and mas undefeated until June 14, 1870. During the successful career of the Cincinnati team rival clubs became imbued with an eager desire to win from it, throwing aside all restraint of policy relative to being amateurs in order to engage the best players available. Most of the important clubs abandoned every attempt to preserve an amateur standing, despite the fact that they were members of the Xational association, which was an amateur body. Once professionalism had entered the game it was impossible to keep the professional and amateur exponents of the sport reconciled. The organization of the professional Cincinnati team was followed by that of another professional team at Chicago, and in 1870 the National Association of Baseball Players was disrupted, the pure amateurs withdrawing from the annual meeting. A new amateur organization was effected in 1872 but died in 1874, the last of the concerted attempts to keep the control of the game within amateur influence. In 1871 the National Association of Professional Baseball Players was organized in New York. This embraced the Athletics of Philadelphia; Bostons of Boston; White Stockings of Chicago; Eckfords of Brooklyn; Forest Citys of Cleveland, O.; Forest Citys of Rockford, Ill.; Haymakers of Troy, N.Y.; Kekiongas of Fort Wayne, Ind.; Olympics of Washington; and Mutuals of New York. The affairs of the organization were loosely conducted. The circuit was not preserved intact. Many scheduled games never were played. Gambling and contract breaking became so repulsive to players of higher principle and to certain owners that they withdrew. The association dissolved in 1876 when the National League of Professional Base Ball Clubs came into existence with the seceders from the association backing it. It was organized in New York city, Feb. 2, 1876, with a membership made up of the Athletics of Philadelphia; Hartford, Conn.; Boston; Chicago; Cincinnati, O.; Louisville, Ky.; St. Louis; and the Mutuals of New York city.

The first president of the league was Morgan G. Bulkeley, afterward governor of Connecticut and also U.S. senator from that state. He served one year and was succeeded by William A. Hulbert, commended by all baseball folk when in 1877 he expelled from baseball for life four ball players found guilty of dishonesty. From this time confidence was established in the professional branch, and amateur baseball grew with the revived interest in professional baseball. Hulbert remained president of the league until his death in 1882. During his administration baseball had sufficiently developed to be regarded as an institution. Col. A. G. Mills, one of the most notable athletic authorities in the U.S., afterward prominent in the Olympic games, was elected president of the league in 1883. He resigned in 1885. Nicholas E. Young was elected to succeed him in 1885 and held office until 1903. Presidents in succession since then have been Harry Clay Pulliam, Thomas J. Lynch, John K. Tener, former governor of Pennsylvania; John A. Heydler, Ford C. Frick and Warren Giles.

In 1882 the American association was formed in cities not members of the National league circuit. National league owners attempted to equalize salaries of players. regardless of cities and local conditions. by a uniform scale of hire. The players opposed it. and in 1890, after forming a league known as the Players' league, took the field against the National league. In one year the player organization was wrecked. The American association engaged in open rivalry with the National league in 1891, a venture hopelessly destined to failure! and in the winter of 1891 was merged with the National league into a 12-club organization having a monopoly of major league, baseball.

As "the" major league, the National operated with 12 clubs from 1892 to 1899, inclusive. Falling off of patronage in Baltimore and Cleveland, mainly due to the weakening of the two teams' line-ups by trades, resulted in the return to the eight-club membership, starting with the 1900 season. Baltimore, Washington. Cleveland and Louisville were dropped as National league cities, leaving Boston, Brooklyn, Chicago. Cincinnati, New York, Philadelphia, Pittsburgh and St: Louis. This resumption of an eight-club setup by the one and only major league in existence led to the rise of a rival circuit, the Western league, organized as a minor league in 1893, its membership midwest cities covering about the same territory as the present-day American association.

In 1900 Charles A. Comiskey, owner of the St. Paul, Minn., club of the Western league, moved his team to Chicago, and renamed it the Chicago White Sox, although Chicago was a member of the National league, with continuous membership from the league's inception in 1876, when its team was known as the Chicago White Stockings. In the same year the Western league shifted its Grand Rapids, Mich., team to Cleveland, one of the cities abandoned by the National league after 1899.

The move to Chicago by Comiskey received the assent of the National league, but when permission was sought to place teams for the 1901 season in Baltimore and Washington, the National league refused.

Two years of baseball war followed. Having changed its name to the American league, the militant former Western leaguers, headed by their president, Byron Bancroft ("Ban") Johnson, moved their Indianapolis (Ind.), Kansas City (Mo.), Minneapolis (Minn.) and Buffalo (N.Y.) clubs to Baltimore, Washington, Philadelphia and Boston for the start of the 1901 season.

The Xmerican league withdrew from the national agreement, the body of rules governing relations between all professional leagues, major and minor, their transfers of players from one league to another, and their territorial restrictions in the operation of clubs. Its 1901 line-up of eight cities listed, besides the newly invaded four eastern cities, Chicago, Detroit, Cleveland and Milwaukee in the west. For 1902 the Milwaukee club was moved to St. Louis, invading National league territory there, and for 1903 the Baltimore franchise was shifted to New York, establishing the American league's roster of cities as it continued to stand down through the decades after the baseball war until 1953.

In the "war" years, the American league made inroads on the National's galaxies of star players to such a degree that it became firmly established as a major league. When peace was made between the two leagues in midseason, 1903, the new agreement entered into by both gave each of the two leagues equal importance. The agreement forbade the consolidation of two clubs occupying one city into one ownership, prohibited shifting of teams from one city to another by either league without the consent of the other, set rules for transfers of players from one major league to another, as well as re-establishing the rules dealing with securing minor league players.

The "war" brought into prominence two men whose names became baseball tradition, Connie Mack (Cornelius McGillicuddy) and John J. McGraw. In 1901 Mack. a former National league catcher and manager of the Pittsburgh Pirates in 1894–96, was manager of Milwaukee when the Western league changed its name. In 1901 he was placed at the head of the American league's new Philadelphia team, the Athletics. In 1902 he won the first of a long line of championships with his Athletics. The success of the American league's rise to major league status was largely attributed to his leadership and inspiration.

McGraw, a star third baseman of the Baltimore Orioles, National league pennant winners three straight years in the middle

1890s, was manager of Baltimore's American league club starting the 1902 season. In June. a National league countermove to the raids on its ranks by the American league induced McGraw to jump back to the National as manager of the New York Giants. For the next quarter of a century McGraw and his Giants were headliners in the baseball world comparable in prominence to Mack and his Athletics in the American league.

"Ban" Johnson, first president of the American league. continued as president until 1927. He was succeeded by Ernest Sargent Barnard, who held office until his death in March 1931. William H. Harridge, secretary of the league from 1927 on. succeeded Barnard as president. Joseph E. Cronin became president in 1959.

During the period when organized baseball was governed by the National commission (1903–21) there was one attempt by outside interests to conduct championship baseball on a major league level independent of organized baseball This outlaw organization was the Federal league, which conducted pennant races in 1914 and 1915. Baltimore, Brooklyn. Buffalo, Chicago. Indianapolis, Kansas City, Pittsburgh and St. Louis were represented in the 1914 season, with Indianapolis winning the pennant. In 1915 the Indianapolis team was transferred to Newark, N.J. Chicago won the 1915 pennant. The Federal league not only placed teams in organized baseball territory. but offered contracts to the outstanding players and managers of the two major leagues. Its raids were not so successful as those of the American league had been in securing stars. After the 1915 season came another "peace treaty," the Federal league passing out of existence. Two of the men who had backed the outlaw league heavily joined the major leagues as owners of the Chicago National league and the St. Louis American league clubs respectively. Players developed by Federal league clubs and not previously the "property" of organized baseball found places in organized baseball. Those who had left organized baseball to join up with the "Feds" returned to the clubs from which they had jumped.

The "Black Sox" *Scandal.*—The administrative structure of baseball and its future as a national game were severely tested in the period from 1919 through 1921. During these years eight members of one of the game's greatest all-time teams, the Chicago White Sox of 1919, confessed to accepting bribes to throw the world series of that year; the three-man National commission rule was dissolved and major league baseball decided on the one-man commission rule. One player above all the rest, George Herman ("Babe") Ruth, helped the major leagues regain the prestige and popularity they lost during this trying period.

The scandal that threatened for a time to destroy the public faith in the integrity of the sport was known as the "Black Sox" scandal. Eight members of the Chicago White Sox of 1919 were indicted on a charge of fraud and later were given lifetime bans from holding any position in organized (professional) baseball. They were: Edward Cicotte, who confessed to accepting money for the purpose of deliberately allowing the Cincinnati (National league) team to win the 1919 series, Oscar E. ("Happy") Felsch, Joseph ("Shoeless Joe") Jackson, Charles A. ("Swede") Risberg, Claude Williams, Frederick McMullin, Charles A. ("Chick") Gandil and George D. ("Buck") Weaver. Cicotte implicated his seven teammates, and, in Sept. 1920, all were indicted on a charge of fraud in Cook county, Ill. The presiding judge for the grand jury was Kenesaw Mountain Landis, who one year later was to be named baseball's first commissioner. Charles **A.** Comiskey, president of the Chicago White Sox, suspended the eight players for the 1921 season. In July of that year all eight were found not guilty by a jury, but Landis, then commissioner, was not so lenient. During this period "Babe" Ruth was becoming baseball's newest hero. He began smashing balls at a greater distance than any other hitter the game had known and was a tremendous factor in arousing the fans' desire to see a new idol who would go down in history as the greatest of all home run hitters.

The National and American leagues co-operated in arranging their schedules so that in cities represented in both leagues there would be a dovetailing of the home games, one team being away on all dates on which the other had a home game scheduled.

3. The World Series.—In the fall of 1903 the pennant winners of the two leagues met in a postseason series, won by the Boston Red Sox of the American league from the Pittsburgh Pirates, National league champions, 5 games to 3. This postseason series was no new idea. In seven successive years. starting with 1884, postseason games had been played between the pennant winners of the National league and the American association.

In the world series of the 1880s, the teams arranged matters between themselves, scheduling games and dividing the proceeds by mutual agreement. The 1903 world series was likewise arranged between the two clubs concerned. In 1904, the Boston Red Sox, who had won the 1903 world championship, won the American league pennant, and issued a challenge to the National pennant winners, the New York Giants. The Giants refused, on the ground that there should be formal rules and central supervision of a contest in which the prestige of the rival leagues was involved as well as that of the individual clubs Boston claimed the 1904 world championship by default. The New York president, John T. Brush, offered a code of rules to the two leagues for the governance of postseason championship games, which were adopted for permanent use, starting with the 1905 world series.

Details in the Brush rules were changed through the decades following, but the main features were unchanged. For three years (1919–21) the number of victories required to win the series was raised to five, but was returned to the original four in 1922 and has continued at that figure.

The scheduling of games originally involved choosing by lot or by tossing a coin. The major leagues now alternate in opening the series. In the even-numbered years the series opens in the park of the National league pennant winner. In the odd-numbered years the American league champion plays its first world series

*Record of World Series Competition**

Year	Winning team and games won		Losing team and games won	
1903	Boston (A.L.)	5	Pittsburgh (N.L.)	3
1904	No series			
1905	New York (N.L.)	4	Philadelphia (A.L.)	1
1906	Chicago (A.L.)	4	Chicago (N.L.)	2
1907†	Chicago (N.L.)	4	Detroit (A.L.)	0
1908	Chicago (N.L.)	4	Detroit (A.L.)	1
1909	Pittsburgh (N.L.)	4	Detroit (A.L.)	3

1958	New York (A.L.)	4	Milwaukee (N.L.)	3
1959	Los Angeles (N.L.)	4	Chicago (A.L.)	2
1960	Pittsburgh (N.L.)	4	New York (A.L.)	3
1961	New York (A.L.)	4	Cincinnati (N.L.)	1

*A.L.—American League; N.L.—National League †Or

games at home. Instead of 3–3–1, the distribution of the games is 2–3–2. After the first two games in the series-opening park, the teams shift to the park of the rival league's champions for three games. If neither has won four games after five games have been played, the scene shifts back to the field on which its first game was played and remains there for as many more games as are necessary to decide the winner.

During World War II, starting with 1943, transportation emergencies changed this order. Again the system became three games in the series-opening park, then the shift to the other team's field, with the difference from the original Brush plan that regardless of how many games should become necessary, there would be no return trip to the first city. After the war the 2–3–2 system was once again adopted.

4. The All-Star Game.— Starting with 1933, the major leagues have played an annual All-Star game in July, one game between teams of players chosen from all the teams of both leagues. They oppose each other as league against league. No championship. flag or trophy is involved. The players do nbt receive any part of the gate receipts, which are donated to the players' pension fund and charitable purposes. The first All-Star game, held in conjunction with the Century of Progress world's fair in Chicago, was played in Comiskey park: home field of the Chicago White Sox (American league). In subsequent years the leagues have alternated as "home" teams. In 1959 the major leagues voted to play two All-Star games in one season.

5. Negroes in Baseball.— In 1947 infielder Jack Roosevelt ("Jackie") Robinson became the first Negro player in the major leagues since Welday and Moses Walker, brothers. played for Toledo in the American association, then a major league, in 1884. Robinson, brought into organized baseball by Branch Rickey, president of the Dodgers, then in Brooklyn. helped the Dodgers win the pennant in his first year and received the National league's Most Valuable Player award in his third. The Cleveland Indians followed Rickey's lead with Lawrence ("Larry") Doby, slugging outfielder, and, in 1948, with Leroy ("Satchel") Paige. then past 40, famous pitching star of the Negro leagues. Within a few years all of the major league teams had added Negro athletes to their rosters and there were many Negroes in the minors.

There had been several Negro players in the minor leagues in the 19th century and in the 20th century many Negroes played winter ball in Cuba, Mexico and Venezuela. The first professional Negro team, the Cuban Giants, of Long Island, was organized in 1885. A number of other Negro teams mere formed and the Negro National league was set up in 1920 and the Negro Eastern league in 1921, inaugurating a world series in 1924, but these failed in 1932 because of the depression. A second Negro National league, founded in the late 1930s, was dissolved in 1952. The Negro American league. founded in 1936, formed an Eastern and a Western division in 1952 to conduct the annual Negro East-West classic.

After World War II the Negro leagues suffered the decline in attendance and revenue that affected the minor leagues of organized baseball (see *Organized Baseball*, above), accentuated by the loss of outstanding players to formerly all-white teams.

6. The Hall of Fame.— The National Baseball Hall of Fame and Museum is at Cooperstown, S.Y. (see *Origin of the Game*, above). It contains relics, pictures and documents, and its central chamber is Baseball's Hall of Fame in which are memorialized players and personalities who have made major contributions to baseball. The first five players selected for membership in the Hall of Fame in 1936 were "Ty" Cobb, "Babe" Ruth. Walter Johnson, John P. ("Honus") Wagner and Christy Mathewson. Additions to the roll of immortals are made from time to time by election in polls conducted by the Baseball Writers' Association of America and by the Hall of Fame committee appointed by the commissioner of baseball.

VII. GLOSSARY

The following are terms not defined or explained in the foregoing text but which are used in printed accounts of baseball games; some are vernacular expressions in common usage among players.

Ace.—The best pitcher on the team, the one who is most dependable, the manager's first choice for that position in his line-up whenever the pitcher has had enough rest and is otherwise physically fit.

Apple.—A baseball.

Arbiter.—An umpire.

Aspirin tablets.—A pitcher whose speed is dazzling in any given game is said to be throwing aspirin tablets.

"Average" player.—One who is more concerned with his personal ieats than with the success of his team. He would rather make a hit in a losing game than go hitless in a game won by his team. In the field he would rather not get his hands in contact with a batted ball difficult to field than risk the danger of being charged with a fielding error.

Backing *up*.—A player on the fielding team who anticipates a throw about to be made to a teammate and who runs to a point where he can field the ball if his teammate fails to stop its course is said to "back up" his teammate. The term is also used when the ball is a batted ball and a fielder shifts to a position behind the man actually fielding the ball. Thus, on every grounder to an infielder, one or more outfielders will move so as to be ready in case the ball gets past the infielder. On flies to the outfield that are not driven directly to an outfielder, there are usually two outfielders converging toward the point where the fly is falling, one to catch it, the other deeper in the outfield as a "backer-up."

Bag.—Any base except home plate.

Bean ball.—A pitched ball that passes close to the batter's head or hits the batter's head.

Bench jockey.—A player with a sharp tongue, a quick wit and a voice that carries irom the bench to the playing field. He rides the opposing team's players, preferably the pitcher, his aim being to arouse their emotional reactions and distract their attention from the performance of their assignments in the game.

Blank.—When a pitcher holds the opposing team runless in an inning, a succession of innings. or in an entire game, he is said to blank the team ior that extent oi play. Usually used in enumerating a series of consecutive scoreless innings credited to a pitcher's record.

Bleachers.—The section of a ball park's stands ior spectators which is unrooied, usually located beyond the outfield's boundaries, and leaves the occupants unprotected irom the sun's rays by any structural feature of the stands.

Blooper.—A Texas leaguer (see below).

Blow.—(noun) A saie hit.

Bobble.—To fail to hold on to a batted ball which has been fielded; applied both to a momentary hesitation in the execution oi a play and to a true fielding error.

Boner.—A mistake of judgment or ignorance of some playing rule or of the existing situation in the game. Originally "bonehead play," now usually contracted.

Bonus player.—Usually a young amateur athlete—hence the phrase "bonus baby"—receiving a sum of money in excess oi a maximum established by the commissioner's office ior signing a contract with a professional club. The club is required to keep the player on its roster for two seasons under penalty of forfeiting its rights in him.

Book.—(a) The collective all-time records of baseball; (b) the rule-book; (c) a player's store of knowledge about the weaknesses of opposing players, batting, fielding or pitching. If a batter, ior instance, has learned to detect some peculiarity in a pitcher's delivery which enables him to know beiorehand when a curve is coming, he is said to have that pitcher "in his book."

Boot.—A fielding error. Originally it meant the missing of a grounder by an infielder expressed in verbal form as, "He booted it"; now means an error, the booting of a chance to retire an opposing player.

Break.—(a) A iortuitous happening which helps or hampers a player or a team in the course of a game, such as the oblique bounce of a grounder or the direction of a hard-hit drive when it points straight at a fielder; (b) the point of deviation oi a curve pitch irom the straight trajectory.

Brittle.—Adjective applied to a player who is frequently out of the line-up because of injuries.

Bunched /zits.—Hits are said to be bunched when they occur in the same inning, thus scoring runs. When hits occur in the same inning with bases on balls and/or fielding errors, the team making the hits is said to bunch its hits with passes and errors.

Bush.—Term used loftily by major league players and writers to describe the baseball hinterland, the deeper minor leagues. A player new to the big leagues whose behaviour or speech does not please his associates is reprimanded by being called a "busher." When a player is transierred to the minors by a major league club, it is sometimes reierred to as sending him back to the bush, or to the bushes.

Caught napping.—A base runner is said to be caught napping when the pitcher or catcher, by a quick throw to one of the bases, succeeds in eiiecting a tag-out of the runner as he tries to scramble to safety.
